What is Amazon EC2?

Amazon Elastic Compute Cloud (Amazon EC2) provides on-demand, scalable computing capacity in the Amazon Web Services (AWS) Cloud. Using Amazon EC2 reduces hardware costs so you can develop and deploy applications faster. You can use Amazon EC2 to launch as many or as few virtual servers as you need, configure security and networking, and manage storage. You can add capacity (scale up) to handle compute-heavy tasks, such as monthly or yearly processes, or spikes in website traffic. When usage decreases, you can reduce capacity (scale down) again.

An EC2 instance is a virtual server in the AWS Cloud. When you launch an EC2 instance, the instance type that you specify determines the hardware available to your instance. Each instance type offers a different balance of compute, memory, network, and storage resources. For more information, see the Amazon EC2 Instance Types Guide.

Features of Amazon EC2

Amazon EC2 provides the following high-level features:

Instances

Virtual servers.

Amazon Machine Images (AMIs)

Preconfigured templates for your instances that package the components you need for your server (including the operating system and additional software).

Instance types

Various configurations of CPU, memory, storage, networking capacity, and graphics hardware for your instances.
Amazon EBS volumes

Persistent storage volumes for your data using Amazon Elastic Block Store (Amazon EBS).

Instance store volumes

Storage volumes for temporary data that is deleted when you stop, hibernate, or terminate your instance.

Key pairs

Secure login information for your instances. AWS stores the public key and you store the private key in a secure place.

Security groups

A virtual firewall that allows you to specify the protocols, ports, and source IP ranges that can reach your instances, and the destination IP ranges to which your instances can connect.

Amazon EC2 supports the processing, storage, and transmission of credit card data by a merchant or service provider, and has been validated as being compliant with Payment Card Industry (PCI) Data Security Standard (DSS). For more information about PCI DSS, including how to request a copy of the AWS PCI Compliance Package, see PCI DSS Level 1.

Related services

Services to use with Amazon EC2

You can use other AWS services with the instances that you deploy using Amazon EC2.

Amazon EC2 Auto Scaling

Helps ensure you have the correct number of Amazon EC2 instances available to handle the load for your application.

AWS Backup

Automate backing up your Amazon EC2 instances and the Amazon EBS volumes attached to them.

Amazon CloudWatch

Monitor your instances and Amazon EBS volumes.
Elastic Load Balancing

Automatically distribute incoming application traffic across multiple instances.

Amazon GuardDuty

Detect potentially unauthorized or malicious use of your EC2 instances.

EC2 Image Builder

Automate the creation, management, and deployment of customized, secure, and up-to-date server images.

AWS Launch Wizard

Size, configure, and deploy AWS resources for third-party applications without having to manually identify and provision individual AWS resources.

AWS Systems Manager

Perform operations at scale on EC2 instances with this secure end-to-end management solution.

Additional compute services

You can launch instances using another AWS compute service instead of using Amazon EC2.

Amazon Lightsail

Build websites or web applications using Amazon Lightsail, a cloud platform that provides the resources that you need to deploy your project quickly, for a low, predictable monthly price. To compare Amazon EC2 and Lightsail, see Amazon Lightsail or Amazon EC2.

Amazon Elastic Container Service (Amazon ECS)

Deploy, manage, and scale containerized applications on a cluster of EC2 instances. For more information, see Choosing an AWS container service.

Amazon Elastic Kubernetes Service (Amazon EKS)

Run your Kubernetes applications on AWS. For more information, see Choosing an AWS container service.
Access Amazon EC2

You can create and manage your Amazon EC2 instances using the following interfaces:

Amazon EC2 console

A simple web interface to create and manage Amazon EC2 instances and resources. If you've signed up for an AWS account, you can access the Amazon EC2 console by signing into the AWS Management Console and selecting EC2 from the console home page.

AWS Command Line Interface

Enables you to interact with AWS services using commands in your command-line shell. It is supported on Windows, Mac, and Linux. For more information about the AWS CLI, see AWS Command Line Interface User Guide. You can find the Amazon EC2 commands in the AWS CLI Command Reference.

AWS CloudFormation

Amazon EC2 supports creating resources using AWS CloudFormation. You create a template, in JSON or YAML format, that describes your AWS resources, and AWS CloudFormation provisions and configures those resources for you. You can reuse your CloudFormation templates to provision the same resources multiple times, whether in the same Region and account or in multiple Regions and accounts. For more information about supported resource types and properties for Amazon EC2, see EC2 resource type reference in the AWS CloudFormation User Guide.

AWS SDKs

If you prefer to build applications using language-specific APIs instead of submitting a request over HTTP or HTTPS, AWS provides libraries, sample code, tutorials, and other resources for software developers. These libraries provide basic functions that automate tasks such as cryptographically signing your requests, retrying requests, and handling error responses, making it easier for you to get started. For more information, see Tools to Build on AWS.

AWS Tools for PowerShell

A set of PowerShell modules that are built on the functionality exposed by the AWS SDK for .NET. The Tools for PowerShell enable you to script operations on your AWS resources from the PowerShell command line. To get started, see the AWS Tools for Windows PowerShell User Guide. You can find the cmdlets for Amazon EC2, in the AWS Tools for PowerShell Cmdlet Reference.
Query API

Amazon EC2 provides a Query API. These requests are HTTP or HTTPS requests that use the HTTP verbs GET or POST and a Query parameter named Action. For more information about the API actions for Amazon EC2, see Actions in the Amazon EC2 API Reference.

Pricing for Amazon EC2

Amazon EC2 provides the following pricing options:

Free Tier

You can get started with Amazon EC2 for free. To explore the Free Tier options, see AWS Free Tier.

On-Demand Instances

Pay for the instances that you use by the second, with a minimum of 60 seconds, with no long-term commitments or upfront payments.

Savings Plans

You can reduce your Amazon EC2 costs by making a commitment to a consistent amount of usage, in USD per hour, for a term of 1 or 3 years.

Reserved Instances

You can reduce your Amazon EC2 costs by making a commitment to a specific instance configuration, including instance type and Region, for a term of 1 or 3 years.

Spot Instances

Request unused EC2 instances, which can reduce your Amazon EC2 costs significantly.

Dedicated Hosts

Reduce costs by using a physical EC2 server that is fully dedicated for your use, either On-Demand or as part of a Savings Plan. You can use your existing server-bound software licenses and get help meeting compliance requirements.

On-Demand Capacity Reservations

Reserve compute capacity for your EC2 instances in a specific Availability Zone for any duration of time.
Per-second billing

Removes the cost of unused minutes and seconds from your bill.

For a complete list of charges and prices for Amazon EC2 and more information about the purchase models, see Amazon EC2 pricing.

Estimates, billing, and cost optimization

To create estimates for your AWS use cases, use the AWS Pricing Calculator.

To estimate the cost of transforming Microsoft workloads to a modern architecture that uses open source and cloud-native services deployed on AWS, use the AWS Modernization Calculator for Microsoft Workloads.

To see your bill, go to the Billing and Cost Management Dashboard in the AWS Billing and Cost Management console. Your bill contains links to usage reports that provide details about your bill. To learn more about AWS account billing, see AWS Billing and Cost Management User Guide.

If you have questions concerning AWS billing, accounts, and events, contact AWS Support.

To calculate the cost of a sample provisioned environment, see Cloud Economics Center. When calculating the cost of a provisioned environment, remember to include incidental costs such as snapshot storage for EBS volumes.

You can optimize the cost, security, and performance of your AWS environment using AWS Trusted Advisor.

You can use AWS Cost Explorer to analyze the cost and usage of your EC2 instances. You can view data up to the last 13 months, and forecast how much you are likely to spend for the next 12 months. For more information, see Analyzing your costs with AWS Cost Explorer in the AWS Cost Management User Guide.

Get started with Amazon EC2

Use this tutorial to get started with Amazon Elastic Compute Cloud (Amazon EC2). You'll learn how to launch and connect to an EC2 instance. An instance is a virtual server in the AWS Cloud. With Amazon EC2, you can set up and configure the operating system and applications that run on your instance.

Overview

The following diagram shows the key components that you'll use in this tutorial:

- **An image** – A template that contains the software to run on your instance, such as the operating system.
- **A key pair** – A set of security credentials that you use to prove your identity when connecting to your instance. The public key is on your instance and the private key is on your computer.
- **A network** – A virtual private cloud (VPC) is a virtual network dedicated to your AWS account. To help you get started quickly, your account comes with a default VPC in each AWS Region, and each default VPC has a default subnet in each Availability Zone.
- **A security group** – Acts as a virtual firewall to control inbound and outbound traffic.
- **An EBS volume** – We require a root volume for the image. You can optionally add data volumes.
Cost for this tutorial

When you sign up for AWS, you can get started with Amazon EC2 using the AWS Free Tier. If you created your AWS account less than 12 months ago, and have not already exceeded the Free Tier benefits for Amazon EC2, it won't cost you anything to complete this tutorial, because we help you select options that are within the Free Tier benefits. Otherwise, you'll incur the standard Amazon EC2 usage fees from the time that you launch the instance until you terminate the instance (which is the final task of this tutorial), even if it remains idle.

For instructions to determine whether you are eligible for the Free Tier, see the section called “Track your Free Tier usage”.

Tasks

- **Step 1:** Launch an instance
- **Step 2:** Connect to your instance
- **Step 3:** Clean up your instance
- **Next steps**
Step 1: Launch an instance

You can launch an EC2 instance using the AWS Management Console as described in the following procedure. This tutorial is intended to help you quickly launch your first instance, so it doesn't cover all possible options.

To launch an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, we display the current AWS Region — for example, Ohio. You can use the selected Region, or optionally select a Region that is closer to you.
3. From the EC2 console dashboard, in the Launch instance pane, choose Launch instance.
4. Under Name and tags, for Name, enter a descriptive name for your instance.
5. Under Application and OS Images (Amazon Machine Image), do the following:
   a. Choose Quick Start, and then choose the operating system (OS) for your instance. For your first Linux instance, we recommend that you choose Amazon Linux.
   b. From Amazon Machine Image (AMI), select an AMI that is marked Free Tier eligible.
6. Under Instance type, for Instance type, choose t2.micro, which is eligible for the Free Tier. In Regions where t2.micro is not available, t3.micro is eligible for the Free Tier.
7. Under Key pair (login), for Key pair name, choose an existing key pair or choose Create new key pair to create your first key pair.

⚠️ Warning

If you choose Proceed without a key pair (Not recommended), you won't be able to connect to your instance using the methods described in this tutorial.

8. Under Network settings, notice that we selected your default VPC, selected the option to use the default subnet in an Availability Zone that we choose for you, and configured a security group with a rule that allows connections to your instance from anywhere. For your first instance, we recommend that you use the default settings. Otherwise, you can update your network settings as follows:
   • (Optional) To use a specific default subnet, choose Edit and then choose a subnet.
• (Optional) To use a different VPC, choose Edit and then choose an existing VPC. If the VPC isn't configured for public internet access, you won't be able to connect to your instance.

• (Optional) To restrict inbound connection traffic to a specific network, choose Custom instead of Anywhere, and enter the CIDR block for your network.

• (Optional) To use a different security group, choose Select existing security group and choose an existing security group. If the security group does not have a rule that allows connection traffic from your network, you won't be able to connect to your instance. For a Linux instance, you must allow SSH traffic. For a Windows instance, you must allow RDP traffic.

9. Under Configure storage, notice that we configured a root volume but no data volumes. This is sufficient for test purposes.

10. Review a summary of your instance configuration in the Summary panel, and when you're ready, choose Launch instance.

11. If the launch is successful, choose the ID of the instance from the Success notification to open the Instances page and monitor the status of the launch.

12. Select the check box for the instance. The initial instance state is pending. After the instance starts, its state changes to running. Choose the Status and alarms tab. After your instance passes its status checks, it is ready to receive connection requests.

**Step 2: Connect to your instance**

The procedure that you use depends on the operating system of the instance. If you can't connect to your instance, see Troubleshoot issues connecting to your Amazon EC2 Linux instance for assistance.

**Linux instances**

You can connect to your Linux instance using any SSH client. If you are running Windows on your computer, open a terminal and run the ssh command to verify that you have an SSH client installed. If the command is not found, install OpenSSH for Windows.

**To connect to your instance using SSH**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and then choose Connect.
4. On the **Connect to instance** page, choose the **SSH client** tab.

5. (Optional) If you created a key pair when you launched the instance and downloaded the private key (.pem file) to a computer running Linux or macOS, run the example `chmod` command to set the permissions for your private key.

6. Copy the example SSH command. The following is an example, where `key-pair-name`.pem is the name of your private key file, `ec2-user` is the user name associated with the image, and the string after the @ symbol is the public DNS name of the instance.

   ```bash
   ssh -i key-pair-name.pem ec2-user@ec2-198-51-100-1.us-east-2.compute.amazonaws.com
   ```

7. In a terminal window on your computer, run the `ssh` command that you saved in the previous step. If the private key file is not in the current directory, you must specify the fully-qualified path to the key file in this command.

   The following is an example response:

   ```
   The authenticity of host 'ec2-198-51-100-1.us-east-2.compute.amazonaws.com (198-51-100-1)' can't be established.
   ECDSA key fingerprint is l4UB/neBad9tvkgJf1QZWheQmR59WgrgzEimCG6kZy.
   Are you sure you want to continue connecting (yes/no)?
   ```

8. (Optional) Verify that the fingerprint in the security alert matches the instance fingerprint contained in the console output when you first start an instance. To get the console output, choose **Actions, Monitor and troubleshoot, Get system log**. If the fingerprints don’t match, someone might be attempting a man-in-the-middle attack. If they match, continue to the next step.

9. Enter **yes**.

   The following is an example response:

   ```
   Warning: Permanently added 'ec2-198-51-100-1.us-east-2.compute.amazonaws.com' (ECDSA) to the list of known hosts.
   ```

### Windows instances

To connect to a Windows instance, you must retrieve the initial administrator password and use this password when you connect to your instance using Remote Desktop. It takes a few minutes after instance launch before this password is available.
The default username for the Administrator account depends on the language of the operating system (OS) contained in the AMI. To ascertain the correct username, identify the language of your AMI's OS, and then choose the corresponding username. For example, for an English OS, the username is Administrator, for a French OS it's Administrateur, and for a Portuguese OS it's Administrador. If a language version of the OS does not have a username in the same language, choose the username Administrator (Other). For more information, see Localized Names for Administrator Account in Windows in the Microsoft TechNet Wiki.

If you've joined your instance to a domain, you can connect to your instance using domain credentials you've defined in AWS Directory Service. On the Remote Desktop login screen, instead of using the local computer name and the generated password, use the fully-qualified user name for the administrator (for example, corp.example.com\Admin), and the password for this account.

If you receive an error while attempting to connect to your instance, see the section called “Remote Desktop can't connect to the remote computer”.

To connect to your Windows instance using an RDP client

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and then choose Connect.
4. On the Connect to instance page, choose the RDP client tab.
5. For Username, choose the default username for the Administrator account. The username you choose must match the language of the operating system (OS) contained in the AMI that you used to launch your instance. If there is no username in the same language as your OS, choose Administrator (Other).
6. Choose Get password.
7. On the Get Windows password page, do the following:
   a. Choose Upload private key file and navigate to the private key (.pem) file that you specified when you launched the instance. Select the file and choose Open to copy the entire contents of the file to this window.
   b. Choose Decrypt password. The Get Windows password page closes, and the default administrator password for the instance appears under Password, replacing the Get password link shown previously.
c. Copy the password and save it in a safe place. This password is required to connect to the instance.

8. Choose Download remote desktop file. When you have finished downloading the file, choose Cancel to return to the Instances page. Navigate to your downloads directory, and open the RDP file.

9. You might get a warning that the publisher of the remote connection is unknown. Choose Connect to continue to connect to your instance.

10. The administrator account is chosen by default. Paste the password that you copied previously, and then choose OK.

11. Due to the nature of self-signed certificates, you might get a warning that the security certificate could not be authenticated. Do one of the following:
   - If you trust the certificate, choose Yes to connect to your instance.
   - [Windows] Before you proceed, compare the thumbprint of the certificate with the value in the system log to confirm the identity of the remote computer. Choose View certificate and then choose Thumbprint from the Details tab. Compare this value to the value of RDPCERTIFICATE-THUMBPRINT in Actions, Monitor and troubleshoot, Get system log.
   - [Mac OS X] Before you proceed, compare the fingerprint of the certificate with the value in the system log to confirm the identity of the remote computer. Choose Show Certificate, expand Details, and choose SHA1 Fingerprints. Compare this value to the value of RDPCERTIFICATE-THUMBPRINT in Actions, Monitor and troubleshoot, Get system log.

Step 3: Clean up your instance

After you've finished with the instance that you created for this tutorial, you should clean up by terminating the instance. If you want to do more with this instance before you clean up, see Next steps.

⚠️ Important
Terminating an instance effectively deletes it; you can't reconnect to an instance after you've terminated it.
You'll stop incurring charges for that instance or usage that counts against your Free Tier limits as soon as the instance status changes to shutting down or terminated. To keep your instance for later, but not incur charges or usage that counts against your Free Tier limits, you can stop the instance now and then start it again later. For more information, see Stop and start Amazon EC2 instances.

To terminate your instance

1. In the navigation pane, choose Instances. In the list of instances, select the instance.
2. Choose Instance state, Terminate instance.
3. Choose Terminate when prompted for confirmation.

Amazon EC2 shuts down and terminates your instance. After your instance is terminated, it remains visible on the console for a short while, and then the entry is automatically deleted. You cannot remove the terminated instance from the console display yourself.

Next steps

After you start your instance, you might want to explore the following next steps:

- Learn how to track your Amazon EC2 Free Tier usage using the console. For more information, see the section called “Track your Free Tier usage”.
- Configure a CloudWatch alarm to notify you if your usage exceeds the Free Tier. For more information, see Tracking your AWS Free Tier usage in the AWS Billing User Guide.
- Add an EBS volume. For more information, see Create an Amazon EBS volume in the Amazon EBS User Guide.
- Learn how to remotely manage your EC2 instance using the Run command. For more information, see AWS Systems Manager Run Command in the AWS Systems Manager User Guide.
- Learn about instance purchasing options. For more information, see Instance purchasing options.
- Get advice about instance types. For more information, see Get instance type recommendations for a new workload.
Best practices for Amazon EC2

To ensure the maximum benefit from Amazon EC2, we recommend that you perform the following best practices.

Security

- Manage access to AWS resources and APIs using identity federation with an identity provider and IAM roles whenever possible. For more information, see Creating IAM policies in the IAM User Guide.
- Implement the least permissive rules for your security group. For more information, see Security group rules.
- Regularly patch, update, and secure the operating system and applications on your instance. For more information, see Update management. For guidelines specific to Windows operating systems, see Security best practices for Windows instances.
- Use Amazon Inspector to automatically discover and scan Amazon EC2 instances for software vulnerabilities and unintended network exposure. For more information, see the Amazon Inspector User Guide.
- Use AWS Security Hub controls to monitor your Amazon EC2 resources against security best practices and security standards. For more information about using Security Hub, see Amazon Elastic Compute Cloud controls in the AWS Security Hub User Guide.

Storage

- Understand the implications of the root device type for data persistence, backup, and recovery. For more information, see Storage for the root device.
- Use separate Amazon EBS volumes for the operating system versus your data. Ensure that the volume with your data persists after instance termination. For more information, see Preserve data when an instance is terminated.
- Use the instance store available for your instance to store temporary data. Remember that the data stored in instance store is deleted when you stop, hibernate, or terminate your instance. If you use instance store for database storage, ensure that you have a cluster with a replication factor that ensures fault tolerance.
- Encrypt EBS volumes and snapshots. For more information, see Amazon EBS encryption in the Amazon EBS User Guide.
Resource management

- Use instance metadata and custom resource tags to track and identify your AWS resources. For more information, see [Work with instance metadata](#) and [Tag your Amazon EC2 resources](#).
- View your current limits for Amazon EC2. Plan to request any limit increases in advance of the time that you'll need them. For more information, see [Amazon EC2 service quotas](#).
- Use AWS Trusted Advisor to inspect your AWS environment, and then make recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. For more information, see [AWS Trusted Advisor](#) in the [AWS Support User Guide](#).

Backup and recovery

- Regularly back up your EBS volumes using [Amazon EBS snapshots](#), and create an [Amazon Machine Image (AMI)](#) from your instance to save the configuration as a template for launching future instances. For more information about AWS services that help achieve this use case, see [AWS Backup](#) and [Amazon Data Lifecycle Manager](#).
- Deploy critical components of your application across multiple Availability Zones, and replicate your data appropriately.
- Design your applications to handle dynamic IP addressing when your instance restarts. For more information, see [Amazon EC2 instance IP addressing](#).
- Monitor and respond to events. For more information, see [Monitor Amazon EC2 resources](#).
- Ensure that you are prepared to handle failover. For a basic solution, you can manually attach a network interface or Elastic IP address to a replacement instance. For more information, see [Elastic network interfaces](#). For an automated solution, you can use Amazon EC2 Auto Scaling. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).
- Regularly test the process of recovering your instances and Amazon EBS volumes to ensure data and services are restored successfully.

Networking

- Set the time-to-live (TTL) value for your applications to 255, for IPv4 and IPv6. If you use a smaller value, there is a risk that the TTL will expire while application traffic is in transit, causing reachability issues for your instances.
Amazon Machine Images (AMIs)

An Amazon Machine Image (AMI) is an image provided by AWS that provides the information required to launch an instance. You must specify an AMI when you launch an instance. You can launch multiple instances from a single AMI when you require multiple instances with the same configuration. You can use different AMIs to launch instances when you require instances with different configurations.

An AMI includes the following:

• One or more Amazon Elastic Block Store (Amazon EBS) snapshots, or, for instance-store-backed AMIs, a template for the root volume of the instance (for example, an operating system, an application server, and applications).
• Launch permissions that control which AWS accounts can use the AMI to launch instances.
• A block device mapping that specifies the volumes to attach to the instance when it's launched.

Amazon Machine Image (AMI) topics

• Use an AMI
• Create your own AMI
• Buy, share, and sell AMIs
• Deregister your AMI
• Amazon Linux 2023 and Amazon Linux 2
• Windows AMIs
• AMI types
• AMI virtualization types
• Amazon EC2 boot modes
• Find an AMI
• Shared AMIs
• Paid AMIs
• AMI lifecycle
• Use encryption with EBS-backed AMIs
Use an AMI

The following diagram summarizes the AMI lifecycle. After you create and register an AMI, you can use it to launch new instances. (You can also launch instances from an AMI if the AMI owner grants you launch permissions.) You can copy an AMI within the same AWS Region or to different AWS Regions. When you no longer require an AMI, you can deregister it.

![AMI Lifecycle Diagram]

You can search for an AMI that meets the criteria for your instance. You can search for AMIs provided by AWS or AMIs provided by the community. For more information, see AMI types and Find an AMI.

After you launch an instance from an AMI, you can connect to it. When you are connected to an instance, you can use it just like you use any other server. For information about launching, connecting, and using your instance, see Get started with Amazon EC2.

Create your own AMI

You can launch an instance from an existing AMI, customize the instance (for example, install software on the instance), and then save this updated configuration as a custom AMI. Instances launched from this new custom AMI include the customizations that you made when you created the AMI.

The root storage device of the instance determines the process you follow to create an AMI. The root volume of an instance is either an Amazon Elastic Block Store (Amazon EBS) volume or an
instance store volume. For more information about the root device volume, see Root volumes for your Amazon EC2 instances.

- To create an Amazon EBS-backed AMI, see Create an Amazon EBS-backed AMI.
- To create an instance store-backed AMI, see Create an instance store-backed Linux AMI.

To help categorize and manage your AMIs, you can assign custom tags to them. For more information, see Tag your Amazon EC2 resources.

**Buy, share, and sell AMIs**

After you create an AMI, you can keep it private so that only you can use it, or you can share it with a specified list of AWS accounts. You can also make your custom AMI public so that the community can use it. Building a safe, secure, usable AMI for public consumption is a fairly straightforward process, if you follow a few simple guidelines. For information about how to create and use shared AMIs, see Shared AMIs.

You can purchase AMIs from a third party, including AMIs that come with service contracts from organizations such as Red Hat. You can also create an AMI and sell it to other Amazon EC2 users. For more information about buying or selling AMIs, see Paid AMIs.

**Deregister your AMI**

You can deregister an AMI when you have finished with it. After you deregister an AMI, it can't be used to launch new instances. Existing instances launched from the AMI are not affected. For more information, see Deregister (delete) an AMI.

**Amazon Linux 2023 and Amazon Linux 2**

The latest release of Amazon Linux, AL2023, is optimized for Amazon EC2 and is provided at no additional cost to Amazon EC2 users. The features of AL2023 include a predictable release cadence, frequent updates, and long-term support.

For more information about AL2023 features and launching an AL2023 AMI, see:

- AL2023 Features
• Get started with AL2023

Amazon Linux 2 (AL2) provides a stable, secure, and high performance execution environment for applications running on Amazon EC2. For more information about Amazon Linux 2, see Amazon Linux 2 on Amazon EC2 in the Amazon Linux 2 User Guide.

Note
The Amazon Linux AMI reached its end-of-life on December 31, 2023 and will not receive any security updates or bug fixes starting January 1, 2024. For more information about the Amazon Linux AMI end-of-life and maintenance support, see the blog post Update on Amazon Linux AMI end-of-life. We recommend that you upgrade applications to AL2023, which includes long-term support until 2028.

Windows AMIs

AWS provides a set of publicly available AMIs that contain software configurations specific to the Windows platform. You can quickly start building and deploying your applications with Amazon EC2 by using these AMIs. First choose the AMI that meets your specific requirements, and then launch an instance using that AMI. You retrieve the password for the administrator account and then log in to the instance using Remote Desktop Connection, just as you would with any other Windows server. For more information about AWS Windows AMIs, see the AWS Windows AMI reference.

When you launch an instance from a Windows AMI, the root device for the Windows instance is an Amazon Elastic Block Store (Amazon EBS) volume. Windows AMIs don't support instance store for the root device.

Windows AMIs that are configured for faster launching with EC2 Fast Launch are pre-provisioned, using snapshots to launch instances up to 65% faster. To learn more about EC2 Fast Launch, see Use EC2 Fast Launch for your Windows instances.

Note
Microsoft no longer supports Windows Server versions prior to Windows Server 2016. We recommend that you launch new EC2 instances using a supported version of Windows Server. If you have existing EC2 instances that are running an unsupported version of
Windows Server, we recommend that you upgrade those instances to a supported version of Windows Server. For more information, see [Upgrade an Amazon EC2 Windows instance to a newer version of Windows Server](#).

**AMI types**

You can select an AMI to use based on the following characteristics:

- Region (see [Regions and Zones](#))
- Operating system
- Architecture (32-bit or 64-bit)
- **Launch permissions**
- **Storage for the root device**

**Launch permissions**

The owner of an AMI determines its availability by specifying launch permissions. Launch permissions fall into the following categories.

<table>
<thead>
<tr>
<th>Launch permission</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>The owner grants launch permissions to all AWS accounts.</td>
</tr>
<tr>
<td>explicit</td>
<td>The owner grants launch permissions to specific AWS accounts, organizations, or organizational units (OUs).</td>
</tr>
<tr>
<td>implicit</td>
<td>The owner has implicit launch permissions for an AMI.</td>
</tr>
</tbody>
</table>

Amazon and the Amazon EC2 community provide a large selection of public AMIs. For more information, see [Shared AMIs](#). Developers can charge for their AMIs. For more information, see [Paid AMIs](#).

**Storage for the root device**

All AMIs are categorized as either *backed by Amazon EBS* or *backed by instance store*. 
- Amazon EBS-backed AMI – The root device for an instance launched from the AMI is an Amazon Elastic Block Store (Amazon EBS) volume created from an Amazon EBS snapshot. Supported for both Linux and Windows AMIs.

- Amazon instance store-backed AMI – The root device for an instance launched from the AMI is an instance store volume created from a template stored in Amazon S3. Supported for Linux AMIs only. Windows AMIs do not support instance store for the root device.

For more information, see [Root volumes for your Amazon EC2 instances](#).

The following table summarizes the important differences when using the two types of AMIs.

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Amazon EBS-backed AMI</th>
<th>Amazon instance store-backed AMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boot time for an instance</td>
<td>Usually less than 1 minute</td>
<td>Usually less than 5 minutes</td>
</tr>
<tr>
<td>Size limit for a root device</td>
<td>64 TiB**</td>
<td>10 GiB</td>
</tr>
<tr>
<td>Root device volume</td>
<td>EBS volume</td>
<td>Instance store volume</td>
</tr>
<tr>
<td>Data persistence</td>
<td>By default, the root volume is deleted when the instance terminates.* Data on any other EBS volumes persists after instance termination by default.</td>
<td>Data on any instance store volumes persists only during the life of the instance.</td>
</tr>
<tr>
<td>Modifications</td>
<td>The instance type, kernel, RAM disk, and user data can be changed while the instance is stopped.</td>
<td>Instance attributes are fixed for the life of an instance.</td>
</tr>
<tr>
<td>Charges</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Characteristic</td>
<td>Amazon EBS-backed AMI</td>
<td>Amazon instance store-backed AMI</td>
</tr>
<tr>
<td>------------------------</td>
<td>--------------------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>You're charged for instance usage, EBS volume usage, and storing your AMI as an EBS snapshot.</td>
<td>You're charged for instance usage and storing your AMI in Amazon S3.</td>
</tr>
<tr>
<td>AMI creation/bundling</td>
<td>Uses a single command/call</td>
<td>Requires installation and use of AMI tools</td>
</tr>
<tr>
<td>Stopped state</td>
<td>Can be in a stopped state. Even when the instance is stopped and not running, the root volume is persisted in Amazon EBS</td>
<td>Cannot be in a stopped state; instances are running or terminated</td>
</tr>
</tbody>
</table>

* By default, EBS root volumes have the `DeleteOnTermination` flag set to `true`. For information about how to change this flag so that the volume persists after termination, see [Configure an Amazon EBS root volume to persist after terminating an Amazon EC2 instance](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/configure-root-volume-after-termination.html).

** Supported with io2 EBS Block Express only. For more information, see [Provisioned IOPS SSD Block Express volumes](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/BlockExpressVolumes.html) in the *Amazon EBS User Guide*.**

**Determine the root device type of your AMI**

**To determine the root device type of an AMI using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **AMIs**, and select the AMI.
3. On the **Details** tab, check the value of **Root device type** as follows:
   - `ebs` – This is an EBS-backed AMI.
   - `instance store` – This is an an instance store-backed AMI.
To determine the root device type of an AMI using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2.

- `describe-images` (AWS CLI)
- `Get-EC2Image` (AWS Tools for Windows PowerShell)

**Stopped state**

You can stop an instance that has an EBS volume for its root device, but you can't stop an instance that has an instance store volume for its root device.

Stopping causes the instance to stop running (its status goes from running to stopping to stopped). A stopped instance persists in Amazon EBS, which allows it to be restarted. Stopping is different from terminating; you can't restart a terminated instance. Because instances with an instance store volume for the root device can't be stopped, they're either running or terminated. For more information about what happens and what you can do while an instance is stopped, see Stop and start Amazon EC2 instances.

**Default data storage and persistence**

Instances that have an instance store volume for the root device automatically have instance store available (the root volume contains the root partition and you can store additional data). You can add persistent storage to your instance by attaching one or more EBS volumes. Any data on an instance store volume is deleted when the instance fails or terminates. For more information, see Data persistence for Amazon EC2 instance store volumes.

Instances that have Amazon EBS for the root device automatically have an EBS volume attached. The volume appears in your list of volumes like any other. With most instance types, instances that have an EBS volume for the root device don't have instance store volumes by default. You can add instance store volumes or additional EBS volumes using a block device mapping. For more information, see Block device mappings for Amazon EBS and instance store volumes on Amazon EC2 instances.

**Boot times**

Instances launched from an Amazon EBS-backed AMI launch faster than instances launched from an instance store-backed AMI. When you launch an instance from an instance store-backed
AMI, all the parts have to be retrieved from Amazon S3 before the instance is available. With an Amazon EBS-backed AMI, only the parts required to boot the instance need to be retrieved from the snapshot before the instance is available. However, the performance of an instance that uses an EBS volume for its root device is slower for a short time while the remaining parts are retrieved from the snapshot and loaded into the volume. When you stop and restart the instance, it launches quickly, because the state is stored in an EBS volume.

**AMI creation**

To create Linux AMIs backed by instance store, you must create an AMI from your instance on the instance itself using the Amazon EC2 AMI tools. Note that Windows AMIs don't support instance store for the root device.

AMI creation is much easier for AMIs backed by Amazon EBS. The `CreateImage` API action creates your Amazon EBS-backed AMI and registers it. There's also a button in the AWS Management Console that lets you create an AMI from a running instance. For more information, see [Create an Amazon EBS-backed AMI](#).

**How you're charged**

With AMIs backed by instance store, you're charged for instance usage and storing your AMI in Amazon S3. With AMIs backed by Amazon EBS, you're charged for instance usage, EBS volume storage and usage, and storing your AMI as an EBS snapshot.

With Amazon EC2 instance store-backed AMIs, each time you customize an AMI and create a new one, all of the parts are stored in Amazon S3 for each AMI. So, the storage footprint for each customized AMI is the full size of the AMI. For Amazon EBS-backed AMIs, each time you customize an AMI and create a new one, only the changes are stored. So, the storage footprint for subsequent AMIs that you customize after the first is much smaller, resulting in lower AMI storage charges.

When an instance with an EBS volume for its root device is stopped, you're not charged for instance usage; however, you're still charged for volume storage. As soon as you start your instance, we charge a minimum of one minute for usage. After one minute, we charge only for the seconds used. For example, if you run an instance for 20 seconds and then stop it, we charge for a full one minute. If you run an instance for 3 minutes and 40 seconds, we charge for exactly 3 minutes and 40 seconds of usage. We charge you for each second, with a one-minute minimum, that you keep the instance running, even if the instance remains idle and you don't connect to it.
AMI virtualization types

Amazon Machine Images use one of two types of virtualization: paravirtual (PV) or hardware virtual machine (HVM). The main differences between PV and HVM AMIs are the way in which they boot and whether they can take advantage of special hardware extensions (CPU, network, and storage) for better performance. Windows AMIs are HVM AMIs.

For the best performance, we recommend that you use current generation instance types and HVM AMIs when you launch your instances. For more information about current generation instance types, see [Amazon EC2 Instance Types](#). If you are using previous generation instance types and would like to upgrade, see [Upgrade Paths](#) and [Change the instance type](#).

The following table compares HVM and PV AMIs.

<table>
<thead>
<tr>
<th></th>
<th>HVM</th>
<th>PV</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>HVM AMIs are presented with a fully virtualized set of hardware and boot by executing the master boot record of the root block device of your image. This virtualization type provides the ability to run an operating system directly on top of a virtual machine without any modification, as if it were run on the bare-metal hardware. The Amazon EC2 host system emulates some or all of the underlying hardware that is presented to the guest.</td>
<td>PV AMIs boot with a special boot loader called PV-GRUB, which starts the boot cycle and then chain loads the kernel specified in the menu.lst file on your image. Paravirtual guests can run on host hardware that does not have explicit support for virtualization. Historically, PV guests had better performance than HVM guests in many cases, but because of enhancements in HVM virtualization and the availability of PV drivers for HVM AMIs, this is no longer true. For more information about PV-GRUB and its use in Amazon EC2, see <a href="#">User provided kernels</a>.</td>
</tr>
<tr>
<td></td>
<td>HVM</td>
<td>PV</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Support for hardware extensions</td>
<td>Yes. Unlike PV guests, HVM guests can take advantage of hardware extensions that provide fast access to the underlying hardware on the host system. For more information about CPU virtualization extensions that are available in Amazon EC2, see Intel Virtualization Technology on the Intel website. HVM AMIs are required to take advantage of enhanced networking and GPU processing. In order to pass through instructions to specialized network and GPU devices, the OS needs to be able to have access to the native hardware platform; HVM virtualization provides this access. For more information, see Enhanced networking on Amazon EC2 instances.</td>
<td>No, they cannot take advantage of special hardware extensions such as enhanced networking or GPU processing.</td>
</tr>
<tr>
<td>Supported instance types</td>
<td>All current generation instance types support HVM AMIs.</td>
<td>The following previous generation instance types support PV AMIs: C1, C3, M1, M3, M2, and T1. Current generation instance types do not support PV AMIs.</td>
</tr>
</tbody>
</table>
**Supported Regions**

<table>
<thead>
<tr>
<th></th>
<th>HVM</th>
<th>PV</th>
</tr>
</thead>
<tbody>
<tr>
<td>All Regions support HVM instances.</td>
<td>Asia Pacific (Tokyo), Asia Pacific (Singapore), Asia Pacific (Sydney), Europe (Frankfurt), Europe (Ireland), South America (São Paulo), US East (N. Virginia), US West (N. California), and US West (Oregon)</td>
<td></td>
</tr>
</tbody>
</table>

**How to find**

- Verify that the virtualization type of the AMI is set to `hvm`, using the console or the `describe-images` command. For more information, see [Find an AMI](#).

- Verify that the virtualization type of the AMI is set to `paravirtual`, using the console or the `describe-images` command. For more information, see [Find an AMI](#).

---

**PV on HVM**

Paravirtual guests traditionally performed better with storage and network operations than HVM guests because they could leverage special drivers for I/O that avoided the overhead of emulating network and disk hardware, whereas HVM guests had to translate these instructions to emulated hardware. Now PV drivers are available for HVM guests, so operating systems that cannot be ported to run in a paravirtualized environment can still see performance advantages in storage and network I/O by using them. With these PV on HVM drivers, HVM guests can get the same, or better, performance than paravirtual guests.

**Amazon EC2 boot modes**

When a computer boots, the first software that it runs is responsible for initializing the platform and providing an interface for the operating system to perform platform-specific operations.

In Amazon EC2, two variants of the boot mode software are supported: Unified Extensible Firmware Interface (UEFI) and Legacy BIOS.

**Possible boot mode parameters on an AMI**
An AMI can have one of the following boot mode parameter values: uefi, legacy-bios, or uefi-preferred. The AMI boot mode parameter is optional. For AMIs with no boot mode parameter, the instances launched from these AMIs use the default boot mode value of the instance type.

**Purpose of the AMI boot mode parameter**

The AMI boot mode parameter signals to Amazon EC2 which boot mode to use when launching an instance. When the boot mode parameter is set to uefi, EC2 attempts to launch the instance on UEFI. If the operating system is not configured to support UEFI, the instance launch will be unsuccessful.

**UEFI Preferred boot mode parameter**

You can create AMIs that support both UEFI and Legacy BIOS by using the uefi-preferred boot mode parameter. When the boot mode parameter is set to uefi-preferred, and if the instance type supports UEFI, the instance is launched on UEFI. If the instance type does not support UEFI, the instance is launched on Legacy BIOS.

⚠️ **Warning**

Some features, like UEFI Secure Boot, are only available on instances that boot on UEFI. When you use the uefi-preferred AMI boot mode parameter with an instance type that does not support UEFI, the instance will launch as Legacy BIOS and the UEFI-dependent feature will be disabled. If you rely on the availability of a UEFI-dependent feature, set your AMI boot mode parameter to uefi.

**Default boot modes for instance types**

- Graviton instance types: UEFI
- Intel and AMD instance types: Legacy BIOS

**Running Intel and AMD instances types on UEFI**

Most Intel and AMD instance types can run on both UEFI and Legacy BIOS. To use UEFI, you must select an AMI with the boot mode parameter set either to uefi or uefi-preferred, and the operating system contained in the AMI must be configured to support UEFI.
Boot mode topics

- Launch an instance
- Determine the boot mode parameter of an AMI
- Determine the supported boot modes of an instance type
- Determine the boot mode of an instance
- Determine the boot mode of the operating system
- Set the boot mode of an AMI
- UEFI variables
- UEFI Secure Boot

Launch an instance

You can launch an instance in UEFI or Legacy BIOS boot mode.

Topics

- Limitations
- Considerations
- Requirements for launching an instance on UEFI

Limitations

UEFI boot is not supported in Local Zones, Wavelength Zones, or with AWS Outposts.

Considerations

Consider the following when launching an instance:

- The boot mode of the instance is determined by the configuration of the AMI, the operating system contained in it, and the instance type, illustrated by the following image:
The following table shows that the boot mode of an instance (indicated by the Resulting instance boot mode column) is determined by a combination of the boot mode parameter of the AMI (column 1), the boot mode configuration of the operating system contained in the AMI (column 2), and the boot mode support of the instance type (column 3).

<table>
<thead>
<tr>
<th>AMI boot mode parameter</th>
<th>Operating system boot mode configuration</th>
<th>Instance type boot mode support</th>
<th>Resulting instance boot mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>UEFI</td>

<td>UEFI and Legacy BIOS</td>
<td>Legacy BIOS</td>
</tr>
</tbody>
</table>

- Default boot modes:
  - Graviton instance types: UEFI
  - Intel and AMD instance types: Legacy BIOS
- Intel and AMD instance types that support UEFI, in addition to Legacy BIOS:
  - All instances built on the AWS Nitro System, except: bare metal instances, DL1, G4ad, P4, u-3tb1, u-6tb1, u-9tb1, u-12tb1, u-18tb1, u-24tb1, and VT1

To see the available instance types that support UEFI in a specific Region

The available instance types vary by AWS Region. To see the available instance types that support UEFI in a Region, use the `describe-instance-types` command with the `--region` parameter. If you omit the `--region` parameter, your default Region is used in the request. Include the `--filters` parameter to scope the results to the instance types that support UEFI and the `--query` parameter to scope the output to the value of `InstanceType`.

Use the command for your operating system.

**Linux**

AWS CLI

```bash
$ aws ec2 describe-instance-types --filters Name=supported-boot-mode,Values=uefi --query "InstanceTypes[*].[InstanceType]" --output text | sort

a1.2xlarge
a1.4xlarge
a1.large
a1.medium
a1.metal
a1.xlarge
c5.12xlarge
```
PowerShell

```powershell
PS C:\> Get-EC2InstanceType | 
    Where-Object {$_ SupportedBootModes -Contains "uefi"} | 
    Sort-Object InstanceType | 
    Format-Table InstanceType -GroupBy CurrentGeneration
```

CurrentGeneration: False

<table>
<thead>
<tr>
<th>InstanceType</th>
</tr>
</thead>
<tbody>
<tr>
<td>a1.2xlarge</td>
</tr>
<tr>
<td>a1.4xlarge</td>
</tr>
<tr>
<td>a1.large</td>
</tr>
<tr>
<td>a1.medium</td>
</tr>
<tr>
<td>a1.metal</td>
</tr>
<tr>
<td>a1.xlarge</td>
</tr>
</tbody>
</table>

CurrentGeneration: True

<table>
<thead>
<tr>
<th>InstanceType</th>
</tr>
</thead>
<tbody>
<tr>
<td>c5.12xlarge</td>
</tr>
<tr>
<td>c5.18xlarge</td>
</tr>
<tr>
<td>c5.24xlarge</td>
</tr>
<tr>
<td>c5.2xlarge</td>
</tr>
<tr>
<td>c5.4xlarge</td>
</tr>
<tr>
<td>c5.9xlarge</td>
</tr>
</tbody>
</table>

Windows

AWS CLI

```bash
$ aws ec2 describe-instance-types --filters Name=supported-boot-mode,Values=uefi 
    Name=processor-info.supported-architecture,Values=x86_64 --query "InstanceTypes[*].
    [InstanceType]" --output text | sort
```

<table>
<thead>
<tr>
<th>InstanceType</th>
</tr>
</thead>
<tbody>
<tr>
<td>c5.12xlarge</td>
</tr>
<tr>
<td>c5.18xlarge</td>
</tr>
</tbody>
</table>
To see the available instance types that support UEFI Secure Boot and persist non-volatile variables in a specific Region

Currently, bare metal instances do not support UEFI Secure Boot and non-volatile variables. Use the `describe-instance-types` command as described in the preceding example, but filter out the bare metal instances by including the `Name=bare-metal,Values=false` filter. For information about UEFI Secure Boot, see [UEFI Secure Boot](#).

Use the command for your operating system.
Linux

AWS CLI

```
$ aws ec2 describe-instance-types --filters Name=supported-boot-mode,Values=uefi Name=bare-metal,Values=false --query "InstanceTypes[*].[InstanceType]" --output text | sort

a1.2xlarge
a1.4xlarge
a1.large
a1.medium
...
```

PowerShell

```
PS C:\> Get-EC2InstanceType | 
    Where-Object { 
        $_.SupportedBootModes -Contains "uefi" -and 
        $_.BareMetal -eq $False 
    } | 
    Sort-Object InstanceType | 
    Format-Table InstanceType, SupportedBootModes, BareMetal, @
    @{Name="SupportedArchitectures"; 
    Expression={$_.ProcessorInfo.SupportedArchitectures}}

</table>

Requirements for launching an instance on UEFI

To launch an instance in UEFI boot mode, you must select an instance type that supports UEFI, and configure the AMI and the operating system for UEFI, as follows:

Instance type

When launching an instance, you must select an instance type that supports UEFI. For more information, see [Determine the supported boot modes of an instance type](#).
When launching an instance, you must select an AMI that is configured for UEFI. The AMI must be configured as follows:

- **Operating system** – The operating system contained in the AMI must be configured to use UEFI; otherwise, the instance launch will fail. For more information, see [Determine the boot mode of the operating system](#).

- **AMI boot mode parameter** – The boot mode parameter of the AMI must be set to `uefi` or `uefi-preferred`. For more information, see [Determine the boot mode parameter of an AMI](#).

**Linux** – The following Linux AMIs support UEFI:

- Amazon Linux 2023
- Amazon Linux 2 (Graviton instance types only)

For other Linux AMIs, you must [configure the AMI](#), import the AMI through [VM Import/Export](#), or import the AMI through [CloudEndure](#).

**Windows** – The following Windows AMIs support UEFI:

- TPM-Windows_Server-2022-English-Full-Base
- TPM-Windows_Server-2022-English-Core-Base
- TPM-Windows_Server-2019-English-Full-Base
- TPM-Windows_Server-2019-English-Core-Base
- TPM-Windows_Server-2016-English-Full-Base
- TPM-Windows_Server-2016-English-Core-Base

**Determine the boot mode parameter of an AMI**

The AMI boot mode parameter is optional. An AMI can have one of the following boot mode parameter values: `uefi`, `legacy-bios`, or `uefi-preferred`.

Some AMIs don't have a boot mode parameter. When an AMI has no boot mode parameter, the instances launched from the AMI use the default value of the instance type, which is `uefi` on Graviton, and `legacy-bios` on Intel and AMD instance types.
To determine the boot mode parameter of an AMI (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose AMIs, and then select the AMI.
3. Inspect the Boot mode field.
   - A value of uefi indicates that the AMI supports UEFI.
   - A value of uefi-preferred indicates that the AMI supports both UEFI and Legacy BIOS.
   - If there is no value, the instances launched from the AMI use the default value of the instance type.

To determine the boot mode parameter of an AMI when launching an instance (console)

When launching an instance using the launch instance wizard, at the step to select an AMI, inspect the Boot mode field. For more information, see Application and OS Images (Amazon Machine Image).

AWS CLI

To determine the boot mode parameter of an AMI (AWS CLI)

Use the describe-images operation to determine the boot mode of an AMI.

```bash
aws ec2 describe-images --region us-east-1 --image-id ami-0abcdef1234567890

{
  "Images": [
    ...
    "EnaSupport": true,
    "Hypervisor": "xen",
    "ImageOwnerAlias": "amazon",
    "Name": "UEFI_Boot_Mode_Enabled-Windows_Server-2016-English-Full-Base-2020.09.30",
    "RootDeviceName": "/dev/sda1",
    "RootDeviceType": "ebs",
    "SriovNetSupport": "simple",
    "VirtualizationType": "hvm",
  ]
}
In the output, the BootMode field indicates the boot mode of the AMI. A value of uefi indicates that the AMI supports UEFI. A value of uefi-preferred indicates that the AMI supports both UEFI and Legacy BIOS. If there is no value, the instances launched from the AMI use the default value of the instance type.

**PowerShell**

**To determine the boot mode parameter of an AMI (Tools for PowerShell)**

Use the `Get-EC2Image` Cmdlet to determine the boot mode of an AMI.

```
PS C:\> Get-EC2Image -Region us-east-1 -ImageId ami-0abcdef1234567890 | Format-List Name, BootMode, TpmSupport
Name       : TPM-Windows_Server-2016-English-Full-Base-2023.05.10
BootMode   : uefi
TpmSupport : v2.0
```

In the output, the BootMode field indicates the boot mode of the AMI. A value of uefi indicates that the AMI supports UEFI. A value of uefi-preferred indicates that the AMI supports both UEFI and Legacy BIOS. If there is no value, the instances launched from the AMI use the default value of the instance type.

**Determine the supported boot modes of an instance type**

You can use the AWS CLI or the Tools for PowerShell to determine the supported boot modes of an instance type.

**To determine the supported boot modes of an instance type**

You can use the following methods to determine the supported boot modes of an instance type.
AWS CLI

You can use the `describe-instance-types` command to determine the supported boot modes of an instance type. By including the `--query` parameter, you can filter the output. In this example, the output is filtered to return only the supported boot modes.

The following example shows that `m5.2xlarge` supports both UEFI and Legacy BIOS boot modes.

```
aws ec2 describe-instance-types --region us-east-1 --instance-types m5.2xlarge --query "InstanceTypes[*].SupportedBootModes"
```

Expected output:

```json
[
  [
    "legacy-bios",
    "uefi"
  ]
]
```

The following example shows that `t2.xlarge` supports only Legacy BIOS.

```
aws ec2 describe-instance-types --region us-east-1 --instance-types t2.xlarge --query "InstanceTypes[*].SupportedBootModes"
```

Expected output:

```json
[
  [
    "legacy-bios"
  ]
]
```

PowerShell

You can use the `Get-EC2InstanceType` (Tools for PowerShell) Cmdlet to determine the supported boot modes of an instance type.

The following example shows that `m5.2xlarge` supports both UEFI and Legacy BIOS boot modes.
Get-EC2InstanceType -Region *us-east-1* -InstanceType m5.2xlarge | Format-List InstanceType, SupportedBootModes

Expected output:

<table>
<thead>
<tr>
<th>InstanceType</th>
<th>m5.2xlarge</th>
</tr>
</thead>
<tbody>
<tr>
<td>SupportedBootModes</td>
<td>{legacy-bios, uefi}</td>
</tr>
</tbody>
</table>

The following example shows that t2.xlarge supports only Legacy BIOS.

Get-EC2InstanceType -Region *us-east-1* -InstanceType t2.xlarge | Format-List InstanceType, SupportedBootModes

Expected output:

<table>
<thead>
<tr>
<th>InstanceType</th>
<th>t2.xlarge</th>
</tr>
</thead>
<tbody>
<tr>
<td>SupportedBootModes</td>
<td>{legacy-bios}</td>
</tr>
</tbody>
</table>

### Determine the boot mode of an instance

The boot mode of an instance is displayed in the **Boot mode** field in the Amazon EC2 console, and by the `currentInstanceBootMode` parameter in the AWS CLI.

When an instance is launched, the value for its boot mode parameter is determined by the value of the boot mode parameter of the AMI used to launch it, as follows:

- An AMI with a boot mode parameter of `uefi` creates an instance with a `currentInstanceBootMode` parameter of `uefi`.
- An AMI with a boot mode parameter of `legacy-bios` creates an instance with a `currentInstanceBootMode` parameter of `legacy-bios`.
- An AMI with a boot mode parameter of `uefi-preferred` creates an instance with a `currentInstanceBootMode` parameter of `uefi` if the instance type supports UEFI; otherwise, it creates an instance with a `currentInstanceBootMode` parameter of `legacy-bios`.
- An AMI with no boot mode parameter value creates an instance with a `currentInstanceBootMode` parameter value that is dependent on whether the AMI architecture is ARM or x86 and the supported boot mode of the instance type. The default boot mode is `uefi` on Graviton instance types, and `legacy-bios` on Intel and AMD instance types.
Console

To determine the boot mode of an instance (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select your instance.
3. On the Details tab, inspect the Boot mode field.

AWS CLI

To determine the boot mode of an instance (AWS CLI)

Use the describe-instances command to determine the boot mode of an instance. You can also determine the boot mode of the AMI that was used to create the instance.

```
aws ec2 describe-instances --region us-east-1 --instance-ids i-1234567890abcdef0
```

```json
{
   "Reservations": [
      {
         "Groups": [],
         "Instances": [
            {
               "AmiLaunchIndex": 0,
               "ImageId": "ami-0e2063e7f6dc3bee8",
               "InstanceId": "i-1234567890abcdef0",
               "InstanceType": "m5.2xlarge",
               "BootMode": "uefi",
               "CurrentInstanceBootMode": "uefi"
            }
         ],
         "OwnerId": "1234567890",
         "ReservationId": "r-1234567890abcdef0"
      }
   ]
}
```

PowerShell

To determine the boot mode of an instance (Tools for PowerShell)
Use the **Get-EC2Image** Cmdlet to determine the boot mode of an instance. You can also determine the boot mode of the AMI that was used to create the instance.

**Get-EC2Image** (AWS Tools for Windows PowerShell)

```
(Get-EC2Instance -InstanceId i-1234567890abcdef0).Instances | Format-List BootMode, CurrentInstanceBootMode, InstanceType, ImageId
```

<table>
<thead>
<tr>
<th>BootMode</th>
<th>uefi</th>
</tr>
</thead>
<tbody>
<tr>
<td>CurrentInstanceBootMode</td>
<td>uefi</td>
</tr>
<tr>
<td>InstanceType</td>
<td>c5a.large</td>
</tr>
<tr>
<td>ImageId</td>
<td>ami-0265446f88eb4021b</td>
</tr>
</tbody>
</table>

In the output, the following parameters describe the boot mode:

- **BootMode** – The boot mode of the AMI that was used to create the instance.
- **CurrentInstanceBootMode** – The boot mode that is used to boot the instance at launch or start.

**Determine the boot mode of the operating system**

The boot mode of the AMI guides Amazon EC2 on which boot mode to use to boot an instance. To view whether the operating system of your instance is configured for UEFI, you need to connect to your instance using SSH (Linux instances) or RDP (Windows instances).

Use the instructions for your instance's operating system.

**Linux**

To determine the boot mode of the instance’s operating system

1. **Connect to your Linux instance using SSH.**
2. To view the boot mode of the operating system, try one of the following:
   - Run the following command.

```
[ec2-user ~]$ sudo /usr/sbin/efibootmgr
```

Expected output from an instance booted in UEFI boot mode
• Run the following command to verify the existence of the /sys/firmware/efi directory. This directory exists only if the instance boots using UEFI. If this directory doesn't exist, the command returns Legacy BIOS Boot Detected.

    [ec2-user ~]$ [ -d /sys/firmware/efi ] && echo "UEFI Boot Detected" || echo "Legacy BIOS Boot Detected"

Expected output from an instance booted in UEFI boot mode

UEFI Boot Detected

Expected output from an instance booted in Legacy BIOS boot mode

Legacy BIOS Boot Detected

• Run the following command to verify that EFI appears in the dmesg output.

    [ec2-user ~]$ dmesg | grep -i "EFI"

Expected output from an instance booted in UEFI boot mode

    [ 0.000000] efi: Getting EFI parameters from FDT:
    [ 0.000000] efi: EFI v2.70 by EDK II

**Windows**

To determine the boot mode of the instance’s operating system

1. Connect to your Windows instance using RDP.
2. Go to System Information and check the BIOS Mode row.
Set the boot mode of an AMI

When you create an AMI using the `register-image` command, you can set the boot mode of the AMI to either `uefi`, `legacy-bios`, or `uefi-preferred`.

When the AMI boot mode is set to `uefi-preferred`, the instance boots as follows:

- For instance types that support both UEFI and Legacy BIOS (for example, `m5.large`), the instance boots using UEFI.
- For instance types that support only Legacy BIOS (for example, `m4.large`), the instance boots using Legacy BIOS.

**Note**

If you set the AMI boot mode to `uefi-preferred`, the operating system must support the ability to boot both UEFI and Legacy BIOS. Currently, you can't use the `register-image` command to create an AMI that supports both NitroTPM and UEFI Preferred.
**Warning**

Some features, like UEFI Secure Boot, are only available on instances that boot on UEFI. When you use the `uefi-preferred` AMI boot mode parameter with an instance type that does not support UEFI, the instance will launch as Legacy BIOS and the UEFI-dependent feature will be disabled. If you rely on the availability of a UEFI-dependent feature, set your AMI boot mode parameter to `uefi`.

To convert an existing Legacy BIOS-based instance to UEFI, or an existing UEFI-based instance to Legacy BIOS, you need to perform a number of steps: First, modify the instance's volume and operating system to support the selected boot mode. Then, create a snapshot of the volume. Finally, use `register-image` to create the AMI using the snapshot.

You can't set the boot mode of an AMI using the `create-image` command. With `create-image`, the AMI inherits the boot mode of the EC2 instance used for creating the AMI. For example, if you create an AMI from an EC2 instance running on Legacy BIOS, the AMI boot mode will be configured as `legacy-bios`. If you create an AMI from an EC2 instance that was launched using an AMI with a boot mode set to `uefi-preferred`, the AMI that is created will also have its boot mode set to `uefi-preferred`.

**Warning**

Setting the AMI boot mode parameter does not automatically configure the operating system for the specified boot mode. Before proceeding with these steps, you must first make suitable modifications to the instance's volume and operating system to support booting using the selected boot mode; otherwise, the resulting AMI will not be usable. For example, if you are converting a Legacy BIOS-based Windows instance to UEFI, you can use the `MBR2GPT` tool from Microsoft to convert the system disk from MBR to GPT. The modifications that are required are operating system-specific. For more information, see the manual for your operating system.

**To set the boot mode of an AMI (AWS CLI)**

1. Make suitable modifications to the instance's volume and operating system to support booting via the selected boot mode. The modifications that are required are operating system-specific. For more information, see the manual for your operating system.
Note
If you don’t perform this step, the AMI will not be usable.

2. To find the volume ID of the instance, use the `describe-instances` command. You'll create a snapshot of this volume in the next step.

```
aws ec2 describe-instances --region us-east-1 --instance-ids i-1234567890abcdef0
```

**Expected output**

```json
...
   "BlockDeviceMappings": [
       {
           "DeviceName": "/dev/sda1",
           "Ebs": {
               "AttachTime": "",
               "DeleteOnTermination": true,
               "Status": "attached",
               "VolumeId": "vol-1234567890abcdef0"
           }
       }
   ...
```

3. To create a snapshot of the volume, use the `create-snapshot` command. Use the volume ID from the previous step.

```
aws ec2 create-snapshot --region us-east-1 --volume-id vol-1234567890abcdef0 --description "add text"
```

**Expected output**

```json
{
   "Description": "add text",
   "Encrypted": false,
   "OwnerId": "123",
   "Progress": "",
   "SnapshotId": "snap-01234567890abcdef",
   "StartTime": "",
   "State": "pending",
}```
4. Note the snapshot ID in the output from the previous step.

5. Wait until the snapshot creation is completed before going to the next step. To query the state of the snapshot, use the `describe-snapshots` command.

   ```bash
   aws ec2 describe-snapshots --region us-east-1 --snapshot-ids snap-01234567890abcdef
   ```

   **Example output**

   ```json
   {
     "Snapshots": [
       {
         "Description": "This is my snapshot",
         "Encrypted": false,
         "VolumeId": "vol-049df61146c4d7901",
         "State": "completed",
         "VolumeSize": 8,
         "StartTime": "2019-02-28T21:28:32.000Z",
         "Progress": "100%",
         "OwnerId": "012345678910",
         "SnapshotId": "snap-01234567890abcdef",
         ...
       }
     ]
   }
   ```

6. To create a new AMI, use the `register-image` command. Use the snapshot ID that you noted in the earlier step.

   - To set the boot mode to UEFI, add the `--boot-mode` parameter to the command and specify `uefi` as the value.

   ```bash
   aws ec2 register-image \
   --region us-east-1 \
   --description "add description" \
   --name "add name" \
   --block-device-mappings "DeviceName=/dev/sda1,Ebs={SnapshotId=snap-01234567890abcdef,DeleteOnTermination=true}" \
   --architecture x86_64 \
   --root-device-name /dev/sda1 \
   --virtualization-type hvm \
   ```
To set the boot mode to uEFI-preferred, add the `--boot-mode` parameter to the command and specify `uefi-preferred` as the value:

```
aws ec2 register-image
  --region us-east-1
  --description "add description"
  --name "add name"
  --block-device-mappings "DeviceName=/dev/sda1,Ebs={SnapshotId=snap-01234567890abcdef,DeleteOnTermination=true}"
  --architecture x86_64
  --root-device-name /dev/sda1
  --virtualization-type hvm
  --ena-support
  --boot-mode uEFI-preferred
```

Expected output:

```
{
  "ImageId": "ami-new_ami_123"
}
```

7. To verify that the newly-created AMI has the boot mode that you specified in the previous step, use the `describe-images` command:

```
aws ec2 describe-images --region us-east-1 --image-id ami-new_ami_123
```

Expected output:

```
{
  "Images": [
    {
      "Architecture": "x86_64",
      "CreationDate": "2021-01-06T14:31:04.000Z",
      "ImageId": "ami-new_ami_123",
      "ImageLocation": ",",
      ...
      "BootMode": "uefi"
    }
  ]
}
```
8. Launch a new instance using the newly-created AMI.

   If the AMI boot mode is `uefi` or `legacy-bios`, instances created from this AMI will have the same boot mode as the AMI. If the AMI boot mode is `uefi-preferred`, the instance will boot using UEFI if the instance type supports UEFI; otherwise, the instance will boot using Legacy BIOS. For more information, see Considerations.

9. To verify that the new instance has the expected boot mode, use the `describe-instances` command.

**UEFI variables**

When you launch an instance where the boot mode is set to UEFI, a key-value store for variables is created. The store can be used by UEFI and the instance operating system for storing UEFI variables.

UEFI variables are used by the boot loader and the operating system to configure early system startup. They allow the operating system to manage certain settings of the boot process, like the boot order, or managing the keys for UEFI Secure Boot.

⚠️ **Warning**

Anyone who can connect to the instance (and potentially any software running on the instance), or anyone with permissions to use the `GetInstanceUefiData` API on the instance can read the variables. You should never store sensitive data, such as passwords or personally identifiable information, in the UEFI variable store.

**UEFI variable persistence**

- For instances that were launched on or before May 10, 2022, UEFI variables are wiped on reboot or stop.
- For instances that are launched on or after May 11, 2022, UEFI variables that are marked as non-volatile are persisted on reboot and stop/start.
- Bare metal instances don't preserve UEFI non-volatile variables across instance stop/start operations.
UEFI Secure Boot

UEFI Secure Boot builds on the long-standing secure boot process of Amazon EC2, and provides additional defense-in-depth that helps customers secure software from threats that persist across reboots. It ensures that the instance only boots software that is signed with cryptographic keys. The keys are stored in the key database of the UEFI non-volatile variable store. UEFI Secure Boot prevents unauthorized modification of the instance boot flow.

Topics

- How UEFI Secure Boot works
- Launch an instance with UEFI Secure Boot support
- Verify whether an instance is enabled for UEFI Secure Boot
- Create a Linux AMI to support UEFI Secure Boot
- How the AWS binary blob is created

How UEFI Secure Boot works

UEFI Secure Boot is a feature specified in UEFI, which provides verification about the state of the boot chain. It is designed to ensure that only cryptographically verified UEFI binaries are executed after the self-initialization of the firmware. These binaries include UEFI drivers and the main bootloader, as well as chain-loaded components.

UEFI Secure Boot specifies four key databases, which are used in a chain of trust. The databases are stored in the UEFI variable store.

The chain of trust is as follows:

Platform key (PK) database

The PK database is the root of trust. It contains a single public PK key that is used in the chain of trust for updating the key exchange key (KEK) database.

To change the PK database, you must have the private PK key to sign an update request. This includes deleting the PK database by writing an empty PK key.

Key exchange key (KEK) database

The KEK database is a list of public KEK keys that are used in the chain of trust for updating the signature (db) and denylist (dbx) databases.
To change the public KEK database, you must have the private PK key to sign an update request.

**Signature (db) database**

The db database is a list of public keys and hashes that are used in the chain of trust to validate all UEFI boot binaries.

To change the db database, you must have the private PK key or any of the private KEK keys to sign an update request.

**Signature denylist (dbx) database**

The dbx database is a list of public keys and binary hashes that are not trusted, and are used in the chain of trust as a revocation file.

The dbx database always takes precedence over all other key databases.

To change the dbx database, you must have the private PK key or any of the private KEK keys to sign an update request.

The UEFI Forum maintains a publicly available dbx for many known-bad binaries and certs at https://uefi.org/revocationlistfile.

---

**Important**

UEFI Secure Boot enforces signature validation on any UEFI binaries. To permit execution of a UEFI binary in UEFI Secure Boot, you sign it with any of the private db keys described above.

---

By default, UEFI Secure Boot is disabled and the system is in SetupMode. When the system is in SetupMode, all key variables can be updated without a cryptographic signature. When the PK is set, UEFI Secure Boot is enabled and the SetupMode is exited.

**Launch an instance with UEFI Secure Boot support**

When you launch an instance with the following prerequisites, the instance will automatically validate UEFI boot binaries against its UEFI Secure Boot database. You can also configure UEFI Secure Boot on an instance after launch.
Note

UEFI Secure Boot protects your instance and its operating system against boot flow modifications. If you create a new AMI from a source AMI that has UEFI Secure Boot enabled and modify certain parameters during the copy process, such as changing the UefiData within the AMI, you can disable UEFI Secure Boot.

Prerequisites

Linux AMIs

To launch a Linux instance, the Linux AMI must have UEFI Secure Boot enabled.

Amazon Linux supports UEFI Secure Boot starting with AL2023 release 2023.1. However, UEFI Secure Boot isn't enabled in the default AMIs. For more information, see UEFI Secure Boot in the AL2023 User Guide. Older versions of Amazon Linux AMIs aren't enabled for UEFI Secure Boot. To use a supported AMI, you must perform a number of configuration steps on your own Linux AMI. For more information, see Create a Linux AMI to support UEFI Secure Boot.

Windows AMIs

To launch a Windows instance, the Windows AMI must have UEFI Secure Boot enabled.

The following Windows AMIs are preconfigured to enable UEFI Secure Boot with Microsoft keys:

- TPM-Windows_Server-2022-English-Core-Base
- TPM-Windows_Server-2022-English-Full-Base
- TPM-Windows_Server-2022-English-Full-SQL_2022_Enterprise
- TPM-Windows_Server-2019-English-Core-Base
- TPM-Windows_Server-2019-English-Full-Base
- TPM-Windows_Server-2016-English-Core-Base
- TPM-Windows_Server-2016-English-Full-Base

Currently, we do not support importing Windows with UEFI Secure Boot by using the import-image command.
Instance type

- Supported: All virtualized instance types that support UEFI also support UEFI Secure Boot. For the instance types that support UEFI Secure Boot, see Considerations.
- Not supported: Bare metal instance types do not support UEFI Secure Boot.

Verify whether an instance is enabled for UEFI Secure Boot

Linux instances

You can use the mokutil utility to verify whether a Linux instance is enabled for UEFI Secure Boot. If mokutil is not installed on your instance, you must install it. For the installation instructions for Amazon Linux 2, see https://docs.aws.amazon.com/linux/al2/ug/find-install-software.html. For other Linux distributions, see their specific documentation.

To verify whether a Linux instance is enabled for UEFI Secure Boot

Run the following command as root on the instance.

```
mokutil --sb-state
```

Expected output:

- If UEFI Secure Boot is enabled, the output contains SecureBoot enabled.
- If UEFI Secure Boot is not enabled, the output contains SecureBoot disabled or Failed to read SecureBoot.

Windows instances

To verify whether a Windows instance is enabled for UEFI Secure Boot

1. Open the msinfo32 tool.
2. Check the Secure Boot State field. Supported indicates that UEFI Secure Boot is enabled.
You can also use the Windows PowerShell Cmdlet `Confirm-SecureBootUEFI` to check the Secure Boot status. For more information about the cmdlet, see `Confirm-SecureBootUEFI` in the Microsoft Documentation website.

**Create a Linux AMI to support UEFI Secure Boot**

The following procedures describe how to create your own UEFI variable store for secure boot with custom-made private keys. Amazon Linux supports UEFI Secure Boot starting with AL2023 release 2023.1. For more information, see **UEFI Secure Boot** in the *AL2023 User Guide*.

⚠️ **Important**

The following procedures for creating an AMI to support UEFI Secure Boot are intended for advanced users only. You must have sufficient knowledge of SSL and Linux distribution boot flow to use these procedures.

**Prerequisites**

- The following tools will be used:
  - OpenSSL – [https://www.openssl.org/](https://www.openssl.org/)
• efivar – [https://github.com/rhboot/efivar](https://github.com/rhboot/efivar)
• get-instance-uefi-data AWS CLI command

Your Linux instance must have been launched with a Linux AMI that supports UEFI boot mode, and have non-volatile data present.

Newly created instances without UEFI Secure Boot keys are created in SetupMode, which allows you to enroll your own keys. Some AMIs come preconfigured with UEFI Secure Boot and you cannot change the existing keys. If you want to change the keys, you must create a new AMI based on the original AMI.

You have two ways to propagate the keys in the variable store, which are described in Option A and Option B that follow. Option A describes how to do this from within the instance, mimicking the flow of real hardware. Option B describes how to create a binary blob, which is then passed as a base64-encoded file when you create the AMI. For both options, you must first create the three key pairs, which are used for the chain of trust.

To create a Linux AMI to support UEFI Secure Boot, first create the three key pairs, and then complete either Option A or Option B:

• Create three key pairs
• Option A: Add keys to the variable store from within the instance
• Option B: Create a binary blob containing a pre-filled variable store

Note
These instructions can only be used to create a Linux AMI. If you need a Windows AMI, use one of the supported Windows AMIs. For more information, see [Launch an instance with UEFI Secure Boot support](#).

Create three key pairs

UEFI Secure Boot is based on the following three key databases, which are used in a chain of trust: the platform key (PK), the key exchange key (KEK), and the signature database (db).¹
You create each key on the instance. To prepare the public keys in a format that is valid for the UEFI Secure Boot standard, you create a certificate for each key. DER defines the SSL format (binary encoding of a format). You then convert each certificate into a UEFI signature list, which is the binary format that is understood by UEFI Secure Boot. And finally, you sign each certificate with the relevant key.

**Topics**

- **Prepare to create the key pairs**
- **Key pair 1: Create the platform key (PK)**
- **Key pair 2: Create the key exchange key (KEK)**
- **Key pair 3: Create the signature database (db)**
- **Sign the boot image (kernel) with the private key**

**Prepare to create the key pairs**

Before creating the key pairs, create a globally unique identifier (GUID) to be used in key generation.

1. **Connect to the instance.**
2. Run the following command in a shell prompt.

```
uuidgen --random > GUID.txt
```

**Key pair 1: Create the platform key (PK)**

The PK is the root of trust for UEFI Secure Boot instances. The private PK is used to update the KEK, which in turn can be used to add authorized keys to the signature database (db).

The X.509 standard is used for creating the key pair. For information about the standard, see [X.509](http://en.wikipedia.org/wiki/X.509) on Wikipedia.

**To create the PK**

1. Create the key. You must name the variable PK.

```
openssl req -newkey rsa:4096 -nodes -keyout PK.key -new -x509 -sha256 -days 3650 -subj "/CN=Platform key/" -out PK.crt
```
The following parameters are specified:

- `-keyout PK.key` – The private key file.
- `-days 3650` – The number of days that the certificate is valid.
- `-out PK.crt` – The certificate that is used to create the UEFI variable.
- `CN=Platform key` – The common name (CN) for the key. You can enter the name of your own organization instead of `Platform key`.

2. Create the certificate.

```bash
openssl x509 -outform DER -in PK.crt -out PK.cer
```

3. Convert the certificate into a UEFI signature list.

```bash
cert-to-efi-sig-list -g "$(< GUID.txt)" PK.crt PK.esl
```

4. Sign the UEFI signature list with the private PK (self-signed).

```bash
sign-efi-sig-list -g "$(< GUID.txt)" -k PK.key -c PK.crt PK PK.esl PK.auth
```

**Key pair 2: Create the key exchange key (KEK)**

The private KEK is used to add keys to the db, which is the list of authorized signatures to boot on the system.

**To create the KEK**

1. Create the key.

```bash
openssl req -newkey rsa:4096 -nodes -keyout KEK.key -new -x509 -sha256 -days 3650 -subj "/CN=Key Exchange Key/" -out KEK.crt
```

2. Create the certificate.

```bash
openssl x509 -outform DER -in KEK.crt -out KEK.cer
```

3. Convert the certificate into a UEFI signature list.

```bash
cert-to-efi-sig-list -g "$(< GUID.txt)" KEK.crt KEK.esl
```
4. Sign the signature list with the private PK.

   sign-efi-sig-list -g "$(< GUID.txt)" -k PK.key -c PK.crt KEK KEK.esl KEK.auth

**Key pair 3: Create the signature database (db)**

The db list contains authorized keys that are authorized to be booted on the system. To modify the list, the private KEK is necessary. Boot images will be signed with the private key that is created in this step.

**To create the db**

1. Create the key.

   openssl req -newkey rsa:4096 -nodes -keyout db.key -new -x509 -sha256 -days 3650 -subj "/CN=Signature Database key/" -out db.crt

2. Create the certificate.

   openssl x509 -outform DER -in db.crt -out db.cer

3. Convert the certificate into a UEFI signature list.

   cert-to-efi-sig-list -g "$(< GUID.txt)" db.crt db.esl

4. Sign the signature list with the private KEK.

   sign-efi-sig-list -g "$(< GUID.txt)" -k KEK.key -c KEK.crt db db.esl db.auth

**Sign the boot image (kernel) with the private key**

For Ubuntu 22.04, the following images require signatures.

/boot/efi/EFI/ubuntu/shimx64.efi
/boot/efi/EFI/ubuntu/mmx64.efi
/boot/efi/EFI/ubuntu/grubx64.efi
/boot/vmlinuz

**To sign an image**
Use the following syntax to sign an image.

sbsign --key db.key --cert db.crt --output /boot/vmlinuz /boot/vmlinuz

Note
You must sign all new kernels. /boot/vmlinuz will usually symlink to the last installed kernel.

Refer to the documentation for your distribution to find out about your boot chain and required images.

¹ Thanks to the ArchWiki community for all of the work they have done. The commands for creating the PK, creating the KEK, creating the DB, and signing the image are from Creating keys, authored by the ArchWiki Maintenance Team and/or the ArchWiki contributors.

Option A: Add keys to the variable store from within the instance

After you have created the three key pairs, you can connect to your instance and add the keys to the variable store from within the instance by completing the following steps.

Option A steps:

- Step 1: Launch an instance that will support UEFI Secure Boot
- Step 2: Configure an instance to support UEFI Secure Boot
- Step 3: Create an AMI from the instance

Step 1: Launch an instance that will support UEFI Secure Boot

When you launch an instance with the following prerequisites, the instance will then be ready to be configured to support UEFI Secure Boot. You can only enable support for UEFI Secure Boot on an instance at launch; you can't enable it later.

Prerequisites

- AMI – The Linux AMI must support UEFI boot mode. To verify that the AMI supports UEFI boot mode, the AMI boot mode parameter must be uefi. For more information, see Determine the boot mode parameter of an AMI.
Note that AWS only provides Linux AMIs configured to support UEFI for Graviton-based instance types. AWS currently does not provide x86_64 Linux AMIs that support UEFI boot mode. You can configure your own AMI to support UEFI boot mode for all architectures. To configure your own AMI to support UEFI boot mode, you must perform a number of configuration steps on your own AMI. For more information, see Set the boot mode of an AMI.

- **Instance type** – All virtualized instance types that support UEFI also support UEFI Secure Boot. Bare metal instance types do not support UEFI Secure Boot. For the instance types that support UEFI Secure Boot, see Considerations.

- Launch your instance after the release of UEFI Secure Boot. Only instances launched after May 10, 2022 (when UEFI Secure Boot was released) can support UEFI Secure Boot.

After you’ve launched your instance, you can verify that it is ready to be configured to support UEFI Secure Boot (in other words, you can proceed to Step 2) by checking whether UEFI data is present. The presence of UEFI data indicates that non-volatile data is persisted.

To verify whether your instance is ready for Step 2

Use the **get-instance-uefi-data** command and specify the instance ID.

```bash
aws ec2 get-instance-uefi-data --instance-id i-0123456789example
```

The instance is ready for Step 2 if UEFI data is present in the output. If the output is empty, the instance cannot be configured to support UEFI Secure Boot. This can happen if your instance was launched before UEFI Secure Boot support became available. Launch a new instance and try again.

**Step 2: Configure an instance to support UEFI Secure Boot**

**Enroll the key pairs in your UEFI variable store on the instance**

⚠️ **Warning**

You must sign your boot images after you enroll the keys, otherwise you won’t be able to boot your instance.

After you create the signed UEFI signature lists (PK, KEK, and db), they must be enrolled into the UEFI firmware.
Writing to the PK variable is possible only if:

- No PK is enrolled yet, which is indicated if the SetupMode variable is 1. Check this by using the following command. The output is either 1 or 0.

  ```
  efivar -d -n 8be4df61-93ca-11d2-aa0d-00e098032b8c-SetupMode
  ```

- The new PK is signed by the private key of the existing PK.

To enroll the keys in your UEFI variable store

The following commands must be run on the instance.

If SetupMode is enabled (the value is 1), the keys can be enrolled by running the following commands on the instance:

```
[ec2-user ~]$ efi-updatevar -f db.auth db
[ec2-user ~]$ efi-updatevar -f KEK.auth KEK
[ec2-user ~]$ efi-updatevar -f PK.auth PK
```

To verify that UEFI Secure Boot is enabled

To verify that UEFI Secure Boot is enabled, follow the steps in Verify whether an instance is enabled for UEFI Secure Boot.

You can now export your UEFI variable store with the get-instance-uefi-data CLI command, or you continue to the next step and sign your boot images to reboot into a UEFI Secure Boot-enabled instance.

**Step 3: Create an AMI from the instance**

To create an AMI from the instance, you can use the console or the CreateImage API, CLI, or SDKs. For the console instructions, see Create an Amazon EBS-backed AMI. For the API instructions, see CreateImage.
Note
The CreateImage API automatically copies the UEFI variable store of the instance to the AMI. The console uses the CreateImage API. After you launch instances using this AMI, the instances will have the same UEFI variable store.

Option B: Create a binary blob containing a pre-filled variable store

After you have created the three key pairs, you can create a binary blob containing a pre-filled variable store containing the UEFI Secure Boot keys.

Warning
You must sign your boot images before you enroll the keys, otherwise you won’t be able to boot your instance.

Option B steps:
- Step 1: Create a new variable store or update an existing one
- Step 2: Upload the binary blob on AMI creation

Step 1: Create a new variable store or update an existing one

You can create the variable store offline without a running instance by using the python-uefivars tool. The tool can create a new variable store from your keys. The script currently supports the EDK2 format, the AWS format, and a JSON representation that is easier to edit with higher-level tooling.

To create the variable store offline without a running instance

1. Download the tool at the following link.
   https://github.com/awslabs/python-uefivars
2. Create a new variable store from your keys by running the following command. This will create a base64-encoded binary blob in your_binary_blob.bin. The tool also supports updating a binary blob via the -I parameter.
Step 2: Upload the binary blob on AMI creation

Use `register-image` to pass your UEFI variable store data. For the `--uefi-data` parameter, specify your binary blob, and for the `--boot-mode` parameter, specify `uefi`.

```bash
aws ec2 register-image \
  --name uefi_SB_tpm_register_image_test \
  --uefi-data $(cat your_binary_blob.bin) \
  --block-device-mappings "DeviceName=/dev/sda1,Ebs=\n  {SnapshotId=snap-0123456789example,DeleteOnTermination=true}" \
  --architecture x86_64 \
  --root-device-name /dev/sda1 \
  --virtualization-type hvm \
  --ena-support \n  --boot-mode uefi
```

How the AWS binary blob is created

You can use the following steps to customize the UEFI Secure Boot variables during AMI creation. The KEK that is used in these steps is current as of September 2021. If Microsoft updates the KEK, you must use the latest KEK.

To create the AWS binary blob

1. Create an empty PK signature list.

   ```
touch empty_key.crt
cert-to-efi-sig-list empty_key.crt PK.esl
   ```

2. Download the KEK certificates.

   ```
https://go.microsoft.com/fwlink/?LinkId=321185
   ```

3. Wrap the KEK certificates in a UEFI signature list (siglist).
4. **Download Microsoft's db certificates.**

   https://www.microsoft.com/pkiops/certs/MicCorUEFCA2011_2011-06-27.crt

5. **Generate the db signature list.**

   sbsiglist --owner 77fa9abd-0359-4d32-bd60-28f4e78f784b --type x509 --output
   MS_Win_DB.esl MicWinProPCA2011_2011-10-19.crt
   sbsiglist --owner 77fa9abd-0359-4d32-bd60-28f4e78f784b --type x509 --output
   MS_UEFI_DB.esl MicCorUEFCA2011_2011-06-27.crt
   cat MS_Win_DB.esl MS_UEFI_DB.esl > MS_DB.esl

6. **Download an updated dbx change request from the following link.**

   https://uefi.org/revocationlistfile

7. **The dbx change request that you downloaded in the previous step is already signed with the Microsoft KEK, so you need to strip or unpack it. You can use the following links.**

   https://gist.github.com/out0xb2/f8e0bae94214889a89ac67fceb37f8c0
   

8. **Build a UEFI variable store using the uefivars.py script.**

   ./uefivars.py -i none -o aws -0 uefiblob-microsoft-keys-empty-pk.bin -P ~/PK.esl -K
   ~/MS_Win KEK.esl --db ~/MS_DB.esl --dbx ~/dbx-2021-April.bin

9. **Check the binary blob and the UEFI variable store.**

   ./uefivars.py -i aws -I uefiblob-microsoft-keys-empty-pk.bin -o json | less

10. **You can update the blob by passing it to the same tool again.**
Expected output

Replacing PK
Replacing KEK
Replacing db
Replacing dbx

Find an AMI

An AMI includes the components and applications, such as the operating system and type of root volume, required to launch an instance. To launch an instance that meets your needs, you must find an AMI that meets your needs.

When selecting an AMI, consider the following requirements you might have for the instances that you want to launch:

- The Region – AMI IDs are unique to each AWS Region.
- The operating system
- The architecture: 32-bit (i386), 64-bit (x86_64), or 64-bit ARM (arm64)
- The root device type: Amazon EBS or instance store
- The provider (for example, Amazon Web Services)
- Additional software (for example, SQL Server)

There are various ways to find an AMI that meets your needs. This topic describes how to find an AMI using the Amazon EC2 console, AWS CLI, AWS Tools for Windows PowerShell, and AWS Systems Manager.

Topics

- Find an AMI using the Amazon EC2 console
- Find an AMI using the AWS CLI
- Find an AMI using the AWS Tools for Windows PowerShell
Find an AMI using the Amazon EC2 console

You can find AMIs using the Amazon EC2 console. You can select from the list of AMIs when you use the launch instance wizard to launch an instance, or you can search through all available AMIs using the Images page.

To find an AMI using the launch instance wizard

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location. AMI IDs are unique to each AWS Region.
3. From the console dashboard, choose Launch instance.
4. (New console) Under Application and OS Images (Amazon Machine Image), choose Quick Start, choose the operating system (OS) for your instance, and then, from Amazon Machine Image (AMI), select from one of the commonly used AMIs in the list. If you don't see the AMI that you want to use, choose Browse more AMIs to browse the full AMI catalog. For more information, see Application and OS Images (Amazon Machine Image).
   
   (Old console) On the Quick Start tab, select from one of the commonly used AMIs in the list. If you don't see the AMI that you want to use, choose the My AMIs, AWS Marketplace, or Community AMIs tab to find additional AMIs. For more information, see Step 1: Choose an Amazon Machine Image (AMI).

To find an AMI using the AMIs page

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location. AMI IDs are unique to each AWS Region.
3. In the navigation pane, choose AMIs.
4. (Optional) Use the filter and search options to scope the list of displayed AMIs to see only the
AMIs that match your criteria.

For example, to list all AMIs provided by AWS, choose **Public images**. Then use the search
options to further scope the list of displayed AMIs. Choose the **Search** bar and, from the menu,
choose **Owner alias**, then the = operator, and then the value **amazon**. To find AMIs that match
a specific platform, for example Linux or Windows, choose the **Search** bar again to choose
**Platform**, then the = operator, and then the operating system from the list provided.

5. (Optional) Choose the **Preferences** icon to select which image attributes to display, such as the
root device type. Alternatively, you can select an AMI from the list and view its properties on
the **Details** tab.

6. Before you select an AMI, it's important that you check whether it's backed by instance store or
by Amazon EBS and that you are aware of the effects of this difference. For more information,
see **Storage for the root device**.

7. To launch an instance from this AMI, select it and then choose **Launch instance from image**.
For more information about launching an instance using the console, see **Launch an instance
using the new launch instance wizard**. If you're not ready to launch the instance now, make
note of the AMI ID for later.

### Find an AMI using the AWS CLI

You can use the **describe-images** AWS CLI command to list only the AMIs that match your
requirements. After locating an AMI that matches your requirements, make note of its ID so that
you can use it to launch instances. For more information, see **Launch your instance** in the **AWS
Command Line Interface User Guide**.

The **describe-images** command supports filtering parameters. For example, use the **--owners**
parameter to display public AMIs owned by Amazon.

```bash
aws ec2 describe-images --owners amazon
```

You can add the following filter to the previous command to display only Windows AMIs.

```bash
--filters "Name=platform,Values=windows"
```

You can add the following filter to the previous command to display only AMIs backed by Amazon
EBS.
Important

If you omit the `--owners` parameter from the `describe-images` command, all images are returned for which you have launch permissions, regardless of ownership.

Find an AMI using the AWS Tools for Windows PowerShell

You can use PowerShell cmdlets to list only the Windows AMIs that match your requirements. For information and examples, see Find an Amazon Machine Image Using Windows PowerShell in the AWS Tools for Windows PowerShell User Guide.

After locating an AMI that matches your requirements, make note of its ID so that you can use it to launch instances. For more information, see Launch an Amazon EC2 Instance Using Windows PowerShell in the AWS Tools for Windows PowerShell User Guide.

Find an AMI using a Systems Manager parameter

When you launch an instance using the EC2 launch instance wizard in the Amazon EC2 console, you can either select an AMI from the list (described in Find an AMI using the Amazon EC2 console), or you can select an AWS Systems Manager parameter that points to an AMI ID (described in this section). If you use automation code to launch your instances, you can specify the Systems Manager parameter instead of the AMI ID.

A Systems Manager parameter is a customer-defined key-value pair that you can create in Systems Manager Parameter Store. The Parameter Store provides a central store to externalize your application configuration values. For more information, see AWS Systems Manager Parameter Store in the AWS Systems Manager User Guide.

When you create a parameter that points to an AMI ID, make sure that you specify the data type as `aws:ec2:image`. Specifying this data type ensures that when the parameter is created or modified, the parameter value is validated as an AMI ID. For more information, see Native parameter support for Amazon Machine Image IDs in the AWS Systems Manager User Guide.

Topics

- Use cases
• Permissions

• Limitations

• Launch an instance using a Systems Manager parameter

Use cases

When you use Systems Manager parameters to point to AMI IDs, it is easier for your users to select the correct AMI when launching instances. Systems Manager parameters can also simplify the maintenance of automation code.

Easier for users

If you require instances to be launched using a specific AMI, and the AMI is regularly updated, we recommend that you require your users to select a Systems Manager parameter to find the AMI. Requiring your users to select a Systems Manager parameter ensures that the latest AMI is used to launch instances.

For example, every month in your organization you might create a new version of your AMI that has the latest operating system and application patches. You also require your users to launch instances using the latest version of your AMI. To ensure that your users use the latest version, you can create a Systems Manager parameter (for example, golden-ami) that points to the correct AMI ID. Each time a new version of the AMI is created, you update the AMI ID value in the parameter so that it always points to the latest AMI. Your users don't have to know about the periodic updates to the AMI because they continue to select the same Systems Manager parameter each time. Using a Systems Manager parameter for your AMI makes it easier for them to select the correct AMI for an instance launch.

Simplify automation code maintenance

If you use automation code to launch your instances, you can specify the Systems Manager parameter instead of the AMI ID. If a new version of the AMI is created, you can change the AMI ID value in the parameter so that it points to the latest AMI. The automation code that references the parameter doesn't have to be modified each time a new version of the AMI is created. This simplifies the maintenance of the automation and helps to drive down deployment costs.
Note

Running instances are not affected when you change the AMI ID pointed to by the Systems Manager parameter.

Permissions

If you use Systems Manager parameters that point to AMI IDs in the launch instance wizard, you must add the following permissions to your IAM policy:

- `ssm:DescribeParameters` – Grants permission to view and select Systems Manager parameters.
- `ssm:GetParameters` – Grants permission to retrieve the values of the Systems Manager parameters.

You can also restrict access to specific Systems Manager parameters. For more information and example IAM policies, see Example: Use the EC2 launch instance wizard.

Limitations

AMIs and Systems Manager parameters are Region specific. To use the same Systems Manager parameter name across Regions, create a Systems Manager parameter in each Region with the same name (for example, golden-ami). In each Region, point the Systems Manager parameter to an AMI in that Region.

Launch an instance using a Systems Manager parameter

You can launch an instance using the console or the AWS CLI. Instead of specifying an AMI ID, you can specify an AWS Systems Manager parameter that points to an AMI ID.

New console

To find an AMI using a Systems Manager parameter (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. From the console dashboard, choose Launch instance.
4. Under **Application and OS Images (Amazon Machine Image)**, choose **Browse more AMIs**.

5. Choose the arrow button to the right of the search bar, and then choose **Search by Systems Manager parameter**.

6. For **Systems Manager parameter**, select a parameter. The corresponding AMI ID appears below **Currently resolves to**.

7. Choose **Search**. The AMIs that match the AMI ID appear in the list.

8. Select the AMI from the list, and choose **Select**.

For more information about launching an instance using the launch instance wizard, see **Launch an instance using the new launch instance wizard**.

**Old console**

**To find an AMI using a Systems Manager parameter (console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. From the console dashboard, choose **Launch instance**.
4. Choose **Search by Systems Manager parameter** (at top right).
5. For **Systems Manager parameter**, select a parameter. The corresponding AMI ID appears next to **Currently resolves to**.
6. Choose **Search**. The AMIs that match the AMI ID appear in the list.
7. Select the AMI from the list, and choose **Select**.

For more information about launching an instance from an AMI using the launch instance wizard, see **Step 1: Choose an Amazon Machine Image (AMI)**.

**To launch an instance using an AWS Systems Manager parameter instead of an AMI ID (AWS CLI)**

The following example uses the Systems Manager parameter `golden-ami` to launch an `m5.xlarge` instance. The parameter points to an AMI ID.

To specify the parameter in the command, use the following syntax: `resolve:ssm:/parameter-name`, where `resolve:ssm` is the standard prefix and `parameter-name` is the unique parameter.
name. Note that the parameter name is case-sensitive. Backslashes for the parameter name are only necessary when the parameter is part of a hierarchy, for example, /amis/production/golden-ami. You can omit the backslash if the parameter is not part of a hierarchy.

In this example, the --count and --security-group parameters are not included. For --count, the default is 1. If you have a default VPC and a default security group, they are used.

```
aws ec2 run-instances
  --image-id resolve:ssm:/golden-ami
  --instance-type m5.xlarge
  ...
```

To launch an instance using a specific version of an AWS Systems Manager parameter (AWS CLI)

Systems Manager parameters have version support. Each iteration of a parameter is assigned a unique version number. You can reference the version of the parameter as follows resolve:ssm:parameter-name:version, where version is the unique version number. By default, the latest version of the parameter is used when no version is specified.

The following example uses version 2 of the parameter.

In this example, the --count and --security-group parameters are not included. For --count, the default is 1 if you have a default VPC and a default security group, they are used.

```
aws ec2 run-instances
  --image-id resolve:ssm:/golden-ami:2
  --instance-type m5.xlarge
  ...
```

To launch an instance using a public parameter provided by AWS

Systems Manager provides public parameters for public AMIs provided by AWS. You can use the public parameters when launching instances to ensure that you're using the latest AMIs.

For more information, see Find the latest AMIs using Systems Manager.

Find the latest AMIs using Systems Manager

AWS Systems Manager provides public parameters for public AMIs maintained by AWS. You can use the public parameters when launching instances to ensure that you're using the latest AMIs.
For example, the public parameter /aws/service/ami-amazon-linux-latest/al2023-ami-kernel-default-arm64 is available in all Regions and always points to the latest version of the Amazon Linux 2023 AMI for arm64 architecture in a given Region.

The public parameters are available from the following paths:

- **Linux** – /aws/service/ami-amazon-linux-latest
- **Windows** – /aws/service/ami-windows-latest

**To view a list of all the Linux or Windows AMIs in the current AWS Region**

Use the following `get-parameters-by-path` AWS CLI command to view a list of all the Linux or Windows AMIs in the current AWS Region. The value for the `--path` parameter is different for Linux and Windows.

For Linux:

```bash
aws ssm get-parameters-by-path \
    --path /aws/service/ami-amazon-linux-latest \
    --query "Parameters[].Name"
```

For Windows:

```bash
aws ssm get-parameters-by-path \
    --path /aws/service/ami-windows-latest \
    --query "Parameters[].Name"
```

**To launch an instance using a public parameter**

The following example specifies a Systems Manager public parameter for the image ID to launch an instance using the latest Amazon Linux 2023 AMI.

To specify the parameter in the command, use the following syntax: `resolve:ssm:public-parameter`, where `resolve:ssm` is the standard prefix and `public-parameter` is the path and name of the public parameter.

In this example, the `--count` and `--security-group` parameters are not included. For `--count`, the default is 1. If you have a default VPC and a default security group, they are used.

```bash
aws ec2 run-instances \
```
For more information, see Working with public parameters in the AWS Systems Manager User Guide.

For examples that use Systems Manager parameters, see Query for the latest Amazon Linux AMI IDs Using AWS Systems Manager Parameter Store and Query for the Latest Windows AMI Using AWS Systems Manager Parameter Store.

More information for finding AMIs

To find an Amazon Linux 2023 AMI, see AL2023 on Amazon EC2 in the Amazon Linux 2023 User Guide.

To find an Ubuntu AMI, see Amazon EC2 AMI Locator on the Canonical Ubuntu website.

To find a RHEL AMI, see Red Hat Enterprise Linux Images (AMI) Available on Amazon Web Services (AWS) on the Red Hat website.

Shared AMIs

A shared AMI is an AMI that a developer created and made available for others to use. One of the easiest ways to get started with Amazon EC2 is to use a shared AMI that has the components you need and then add custom content. You can also create your own AMIs and share them with others.

You use a shared AMI at your own risk. Amazon can't vouch for the integrity or security of AMIs shared by other Amazon EC2 users. Therefore, you should treat shared AMIs as you would any foreign code that you might consider deploying in your own data center, and perform the appropriate due diligence. We recommend that you get an AMI from a trusted source, such as a verified provider.

Verified provider

In the Amazon EC2 console, public AMIs that are owned by Amazon or a verified Amazon partner are marked Verified provider.
You can also use the `describe-images` AWS CLI command to identify the public AMIs that come from a verified provider. Public images that are owned by Amazon or a verified partner have an aliased owner, which is either `amazon` or `aws-marketplace`. In the CLI output, these values appear for `ImageOwnerAlias`. Other users can't alias their AMIs. This enables you to easily find AMIs from Amazon or verified partners.

To become a verified provider, you must register as a seller on the AWS Marketplace. Once registered, you can list your AMI on the AWS Marketplace. For more information, see [Getting started as a seller](#) and [AMI-based products](#) in the *AWS Marketplace Seller Guide*.

**Shared AMI topics**

- Find shared AMIs
- Make an AMI public
- Share an AMI with specific organizations or organizational units
- Share an AMI with specific AWS accounts
- Cancel having an AMI shared with your AWS account
- Use bookmarks
- Guidelines for shared Linux AMIs

**If you're looking for information about other topics**

- For information about creating an AMI, see the section called “Create an instance store-backed Linux AMI” or the section called “Create an Amazon EBS-backed AMI”.
- For information about building, delivering, and maintaining your applications on the AWS Marketplace, see the *AWS Marketplace Documentation*.

**Find shared AMIs**

You can use the Amazon EC2 console or the command line to find shared AMIs.

AMIs are a Regional resource. When you search for a shared AMI (public or private), you must search for it from the same Region from which it is shared. To make an AMI available in a different Region, copy the AMI to the Region, and then share it. For more information, see [Copy an AMI](#).

**Tasks**
- Find a shared AMI (console)
- Find a shared AMI (AWS CLI)
- Find a shared AMI (Tools for Windows PowerShell)
- Use shared AMIs

**Find a shared AMI (console)**

**To find a shared private AMI using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **AMIs**.
3. In the first filter, choose **Private images**. All AMIs that have been shared with you are listed. To granulate your search, choose the **Search** bar and use the filter options provided in the menu.

**To find a shared public AMI using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **AMIs**.
3. In the first filter, choose **Public images**. To granulate your search, choose the **Search** field and use the filter options provided in the menu.

**To find Amazon's shared public AMIs using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **AMIs**.
3. In the first filter, choose **Public images**.
4. Choose the **Search** field and then, from the menu options that appear, choose **Owner alias**, then =, and then **amazon** to display only Amazon's public images.

**To find a shared public AMI from a verified provider using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **AMI Catalog**.
3. Choose **Community AMIs**.
4. The **Verified provider** label indicates the AMIs that are from Amazon or a verified partner.

**Find a shared AMI (AWS CLI)**

Use the `describe-images` command (AWS CLI) to list AMIs. You can scope the list to the types of AMIs that interest you, as shown in the following examples.

**Example: List all public AMIs**

The following command lists all public AMIs, including any public AMIs that you own.

```
aws ec2 describe-images --executable-users all
```

**Example: List AMIs with explicit launch permissions**

The following command lists the AMIs for which you have explicit launch permissions. This list does not include any AMIs that you own.

```
aws ec2 describe-images --executable-users self
```

**Example: List AMIs owned by verified providers**

The following command lists the AMIs owned by verified providers. Public AMIs owned by verified providers (either Amazon or verified partners) have an aliased owner, which appears as `amazon` or `aws-marketplace` in the account field. This helps you to easily find AMIs from verified providers. Other users can't alias their AMIs.

```
aws ec2 describe-images --owners amazon aws-marketplace --query 'Images[*].[ImageId]' --output text
```

**Example: List AMIs owned by an account**

The following command lists the AMIs owned by the specified AWS account.

```
aws ec2 describe-images --owners 123456789012
```

**Example: Scope AMIs using a filter**

Find shared AMIs
To reduce the number of displayed AMIs, use a filter to list only the types of AMIs that interest you. For example, use the following filter to display only EBS-backed AMIs.

```
--filters "Name=root-device-type,Values=ebs"
```

**Find a shared AMI (Tools for Windows PowerShell)**

Use the `Get-EC2Image` command (Tools for Windows PowerShell) to list AMIs. You can scope the list to the types of AMIs that interest you, as shown in the following examples.

**Example: List all public AMIs**

The following command lists all public AMIs, including any public AMIs that you own.

```
PS C:\> Get-EC2Image -ExecutableUser all
```

**Example: List AMIs with explicit launch permissions**

The following command lists the AMIs for which you have explicit launch permissions. This list does not include any AMIs that you own.

```
PS C:\> Get-EC2Image -ExecutableUser self
```

**Example: List AMIs owned by verified providers**

The following command lists the AMIs owned by verified providers. Public AMIs owned by verified providers (either Amazon or verified partners) have an aliased owner, which appears as `amazon` or `aws-marketplace` in the account field. This helps you to easily find AMIs from verified providers. Other users can't alias their AMIs.

```
PS C:\> Get-EC2Image -Owner amazon aws-marketplace
```

**Example: List AMIs owned by an account**

The following command lists the AMIs owned by the specified AWS account.

```
PS C:\> Get-EC2Image -Owner 123456789012
```

**Example: Scope AMIs using a filter**

Find shared AMIs
To reduce the number of displayed AMIs, use a filter to list only the types of AMIs that interest you. For example, use the following filter to display only EBS-backed AMIs.

```
-Filter @{ Name="root-device-type"; Values="ebs" }
```

### Use shared AMIs

Before you use a shared AMI, take the following steps to confirm that there are no pre-installed credentials that would allow unwanted access to your instance by a third party and no pre-configured remote logging that could transmit sensitive data to a third party. Check the documentation for the Linux distribution used by the AMI for information about improving the security of the system.

To ensure that you don't accidentally lose access to your instance, we recommend that you initiate two SSH sessions and keep the second session open until you've removed credentials that you don't recognize and confirmed that you can still log into your instance using SSH.

1. Identify and disable any unauthorized public SSH keys. The only key in the file should be the key you used to launch the AMI. The following command locates `authorized_keys` files:

   ```
   [ec2-user ~]$ sudo find / -name "authorized_keys" -print -exec cat {} \;
   ```

2. Disable password-based authentication for the root user. Open the `sshd_config` file and edit the `PermitRootLogin` line as follows:

   ```
   PermitRootLogin without-password
   ```

   Alternatively, you can disable the ability to log into the instance as the root user:

   ```
   PermitRootLogin No
   ```

   Restart the `sshd` service.

3. Check whether there are any other users that are able to log in to your instance. Users with superuser privileges are particularly dangerous. Remove or lock the password of any unknown accounts.

4. Check for open ports that you aren't using and running network services listening for incoming connections.
5. To prevent preconfigured remote logging, you should delete the existing configuration file and restart the `rsyslog` service. For example:

```bash
[ec2-user ~]$ sudo rm /etc/rsyslog.conf
[ec2-user ~]$ sudo service rsyslog restart
```

6. Verify that all cron jobs are legitimate.

If you discover a public AMI that you feel presents a security risk, contact the AWS security team. For more information, see the [AWS Security Center](https://aws.amazon.com/security/).

## Make an AMI public

You can make your AMI publicly available by sharing it with all AWS accounts.

If you want to prevent the public sharing of your AMIs, you can enable *block public access for AMIs*. This blocks any attempts to make an AMI public, helping to prevent unauthorized access and potential misuse of AMI data. Note that enabling block public access does not affect your AMIs that are already publicly available; they remain publicly available.

To allow only specific accounts to use your AMI to launch instances, see [Share an AMI with specific AWS accounts](#).

### Contents

- [Considerations](#)
- [Share an AMI with all AWS accounts (share publicly)](#)
- [Block public access to your AMIs](#)

### Considerations

Consider the following before making an AMI public.

- **Ownership** – To make an AMI public, your AWS account must own the AMI.
- **Region** – AMIs are a Regional resource. When you share an AMI, it is available only in the Region from which you shared it. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see [Copy an AMI](#).
• **Block public access** – To publicly share an AMI, [block public access for AMIs](https://console.aws.amazon.com/ec2/) must be disabled in each Region in which the AMI will be publicly shared. After you’ve publicly shared the AMI, you can re-enable block public access for AMIs to prevent further public sharing of your AMIs.

• **Some AMIs can't be made public** – If your AMI includes one of the following components, you can't make it public (but you can [share the AMI with specific AWS accounts](https)):
  - Encrypted volumes
  - Snapshots of encrypted volumes
  - Product codes

• **Avoid exposing sensitive data** – To avoid exposing sensitive data when you share an AMI, read the security considerations in [Guidelines for shared Linux AMIs](https://console.aws.amazon.com/ec2/) and follow the recommended actions.

• **Usage** – When you share an AMI, users can only launch instances from the AMI. They can’t delete, share, or modify it. However, after they have launched an instance using your AMI, they can then create an AMI from the instance they launched.

• **Automatic deprecation** – By default, the deprecation date of all public AMIs is set to two years from the AMI creation date. You can set the deprecation date to earlier than two years. To cancel the deprecation date, or to move the deprecation to a later date, you must make the AMI private by only [sharing it with specific AWS accounts](https://console.aws.amazon.com/ec2/).

• **Remove obsolete AMIs** – After a public AMI reaches its deprecation date, if no new instances were launched from the AMI for six or more months, AWS eventually removes the public sharing property so that obsolete AMIs don’t appear in the public AMI lists.

• **Billing** – You are not billed when your AMI is used by other AWS accounts to launch instances. The accounts that launch instances using the AMI are billed for the instances that they launch.

**Share an AMI with all AWS accounts (share publicly)**

After you make an AMI public, it is available in **Community AMIs** in the console, which you can access from the **AMI Catalog** in the left navigator in the EC2 console or when launching an instance using the console. Note that it can take a short while for an AMI to appear in **Community AMIs** after you make it public.

**Console**

**To make an AMI public**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose AMIs.
3. Select your AMI from the list, and then choose Actions, Edit AMI permissions.
4. Under AMI availability, choose Public.
5. Choose Save changes.

AWS CLI

Each AMI has a launchPermission property that controls which AWS accounts, besides the owner’s, are allowed to use that AMI to launch instances. By modifying the launchPermission property of an AMI, you can make the AMI public (which grants launch permissions to all AWS accounts), or share it with only the AWS accounts that you specify.

You can add or remove account IDs from the list of accounts that have launch permissions for an AMI. To make the AMI public, specify the all group. You can specify both public and explicit launch permissions.

To make an AMI public

1. Use the modify-image-attribute command as follows to add the all group to the launchPermission list for the specified AMI.

```bash
aws ec2 modify-image-attribute \
  --image-id ami-0abcdef1234567890 \n  --launch-permission "Add=[[Group=all]]"
```

2. To verify the launch permissions of the AMI, use the describe-image-attribute command.

```bash
aws ec2 describe-image-attribute \
  --image-id ami-0abcdef1234567890 \n  --attribute launchPermission
```

3. (Optional) To make the AMI private again, remove the all group from its launch permissions. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```bash
aws ec2 modify-image-attribute \
  --image-id ami-0abcdef1234567890 \n  --launch-permission "Remove=[[Group=all]]"
```
PowerShell

Each AMI has a launchPermission property that controls which AWS accounts, besides the owner's, are allowed to use that AMI to launch instances. By modifying the launchPermission property of an AMI, you can make the AMI public (which grants launch permissions to all AWS accounts), or share it with only the AWS accounts that you specify.

You can add or remove account IDs from the list of accounts that have launch permissions for an AMI. To make the AMI public, specify the all group. You can specify both public and explicit launch permissions.

To make an AMI public

1. Use the `Edit-EC2ImageAttribute` command as follows to add the all group to the launchPermission list for the specified AMI.

   ```powershell
   PS C:\> Edit-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute launchPermission -OperationType add -UserGroup all
   ``

2. To verify the launch permissions of the AMI, use the following `Get-EC2ImageAttribute` command.

   ```powershell
   PS C:\> Get-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute launchPermission
   ```

3. (Optional) To make the AMI private again, remove the all group from its launch permissions. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

   ```powershell
   PS C:\> Edit-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute launchPermission -OperationType remove -UserGroup all
   ```

Block public access to your AMIs

To prevent the public sharing of your AMIs, you can enable block public access for AMIs. This setting is enabled at the account level, but you need to enable it in each AWS Region in which you want to prevent the public sharing of your AMIs.

When block public access is enabled, any attempt to make an AMI public is automatically blocked. However, if you already have public AMIs, they remain publicly available.
To publicly share AMIs, you must disable block public access. When you’re done sharing, it's best practice to re-enable block public access to prevent any unintended public sharing of your AMIs.

You can restrict IAM permissions to an administrator user so that only they can enable or disable block public access for AMIs.

Contents

- Default settings
- Required IAM permissions
- Enable block public access for AMIs
- Disable block public access for AMIs
- View the block public access state for AMIs

Default settings

The **Block public access for AMIs** setting is either enabled or disabled by default depending on whether your account is new or existing, and whether you have public AMIs. The following table lists the default settings:

<table>
<thead>
<tr>
<th>AWS account</th>
<th>Block public access for AMIs default setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>New accounts</td>
<td>Enabled</td>
</tr>
<tr>
<td>Existing accounts with no public AMIs¹</td>
<td>Enabled</td>
</tr>
<tr>
<td>Existing accounts with one or more public AMIs</td>
<td>Disabled</td>
</tr>
</tbody>
</table>

¹ If your account had one or more public AMIs on or after July 15, 2023, **Block public access for AMIs** is disabled by default for your account, even if you subsequently made all the AMIs private.

Required IAM permissions

To use block public access for AMIs, you must have the following IAM permissions:

- EnableImageBlockPublicAccess
Enable block public access for AMIs

To prevent the public sharing of your AMIs, enable block public access for AMIs at the account level. You must enable block public access for AMIs in each AWS Region in which you want to prevent the public sharing of your AMIs. If you already have public AMIs, they will remain publicly available.

Console

To enable block public access for AMIs in the specified Region

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar (at the top of the screen), select the Region in which to enable block public access for AMIs.
3. If the dashboard is not displayed, in the navigation pane, choose EC2 Dashboard.
4. Under Account attributes, choose Data protection and security.
5. Under Block public access for AMIs, choose Manage.
6. Select the Block new public sharing check box, and then choose Update.

Note

The API can take up to 10 minutes to configure this setting. During this time, the value will be New public sharing allowed. When the API has completed the configuration, the value will automatically change to New public sharing blocked.

AWS CLI

To enable block public access for AMIs

Use the enable-image-block-public-access command.

- For a specific Region

```bash
aws ec2 enable-image-block-public-access \ --region us-east-1 
```
- `--image-block-public-access-state block-new-sharing`

**Expected output**

```
{
  "ImageBlockPublicAccessState": "block-new-sharing"
}
```

- **For all Regions in your account**

  ```bash
  echo -e "Region   \t Public Access State" ; \\
  echo -e "-------------- \t ----------------------" ; \\
  for region in $(
    aws ec2 describe-regions \\
    --region us-east-1 \\
    --query "Regions[*].[RegionName]" \\
    --output text
  );
  do (output=$( 
    aws ec2 enable-image-block-public-access \\
    --region $region \\
    --image-block-public-access-state block-new-sharing \\
    --output text)
    echo -e "$region \t $output"
  );
  done
  ```

**Expected output**

<table>
<thead>
<tr>
<th>Region</th>
<th>Public Access State</th>
</tr>
</thead>
<tbody>
<tr>
<td>ap-south-1</td>
<td>block-new-sharing</td>
</tr>
<tr>
<td>eu-north-1</td>
<td>block-new-sharing</td>
</tr>
<tr>
<td>eu-west-3</td>
<td>block-new-sharing</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>

**Note**

The API can take up to 10 minutes to configure this setting. During this time, if you run the `get-image-block-public-access-state` command, the response will be unblocked.
Disable block public access for AMIs

To allow the users in your account to publicly share your AMIs, disable block public access at the account level. You must disable block public access for AMIs in each AWS Region in which you want to allow the public sharing of your AMIs.

Console

To disable block public access for AMIs in the specified Region

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar (at the top of the screen), select the Region in which to disable block public access for AMIs.
3. If the dashboard is not displayed, in the navigation pane, choose EC2 Dashboard.
4. Under Account attributes, choose Data protection and security.
5. Under Block public access for AMIs, choose Manage.
6. Clear the Block new public sharing check box, and then choose Update.
7. Enter confirm when prompted for confirmation, and then choose Allow public sharing.

Note

The API can take up to 10 minutes to configure this setting. During this time, the value will be New public sharing blocked. When the API has completed the configuration, the value will automatically change to New public sharing allowed.

AWS CLI

To disable block public access for AMIs

Use the disable-image-block-public-access command.

- For a specific Region
aws ec2 disable-image-block-public-access --region us-east-1

Expected output

```
{
   "ImageBlockPublicAccessState": "unblocked"
}
```

- For all Regions in your account

```
echo -e "Region    \t Public Access State" ; \\
echo -e "--------------    \t ----------------------" ; \\
for region in $(
   aws ec2 describe-regions \\
   --region us-east-1 \\
   --query "Regions[*].[RegionName]" \\
   --output text
);
   do (output=$(n
   aws ec2 disable-image-block-public-access \\
   --region $region \\
   --output text)
   echo -e "$region \t $output"
   done
```

Expected output

<table>
<thead>
<tr>
<th>Region</th>
<th>Public Access State</th>
</tr>
</thead>
<tbody>
<tr>
<td>ap-south-1</td>
<td>unblocked</td>
</tr>
<tr>
<td>eu-north-1</td>
<td>unblocked</td>
</tr>
<tr>
<td>eu-west-3</td>
<td>unblocked</td>
</tr>
</tbody>
</table>

**Note**

The API can take up to 10 minutes to configure this setting. During this time, if you run the `get-image-block-public-access-state` command, the response will be `block-`
new-sharing. When the API has completed the configuration, the response will be unblocked.

View the block public access state for AMIs

To see whether the public sharing of your AMIs is blocked in your account, you can view the state for block public access for AMIs. You must view the state in each AWS Region in which you want to see whether the public sharing of your AMIs is blocked.

Console

To view the block public access state for AMIs in the specified Region

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar (at the top of the screen), select the Region in which to view the block public access state for AMIs.
3. If the dashboard is not displayed, in the navigation pane, choose EC2 Dashboard.
4. Under Account attributes, choose Data protection and security.
5. Under Block public access for AMIs, check the Public access field. The value is either New public sharing blocked or New public sharing allowed.

AWS CLI

To get the block public access state for AMIs

Use the get-image-block-public-access-state command.

• For a specific Region

```
aws ec2 get-image-block-public-access-state --region us-east-1
```

Expected output – The value is either block-new-sharing or unblocked.

```
{
  "ImageBlockPublicAccessState": "block-new-sharing"
}
```

• For all Regions in your account
echo -e "Region \t Public Access State" ; \
echo -e "----------------------\t----------------------" ; \
f\or region in $(
    aws ec2 describe-regions \n    --region us-east-1 \n    --query "Regions[*].[RegionName]" \n    --output text
)
    do (output=${
        aws ec2 get-image-block-public-access-state \n        --region $region \n        --output text
        echo -e "$region \t $output"
    });
done

Expected output – The value is either block-new-sharing or unblocked.

<table>
<thead>
<tr>
<th>Region</th>
<th>Public Access State</th>
</tr>
</thead>
<tbody>
<tr>
<td>ap-south-1</td>
<td>block-new-sharing</td>
</tr>
<tr>
<td>eu-north-1</td>
<td>unblocked</td>
</tr>
<tr>
<td>eu-west-3</td>
<td>block-new-sharing</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>

**Share an AMI with specific organizations or organizational units**

[AWS Organizations](https://aws.amazon.com/organizations/) is an account management service that enables you to consolidate multiple AWS accounts into an organization that you create and centrally manage. You can share an AMI with an organization or an organizational unit (OU) that you have created, in addition to sharing it with specific accounts.

An organization is an entity that you create to consolidate and centrally manage your AWS accounts. You can organize the accounts in a hierarchical, tree-like structure, with a **root** at the top and **organizational units** nested under the organization root. Each account can be added directly to the root, or placed in one of the OUs in the hierarchy. For more information, see [AWS Organizations terminology and concepts](https://docs.aws.amazon.com/organizations/latest/userguide/orgs_concepts.html) in the [AWS Organizations User Guide](https://docs.aws.amazon.com/organizations/latest/userguide/).
When you share an AMI with an organization or an OU, all of the children accounts gain access to the AMI. For example, in the following diagram, the AMI is shared with a top-level OU (indicated by the arrow at the number 1). All of the OUs and accounts that are nested underneath that top-level OU (indicated by the dotted line at number 2) also have access to the AMI. The accounts in the organization and OU outside the dotted line (indicated by the number 3) do not have access to the AMI because they are not children of the OU that the AMI is shared with.

Considerations

Consider the following when sharing AMIs with specific organizations or organizational units.

- **Ownership** – To share an AMI, your AWS account must own the AMI.
- **Sharing limits** – The AMI owner can share an AMI with any organization or OU, including organizations and OUs that they’re not a member of.

For the maximum number of entities to which an AMI can be shared within a Region, see the Amazon EC2 service quotas.
• **Tags** – You can't share user-defined tags (tags that you attach to an AMI). When you share an AMI, your user-defined tags are not available to any AWS account in an organization or OU with which the AMI is shared.

• **ARN format** – When you specify an organization or OU in a command, make sure to use the correct ARN format. You'll get an error if you specify only the ID, for example, if you specify only o-123example or ou-1234-5example.

Correct ARN formats:

• Organization ARN: arn:aws:organizations::account-id:organization/organization-id

• OU ARN: arn:aws:organizations::account-id:ou/organization-id/ou-id

Where:

• `account-id` is the 12-digit management account number, for example, 123456789012. If you don’t know the management account number, you can describe the organization or the organizational unit to get the ARN, which includes the management account number. For more information, see [Get the ARN](#).

• `organization-id` is the organization ID, for example, o-123example.

• `ou-id` is the organizational unit ID, for example, ou-1234-5example.

For more information about the format of ARNs, see [Amazon Resource Names (ARNs)](#) in the IAM User Guide.

• **Encryption and keys** – You can share AMIs that are backed by unencrypted and encrypted snapshots.

  • The encrypted snapshots must be encrypted with a customer managed key. You can’t share AMIs that are backed by snapshots that are encrypted with the default AWS managed key.

  • If you share an AMI that is backed by encrypted snapshots, you must allow the organizations or OUs to use the customer managed keys that were used to encrypt the snapshots. For more information, see [Allow organizations and OUs to use a KMS key](#).

• **Region** – AMIs are a Regional resource. When you share an AMI, it is available only in the Region from which you shared it. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see [Copy an AMI](#).

• **Usage** – When you share an AMI, users can only launch instances from the AMI. They can't delete, share, or modify it. However, after they have launched an instance using your AMI, they can then create an AMI from the instance they launched.
• **Billing** – You are not billed when your AMI is used by other AWS accounts to launch instances. The accounts that launch instances using the AMI are billed for the instances that they launch.

**Allow organizations and OUs to use a KMS key**

If you share an AMI that is backed by encrypted snapshots, you must also allow the organizations or OUs to use the AWS KMS keys that were used to encrypt the snapshots.

Use the `aws:PrincipalOrgID` and `aws:PrincipalOrgPaths` keys to compare the AWS Organizations path for the principal who is making the request to the path in the policy. That principal can be a user, IAM role, federated user, or AWS account root user. In a policy, this condition key ensures that the requester is an account member within the specified organization root or OUs in AWS Organizations. For more example condition statements, see `aws:PrincipalOrgID` and `aws:PrincipalOrgPaths` in the [IAM User Guide](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles Assume-role-support.html).

For information about editing a key policy, see [Allowing users in other accounts to use a KMS key](https://docs.aws.amazon.com/kms/latest/developerguide/key-pol-reference.html) in the AWS Key Management Service Developer Guide.

To give an organization or OU permission to use a KMS key, add the following statement to the key policy.

```json
{
    "Sid": "Allow access for organization root",
    "Effect": "Allow",
    "Principal": "*",
    "Action": [
        "kms:Describe*",
        "kms:List*",
        "kms:Get*",
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*"
    ],
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:PrincipalOrgID": "o-123example"
        }
    }
}
```
To share a KMS key with multiple OUs, you can use a policy similar to the following example.

```json
{
    "Sid": "Allow access for specific OUs and their descendants",
    "Effect": "Allow",
    "Principal": "*",
    "Action": [
        "kms:Describe*",
        "kms:List*",
        "kms:Get*",
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*"
    ],
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:PrincipalOrgID": "o-123example"
        },
        "ForAnyValue:StringLike": {
            "aws:PrincipalOrgPaths": [
                "o-123example/r-ab12/ou-ab12-33333333/*",
                "o-123example/r-ab12/ou-ab12-22222222/*"
            ]
        }
    }
}
```

Share an AMI

You can use the Amazon EC2 console or the AWS CLI to share an AMI with an organization or OU.

Share an AMI (console)

To share an AMI with an organization or an OU using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose AMIs.
3. Select your AMI in the list, and then choose Actions, Edit AMI permissions.
5. Next to Shared organizations/OUs, choose Add organization/OU ARN.
6. For **Organization/OU ARN**, enter the organization ARN or OU ARN with which you want to share the AMI, and then choose **Share AMI**. Note that you must specify the full ARN, not just the ID.

To share this AMI with multiple organizations or OUs, repeat this step until you have added all of the required organizations or OUs.

```
3 Note
You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared, and the system automatically provides the instance with access to the referenced Amazon EBS snapshots for the launch. However, you do need to share the KMS keys used to encrypt snapshots that the AMI references. For more information, see Allow organizations and OUs to use a KMS key.
```

7. Choose **Save changes** when you're done.

8. (Optional) To view the organizations or OUs with which you have shared the AMI, select the AMI in the list, choose the Permissions tab, and scroll down to **Shared organizations/OUs**. To find AMIs that are shared with you, see Find shared AMIs.

**Share an AMI (Tools for Windows PowerShell)**

Use the **Edit-EC2ImageAttribute** command (Tools for Windows PowerShell) to share an AMI as shown in the following examples.

**To share an AMI with an organization or an OU**

The following command grants launch permissions for the specified AMI to the specified organization.

```
PS C:\> Edit-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute launchPermission -OperationType add -OrganizationArn "arn:aws:organizations::123456789012:organization/o-123example"
```

```
3 Note
You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared, and the system automatically
```
provides the instance with access to the referenced Amazon EBS snapshots for the launch. However, you do need to share the KMS keys used to encrypt snapshots that the AMI references. For more information, see Allow organizations and OUs to use a KMS key.

To stop sharing an AMI with an organization or OU

The following command removes launch permissions for the specified AMI from the specified organization:

```
PS C:\> Edit-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute launchPermission -OperationType remove -OrganizationArn "arn:aws:organizations::123456789012:organization/o-123example"
```

To stop sharing an AMI with all organizations, OUs, and AWS accounts

The following command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
PS C:\> Reset-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute launchPermission
```

Share an AMI (AWS CLI)

Use the modify-image-attribute command (AWS CLI) to share an AMI.

To share an AMI with an organization using the AWS CLI

The modify-image-attribute command grants launch permissions for the specified AMI to the specified organization. Note that you must specify the full ARN, not just the ID.

```
aws ec2 modify-image-attribute \
   --image-id ami-0abcdef1234567890 \
   --launch-permission
   "Add=[[OrganizationArn=arn:aws:organizations::123456789012:organization/o-123example]]"
```

To share an AMI with an OU using the AWS CLI
The `modify-image-attribute` command grants launch permissions for the specified AMI to the specified OU. Note that you must specify the full ARN, not just the ID.

```
aws ec2 modify-image-attribute \
  --image-id ami-0abcdef1234567890 \n  --launch-permission 
  "Add=[{"OrganizationalUnitArn=arn:aws:organizations::123456789012:o-123example/ou-1234-5example}]"
```

**Note**

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared, and the system automatically provides the instance with access to the referenced Amazon EBS snapshots for the launch. However, you do need to share the KMS keys used to encrypt snapshots that the AMI references. For more information, see [Allow organizations and OUs to use a KMS key](#).

---

**Stop sharing an AMI**

You can use the Amazon EC2 console or the AWS CLI to stop sharing an AMI with an organization or OU.

**Stop sharing an AMI (console)**

**To stop sharing an AMI with an organization or OU using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose AMIs.
3. Select your AMI in the list, and then choose Actions, Edit AMI permissions.
4. Under Shared organizations/OUs, select the organizations or OUs with which you want to stop sharing the AMI, and then choose Remove selected.
5. Choose Save changes when you're done.
6. (Optional) To confirm that you have stopped sharing the AMI with the organizations or OUs, select the AMI in the list, choose the Permissions tab, and scroll down to Shared organizations/OUs.
Stop sharing an AMI (AWS CLI)

Use the modify-image-attribute or reset-image-attribute commands (AWS CLI) to stop sharing an AMI.

To stop sharing an AMI with an organization or OU using the AWS CLI

The modify-image-attribute command removes launch permissions for the specified AMI from the specified organization. Note that you must specify the ARN.

```
aws ec2 modify-image-attribute \\
   --image-id ami-0abcdef1234567890 \\
   --launch-permission
"Remove=[[OrganizationArn=arn:aws:organizations::123456789012:organization/o-123example]]"
```

To stop sharing an AMI with all organizations, OUs, and AWS accounts using the AWS CLI

The reset-image-attribute command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command.

```
aws ec2 reset-image-attribute \\
   --image-id ami-0abcdef1234567890 \\
   --attribute launchPermission
```

Note

You can't stop sharing an AMI with a specific account if it's in an organization or OU with which an AMI is shared. If you try to stop sharing the AMI by removing launch permissions for the account, Amazon EC2 returns a success message. However, the AMI continues to be shared with the account.

View the organizations and OUs with which an AMI is shared

You can use the Amazon EC2 console or the AWS CLI to check with which organizations and OUs you've shared your AMI.
View the organizations and OUs with which an AMI is shared (console)

To check with which organizations and OUs you've shared your AMI using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose AMIs.
3. Select your AMI in the list, choose the Permissions tab, and scroll down to Shared organizations/OUs.

To find AMIs that are shared with you, see Find shared AMIs.

View the organizations and OUs with which an AMI is shared (AWS CLI)

You can check which organizations and OUs you've shared your AMI with by using the describe-image-attribute command (AWS CLI) and the launchPermission attribute.

To check with which organizations and OUs you've shared your AMI using the AWS CLI

The describe-image-attribute command describes the launchPermission attribute for the specified AMI, and returns the organizations and OUs with which you've shared the AMI.

```
aws ec2 describe-image-attribute \\
    --image-id ami-0abcdef1234567890 \\
    --attribute launchPermission
```

Example response

```
{
    "ImageId": "ami-0abcdef1234567890",
    "LaunchPermissions": [
        {
            "OrganizationalUnitArn": "arn:aws:organizations::111122223333:ou/o-123example/ou-1234-5example"
        }
    ]
}
```

Get the ARN

The organization and the organizational unit ARNs contain the 12-digit management account number. If you don't know the management account number, you can describe the organization
and the organizational unit to get the ARN for each. In the following examples, 123456789012 is the management account number.

Before you can get the ARNs, you must have the permission to describe organizations and organizational units. The following policy provides the necessary permission.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "organizations:Describe*"
      ],
      "Resource": "*"
    }
  ]
}
```

**To get the ARN of an organization**

Use the `describe-organization` command and the `--query` parameter set to `'Organization.Arn'` to return only the organization ARN.

```
aws organizations describe-organization --query 'Organization.Arn'
```

Example response

"arn:aws:organizations::123456789012:organization/o-123example"

**To get the ARN of an organizational unit**

Use the `describe-organizational-unit` command, specify the OU ID, and set the `--query` parameter to `'OrganizationalUnit.Arn'` to return only the organizational unit ARN.

```
aws organizations describe-organizational-unit --organizational-unit-id ou-1234-5example --query 'OrganizationalUnit.Arn'
```

Example response

"arn:aws:organizations::123456789012:ou/o-123example/ou-1234-5example"
Share an AMI with specific AWS accounts

You can share an AMI with specific AWS accounts without making the AMI public. All you need are the AWS account IDs.

An AWS account ID is a 12-digit number, such as 012345678901, that uniquely identifies an AWS account. For more information, see Viewing AWS account identifiers in the AWS Account Management Reference Guide.

Considerations

Consider the following when sharing AMIs with specific AWS accounts.

- **Ownership** – To share an AMI, your AWS account must own the AMI.
- **Sharing limits** – For the maximum number of entities to which an AMI can be shared within a Region, see the Amazon EC2 service quotas.
- **Tags** – You can't share user-defined tags (tags that you attach to an AMI). When you share an AMI, your user-defined tags are not available to any AWS account that the AMI is shared with.
- **Encryption and keys** – You can share AMIs that are backed by unencrypted and encrypted snapshots.
  - The encrypted snapshots must be encrypted with a KMS key. You can't share AMIs that are backed by snapshots that are encrypted with the default AWS managed key.
  - If you share an AMI that is backed by encrypted snapshots, you must allow the AWS accounts to use the KMS keys that were used to encrypt the snapshots. For more information, see Allow organizations and OUs to use a KMS key. To set up the key policy that you need to launch Auto Scaling instances when you use a customer managed key for encryption, see Required AWS KMS key policy for use with encrypted volumes in the Amazon EC2 Auto Scaling User Guide.
- **Region** – AMIs are a Regional resource. When you share an AMI, it is only available in that Region. To make an AMI available in a different Region, copy the AMI to the Region and then share it. For more information, see Copy an AMI.
- **Usage** – When you share an AMI, users can only launch instances from the AMI. They can’t delete, share, or modify it. However, after they have launched an instance using your AMI, they can then create an AMI from their instance.
- **Copying shared AMIs** – If users in another account want to copy a shared AMI, you must grant them read permissions for the storage that backs the AMI. For more information, see Cross-account copying.
• **Billing** – You are not billed when your AMI is used by other AWS accounts to launch instances. The accounts that launch instances using the AMI are billed for the instances that they launch.

### Share an AMI (console)

#### To grant explicit launch permissions using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **AMIs**.
3. Select your AMI in the list, and then choose **Actions, Edit AMI permissions**.
4. Choose **Private**.
5. Under **Shared accounts**, choose **Add account ID**.
6. For **AWS account ID**, enter the AWS account ID with which you want to share the AMI, and then choose **Share AMI**.

To share this AMI with multiple accounts, repeat Steps 5 and 6 until you have added all the required account IDs.

#### Note

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared; the system automatically provides the instance access to the referenced Amazon EBS snapshots for the launch. However, you do need to share any KMS keys used to encrypt snapshots that the AMI references. For more information, see [Share an Amazon EBS snapshot](https://docs.aws.amazon.com/AmazonEBS/UserGuide/) in the *Amazon EBS User Guide*.

7. Choose **Save changes** when you are done.
8. (Optional) To view the AWS account IDs with which you have shared the AMI, select the AMI in the list, and choose the **Permissions** tab. To find AMIs that are shared with you, see [Find shared AMIs](https://docs.aws.amazon.com/AmazonEBS/UserGuide/).

### Share an AMI (Tools for Windows PowerShell)

Use the **Edit-EC2ImageAttribute** command (Tools for Windows PowerShell) to share an AMI as shown in the following examples.
To grant explicit launch permissions

The following command grants launch permissions for the specified AMI to the specified AWS account. In the following example, replace the example AMI ID with a valid AMI ID, and replace `account-id` with the 12-digit AWS account ID.

```
PS C:\> Edit-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute launchPermission -OperationType add -UserId "account-id"
```

**Note**

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared; the system automatically provides the instance access to the referenced Amazon EBS snapshots for the launch. However, you do need to share any KMS keys used to encrypt snapshots that the AMI references. For more information, see [Share an Amazon EBS snapshot](https://docs.aws.amazon.com/AmazonEBS/latest/UserGuide/share.html) in the *Amazon EBS User Guide*.

To remove launch permissions for an account

The following command removes launch permissions for the specified AMI from the specified AWS account. In the following example, replace the example AMI ID with a valid AMI ID, and replace `account-id` with the 12-digit AWS account ID.

```
PS C:\> Edit-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute launchPermission -OperationType remove -UserId "account-id"
```

To remove all launch permissions

The following command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command. In the following example, replace the example AMI ID with a valid AMI ID.

```
PS C:\> Reset-EC2ImageAttribute -ImageId ami-0abcdef1234567890 -Attribute launchPermission
```

Share an AMI (AWS CLI)

Use the `modify-image-attribute` command (AWS CLI) to share an AMI as shown in the following examples.
To grant explicit launch permissions

The following command grants launch permissions for the specified AMI to the specified AWS account. In the following example, replace the example AMI ID with a valid AMI ID, and replace `account-id` with the 12-digit AWS account ID.

```
aws ec2 modify-image-attribute \
  --image-id ami-0abcdef1234567890 \
  --launch-permission "Add=[{UserId=account-id}]"
```

**Note**

You do not need to share the Amazon EBS snapshots that an AMI references in order to share the AMI. Only the AMI itself needs to be shared; the system automatically provides the instance access to the referenced Amazon EBS snapshots for the launch. However, you do need to share any KMS keys used to encrypt snapshots that the AMI references. For more information, see [Share an Amazon EBS snapshot](#) in the *Amazon EBS User Guide*.

To remove launch permissions for an account

The following command removes launch permissions for the specified AMI from the specified AWS account. In the following example, replace the example AMI ID with a valid AMI ID, and replace `account-id` with the 12-digit AWS account ID.

```
aws ec2 modify-image-attribute \
  --image-id ami-0abcdef1234567890 \
  --launch-permission "Remove=[{UserId=account-id}]"
```

To remove all launch permissions

The following command removes all public and explicit launch permissions from the specified AMI. Note that the owner of the AMI always has launch permissions and is therefore unaffected by this command. In the following example, replace the example AMI ID with a valid AMI ID.

```
aws ec2 reset-image-attribute \
  --image-id ami-0abcdef1234567890 \
  --attribute launchPermission
```
Cancel having an AMI shared with your AWS account

An Amazon Machine Image (AMI) can be shared with specific AWS accounts by adding the accounts to the AMI's launch permissions. If an AMI has been shared with your AWS account and you no longer want it shared with your account, you can remove your account from the AMI's launch permissions. You do this by running the `cancel-image-launch-permission` AWS CLI command. When running this command, your AWS account is removed from the launch permissions for the specified AMI.

You might cancel having an AMI shared with your account, for example, to reduce the likelihood of launching an instance with an unused or deprecated AMI that was shared with you. When you cancel having an AMI shared with your account, it no longer appears in any AMI lists in the EC2 console or in the output for `describe-images`.

Topics

- Limitations
- Cancel having an AMI shared with your account
- Find AMIs that are shared with your account

Limitations

- You can remove your account from the launch permissions of an AMI that is shared with your AWS account only. You can't use `cancel-image-launch-permission` to remove your account from the launch permissions of an AMI that is shared with an organization or organizational unit (OU) or to remove access to public AMIs.
- You can’t permanently remove your account from the launch permissions of an AMI. An AMI owner can share an AMI with your account again.
- AMIs are a Regional resource. When running `cancel-image-launch-permission`, you must specify the Region in which the AMI is located. Either specify the Region in the command, or use the `AWS_DEFAULT_REGION` environment variable.
- Only the AWS CLI and SDKs support removing your account from the launch permissions of an AMI. The EC2 console does not currently support this action.
Cancel having an AMI shared with your account

**Note**

After you cancel having an AMI shared with your account, you can't undo it. To regain access to the AMI, the AMI owner must share it with your account.

AWS CLI

**To cancel having an AMI shared with your AWS account**

Use the `cancel-image-launch-permission` command and specify the AMI ID.

```bash
aws ec2 cancel-image-launch-permission \
   --image-id ami-0123456789example \
   --region us-east-1
```

**Expected output**

```json
{
   "Return": true
}
```

PowerShell

**To cancel having an AMI shared with your AWS account using the AWS Tools for PowerShell**

Use the `Stop-EC2ImageLaunchPermission` command and specify the AMI ID.

```powershell
Stop-EC2ImageLaunchPermission \
   -ImageId ami-0123456789example \
   -Region us-east-1
```

**Expected output**

```
True
```
Find AMIs that are shared with your account

To find the AMIs that are shared with your AWS account, see [Find shared AMIs](#).

Use bookmarks

If you have created a public AMI, or shared an AMI with another AWS account, you can create a bookmark that allows a user to access your AMI and launch an instance in their own account immediately. This is an easy way to share AMI references, so users don't have to spend time finding your AMI in order to use it.

Note that your AMI must be public, or you must have shared it with the user to whom you want to send the bookmark.

**To create a bookmark for your AMI**

1. Type a URL with the following information, where `region` is the Region in which your AMI resides:

   ```
   https://console.aws.amazon.com/ec2/v2/home?
   region=region#LaunchInstanceWizard:ami=ami_id
   ```

   For example, this URL launches an instance from the ami-0abcdef1234567890 AMI in the US East (N. Virginia) `us-east-1` Region:

   ```
   https://console.aws.amazon.com/ec2/v2/home?region=us-east-1#LaunchInstanceWizard:ami=ami-0abcdef1234567890
   ```

2. Distribute the link to users who want to use your AMI.
3. To use a bookmark, choose the link or copy and paste it into your browser. The launch wizard opens, with the AMI already selected.

**Guidelines for shared Linux AMIs**

Use the following guidelines to reduce the attack surface and improve the reliability of the AMIs you create.
Important

No list of security guidelines can be exhaustive. Build your shared AMIs carefully and take time to consider where you might expose sensitive data.

Contents

- Update the AMI tools before using them
- Disable password-based remote logins for the root user
- Disable local root access
- Remove SSH host key pairs
- Install public key credentials
- Disable sshd DNS checks (optional)
- Protect yourself

If you are building AMIs for AWS Marketplace, see Best practices for building AMIs in the AWS Marketplace Seller Guide for guidelines, policies, and best practices.

For additional information about sharing AMIs safely, see the following articles:

- How To Share and Use Public AMIs in A Secure Manner
- Public AMI Publishing: Hardening and Clean-up Requirements

Update the AMI tools before using them

For AMIs backed by instance store, we recommend that your AMIs download and upgrade the Amazon EC2 AMI creation tools before you use them. This ensures that new AMIs based on your shared AMIs have the latest AMI tools.

For Amazon Linux 2, install the aws-amitools-ec2 package and add the AMI tools to your PATH with the following command. For the Amazon Linux AMI, aws-amitools-ec2 package is already installed by default.

```
[ec2-user ~]$ sudo yum install -y aws-amitools-ec2 && export PATH=$PATH:/opt/aws/bin > /etc/profile.d/aws-amitools-ec2.sh && . /etc/profile.d/aws-amitools-ec2.sh
```
Upgrade the AMI tools with the following command:

```
[ec2-user ~]$ sudo yum upgrade -y aws-amitools-ec2
```

For other distributions, make sure you have the latest AMI tools.

**Disable password-based remote logins for the root user**

Using a fixed root password for a public AMI is a security risk that can quickly become known. Even relying on users to change the password after the first login opens a small window of opportunity for potential abuse.

To solve this problem, disable password-based remote logins for the root user.

**To disable password-based remote logins for the root user**

1. Open the `/etc/ssh/sshd_config` file with a text editor and locate the following line:

   ```
   #PermitRootLogin yes
   ```

2. Change the line to:

   ```
   PermitRootLogin without-password
   ```

   The location of this configuration file might differ for your distribution, or if you are not running OpenSSH. If this is the case, consult the relevant documentation.

**Disable local root access**

When you work with shared AMIs, a best practice is to disable direct root logins. To do this, log into your running instance and issue the following command:

```
[ec2-user ~]$ sudo passwd -l root
```

**Note**

This command does not impact the use of `sudo`.

---

**Guidelines for shared Linux AMIs**

111
Remove SSH host key pairs

If you plan to share an AMI derived from a public AMI, remove the existing SSH host key pairs located in /etc/ssh. This forces SSH to generate new unique SSH key pairs when someone launches an instance using your AMI, improving security and reducing the likelihood of "man-in-the-middle" attacks.

Remove all of the following key files that are present on your system.

- ssh_host_dsa_key
- ssh_host_dsa_key.pub
- ssh_host_key
- ssh_host_key.pub
- ssh_host_rsa_key
- ssh_host_rsa_key.pub
- ssh_host_ecdsa_key
- ssh_host_ecdsa_key.pub
- ssh_host_ed25519_key
- ssh_host_ed25519_key.pub

You can securely remove all of these files with the following command.

```
[ec2-user ~]$ sudo shred -u /etc/ssh/*_key /etc/ssh/*_key.pub
```

⚠️ Warning

Secure deletion utilities such as `shred` may not remove all copies of a file from your storage media. Hidden copies of files may be created by journalling file systems (including Amazon Linux default ext4), snapshots, backups, RAID, and temporary caching. For more information see the `shred` documentation.
Important

If you forget to remove the existing SSH host key pairs from your public AMI, our routine auditing process notifies you and all customers running instances of your AMI of the potential security risk. After a short grace period, we mark the AMI private.

Install public key credentials

After configuring the AMI to prevent logging in using a password, you must make sure users can log in using another mechanism.

Amazon EC2 allows users to specify a public-private key pair name when launching an instance. When a valid key pair name is provided to the RunInstances API call (or through the command line API tools), the public key (the portion of the key pair that Amazon EC2 retains on the server after a call to CreateKeyPair or ImportKeyPair) is made available to the instance through an HTTP query against the instance metadata.

To log in through SSH, your AMI must retrieve the key value at boot and append it to /root/.ssh/authorized_keys (or the equivalent for any other user account on the AMI). Users can launch instances of your AMI with a key pair and log in without requiring a root password.

Many distributions, including Amazon Linux and Ubuntu, use the cloud-init package to inject public key credentials for a configured user. If your distribution does not support cloud-init, you can add the following code to a system start-up script (such as /etc/rc.local) to pull in the public key you specified at launch for the root user.

Note

In the following example, the IP address http://169.254.169.254/ is a link-local address and is valid only from the instance.

IMDSv2

```bash
if [ ! -d /root/.ssh ]; then
    mkdir -p /root/.ssh
    chmod 700 /root/.ssh
fi
# Fetch public key using HTTP
```
if [ $? -eq 0 ] ; then 
cat /tmp/my-key >> /root/.ssh/authorized_keys 
chmod 700 /root/.ssh/authorized_keys 
rm /tmp/my-key 
fi

IMDSv1

if [ ! -d /root/.ssh ] ; then 
    mkdir -p /root/.ssh 
    chmod 700 /root/.ssh 
fi 

# Fetch public key using HTTP 
if [ $? -eq 0 ] ; then 
cat /tmp/my-key >> /root/.ssh/authorized_keys 
chmod 700 /root/.ssh/authorized_keys 
rm /tmp/my-key 
fi

This can be applied to any user; you do not need to restrict it to the root user.

Note

Rebundling an instance based on this AMI includes the key with which it was launched. To prevent the key's inclusion, you must clear out (or delete) the authorized_keys file or exclude this file from rebundling.

Disable sshd DNS checks (optional)

Disabling sshd DNS checks slightly weakens your sshd security. However, if DNS resolution fails, SSH logins still work. If you do not disable sshd checks, DNS resolution failures prevent all logins.

To disable sshd DNS checks

1. Open the /etc/ssh/sshd_config file with a text editor and locate the following line:
# UseDNS yes

2. Change the line to:

UseDNS no

**Note**
The location of this configuration file can differ for your distribution or if you are not running OpenSSH. If this is the case, consult the relevant documentation.

## Protect yourself

We recommend against storing sensitive data or software on any AMI that you share. Users who launch a shared AMI might be able to rebundle it and register it as their own. Follow these guidelines to help you to avoid some easily overlooked security risks:

- We recommend using the `--exclude directory` option on `ec2-bundle-vol` to skip any directories and subdirectories that contain secret information that you would not like to include in your bundle. In particular, exclude all user-owned SSH public/private key pairs and SSH `authorized_keys` files when bundling the image. The Amazon public AMIs store these in `/root/.ssh` for the root user, and `/home/user_name/.ssh/` for regular users. For more information, see `ec2-bundle-vol`.

- Always delete the shell history before bundling. If you attempt more than one bundle upload in the same AMI, the shell history contains your access key. The following example should be the last command you run before bundling from within the instance.

  ```
  [ec2-user ~]$ shred -u ~/.history
  ```

**Warning**
The limitations of `shred` described in the warning above apply here as well. Be aware that bash writes the history of the current session to the disk on exit. If you log out of your instance after deleting `~/.bash_history`, and then log back in, you will
find that ~/.bash_history has been re-created and contains all of the commands you ran during your previous session.
Other programs besides bash also write histories to disk. Use caution and remove or exclude unnecessary dot-files and dot-directories.

- Bundling a running instance requires your private key and X.509 certificate. Put these and other credentials in a location that is not bundled (such as the instance store).

**Paid AMIs**

A *paid AMI* is an AMI that is listed for sale in the AWS Marketplace. The AWS Marketplace is an online store where you can buy software that runs on AWS, including AMIs that you can use to launch your EC2 instance. The AWS Marketplace AMIs are organized into categories, such as Developer Tools, to enable you to find products to suit your requirements. For more information about AWS Marketplace, see the [AWS Marketplace](https://aws.amazon.com/marketplace) website.

You can purchase AMIs in the AWS Marketplace from a third party, including AMIs that come with service contracts from organizations such as Red Hat. You can also create an AMI and sell it in the AWS Marketplace to other Amazon EC2 users. Building a safe, secure, usable AMI for public consumption is a fairly straightforward process, if you follow a few simple guidelines. For information about how to create and use shared AMIs, see [Shared AMIs](#).

Launching an instance from a paid AMI is the same as launching an instance from any other AMI. No additional parameters are required. The instance is charged according to the rates set by the owner of the AMI, as well as the standard usage fees for the related web services, for example, the hourly rate for running an m5.small instance type in Amazon EC2. Additional taxes might also apply. The owner of the paid AMI can confirm whether a specific instance was launched using that paid AMI.

⚠️ **Important**

Amazon DevPay is no longer accepting new sellers or products. AWS Marketplace is now the single, unified e-commerce platform for selling software and services through AWS. For information about how to deploy and sell software from AWS Marketplace, see [Selling in AWS Marketplace](https://aws.amazon.com/marketplace). AWS Marketplace supports AMIs backed by Amazon EBS.

**Contents**

- Paid AMIs
• **Sell your AMI**

• **Find a paid AMI**

• **Purchase a paid AMI**

• **Get the product code for your instance**

• **Use paid support**

• **Bills for paid and supported AMIs**

• **Manage your AWS Marketplace subscriptions**

### Sell your AMI

You can sell your AMI using AWS Marketplace. AWS Marketplace offers an organized shopping experience. Additionally, AWS Marketplace also supports AWS features such as Amazon EBS-backed AMIs, Reserved Instances, and Spot Instances.

For information about how to sell your AMI on the AWS Marketplace, see [Selling in AWS Marketplace](#).

### Find a paid AMI

There are several ways that you can find AMIs that are available for you to purchase. For example, you can use [AWS Marketplace](https://aws.amazon.com/marketplace/), the Amazon EC2 console, or the command line. Alternatively, a developer might let you know about a paid AMI themselves.

#### Find a paid AMI using the console

**To find a paid AMI using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose AMIs.
3. Choose **Public images** for the first filter.
4. In the Search bar, choose **Owner alias**, then =, and then **aws-marketplace**.
5. If you know the product code, choose **Product code**, then =, and then enter the product code.
Find a paid AMI using AWS Marketplace

To find a paid AMI using AWS Marketplace

1. Open AWS Marketplace.
2. Enter the name of the operating system in the search field, and then choose the search button (magnifying glass).
3. To scope the results further, use one of the categories or filters.
4. Each product is labeled with its product type: either AMI or Software as a Service.

Find a paid AMI using the AWS CLI

You can find a paid AMI using the following describe-images command (AWS CLI).

```
aws ec2 describe-images
   --owners aws-marketplace
```

This command returns numerous details that describe each AMI, including the product code for a paid AMI. The output from describe-images includes an entry for the product code like the following:

```
"ProductCodes": [
   {
      "ProductCodeId": "product_code",
      "ProductCodeType": "marketplace"
   }
],
```

If you know the product code, you can filter the results by product code. This example returns the most recent AMI with the specified product code.

```
aws ec2 describe-images
   --owners aws-marketplace \
   --filters "Name=product-code,Values=product_code" \
   --query "sort_by(Images, &CreationDate)[-1].[ImageId]"
```

Find a paid AMI using the Tools for Windows PowerShell

You can find a paid AMI using the following Get-EC2Image command.
Amazon Elastic Compute Cloud

User Guide

PS C:\> Get-EC2Image -Owner aws-marketplace

The output for a paid AMI includes the product code.
ProductCodeId
------------product_code

ProductCodeType
--------------marketplace

If you know the product code, you can ﬁlter the results by product code. This example returns the
most recent AMI with the speciﬁed product code.
PS C:\> (Get-EC2Image -Owner aws-marketplace -Filter @{"Name"="productcode";"Value"="product_code"} | sort CreationDate -Descending | Select-Object -First
1).ImageId

Purchase a paid AMI
You must sign up for (purchase) a paid AMI before you can launch an instance using the AMI.
Typically a seller of a paid AMI presents you with information about the AMI, including its price and
a link where you can buy it. When you click the link, you're ﬁrst asked to log into AWS, and then
you can purchase the AMI.

Purchase a paid AMI using the console
You can purchase a paid AMI by using the Amazon EC2 launch wizard. For more information, see
Launch an AWS Marketplace instance.

Subscribe to a product using AWS Marketplace
To use the AWS Marketplace, you must have an AWS account. To launch instances from AWS
Marketplace products, you must be signed up to use the Amazon EC2 service, and you must be
subscribed to the product from which to launch the instance. There are two ways to subscribe to
products in the AWS Marketplace:
• AWS Marketplace website: You can launch preconﬁgured software quickly with the 1-Click
deployment feature.
• Amazon EC2 launch wizard: You can search for an AMI and launch an instance directly from the
wizard. For more information, see Launch an AWS Marketplace instance.
Purchase a paid AMI

119


Get the product code for your instance

You can retrieve the AWS Marketplace product code for your instance using its instance metadata. If the instance has a product code, Amazon EC2 returns it. For more information about retrieving metadata, see Retrieve instance metadata.

To retrieve a product code, use the command for your instance's operating system.

**Linux**

**IMDSv2**

```
```

**IMDSv1**

```
```

**Windows**

```
```

Use paid support

Amazon EC2 also enables developers to offer support for software (or derived AMIs). Developers can create support products that you can sign up to use. During sign-up for the support product, the developer gives you a product code, which you must then associate with your own AMI. This enables the developer to confirm that your instance is eligible for support. It also ensures that when you run instances of the product, you are charged according to the terms for the product specified by the developer.

⚠️ Important

You can't use a support product with Reserved Instances. You always pay the price that's specified by the seller of the support product.
To associate a product code with your AMI, use one of the following commands, where `ami_id` is the ID of the AMI and `product_code` is the product code:

- **modify-image-attribute** (AWS CLI)

  ```bash
  aws ec2 modify-image-attribute --image-id ami_id --product-codes "product_code"
  ```

- **Edit-EC2ImageAttribute** (AWS Tools for Windows PowerShell)

  ```powershell
  PS C:\> Edit-EC2ImageAttribute -ImageId ami_id -ProductCode product_code
  ```

After you set the product code attribute, it cannot be changed or removed.

**Bills for paid and supported AMIs**

At the end of each month, you receive an email with the amount your credit card has been charged for using any paid or supported AMIs during the month. This bill is separate from your regular Amazon EC2 bill. For more information, see [Paying for products](#) in the *AWS Marketplace Buyer Guide*.

**Manage your AWS Marketplace subscriptions**

On the AWS Marketplace website, you can check your subscription details, view the vendor's usage instructions, manage your subscriptions, and more.

**To check your subscription details**

1. Log in to the [AWS Marketplace](#).
2. Choose Your Marketplace Account.
3. Choose Manage your software subscriptions.
4. All your current subscriptions are listed. Choose Usage Instructions to view specific instructions for using the product, for example, a user name for connecting to your running instance.

**To cancel an AWS Marketplace subscription**

1. Ensure that you have terminated any instances running from the subscription.
a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
b. In the navigation pane, choose Instances.
c. Select the instance, and then choose Instance state, Terminate instance.
d. Choose Terminate when prompted for confirmation.

2. Log in to the AWS Marketplace, and choose Your Marketplace Account, then Manage your software subscriptions.

3. Choose Cancel subscription. You are prompted to confirm your cancellation.

Note

After you've canceled your subscription, you are no longer able to launch any instances from that AMI. To use that AMI again, you need to resubscribe to it, either on the AWS Marketplace website, or through the launch wizard in the Amazon EC2 console.

AMI lifecycle

You can create your own AMIs, copy them, back them up, and maintain them until you are ready to deprecate or deregister them.

Contents

- Create an AMI
- Modify an AMI
- Copy an AMI
- Store and restore an AMI using S3
- Deprecate an AMI
- Disable an AMI
- Archive AMI snapshots
- Deregister (delete) an AMI
- Automate the EBS-backed AMI lifecycle
Create an AMI

You can create Linux or Windows AMIs that are backed by Amazon EBS volumes. You can also create Linux AMIs backed by instance store volumes (Windows AMIs don't support instance store for the root device). You can also use Windows Sysprep to create Windows AMIs.

Topics

- Create an Amazon EBS-backed AMI
- Create an instance store-backed Linux AMI
- Use EC2 launch agents to create an AMI with Windows Sysprep

Create an Amazon EBS-backed AMI

To create an Amazon EBS-backed AMI, start from an instance that you've launched from an existing Amazon EBS-backed AMI. This can be an AMI you have obtained from the AWS Marketplace, an AMI you have created using the AWS Server Migration Service or VM Import/Export, or any other AMI you can access. After you customize the instance to suit your needs, create and register a new AMI, which you can use to launch new instances with these customizations.

The procedures described below work for Amazon EC2 instances backed by encrypted Amazon Elastic Block Store (Amazon EBS) volumes (including the root volume) as well as for unencrypted volumes.

The AMI creation process is different for instance store-backed AMIs. For information about the differences between Amazon EBS-backed and instance store-backed instances, and how to determine the root device type for your instance, see Storage for the root device. For information about creating an instance store-backed AMI, see Create an instance store-backed Linux AMI.

Overview of creating Amazon EBS-backed AMIs

The following diagram summarizes the process for creating an Amazon EBS-backed AMI from a running EC2 instance: Start with an existing AMI, launch an instance, customize it, create a new AMI from it, and finally launch an instance of your new AMI. The numbers in the diagram match the numbers in the description that follows.
1 – AMI #1: Start with an existing AMI

Find an existing AMI that is similar to the AMI that you’d like to create. This can be an AMI you have obtained from the AWS Marketplace, an AMI you have created using the AWS Server Migration Service or VM Import/Export, or any other AMI you can access. You’ll customize this AMI for your needs.

In the diagram, EBS root volume snapshot #1 indicates that the AMI is an Amazon EBS-backed AMI and that information about the root volume is stored in this snapshot.

2 – Launch instance from existing AMI

The way to configure an AMI is to launch an instance from the AMI on which you’d like to base your new AMI, and then customize the instance (indicated at 3 in the diagram). Then, you'll create a new AMI that includes the customizations (indicated at 4 in the diagram).

3 – EC2 instance #1: Customize the instance

Connect to your instance and customize it for your needs. Your new AMI will include these customizations.

You can perform any of the following actions on your instance to customize it:

• Install software and applications
• Copy data
• Reduce start time by deleting temporary files and defragmenting your hard drive
• Attach additional EBS volumes

4 – Create image

When you create an AMI from an instance, Amazon EC2 powers down the instance before creating the AMI to ensure that everything on the instance is stopped and in a consistent state during the creation process. If you're confident that your instance is in a consistent state appropriate for AMI creation, you can tell Amazon EC2 not to power down and reboot the instance. Some file systems, such as XFS, can freeze and unfreeze activity, making it safe to create the image without rebooting the instance.
During the AMI-creation process, Amazon EC2 creates snapshots of your instance's root volume and any other EBS volumes attached to your instance. You're charged for the snapshots until you deregister the AMI and delete the snapshots. If any volumes attached to the instance are encrypted, the new AMI only launches successfully on instances that support Amazon EBS encryption.

Depending on the size of the volumes, it can take several minutes for the AMI-creation process to complete (sometimes up to 24 hours). You might find it more efficient to create snapshots of your volumes before creating your AMI. This way, only small, incremental snapshots need to be created when the AMI is created, and the process completes more quickly (the total time for snapshot creation remains the same).

5 – AMI #2: New AMI

After the process completes, you have a new AMI and snapshot (snapshot #2) created from the root volume of the instance. If you added instance-store volumes or EBS volumes to the instance, in addition to the root device volume, the block device mapping for the new AMI contains information for these volumes.

Amazon EC2 automatically registers the AMI for you.

6 – Launch instance from new AMI

You can use the new AMI to launch an instance.

7 – EC2 instance #2: New instance

When you launch an instance using the new AMI, Amazon EC2 creates a new EBS volume for the instance's root volume using the snapshot. If you added instance-store volumes or EBS volumes when you customized the instance, the block device mapping for the new AMI contains information for these volumes, and the block device mappings for instances that you launch from the new AMI automatically contain information for these volumes. The instance-store volumes specified in the block device mapping for the new instance are new and don't contain any data from the instance store volumes of the instance you used to create the AMI. The data on EBS volumes persists. For more information, see Block device mappings for Amazon EBS and instance store volumes on Amazon EC2 instances.

When you create a new instance from an EBS-backed AMI, you should initialize both its root volume and any additional EBS storage before putting it into production. For more information, see Initialize Amazon EBS volumes in the Amazon EBS User Guide.
Create an AMI from an instance

You can create an AMI using the AWS Management Console or the command line.

Console

To create an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance from which to create the AMI, and then choose Actions, Image and templates, Create image.

Tip

If this option is disabled, your instance isn't an Amazon EBS-backed instance.

4. On the Create image page, specify the following information:

   a. For Image name, enter a unique name for the image, up to 127 characters.
   b. For Image description, enter an optional description of the image, up to 255 characters.
   c. For No reboot, either keep the Enable check box cleared (the default), or select it.

      • If the Enable check box for No reboot is cleared, when Amazon EC2 creates the new AMI, it reboots the instance so that it can take snapshots of the attached volumes while data is at rest, in order to ensure a consistent state.
      • If the Enable check box for No reboot is selected, when Amazon EC2 creates the new AMI, it does not shut down and reboot the instance.

   d. Instance volumes – You can modify the root volume, and add additional Amazon EBS and instance store volumes, as follows:

   Warning

   If you choose to enable No reboot, we can't guarantee the file system integrity of the created image.
i. The root volume is defined in the first row.
   - To change the size of the root volume, for **Size**, enter the required value.
   - If you select **Delete on termination**, when you terminate the instance created from this AMI, the EBS volume is deleted. If you clear **Delete on termination**, when you terminate the instance, the EBS volume is not deleted. For more information, see **Preserve data when an instance is terminated**.

ii. To add an EBS volume, choose **Add volume** (which adds a new row). For **Storage type**, choose **EBS**, and fill in the fields in the row. When you launch an instance from your new AMI, additional volumes are automatically attached to the instance. Empty volumes must be formatted and mounted. Volumes based on a snapshot must be mounted.

iii. To add an instance store volume, see **Add instance store volumes to an AMI**. When you launch an instance from your new AMI, additional volumes are automatically initialized and mounted. These volumes do not contain data from the instance store volumes of the running instance on which you based your AMI.

e. **Tags** – You can tag the AMI and the snapshots with the same tags, or you can tag them with different tags.
   - To tag the AMI and the snapshots with the same tags, choose **Tag image and snapshots together**. The same tags are applied to the AMI and every snapshot that is created.
   - To tag the AMI and the snapshots with different tags, choose **Tag image and snapshots separately**. Different tags are applied to the AMI and the snapshots that are created. However, all the snapshots get the same tags; you can't tag each snapshot with a different tag.

   To add a tag, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.

f. When you're ready to create your AMI, choose **Create image**.

5. To view the status of your AMI while it is being created:
   a. In the navigation pane, choose **AMIs**.
   b. Set the filter to **Owned by me**, and find your AMI in the list.
Initially, the status is pending but should change to available after a few minutes.

6. (Optional) To view the snapshot that was created for the new AMI:
   a. Note the ID of your AMI that you located in the previous step.
   b. In the navigation pane, choose Snapshots.
   c. Set the filter to Owned by me, and then find the snapshot with the new AMI ID in the Description column.

When you launch an instance from this AMI, Amazon EC2 uses this snapshot to create its root device volume.

AWS CLI

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2.

- create-image (AWS CLI)
- New-EC2Image (AWS Tools for Windows PowerShell)

Create a Linux AMI from a snapshot

If you have a snapshot of the root device volume of an instance, you can create a Linux AMI from this snapshot using the AWS Management Console or the command line. This feature is not currently available for Windows instances.

Console

To create an AMI from a snapshot

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots.
3. Select the snapshot from which to create the AMI, and then choose Actions, Create image from snapshot.
4. On the Create image from snapshot page, specify the following information:
   a. For Image name, enter a descriptive name for the image.
   b. For Description, enter a brief description for the image.
c. For **Architecture**, choose the image architecture. Choose **i386** for 32-bit, **x86_64** for 64-bit, **arm64** for 64-bit ARM, or **x86_64** for 64-bit macOS.

d. For **Root device name**, enter the device name to use for the root device volume. For more information, see [Device names for Amazon EBS and instance store volumes on Amazon EC2 instances](#).

e. For **Virtualization type**, choose the virtualization type to be used by instances launched from this AMI. For more information, see [AMI virtualization types](#).

f. (For paravirtual virtualization only) For **Kernel ID**, select the operating system kernel for the image. If you're using a snapshot of the root device volume of an instance, select the same kernel ID as the original instance. If you're unsure, use the default kernel.

g. (For paravirtual virtualization only) For **RAM disk ID**, select the RAM disk for the image. If you select a specific kernel, you may need to select a specific RAM disk with the drivers to support it.

h. For **Boot mode**, choose the boot mode for the image, or choose **Use default** so that when an instance is launched with this AMI, it boots with the boot mode supported by the instance type. For more information, see [Set the boot mode of an AMI](#).

i. (Optional) Under **Block device mappings**, customize the root volume and add additional data volumes.

   For each volume, you can specify the size, type, performance characteristics, the behavior of delete on termination, and encryption status. For the root volume, the size can't be smaller than the size of the snapshot. For volume type, General Purpose SSD gp3 is the default selection.

j. (Optional) Under **Tags**, you can add one or more tags to the new AMI. To add a tag, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.

k. When you're ready to create your AMI, choose **Create image**.

**AWS CLI**

*To create an AMI from a snapshot using the command line*

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](#).

- `register-image` (AWS CLI)
Launch an instance from an AMI that you created

You can launch an instance from an AMI that you created from an instance or snapshot.

To launch an instance from your AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, under Images, choose AMIs.
3. Set the filter to Owned by me and select your AMI.
4. Choose Launch instance from AMI.
5. Accept the default values or specify custom values in the launch instance wizard. For more information, see Launch an instance using the new launch instance wizard.

Create an instance store-backed Linux AMI

The AMI that you specify when you launch your instance determines the type of root device volume.

To create an instance store-backed Linux AMI, start from an instance that you've launched from an existing instance store-backed Linux AMI. After you've customized the instance to suit your needs, bundle the volume and register a new AMI, which you can use to launch new instances with these customizations.

You can't create an instance-store backed Windows AMI because Windows AMIs don't support instance store for the root device.

⚠️ Important

Only the following instance types support an instance store volume as the root device: C1, C3, D2, I2, M1, M2, M3, R3, and X1.

The AMI creation process is different for Amazon EBS-backed AMIs. For more information about the differences between Amazon EBS-backed and instance store-backed instances, and how to determine the root device type for your instance, see Storage for the root device. If you need to create an Amazon EBS-backed AMI, see Create an Amazon EBS-backed AMI.
Overview of the creation process for instance store-backed AMIs

The following diagram summarizes the process of creating an AMI from an instance store-backed instance.

First, launch an instance from an AMI that's similar to the AMI that you'd like to create. You can connect to your instance and customize it. When the instance is set up the way you want it, you can bundle it. It takes several minutes for the bundling process to complete. After the process completes, you have a bundle, which consists of an image manifest (image.manifest.xml) and files (image.part.xx) that contain a template for the root volume. Next you upload the bundle to your Amazon S3 bucket and then register your AMI.

**Note**

To upload objects to an S3 bucket for your instance store-backed Linux AMI, ACLs must be enabled for the bucket. Otherwise, Amazon EC2 will not be able to set ACLs on the objects to upload. If your destination bucket uses the bucket owner enforced setting for S3 Object Ownership, this won't work because ACLs are disabled. For more information, see Controlling ownership of uploaded objects using S3 Object Ownership.

When you launch an instance using the new AMI, we create the root volume for the instance using the bundle that you uploaded to Amazon S3. The storage space used by the bundle in Amazon S3 incurs charges to your account until you delete it. For more information, see Deregister (delete) an AMI.
If you add instance store volumes to your instance in addition to the root device volume, the block device mapping for the new AMI contains information for these volumes, and the block device mappings for instances that you launch from the new AMI automatically contain information for these volumes. For more information, see Block device mappings for Amazon EBS and instance store volumes on Amazon EC2 instances.

Prerequisites

Before you can create an AMI, you must complete the following tasks:

- Install the AMI tools. For more information, see Set up the AMI tools.
- Install the AWS CLI. For more information, see Getting Set Up with the AWS Command Line Interface.
- Ensure that you have an S3 bucket for the bundle, and that your bucket has ACLs enabled. For more information on configuring ACLs, see Configuring ACLs.
  - To create an S3 bucket using the AWS Management Console, open the Amazon S3 console at https://console.aws.amazon.com/s3/ and choose Create Bucket.
  - To create an S3 bucket with the AWS CLI, you can use the mb command. If your installed version of the AMI tools is 1.5.18 or later, you can also use the ec2-upload-bundle command to create the S3 bucket. For more information, see ec2-upload-bundle.
- Ensure that you have your AWS account ID. For more information, see View AWS account identifiers in the AWS Account Management Reference Guide.
- Ensure that you have credentials to use the AWS CLI. For more information, see Best Practices for AWS accounts in the AWS Account Management Reference Guide.
- Ensure that you have an X.509 certificate and corresponding private key.
  - If you need to create an X.509 certificate, see Manage signing certificates. The X.509 certificate and private key are used to encrypt and decrypt your AMI.
  - [China (Beijing)] Use the $EC2_AMITOOL_HOME/etc/ec2/amitools/cert-ec2-cn-north-1.pem certificate.
  - [AWS GovCloud (US-West)] Use the $EC2_AMITOOL_HOME/etc/ec2/amitools/cert-ec2-gov.pem certificate.
- Connect to your instance and customize it. For example, you can install software and applications, copy data, delete temporary files, and modify the Linux configuration.
Tasks

- Set up the AMI tools
- Create an AMI from an instance store-backed Amazon Linux instance
- Create an AMI from an instance store-backed Ubuntu instance
- Convert your instance store-backed AMI to an Amazon EBS-backed AMI

Set up the AMI tools

You can use the AMI tools to create and manage instance store-backed Linux AMIs. To use the tools, you must install them on your Linux instance. The AMI tools are available as both an RPM and as a .zip file for Linux distributions that don't support RPM.

To set up the AMI tools using the RPM

1. Install Ruby using the package manager for your Linux distribution, such as yum. For example:

   ```
   [ec2-user ~]$ sudo yum install -y ruby
   ```

2. Download the RPM file using a tool such as wget or curl. For example:

   ```
   ```

3. Verify the RPM file's signature using the following command:

   ```
   [ec2-user ~]$ rpm -K ec2-ami-tools.noarch.rpm
   ```

   The command above should indicate that the file's SHA1 and MD5 hashes are OK. If the command indicates that the hashes are NOT OK, use the following command to view the file's Header SHA1 and MD5 hashes:

   ```
   [ec2-user ~]$ rpm -Kv ec2-ami-tools.noarch.rpm
   ```

   Then, compare your file's Header SHA1 and MD5 hashes with the following verified AMI tools hashes to confirm the file's authenticity:

   - Header SHA1: a1f662d6f25f69871104e6a62187fa4df508f880
   - MD5: 9faff05258064e2f7909b66142de6782
If your file's Header SHA1 and MD5 hashes match the verified AMI tools hashes, continue to the next step.

4. Install the RPM using the following command:

```
[ec2-user ~]$ sudo yum install ec2-ami-tools.noarch.rpm
```

5. Verify your AMI tools installation using the `ec2-ami-tools-version` command.

```
[ec2-user ~]$ ec2-ami-tools-version
```

### Note
If you receive a load error such as "cannot load such file -- ec2/amitools/version (LoadError)", complete the next step to add the location of your AMI tools installation to your RUBYLIB path.

6. (Optional) If you received an error in the previous step, add the location of your AMI tools installation to your RUBYLIB path.

   a. Run the following command to determine the paths to add.

   ```
   [ec2-user ~]$ rpm -qil ec2-ami-tools | grep ec2/amitools/version
   /usr/lib/ruby/site_ruby/ec2/amitools/version.rb
   /usr/lib64/ruby/site_ruby/ec2/amitools/version.rb
   ```

   In the above example, the missing file from the previous load error is located at `/usr/lib/ruby/site_ruby` and `/usr/lib64/ruby/site_ruby`.

   b. Add the locations from the previous step to your RUBYLIB path.

   ```
   [ec2-user ~]$ export RUBYLIB=$RUBYLIB:/usr/lib/ruby/site_ruby:/usr/lib64/ruby/site_ruby
   ```

   c. Verify your AMI tools installation using the `ec2-ami-tools-version` command.

   ```
   [ec2-user ~]$ ec2-ami-tools-version
   ```
To set up the AMI tools using the .zip file

1. Install Ruby and unzip using the package manager for your Linux distribution, such as `apt-get`. For example:

   ```bash
   [ec2-user ~]$ sudo apt-get update -y && sudo apt-get install -y ruby unzip
   ```

2. Download the .zip file using a tool such as `wget` or `curl`. For example:

   ```bash
   ```

3. Unzip the files into a suitable installation directory, such as `/usr/local/ec2`.

   ```bash
   [ec2-user ~]$ sudo mkdir -p /usr/local/ec2
   $ sudo unzip ec2-ami-tools.zip -d /usr/local/ec2
   ```

   Notice that the .zip file contains a folder `ec2-ami-tools-x.x.x`, where `x.x.x` is the version number of the tools (for example, `ec2-ami-tools-1.5.7`).

4. Set the `EC2_AMITOOL_HOME` environment variable to the installation directory for the tools. For example:

   ```bash
   [ec2-user ~]$ export EC2_AMITOOL_HOME=/usr/local/ec2/ec2-ami-tools-x.x.x
   ```

5. Add the tools to your `PATH` environment variable. For example:

   ```bash
   [ec2-user ~]$ export PATH=$EC2_AMITOOL_HOME/bin:$PATH
   ```

6. You can verify your AMI tools installation using the `ec2-ami-tools-version` command.

   ```bash
   [ec2-user ~]$ ec2-ami-tools-version
   ```

Manage signing certificates

Certain commands in the AMI tools require a signing certificate (also known as X.509 certificate). You must create the certificate and then upload it to AWS. For example, you can use a third-party tool such as OpenSSL to create the certificate.
To create a signing certificate

1. Install and configure OpenSSL.
2. Create a private key using the `openssl genrsa` command and save the output to a `.pem` file. We recommend that you create a 2048- or 4096-bit RSA key.

```
openssl genrsa 2048 > private-key.pem
```
3. Generate a certificate using the `openssl req` command.

```
openssl req -new -x509 -nodes -sha256 -days 365 -key private-key.pem -outform PEM -out certificate.pem
```

To upload the certificate to AWS, use the `upload-signing-certificate` command.

```
aws iam upload-signing-certificate --user-name user-name --certificate-body file://path/to/certificate.pem
```

To list the certificates for a user, use the `list-signing-certificates` command:

```
aws iam list-signing-certificates --user-name user-name
```

To disable or re-enable a signing certificate for a user, use the `update-signing-certificate` command. The following command disables the certificate:

```
aws iam update-signing-certificate --certificate-id OFHPLP4ZULTHYPMSYEX7O4BEXAMPLE --status Inactive --user-name user-name
```

To delete a certificate, use the `delete-signing-certificate` command:

```
aws iam delete-signing-certificate --user-name user-name --certificate-id OFHPLP4ZULTHYPMSYEX7O4BEXAMPLE
```

Create an AMI from an instance store-backed instance

The following procedures are for creating an instance store-backed AMI from an instance store-backed instance. Before you begin, ensure that you've read the Prerequisites.

Topics
Create an AMI from an instance store-backed Amazon Linux instance

This section describes the creation of an AMI from an Amazon Linux instance. The following procedures may not work for instances running other Linux distributions. For Ubuntu-specific procedures, see Create an AMI from an instance store-backed Ubuntu instance.

To prepare to use the AMI tools (HVM instances only)

1. The AMI tools require GRUB Legacy to boot properly. Use the following command to install GRUB:

   ```bash
   [ec2-user ~]$ sudo yum install -y grub
   ```

2. Install the partition management packages with the following command:

   ```bash
   [ec2-user ~]$ sudo yum install -y gdisk kpartx parted
   ```

To create an AMI from an instance store-backed Amazon Linux instance

This procedure assumes that you have satisfied the prerequisites in Prerequisites.

In the following commands, replace each user input placeholder with your own information.

1. Upload your credentials to your instance. We use these credentials to ensure that only you and Amazon EC2 can access your AMI.

   a. Create a temporary directory on your instance for your credentials as follows:

      ```bash
      [ec2-user ~]$ mkdir /tmp/cert
      ```

      This enables you to exclude your credentials from the created image.

   b. Copy your X.509 certificate and corresponding private key from your computer to the /tmp/cert directory on your instance using a secure copy tool such as scp. The -i my-private-key.pem option in the following scp command is the private key you use to connect to your instance with SSH, not the X.509 private key. For example:
Alternatively, because these are plain text files, you can open the certificate and key in a text editor and copy their contents into new files in /tmp/cert.

2. Prepare the bundle to upload to Amazon S3 by running the `ec2-bundle-vol` command from inside your instance. Be sure to specify the `-e` option to exclude the directory where your credentials are stored. By default, the bundle process excludes files that might contain sensitive information. These files include `*.sw`, `*.swo`, `*.swp`, `*.pem`, `*.priv`, `*id_rsa*`, `*id_dsa*`, `*.gpg`, `*.jks`, `*/.ssh/authorized_keys`, and `*/.bash_history`. To include all of these files, use the `--no-filter` option. To include some of these files, use the `--include` option.

⚠️ **Important**

By default, the AMI bundling process creates a compressed, encrypted collection of files in the `/tmp` directory that represents your root volume. If you do not have enough free disk space in `/tmp` to store the bundle, you need to specify a different location for the bundle to be stored with the `-d` `/path/to/bundle/storage` option. Some instances have ephemeral storage mounted at `/mnt` or `/media/ephemeral0` that you can use, or you can also create, attach, and mount a new Amazon EBS volume to store the bundle. For more information, see Create an Amazon EBS volume in the Amazon EBS User Guide.

a. You must run the `ec2-bundle-vol` command as root. For most commands, you can use `sudo` to gain elevated permissions, but in this case, you should run `sudo -E su` to keep your environment variables.

```
[ec2-user ~]$ sudo -E su
```
Note that bash prompt now identifies you as the root user, and that the dollar sign has been replaced by a hash tag, signalling that you are in a root shell:

```
[root ec2-user]#
```

b. To create the AMI bundle, run the `ec2-bundle-vol` command as follows:

```
[root ec2-user]# ec2-bundle-vol -k /tmp/cert/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c /tmp/cert/cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u 123456789012 -r x86_64 -e /tmp/cert --partition gpt
```

**Note**

For the China (Beijing) and AWS GovCloud (US-West) Regions, use the `--ec2cert` parameter and specify the certificates as per the prerequisites.

It can take a few minutes to create the image. When this command completes, your `/tmp` (or non-default) directory contains the bundle (`image.manifest.xml`, plus multiple `image.part.xx` files).

c. Exit from the root shell.

```
[root ec2-user]# exit
```

3. (Optional) To add more instance store volumes, edit the block device mappings in the `image.manifest.xml` file for your AMI. For more information, see [Block device mappings for Amazon EBS and instance store volumes on Amazon EC2 instances](#).

a. Create a backup of your `image.manifest.xml` file.

```
[ec2-user ~]$ sudo cp /tmp/image.manifest.xml /tmp/image.manifest.xml.bak
```

b. Reformat the `image.manifest.xml` file so that it is easier to read and edit.

```
[ec2-user ~]$ sudo xmllint --format /tmp/image.manifest.xml.bak > /tmp/image.manifest.xml
```
c. Edit the block device mappings in image.manifest.xml with a text editor. The example below shows a new entry for the ephemeral1 instance store volume.

   **Note**
   For a list of excluded files, see ec2-bundle-vol.

   ```xml
   <block_device_mapping>
     <mapping>
       <virtual>ami</virtual>
       <device>sda</device>
     </mapping>
     <mapping>
       <virtual>ephemeral0</virtual>
       <device>sdb</device>
     </mapping>
     <mapping>
       <virtual>ephemeral1</virtual>
       <device>sdc</device>
     </mapping>
     <mapping>
       <virtual>root</virtual>
       <device>/dev/sda1</device>
     </mapping>
   </block_device_mapping>
   ```

d. Save the image.manifest.xml file and exit your text editor.

4. To upload your bundle to Amazon S3, run the ec2-upload-bundle command as follows.

   ```bash
   [ec2-user ~]$ ec2-upload-bundle -b DOC-EXAMPLE-BUCKET/bundle_folder/bundle_name -m /tmp/image.manifest.xml -a your_access_key_id -s your_secret_access_key
   ```

   **Important**
   To register your AMI in a Region other than US East (N. Virginia), you must specify both the target Region with the --region option and a bucket path that already exists in the target Region or a unique bucket path that can be created in the target Region.
5. (Optional) After the bundle is uploaded to Amazon S3, you can remove the bundle from the /tmp directory on the instance using the following `rm` command:

```
[ec2-user ~]$ sudo rm /tmp/image.manifest.xml /tmp/image.part.* /tmp/image
```

⚠️ Important

If you specified a path with the `-d /path/to/bundle/storage` option in Step 2, use that path instead of /tmp.

6. To register your AMI, run the `register-image` command as follows.

```
[ec2-user ~]$ aws ec2 register-image --image-location DOC-EXAMPLE-BUCKET/bundle_folder/bundle_name/image.manifest.xml --name AMI_name --virtualization-type hvm
```

⚠️ Important

If you previously specified a Region for the `ec2-upload-bundle` command, specify that Region again for this command.

---

Create an AMI from an instance store-backed Ubuntu instance

This section describes the creation of an AMI from an Ubuntu Linux instance with an instance store volume as the root volume. The following procedures may not work for instances running other Linux distributions. For procedures specific to Amazon Linux, see Create an AMI from an instance store-backed Amazon Linux instance.

To prepare to use the AMI tools (HVM instances only)

The AMI tools require GRUB Legacy to boot properly. However, Ubuntu is configured to use GRUB 2. You must check to see that your instance uses GRUB Legacy, and if not, you need to install and configure it.

HVM instances also require partitioning tools to be installed for the AMI tools to work properly.

1. GRUB Legacy (version 0.9x or less) must be installed on your instance. Check to see if GRUB Legacy is present and install it if necessary.
a. Check the version of your GRUB installation.

```
ubuntu:~$ grub-install --version
grub-install (GRUB) 1.99-21ubuntu3.10
```

In this example, the GRUB version is greater than 0.9x, so you must install GRUB Legacy. Proceed to Step 1.b. If GRUB Legacy is already present, you can skip to Step 2.

b. Install the `grub` package using the following command.

```
ubuntu:~$ sudo apt-get install -y grub
```

2. Install the following partition management packages using the package manager for your distribution.

- gdisk (some distributions may call this package `gptfdisk` instead)
- kpartx
- parted

Use the following command.

```
ubuntu:~$ sudo apt-get install -y gdisk kpartx parted
```

3. Check the kernel parameters for your instance.

```
ubuntu:~$ cat /proc/cmdline
BOOT_IMAGE=/boot/vmlinuz-3.2.0-54-virtual root=UUID=4f392932-ed93-4f8f-aee7-72bc5bb6ca9d ro console=ttyS0 xen_emul_unplug=unnecessary
```

Note the options following the kernel and root device parameters: `ro`, `console=ttyS0`, and `xen_emul_unplug=unnecessary`. Your options may differ.

4. Check the kernel entries in `/boot/grub/menu.lst`.

```
ubuntu:~$ grep ^kernel /boot/grub/menu.lst
kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro console=hvc0
kernel /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro single
kernel /boot/memtest86+.bin
```
Note that the console parameter is pointing to hvc0 instead of ttyS0 and that the xen_emul_unplug=unnecessary parameter is missing. Again, your options may differ.

5. Edit the /boot/grub/menu.lst file with your favorite text editor (such as `vim` or `nano`) to change the console and add the parameters you identified earlier to the boot entries.

```plaintext
title           Ubuntu 12.04.3 LTS, kernel 3.2.0-54-virtual
root            (hd0)
kernell        /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro console=ttyS0 xen_emul_unplug=unnecessary
initrd          /boot/initrd.img-3.2.0-54-virtual

title           Ubuntu 12.04.3 LTS, kernel 3.2.0-54-virtual (recovery mode)
root            (hd0)
kernell        /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro single console=ttyS0 xen_emul_unplug=unnecessary
initrd          /boot/initrd.img-3.2.0-54-virtual

title           Ubuntu 12.04.3 LTS, memtest86+
root            (hd0)
kernell        /boot/memtest86+.bin
```

6. Verify that your kernel entries now contain the correct parameters.

```plaintext
ubuntu:~$ grep ^kernel /boot/grub/menu.lst
kernel   /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro console=ttyS0 xen_emul_unplug=unnecessary
kernel   /boot/vmlinuz-3.2.0-54-virtual root=LABEL=cloudimg-rootfs ro single console=ttyS0 xen_emul_unplug=unnecessary
kernel   /boot/memtest86+.bin
```

7. [For Ubuntu 14.04 and later only] Starting with Ubuntu 14.04, instance store backed Ubuntu AMIs use a GPT partition table and a separate EFI partition mounted at /boot/efi. The `ec2-bundle-vol` command will not bundle this boot partition, so you need to comment out the `/etc/fstab` entry for the EFI partition as shown in the following example.

```plaintext
LABEL=cloudimg-rootfs   /        ext4   defaults        0 0
LABEL=UEFI     /boot/efi       vfat    defaults        0 0
/dev/xvdb       /mnt    auto    defaults,nobootwait,comment=cloudconfig 0 2
```
To create an AMI from an instance store-backed Ubuntu instance

This procedure assumes that you have satisfied the prerequisites in Prerequisites.

In the following commands, replace each user input placeholder with your own information.

1. Upload your credentials to your instance. We use these credentials to ensure that only you and Amazon EC2 can access your AMI.
   a. Create a temporary directory on your instance for your credentials as follows:

   ```
   ubuntu:~$ mkdir /tmp/cert
   ```

   This enables you to exclude your credentials from the created image.
   b. Copy your X.509 certificate and private key from your computer to the /tmp/cert directory on your instance, using a secure copy tool such as scp. The -i my-private-key.pem option in the following scp command is the private key you use to connect to your instance with SSH, not the X.509 private key. For example:

   ```
   you@your_computer:~ $ scp -i my-private-key.pem /path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem /path/to/cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem ec2-user@ec2-203-0-113-25.compute-1.amazonaws.com:/tmp/cert/
   pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem  100%  717  0.7KB/s  00:00
cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem 100%  685  0.7KB/s  00:00
   ```

   Alternatively, because these are plain text files, you can open the certificate and key in a text editor and copy their contents into new files in /tmp/cert.

2. Prepare the bundle to upload to Amazon S3 by running the ec2-bundle-vol command from your instance. Be sure to specify the -e option to exclude the directory where your credentials are stored. By default, the bundle process excludes files that might contain sensitive information. These files include *.sw, *.swo, *.swp, *.pem, *.priv, *id_rsa, *id_dsa* *.gpg, *.jks, */.ssh/authorized_keys, and */.bash_history. To include all of these files, use the --no-filter option. To include some of these files, use the --include option.
**Important**

By default, the AMI bundling process creates a compressed, encrypted collection of files in the `/tmp` directory that represents your root volume. If you do not have enough free disk space in `/tmp` to store the bundle, you need to specify a different location for the bundle to be stored with the `-d /path/to/bundle/storage` option. Some instances have ephemeral storage mounted at `/mnt` or `/media/ephemeral0` that you can use, or you can also create, attach, and mount a new Amazon EBS volume to store the bundle. For more information, see [Create an Amazon EBS volume](#) in the *Amazon EBS User Guide*.

---

a. You must run the `ec2-bundle-vol` command needs as root. For most commands, you can use `sudo` to gain elevated permissions, but in this case, you should run `sudo -E su` to keep your environment variables.

```bash
ubuntu:~$ sudo -E su
```

Note that bash prompt now identifies you as the root user, and that the dollar sign has been replaced by a hash tag, signalling that you are in a root shell:

```bash
root@ubuntu:#
```

b. To create the AMI bundle, run the `ec2-bundle-vol` command as follows.

```bash
root@ubuntu:~# ec2-bundle-vol -k /tmp/cert/pk-HKZYKTAIG2ECMXYIBH3HXS4ZBEXAMPLE.pem -c /tmp/cert/cert-HKZYKTAIG2ECMXYIBH3HXS4ZBEXAMPLE.pem -u your_aws_account_id -r x86_64 -e /tmp/cert --partition gpt
```

---

**Important**

For Ubuntu 14.04 and later HVM instances, add the `--partition mbr` flag to bundle the boot instructions properly; otherwise, your newly-created AMI will not boot.
It can take a few minutes to create the image. When this command completes, your tmp directory contains the bundle (image.manifest.xml, plus multiple image.part.xx files).

c. Exit from the root shell.

```
root@ubuntu:~# exit
```

3. (Optional) To add more instance store volumes, edit the block device mappings in the image.manifest.xml file for your AMI. For more information, see Block device mappings for Amazon EBS and instance store volumes on Amazon EC2 instances.

a. Create a backup of your image.manifest.xml file.

```
ubuntu:~$ sudo cp /tmp/image.manifest.xml /tmp/image.manifest.xml.bak
```

b. Reformat the image.manifest.xml file so that it is easier to read and edit.

```
ubuntu:~$ sudo xmllint --format /tmp/image.manifest.xml.bak > /tmp/image.manifest.xml
```

c. Edit the block device mappings in image.manifest.xml with a text editor. The example below shows a new entry for the ephemeral1 instance store volume.

```
<block_device_mapping>
  <mapping>
    <virtual>ami</virtual>
    <device>sda</device>
  </mapping>
  <mapping>
    <virtual>ephemeral0</virtual>
    <device>sdb</device>
  </mapping>
  <mapping>
    <virtual>ephemeral1</virtual>
    <device>sdc</device>
  </mapping>
  <mapping>
    <virtual>root</virtual>
    <device>/dev/sda1</device>
  </mapping>
</block_device_mapping>
```
d. Save the image.manifest.xml file and exit your text editor.

4. To upload your bundle to Amazon S3, run the `ec2-upload-bundle` command as follows.

   ```
   ubuntu:~$ ec2-upload-bundle -b DOC-EXAMPLE-BUCKET/bundle_folder/bundle_name -m /tmp/image.manifest.xml -a your_access_key_id -s your_secret_access_key
   ```

   **Important**
   If you intend to register your AMI in a Region other than US East (N. Virginia), you must specify both the target Region with the `--region` option and a bucket path that already exists in the target Region or a unique bucket path that can be created in the target Region.

5. (Optional) After the bundle is uploaded to Amazon S3, you can remove the bundle from the `/tmp` directory on the instance using the following `rm` command:

   ```
   ubuntu:~$ sudo rm /tmp/image.manifest.xml /tmp/image.part.* /tmp/image
   ```

   **Important**
   If you specified a path with the `-d /path/to/bundle/storage` option in Step 2, use that same path below, instead of `/tmp`.

6. To register your AMI, run the `register-image` AWS CLI command as follows.

   ```
   ubuntu:~$ aws ec2 register-image --image-location DOC-EXAMPLE-BUCKET/bundle_folder/bundle_name/image.manifest.xml --name AMI_name --virtualization-type hvm
   ```

   **Important**
   If you previously specified a Region for the `ec2-upload-bundle` command, specify that Region again for this command.

7. [Ubuntu 14.04 and later] Uncomment the EFI entry in `/etc/fstab`; otherwise, your running instance will not be able to reboot.
Convert your instance store-backed AMI to an Amazon EBS-backed AMI

You can convert an instance store-backed Linux AMI that you own to an Amazon EBS-backed Linux AMI.

⚠️ Important
You can't convert an AMI that you don't own.

To convert an instance store-backed AMI to an Amazon EBS-backed AMI

1. Launch an Amazon Linux instance from an Amazon EBS-backed AMI. For more information, see Launch an instance using the new launch instance wizard. Amazon Linux instances have the AWS CLI and AMI tools pre-installed.

2. Upload the X.509 private key that you used to bundle your instance store-backed AMI to your instance. We use this key to ensure that only you and Amazon EC2 can access your AMI.

   a. Create a temporary directory on your instance for your X.509 private key as follows:

   ```bash
   [ec2-user ~]$ mkdir /tmp/cert
   ```

   b. Copy your X.509 private key from your computer to the /tmp/cert directory on your instance, using a secure copy tool such as `scp`. The `my-private-key` parameter in the following command is the private key you use to connect to your instance with SSH. For example:

   ```bash
   you@your_computer:~ $ scp -i my-private-key.pem /path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem ec2-user@ec2-203-0-113-25.compute-1.amazonaws.com:/tmp/cert/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem 100% 717 0.7KB/s 00:00
   ```

3. Configure your environment variables to use the AWS CLI. For more information, see Creating a key pair.

   a. (Recommended) Set environment variables for your AWS access key, secret key, and session token.

   ```bash
   [ec2-user ~]$ export AWS_ACCESS_KEY_ID=your_access_key_id
   [ec2-user ~]$ export AWS_SECRET_ACCESS_KEY=your_secret_access_key
   ```
4. Prepare an Amazon Elastic Block Store (Amazon EBS) volume for your new AMI.

a. Create an empty EBS volume in the same Availability Zone as your instance using the `create-volume` command. Note the volume ID in the command output.

```
[ec2-user ~]$ aws ec2 create-volume --size 10 --region us-west-2 --availability-zone us-west-2b
```

b. Attach the volume to your Amazon EBS-backed instance using the `attach-volume` command.

```
[ec2-user ~]$ aws ec2 attach-volume --volume-id volume_id --instance-id instance_id --device /dev/sdb --region us-west-2
```

5. Create a folder for your bundle.

```
[ec2-user ~]$ mkdir /tmp/bundle
```

6. Download the bundle for your instance store-based AMI to /tmp/bundle using the `ec2-download-bundle` command.

```
[ec2-user ~]$ ec2-download-bundle -b DOC-EXAMPLE-BUCKET/bundle_folder/bundle_name -m image.manifest.xml -a $AWS_ACCESS_KEY_ID -s $AWS_SECRET_ACCESS_KEY --privatekey /path/to/pk-HKZYKTAIG2ECMXYIB3HXV4ZBEXAMPLE.pem -d /tmp/bundle
```

7. Reconstitute the image file from the bundle using the `ec2-unbundle` command.

a. Change directories to the bundle folder.
b. Run the `ec2-unbundle` command.

```
[ec2-user bundle]$ ec2-unbundle -m image.manifest.xml --privatekey /path/to/pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem
```

8. Copy the files from the unbundled image to the new EBS volume.

```
[ec2-user bundle]$ sudo dd if=/tmp/bundle/image of=/dev/sdb bs=1M
```

9. Probe the volume for any new partitions that were unbundled.

```
[ec2-user bundle]$ sudo partprobe /dev/sdb1
```

10. List the block devices to find the device name to mount.

```
[ec2-user bundle]$ lsblk
NAME     MAJ:MIN   RM  SIZE RO TYPE MOUNTPOINT
/dev/sda 202:0    0  8G  0 disk
##/dev/sda1 202:1    0  8G  0 part /
/dev/sdb 202:80  0 10G  0 disk
##/dev/sdb1 202:81  0 10G  0 part
```

In this example, the partition to mount is `/dev/sdb1`, but your device name will likely be different. If your volume is not partitioned, then the device to mount will be similar to `/dev/sdb` (without a device partition trailing digit).

11. Create a mount point for the new EBS volume and mount the volume.

```
[ec2-user bundle]$ sudo mkdir /mnt/ebs
[ec2-user bundle]$ sudo mount /dev/sdb1 /mnt/ebs
```

12. Open the `/etc/fstab` file on the EBS volume with your favorite text editor (such as `vim` or `nano`) and remove any entries for instance store (ephemeral) volumes. Because the EBS volume is mounted on `/mnt/ebs`, the `fstab` file is located at `/mnt/ebs/etc/fstab`.

```
[ec2-user bundle]$ sudo nano /mnt/ebs/etc/fstab
# LABEL=/   /           ext4    defaults,noatime  1   1
tmpfs      /dev/shm    tmpfs    defaults        0   0
```
In this example, the last line should be removed.

13. Unmount the volume and detach it from the instance.

```bash
[ec2-user bundle]$ sudo umount /mnt/ebs
[ec2-user bundle]$ aws ec2 detach-volume --volume-id volume_id --region us-west-2
```

14. Create an AMI from the new EBS volume as follows.

a. Create a snapshot of the new EBS volume.

```bash
[ec2-user bundle]$ aws ec2 create-snapshot --region us-west-2 --description "your_snapshot_description" --volume-id volume_id
```

b. Check to see that your snapshot is complete.

```bash
[ec2-user bundle]$ aws ec2 describe-snapshots --region us-west-2 --snapshot-id snapshot_id
```

c. Identify the processor architecture, virtualization type, and the kernel image (aki) used on the original AMI with the `describe-images` command. You need the AMI ID of the original instance store-backed AMI for this step.

```bash
[ec2-user bundle]$ aws ec2 describe-images --region us-west-2 --image-id ami-id --output text
```

```
IMAGES x86_64 amazon/amzn-ami-pv-2013.09.2.x86_64-s3 ami-8ef297be amazon available public machine aki-fc8f11cc instance-store paravirtual xen
```

In this example, the architecture is x86_64 and the kernel image ID is aki-fc8f11cc. Use these values in the following step. If the output of the above command also lists an ari ID, take note of that as well.

d. Register your new AMI with the snapshot ID of your new EBS volume and the values from the previous step. If the previous command output listed an ari ID, include that in the following command with `--ramdisk-id ari_id`.

Create an AMI
15. (Optional) After you have tested that you can launch an instance from your new AMI, you can delete the EBS volume that you created for this procedure.

```
aws ec2 delete-volume --volume-id volume_id
```

**AMI tools reference**

You can use the AMI tools commands to create and manage instance store-backed Linux AMIs. To set up the tools, see [Set up the AMI tools](#).

For information about your access keys, see [Managing access keys for IAM users](#) in the *IAM User Guide*.

**Commands**

- `ec2-ami-tools-version`
- `ec2-bundle-image`
- `ec2-bundle-vol`
- `ec2-delete-bundle`
- `ec2-download-bundle`
- `ec2-migrate-manifest`
- `ec2-unbundle`
- `ec2-upload-bundle`
- [Common options for AMI tools](#)

**ec2-ami-tools-version**

**Description**

Describes the version of the AMI tools.
Syntax

c2-ami-tools-version

Output

The version information.

Example

This example command displays the version information for the AMI tools that you're using.

```
[ec2-user ~]$ c2-ami-tools-version
1.5.2 20071010
```

c2-bundle-image

Description

Creates an instance store-backed Linux AMI from an operating system image created in a loopback file.

Syntax

```
c2-bundle-image -c path -k path -u account -i path [-d path] [--ec2cert path] [-r architecture] [--productcodes code1,code2,...] [-B mapping] [-p prefix]
```

Options

- **-c, --cert path**
  
  The user's PEM encoded RSA public key certificate file.
  
  Required: Yes

- **-k, --privatekey path**
  
  The path to a PEM-encoded RSA key file. You'll need to specify this key to unbundle this bundle, so keep it in a safe place. Note that the key doesn't have to be registered to your AWS account.
  
  Required: Yes

- **-u, --user account**
  
  The user's AWS account ID, without dashes.
Required: Yes

-i, --image path

The path to the image to bundle.

Required: Yes

-d, --destination path

The directory in which to create the bundle.

Default: /tmp

Required: No

--ec2cert path

The path to the Amazon EC2 X.509 public key certificate used to encrypt the image manifest.

The us-gov-west-1 and cn-north-1 Regions use a non-default public key certificate and the path to that certificate must be specified with this option. The path to the certificate varies based on the installation method of the AMI tools. For Amazon Linux, the certificates are located at /opt/aws/amitools/ec2/etc/ec2/amitools/. If you installed the AMI tools from the RPM or ZIP file in Set up the AMI tools, the certificates are located at $EC2_AMITOOL_HOME/etc/ec2/amitools/.

Required: Only for the us-gov-west-1 and cn-north-1 Regions.

-r, --arch architecture

Image architecture. If you don't provide the architecture on the command line, you'll be prompted for it when bundling starts.

Valid values: i386 | x86_64

Required: No

--productcodes code1,code2,...

Product codes to attach to the image at registration time, separated by commas.

Required: No

-B, --block-device-mapping mapping

Defines how block devices are exposed to an instance of this AMI if its instance type supports the specified device.
Specify a comma-separated list of key-value pairs, where each key is a virtual name and each value is the corresponding device name. Virtual names include the following:

- **ami**—The root file system device, as seen by the instance
- **root**—The root file system device, as seen by the kernel
- **swap**—The swap device, as seen by the instance
- **ephemeralN**—The Nth instance store volume

Required: No

`-p, --prefix prefix`

The filename prefix for bundled AMI files.

Default: The name of the image file. For example, if the image path is `/var/spool/my-image/version-2/debian.img`, then the default prefix is `debian.img`.

Required: No

`--kernel kernel_id`

Deprecated. Use `register-image` to set the kernel.

Required: No

`--ramdisk ramdisk_id`

Deprecated. Use `register-image` to set the RAM disk if required.

Required: No

**Output**

Status messages describing the stages and status of the bundling process.

**Example**

This example creates a bundled AMI from an operating system image that was created in a loopback file.

```
[ec2-user ~]$ ec2-bundle-image -k pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u 111122223333 -i image.img -d bundled/ -r x86_64
Please specify a value for arch [i386]:

ec2-bundle-vol

Description

Creates an instance store-backed Linux AMI by compressing, encrypting, and signing a copy of the root device volume for the instance.

Amazon EC2 attempts to inherit product codes, kernel settings, RAM disk settings, and block device mappings from the instance.

By default, the bundle process excludes files that might contain sensitive information. These files include 
*.*sw, *.*swo, *.*swp, *.*pem, *.*priv, *id_rsa*, *id_dsa*, *gpg, *jks, */.ssh/authorized_keys, and */.bash_history. To include all of these files, use the --no-filter option. To include some of these files, use the --include option.

For more information, see Create an instance store-backed Linux AMI.

Syntax

```
ec2-bundle-vol -c path -k path -u account [-d path] [--ec2cert path] [-r architecture] [--productcodes code1,code2,...] [-B mapping] [--all] [-e
```

Options

-c, --cert path

The user's PEM encoded RSA public key certificate file.

Required: Yes

-k, --privatekey path

The path to the user's PEM-encoded RSA key file.

Required: Yes

-u, --user account

The user's AWS account ID, without dashes.

Required: Yes

-d, --destination destination

The directory in which to create the bundle.

Default: /tmp

Required: No

--ec2cert path

The path to the Amazon EC2 X.509 public key certificate used to encrypt the image manifest.

The us-gov-west-1 and cn-north-1 Regions use a non-default public key certificate and the path to that certificate must be specified with this option. The path to the certificate varies based on the installation method of the AMI tools. For Amazon Linux, the certificates are located at /opt/aws/amitools/ec2/etc/ec2/amitools/. If you installed the AMI tools from the RPM or ZIP file in Set up the AMI tools, the certificates are located at $EC2_AMITOOL_HOME/etc/ec2/amitools/.

Required: Only for the us-gov-west-1 and cn-north-1 Regions.
-r, --arch architecture

The image architecture. If you don't provide this on the command line, you'll be prompted to provide it when the bundling starts.

Valid values: i386 | x86_64

Required: No

--productcodes code1,code2,...

Product codes to attach to the image at registration time, separated by commas.

Required: No

-B, --block-device-mapping mapping

Defines how block devices are exposed to an instance of this AMI if its instance type supports the specified device.

Specify a comma-separated list of key-value pairs, where each key is a virtual name and each value is the corresponding device name. Virtual names include the following:

- ami—The root file system device, as seen by the instance
- root—The root file system device, as seen by the kernel
- swap—The swap device, as seen by the instance
- ephemeralN—The Nth instance store volume

Required: No

-a, --all

Bundle all directories, including those on remotely mounted file systems.

Required: No

-e, --exclude directory1,directory2,...

A list of absolute directory paths and files to exclude from the bundle operation. This parameter overrides the --all option. When exclude is specified, the directories and subdirectories listed with the parameter will not be bundled with the volume.

Required: No
-i, --include  file1,file2,...

A list of files to include in the bundle operation. The specified files would otherwise be excluded from the AMI because they might contain sensitive information.

Required: No

--no-filter

If specified, we won't exclude files from the AMI because they might contain sensitive information.

Required: No

-p, --prefix  prefix

The file name prefix for bundled AMI files.

Default: image

Required: No

-s, --size  size

The size, in MB (1024 * 1024 bytes), of the image file to create. The maximum size is 10240 MB.

Default: 10240

Required: No

--[no-]inherit

Indicates whether the image should inherit the instance's metadata (the default is to inherit). Bundling fails if you enable --inherit but the instance metadata is not accessible.

Required: No

-v, --volume  volume

The absolute path to the mounted volume from which to create the bundle.

Default: The root directory (/)

Required: No
-P, --partition type

Indicates whether the disk image should use a partition table. If you don't specify a partition table type, the default is the type used on the parent block device of the volume, if applicable, otherwise the default is gpt.

Valid values: mbr | gpt | none

Required: No

-S, --script script

A customization script to be run right before bundling. The script must expect a single argument, the mount point of the volume.

Required: No

--fstab path

The path to the fstab to bundle into the image. If this is not specified, Amazon EC2 bundles /etc/fstab.

Required: No

--generate-fstab

Bundles the volume using an Amazon EC2-provided fstab.

Required: No

--grub-config

The path to an alternate grub configuration file to bundle into the image. By default, ec2-bundle-vol expects either /boot/grub/menu.lst or /boot/grub/grub.conf to exist on the cloned image. This option allows you to specify a path to an alternative grub configuration file, which will then be copied over the defaults (if present).

Required: No

--kernel kernel_id

Deprecated. Use register-image to set the kernel.

Required: No
--ramdiskramdisk_id

Deprecated. Use register-image to set the RAM disk if required.

Required: No

Output

Status messages describing the stages and status of the bundling.

Example

This example creates a bundled AMI by compressing, encrypting and signing a snapshot of the local machine's root file system.

[ec2-user ~]$ ec2-bundle-vol -d /mnt -k pk-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -c cert-HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -u 111122223333 -r x86_64

ec2-delete-bundle

Description

Deletes the specified bundle from Amazon S3 storage. After you delete a bundle, you can't launch instances from the corresponding AMI.

Syntax

```
ec2-delete-bundle -b bucket -a access_key_id -s secret_access_key [-t
[--clear] [--retry] [-y]
```

Options

- **-b, --bucket bucket**
  
The name of the Amazon S3 bucket containing the bundled AMI, followed by an optional '/'-delimited path prefix
  
  Required: Yes
- **-a, --access-key access_key_id**
  
The AWS access key ID.
  
  Required: Yes
- **-s, --secret-key secret_access_key**
  
The AWS secret access key.
  
  Required: Yes
- **-t, --delegation-token token**
  
The delegation token to pass along to the AWS request. For more information, see the [Using Temporary Security Credentials](#)
  
  Required: Only when you are using temporary security credentials.
Default: The value of the AWS_DELEGATION_TOKEN environment variable (if set).

--region region

The Region to use in the request signature.

Default: us-east-1

Required: Required if using signature version 4

--sigversion

The signature version to use when signing the request.

Valid values: 2 | 4

Default: 4

Required: No

-m, --manifest path

The path to the manifest file.

Required: You must specify --prefix or --manifest.

-p, --prefix prefix

The bundled AMI filename prefix. Provide the entire prefix. For example, if the prefix is image.img, use -p image.img and not -p image.

Required: You must specify --prefix or --manifest.

--clear

Deletes the Amazon S3 bucket if it's empty after deleting the specified bundle.

Required: No

--retry

Automatically retries on all Amazon S3 errors, up to five times per operation.

Required: No

-y, --yes

Automatically assumes the answer to all prompts is yes.

Required: No
Output

Amazon EC2 displays status messages indicating the stages and status of the delete process.

Example

This example deletes a bundle from Amazon S3.

[ec2-user ~]$ ec2-delete-bundle -b DOC-EXAMPLE-BUCKET -a your_access_key_id -s your_secret_access_key
Deleting files:
DOC-EXAMPLE-BUCKET/image.manifest.xml

Deleted DOC-EXAMPLE-BUCKET/image.part.06
ec2-delete-bundle complete.

ec2-download-bundle

Description

Downloads the specified instance store-backed Linux AMIs from Amazon S3 storage.

Syntax

```
ec2-download-bundle -b bucket -a access_key_id -s secret_access_key -k path
```
Options

-b, --bucket bucket

The name of the Amazon S3 bucket where the bundle is located, followed by an optional '/'-delimited path prefix.

Required: Yes

-a, --access-key access_key_id

The AWS access key ID.

Required: Yes

-s, --secret-key secret_access_key

The AWS secret access key.

Required: Yes

-k, --privatekey path

The private key used to decrypt the manifest.

Required: Yes

--url url

The Amazon S3 service URL.

Default: https://s3.amazonaws.com/

Required: No

--region region

The Region to use in the request signature.

Default: us-east-1

Required: Required if using signature version 4

--sigv version

The signature version to use when signing the request.

Valid values: 2 | 4
Default: 4

Required: No

\texttt{-m, \texttt{--manifest\ file}}

The name of the manifest file (without the path). We recommend that you specify either the manifest (\texttt{-m}) or a prefix (\texttt{-p}).

Required: No

\texttt{-p, \texttt{--prefix\ prefix}}

The filename prefix for the bundled AMI files.

Default: \texttt{image}

Required: No

\texttt{-d, \texttt{--directory\ directory}}

The directory where the downloaded bundle is saved. The directory must exist.

Default: The current working directory.

Required: No

\texttt{--retry}

Automatically retries on all Amazon S3 errors, up to five times per operation.

Required: No

\section*{Output}

Status messages indicating the various stages of the download process are displayed.

\section*{Example}

This example creates the \texttt{bundled} directory (using the Linux \texttt{mkdir} command) and downloads the bundle from the DOC-EXAMPLE-BUCKET Amazon S3 bucket.

\begin{verbatim}
[ec2-user ~]$ mkdir bundled
[ec2-user ~]$ ec2-download-bundle -b DOC-EXAMPLE-BUCKET/bundles/bundle_name
  -m image.manifest.xml -a \texttt{your_access_key_id} -s \texttt{your_secret_access_key} -k pk-
  HKZYKTAIG2ECMXYIBH3HXV4ZBEXAMPLE.pem -d \texttt{mybundle}
\end{verbatim}
ec2-migrate-manifest

Description

Modifies an instance store-backed Linux AMI (for example, its certificate, kernel, and RAM disk) so that it supports a different Region.

Syntax

```
ec2-migrate-manifest -c path -k path -m path {(-a access_key_id -s secret_access_key --region region) | (--no-mapping)} [--ec2cert ec2_cert_path] [--kernel kernel-id] [--ramdisk ramdisk_id]
```

Options

- `-c, --cert path`

  The user's PEM encoded RSA public key certificate file.

  Required: Yes
-k, --privatekey path

The path to the user's PEM-encoded RSA key file.

Required: Yes

--manifest path

The path to the manifest file.

Required: Yes

-a, --access-key access_key_id

The AWS access key ID.

Required: Required if using automatic mapping.

-s, --secret-key secret_access_key

The AWS secret access key.

Required: Required if using automatic mapping.

--region region

The Region to look up in the mapping file.

Required: Required if using automatic mapping.

--no-mapping

Disables automatic mapping of kernels and RAM disks.

During migration, Amazon EC2 replaces the kernel and RAM disk in the manifest file with a kernel and RAM disk designed for the destination region. Unless the --no-mapping parameter is given, ec2-migrate-bundle might use the DescribeRegions and DescribeImages operations to perform automated mappings.

Required: Required if you're not providing the -a, -s, and --region options used for automatic mapping.

--ec2cert path

The path to the Amazon EC2 X.509 public key certificate used to encrypt the image manifest.
The us-gov-west-1 and cn-north-1 Regions use a non-default public key certificate and the path to that certificate must be specified with this option. The path to the certificate varies based on the installation method of the AMI tools. For Amazon Linux, the certificates are located at /opt/aws/amitools/ec2/etc/ec2/amitools/. If you installed the AMI tools from the ZIP file in Set up the AMI tools, the certificates are located at $EC2_AMITOOL_HOME/etc/ec2/amitools/.

Required: Only for the us-gov-west-1 and cn-north-1 Regions.

--kernel kernel_id

The ID of the kernel to select.

⚠️ Important

We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see User provided kernels in the Amazon Linux 2 User Guide.

Required: No

--ramdisk ramdisk_id

The ID of the RAM disk to select.

⚠️ Important

We recommend that you use PV-GRUB instead of kernels and RAM disks. For more information, see User provided kernels in the Amazon Linux 2 User Guide.

Required: No

Output

Status messages describing the stages and status of the bundling process.

Example

This example copies the AMI specified in the my-ami.manifest.xml manifest from the US to the EU.
ec2-unbundle

Description

Re-creates the bundle from an instance store-backed Linux AMI.

Syntax

ec2-unbundle -k path -m path [-s source_directory] [-d destination_directory]

Options

-k, --privatekey path

The path to your PEM-encoded RSA key file.

Required: Yes

-m, --manifest path

The path to the manifest file.

Required: Yes

-s, --source source_directory

The directory containing the bundle.

Default: The current directory.

Required: No

d, --destination destination_directory

The directory in which to unbundle the AMI. The destination directory must exist.

Default: The current directory.
Example

This Linux and UNIX example unbundles the AMI specified in the image.manifest.xml file.

```bash
[ec2-user ~]$ mkdir unbundled
$ ec2-unbundle -m mybundle/image.manifest.xml -k pk-HKZYKTAIG2ECMXYIB3HXXV4ZBEXAMPLE.pem -s mybundle -d unbundled
$ ls -l unbundled
total 1025008
-rw-r--r-- 1 root root 1048578048 Aug 25 23:46 image.img
```

Output

Status messages indicating the various stages of the unbundling process are displayed.

ec2-upload-bundle

Description

Uploads the bundle for an instance store-backed Linux AMI to Amazon S3 and sets the appropriate access control lists (ACLs) on the uploaded objects. For more information, see Create an instance store-backed Linux AMI.

Note

To upload objects to an S3 bucket for your instance store-backed Linux AMI, ACLs must be enabled for the bucket. Otherwise, Amazon EC2 will not be able to set ACLs on the objects to upload. If your destination bucket uses the bucket owner enforced setting for S3 Object Ownership, this won’t work because ACLs are disabled. For more information, see Controlling ownership of uploaded objects using S3 Object Ownership.

Syntax

```
```
Options

-b, --bucket *bucket*

The name of the Amazon S3 bucket in which to store the bundle, followed by an optional '/'-delimited path prefix. If the bucket doesn't exist, it's created if the bucket name is available. Additionally, if the bucket doesn't exist and the AMI tools version is 1.5.18 or later, this command sets the ACLs for the bucket.

Required: Yes

-a, --access-key *access_key_id*

Your AWS access key ID.

Required: Yes

-s, --secret-key *secret_access_key*

Your AWS secret access key.

Required: Yes

-t, --delegation-token *token*

The delegation token to pass along to the AWS request. For more information, see the Using Temporary Security Credentials.

Required: Only when you are using temporary security credentials.

Default: The value of the AWS_DELEGATION_TOKEN environment variable (if set).

-m, --manifest *path*

The path to the manifest file. The manifest file is created during the bundling process and can be found in the directory containing the bundle.

Required: Yes

--url *url*

Deprecated. Use the --region option instead unless your bucket is constrained to the EU location (and not eu-west-1). The --location flag is the only way to target that specific location restraint.
The Amazon S3 endpoint service URL.

Default: https://s3.amazonaws.com/

Required: No

--region region

The Region to use in the request signature for the destination S3 bucket.

- If the bucket doesn't exist and you don't specify a Region, the tool creates the bucket without a location constraint (in us-east-1).
- If the bucket doesn't exist and you specify a Region, the tool creates the bucket in the specified Region.
- If the bucket exists and you don't specify a Region, the tool uses the bucket's location.
- If the bucket exists and you specify us-east-1 as the Region, the tool uses the bucket's actual location without any error message, any existing matching files are over-written.
- If the bucket exists and you specify a Region (other than us-east-1) that doesn't match the bucket's actual location, the tool exits with an error.

If your bucket is constrained to the EU location (and not eu-west-1), use the --location flag instead. The --location flag is the only way to target that specific location restraint.

Default: us-east-1

Required: Required if using signature version 4

--sigv version

The signature version to use when signing the request.

Valid values: 2 | 4

Default: 4

Required: No

--acl acl

The access control list policy of the bundled image.

Valid values: public-read | aws-exec-read
Default: `aws-exec-read`

Required: No

```
-d, --directory directory
```

The directory containing the bundled AMI parts.

Default: The directory containing the manifest file (see the `-m` option).

Required: No

```
--part part
```

Starts uploading the specified part and all subsequent parts. For example, `--part 04`.

Required: No

```
--retry
```

Automatically retries on all Amazon S3 errors, up to five times per operation.

Required: No

```
--skipmanifest
```

Does not upload the manifest.

Required: No

```
--location location
```

Deprecated. Use the `--region` option instead, unless your bucket is constrained to the EU location (and not `eu-west-1`). The `--location` flag is the only way to target that specific location restraint.

The location constraint of the destination Amazon S3 bucket. If the bucket exists and you specify a location that doesn't match the bucket's actual location, the tool exits with an error. If the bucket exists and you don't specify a location, the tool uses the bucket's location. If the bucket doesn't exist and you specify a location, the tool creates the bucket in the specified location. If the bucket doesn't exist and you don't specify a location, the tool creates the bucket without a location constraint (in `us-east-1`).

Default: If `--region` is specified, the location is set to that specified Region. If `--region` is not specified, the location defaults to `us-east-1`.

Create an AMI
Output

Amazon EC2 displays status messages that indicate the stages and status of the upload process.

Example

This example uploads the bundle specified by the `image.manifest.xml` manifest.

```
[ec2-user ~]$ ec2-upload-bundle -b DOC-EXAMPLE-BUCKET/bundles/bundle_name -m image.manifest.xml -a your_access_key_id -s your_secret_access_key
Creating bucket...
Uploading bundled image parts to the S3 bucket DOC-EXAMPLE-BUCKET ...

Uploaded image.part.01
Uploaded image.part.02
Uploaded image.part.03
Uploaded image.part.04
Uploaded image.part.05
Uploaded image.part.06
Uploaded image.part.07
Uploaded image.part.08
Uploaded image.part.09
Uploaded image.part.10
Uploaded image.part.11
Uploaded image.part.12
Uploaded image.part.13
Uploaded image.part.14
Uploading manifest ...
Uploaded manifest.
Bundle upload completed.
```

Common options for AMI tools

Most of the AMI tools accept the following optional parameters.

```
--help, -h

 Displays the help message.

--version

 Displays the version and copyright notice.
```
Displays the manual entry.

--batch

Runs in batch mode, suppressing interactive prompts.

--debug

Displays information that can be useful when troubleshooting problems.

**Use EC2 launch agents to create an AMI with Windows Sysprep**

The Microsoft System Preparation (Windows Sysprep) tool creates a generalized version of the operating system, with instance-specific system configuration removed before it captures a new image. You can use Windows Sysprep to create a standardized Amazon Machine Image (AMI) when you start with an AMI that has one of the Windows launch agents installed.

We recommend that you use [EC2 Image Builder](https://docs.aws.amazon.com/AmazonEBS/latest/userguide/EC2-ImageBuilder.html) to automate the creation, management, and deployment of customized, secure, and up-to-date "golden" server images that are pre-installed and preconfigured with software and settings.

You can also create a standardized AMI with Windows Sysprep directly from the following Windows launch agents:

- **Use Windows Sysprep with EC2Launch v2** (recommended)
- **Use Windows Sysprep with EC2Launch** (Windows Server 2016 and 2019)
- **Use Windows Sysprep with EC2Config** (Windows Server 2012 R2 and earlier)

**Important**

Do not use Windows Sysprep to create an instance backup. Windows Sysprep removes system-specific information; removing this information might have unintended consequences for an instance backup.

To troubleshoot Windows Sysprep, see [Troubleshoot Sysprep issues with Amazon EC2 Windows instances](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/sysprep.html).
Contents

- Windows Sysprep phases
- Before you begin
- Use Windows Sysprep with EC2Launch v2
- Use Windows Sysprep with EC2Launch
- Use Windows Sysprep with EC2Config

Windows Sysprep phases

Windows Sysprep runs through the following phases:

- **Generalize**: The Sysprep tool removes image-specific information and configurations. For example, Windows Sysprep removes the security identifier (SID), the computer name, the event logs, and specific drivers, to name a few. After this phase is completed, the operating system (OS) is ready to create an AMI.

  **Note**

  When you run Windows Sysprep with the Windows launch agents, the system prevents drivers from being removed because `PersistAllDeviceInstalls` is set to true by default.

- **Specialize**: Plug and Play scans the computer and installs drivers for any detected devices. The Sysprep tool generates OS requirements, like the computer name and SID. Optionally, you can run commands in this phase.

- **Out-of-Box Experience (OOBE)**: The system runs an abbreviated version of Windows Setup and asks you to enter information such as system language, time zone, and registered organization. When you run Windows Sysprep with Windows launch agents, the answer file automates this phase.

Before you begin

- Before performing Windows Sysprep, we recommend that you remove all local user accounts and all account profiles other than a single administrator account under which Windows Sysprep will be run. If you perform Windows Sysprep with additional accounts and profiles, unexpected behavior could result, including loss of profile data or failure to complete Windows Sysprep.
Learn more about Windows Sysprep on Microsoft TechNet.

Learn which server roles are supported for Windows Sysprep.

Use Windows Sysprep with EC2Launch v2

This section contains details about the tasks performed by the EC2Launch v2 service as the image is prepared. It also includes the steps to create a standardized AMI using Windows Sysprep with the EC2Launch v2 service.

Windows Sysprep with EC2Launch v2 topics

- Windows Sysprep actions
- Post Sysprep
- Run Windows Sysprep with EC2Launch v2

Windows Sysprep actions

Windows Sysprep and EC2Launch v2 perform the following actions when preparing an image.

1. When you choose Shutdown with Sysprep in the EC2Launch settings dialog box, the system runs the ec2launch sysprep command.

2. EC2Launch v2 edits the content of the unattend.xml file by reading the registry value at HKEY_USERS\.DEFAULT\Control Panel\International\LocaleName. This file is located in the following directory: C:\ProgramData\Amazon\EC2Launch\sysprep.

3. The system run the BeforeSysprep.cmd. This command creates a registry key as follows:

   `reg add "HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Terminal Server" /v fDenyTSConnections /t REG_DWORD /d 1 /f`

   The registry key disables RDP connections until they are re-enabled. Disabling RDP connections is a necessary security measure because, during the first boot session after Windows Sysprep has run, there is a short period of time where RDP allows connections and the Administrator password is blank.

4. The EC2Launch v2 service calls Windows Sysprep by running the following command:

   `sysprep.exe /oobe /generalize /shutdown /unattend: "C:\ProgramData\Amazon\EC2Launch\sysprep\unattend.xml"`
Generalize phase

- EC2Launch v2 removes image-specific information and configurations, such as the computer name and the SID. If the instance is a member of a domain, it is removed from the domain. The unattend.xml answer file includes the following settings that affect this phase:
  - **PersistAllDeviceInstalls**: This setting prevents Windows Setup from removing and reconfiguring devices, which speeds up the image preparation process because Amazon AMIs require certain drivers to run and re-detection of those drivers would take time.
  - **DoNotCleanUpNonPresentDevices**: This setting retains Plug and Play information for devices that are not currently present.
  - Windows Sysprep shuts down the OS as it prepares to create the AMI. The system either launches a new instance or starts the original instance.

Specialize phase

The system generates OS-specific requirements, such as a computer name and an SID. The system also performs the following actions based on configurations that you specify in the unattend.xml answer file.

- **CopyProfile**: Windows Sysprep can be configured to delete all user profiles, including the built-in Administrator profile. This setting retains the built-in Administrator account so that any customizations you make to that account are carried over to the new image. The default value is True.
  
  **CopyProfile** replaces the default profile with the existing local administrator profile. All accounts that you log in to after running Windows Sysprep receive a copy of that profile and its contents at first login.

  If you don’t have specific user-profile customizations that you want to carry over to the new image, then change this setting to False. Windows Sysprep will remove all user profiles (this saves time and disk space).

  - **TimeZone**: The time zone is set to Coordinate Universal Time (UTC) by default.

  - **Synchronous command with order 1**: The system runs the following command, which enables the administrator account and specifies the password requirement:

    ```
    net user Administrator /ACTIVE:YES /LOGONPASSWORDCHG:NO /EXPIRES:NEVER /
    PASSWORDREQ:YES
    ```
• **Synchronous command with order 2**: The system scrambles the administrator password. This security measure is designed to prevent the instance from being accessible after Windows Sysprep completes if you did not configure the `setAdminAccount` task.

The system runs the following command from your local launch agent directory (`C:\Program Files\Amazon\EC2Launch\`).

```
EC2Launch.exe internal randomize-password --username Administrator
```

• To enable remote desktop connections, the system sets the Terminal Server `fDenyTSConnections` registry key to false.

**OOBE phase**

1. The system specifies the following configurations using the EC2Launch v2 answer file:

   - `<InputLocale>en-US</InputLocale>`
   - `<SystemLocale>en-US</SystemLocale>`
   - `<UILanguage>en-US</UILanguage>`
   - `<UserLocale>en-US</UserLocale>`

   - `<RegisteredOwner>EC2</RegisteredOwner>`

    **Note**

    During the generalize and specialize phases, EC2Launch v2 monitors the status of the OS. If EC2Launch v2 detects that the OS is in a Sysprep phase, then it publishes the following message to the system log:

    Windows is being configured. SysprepState=IMAGE_STATE_UNDEPLOYABLE

2. The system runs EC2Launch v2.
Post Sysprep

After Windows Sysprep completes, EC2Launch v2 sends the following message to the console output:

Windows sysprep configuration complete.

EC2Launch v2 then performs the following actions:

1. Reads the content of the agent-config.yml file and runs configured tasks.
2. Executes all tasks in the preReady stage.
3. After it is finished, sends a Windows is ready message to the instance system logs.
4. Executes all tasks in the PostReady stage.

For more information about EC2Launch v2, see Configure a Windows instance using EC2Launch v2.

Run Windows Sysprep with EC2Launch v2

Use the following procedure to create a standardized AMI using Windows Sysprep with EC2Launch v2.

1. In the Amazon EC2 console, locate an AMI that you want to duplicate.
2. Launch and connect to your Windows instance.
3. Customize it.
4. From the Windows Start menu, search for and choose Amazon EC2Launch settings. For more information about the options and settings in the Amazon EC2Launch settings dialog box, see EC2Launch v2 settings.
5. Select Shutdown with Sysprep or Shutdown without Sysprep.

When you are asked to confirm that you want to run Windows Sysprep and shut down the instance, click Yes. EC2Launch v2 runs Windows Sysprep. Next, you are logged off the instance, and the instance shuts down. If you check the Instances page in the Amazon EC2 console, the instance state changes from Running to Stopping to Stopped. At this point, it's safe to create an AMI from this instance.
You can manually invoke the Windows Sysprep tool from the command line using the following command:

```
"%programfiles%\amazon\ec2launch\ec2launch.exe" sysprep --shutdown=true
```

**Use Windows Sysprep with EC2Launch**

EC2Launch offers a default answer file and batch files for Windows Sysprep that automate and secure the image-preparation process on your AMI. Modifying these files is optional. These files are located in the following directory by default: `C:\ProgramData\Amazon\EC2-Windows\Launch\Sysprep`.

⚠️ **Important**

Do not use Windows Sysprep to create an instance backup. Windows Sysprep removes system-specific information. If you remove this information there might be unintended consequences for an instance backup.

**Windows Sysprep with EC2Launch topics**

- [EC2Launch answer and batch files for Windows Sysprep](#)
- [Run Windows Sysprep with EC2Launch](#)
- [Update metadata/KMS routes for Server 2016 and later when launching a custom AMI](#)

**EC2Launch answer and batch files for Windows Sysprep**

The EC2Launch answer file and batch files for Windows Sysprep include the following:

**Unattend.xml**

This is the default answer file. If you run `SysprepInstance.ps1` or choose `ShutdownWithSysprep` in the user interface, the system reads the setting from this file.

**BeforeSysprep.cmd**

Customize this batch file to run commands before EC2Launch runs Windows Sysprep.

**SysprepSpecialize.cmd**

Customize this batch file to run commands during the Windows Sysprep specialize phase.
Run Windows Sysprep with EC2Launch

On the full installation of Windows Server 2016 and later (with a desktop experience), you can run Windows Sysprep with EC2Launch manually or by using the EC2 Launch Settings application.

To run Windows Sysprep using the EC2Launch Settings application

1. In the Amazon EC2 console, locate or create a Windows Server 2016 or later AMI.
2. Launch a Windows instance from the AMI.
3. Connect to your Windows instance and customize it.
4. Search for and run the EC2LaunchSettings application. It is located in the following directory by default: C:\ProgramData\Amazon\EC2-Windows\Launch\Settings.
5. Select or clear options as needed. These settings are stored in the `LaunchConfig.json` file.

6. For **Administrator Password**, do one of the following:
Choose **Random**. EC2Launch generates a password and encrypts it using the user's key. The system disables this setting after the instance is launched so that this password persists if the instance is rebooted or stopped and started.

Choose **Specify** and type a password that meets the system requirements. The password is stored in `LaunchConfig.json` as clear text and is deleted after Windows Sysprep sets the administrator password. If you shut down now, the password is set immediately. EC2Launch encrypts the password using the user's key.

Choose **DoNothing** and specify a password in the `unattend.xml` file. If you don't specify a password in `unattend.xml`, the administrator account is disabled.

7. Choose **Shutdown with Sysprep**.

**To manually run Windows Sysprep using EC2Launch**

1. In the Amazon EC2 console locate or create a Windows Server 2016 or later Datacenter edition AMI that you want to duplicate.
2. Launch and connect to your Windows instance.
3. Customize the instance.
4. Specify settings in the `LaunchConfig.json` file. This file is located in the `C:\ProgramData\Amazon\EC2-Windows\Launch\Config` directory by default.

For `adminPasswordType`, specify one of the following values:

**Random**

EC2Launch generates a password and encrypts it using the user's key. The system disables this setting after the instance is launched so that this password persists if the instance is rebooted or stopped and started.

**Specify**

EC2Launch uses the password you specify in `adminPassword`. If the password does not meet the system requirements, EC2Launch generates a random password instead. The password is stored in `LaunchConfig.json` as clear text and is deleted after Windows Sysprep sets the administrator password. EC2Launch encrypts the password using the user's key.
EC2Launch uses the password you specify in the unattend.xml file. If you don’t specify a password in unattend.xml, the administrator account is disabled.

5. (Optional) Specify settings in unattend.xml and other configuration files. If plan to attend the installation, then you don’t need to make changes in these files. The files are located in the following directory by default: C:\ProgramData\Amazon\EC2-Windows\Launch\Sysprep.

6. In Windows PowerShell, run ./InitializeInstance.ps1 -Schedule. The script is located in the following directory, by default: C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts. This script schedules the instance to initialize during the next boot. You must run this script before you run the SysprepInstance.ps1 script in the next step.

7. In Windows PowerShell, run ./SysprepInstance.ps1. The script is located in the following directory by default: C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts.

You are logged off the instance and the instance shuts down. If you check the Instances page in the Amazon EC2 console, the instance state changes from Running to Stopping, and then to Stopped. At this point, it is safe to create an AMI from this instance.

**Update metadata/KMS routes for Server 2016 and later when launching a custom AMI**

To update metadata/KMS routes for Server 2016 and later when launching a custom AMI, do one of the following:

- Run the EC2LaunchSettings GUI (C:\ProgramData\Amazon\EC2-Windows\Launch\Settings\Ec2LaunchSettings.exe) and select the option to shut down with Windows Sysprep.
- Run EC2LaunchSettings and shut down without Windows Sysprep before creating the AMI. This sets the EC2 Launch Initialize tasks to run at the next boot, which will set routes based on the subnet for the instance.
- Manually reschedule EC2 Launch initialize tasks before creating an AMI from PowerShell.

⚠️ **Important**

Take note of the default password reset behavior before rescheduling tasks.

- To update the routes on a running instance that is experiencing Windows activation or communication with instance metadata failures, see [Unable to activate Windows](#).
Use Windows Sysprep with EC2Config

This section contains details about the tasks performed by the EC2Config service as the image is prepared. It also includes the steps to create a standardized AMI using Windows Sysprep with the EC2Config service.

Windows Sysprep with EC2Config topics

- Windows Sysprep actions
- Post Sysprep
- Run Windows Sysprep with the EC2Config service

Windows Sysprep actions

Windows Sysprep and the EC2Config service perform the following actions when preparing an image.

1. When you choose Shutdown with Sysprep in the EC2 Service Properties dialog box, the system runs the `ec2config.exe -sysprep` command.

2. The EC2Config service reads the content of the BundleConfig.xml file. This file is located in the following directory, by default: C:\Program Files\Amazon\Ec2ConfigService\Settings.

The BundleConfig.xml file includes the following settings. You can change these settings:

- **AutoSysprep**: Indicates whether to use Windows Sysprep automatically. You do not need to change this value if you are running Windows Sysprep from the EC2 Service Properties dialog box. The default value is No.

- **SetRDPCertificate**: Sets a self-signed certificate for the Remote Desktop server. This enables you to securely use the Remote Desktop Protocol (RDP) to connect to the instance. Change the value to Yes if new instances should use a certificate. This setting is not used with Windows Server 2012 instances because these operating systems can generate their own certificates. The default value is No.

- **SetPasswordAfterSysprep**: Sets a random password on a newly launched instance, encrypts it with the user launch key, and outputs the encrypted password to the console. Change the value to No if new instances should not be set to a random encrypted password. The default value is Yes.
• **PreSysprepRunCmd**: The location of the command to run. The command is located in the following directory, by default: `C:\Program Files\Amazon\Ec2ConfigService\Scripts\BeforeSysprep.cmd`

3. The system runs `BeforeSysprep.cmd`. This command creates a registry key as follows:

```bash
reg add "HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Terminal Server" /v fDenyTSConnections /t REG_DWORD /d 1 /f
```

The registry key disables RDP connections until they are re-enabled. Disabling RDP connections is a necessary security measure because, during the first boot session after Windows Sysprep has run, there is a short period of time where RDP allows connections and the Administrator password is blank.

4. The EC2Config service calls Windows Sysprep by running the following command:

```bash
sysprep.exe /unattend: "C:\Program Files\Amazon\Ec2ConfigService\sysprep2008.xml" /oobe /generalize /shutdown
```

**Generalize phase**

• The tool removes image-specific information and configurations such as the computer name and the SID. If the instance is a member of a domain, it is removed from the domain. The `sysprep2008.xml` answer file includes the following settings that affect this phase:

  • **PersistAllDeviceInstalls**: This setting prevents Windows Setup from removing and reconfiguring devices, which speeds up the image preparation process because Amazon AMIs require certain drivers to run and re-detection of those drivers would take time.

  • **DoNotCleanUpNonPresentDevices**: This setting retains Plug and Play information for devices that are not currently present.

• Windows Sysprep shuts down the OS as it prepares to create the AMI. The system either launches a new instance or starts the original instance.

**Specialize phase**

The system generates OS specific requirements such as a computer name and a SID. The system also performs the following actions based on configurations that you specify in the `sysprep2008.xml` answer file.
• **CopyProfile**: Windows Sysprep can be configured to delete all user profiles, including the built-in Administrator profile. This setting retains the built-in Administrator account so that any customizations you made to that account are carried over to the new image. The default value is True.

*CopyProfile* replaces the default profile with the existing local administrator profile. All accounts logged into after running Windows Sysprep will receive a copy of that profile and its contents at first login.

If you don't have specific user-profile customizations that you want to carry over to the new image then change this setting to False. Windows Sysprep will remove all user profiles; this saves time and disk space.

• **TimeZone**: The time zone is set to Coordinate Universal Time (UTC) by default.

• **Synchronous command with order 1**: The system runs the following command that enables the administrator account and specifies the password requirement.

```bash
net user Administrator /ACTIVE:YES /LOGONPASSWORDCHG:NO /EXPIRES:NEVER /PASSWORDREQ:YES
```

• **Synchronous command with order 2**: The system scrambles the administrator password. This security measure is designed to prevent the instance from being accessible after Windows Sysprep completes if you did not enable the ec2setpassword setting.

```bash
C:\Program Files\Amazon\Ec2ConfigService\ScramblePassword.exe" -u Administrator
```

• **Synchronous command with order 3**: The system runs the following command:

```bash
C:\Program Files\Amazon\Ec2ConfigService\Scripts\SysprepSpecializePhase.cmd
```

This command adds the following registry key, which re-enables RDP:

```bash
reg add "HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Terminal Server" /v fDenyTSConnections /t REG_DWORD /d 0 /f
```

**OOBE phase**

1. Using the EC2Config service answer file, the system specifies the following configurations:
   • `<InputLocale>en-US</InputLocale>`
   • `<SystemLocale>en-US</SystemLocale>`
2. After the OOBE phase completes, the system runs SetupComplete.cmd from the following location: `C:\Windows\Setup\Scripts\SetupComplete.cmd`. In Amazon public AMIs before April 2015 this file was empty and ran nothing on the image. In public AMIs dated after April 2015, the file includes the following value: `call "C:\Program Files\Amazon\Ec2ConfigService\Scripts\PostSysprep.cmd"`.

3. The system runs PostSysprep.cmd, which performs the following operations:
   - Sets the local Administrator password to not expire. If the password expired, Administrators might not be able to log on.
   - Sets the MSSQLServer machine name (if installed) so that the name will be in sync with the AMI.

**Post Sysprep**

After Windows Sysprep completes, the EC2Config services sends the following message to the console output:
EC2Config then performs the following actions:

1. Reads the content of the config.xml file and lists all enabled plug-ins.
2. Executes all “Before Windows is ready” plug-ins at the same time.
   - Ec2SetPassword
   - Ec2SetComputerName
   - Ec2InitializeDrives
   - Ec2EventLog
   - Ec2ConfigureRDP
   - Ec2OutputRDPCert
   - Ec2SetDriveLetter
   - Ec2WindowsActivate
   - Ec2DynamicBootVolumeSize
3. After it is finished, sends a “Windows is ready” message to the instance system logs.
4. Runs all “After Windows is ready” plug-ins at the same time.
   - Amazon CloudWatch Logs
   - UserData
   - AWS Systems Manager (Systems Manager)

For more information about Windows plug-ins, see Configure a Windows instance using the EC2Config service (legacy).

Run Windows Sysprep with the EC2Config service

Use the following procedure to create a standardized AMI using Windows Sysprep and the EC2Config service.

1. In the Amazon EC2 console, locate or create an AMI that you want to duplicate.
2. Launch and connect to your Windows instance.
3. Customize it.
4. Specify configuration settings in the EC2Config service answer file:

   C:\Program Files\Amazon\Ec2ConfigService\sysprep2008.xml

5. From the Windows Start menu, choose All Programs, and then choose EC2ConfigService Settings.

6. Choose the Image tab in the Ec2 Service Properties dialog box. For more information about the options and settings in the Ec2 Service Properties dialog box, see Ec2 Service Properties.

7. Select an option for the Administrator password, and then select Shutdown with Sysprep or Shutdown without Sysprep. EC2Config edits the settings files based on the password option that you selected.

   • Random: EC2Config generates a password, encrypts it with user's key, and displays the encrypted password to the console. We disable this setting after the first launch so that this password persists if the instance is rebooted or stopped and started.

   • Specify: The password is stored in the Windows Sysprep answer file in unencrypted form (clear text). When Windows Sysprep runs next, it sets the Administrator password. If you shut down now, the password is set immediately. When the service starts again, the Administrator password is removed. It's important to remember this password, as you can't retrieve it later.

   • Keep Existing: The existing password for the Administrator account doesn't change when Windows Sysprep is run or EC2Config is restarted. It's important to remember this password, as you can't retrieve it later.

8. Choose OK.

When you are asked to confirm that you want to run Windows Sysprep and shut down the instance, click Yes. You'll notice that EC2Config runs Windows Sysprep. Next, you are logged off the instance, and the instance is shut down. If you check the Instances page in the Amazon EC2 console, the instance state changes from Running to Stopping, and then finally to Stopped. At this point, it's safe to create an AMI from this instance.

You can manually invoke the Windows Sysprep tool from the command line using the following command:

```
"%programfiles%\amazon\ec2configservice\"ec2config.exe -sysprep"
```
Note

The double quotation marks in the command are not required if your CMD shell is already in the C:\Program Files\Amazon\EC2ConfigService\ directory.

However, you must be very careful that the XML file options specified in the Ec2ConfigService\Settings folder are correct; otherwise, you might not be able to connect to the instance. For more information about the settings files, see EC2Config settings files. For an example of configuring and then running Windows Sysprep from the command line, see Ec2ConfigService\Scripts\InstallUpdates.ps1.

Modify an AMI

You can modify a limited set of Amazon Machine Image (AMI) attributes, such as the AMI's description and sharing properties. However, AMI content (volume binary data) can't be modified. To modify the AMI content, you must create a new AMI.

Important

You can't modify the content (volume binary data) of an EBS-backed AMI because the snapshots that back them are immutable. You also can't modify the content (volume binary data) of an instance store-backed (S3-backed) Linux AMI because the content is signed, and instance launches will fail if the signatures do not match.

For the AMI attributes that can be modified, see ModifyImageAttribute in the Amazon EC2 API Reference.

The following topics provide instructions for using the Amazon EC2 console and AWS CLI to modify the attributes of an AMI:

- Make an AMI public
- Share an AMI with specific organizations or organizational units
- Share an AMI with specific AWS accounts
- Use paid support
- Configure the AMI
Copy an AMI

You can copy an Amazon Machine Image (AMI) within or across AWS Regions. You can copy both Amazon EBS-backed AMIs and instance store-backed AMIs. You can copy EBS-backed AMIs with encrypted snapshots, and also change encryption status during the copy process. You can copy AMIs that are shared with you.

Copying a source AMI results in an identical but distinct new AMI that we also refer to as the target AMI. The target AMI has its own unique AMI ID. You can change or deregister the source AMI with no effect on the target AMI. The reverse is also true.

With an EBS-backed AMI, each of its backing snapshots is copied to an identical but distinct target snapshot. If you copy an AMI to a new Region, the snapshots are complete (non-incremental) copies. If you encrypt unencrypted backing snapshots or encrypt them to a new KMS key, the snapshots are complete (non-incremental) copies. Subsequent copy operations of an AMI result in incremental copies of the backing snapshots.

Contents

• Considerations
• Costs
• IAM permissions
• Copy an AMI
• Stop a pending AMI copy operation
• Cross-Region copying
• Cross-account copying
• Encryption and copying

Considerations

• Permission to copy AMIs – You can use IAM policies to grant or deny users permission to copy AMIs. Resource-level permissions specified for the CopyImage action apply only to the new AMI. You cannot specify resource-level permissions for the source AMI.

• Launch permissions and Amazon S3 bucket permissions – AWS does not copy launch permissions or Amazon S3 bucket permissions from the source AMI to the new AMI. After the copy operation is complete, you can apply launch permissions and Amazon S3 bucket permissions to the new AMI.
• **Tags** – You can only copy user-defined AMI tags that you attached to the source AMI. System tags (prefixed with `aws:`) and user-defined tags that are attached by other AWS accounts will not be copied. When copying an AMI, you can attach new tags to the target AMI and its backing snapshots.

**Costs**

There are no charges for copying an AMI. However, standard storage and data transfer rates apply. If you copy an EBS-backed AMI, you will incur charges for the storage of any additional EBS snapshots.

**IAM permissions**

To copy an EBS-backed or instance store-backed AMI, you need the following IAM permissions:

- `ec2:CopyImage` – To copy the AMI. For EBS-backed AMIs, it also grants permission to copy the AMI's backing snapshots.
- `ec2:CreateTags` – To tag the target AMI. For EBS-backed AMIs, it also grants permission to tag the target AMI's backing snapshots.

If you're copying an instance stored-backed AMI, you need the following additional IAM permissions:

- `s3:CreateBucket` – To create the S3 bucket in the target Region for the new AMI
- `s3:GetBucketAcl` – To read the ACL permissions for the source bucket
- `s3:ListAllMyBuckets` – To find an existing S3 bucket for AMIs in the target Region
- `s3:GetObject` – To read the objects in the source bucket
- `s3:PutObject` – To write the objects in the target bucket
- `s3:PutObjectAcl` – To write the permissions for the new objects in the target bucket

**Example IAM policy for copying an EBS-backed AMI and tagging the target AMI and snapshots**

The following example policy grants you permission to copy any EBS-backed AMI and tag the target AMI and its backing snapshots.

```json
{
    "Version": "2012-10-17",
```
Example IAM policy for copying an EBS-backed AMI but denying tagging the new snapshots

The `ec2:CopySnapshot` permission is automatically granted when you get the `ec2:CopyImage` permission. This includes the permission to tag the new backing snapshots of the target AMI. Permission to tag the new backing snapshots can be explicitly denied.

The following example policy grants you permission to copy any EBS-backed AMI, but denies you from tagging the new backing snapshots of the target AMI.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CopyImage",
        "ec2:CreateTags"
      ],
      "Resource": "arn:aws:ec2::*:image/*"
    },
    {
      "Effect": "Deny",
      "Action": "ec2:CreateTags",
      "Resource": "arn:aws:ec2:::snapshot/*"
    }
  ]
}
```

Example IAM policy for copying an instance store-backed AMI and tagging the target AMI

The following example policy grants you permission to copy any instance store-backed AMI in the specified source bucket to the specified Region, and tag the target AMI.
To find the Amazon Resource Name (ARN) of the AMI source bucket, open the Amazon EC2 console at https://console.aws.amazon.com/ec2/, in the navigation pane choose AMIs, and locate the bucket name in the Source column.
The \texttt{s3:CreateBucket} permission is only needed the first time that you copy an instance store-backed AMI to an individual Region. After that, the Amazon S3 bucket that is already created in the Region is used to store all future AMIs that you copy to that Region.

## Copy an AMI

You can copy an AMI using the AWS Management Console, the AWS Command Line Interface or SDKs, or the Amazon EC2 API, all of which support the \texttt{CopyImage} action.

### Console

**To copy an AMI**

1. Open the Amazon EC2 console at \url{https://console.aws.amazon.com/ec2/}.
2. From the console navigation bar, select the Region that contains the AMI.
3. In the navigation pane, choose **AMIs** to display the list of AMIs available to you in the Region.
4. If you don't see the AMI you want to copy, choose a different filter. You can filter by AMIs \textit{Owned by me}, \textit{Private images}, \textit{Public images}, and \textit{Disabled images}.
5. Select the AMI to copy, and then choose **Actions, Copy AMI**.
6. On the **Copy AMI** page, specify the following information:
   
   a. **AMI copy name**: A name for the new AMI. You can include the operating system information in the name because Amazon EC2 does not provide this information when displaying details about the AMI.
   
   b. **AMI copy description**: By default, the description includes information about the source AMI so that you can distinguish a copy from its original. You can change this description as needed.
   
   c. **Destination Region**: The Region in which to copy the AMI. For more information, see \textit{Cross-Region copying}.
   
   d. **Copy tags**: Select this check box to include your user-defined AMI tags when copying the AMI. System tags (prefixed with \texttt{aws:}) and user-defined tags that are attached by other AWS accounts will not be copied.
e. (EBS-backed AMIs only) **Encrypt EBS snapshots of AMI copy**: Select this check box to encrypt the target snapshots, or to re-encrypt them using a different key. If encryption by default is enabled, the **Encrypt EBS snapshots of AMI copy** check box is selected and cannot be cleared. For more information, see Encryption and copying.

f. (EBS-backed AMIs only) **KMS key**: The KMS key to used to encrypt the target snapshots.

g. **Tags**: You can tag the new AMI and the new snapshots with the same tags, or you can tag them with different tags.

   - To tag the new AMI and the new snapshots with the *same* tags, choose **Tag image and snapshots together**. The same tags are applied to the new AMI and every snapshot that is created.

   - To tag the new AMI and the new snapshots with *different* tags, choose **Tag image and snapshots separately**. Different tags are applied to the new AMI and the snapshots that are created. Note, however, that all the new snapshots that are created get the same tags; you can't tag each new snapshot with a different tag.

To add a tag, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.

h. When you're ready to copy the AMI, choose **Copy AMI**.

   The initial status of the new AMI is Pending. The AMI copy operation is complete when the status is Available.

**AWS CLI**

**To copy an AMI using the AWS CLI**

You can copy an AMI using the `copy-image` command. You must specify both the source and destination Regions. You specify the source Region using the `--source-region` parameter. You can specify the destination Region using either the `--region` parameter or an environment variable. For more information, see Configuring the AWS Command Line Interface.

(EBS-backed AMIs only) When you encrypt a target snapshot during copying, you must specify these additional parameters: `--encrypted` and `--kms-key-id`. 
For example commands, see the Examples under copy-image in the AWS CLI Command Reference.

PowerShell

**To copy an AMI using the Tools for Windows PowerShell**

You can copy an AMI using the Copy-EC2Image command. You must specify both the source and destination Regions. You specify the source Region using the -SourceRegion parameter. You can specify the destination Region using either the -Region parameter or the Set-AWSDefaultRegion command. For more information, see Specifying AWS Regions.

(EBS-backed AMIs only) When you encrypt a target snapshot during copying, you must specify these additional parameters: -Encrypted and -KmsKeyId.

**Stop a pending AMI copy operation**

You can stop a pending AMI copy using the AWS Management Console or the command line.

**Console**

**To stop an AMI copy operation using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the destination Region from the Region selector.
3. In the navigation pane, choose AMIs.
4. Select the AMI to stop copying, and then choose Actions, Deregister AMI.
5. When asked for confirmation, choose Deregister AMI.

**Command line**

**To stop an AMI copy operation using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2.

- **deregister-image** (AWS CLI)
- **Unregister-EC2Image** (AWS Tools for Windows PowerShell)
Cross-Region copying

Copying an AMI across geographically diverse Regions provides the following benefits:

- Consistent global deployment: Copying an AMI from one Region to another enables you to launch consistent instances in different Regions based on the same AMI.
- Scalability: You can more easily design and build global applications that meet the needs of your users, regardless of their location.
- Performance: You can increase performance by distributing your application, as well as locating critical components of your application in closer proximity to your users. You can also take advantage of Region-specific features, such as instance types or other AWS services.
- High availability: You can design and deploy applications across AWS Regions, to increase availability.

The following diagram shows the relationship between a source AMI and two copied AMIs in different Regions, as well as the EC2 instances launched from each. When you launch an instance from an AMI, it resides in the same Region where the AMI resides. If you make changes to the source AMI and want those changes to be reflected in the AMIs in the target Regions, you must recopy the source AMI to the target Regions.

When you first copy an instance store-backed AMI to a Region, we create an Amazon S3 bucket for the AMIs copied to that Region. All instance store-backed AMIs that you copy to that Region are stored in this bucket. The bucket names have the following format: amis-for-<account-in-region-hash>. For example: amis-for-123456789012-in-us-east-2-yhjmxvp6.
Prerequisite

Prior to copying an AMI, you must ensure that the contents of the source AMI are updated to support running in a different Region. For example, you should update any database connection strings or similar application configuration data to point to the appropriate resources. Otherwise, instances launched from the new AMI in the destination Region might still use the resources from the source Region, which can impact performance and cost.

Limitations

- Destination Regions are limited to 100 concurrent AMI copies.
- You can't copy a paravirtual (PV) AMI to a Region that does not support PV AMIs. For more information, see AMI virtualization types.

Cross-account copying

If an AMI from another AWS account is shared with your AWS account, you can copy the shared AMI. This is known as cross-account copying. The AMI that is shared with you is the source AMI. When you copy the source AMI, you create a new AMI. The new AMI is often referred to as the target AMI.

AMI costs

- For a shared AMI, the account of the shared AMI is charged for the storage in the Region.
- If you copy an AMI that is shared with your account, you are the owner of the target AMI in your account.
  - The owner of the source AMI is charged standard Amazon EBS or Amazon S3 transfer fees.
  - You are charged for the storage of the target AMI in the destination Region.

Resource permissions

To copy an AMI that was shared with you from another account, the owner of the source AMI must grant you read permissions for the storage that backs the AMI. The storage is either the associated EBS snapshot (for an Amazon EBS-backed AMI) or an associated S3 bucket (for an instance store-backed AMI). If the shared AMI has encrypted snapshots, the owner must share the key or keys with you as well. For more information about granting resource permissions, for EBS snapshots, see Share an Amazon EBS snapshot in the Amazon EBS User Guide, and for S3 buckets, see Identity and access management in Amazon S3 in the Amazon Simple Storage Service User Guide.
Encryption and copying

The following table shows encryption support for various AMI-copying scenarios. While it is possible to copy an unencrypted snapshot to yield an encrypted snapshot, you cannot copy an encrypted snapshot to yield an unencrypted one.

<table>
<thead>
<tr>
<th>Scenario</th>
<th>Description</th>
<th>Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Unencrypted-to-unencrypted</td>
<td>Yes</td>
</tr>
<tr>
<td>2</td>
<td>Encrypted-to-encrypted</td>
<td>Yes</td>
</tr>
<tr>
<td>3</td>
<td>Unencrypted-to-encrypted</td>
<td>Yes</td>
</tr>
<tr>
<td>4</td>
<td>Encrypted-to-unencrypted</td>
<td>No</td>
</tr>
</tbody>
</table>

Encrypted during the CopyImage action applies only to Amazon EBS-backed AMIs. Because an instance store-backed AMI does not rely on snapshots, you cannot use copying to change its encryption status.

By default (i.e., without specifying encryption parameters), the backing snapshot of an AMI is copied with its original encryption status. Copying an AMI backed by an unencrypted snapshot results in an identical target snapshot that is also unencrypted. If the source AMI is backed by an encrypted snapshot, copying it results in an identical target snapshot that is encrypted by the same AWS KMS key. Copying an AMI backed by multiple snapshots preserves, by default, the source encryption status in each target snapshot.

If you specify encryption parameters while copying an AMI, you can encrypt or re-encrypt its backing snapshots. The following example shows a non-default case that supplies encryption parameters to the CopyImage action in order to change the target AMI's encryption state.
Copy an unencrypted source AMI to an encrypted target AMI

In this scenario, an AMI backed by an unencrypted root snapshot is copied to an AMI with an encrypted root snapshot. The CopyImage action is invoked with two encryption parameters, including a customer managed key. As a result, the encryption status of the root snapshot changes, so that the target AMI is backed by a root snapshot containing the same data as the source snapshot, but encrypted using the specified key. You incur storage costs for the snapshots in both AMIs, as well as charges for any instances you launch from either AMI.

Note

Enabling encryption by default has the same effect as setting the Encrypted parameter to true for all snapshots in the AMI.

Setting the Encrypted parameter encrypts the single snapshot for this instance. If you do not specify the KmsKeyId parameter, the default customer managed key is used to encrypt the snapshot copy.

For more information about copying AMIs with encrypted snapshots, see Use encryption with EBS-backed AMIs.

Store and restore an AMI using S3

You can store an Amazon Machine Image (AMI) in an Amazon S3 bucket, copy the AMI to another S3 bucket, and then restore it from the S3 bucket. By storing and restoring an AMI using S3
buckets, you can copy AMIs from one AWS partition to another, for example, from the main commercial partition to the AWS GovCloud (US) partition. You can also make archival copies of AMIs by storing them in an S3 bucket.

The supported APIs for storing and restoring an AMI using S3 are CreateStoreImageTask, DescribeStoreImageTasks, and CreateRestoreImageTask.

CopyImage is the recommended API to use for copying AMIs within an AWS partition. However, CopyImage can't copy an AMI to another partition.

For information about the AWS partitions, see partition on the Amazon Resource Names (ARNs) page in the IAM User Guide.

⚠️ Warning

Ensure that you comply with all applicable laws and business requirements when moving data between AWS partitions or AWS Regions, including, but not limited to, any applicable government regulations and data residency requirements.

Topics

- Use cases
- How the AMI store and restore APIs work
- Limitations
- Costs
- Securing your AMIs
- Permissions for storing and restoring AMIs using S3
- Work with the AMI store and restore APIs
- Use file paths in S3

Use cases

Use the store and restore APIs to do the following:

- Copy an AMI from one AWS partition to another AWS partition
- Make archival copies of AMIs
Copy an AMI from one AWS partition to another AWS partition

By storing and restoring an AMI using S3 buckets, you can copy an AMI from one AWS partition to another, or from one AWS Region to another. In the following example, you copy an AMI from the main commercial partition to the AWS GovCloud (US) partition, specifically from the us-east-2 Region to the us-gov-east-1 Region.

To copy an AMI from one partition to another, follow these steps:

- Store the AMI in an S3 bucket in the current Region by using CreateStoreImageTask. In this example, the S3 bucket is located in us-east-2. For an example command, see Store an AMI in an S3 bucket.
- Monitor the progress of the store task by using DescribeStoreImageTasks. The object becomes visible in the S3 bucket when the task is completed. For an example command, see Describe the progress of an AMI store task.
- Copy the stored AMI object to an S3 bucket in the target partition using a procedure of your choice. In this example, the S3 bucket is located in us-gov-east-1.

Note

Because you need different AWS credentials for each partition, you can't copy an S3 object directly from one partition to another. The process for copying an S3 object across partitions is outside the scope of this documentation. We provide the following copy processes as examples, but you must use the copy process that meets your security requirements.

- To copy one AMI across partitions, the copy process could be as straightforward as the following: Download the object from the source bucket to an intermediate host (for example, an EC2 instance or a laptop), and then upload the object from the intermediate host to the target bucket. For each stage of the process, use the AWS credentials for the partition.
- For more sustained usage, consider developing an application that manages the copies, potentially using S3 multipart downloads and uploads.

- Restore the AMI from the S3 bucket in the target partition by using CreateRestoreImageTask. In this example, the S3 bucket is located in us-gov-east-1. For an example command, see Restore an AMI from an S3 bucket.
Monitor the progress of the restore task by describing the AMI to check when its state becomes available. You can also monitor the progress percentages of the snapshots that make up the restored AMI by describing the snapshots.

**Make archival copies of AMIs**

You can make archival copies of AMIs by storing them in an S3 bucket. For an example command, see [Store an AMI in an S3 bucket](#).

The AMI is packed into a single object in S3, and all of the AMI metadata (excluding sharing information) is preserved as part of the stored AMI. The AMI data is compressed as part of the storage process. AMIs that contain data that can easily be compressed will result in smaller objects in S3. To reduce costs, you can use less expensive S3 storage tiers. For more information, see [Amazon S3 Storage Classes](#) and [Amazon S3 pricing](#).

**How the AMI store and restore APIs work**

To store and restore an AMI using S3, you use the following APIs:

- **CreateStoreImageTask** – Stores the AMI in an S3 bucket
- **DescribeStoreImageTasks** – Provides the progress of the AMI store task
- **CreateRestoreImageTask** – Restores the AMI from an S3 bucket

**How the APIs work**

- [CreateStoreImageTask](#)
- [DescribeStoreImageTasks](#)
- [CreateRestoreImageTask](#)

**CreateStoreImageTask**

The [CreateStoreImageTask](#) API stores an AMI as a single object in an S3 bucket.

The API creates a task that reads all of the data from the AMI and its snapshots, and then uses an [S3 multipart upload](#) to store the data in an S3 object. The API takes all of the components of the AMI, including most of the non-Region-specific AMI metadata, and all the EBS snapshots contained in the AMI, and packs them into a single object in S3. The data is compressed as part of the upload.
process to reduce the amount of space used in S3, so the object in S3 might be smaller than the sum of the sizes of the snapshots in the AMI.

If there are AMI and snapshot tags visible to the account calling this API, they are preserved.

The object in S3 has the same ID as the AMI, but with a .bin extension. The following data is also stored as S3 metadata tags on the S3 object: AMI name, AMI description, AMI registration date, AMI owner account, and a timestamp for the store operation.

The time it takes to complete the task depends on the size of the AMI. It also depends on how many other tasks are in progress because tasks are queued. You can track the progress of the task by calling the DescribeStoreImageTasks API.

The sum of the sizes of all the AMIs in progress is limited to 600 GB of EBS snapshot data per account. Further task creation will be rejected until the tasks in progress are less than the limit. For example, if an AMI with 100 GB of snapshot data and another AMI with 200 GB of snapshot data are currently being stored, another request will be accepted, because the total in progress is 300 GB, which is less than the limit. But if a single AMI with 800 GB of snapshot data is currently being stored, further tasks are rejected until the task is completed.

DescribeStoreImageTasks

The DescribeStoreImageTasks API describes the progress of the AMI store tasks. You can describe tasks for specified AMIs. If you don't specify AMIs, you get a paginated list of all of the store image tasks that have been processed in the last 31 days.

For each AMI task, the response indicates if the task is InProgress, Completed, or Failed. For tasks InProgress, the response shows an estimated progress as a percentage.

Tasks are listed in reverse chronological order.

Currently, only tasks from the previous month can be viewed.

CreateRestoreImageTask

The CreateRestoreImageTask API starts a task that restores an AMI from an S3 object that was previously created by using a CreateStoreImageTask request.

The restore task can be performed in the same or a different Region in which the store task was performed.
The S3 bucket from which the AMI object will be restored must be in the same Region in which the restore task is requested. The AMI will be restored in this Region.

The AMI is restored with its metadata, such as the name, description, and block device mappings corresponding to the values of the stored AMI. The name must be unique for AMIs in the Region for this account. If you do not provide a name, the new AMI gets the same name as the original AMI. The AMI gets a new AMI ID that is generated at the time of the restore process.

The time it takes to complete the AMI restoration task depends on the size of the AMI. It also depends on how many other tasks are in progress because tasks are queued. You can view the progress of the task by describing the AMI ([describe-images](#)) or its EBS snapshots ([describe-snapshots](#)). If the task fails, the AMI and snapshots are moved to a failed state.

The sum of the sizes of all of the AMIs in progress is limited to 300 GB (based on the size after restoration) of EBS snapshot data per account. Further task creation will be rejected until the tasks in progress are less than the limit.

**Limitations**

- To store an AMI, your AWS account must either own the AMI and its snapshots, or the AMI and its snapshots must be shared directly with your account. You can't store an AMI if it is only publicly shared.
- Only EBS-backed AMIs can be stored using these APIs.
- Paravirtual (PV) AMIs are not supported.
- The size of an AMI (before compression) that can be stored is limited to 5,000 GB.
- Quota on [store image](#) requests: 600 GB of storage work (snapshot data) in progress.
- Quota on [restore image](#) requests: 300 GB of restore work (snapshot data) in progress.
- For the duration of the store task, the snapshots must not be deleted and the IAM principal doing the store must have access to the snapshots, otherwise the store process will fail.
- You can’t create multiple copies of an AMI in the same S3 bucket.
- An AMI that is stored in an S3 bucket can't be restored with its original AMI ID. You can mitigate this by using [AMI aliasing](#).
- Currently the store and restore APIs are only supported by using the AWS Command Line Interface, AWS SDKs, and Amazon EC2 API. You can’t store and restore an AMI using the Amazon EC2 console.
Costs

When you store and restore AMIs using S3, you are charged for the services that are used by the store and restore APIs, and for data transfer. The APIs use S3 and the EBS Direct API (used internally by these APIs to access the snapshot data). For more information, see Amazon S3 pricing and Amazon EBS pricing.

Securing your AMIs

To use the store and restore APIs, the S3 bucket and the AMI must be in the same Region. It is important to ensure that the S3 bucket is configured with sufficient security to secure the content of the AMI and that the security is maintained for as long as the AMI objects remain in the bucket. If this can’t be done, use of these APIs is not recommended. Ensure that public access to the S3 bucket is not allowed. We recommend enabling Server Side Encryption for the S3 buckets in which you store the AMIs, although it’s not required.

For information about how to set the appropriate security settings for your S3 buckets, review the following security topics:

- Blocking public access to your Amazon S3 storage
- Setting default server-side encryption behavior for Amazon S3 buckets
- What S3 bucket policy can I use to comply with the AWS Config rule s3-bucket-ssl-requests-only?
- Enabling Amazon S3 server access logging

When the AMI snapshots are copied to the S3 object, the data is then copied over TLS connections. You can store AMIs with encrypted snapshots, but the snapshots are decrypted as part of the store process.

Permissions for storing and restoring AMIs using S3

If your IAM principals will store or restore AMIs using Amazon S3, you need to grant them the required permissions.

The following example policy includes all of the actions that are required to allow an IAM principal to carry out the store and restore tasks.

You can also create IAM policies that grant principals access to specific resources only. For more example policies, see Access management for AWS resources in the IAM User Guide.
Note

If the snapshots that make up the AMI are encrypted, or if your account is enabled for encryption by default, your IAM principal must have permission to use the KMS key.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "s3:DeleteObject",
            "s3:GetObject",
            "s3:ListBucket",
            "s3:PutObject",
            "s3:PutObjectTagging",

            "ec2:DescribeTags",
            "ec2:CreateTags"
         ],
         "Resource": "*"
      }
   ]
}
```

Work with the AMI store and restore APIs

Topics

- [Store an AMI in an S3 bucket](#)
- [Describe the progress of an AMI store task](#)
Store an AMI in an S3 bucket

To store an AMI (AWS CLI)

Use the `create-store-image-task` command. Specify the ID of the AMI and the name of the S3 bucket in which to store the AMI.

```
aws ec2 create-store-image-task \
  --image-id ami-1234567890abcdef0 \
  --bucket DOC-EXAMPLE-BUCKET
```

Expected output

```
{
  "ObjectKey": "ami-1234567890abcdef0.bin"
}
```

Describe the progress of an AMI store task

To describe the progress of an AMI store task (AWS CLI)

Use the `describe-store-image-tasks` command.

```
aws ec2 describe-store-image-tasks
```

Expected output

```
{
  "StoreImageTaskResults": [ 
    {
      "AmiId": "ami-1234567890abcdef0",
      "Bucket": "DOC-EXAMPLE-BUCKET",
      "ProgressPercentage": 17,
      "S3objectKey": "ami-1234567890abcdef0.bin",
      "StoreTaskState": "InProgress",
      "StoreTaskFailureReason": null,
      "TaskStartTime": "2022-01-01T01:01:01.001Z"
    }
  ]
}
```
Restore an AMI from an S3 bucket

To restore an AMI (AWS CLI)

Use the `create-restore-image-task` command. Using the values for `S3ObjectKey` and `Bucket` from the `describe-store-image-tasks` output, specify the object key of the AMI and the name of the S3 bucket to which the AMI was copied. Also, specify a name for the restored AMI. The name must be unique for AMIs in the Region for this account.

```
aws ec2 create-restore-image-task
   --object-key ami-1234567890abcdef0.bin
   --bucket DOC-EXAMPLE-BUCKET
   --name "New AMI Name"
```

Expected output

```json
{
   "ImageId": "ami-0eab20fe36f83e1a8"
}
```

Use file paths in S3

You can use file paths when storing and restoring AMIs, in the following way:

- When storing an AMI in S3, the file path can be added to the bucket name. Internally, the system separates the path from the bucket name, and then adds the path to the object key that is generated to store the AMI. The full object path is shown in the response from the API call.
- When restoring the AMI, because an object key parameter is available, the path can be added to the beginning of the object key value.

You can use file paths when using the AWS CLI and SDKs.
Example: Use a file path when storing and restoring an AMI (AWS CLI)

The following example first stores an AMI in S3, with the file path appended to the bucket name. The example then restores the AMI from S3, with the file path prepended to the object key parameter.

1. Store the AMI. For `--bucket`, specify the file path after the bucket name, as follows:

```
aws ec2 create-store-image-task \
  --image-id ami-1234567890abcdef0 \
  --bucket DOC-EXAMPLE-BUCKET/path1/path2
```

Expected output

```
{
  "ObjectKey": "path1/path2/ami-1234567890abcdef0.bin"
}
```

2. Restore the AMI. For `--object-key`, specify the value from the output in the previous step, which includes the file path.

```
aws ec2 create-restore-image-task \
  --object-key path1/path2/ami-1234567890abcdef0.bin \
  --bucket DOC-EXAMPLE-BUCKET \
  --name "New AMI Name"
```

Deprecate an AMI

You can deprecate an AMI to indicate that it is out of date and should not be used. You can also specify a future deprecation date for an AMI, indicating when the AMI will be out of date. For example, you might deprecate an AMI that is no longer actively maintained, or you might deprecate an AMI that has been superseded by a newer version. By default, deprecated AMIs do not appear in AMI listings, preventing new users from using out-of-date AMIs. However, existing users and launch services, such as launch templates and Auto Scaling groups, can continue to use a deprecated AMI by specifying its ID. To delete the AMI so that users and services cannot use it, you must deregister it.

After an AMI is deprecated:
For AMI users, the deprecated AMI does not appear in DescribeImages API calls unless you specify its ID or specify that deprecated AMIs must appear. AMI owners continue to see deprecated AMIs in DescribeImages API calls.

For AMI users, the deprecated AMI is not available to select via the EC2 console. For example, a deprecated AMI does not appear in the AMI catalog in the launch instance wizard. AMI owners continue to see deprecated AMIs in the EC2 console.

For AMI users, if you know the ID of a deprecated AMI, you can continue to launch instances using the deprecated AMI by using the API, CLI, or the SDKs.

Launch services, such as launch templates and Auto Scaling groups, can continue to reference deprecated AMIs.

EC2 instances that were launched using an AMI that is subsequently deprecated are not affected, and can be stopped, started, and rebooted.

You can deprecate both private and public AMIs.

You can also create Amazon Data Lifecycle Manager EBS-backed AMI policies to automate the deprecation of EBS-backed AMIs. For more information, see Automate AMI lifecycles.

**Note**

By default, the deprecation date of all public AMIs is set to two years from the AMI creation date. You can set the deprecation date to earlier than two years. To cancel the deprecation date, or to move the deprecation to a later date, you must make the AMI private by only sharing it with specific AWS accounts.

**Topics**

- Costs
- Limitations
- Deprecate an AMI
- Describe deprecated AMIs
- Cancel the deprecation of an AMI
Costs

When you deprecate an AMI, the AMI is not deleted. The AMI owner continues to pay for the AMI's snapshots. To stop paying for the snapshots, the AMI owner must delete the AMI by deregistering it.

Limitations

- To deprecate an AMI, you must be the owner of the AMI.

Deprecate an AMI

You can deprecate an AMI on a specific date and time. You must be the AMI owner to perform this procedure.

Console

To deprecate an AMI on a specific date

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigator, choose AMIs.
3. From the filter bar, choose Owned by me.
4. Select the AMI, and then choose Actions, Manage AMI Deprecation. You can select multiple AMIs to set the same deprecation date of several AMIs at once.
5. Select the Enable check box, and then enter the deprecation date and time.

   The upper limit for the deprecation date is 10 years from now, except for public AMIs, where the upper limit is 2 years from the creation date. You can't specify a date in the past.
6. Choose Save.

AWS CLI

To deprecate an AMI on a specific date

Use the enable-image-deprecation command. Specify the ID of the AMI and the date and time on which to deprecate the AMI. If you specify a value for seconds, Amazon EC2 rounds the seconds to the nearest minute.
The upper limit for deprecate-at is 10 years from now, except for public AMIs, where the upper limit is 2 years from the creation date. You can't specify a date in the past.

```bash
aws ec2 enable-image-deprecation \
  --image-id ami-1234567890abcdef0 \
  --deprecate-at "2021-10-15T13:17:12.000Z"
```

Expected output

```json
{
  "Return": "true"
}
```

**Check when an AMI was last used**

LastLaunchedTime is a timestamp that indicates when your AMI was last used to launch an instance. AMIs that have not been used recently to launch an instance might be good candidates for deprecation or deregistering.

**Note**

- When an AMI is used to launch an instance, there is a 24-hour delay before that usage is reported.
- lastLaunchedTime data is available starting April 2017.

**Console**

**To view the last launched time of an AMI**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the left navigator, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.
4. Select the AMI, and then check the **Last launched time** field (if you selected the check box next to the AMI, it's located on the **Details** tab). The field shows the date and time when the AMI was last used to launch an instance.
**AWS CLI**

**To view the last launched time of an AMI**

Run the `describe-image-attribute` command and specify `--attribute lastLaunchedTime`. You must be the AMI owner to run this command.

```
aws ec2 describe-image-attribute \
  --image-id ami-1234567890example \
  --attribute lastLaunchedTime
```

**Example output**

```json
{
   "LastLaunchedTime": {
      "Value": "2022-02-10T02:03:18Z"
   },
   "ImageId": "ami-1234567890example"
}
```

**Describe deprecated AMIs**

You can view the deprecation date and time of an AMI, and filter all the AMIs by deprecation date. You can also use the AWS CLI to describe all the AMIs that have been deprecated, where the deprecation date is in the past.

**Console**

**To view the deprecation date of an AMI**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the left navigator, choose AMIs, and then select the AMI.
3. Check the **Deprecation time** field (if you selected the check box next to the AMI, it's located on the **Details** tab). The field shows the deprecation date and time of the AMI. If the field is empty, the AMI is not deprecated.

**To filter AMIs by deprecation date**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the left navigator, choose **AMIs**.

3. From the filter bar, choose **Owned by me** or **Private images** (private images include AMIs that are shared with you as well as owned by you).

4. In the Search bar, enter **Deprecation time** (as you enter the letters, the **Deprecation time** filter appears), and then choose an operator and a date and time.

**AWS CLI**

When you describe all AMIs using the **describe-images** command, the results are different depending on whether you are an AMI user or the AMI owner.

- **If you are an AMI user:**
  
  By default, when you describe all AMIs using the **describe-images** command, deprecated AMIs that are not owned by you, but which are shared with you, do not appear in the results. This is because the default is **--no-include-deprecated**. To include deprecated AMIs in the results, you must specify the **--include-deprecated** parameter.

- **If you are the AMI owner:**

  When you describe all AMIs using the **describe-images** command, all the AMIs that you own, including deprecated AMIs, appear in the results. You do not need to specify the **--include-deprecated** parameter. Furthermore, you cannot exclude deprecated AMIs that you own from the results by using **--no-include-deprecated**.

If an AMI is deprecated, the **DeprecationTime** field appears in the results.

**Note**

A deprecated AMI is an AMI whose deprecation date is in the past. If you have set the deprecation date to a date in the future, the AMI is not yet deprecated.

**To include all deprecated AMIs when describing all AMIs**

Use the **describe-images** command and specify the **--include-deprecated** parameter to include all deprecated AMIs that are not owned by you in the results.

```bash
aws ec2 describe-images
```
To describe the deprecation date of an AMI

Use the `describe-images` command and specify the ID of the AMI.

Note that if you specify `--no-include-deprecated` together with the AMI ID, the deprecated AMI will be returned in the results.

```bash
aws ec2 describe-images \
  --region us-east-1 \
  --image-ids ami-1234567890EXAMPLE
```

Expected output

The `DeprecationTime` field displays the date on which the AMI is set to be deprecated. If the AMI is not set to be deprecated, the `DeprecationTime` field does not appear in the output.

```json
{
  "Images": [
    {
      "VirtualizationType": "hvm",
      "Description": "Provided by Red Hat, Inc.",
      "PlatformDetails": "Red Hat Enterprise Linux",
      "EnaSupport": true,
      "Hypervisor": "xen",
      "State": "available",
      "SriovNetSupport": "simple",
      "ImageId": "ami-1234567890EXAMPLE",
      "DeprecationTime": "2021-05-10T13:17:12.000Z"
    }
  ],
  "UsageOperation": "RunInstances:0010",
  "BlockDeviceMappings": [
    {
      "DeviceName": "/dev/sda1",
      "Ebs": {
        "SnapshotId": "snap-111222333444aaabb",
        "DeleteOnTermination": true,
        "VolumeType": "gp2",
        "VolumeSize": 10,
        "Encrypted": false
      }
    }
  ]
}
```
Cancel the deprecation of an AMI

You can cancel the deprecation of an AMI, which removes the date and time from the Deprecation time field (console) or the DeprecationTime field from the describe-images output (AWS CLI). You must be the AMI owner to perform this procedure.

Console

To cancel the deprecation of an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigator, choose AMIs.
3. From the filter bar, choose Owned by me.
4. Select the AMI, and then choose Actions, Manage AMI Deprecation. You can select multiple AMIs to cancel the deprecation of several AMIs at once.
5. Clear the Enable check box, and then choose Save.

AWS CLI

To cancel the deprecation of an AMI

Use the disable-image-deprecation command and specify the ID of the AMI.

aws ec2 disable-image-deprecation
Expected output

```json
{
  "Return": "true"
}
```

## Disable an AMI

You can disable an AMI to prevent it from being used for instance launches. You can’t launch new instances from a disabled AMI. You can re-enable a disabled AMI so that it can be used again for instance launches.

⚠️ **Warning**

Disabling an AMI removes all its launch permissions.

When an AMI is disabled:

- The AMI's state changes to disabled.
- A disabled AMI can't be shared. If an AMI was public or previously shared, it is made private. If an AMI was shared with an AWS account, organization, or Organizational Unit, they lose access to the disabled AMI.
- A disabled AMI does not appear in `DescribeImages` API calls by default.
- A disabled AMI does not appear under the **Owned by me** console filter. To find disabled AMIs, use the **Disabled images** console filter.
- A disabled AMI is not available to select for instance launches in the EC2 console. For example, a disabled AMI does not appear in the AMI catalog in the launch instance wizard or when creating a launch template.
- Launch services, such as launch templates and Auto Scaling groups, can continue to reference disabled AMIs. Subsequent instance launches from a disabled AMI will fail, so we recommend updating launch templates and Auto Scaling groups to reference available AMIs only.
- EC2 instances that were previously launched using an AMI that is subsequently disabled are not affected, and can be stopped, started, and rebooted.
• You can't delete snapshots associated with disabled AMIs. Attempting to delete an associated snapshot results in the snapshot is currently in use error.

When an AMI is re-enabled:

• The AMI's state changes to available, and it can be used to launch instances.
• The AMI can be shared.
• AWS accounts, organizations, and Organizational Units that lost access to the AMI when it was disabled do not regain access automatically, but the AMI can be shared with them again.

You can disable both private and public AMIs.

**Topics**

• **Costs**
• **Prerequisites**
• **Required IAM permissions**
• **Disable an AMI**
• **Describe disabled AMIs**
• **Re-enable a disabled AMI**

**Costs**

When you disable an AMI, the AMI is not deleted. If the AMI is an EBS-backed AMI, you continue to pay for the AMI's EBS snapshots. If you want to keep the AMI, you might be able to reduce your storage costs by archiving the snapshots. For more information, see [Archive Amazon EBS snapshots](https://docs.aws.amazon.com/AmazonEBS/latest/UserGuide/) in the *Amazon EBS User Guide*. If you don't want to keep the AMI and its snapshots, you must deregister the AMI and delete the snapshots. For more information, see [Delete resources associated with your Amazon EBS-backed AMI](https://docs.aws.amazon.com/AmazonEBS/latest/UserGuide/).  

**Prerequisites**

To disable or re-enable an AMI, you must be the owner of the AMI.

**Required IAM permissions**

To disable and re-enable an AMI, you must have the following IAM permissions:
**Disable an AMI**

You can disable an AMI by using the EC2 console or the AWS Command Line Interface (AWS CLI). You must be the AMI owner to perform this procedure.

### Console

**To disable an AMI**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the left navigation pane, choose **AMIs**.
3. From the filter bar, choose **Owned by me**.
4. Select the AMI, and then choose **Actions, Disable AMI**. You can select multiple AMIs to disable at once.
5. In the **Disable AMI** window, choose **Disable AMI**.

### AWS CLI

**To disable an AMI**

Use the `disable-image` command and specify the ID of the AMI.

```
aws ec2 disable-image --image-id ami-1234567890abcdef0
```

**Expected output**

```
{
    "Return": "true"
}
```

### Describe disabled AMIs

You can view disabled AMIs in the EC2 console and by using the AWS CLI.
You must be the AMI owner to view disabled AMIs. Because disabled AMIs are made private, you can't view disabled AMIs if you're not the owner.

**Console**

**To view disabled AMIs**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose AMIs.
3. From the filter bar, choose Disabled images.

![Amazon Machine Images (AMIs) Info](image)

**AWS CLI**

By default, when you use the `describe-images` command to describe all AMIs, disabled AMIs do not appear in the results. This is because the default is `--no-include-disabled`. To include disabled AMIs in the results, you must specify the `--include-disabled` parameter.

**To include all disabled AMIs when describing all AMIs**

Use the `describe-images` command and specify the `--include-disabled` parameter to retrieve disabled AMIs in addition to all other AMIs. Optionally, specify `--owners self` to retrieve only the AMIs that you own.

```
aws ec2 describe-images \
  --region us-east-1 \
  --owners self \
  --include-disabled
```

If you specify the ID of a disabled AMI, but do not specify `--include-disabled`, the disabled AMI is returned in the results.
To retrieve only disabled AMIs

Specify `--filters Name=state,Values=disabled`. You must also specify `--include-disabled`, otherwise you'll get an error.

```
aws ec2 describe-images
  --include-disabled
  --filters Name=state,Values=disabled
```

Example output

The State field displays the state of an AMI. `disabled` indicates that the AMI is disabled.

```json
{
  "Images": [
    {
      "VirtualizationType": "hvm",
      "Description": "Provided by Red Hat, Inc.",
      "PlatformDetails": "Red Hat Enterprise Linux",
      "EnaSupport": true,
      "Hypervisor": "xen",
      "State": "disabled",
      "SriovNetSupport": "simple",
      "ImageId": "ami-1234567890EXAMPLE",
      "DeprecationTime": "2023-05-10T13:17:12.000Z"
    }
  ]
}
```
Re-enable a disabled AMI

You can re-enable a disabled AMI. You must be the AMI owner to perform this procedure.

Console

To re-enable a disabled AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose AMIs.
3. From the filter bar, choose Disabled images.
4. Select the AMI, and then choose Actions, Enable AMI. You can select multiple AMIs to re-enable several AMIs at once.
5. In the Enable AMI window, choose Enable.

AWS CLI

To re-enable a disabled AMI

Use the enable-image command and specify the ID of the AMI.

```bash
aws ec2 enable-image --image-id ami-1234567890abcdef0
```

Expected output
Archive AMI snapshots

You can archive the snapshots that are associated with your disabled EBS-backed AMIs. This can help you to reduce the storage costs associated with your rarely-used AMIs that need to be retained for long periods. For more information, see Archive Amazon EBS snapshots in the Amazon EBS User Guide.

To archive snapshots associated with an AMI

1. Disable the AMI.
2. Archive the snapshots.

You can't use an AMI while it is disabled and its associated snapshots are archived.

To restore a disabled AMI with archived snapshots for use

1. Restore the archived snapshots associated with the AMI.
2. Enable the AMI.

Deregister (delete) an AMI

When you deregister an AMI, Amazon EC2 permanently deletes it. Once deregistered, you can't use the AMI to launch new instances. You might consider deregistering an AMI when you have finished using it.

To protect against accidental or malicious deregistering of an AMI, you can turn on deregistration protection. If you accidentally deregister an EBS-backed AMI, you can use the Recycle Bin to restore it only if you restore it within the allowed time period before it is permanently deleted.

Deregistering an AMI has no effect on any instances that were launched from the AMI. You can continue to use these instances. Deregistering an AMI also has no effect on any snapshots that were created during the AMI creation process. You'll continue to incur usage costs for these instances and storage costs for the snapshots. Therefore, to avoid incurring unnecessary costs, we
recommend that you terminate any instances and delete any snapshots that you do not need. For more information, see Avoid costs from unused resources.

Contents

• Considerations
• Deregister an AMI
• Check when an AMI was last used
• Protect an AMI from deregistration
• Avoid costs from unused resources

Considerations

• You can't deregister an AMI that is not owned by your account.
• You can't use Amazon EC2 to deregister an AMI that is managed by the AWS Backup service. Instead, use AWS Backup to delete the corresponding recovery points in the backup vault. For more information, see Deleting backups in the AWS Backup Developer Guide.

Deregister an AMI

Use any of the following methods to deregister an EBS-backed AMI or instance store-backed AMI.

Tip
To avoid incurring unnecessary costs, you should delete any resources that you do not need. For example, for EBS-backed AMIs, if you do not need the snapshots associated with the deregistered AMI, you should delete them. For more information, see Avoid costs from unused resources.

Console

To deregister an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose AMIs.
3. From the filter bar, choose **Owned by me** to list your available AMIs, or choose **Disabled images** to list your disabled AMIs.

4. Select the AMI to deregister.

5. Choose **Actions, Deregister AMI**.

6. When you are prompted for confirmation, choose **Deregister AMI**.

   It might take a few minutes before the console removes the AMI from the list. Choose **Refresh** to refresh the status.

**AWS CLI**

**To deregister an AMI**

Use the `deregister-image` command and specify the ID of the AMI to deregister.

```
aws ec2 deregister-image --image-id ami-0123456789example
```

**Powershell**

**To deregister an AMI**

Use the `Unregister-EC2Image` cmdlet and specify the ID of the AMI to deregister.

```
Unregister-EC2Image -ImageId ami-0123456789example
```

**Check when an AMI was last used**

`LastLaunchedTime` is a timestamp that indicates when your AMI was last used to launch an instance. AMIs that have not been used recently to launch an instance might be good candidates for deregistering or **deprecation**.

**Note**

- When the AMI is used to launch an instance, there is a 24-hour delay before that usage is reported.
- `lastLaunchedTime` data is available starting April 2017.
To view the last launched time of an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose AMIs.
3. From the filter bar, choose Owned by me.
4. Select the AMI, and then check the Last launched time field (if you selected the check box next to the AMI, it's located on the Details tab). The field shows the date and time when the AMI was last used to launch an instance.

AWS CLI

You can use either the describe-images or describe-image-attribute command to view the last launched time of an AMI.

To view the last launched time of an AMI by using describe-images

Use the describe-images command and specify the ID of the AMI.

```
aws ec2 describe-images --image-id ami-0123456789example
```

Example output

```
{
   "Images": [
   {
      ...  
      "LastLaunchedTime": {
       "Value": "2024-04-02T02:03:18Z"
      },
      ...
   }
```

Note

The LastLaunchedTime field only appears in the output for AMIs that you own.
To view the last launched time of an AMI

Use the `describe-image-attribute` command and specify `--attribute lastLaunchedTime`. You must be owner of the AMI to run this command.

```bash
aws ec2 describe-image-attribute \
    --image-id ami-0123456789example \
    --attribute lastLaunchedTime
```

Example output

```json
{
    "ImageId": "ami-1234567890example",
    "LastLaunchedTime": {
        "Value": "2022-02-10T02:03:18Z"
    }
}
```

Protect an AMI from deregistration

You can turn on `deregistration protection` on an AMI to prevent accidental or malicious deletion. When you turn on deregistration protection, the AMI can’t be deregistered by any user, regardless of their IAM permissions. If you want to deregister the AMI, you must first turn off the deregistration protection on it.

When you turn on deregistration protection on an AMI, you have the option to include a 24-hour cooldown period. This cooldown period is the time during which deregistration protection remains in effect after you turn it off. During this cooldown period, the AMI can’t be deregistered. When the cooldown period ends, the AMI can be deregistered.

Deregistration protection is turned off by default on all existing and new AMIs.

Turn on deregistration protection

Use any of the following methods to turn on deregistration protection on an AMI. To do this, you must be the owner of the AMI.
To turn on deregistration protection on an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose AMIs.
3. From the filter bar, choose Owned by me to list your available AMIs, or choose Disabled images to list your disabled AMIs.
4. Select the AMI on which you want to turn on deregistration protection, and then choose Actions, Manage AMI deregistration protection.
5. In the Manage AMI deregistration protection dialog box, you can turn on deregistration protection with or without a cooldown period. Choose one of the following options:
   - Enable with a 24-hour cooldown period – With a cooldown period, the AMI can’t be deregistered for 24 hours when deregistration protection is turned off.
   - Enable without cooldown – Without a cooldown period, the AMI can be deregistered immediately when deregistration protection is turned off.
6. Choose Save.

AWS CLI

To turn on deregistration protection on an AMI

Use the enable-image-deregistration-protection command and specify the AMI ID. To include the optional 24-hour cooldown period, include --with-cooldown set to true. To exclude the cooldown period, omit the --with-cooldown parameter.

```
aws ec2 enable-image-deregistration-protection \
  --image-id ami-0123456789example \
  --with-cooldown true
```

Turn off deregistration protection

Use any of the following methods to turn off deregistration protection on an AMI. To do this, you must be the owner of the AMI.
Note

If you chose to include a 24-hour cooldown period when you turned on deregistration protection for the AMI, then, when you turn off deregistration protection, you won’t immediately be able to deregister the AMI. The cooldown period is the 24-hour time period during which deregistration protection remains in effect even after you turn it off. During this cooldown period, the AMI can’t be deregistered. After the cooldown period ends, the AMI can be deregistered.

Console

To turn off deregistration protection on an AMI

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose AMIs.
3. From the filter bar, choose Owned by me to list your available AMIs, or choose Disabled images to list your disabled AMIs.
4. Select the AMI to turn off deregistration protection, and then choose Actions, Manage AMI deregistration protection.
5. In the Manage AMI deregistration protection dialog box, choose Disable.
6. Choose Save.

AWS CLI

To turn off deregistration protection on an AMI

Use the disable-image-deregistration-protection command and specify the AMI ID.

```
aws ec2 disable-image-deregistration-protection --image-id ami-0123456789example
```

Avoid costs from unused resources

When you deregister an AMI, you don’t delete the resources that are associated with the AMI. These resources include the snapshots for EBS-backed AMIs and the files in Amazon S3 for instance store-backed AMIs. When you deregister an AMI, you also don’t terminate or stop any instances launched from the AMI.
You will continue to incur costs for storing the snapshots and files, and you will incur costs for any running instances. For more information, see [How you’re charged](#).

To avoid incurring these types of unnecessary costs, we recommend deleting any resources that you don’t need.

To determine whether your AMI is EBS-backed or instance store-backed, see [Determine the root device type of your AMI](#).

**Delete resources associated with your Amazon EBS-backed AMI**

Use any of the following methods to delete the resources associated with your EBS-backed AMI.

**Console**

**To delete resources associated with your EBS-backed AMI**

1. **Deregister the AMI.**
   
   Note the AMI ID—this can help you find the snapshots to delete in the next step.

2. **Delete snapshots** that you don't need.
   
   The ID of the associated AMI is displayed in the **Description** column on the **Snapshots** screen.

3. **Terminate instances** that you don't need.

**AWS CLI**

**To delete resources associated with your EBS-backed AMI**

1. Deregister the AMI by using the **deregister-image** command.

   ```bash
   aws ec2 deregister-image --image-id ami-0123456789example
   ```

2. Delete snapshots that you don't need by using the **delete-snapshot** command.

   ```bash
   aws ec2 delete-snapshot --snapshot-id snap-0123456789example
   ```

3. Terminate instances that you don't need by using the **terminate-instances** command.

   ```bash
   aws ec2 terminate-instances --instance-ids i-0123456789example
   ```
**PowerShell**

**To delete resources associated with your EBS-backed AMI**

1. Deregister the AMI by using the `Unregister-EC2Image` cmdlet.

   ```
   Unregister-EC2Image -ImageId ami-0123456789example
   ```

2. Delete snapshots that you don't need by using the `Remove-EC2Snapshot` cmdlet.

   ```
   Remove-EC2Snapshot -SnapshotId snap-0123456789example
   ```

3. Terminate instances that you don't need by using the `Remove-EC2Instance` cmdlet.

   ```
   Remove-EC2Instance -InstanceId i-0123456789example
   ```

The following diagram illustrates the flow for you to delete resources associated with an EBS-backed AMI.

---

**Delete resources associated with your instance store-backed AMI**

Use the following method to delete the resources associated with your instance store-backed AMI.
To delete resources associated with your instance store-backed AMI

1. Deregister the AMI by using the `deregister-image` command.
   
   ```bash
   aws ec2 deregister-image --image-id ami-0123456789example
   ```

2. Delete the bundle in Amazon S3 by using the `ec2-delete-bundle` (AMI tools) command.
   
   ```bash
   ec2-delete-bundle -b DOC-EXAMPLE-BUCKET/myami -a your_access_key_id -s your_secret_access_key -p image
   ```

3. Terminate instances that you don't need by using the `terminate-instances` command.
   
   ```bash
   aws ec2 terminate-instances --instance-ids i-0123456789example
   ```

4. If you are finished with the Amazon S3 bucket that you uploaded the bundle to, you can delete the bucket. To delete an Amazon S3 bucket, open the Amazon S3 console, select the bucket, choose Actions, and then choose Delete.

The following diagram illustrates the flow for you to delete resources associated with your instance store-backed AMI.
Automate the EBS-backed AMI lifecycle

You can use Amazon Data Lifecycle Manager to automate the creation, retention, copy, deprecation, and deregistration of Amazon EBS-backed AMIs and their backing snapshots. For more information, see Amazon Data Lifecycle Manager.

Use encryption with EBS-backed AMIs

AMIs that are backed by Amazon EBS snapshots can take advantage of Amazon EBS encryption. Snapshots of both data and root volumes can be encrypted and attached to an AMI. You can launch instances and copy images with full EBS encryption support included. Encryption parameters for these operations are supported in all Regions where AWS KMS is available.

EC2 instances with encrypted EBS volumes are launched from AMIs in the same way as other instances. In addition, when you launch an instance from an AMI backed by unencrypted EBS snapshots, you can encrypt some or all of the volumes during launch.

Like EBS volumes, snapshots in AMIs can be encrypted by either your default AWS KMS key, or to a customer managed key that you specify. You must in all cases have permission to use the selected KMS key.

AMIs with encrypted snapshots can be shared across AWS accounts. For more information, see Shared AMIs.

Encryption with EBS-backed AMIs topics

- Instance-launching scenarios
- Image-copying scenarios

Instance-launching scenarios

Amazon EC2 instances are launched from AMIs using the RunInstances action with parameters supplied through block device mapping, either by means of the AWS Management Console or directly using the Amazon EC2 API or CLI. For more information, see Block device mappings for Amazon EBS and instance store volumes on Amazon EC2 instances. For examples of controlling block device mapping from the AWS CLI, see Launch, List, and Terminate EC2 Instances.

By default, without explicit encryption parameters, a RunInstances action maintains the existing encryption state of an AMI’s source snapshots while restoring EBS volumes from them.
If encryption by default is enabled, all volumes created from the AMI (whether from encrypted or unencrypted snapshots) are encrypted. If encryption by default is not enabled, the instance maintains the encryption state of the AMI.

You can also launch an instance and simultaneously apply a new encryption state to the resulting volumes by supplying encryption parameters. Consequently, the following behaviors are observed:

**Launch with no encryption parameters**

- An unencrypted snapshot is restored to an unencrypted volume, unless encryption by default is enabled, in which case all the newly created volumes will be encrypted.
- An encrypted snapshot that you own is restored to a volume that is encrypted to the same KMS key.
- An encrypted snapshot that you do not own (for example, the AMI is shared with you) is restored to a volume that is encrypted by your AWS account's default KMS key.

The default behaviors can be overridden by supplying encryption parameters. The available parameters are `Encrypted` and `KmsKeyId`. Setting only the `Encrypted` parameter results in the following:

**Instance launch behaviors with `Encrypted` set, but no `KmsKeyId` specified**

- An unencrypted snapshot is restored to an EBS volume that is encrypted by your AWS account's default KMS key.
- An encrypted snapshot that you own is restored to an EBS volume encrypted by the same KMS key. (In other words, the `Encrypted` parameter has no effect.)
- An encrypted snapshot that you do not own (i.e., the AMI is shared with you) is restored to a volume that is encrypted by your AWS account's default KMS key. (In other words, the `Encrypted` parameter has no effect.)

Setting both the `Encrypted` and `KmsKeyId` parameters allows you to specify a non-default KMS key for an encryption operation. The following behaviors result:

**Instance with both `Encrypted` and `KmsKeyId` set**

- An unencrypted snapshot is restored to an EBS volume encrypted by the specified KMS key.
- An encrypted snapshot is restored to an EBS volume encrypted not to the original KMS key, but instead to the specified KMS key.
Submitting a KmsKeyId without also setting the Encrypted parameter results in an error.

The following sections provide examples of launching instances from AMIs using non-default encryption parameters. In each of these scenarios, parameters supplied to the RunInstances action result in a change of encryption state during restoration of a volume from a snapshot.

For information about using the console to launch an instance from an AMI, see [Launch your instance](#).

**Encrypt a volume during launch**

In this example, an AMI backed by an unencrypted snapshot is used to launch an EC2 instance with an encrypted EBS volume.

The Encrypted parameter alone results in the volume for this instance being encrypted. Providing a KmsKeyId parameter is optional. If no KMS key ID is specified, the AWS account's default KMS key is used to encrypt the volume. To encrypt the volume to a different KMS key that you own, supply the KmsKeyId parameter.

**Re-encrypt a volume during launch**

In this example, an AMI backed by an encrypted snapshot is used to launch an EC2 instance with an EBS volume encrypted by a new KMS key.
If you own the AMI and supply no encryption parameters, the resulting instance has a volume encrypted by the same KMS key as the snapshot. If the AMI is shared rather than owned by you, and you supply no encryption parameters, the volume is encrypted by your default KMS key. With encryption parameters supplied as shown, the volume is encrypted by the specified KMS key.

**Change encryption state of multiple volumes during launch**

In this more complex example, an AMI backed by multiple snapshots (each with its own encryption state) is used to launch an EC2 instance with a newly encrypted volume and a re-encrypted volume.

In this scenario, the RunInstances action is supplied with encryption parameters for each of the source snapshots. When all possible encryption parameters are specified, the resulting instance is the same regardless of whether you own the AMI.
Image-copying scenarios

Amazon EC2 AMIs are copied using the CopyImage action, either through the AWS Management Console or directly using the Amazon EC2 API or CLI.

By default, without explicit encryption parameters, a CopyImage action maintains the existing encryption state of an AMI's source snapshots during copy. You can also copy an AMI and simultaneously apply a new encryption state to its associated EBS snapshots by supplying encryption parameters. Consequently, the following behaviors are observed:

**Copy with no encryption parameters**

- An unencrypted snapshot is copied to another unencrypted snapshot, unless encryption by default is enabled, in which case all the newly created snapshots will be encrypted.
- An encrypted snapshot that you own is copied to a snapshot encrypted with the same KMS key.
- An encrypted snapshot that you do not own (that is, the AMI is shared with you) is copied to a snapshot that is encrypted by your AWS account's default KMS key.

All of these default behaviors can be overridden by supplying encryption parameters. The available parameters are Encrypted and KmsKeyId. Setting only the Encrypted parameter results in the following:

**Copy-image behaviors with Encrypted set, but no KmsKeyId specified**

- An unencrypted snapshot is copied to a snapshot encrypted by the AWS account's default KMS key.
- An encrypted snapshot is copied to a snapshot encrypted by the same KMS key. (In other words, the Encrypted parameter has no effect.)
- An encrypted snapshot that you do not own (i.e., the AMI is shared with you) is copied to a volume that is encrypted by your AWS account's default KMS key. (In other words, the Encrypted parameter has no effect.)

Setting both the Encrypted and KmsKeyId parameters allows you to specify a customer managed KMS key for an encryption operation. The following behaviors result:

**Copy-image behaviors with both Encrypted and KmsKeyId set**

- An unencrypted snapshot is copied to a snapshot encrypted by the specified KMS key.
• An encrypted snapshot is copied to a snapshot encrypted not to the original KMS key, but instead to the specified KMS key.

Submitting a KmsKeyId without also setting the Encrypted parameter results in an error.

The following section provides an example of copying an AMI using non-default encryption parameters, resulting in a change of encryption state.

For detailed instructions using the console, see Copy an AMI.

**Encrypt an unencrypted image during copy**

In this scenario, an AMI backed by an unencrypted root snapshot is copied to an AMI with an encrypted root snapshot. The CopyImage action is invoked with two encryption parameters, including a customer managed key. As a result, the encryption status of the root snapshot changes, so that the target AMI is backed by a root snapshot containing the same data as the source snapshot, but encrypted using the specified key. You incur storage costs for the snapshots in both AMIs, as well as charges for any instances you launch from either AMI.

**Note**

Enabling encryption by default has the same effect as setting the Encrypted parameter to true for all snapshots in the AMI.
Setting the Encrypted parameter encrypts the single snapshot for this instance. If you do not specify the KmsKeyId parameter, the default customer managed key is used to encrypt the snapshot copy.

Note
You can also copy an image with multiple snapshots and configure the encryption state of each individually.

Monitor AMI events using Amazon EventBridge

When the state of an Amazon Machine Image (AMI) changes, Amazon EC2 generates an event that is sent to Amazon EventBridge (formerly known as Amazon CloudWatch Events). You can use Amazon EventBridge to detect and react to these events. You do this by creating rules in EventBridge that trigger an action in response to an event. For example, you can create an EventBridge rule that detects when the AMI creation process has completed and then invokes an Amazon SNS topic to send an email notification to you.

Amazon EC2 generates an event when an AMI enters any of the following states:

- available
- failed
- deregistered
- disabled

The following table lists the AMI operations and the states that an AMI can enter. In the table, Yes indicates the states that the AMI can enter when the corresponding operation runs.

<table>
<thead>
<tr>
<th>AMI operations</th>

### Topics

- [AMI events](#)
- [Create Amazon EventBridge rules](#)

### AMI events

There are four EC2 AMI State Change events:

- **available**
- **failed**
- **deregistered**
- **disabled**

The events are sent to the default EventBridge event bus in JSON format.

The following fields in the event can be used to create rules that trigger an action:

```json
"source": "aws.ec2"
```

Identifies that the event is from Amazon EC2.

```json
"detail-type": "EC2 AMI State Change"
```

Identifies the event name.

```json
"detail": { "ImageId": "ami-0123456789example", "State": "available", } 
```

Provides the following information:
• The AMI ID – If you want to track a specific AMI.
• The state of the AMI (available, failed, deregistered, or disabled).

available

The following is an example of an event that Amazon EC2 generates when the AMI enters the available state following a successful CreateImage, CopyImage, RegisterImage, CreateRestoreImageTask, or EnableImage operation.

"State": "available" indicates that the operation was successful.

```
{
    "version": "0",
    "id": "example-9f07-51db-246b-d8b8441bcdc0",
    "detail-type": "EC2 AMI State Change",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": ["arn:aws:ec2:us-east-1::image/ami-0123456789example"],
    "detail": {
        "RequestId": "example-9dcc-40a6-aa77-7ce457d5442b",
        "ImageId": "ami-0123456789example",
        "State": "available",
        "ErrorMessage": ""
    }
}
```

failed

The following is an example of an event that Amazon EC2 generates when the AMI enters the failed state following a failed CreateImage, CopyImage, RegisterImage, or CreateRestoreImageTask operation.

The following fields provide pertinent information:

• "State": "failed" – Indicates that the operation failed.
• "ErrorMessage": "" – Provides the reason for the failed operation.

```
{
}
```
The following is an example of an event that Amazon EC2 generates when the AMI enters the deregistered state following a successful DeregisterImage operation. If the operation fails, no event is generated. Any failure is known immediately because DeregisterImage is a synchronous operation.

"State": "deregistered" indicates that the DeregisterImage operation was successful.
disabled

The following is an example of an event that Amazon EC2 generates when the AMI enters the disabled state following a successful DisableImage operation. If the operation fails, no event is generated. Any failure is known immediately because DisableImage is a synchronous operation.

"State": "disabled" indicates that the DisableImage operation was successful.

```
{
  "version": "0",
  "id": "example-9f07-51db-246b-d8b8441bcdcf0",
  "detail-type": "EC2 AMI State Change",
  "source": "aws.ec2",
  "account": "012345678901",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-1",
  "resources": ["arn:aws:ec2:us-east-1::image/ami-0123456789example"],
  "detail": {
    "RequestId": "example-9dcc-40a6-aa77-7ce457d5442b",
    "ImageId": "ami-0123456789example",
    "State": "disabled",
    "ErrorMessage": ""
  }
}
```

Create Amazon EventBridge rules

You can create an Amazon EventBridge rule that specifies an action to take when EventBridge receives an event that matches the event pattern in the rule. When an event matches, EventBridge sends the event to the specified target and triggers the action defined in the rule.

Event patterns have the same structure as the events they match. An event pattern either matches an event or it doesn't.

When creating a rule for an AMI state change event, you can include the following fields in the event pattern:

"source": "aws.ec2"

Identifies that the event is from Amazon EC2.
"detail-type": "EC2 AMI State Change"

Identifies the event name.
"detail": { "ImageId": "ami-0123456789example", "State": "available", }

Provides the following information:

- The AMI ID – If you want to track a specific AMI.
- The state of the AMI (available, failed, deregistered, or disabled).

**Example: Create an EventBridge rule to send a notification**

The following example creates an EventBridge rule to send an email, text message, or mobile push notification when any AMI is in the available state after the CreateImage operation has completed successfully.

Before creating the EventBridge rule, you must create the Amazon SNS topic for the email, text message, or mobile push notification.

**To create an EventBridge rule to send a notification when an AMI is created and in the available state**

1. Open the Amazon EventBridge console at [https://console.aws.amazon.com/events/](https://console.aws.amazon.com/events/).
2. Choose **Create rule**.
3. For **Define rule detail**, do the following:
   a. Enter a **Name** for the rule, and, optionally, a description.

      A rule can't have the same name as another rule in the same Region and on the same event bus.
   b. For **Event bus**, choose **default**. When an AWS service in your account generates an event, it always goes to your account's default event bus.
   c. For **Rule type**, choose **Rule with an event pattern**.
   d. Choose **Next**.
4. For **Build event pattern**, do the following:
   a. For **Event source**, choose **AWS events** or **EventBridge partner events**.
b. For **Event pattern**, for this example you’ll specify the following event pattern to match any EC2 AMI State Change event that is generated when an AMI enters the available state:

```json
{
    "source": ["aws.ec2"],
    "detail-type": ["EC2 AMI State Change"],
    "detail": {"State": ["available"]}
}
```

To add the event pattern, you can either use a template by choosing **Event pattern form**, or specify your own pattern by choosing **Custom pattern (JSON editor)**, as follows:

i. To use a template to create the event pattern, do the following:

   A. Choose **Event pattern form**.
   B. For **Event source**, choose **AWS services**.
   C. For **AWS Service**, choose **EC2**.
   D. For **Event type**, choose **EC2 AMI State Change**.
   E. To customize the template, choose **Edit pattern** and make your changes to match the example event pattern.

ii. To specify a custom event pattern, do the following:

   A. Choose **Custom pattern (JSON editor)**.
   B. In the **Event pattern** box, add the event pattern for this example.

   c. Choose **Next**.

5. For **Select target(s)**, do the following:

   a. For **Target types**, choose **AWS service**.
   b. For **Select a target**, choose **SNS topic** to send an email, text message, or mobile push notification when the event occurs.
   c. For **Topic**, choose an existing topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the Amazon Simple Notification Service Developer Guide.
d. (Optional) Under **Additional settings**, you can optionally configure additional settings. For more information, see *Creating Amazon EventBridge rules that react to events* (step 16) in the *Amazon EventBridge User Guide*.

e. Choose **Next**.

6. (Optional) For **Tags**, you can optionally assign one or more tags to your rule, and then choose **Next**.

7. For **Review and create**, do the following:
   
a. Review the details of the rule and modify them as necessary.

b. Choose **Create rule**.

For more information, see the following topics in the *Amazon EventBridge User Guide*:

- [Amazon EventBridge events](#)
- [Amazon EventBridge event patterns](#)
- [Amazon EventBridge rules](#)

For a tutorial on how to create a Lambda function and an EventBridge rule that runs the Lambda function, see *Tutorial: Log the state of an Amazon EC2 instance using EventBridge* in the *AWS Lambda Developer Guide*.

**Understand AMI billing information**

There are many Amazon Machine Images (AMIs) to choose from when launching your instances, and they support a variety of operating system platforms and features. To understand how the AMI you choose when launching your instance affects the bottom line on your AWS bill, you can research the associated operating system platform and billing information. Do this before you launch any On-Demand or Spot Instances, or purchase a Reserved Instance.

Here are two examples of how researching your AMI in advance can help you choose the AMI that best suits your needs:

- For Spot Instances, you can use the AMI **Platform details** to confirm that the AMI is supported for Spot Instances.

- When purchasing a Reserved Instance, you can make sure that you select the operating system platform (**Platform**) that maps to the AMI **Platform details**.
For more information about instance pricing, see Amazon EC2 pricing.

Contents

- AMI billing information fields
- Finding AMI billing and usage details
- Verify AMI charges on your bill

AMI billing information fields

The following fields provide billing information associated with an AMI:

Platform details

The platform details associated with the billing code of the AMI. For example, Red Hat Enterprise Linux.

Usage operation

The operation of the Amazon EC2 instance and the billing code that is associated with the AMI. For example, RunInstances:0010. **Usage operation** corresponds to the `lineitem/Operation` column on your AWS Cost and Usage Report (CUR) and in the AWS Price List API.

You can view these fields on the Instances or AMIs page in the Amazon EC2 console, or in the response that is returned by the `describe-images` or `Get-EC2Image` command.

Sample data: usage operation by platform

The following table lists some of the platform details and usage operation values that can be displayed on the Instances or AMIs pages in the Amazon EC2 console, or in the response that is returned by the `describe-images` or `Get-EC2Image` command.

<table>
<thead>
<tr>
<th>Platform details</th>
<th>Usage operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux/UNIX</td>
<td>RunInstances</td>
</tr>
<tr>
<td>Red Hat BYOL Linux</td>
<td>RunInstances:00g0</td>
</tr>
</tbody>
</table>

AMI billing fields
<table>
<thead>
<tr>
<th>Platform details</th>
<th>Usage operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Red Hat Enterprise Linux</td>
<td>RunInstances:0010</td>
</tr>
<tr>
<td>Red Hat Enterprise Linux with HA</td>
<td>RunInstances:1010</td>
</tr>
<tr>
<td>Red Hat Enterprise Linux with SQL Server Standard and HA</td>
<td>RunInstances:1014</td>
</tr>
<tr>
<td>Red Hat Enterprise Linux with SQL Server Enterprise and HA</td>
<td>RunInstances:1110</td>
</tr>
<tr>
<td>Red Hat Enterprise Linux with SQL Server Standard</td>

<tr>
<td>Windows with SQL Server Web</td>
<td>RunInstances:0202</td>
</tr>
</tbody>
</table>

1 If two software licenses are associated with an AMI, the **Platform details** field shows both.

2 If you are running Spot Instances, the **lineitem/Operation** on your AWS Cost and Usage Report might be different from the **Usage operation** value that is listed here. For example, if **lineitem/Operation** displays RunInstances:0010:SV006, it means that Amazon EC2 is running Red Hat Enterprise Linux Spot Instance-hour in US East (N. Virginia) in Zone 6.

3 This appears as RunInstances (Linux/UNIX) in your usage reports.

**Finding AMI billing and usage details**

In the Amazon EC2 console, you can view the AMI billing information from the **AMIs** page or from the **Instances** page. You can also find billing information using the AWS CLI or the instance metadata service.

The following fields can help you verify AMI charges on your bill:

- **Platform details**
- **Usage operation**
- **AMI ID**

**Find AMI billing information (console)**

Follow these steps to view AMI billing information in the Amazon EC2 console:

**Look up AMI billing information from the AMIs page**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **AMIs**, and then select an AMI.
3. On the **Details** tab, check the values for **Platform details** and **Usage operation**.
Look up AMI billing information from the Instances page

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select an instance.
3. On the Details tab (or the Description tab if you are using the prior version of the console), check the values for Platform details and Usage operation.

Find AMI billing information (AWS CLI)

To find the AMI billing information using the AWS CLI, you need to know the AMI ID. If you don't know the AMI ID, you can get it from the instance using the describe-instances command.

To find the AMI ID

If you know the instance ID, you can get the AMI ID for the instance by using the describe-instances command.

```bash
aws ec2 describe-instances --instance-ids i-123456789abcde123
```

In the output, the AMI ID is specified in the ImageId field.

```json
"Instances": [
    {
        "AmiLaunchIndex": 0,
        "ImageId": "ami-0123456789EXAMPLE",
        "InstanceId": "i-123456789abcde123",
        ...
    }
]
```

To find the AMI billing information

If you know the AMI ID, you can use the describe-images command to get the AMI platform and usage operation details.

```bash
$ aws ec2 describe-images --image-ids ami-0123456789EXAMPLE
```

The following example output shows the PlatformDetails and UsageOperation fields. In this example, the ami-0123456789EXAMPLE platform is Red Hat Enterprise Linux and the usage operation and billing code is RunInstances:0010.
{  "Images": [    {      "VirtualizationType": "hvm",      "Description": "Provided by Red Hat, Inc.",      "Hypervisor": "xen",      "EnaSupport": true,      "SriovNetSupport": "simple",      "ImageId": "ami-0123456789EXAMPLE",      "State": "available",      "BlockDeviceMappings": [        {          "DeviceName": "/dev/sda1",          "Ebs": {            "SnapshotId": "snap-111222334455aaabb",            "DeleteOnTermination": true,            "VolumeType": "gp2",            "VolumeSize": 10,            "Encrypted": false          }        }      ],      "Architecture": "x86_64",      "ImageLocation": "123456789012/RHEL-8.0.0_HVM-20190618-x86_64-1-Hourly2-GP2",      "RootDeviceType": "ebs",      "OwnerId": "123456789012",      "PlatformDetails": "Red Hat Enterprise Linux",      "UsageOperation": "RunInstances:0010",      "RootDeviceName": "/dev/sda1",      "CreationDate": "2019-05-10T13:17:12.000Z",      "Public": true,      "ImageType": "machine",      "Name": "RHEL-8.0.0_HVM-20190618-x86_64-1-Hourly2-GP2"    }  ]}
Verify AMI charges on your bill

To ensure that you're not incurring unplanned costs, you can verify that the billing information for an instance in your AWS Cost and Usage Report (CUR) matches the billing information that's associated with the AMI that you used to launch the instance.

To verify the billing information, find the instance ID in your CUR and check the corresponding value in the `lineitem/Operation` column. That value should match the value for `Usage operation` that's associated with the AMI.

For example, the AMI `ami-0123456789EXAMPLE` has the following billing information:

- **Platform details** = Red Hat Enterprise Linux
- **Usage operation** = RunInstances:0010

If you launched an instance using this AMI, you can find the instance ID in your CUR, and check the corresponding value in the `lineitem/Operation` column. In this example, the value should be `RunInstances:0010`.

AMI quotas

The following quotas apply to creating and sharing AMIs. The quotas apply per AWS Region.

<table>
<thead>
<tr>
<th>Quota name</th>
<th>Description</th>
<th>Default quota per Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMIs</td>
<td>The maximum number of public and private AMIs allowed per Region. These include available, pending, and disabled AMIs, and AMIs in the Recycle Bin.</td>
<td>50,000</td>
</tr>
<tr>
<td>Public AMIs</td>
<td>The maximum number of public AMIs, including public AMIs in the Recycle Bin, allowed per Region.</td>
<td>5</td>
</tr>
<tr>
<td>Quota name</td>
<td>Description</td>
<td>Default quota per Region</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>AMI sharing</td>
<td>The maximum number of entities (organizations, organizational units (OUs), and accounts) that an AMI can be shared with in a Region. Note that if you share an AMI with an organization or OU, the number of accounts in the organization or OU does not count towards the quota.</td>
<td>1,000</td>
</tr>
</tbody>
</table>

If you exceed your quotas and you want to create or share more AMIs, you can do the following:

- If you exceed your total AMIs or public AMIs quota, consider deregistering unused images.
- If you exceed your public AMIs quota, consider making one or more public AMIs private.
- If you exceed your AMI sharing quota, consider sharing your AMIs with an organization or OU instead of separate accounts.
- Request a quota increase for AMIs.

**Request a quota increase for AMIs**

If you need more than the default quota for AMIs, you can request a quota increase.

**To request a quota increase for AMIs**

2. In the navigation pane, choose *AWS services*.
3. Choose *Amazon Elastic Compute Cloud (Amazon EC2)* from the list, or type the name of the service in the search box.
4. Choose the AMI quota to request an increase. The AMI quotas you can select are:
   - AMIs
   - Public AMIs
• AMI sharing

5. Choose **Request quota increase**.

6. For **Change quota value**, enter the new quota value, and then choose **Request**.

To view any pending or recently resolved requests, choose **Dashboard** from the navigation pane. For pending requests, choose the status of the request to open the request receipt. The initial status of a request is **Pending**. After the status changes to **Quota requested**, you'll see the case number under **Support Center case number**. Choose the case number to open the ticket for your request.

After the request is resolved, the **Applied quota value** for the quota is set to the new value.

For more information, see the [Service Quotas User Guide](#).
Amazon EC2 instances

Before you launch a production environment, you need to answer the following questions.

Q. What instance type best meets my needs?

Amazon EC2 provides different instance types to enable you to choose the CPU, memory, storage, and networking capacity that you need to run your applications. For more information, see Amazon EC2 instance types.

Q. What purchasing option best meets my needs?

Amazon EC2 supports On-Demand Instances (the default), Spot Instances, and Reserved Instances. For more information, see Instance purchasing options.

Q. Which type of root volume meets my needs?

Each instance is backed by Amazon EBS or backed by instance store. Select an AMI based on which type of root volume you need. For more information, see Storage for the root device.

Q. Can I remotely manage a fleet of EC2 instances and machines in my hybrid environment?

AWS Systems Manager enables you to remotely and securely manage the configuration of your Amazon EC2 instances, and your on-premises instances and virtual machines (VMs) in hybrid environments, including VMs from other cloud providers. For more information, see the AWS Systems Manager User Guide.

Instances and AMIs

An Amazon Machine Image (AMI) is a template that contains a software configuration (for example, an operating system, an application server, and applications). From an AMI, you launch an instance, which is a copy of the AMI running as a virtual server in the cloud. You can launch multiple instances of an AMI, as shown in the following figure.
Your instances keep running until you stop, hibernate, or terminate them, or until they fail. If an instance fails, you can launch a new one from the AMI.

**Instances**

An instance is a virtual server in the cloud. Its configuration at launch is a copy of the AMI that you specified when you launched the instance.

You can launch different types of instances from a single AMI. An *instance type* essentially determines the hardware of the host computer used for your instance. Each instance type offers different compute and memory capabilities. Select an instance type based on the amount of memory and computing power that you need for the application or software that you plan to run on the instance. For detailed instance type specifications, see Specifications in the *Amazon EC2 Instance Types Guide*. For pricing information, see Amazon EC2 On-Demand Pricing.

After you launch an instance, it looks like a traditional host, and you can interact with it as you would any computer. You have complete control of your instances; you can use `sudo` to run commands that require root privileges.

Your AWS account has a limit on the number of instances that you can have running. For more information about this limit, and how to request an increase, see How many instances can I run in Amazon EC2 in the Amazon EC2 General FAQ.
Storage for your instance

The root device for your instance contains the image used to boot the instance. The root device is either an Amazon Elastic Block Store (Amazon EBS) volume or an instance store volume. For more information, see Root volumes for your Amazon EC2 instances.

Your instance may include local storage volumes, known as instance store volumes, which you can configure at launch time with block device mapping. For more information, see Block device mappings for Amazon EBS and instance store volumes on Amazon EC2 instances. After these volumes have been added to and mapped on your instance, they are available for you to mount and use. If your instance fails, or if your instance is stopped or terminated, the data on these volumes is lost; therefore, these volumes are best used for temporary data. To keep important data safe, you should use a replication strategy across multiple instances, or store your persistent data in Amazon S3 or Amazon EBS volumes. For more information, see Storage options for your Amazon EC2 instances.

Security best practices

- Use AWS Identity and Access Management (IAM) to control access to your AWS resources, including your instances. For more information, see Identity and access management for Amazon EC2.
- Restrict access by only allowing trusted hosts or networks to access ports on your instance. For example, you can restrict SSH access by restricting incoming traffic on port 22. For more information, see Amazon EC2 security groups for your EC2 instances.
- Review the rules in your security groups regularly, and ensure that you apply the principle of least privilege—only open up permissions that you require. You can also create different security groups to deal with instances that have different security requirements. Consider creating a bastion security group that allows external logins, and keep the remainder of your instances in a group that does not allow external logins.
- Disable password-based logins for instances launched from your AMI. Passwords can be found or cracked, and are a security risk. For more information, see Disable password-based remote logins for the root user. For more information about sharing AMIs safely, see Shared AMIs.

Stop and terminate instances

You can stop or terminate a running instance at any time.

Stop an instance
When an instance is stopped, the instance performs a normal shutdown, and then transitions to a stopped state. All of its Amazon EBS volumes remain attached, and you can start the instance again at a later time.

You are not charged for additional instance usage while the instance is in a stopped state. You are charged for every transition from a stopped state to a running state. If the instance type changed while the instance was stopped, you are charged the rate for the new instance type after the instance is started. You are also charged for the associated Amazon EBS storage for your instance, including the root device volume.

When an instance is in a stopped state, you can attach or detach Amazon EBS volumes. You can also create an AMI from the instance, and you can change the kernel, RAM disk, and instance type.

**Terminate an instance**

When an instance is terminated, the instance performs a normal shutdown. The root device volume is deleted by default, but any attached Amazon EBS volumes are preserved by default, determined by each volume's `deleteOnTermination` attribute setting. The instance itself is also deleted, and you can't start the instance again at a later time.

To prevent accidental termination, you can disable instance termination. If you do so, ensure that the `disableApiTermination` attribute is set to `true` for the instance. To control the behavior of an instance shutdown, such as `shutdown -h` in Linux or `shutdown` in Windows, set the `instanceInitiatedShutdownBehavior` instance attribute to `stop` or `terminate` as desired. Instances with Amazon EBS volumes for the root device default to `stop`, and instances with instance-store root devices are always terminated as the result of an instance shutdown.

For more information, see [Instance lifecycle](#).

---

**Note**

Some AWS resources, such as Amazon EBS volumes and Elastic IP addresses, incur charges regardless of the instance's state. For more information, see [Avoiding Unexpected Charges](#) in the *AWS Billing User Guide*. For more information about Amazon EBS costs, see [Amazon EBS pricing](#).
AMIs

Amazon Web Services (AWS) publishes Amazon Machine Images (AMIs) that contain common software configurations for public use. In addition, members of the AWS developer community have published their own custom AMIs. You can also create your own custom AMIs; doing so enables you to quickly and easily start new instances that have everything you need. For example, if your application is a website or a web service, your AMI could include a web server, the associated static content, and the code for the dynamic pages. As a result, after you launch an instance from this AMI, your web server starts, and your application is ready to accept requests.

All AMIs are categorized as either backed by Amazon EBS, which means that the root device for an instance launched from the AMI is an Amazon EBS volume, or backed by instance store, which means that the root device for an instance launched from the AMI is an instance store volume created from a template stored in Amazon S3.

The description of an AMI indicates the type of root device (either ebs or instance store). This is important because there are significant differences in what you can do with each type of AMI. For more information about these differences, see Storage for the root device.

You can deregister an AMI when you have finished using it. After you deregister an AMI, you can't use it to launch new instances. Existing instances launched from the AMI are not affected. Therefore, if you are also finished with the instances launched from these AMIs, you should terminate them.

Amazon EC2 instance types

When you launch an instance, the instance type that you specify determines the hardware of the host computer used for your instance. Each instance type offers different compute, memory, and storage capabilities, and is grouped in an instance family based on these capabilities. Select an instance type based on the requirements of the application or software that you plan to run on your instance.

Amazon EC2 dedicates some resources of the host computer, such as CPU, memory, and instance storage, to a particular instance. Amazon EC2 shares other resources of the host computer, such as the network and the disk subsystem, among instances. If each instance on a host computer tries to use as much of one of these shared resources as possible, each receives an equal share of that resource. However, when a resource is underused, an instance can consume a higher share of that resource while it's available.
Each instance type provides higher or lower minimum performance from a shared resource. For example, instance types with high I/O performance have a larger allocation of shared resources. Allocating a larger share of shared resources also reduces the variance of I/O performance. For most applications, moderate I/O performance is more than enough. However, for applications that require greater or more consistent I/O performance, consider an instance type with higher I/O performance.

- Performance acceleration with GPU instances

Available instance types

Amazon EC2 provides a wide selection of instance types optimized to fit different use cases. Instance types comprise varying combinations of CPU, memory, storage, and networking capacity and give you the flexibility to choose the appropriate mix of resources for your applications. Each instance type includes one or more instance sizes, allowing you to scale your resources to the requirements of your target workload. For more information about features and use cases, see Amazon EC2 Instance Types Details.

Instance type naming conventions

Names are based on instance family, generation, processor family, capabilities, and size. For more information, see Naming conventions in the Amazon EC2 Instance Types Guide.

Find an instance type

To determine which instance types meet your requirements, such as supported Regions, compute resources, or storage resources, see Find an Amazon EC2 instance type and Amazon EC2 instance type specifications in the Amazon EC2 Instance Types Guide.

- **High-performance computing:** Hpc6a | Hpc6id | Hpc7a | Hpc7g

Previous generation instances

- **General purpose:** A1 | M1 | M2 | M3 | M4 | T1

- **Compute optimized:** C1 | C3 | C4

- **Memory optimized:** R3 | R4

- **Storage optimized:** I2

- **Accelerated computing:** G3

Hardware specifications

For detailed instance type specifications, see Specifications in the Amazon EC2 Instance Types Guide. For pricing information, see Amazon EC2 On-Demand Pricing.

To determine which instance type best meets your needs, we recommend that you launch an instance and use your own benchmark application. Because you pay by the instance second, it's convenient and inexpensive to test multiple instance types before making a decision. If your needs change, even after you make a decision, you can change the instance type later. For more information, see Change the instance type.
Intel processor features

Amazon EC2 instances that run on Intel processors may include the following features. Not all of the following processor features are supported by all instance types. For detailed information about which features are available for each instance type, see Amazon EC2 Instance types.

- **Intel AES New Instructions (AES-NI)** — Intel AES-NI encryption instruction set improves upon the original Advanced Encryption Standard (AES) algorithm to provide faster data protection and greater security. All current generation EC2 instances support this processor feature.

- **Intel Advanced Vector Extensions (Intel AVX, Intel AVX2, and Intel AVX-512)** — Intel AVX and Intel AVX2 are 256-bit, and Intel AVX-512 is a 512-bit instruction set extension designed for applications that are Floating Point (FP) intensive. Intel AVX instructions improve performance for applications like image and audio/video processing, scientific simulations, financial analytics, and 3D modeling and analysis. These features are only available on instances launched with HVM AMIs.

- **Intel Turbo Boost Technology** — Intel Turbo Boost Technology processors automatically run cores faster than the base operating frequency.

- **Intel Deep Learning Boost (Intel DL Boost)** — Accelerates AI deep learning use cases. The 2nd Gen Intel Xeon Scalable processors extend Intel AVX-512 with a new Vector Neural Network Instruction (VNNI/INT8) that significantly increases deep learning inference performance over previous generation Intel Xeon Scalable processors (with FP32) for image recognition/segmentation, object detection, speech recognition, language translation, recommendation systems, reinforcement learning, and more. VNNI may not be compatible with all Linux distributions.

  The following instances support VNNI: M5n, R5n, M5dn, M5zn, R5b, R5dn, D3, D3en, and C6i. C5 and C5d instances support VNNI for only 12xlarge, 24xlarge, and metal instances.

Confusion may result from industry naming conventions for 64-bit CPUs. Chip manufacturer Advanced Micro Devices (AMD) introduced the first commercially successful 64-bit architecture based on the Intel x86 instruction set. Consequently, the architecture is widely referred to as AMD64 regardless of the chip manufacturer. Windows and several Linux distributions follow this practice. This explains why the internal system information on an instance running Ubuntu or Windows displays the CPU architecture as AMD64 even though the instances are running on Intel hardware.
AWS Graviton processors

AWS Graviton is a family of processors designed to deliver the best price performance for your workloads running on Amazon EC2 instances.

For more information, see Getting started with Graviton.

AWS Trainium

Instances powered by AWS Trainium are purpose built for high-performance, cost-effective deep learning training. You can use these instances to train natural language processing, computer vision, and recommender models used across a broad set of applications, such as speech recognition, recommendation, fraud detection, and image and video classification. Use your existing workflows in popular ML frameworks, such as PyTorch and TensorFlow.

AWS Inferentia

Instances powered by AWS Inferentia are designed to accelerate machine learning. They provide high performance and low latency machine learning inference. These instances are optimized for deploying deep learning (DL) models for applications, such as natural language processing, object detection and classification, content personalization and filtering, and speech recognition.

There are a variety of ways that you can get started:

- Use SageMaker, a fully-managed service that is the easiest way to get started with machine learning models. For more information, see Get Started with SageMaker in the Amazon SageMaker Developer Guide.
- Launch an Inf1 or Inf2 instance using the Deep Learning AMI. For more information, see AWS Inferentia with DLAMI in the AWS Deep Learning AMI Developer Guide.
- Launch an Inf1 or Inf2 instance using your own AMI and install the AWS Neuron SDK, which enables you to compile, run, and profile deep learning models for AWS Inferentia.
- Launch a container instance using an Inf1 or Inf2 instance and an Amazon ECS-optimized AMI. For more information, see Amazon Linux 2 (Inferentia) AMIs in the Amazon Elastic Container Service Developer Guide.
- Create an Amazon EKS cluster with nodes running Inf1 instances. For more information, see Inferentia support in the Amazon EKS User Guide.
AMI virtualization types

The virtualization type of your instance is determined by the AMI that you use to launch it. Current generation instance types support hardware virtual machine (HVM) only. Some previous generation instance types support paravirtual (PV) and some AWS Regions support PV instances. For more information, see AMI virtualization types.

For best performance, we recommend that you use an HVM AMI. In addition, HVM AMIs are required to take advantage of enhanced networking. HVM virtualization uses hardware-assist technology provided by the AWS platform. With HVM virtualization, the guest VM runs as if it were on a native hardware platform, except that it still uses PV network and storage drivers for improved performance.

Find an Amazon EC2 instance type

Before you can launch an instance, you must select an instance type to use. The instance type that you choose might depend on the resources that your workload requires, such as compute, memory, or storage resources. It can be beneficial to identify several instance types that might suit your workload and evaluate their performance in a test environment. There is no substitute for measuring the performance of your application under load.

If you already have running EC2 instances, you can use AWS Compute Optimizer to get recommendations about the instance types that you should use to improve performance, save money, or both. For more information, see the section called “For existing workloads”.

Tasks

- Find an instance type using the console
- Find an instance type using the AWS CLI

Find an instance type using the console

You can find an instance type that meets your needs using the Amazon EC2 console.

To find an instance type using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region in which to launch your instances. You can select any Region that's available to you, regardless of your location.
3. In the navigation pane, choose **Instance Types**.

4. (Optional) Choose the preferences (gear) icon to select which instance type attributes to display, such as **On-Demand Linux pricing**, and then choose **Confirm**. Alternatively, select the name of an instance type to open its details page and view all attributes available through the console. The console does not display all the attributes available through the API or the command line.

5. Use the instance type attributes to filter the list of displayed instance types to only the instance types that meet your needs. For example, you can filter on the following attributes:
   - **Availability zones** – The name of the Availability Zone, Local Zone, or Wavelength Zone. For more information, see the section called “Regions and Zones”.
   - **vCPUs** or **Cores** – The number of vCPUs or cores.
   - **Memory (GiB)** – The memory size, in GiB.
   - **Network performance** – The network performance, in Gigabits.
   - **Local instance storage** – Indicates whether the instance type has local instance storage (true | false).

6. (Optional) To see a side-by-side comparison, select the checkbox for multiple instance types. The comparison is displayed at the bottom of the screen.

7. (Optional) To save the list of instance types to a comma-separated values (.csv) file for further review, choose **Actions, Download list CSV**. The file includes all instance types that match the filters you set.

8. (Optional) To launch instances using an instance type that meet your needs, select the checkbox for the instance type and choose **Actions, Launch instance**. For more information, see **Launch an instance using the new launch instance wizard**.

**Find an instance type using the AWS CLI**

You can use AWS CLI commands for Amazon EC2 to find an instance type that meet your needs.

**To find an instance type using the AWS CLI**

1. If you have not done so already, install the AWS CLI For more information, see the **AWS Command Line Interface User Guide**.
2. Use the `describe-instance-types` command to filter instance types based on instance attributes. For example, you can use the following command to display only current generation instance types with 64 GiB (65536 MiB) of memory.

```bash
aws ec2 describe-instance-types --filters "Name=current-generation,Values=true" "Name=memory-info.size-in-mib,Values=65536" --query "InstanceTypes[*].[InstanceType]" --output text | sort
```

3. Use the `describe-instance-type-offerings` command to filter instance types offered by location (Region or Zone). For example, you can use the following command to display the instance types offered in the specified Zone.

```bash
aws ec2 describe-instance-type-offerings --location-type "availability-zone" --filters Name=location,Values=us-east-2a --region us-east-2 --query "InstanceTypeOfferings[*].[InstanceType]" --output text | sort
```

4. After locating the instance types that meet your needs, save the list so that you can use these instance types when you launch instances. For more information, see "Launching your instance" in the `AWS Command Line Interface User Guide`.

### Get recommendations for an instance type

The following tools can help you select the optimal instance types for your new or existing workloads:

- **New workloads** – The EC2 instance type finder considers your use case, workload type, CPU manufacturer preference, and how you prioritize price and performance, as well as additional parameters that you can specify. It then uses this data to provide suggestions and guidance for Amazon EC2 instance types that are best suited to your new workloads.

- **Existing workloads** – AWS Compute Optimizer analyzes your existing instance specifications and utilization metrics. It then uses the compiled data to recommend which Amazon EC2 instance types are optimized for cost or performance, or both, for your existing workloads.

### Get instance type recommendations:

- [Get instance type recommendations for a new workload](#)
- [Get instance type recommendations for an existing workload](#)
Get instance type recommendations for a new workload

EC2 instance type finder considers your use case, workload type, CPU manufacturer preference, and how you prioritize price and performance, as well as additional parameters that you can specify. It then uses this data to provide suggestions and guidance for Amazon EC2 instance types that are best suited to your new workloads.

With so many instance types available, finding the right instance types for your workload can be time-consuming and complex. By using the EC2 instance type finder, you can remain up to date with the latest instance types and achieve the best price-performance for your workloads.

This topic outlines how to get suggestions and guidance for EC2 instance types through the Amazon EC2 console. You can also go directly to Amazon Q to ask for instance type advice. For more information, see the Amazon Q Developer User Guide.

If you're looking for instance type recommendations for an existing workload, use AWS Compute Optimizer. For more information, see Get instance type recommendations for an existing workload.

Use the EC2 instance type finder

In the Amazon EC2 console, you can get instance type suggestions from the EC2 instance type finder in the launch instance wizard, when creating a launch template, or on the Instance types page.

Use the following instructions to get suggestions and guidance for EC2 instance types using the EC2 instance type finder in the Amazon EC2 console. To view an animation of the steps, see View an animation: Get instance type suggestions using the EC2 instance type finder.

To get instance type suggestions using the EC2 instance type finder

1. Start your process using any of the following:
   • Follow the procedure to launch an instance. Next to Instance type, choose the Get advice link.
   • Follow the procedure to create a launch template. Next to Instance type, choose the Get advice link.
   • In the navigation pane, choose Instance Types, and then choose the Instance type finder button.

2. In the Get advice on instance type selection screen, do the following:
a. Specify your instance type requirements by selecting options for **Workload type**, **Use case**, **Priority**, and **CPU manufacturers**.

b. (Optional) To specify more detailed requirements for your workload, do the following:

   i. Expand **Advanced parameters**.

   ii. To add a parameter, select a parameter, choose **Add**, and specify a value for the parameter. Repeat for each additional parameter that you want to add. To indicate no minimum or maximum value, leave the field empty.

   iii. To remove a parameter after adding it, choose the **X** next to the parameter.

c. Choose **Get instance type advice**.

   Amazon EC2 provides you with suggestions for instance families matching your specified requirements.

3. To view the details of each instance type within the suggested instance families, choose **View recommended instance family details**.

4. Select an instance type that meets your requirements, and then choose **Actions, Launch instance** or **Actions, Create launch template**.

   Alternatively, if you started the process in the launch instance wizard or the launch template page, and you prefer to go back to your original flow, make note of the instance type you’d like to use. Then, in the launch instance wizard or launch template, for **Instance type**, choose the instance type, and complete the procedure to launch an instance or create a launch template.
Get instance type recommendations for an existing workload

AWS Compute Optimizer provides Amazon EC2 instance recommendations to help you improve performance, save money, or both. You can use these recommendations to decide whether to move to a new instance type.

To make recommendations, Compute Optimizer analyzes your existing instance specifications and utilization metrics. The compiled data is then used to recommend which Amazon EC2 instance types are best able to handle the existing workload. Recommendations are returned along with per-hour instance pricing.

This topic outlines how to view recommendations through the Amazon EC2 console. For more information, see the AWS Compute Optimizer User Guide.
Note
To get recommendations from Compute Optimizer, you must first opt in to Compute Optimizer. For more information, see Getting Started with AWS Compute Optimizer in the AWS Compute Optimizer User Guide.

If you're looking for instance type recommendations for a new workload, use Amazon Q EC2 instance type selector. For more information, see Get instance type recommendations for a new workload.

Contents

- Limitations
- Findings
- View recommendations
- Considerations for evaluating recommendations
- Additional resources

Limitations

Compute Optimizer currently generates recommendations for C, D, H, I, M, R, T, X, and z instance types. Other instance types are not considered by Compute Optimizer. If you're using other instance types, they will not be listed in the Compute Optimizer recommendations view. For more information about the supported and unsupported instance types, see Amazon EC2 instance requirements in the AWS Compute Optimizer User Guide.

Findings

Compute Optimizer classifies its findings for EC2 instances as follows:

- **Under-provisioned** – An EC2 instance is considered under-provisioned when at least one specification of your instance, such as CPU, memory, or network, does not meet the performance requirements of your workload. Under-provisioned EC2 instances might lead to poor application performance.

- **Over-provisioned** – An EC2 instance is considered over-provisioned when at least one specification of your instance, such as CPU, memory, or network, can be sized down while still
meeting the performance requirements of your workload, and when no specification is under-provisioned. Over-provisioned EC2 instances might lead to unnecessary infrastructure cost.

- **Optimized** – An EC2 instance is considered optimized when all specifications of your instance, such as CPU, memory, and network, meet the performance requirements of your workload, and the instance is not over-provisioned. An optimized EC2 instance runs your workloads with optimal performance and infrastructure cost. For optimized instances, Compute Optimizer might sometimes recommend a new generation instance type.

- **None** – There are no recommendations for this instance. This might occur if you’ve been opted in to Compute Optimizer for less than 12 hours, or when the instance has been running for less than 30 hours, or when the instance type is not supported by Compute Optimizer. For more information, see [Limitations](#) in the previous section.

### View recommendations

After you opt in to Compute Optimizer, you can view the findings that Compute Optimizer generates for your EC2 instances in the EC2 console. You can then access the Compute Optimizer console to view the recommendations. If you recently opted in, findings might not be reflected in the EC2 console for up to 12 hours.

#### To view a recommendation for an EC2 instance through the EC2 console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**, and then choose the instance ID.
3. On the instance summary page, in the **AWS Compute Optimizer** banner near the bottom of the page, choose **View detail**.

The instance opens in Compute Optimizer, where it is labeled as the **Current** instance. Up to three different instance type recommendations, labeled **Option 1**, **Option 2**, and **Option 3**, are provided. The bottom half of the window shows recent CloudWatch metric data for the current instance: **CPU utilization**, **Memory utilization**, **Network in**, and **Network out**.

4. (Optional) In the Compute Optimizer console, choose settings to change the visible columns in the table, or to view the public pricing information for a different purchasing option for the current and recommended instance types.
Note

If you’ve purchased a Reserved Instance, your On-Demand Instance might be billed as a Reserved Instance. Before you change your current instance type, first evaluate the impact on Reserved Instance utilization and coverage.

Determine whether you want to use one of the recommendations. Decide whether to optimize for performance improvement, for cost reduction, or for a combination of the two. For more information, see Viewing Resource Recommendations in the AWS Compute Optimizer User Guide.

To view recommendations for all EC2 instances across all Regions through the Compute Optimizer console

2. Choose View recommendations for all EC2 instances.
3. You can perform the following actions on the recommendations page:
   a. To filter recommendations to one or more AWS Regions, enter the name of the Region in the Filter by one or more Regions text box, or choose one or more Regions in the drop-down list that appears.
   b. To view recommendations for resources in another account, choose Account, and then select a different account ID.

   This option is available only if you are signed in to a management account of an organization, and you opted in all member accounts within the organization.
   c. To clear the selected filters, choose Clear filters.
   d. To change the purchasing option that is displayed for the current and recommended instance types, choose settings ( ), and then choose On-Demand Instances, Reserved Instances, standard 1-year no upfront, or Reserved Instances, standard 3-year no upfront.
   e. To view details, such as additional recommendations and a comparison of utilization metrics, choose the finding (Under-provisioned, Over-provisioned, or Optimized) listed
next to the desired instance. For more information, see Viewing Resource Details in the AWS Compute Optimizer User Guide.

Considerations for evaluating recommendations

Before changing an instance type, consider the following:

• The recommendations don’t forecast your usage. Recommendations are based on your historical usage over the most recent 14-day time period. Be sure to choose an instance type that is expected to meet your future resource needs.

• Focus on the graphed metrics to determine whether actual usage is lower than instance capacity. You can also view metric data (average, peak, percentile) in CloudWatch to further evaluate your EC2 instance recommendations. For example, notice how CPU percentage metrics change during the day and whether there are peaks that need to be accommodated. For more information, see Viewing Available Metrics in the Amazon CloudWatch User Guide.

• Compute Optimizer might supply recommendations for burstable performance instances, which are T3, T3a, and T2 instances. If you periodically burst above the baseline, make sure that you can continue to do so based on the vCPUs of the new instance type. For more information, see Key concepts and definitions for burstable performance instances.

• If you’ve purchased a Reserved Instance, your On-Demand Instance might be billed as a Reserved Instance. Before you change your current instance type, first evaluate the impact on Reserved Instance utilization and coverage.

• Consider conversions to newer generation instances, where possible.

• When migrating to a different instance family, make sure the current instance type and the new instance type are compatible, for example, in terms of virtualization, architecture, or network type. For more information, see Compatibility for changing the instance type.

• Finally, consider the performance risk rating that's provided for each recommendation. Performance risk indicates the amount of effort you might need to spend in order to validate whether the recommended instance type meets the performance requirements of your workload. We also recommend rigorous load and performance testing before and after making any changes.

There are other considerations when resizing an EC2 instance. For more information, see Change the instance type.
Additional resources

For more information:

- [Amazon EC2 instance types](#)
- [AWS Compute Optimizer User Guide](#)

Change the instance type

As your needs change, you might find that your instance is over-utilized (the instance type is too small) or under-utilized (the instance type is too large). If this is the case, you can resize your instance by changing its instance type. For example, if your `t2.micro` instance is too small for its workload, you can increase its size by changing it to a bigger T2 instance type, such as `t2.large`. Or you can change it to another instance type, such as `m5.large`. You might also want to change from a previous generation to a current generation instance type to take advantage of some features, such as support for IPv6.

If you want a recommendation for an instance type that is best able to handle your existing workload, you can use AWS Compute Optimizer. For more information, see [Get instance type recommendations for an existing workload](#).

When you change the instance type, you'll start paying the rate of the new instance type. For the on-demand rates of all instance types, see [Amazon EC2 On-Demand Pricing](#).

To add additional storage to your instance without changing the instance type, add an EBS volume to the instance. For more information, see [Attach an Amazon EBS volume to an instance](#) in the [Amazon EBS User Guide](#).

Which instructions to follow?

There are different instructions for changing the instance type. The instructions to use depend on the instance's root volume, and whether the instance type is compatible with the instance's current configuration. For information about how compatibility is determined, see [Compatibility for changing the instance type](#).

Use the following table to determine which instructions to follow.
# Considerations for compatible instance types

Consider the following when changing the instance type of an existing instance:

- You must stop your Amazon EBS-backed instance before you can change its instance type. Ensure that you plan for downtime while your instance is stopped. Stopping the instance and changing its instance type might take a few minutes, and restarting your instance might take a variable amount of time depending on your application's startup scripts. For more information, see [Stop and start Amazon EC2 instances](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/stop-and-start-instances.html).

- When you stop and start an instance, we move the instance to new hardware. If your instance has a public IPv4 address, we release the address and give your instance a new public IPv4 address. If you require a public IPv4 address that does not change, use an [Elastic IP address](https://docs.aws.amazon.com/AmazonVPC/latest/userguide/EIP.html).

- You can't change the instance type of a Spot Instance.

- [Windows instances] We recommend that you update the AWS PV driver package before changing the instance type. For more information, see the section called “Upgrade PV drivers”.

- If your instance is in an Auto Scaling group, the Amazon EC2 Auto Scaling service marks the stopped instance as unhealthy, and may terminate it and launch a replacement instance. To prevent this, you can suspend the scaling processes for the group while you're changing the instance type. For more information, see [Suspending and resuming a process for an Auto Scaling group](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/suspending-auto-scaling-processes.html) in the [Amazon EC2 Auto Scaling User Guide](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/).  

- When you change the instance type of an instance with NVMe instance store volumes, the updated instance might have additional instance store volumes, because all NVMe instance store volumes are available even if they are not specified in the AMI or instance block device mapping. Otherwise, the updated instance has the same number of instance store volumes that you specified when you launched the original instance.

## Root volume | Compatibility | Use these instructions
--- | --- | ---
EBS | Compatible | [Change the instance type of an EBS-backed instance](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/stop-and-start-instances.html)
EBS | Not compatible | [Change the instance type by launching a new instance](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/stop-and-start-instances.html)
Instance store | Not applicable | [Change the instance type of an instance store-backed instance](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/stop-and-start-instances.html)
• The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. You can't change to an instance type or instance size that does not support the number of volumes that are already attached to your instance. For more information, see Amazon EBS volume limits for Amazon EC2 instances.

Change the instance type of an EBS-backed instance

Use the following instructions to change the instance type of an EBS-backed instance if the instance type that you need is compatible with the instance's current configuration.

To change the instance type of an Amazon EBS-backed instance

1. (Optional) If the new instance type requires drivers that are not installed on the existing instance, you must connect to your instance and install the drivers first. For more information, see Compatibility for changing the instance type.

2. [Windows instances] If you configured your Windows instance to use static IP addressing and you change from an instance type that doesn't support enhanced networking to an instance type that does support enhanced networking, you might get a warning about a potential IP address conflict when you reconfigure static IP addressing. To prevent this, enable DHCP on the network interface for your instance before you change the instance type. From your instance, open the Network and Sharing Center, open Internet Protocol Version 4 (TCP/IPv4) Properties for the network interface, and choose Obtain an IP address automatically. Change the instance type and reconfigure static IP addressing on the network interface.

3. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

4. In the navigation pane, choose Instances.

5. Select the instance and choose Instance state, Stop instance. When prompted for confirmation, choose Stop. It can take a few minutes for the instance to stop.

6. With the instance still selected, choose Actions, Instance settings, Change instance type. This option is grayed out if the instance state is not stopped.

7. On the Change instance type page, do the following:
   a. For Instance type, select the instance type that you want.

      If the instance type is not in the list, then it's not compatible with the configuration of your instance. Instead, use the following instructions: Change the instance type by launching a new instance.
b. (Optional) If the instance type that you selected supports EBS optimization, select **EBS-optimized** to enable EBS optimization, or deselect **EBS-optimized** to disable EBS optimization. If the instance type that you selected is EBS optimized by default, **EBS-optimized** is selected and you can't deselect it.

c. Choose **Apply** to accept the new settings.

8. To start the instance, select the instance and choose **Instance state, Start instance**. It can take a few minutes for the instance to enter the *running* state. If your instance won't start, see [Troubleshoot changing the instance type](#).

9. [Windows instances] If your instance runs Windows Server 2016 or Windows Server 2019 with EC2Launch v1, connect to your Windows instance and run the following EC2Launch PowerShell script to configure the instance after the instance type is changed.

```powershell
PS C:\> C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeInstance.ps1 -Schedule
```

### Important

The administrator password will reset when you enable the initialize instance EC2 Launch script. You can modify the configuration file to disable the administrator password reset by specifying it in the settings for the initialization tasks. For steps on how to disable password reset, see [Configure initialization tasks](#) (EC2Launch) or [Change settings](#) (EC2Launch v2).

---

**Change the instance type by launching a new instance**

If the current configuration of your EBS-backed instance is incompatible with the new instance type that you want, then you can't change the instance type of the original instance. Instead, you must launch a new instance with a configuration that is compatible with the new instance type that you want, and then migrate your application to the new instance. For example, if you launched your original instance from a PV AMI, but want to change to a current generation instance type that requires an HVM AMI, you'll need to launch a new instance from an HVM AMI. For information about how compatibility is determined, see [Compatibility for changing the instance type](#).

To migrate your application to a new instance, do the following:
• Back up the data on your original instance.

• Launch a new instance with a configuration that is compatible with the new instance type that you want, and attach any EBS volumes that were attached to your original instance.

• Install your application and any software on your new instance.

• Restore any data.

• If your original instance has an Elastic IP address, and you want to ensure that your users can continue uninterrupted to use the applications on your new instance, you must associate the Elastic IP address with your new instance. For more information, see Elastic IP address.

To change the instance type for a new instance configuration

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. Back up data that you need to keep, as follows:

   • For data on your instance store volumes, back up the data to persistent storage.
   • For data on your EBS volumes, create a snapshot of the volumes or detach the volumes from the instance so that you can attach them to the new instance later.

3. In the navigation pane, choose Instances.

4. Choose Launch instances. When you configure the instance, do the following:

   a. Select an AMI that will support the instance type that you want. Note that current generation instance types require an HVM AMI.

   b. Select the new instance type that you want. If the instance type that you want isn't available, then it's not compatible with the configuration of the AMI that you selected.

   c. If you're using an Elastic IP address, select the VPC that the original instance is currently running in.

   d. If you want to allow the same traffic to reach the new instance, select the security group that is associated with the original instance.

   e. When you're done configuring your new instance, complete the steps to select a key pair and launch your instance. It can take a few minutes for the instance to enter the running state.

5. If required, attach any new EBS volumes based on the snapshots that you created, or any EBS volumes that you detached from the original instance, to the new instance.

6. Install your application and any required software on the new instance.
7. Restore any data that you backed up from the instance store volumes of the original instance.

8. If you are using an Elastic IP address, assign it to the new instance as follows:

   a. In the navigation pane, choose **Elastic IPs**.

   b. Select the Elastic IP address that is associated with the original instance and choose **Actions, Disassociate Elastic IP address**. When prompted for confirmation, choose **Disassociate**.

   c. With the Elastic IP address still selected, choose **Actions, Associate Elastic IP address**.

   d. For **Resource type**, choose **Instance**.

   e. For **Instance**, choose the new instance with which to associate the Elastic IP address.

   f. (Optional) For **Private IP address**, specify a private IP address with which to associate the Elastic IP address.

   g. Choose **Associate**.

9. (Optional) You can terminate the original instance if it's no longer needed. Select the instance, verify that you are about to terminate the original instance and not the new instance (for example, check the name or launch time), and then choose **Instance state, Terminate instance**.

**Compatibility for changing the instance type**

You can change the instance type only if the instance's current configuration is compatible with the instance type that you want. If the instance type that you want is not compatible with the instance's current configuration, you must launch a new instance with a configuration that is compatible with the instance type, and then migrate your application to the new instance.

[Linux instances] You can use the **AWSSupport-MigrateXenToNitroLinux runbook** to migrate compatible Linux instances from a Xen instance type to a Nitro instance type. For more information, see **AWSSupport-MigrateXenToNitroLinux runbook** in the **AWS Systems Manager Automation runbook reference**.

[Windows instances] For additional guidance on migrating compatible Windows instances from a Xen instance type to a Nitro instance type, see **Migrate to latest generation instance types**.

Compatibility is determined in the following ways:
Virtualization type

Linux AMIs use one of two types of virtualization: paravirtual (PV) or hardware virtual machine (HVM). If an instance was launched from a PV AMI, you can't change to an instance type that is HVM only. For more information, see AMI virtualization types. To check the virtualization type of your instance, check the Virtualization value on the details pane of the Instances screen in the Amazon EC2 console.

Architecture

AMIs are specific to the architecture of the processor, so you must select an instance type with the same processor architecture as the current instance type. For example:

- If the current instance type has a processor based on the Arm architecture, you are limited to the instance types that support a processor based on the Arm architecture, such as C6g and M6g.
- The following instance types are the only instance types that support 32-bit AMIs: t2.nano, t2.micro, t2.small, t2.medium, c3.large, t1.micro, m1.small, m1.medium, and c1.medium. If you are changing the instance type of a 32-bit instance, you are limited to these instance types.

Network adapters

If you switch from a driver for one network adapter to another, the network adapter settings are reset when the operating system creates the new adapter. To reconfigure the settings, you might need access to a local account with administrator permissions. The following are examples of moving from one network adapter to another:

- AWS PV (T2 instances) to Intel 82599 VF (M4 instances)
- Intel 82599 VF (most M4 instances) to ENA (M5 instances)
- ENA (M5 instances) to high-bandwidth ENA (M5n instances)

Network cards

Some instance types support multiple network cards. You must select an instance type that supports the same number of network cards as the current instance type.

Enhanced networking

Instance types that support enhanced networking require the necessary drivers installed. For example, instances built on the AWS Nitro System require EBS-backed AMIs with the Elastic Network Adapter (ENA) drivers installed. To change from an instance type that does not support
enhanced networking to an instance type that supports enhanced networking, you must install the ENA drivers or ixgbevf drivers on the instance, as appropriate.

**Note**

When you resize an instance with ENA Express enabled, the new instance type must also support ENA Express. For a list of instance types that support ENA Express, see Supported instance types for ENA Express.

To change from an instance type that supports ENA Express to an instance type that does not support it, ensure that ENA Express is not currently enabled before you resize the instance.

**NVMe**

EBS volumes are exposed as NVMe block devices on instances built on the AWS Nitro System. If you change from an instance type that does not support NVMe to an instance type that supports NVMe, you must first install the NVMe drivers on your instance. Also, the device names for devices that you specify in the block device mapping are renamed using NVMe device names (/dev/nvme[0-26]n1).

[Linux instances] Therefore, to mount file systems at boot time using /etc/fstab, you must use UUID/Label instead of device names.

**Volumes limits**

The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. For more information, see Amazon EBS volume limits for Amazon EC2 instances.

You can only change to an instance type or instance size that supports the same number or a larger number of volumes than is currently attached to the instance. If you change to an instance type or instance size that does not support the number of currently attached volumes, the request fails. For example, if you change from an m7i.4xlarge instance with 32 attached volumes to an m6i.4xlarge, which supports a maximum of 27 volumes, the request fails.

**Troubleshoot changing the instance type**

Use the following information to help diagnose and fix issues that you might encounter when changing the instance type.
Instance won't start after changing instance type

Possible cause: Requirements for new instance type not met

If your instance won't boot, it is possible that one of the requirements for the new instance type was not met. For more information, see Why is my Linux instance not booting after I changed its type?

Possible cause: AMI does not support instance type

If you use the EC2 console to change the instance type, only the instance types that are supported by the selected AMI are available. However, if you use the AWS CLI to launch an instance, you can specify an incompatible AMI and instance type. If the AMI and instance type are incompatible, the instance can't start. For more information, see Compatibility for changing the instance type.

Possible cause: Instance is in cluster placement group

If your instance is in a cluster placement group and, after changing the instance type, the instance fails to start, try the following:

1. Stop all the instances in the cluster placement group.
2. Change the instance type of the affected instance.
3. Start all the instances in the cluster placement group.

Application or website not reachable from the internet after changing instance type

Possible cause: Public IPv4 address is released

When you change the instance type, you must first stop the instance. When you stop an instance, we release the public IPv4 address and give your instance a new public IPv4 address.

To retain the public IPv4 address between instance stops and starts, we recommend that you use an Elastic IP address, at no extra cost provided your instance is running. For more information, see Elastic IP addresses.

Change the instance type of an instance store-backed instance

An instance store-backed instance is an instance that has an instance store root volume. You can't change the instance type of an instance that has an instance store root volume. Instead, you must create an AMI from your instance, launch a new instance from this AMI and select the instance
type that you want, and then migrate your application to the new instance. Note that the instance type that you want must be compatible with the AMI you create. For information about how compatibility is determined, see Compatibility for changing the instance type.

Process overview

- Back up the data on your original instance.
- Create an AMI from your original instance.
- Launch a new instance from this AMI and select the instance type that you want.
- Install your application on the new instance.
- If your original instance has an Elastic IP address, and you want to ensure that your users can continue uninterrupted to use the applications on your new instance, you must associate the Elastic IP address with your new instance. For more information, see Elastic IP address.

To change the instance type of an instance store-backed instance

1. Back up data that you need to keep, as follows:
   - For data on your instance store volumes, back up the data to persistent storage.
   - For data on your EBS volumes, create a snapshot of the volumes or detach the volume from the instance so that you can attach it to the new instance later.
2. Create an AMI from your instance by satisfying the prerequisites and following the procedures in Create an instance store-backed Linux AMI. When you are finished creating an AMI from your instance, return to this procedure.
3. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
4. In the navigation pane, choose AMIs. From the filter lists, choose Owned by me, and select the image that you created in Step 2. Notice that AMI name is the name that you specified when you registered the image and Source is your Amazon S3 bucket.

   📌 Note

   If you do not see the AMI that you created in Step 2, make sure that you have selected the Region in which you created your AMI.

5. With the AMI selected, choose Launch instance from image. When you configure the instance, do the following:
a. Select the new instance type that you want. If the instance type that you want isn't available, then it's not compatible with the configuration of the AMI that you created. For more information, see [Compatibility for changing the instance type](#).

b. If you're using an Elastic IP address, select the VPC that the original instance is currently running in.

c. If you want to allow the same traffic to reach the new instance, select the security group that is associated with the original instance.

d. When you're done configuring your new instance, complete the steps to select a key pair and launch your instance. It can take a few minutes for the instance to enter the running state.

6. If required, attach any new EBS volumes based on the snapshots that you created, or any EBS volumes that you detached from the original instance, to the new instance.

7. Install your application and any required software on the new instance.

8. If you are using an Elastic IP address, assign it to the new instance as follows:

   a. In the navigation pane, choose **Elastic IPs**.

   b. Select the Elastic IP address that is associated with the original instance and choose **Actions, Disassociate Elastic IP address**. When prompted for confirmation, choose **Disassociate**.

   c. With the Elastic IP address still selected, choose **Actions, Associate Elastic IP address**.

   d. For **Resource type**, choose **Instance**.

   e. For **Instance**, choose the new instance with which to associate the Elastic IP address.

   f. (Optional) For **Private IP address**, specify a private IP address with which to associate the Elastic IP address.

   g. Choose **Associate**.

9. (Optional) You can terminate the original instance if it's no longer needed. Select the instance, verify that you are about to terminate the original instance and not the new instance (for example, check the name or launch time), and then choose **Instance state, Terminate instance**.
Many general purpose workloads are on average not busy, and do not require a high level of sustained CPU performance. The following graph illustrates the CPU utilization for many common workloads that customers run in the AWS Cloud today.

These low-to-moderate CPU utilization workloads lead to wastage of CPU cycles and, as a result, you pay for more than you use. To overcome this, you can leverage the low-cost burstable general purpose instances, which are the T instances.

The T instance family provides a baseline CPU performance with the ability to burst above the baseline at any time for as long as required. The baseline CPU is defined to meet the needs of the majority of general purpose workloads, including large-scale micro-services, web servers, small and medium databases, data logging, code repositories, virtual desktops, development and test environments, and business-critical applications. The T instances offer a balance of compute, memory, and network resources, and provide you with the most cost-effective way to run a broad spectrum of general purpose applications that have a low-to-moderate CPU usage. They can save you up to 15% in costs when compared to M instances, and can lead to even more cost savings with smaller, more economical instance sizes, offering as low as 2 vCPUs and 0.5 GiB of memory.
The smaller T instance sizes, such as nano, micro, small, and medium, are well suited for workloads that need a small amount of memory and do not expect high CPU usage.

Note
This topic describes burstable CPU. For information about burstable network performance, see Amazon EC2 instance network bandwidth.

EC2 burstable instance types

The EC2 burstable instances consist of T4g, T3a and T3 instance types, and the previous generation T2 instance types.

The T4g instance types are the latest generation of burstable instances. They provide the best price for performance, and provide you with the lowest cost of all the EC2 instance types. The T4g instance types are powered by Arm-based AWS Graviton2 processors with extensive ecosystem support from operating systems vendors, independent software vendors, and popular AWS services and applications.

The following table summarizes the key differences between the burstable instance types.

<table>
<thead>
<tr>

For information about instance pricing and additional specifications, see [Amazon EC2 Pricing](https://aws.amazon.com/ec2/pricing/) and [Amazon EC2 Instance Types](https://aws.amazon.com/ec2/instance-types/). For information about burstable network performance, see [Amazon EC2 instance network bandwidth](https://aws.amazon.com/ec2/network-performance/).

If your account is less than 12 months old, you can use a `t2.micro` instance for free (or a `t3.micro` instance in Regions where `t2.micro` is unavailable) within certain usage limits. For more information, see [AWS Free Tier](https://aws.amazon.com/free/).

**Supported purchasing options for T instances**

- On-Demand Instances
- Reserved Instances
- Dedicated Instances (T3 only)
- Dedicated Hosts (T3 only, in standard mode only)
- Spot Instances

For more information, see [Instance purchasing options](https://aws.amazon.com/ec2/purchasing-options/).

Best practices

Follow these best practices to get the maximum benefit from burstable performance instances.

- Ensure that the instance size you choose passes the minimum memory requirements of your operating system and applications. Operating systems with graphical user interfaces that consume significant memory and CPU resources (for example, Windows) might require a t3.micro or larger instance size for many use cases. As the memory and CPU requirements of your workload grow over time, you have the flexibility with the T instances to scale to larger instance sizes of the same instance type, or to select another instance type.

- Enable AWS Compute Optimizer for your account and review the Compute Optimizer recommendations for your workload. Compute Optimizer can help assess whether instances should be upsized to improve performance or downsized for cost savings. Compute Optimizer may also recommend a different instance type based on your scenario. For more information, see Viewing EC2 instance recommendations in the AWS Compute Optimizer User Guide.

Key concepts and definitions for burstable performance instances

Traditional Amazon EC2 instance types provide fixed CPU resources, while burstable performance instances provide a baseline level of CPU utilization with the ability to burst CPU utilization above the baseline level. This ensures that you pay only for baseline CPU plus any additional burst CPU usage resulting in lower compute costs. The baseline utilization and ability to burst are governed by CPU credits. Burstable performance instances are the only instance types that use credits for CPU usage.

Each burstable performance instance continuously earns credits when it stays below the CPU baseline, and continuously spends credits when it bursts above the baseline. The amount of credits earned or spent depends on the CPU utilization of the instance:

- If the CPU utilization is below baseline, then credits earned are greater than credits spent.
- If the CPU utilization is equal to baseline, then credits earned are equal to credits spent.
- If the CPU utilization is higher than baseline, then credits spent are higher than credits earned.

When the credits earned are greater than credits spent, then the difference is called accrued credits, which can be used later to burst above baseline CPU utilization. Similarly, when the credits spent are more than credits earned, then the instance behavior depends on the credit configuration mode—Standard mode or Unlimited mode.
In Standard mode, when credits spent are more than credits earned, the instance uses the accrued credits to burst above baseline CPU utilization. If there are no accrued credits remaining, then the instance gradually comes down to baseline CPU utilization and cannot burst above baseline until it accrues more credits.

In Unlimited mode, if the instance bursts above baseline CPU utilization, then the instance first uses the accrued credits to burst. If there are no accrued credits remaining, then the instance spends surplus credits to burst. When its CPU utilization falls below the baseline, it uses the CPU credits that it earns to pay down the surplus credits that it spent earlier. The ability to earn CPU credits to pay down surplus credits enables Amazon EC2 to average the CPU utilization of an instance over a 24-hour period. If the average CPU usage over a 24-hour period exceeds the baseline, the instance is billed for the additional usage at a flat additional rate per vCPU-hour.

Key concepts and definitions

The following key concepts and definitions are applicable to burstable performance instances.

CPU utilization

CPU utilization is the percentage of allocated EC2 compute units that are currently in use on the instance. This metric measures the percentage of allocated CPU cycles that are being utilized on an instance. The CPU Utilization CloudWatch metric shows CPU usage per instance and not CPU usage per core. The baseline CPU specification of an instance is also based on the CPU usage per instance. To measure CPU utilization using the AWS Management Console or the AWS CLI, see Get statistics for a specific instance.

CPU credit

A unit of vCPU-time.
Examples:

1 CPU credit = 1 vCPU * 100% utilization * 1 minute.

1 CPU credit = 1 vCPU * 50% utilization * 2 minutes

1 CPU credit = 2 vCPU * 25% utilization * 2 minutes

Baseline utilization

The baseline utilization is the level at which the CPU can be utilized for a net credit balance of zero, when the number of CPU credits being earned matches the number of CPU credits being used. Baseline utilization is also known as the baseline. Baseline utilization is expressed as a percentage of vCPU utilization, which is calculated as follows: Baseline utilization % = (number of credits earned/number of vCPUs)/60 minutes.

For the baseline utilization of each burstable performance instance type, see the credit table.

Earned credits

Credits earned continuously by an instance when it is running.

Number of credits earned per hour = % baseline utilization * number of vCPUs * 60 minutes

Example:

A t3.nano with 2 vCPUs and a baseline utilization of 5% earns 6 credits per hour, calculated as follows:

2 vCPUs * 5% baseline * 60 minutes = 6 credits per hour

Spent or used credits

Credits used continuously by an instance when it is running.

CPU credits spent per minute = Number of vCPUs * CPU utilization * 1 minute

Accrued credits

Unspent CPU credits when an instance uses fewer credits than is required for baseline utilization. In other words, accrued credits = (Earned credits – Used credits) below baseline.

Example:
If a t3.nano is running at 2% CPU utilization, which is below its baseline of 5% for an hour, the accrued credits is calculated as follows:

Accrued CPU credits = (Earned credits per hour – Used credits per hour) = 6 – 2 vCPUs * 2% CPU utilization * 60 minutes = 6 – 2.4 = 3.6 accrued credits per hour

Credit accrual limit

Depends on the instance size but in general is equal to the number of maximum credits earned in 24 hours.

Example:

For t3.nano, the credit accrual limit = 24 * 6 = 144 credits

Launch credits

Only applicable for T2 instances configured for Standard mode. Launch credits are a limited number of CPU credits that are allocated to a new T2 instance so that, when launched in Standard mode, it can burst above the baseline.

Surplus credits

Credits that are spent by an instance after it depletes its accrued credit balance. The surplus credits are designed for burstable instances to sustain high performance for an extended period of time, and are only used in Unlimited mode. The surplus credits balance is used to determine how many credits were used by the instance for bursting in Unlimited mode.

Standard mode

Credit configuration mode, which allows an instance to burst above the baseline by spending credits it has accrued in its credit balance.

Unlimited mode

Credit configuration mode, which allows an instance to burst above the baseline by sustaining high CPU utilization for any period of time whenever required. The hourly instance price automatically covers all CPU usage spikes if the average CPU utilization of the instance is at or below the baseline over a rolling 24-hour period or the instance lifetime, whichever is shorter. If the instance runs at higher CPU utilization for a prolonged period, it can do so for a flat additional rate per vCPU-hour.

The following table summarizes the key credit differences between the burstable instance types.
<table>
<thead>
<tr>
<th>Type</th>
<th>Type of CPU credits supported</th>
<th>Credit configuration modes</th>
<th>Accrued CPU credits lifespan between instance starts and stops</th>
</tr>

<td>Earned credits, Accrued credits, Spent credits, Launch credits (Standard mode only), Surplus credits (Unlimited mode only)</td>
<td>Standard (default), Unlimited</td>
<td>0 days (credits are lost when an instance stops)</td>
</tr>
</tbody>
</table>
Note
Unlimited mode is not supported for T3 instances that are launched on a Dedicated Host.

Earn CPU credits

Each burstable performance instance continuously earns (at a millisecond-level resolution) a set rate of CPU credits per hour, depending on the instance size. The accounting process for whether credits are accrued or spent also happens at a millisecond-level resolution, so you don't have to worry about overspending CPU credits; a short burst of CPU uses a small fraction of a CPU credit.

If a burstable performance instance uses fewer CPU resources than is required for baseline utilization (such as when it is idle), the unspent CPU credits are accrued in the CPU credit balance. If a burstable performance instance needs to burst above the baseline utilization level, it spends the accrued credits. The more credits that a burstable performance instance has accrued, the more time it can burst beyond its baseline when more CPU utilization is needed.

The following table lists the burstable performance instance types, the rate at which CPU credits are earned per hour, the maximum number of earned CPU credits that an instance can accrue, the number of vCPUs per instance, and the baseline utilization as a percentage of a full core (using a single vCPU).

</tr>
</tbody>
</table>

* The number of credits that can be accrued is equivalent to the number of credits that can be earned in a 24-hour period.

** The percentage baseline utilization in the table is per vCPU. In CloudWatch, CPU utilization is shown per vCPU. For example, the CPU utilization for a t3.large instance operating at the baseline level is shown as 30% in CloudWatch CPU metrics. For information about how to calculate the baseline utilization, see [Baseline utilization](#).

*** Each vCPU is a thread of either an Intel Xeon core or an AMD EPYC core, except for T2 and T4g instances.

### CPU credit earn rate

The number of CPU credits earned per hour is determined by the instance size. For example, a t3.nano earns six credits per hour, while a t3.small earns 24 credits per hour. The preceding table lists the credit earn rate for all instances.
CPU credit accrual limit

While earned credits never expire on a running instance, there is a limit to the number of earned credits that an instance can accrue. The limit is determined by the CPU credit balance limit. After the limit is reached, any new credits that are earned are discarded, as indicated by the following image. The full bucket indicates the CPU credit balance limit, and the spillover indicates the newly earned earned credits that exceed the limit.

The CPU credit balance limit differs for each instance size. For example, a t3.micro instance can accrue a maximum of 288 earned CPU credits in the CPU credit balance. The preceding table lists the maximum number of earned credits that each instance can accrue.

T2 Standard instances also earn launch credits. Launch credits do not count towards the CPU credit balance limit. If a T2 instance has not spent its launch credits, and remains idle over a 24-hour period while accruing earned credits, its CPU credit balance appears as over the limit. For more information, see Launch credits.

T4g, T3a and T3 instances do not earn launch credits. These instances launch as unlimited by default, and therefore can burst immediately upon start without any launch credits. T3 instances launched on a Dedicated Host launch as standard by default; unlimited mode is not supported for T3 instances on a Dedicated Host.
Accrued CPU credits life span

CPU credits on a running instance do not expire.

For T2, the CPU credit balance does not persist between instance stops and starts. If you stop a T2 instance, the instance loses all its accrued credits.

For T4g, T3a and T3, the CPU credit balance persists for seven days after an instance stops and the credits are lost thereafter. If you start the instance within seven days, no credits are lost.

For more information, see CPUCreditBalance in the CloudWatch metrics table.

Baseline utilization

The baseline utilization is the level at which the CPU can be utilized for a net credit balance of zero, when the number of CPU credits being earned matches the number of CPU credits being used. Baseline utilization is also known as the baseline.

Baseline utilization is expressed as a percentage of vCPU utilization, which is calculated as follows:

\[(\text{number of credits earned/number of vCPUs})/60 \text{ minutes} = \% \text{ baseline utilization}\]

For example, a t3.nano instance, with 2 vCPUs, earns 6 credits per hour, resulting in a baseline utilization of 5%, which is calculated as follows:

\[(6 \text{ credits earned/2 vCPUs})/60 \text{ minutes} = 5\% \text{ baseline utilization}\]

A t3.large instance, with 2 vCPUs, earns 36 credits per hour, resulting in a baseline utilization of 30% ((36/2)/60).

The following graph provides an example of a t3.large with an average CPU utilization below the baseline.
Unlimited mode for burstable performance instances

A burstable performance instance configured as unlimited can sustain high CPU utilization for any period of time whenever required. The hourly instance price automatically covers all CPU usage spikes if the average CPU utilization of the instance is at or below the baseline over a rolling 24-hour period or the instance lifetime, whichever is shorter.

For the vast majority of general-purpose workloads, instances configured as unlimited provide ample performance without any additional charges. If the instance runs at higher CPU utilization for a prolonged period, it can do so for a flat additional rate per vCPU-hour. For information about pricing, see Amazon EC2 pricing and T2/T3/T4 Unlimited Mode Pricing.

If you use a t2.micro or t3.micro instance under the AWS Free Tier offer and use it in unlimited mode, charges might apply if your average utilization over a rolling 24-hour period exceeds the baseline utilization of the instance.

T4g, T3a and T3 instances launch as unlimited by default (unless you change the default). If the average CPU usage over a 24-hour period exceeds the baseline, you incur charges for surplus credits. If you launch Spot Instances as unlimited and plan to use them immediately and for a short duration, with no idle time for accruing CPU credits, you incur charges for surplus credits. We recommend that you launch your Spot Instances in standard mode to avoid paying higher costs. For more information, see Surplus credits can incur charges and Burstable performance instances.
Note

T3 instances launched on a Dedicated Host launch as standard by default; unlimited mode is not supported for T3 instances on a Dedicated Host.

Unlimited mode concepts

The unlimited mode is a credit configuration option for burstable performance instances. It can be enabled or disabled at any time for a running or stopped instance. You can set unlimited as the default credit option at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option.

How Unlimited burstable performance instances work

If a burstable performance instance configured as unlimited depletes its CPU credit balance, it can spend surplus credits to burst beyond the baseline. When its CPU utilization falls below the baseline, it uses the CPU credits that it earns to pay down the surplus credits that it spent earlier. The ability to earn CPU credits to pay down surplus credits enables Amazon EC2 to average the CPU utilization of an instance over a 24-hour period. If the average CPU usage over a 24-hour
period exceeds the baseline, the instance is billed for the additional usage at a flat additional rate per vCPU-hour.

The following graph shows the CPU usage of a t3.large. The baseline CPU utilization for a t3.large is 30%. If the instance runs at 30% CPU utilization or less on average over a 24-hour period, there is no additional charge because the cost is already covered by the instance hourly price. However, if the instance runs at 40% CPU utilization on average over a 24-hour period, as shown in the graph, the instance is billed for the additional 10% CPU usage at a flat additional rate per vCPU-hour.

For more information about the baseline utilization per vCPU for each instance type and how many credits each instance type earns, see the credit table.

**When to use unlimited mode versus fixed CPU**

When determining whether you should use a burstable performance instance in unlimited mode, such as T3, or a fixed performance instance, such as M5, you need to determine the breakeven CPU usage. The breakeven CPU usage for a burstable performance instance is the point at which a burstable performance instance costs the same as a fixed performance instance. The breakeven CPU usage helps you determine the following:

- If the average CPU usage over a 24-hour period is at or below the breakeven CPU usage, use a burstable performance instance in unlimited mode so that you can benefit from the lower price of a burstable performance instance while getting the same performance as a fixed performance instance.
If the average CPU usage over a 24-hour period is above the breakeven CPU usage, the burstable performance instance will cost more than the equivalently-sized fixed performance instance. If a T3 instance continuously bursts at 100% CPU, you end up paying approximately 1.5 times the price of an equivalently-sized M5 instance.

The following graph shows the breakeven CPU usage point where a \( t3.\text{large} \) costs the same as an \( m5.\text{large} \). The breakeven CPU usage point for a \( t3.\text{large} \) is 42.5%. If the average CPU usage is at 42.5%, the cost of running the \( t3.\text{large} \) is the same as an \( m5.\text{large} \), and is more expensive if the average CPU usage is above 42.5%. If the workload needs less than 42.5% average CPU usage, you can benefit from the lower price of the \( t3.\text{large} \) while getting the same performance as an \( m5.\text{large} \).

The following table shows how to calculate the breakeven CPU usage threshold so that you can determine when it's less expensive to use a burstable performance instance in unlimited mode or a fixed performance instance. The columns in the table are labeled A through K.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>vCPUs</th>
<th>T3 price*/hour</th>
<th>M5 price*/hour</th>
<th>Price difference</th>
<th>Baseline utilization per vCPU (%)</th>
<th>Charge per vCPU hour for surplus credits</th>
<th>Charge per vCPU minute available</th>
<th>Additional burst minutes available per vCPU</th>
<th>Breakeven CPU %</th>
<th>CPU %</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
<td>D</td>
<td>E = D - C</td>
<td>F</td>
<td>G</td>
<td>H = G / 60</td>
<td>I = (E / H)</td>
<td>J = (I / F) + J</td>
<td>K =</td>
</tr>
</tbody>
</table>
The table provides the following information:

- Column A shows the instance type, `t3.large`.
- Column B shows the number of vCPUs for the `t3.large`.
- Column C shows the price of a `t3.large` per hour.
- Column D shows the price of an `m5.large` per hour.
- Column E shows the price difference between the `t3.large` and the `m5.large`.
- Column F shows the baseline utilization per vCPU of the `t3.large`, which is 30%. At the baseline, the hourly cost of the instance covers the cost of the CPU usage.
- Column G shows the flat additional rate per vCPU-hour that an instance is charged if it bursts at 100% CPU after it has depleted its earned credits.
- Column H shows the flat additional rate per vCPU-minute that an instance is charged if it bursts at 100% CPU after it has depleted its earned credits.
- Column I shows the number of additional minutes that the `t3.large` can burst per hour at 100% CPU while paying the same price per hour as an `m5.large`.
- Column J shows the additional CPU usage (in %) over baseline that the instance can burst while paying the same price per hour as an `m5.large`.

* Price is based on us-east-1 and Linux OS.
• Column K shows the breakeven CPU usage (in %) that the t3.large can burst without paying more than the m5.large. Anything above this, and the t3.large costs more than the m5.large.

The following table shows the breakeven CPU usage (in %) for T3 instance types compared to the similarly-sized M5 instance types.

<table>
<thead>
<tr>
<th>T3 instance type</th>
<th>Breakeven CPU usage (in %) for T3 compared to M5</th>
</tr>

</tr>
</tbody>
</table>

**Surplus credits can incur charges**

If the average CPU utilization of an instance is at or below the baseline, the instance incurs no additional charges. Because an instance earns a maximum number of credits in a 24-hour period (for example, a t3.micro instance can earn a maximum of 288 credits in a 24-hour period), it can spend surplus credits up to that maximum without being charged.

However, if CPU utilization stays above the baseline, the instance cannot earn enough credits to pay down the surplus credits that it has spent. The surplus credits that are not paid down are charged at a flat additional rate per vCPU-hour. For information about the rate, see [T2/T3/T4g Unlimited Mode Pricing](#).

Surplus credits that were spent earlier are charged when any of the following occurs:

• The spent surplus credits exceed the maximum number of credits the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour.

• The instance is stopped or terminated.

• The instance is switched from unlimited to standard.
Spent surplus credits are tracked by the CloudWatch metric `CPUSurplusCreditBalance`. Surplus credits that are charged are tracked by the CloudWatch metric `CPUSurplusCreditsCharged`. For more information, see [Additional CloudWatch metrics for burstable performance instances](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/burstable-performance-platform.html).

**No launch credits for T2 Unlimited instances**

T2 Standard instances receive [launch credits](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/burstable-performance-platform.html), but T2 Unlimited instances do not. A T2 Unlimited instance can burst beyond the baseline at any time with no additional charge, as long as its average CPU utilization is at or below the baseline over a rolling 24-hour window or its lifetime, whichever is shorter. As such, T2 Unlimited instances do not require launch credits to achieve high performance immediately after launch.

If a T2 instance is switched from standard to unlimited, any accrued launch credits are removed from the `CPUCreditBalance` before the remaining `CPUCreditBalance` is carried over.

T4g, T3a and T3 instances never receive launch credits because they support Unlimited mode. The Unlimited mode credit configuration enables T4g, T3a and T3 instances to use as much CPU as needed to burst beyond baseline and for as long as needed.

**Enable unlimited mode**

You can switch from unlimited to standard, and from standard to unlimited, at any time on a running or stopped instance. For more information, see [Launch a burstable performance instance as Unlimited or Standard](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/burstable-performance-platform.html) and [Modify the credit specification of a burstable performance instance](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/burstable-performance-platform.html).

You can set unlimited as the default credit option at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option. For more information, see [Set the default credit specification for the account](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/burstable-performance-platform.html).

You can check whether your burstable performance instance is configured as unlimited or standard using the Amazon EC2 console or the AWS CLI. For more information, see [View the credit specification of a burstable performance instance](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/burstable-performance-platform.html) and [View the default credit specification](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/burstable-performance-platform.html).

**What happens to credits when switching between Unlimited and Standard**

`CPUCreditBalance` is a CloudWatch metric that tracks the number of credits accrued by an instance. `CPUSurplusCreditBalance` is a CloudWatch metric that tracks the number of surplus credits spent by an instance.

When you change an instance configured as unlimited to standard, the following occurs:
• The CPUCreditBalance value remains unchanged and is carried over.
• The CPUSurplusCreditBalance value is immediately charged.

When a standard instance is switched to unlimited, the following occurs:

• The CPUCreditBalance value containing accrued earned credits is carried over.
• For T2 Standard instances, any launch credits are removed from the CPUCreditBalance value, and the remaining CPUCreditBalance value containing accrued earned credits is carried over.

**Monitor credit usage**

To see if your instance is spending more credits than the baseline provides, you can use CloudWatch metrics to track usage, and you can set up hourly alarms to be notified of credit usage. For more information, see [Monitor your CPU credits for burstable performance instances](#).

**Unlimited mode examples**

The following examples explain credit use for instances that are configured as unlimited.

**Examples**

• [Example 1: Explain credit use with T3 Unlimited](#)
• [Example 2: Explain credit use with T2 Unlimited](#)

**Example 1: Explain credit use with T3 Unlimited**

In this example, you see the CPU utilization of a `t3.nano` instance launched as unlimited, and how it spends *earned* and *surplus* credits to sustain CPU utilization.

A `t3.nano` instance earns 144 CPU credits over a rolling 24-hour period, which it can redeem for 144 minutes of vCPU use. When it depletes its CPU credit balance (represented by the CloudWatch metric CPUCreditBalance), it can spend surplus CPU credits—that it has *not yet earned*—to burst for as long as it needs. Because a `t3.nano` instance earns a maximum of 144 credits in a 24-hour period, it can spend surplus credits up to that maximum without being charged immediately. If it spends more than 144 CPU credits, it is charged for the difference at the end of the hour.

The intent of the example, illustrated by the following graph, is to show how an instance can burst using surplus credits even after it depletes its CPUCreditBalance. The following workflow references the numbered points on the graph:
P1 – At 0 hours on the graph, the instance is launched as unlimited and immediately begins to earn credits. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. For the first 24 hours, CPUCreditUsage is at 0, and the CPUCreditBalance value reaches its maximum of 144.

P2 – For the next 12 hours, CPU utilization is at 2.5%, which is below the 5% baseline. The instance earns more credits than it spends, but the CPUCreditBalance value cannot exceed its maximum of 144 credits.

P3 – For the next 24 hours, CPU utilization is at 7% (above the baseline), which requires a spend of 57.6 credits. The instance spends more credits than it earns, and the CPUCreditBalance value reduces to 86.4 credits.

P4 – For the next 12 hours, CPU utilization decreases to 2.5% (below the baseline), which requires a spend of 36 credits. In the same time, the instance earns 72 credits. The instance earns more credits than it spends, and the CPUCreditBalance value increases to 122 credits.

P5 – For the next 5 hours, the instance bursts at 100% CPU utilization, and spends a total of 570 credits to sustain the burst. About an hour into this period, the instance depletes its entire CPUCreditBalance of 122 credits, and starts to spend surplus credits to sustain the high CPU utilization, totaling 448 surplus credits in this period (570-122=448). When the CPUSurplusCreditBalance value reaches 144 CPU credits (the maximum a t3.nano instance can earn in a 24-hour period), any surplus credits spent thereafter cannot be offset by earned credits. The surplus credits spent thereafter amounts to 304 credits (448-144=304), which results in a small additional charge at the end of the hour for 304 credits.

P6 – For the next 13 hours, CPU utilization is at 5% (the baseline). The instance earns as many credits as it spends, with no excess to pay down the CPUSurplusCreditBalance. The CPUSurplusCreditBalance value remains at 144 credits.

P7 – For the last 24 hours in this example, the instance is idle and CPU utilization is 0%. During this time, the instance earns 144 credits, which it uses to pay down the CPUSurplusCreditBalance.
Example 2: Explain credit use with T2 Unlimited

In this example, you see the CPU utilization of a t2.nano instance launched as unlimited, and how it spends earned and surplus credits to sustain CPU utilization.

A t2.nano instance earns 72 CPU credits over a rolling 24-hour period, which it can redeem for 72 minutes of vCPU use. When it depletes its CPU credit balance (represented by the CloudWatch metric CPUCreditBalance), it can spend surplus CPU credits—that it has not yet earned—to burst for as long as it needs. Because a t2.nano instance earns a maximum of 72 credits in a 24-hour period, it can spend surplus credits up to that maximum without being charged immediately. If it spends more than 72 CPU credits, it is charged for the difference at the end of the hour.

The intent of the example, illustrated by the following graph, is to show how an instance can burst using surplus credits even after it depletes its CPUCreditBalance. You can assume that, at the start of the time line in the graph, the instance has an accrued credit balance equal to the maximum number of credits it can earn in 24 hours. The following workflow references the numbered points on the graph:

1 – In the first 10 minutes, CPUCreditUsage is at 0, and the CPUCreditBalance value remains at its maximum of 72.

2 – At 23:40, as CPU utilization increases, the instance spends CPU credits and the CPUCreditBalance value decreases.
3 – At around 00:47, the instance depletes its entire CPUCreditBalance, and starts to spend surplus credits to sustain high CPU utilization.

4 – Surplus credits are spent until 01:55, when the CPUSurplusCreditBalance value reaches 72 CPU credits. This is equal to the maximum a t2.nano instance can earn in a 24-hour period. Any surplus credits spent thereafter cannot be offset by earned credits within the 24-hour period, which results in a small additional charge at the end of the hour.

5 – The instance continues to spend surplus credits until around 02:20. At this time, CPU utilization falls below the baseline, and the instance starts to earn credits at 3 credits per hour (or 0.25 credits every 5 minutes), which it uses to pay down the CPUSurplusCreditBalance. After the CPUSurplusCreditBalance value reduces to 0, the instance starts to accrue earned credits in its CPUCreditBalance at 0.25 credits every 5 minutes.

Calculating the bill (Linux instance)

Surplus credits cost $0.05 per vCPU-hour. The instance spent approximately 25 surplus credits between 01:55 and 02:20, which is equivalent to 0.42 vCPU-hours. Additional charges for this instance are 0.42 vCPU-hours x $0.05/vCPU-hour = $0.021, rounded to $0.02. Here is the month-end bill for this T2 Unlimited instance:
Calculating the bill (Windows instance)

Surplus credits cost $0.096 per vCPU-hour. The instance spent approximately 25 surplus credits between 01:55 and 02:20, which is equivalent to 0.42 vCPU-hours. Additional charges for this instance are 0.42 vCPU-hours x $0.096/vCPU-hour = $0.04032, rounded to $0.04. Here is the month-end bill for this T2 Unlimited instance:

<table>
<thead>
<tr>
<th>Amazon Elastic Compute Cloud running Windows</th>
</tr>
</thead>
<tbody>
<tr>
<td>$0.0081 per On Demand Windows t2.nano Instance Hour</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Amazon Elastic Compute Cloud T2 CPU Credits</th>
</tr>
</thead>
<tbody>
<tr>
<td>$0.096 per vCPU-Hour of T2 CPU credits</td>
</tr>
</tbody>
</table>

You can set billing alerts to be notified every hour of any accruing charges, and take action if required.

Standard mode for burstable performance instances

A burstable performance instance configured as standard is suited to workloads with an average CPU utilization that is consistently below the baseline CPU utilization of the instance. To burst above the baseline, the instance spends credits that it has accrued in its CPU credit balance. If the instance is running low on accrued credits, CPU utilization is gradually lowered to the baseline level, so that the instance does not experience a sharp performance drop-off when its accrued CPU credit balance is depleted. For more information, see Key concepts and definitions for burstable performance instances.

    • Period 5: 73 – 75 hours
    • Period 6: 76 – 90 hours
    • Period 7: 91 – 96 hours

**Standard mode concepts**

The standard mode is a configuration option for burstable performance instances. It can be enabled or disabled at any time for a running or stopped instance. You can set standard as the default credit option at the account level per AWS Region, per burstable performance instance family, so that all new burstable performance instances in the account launch using the default credit option.

**How standard burstable performance instances work**

When a burstable performance instance configured as standard is in a running state, it continuously earns (at a millisecond-level resolution) a set rate of earned credits per hour. For T2 Standard, when the instance is stopped, it loses all its accrued credits, and its credit balance is reset to zero. When it is restarted, it receives a new set of launch credits, and begins to accrue earned credits. For T4g, T3a and T3 Standard instances, the CPU credit balance persists for seven days after the instance stops and the credits are lost thereafter. If you start the instance within seven days, no credits are lost.

T2 Standard instances receive two types of CPU credits: earned credits and launch credits. When a T2 Standard instance is in a running state, it continuously earns (at a millisecond-level resolution) a set rate of earned credits per hour. At start, it has not yet earned credits for a good startup experience; therefore, to provide a good startup experience, it receives launch credits at start, which it spends first while it accrues earned credits.
T4g, T3a and T3 instances do not receive launch credits because they support Unlimited mode. The Unlimited mode credit configuration enables T4g, T3a and T3 instances to use as much CPU as needed to burst beyond baseline and for as long as needed.

Launch credits

T2 Standard instances get 30 launch credits per vCPU at launch or start, and T1 Standard instances get 15 launch credits. For example, a t2.micro instance has one vCPU and gets 30 launch credits, while a t2.xlarge instance has four vCPUs and gets 120 launch credits. Launch credits are designed to provide a good startup experience to allow instances to burst immediately after launch before they have accrued earned credits.

Launch credits are spent first, before earned credits. Unspent launch credits are accrued in the CPU credit balance, but do not count towards the CPU credit balance limit. For example, a t2.micro instance has a CPU credit balance limit of 144 earned credits. If it is launched and remains idle for 24 hours, its CPU credit balance reaches 174 (30 launch credits + 144 earned credits), which is over the limit. However, after the instance spends the 30 launch credits, the credit balance cannot exceed 144. For more information about the CPU credit balance limit for each instance size, see the credit table.

The following table lists the initial CPU credit allocation received at launch or start, and the number of vCPUs.

</tbody>
</table>
Launch credit limits

There is a limit to the number of times T2 Standard instances can receive launch credits. The default limit is 100 launches or starts of all T2 Standard instances combined per account, per Region, per rolling 24-hour period. For example, the limit is reached when one instance is stopped and started 100 times within a 24-hour period, or when 100 instances are launched within a 24-hour period, or other combinations that equate to 100 starts. New accounts may have a lower limit, which increases over time based on your usage.

Tip
To ensure that your workloads always get the performance they need, switch to Unlimited mode for burstable performance instances or consider using a larger instance size.

Differences between launch credits and earned credits

The following table lists the differences between launch credits and earned credits.

<table>
<thead>
<tr>
<th>Credit earn rate</th>
<th>Launch credits</th>

</table>

The number of accrued launch credits and accrued earned credits is tracked by the CloudWatch metric CPUCreditBalance. For more information, see CPUCreditBalance in the CloudWatch metrics table.

**Standard mode examples**

The following examples explain credit use when instances are configured as standard.

**Examples**

- [Example 1: Explain credit use with T3 Standard](#)
- [Example 2: Explain credit use with T2 Standard](#)

**Example 1: Explain credit use with T3 Standard**

In this example, you see how a t3.nano instance launched as standard earns, accrues, and spends earned credits. You see how the credit balance reflects the accrued earned credits.

A running t3.nano instance earns 144 credits every 24 hours. Its credit balance limit is 144 earned credits. After the limit is reached, new credits that are earned are discarded. For more information about the number of credits that can be earned and accrued, see the credit table.

You might launch a T3 Standard instance and use it immediately. Or, you might launch a T3 Standard instance and leave it idle for a few days before running applications on it. Whether an instance is used or remains idle determines if credits are spent or accrued. If an instance remains
idle for 24 hours from the time it is launched, the credit balance reaches it limit, which is the maximum number of earned credits that can be accrued.

This example describes an instance that remains idle for 24 hours from the time it is launched, and walks you through seven periods of time over a 96-hour period, showing the rate at which credits are earned, accrued, spent, and discarded, and the value of the credit balance at the end of each period.

The following workflow references the numbered points on the graph:

P1 – At 0 hours on the graph, the instance is launched as standard and immediately begins to earn credits. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. For the first 24 hours, CPUCreditUsage is at 0, and the CPUCreditBalance value reaches its maximum of 144.

P2 – For the next 12 hours, CPU utilization is at 2.5%, which is below the 5% baseline. The instance earns more credits than it spends, but the CPUCreditBalance value cannot exceed its maximum of 144 credits. Any credits that are earned in excess of the limit are discarded.

P3 – For the next 24 hours, CPU utilization is at 7% (above the baseline), which requires a spend of 57.6 credits. The instance spends more credits than it earns, and the CPUCreditBalance value reduces to 86.4 credits.

P4 – For the next 12 hours, CPU utilization decreases to 2.5% (below the baseline), which requires a spend of 36 credits. In the same time, the instance earns 72 credits. The instance earns more credits than it spends, and the CPUCreditBalance value increases to 122 credits.

P5 – For the next two hours, the instance bursts at 60% CPU utilization, and depletes its entire CPUCreditBalance value of 122 credits. At the end of this period, with the CPUCreditBalance at zero, CPU utilization is forced to drop to the baseline utilization level of 5%. At the baseline, the instance earns as many credits as it spends.

P6 – For the next 14 hours, CPU utilization is at 5% (the baseline). The instance earns as many credits as it spends. The CPUCreditBalance value remains at 0.

P7 – For the last 24 hours in this example, the instance is idle and CPU utilization is 0%. During this time, the instance earns 144 credits, which it accrues in its CPUCreditBalance.
Example 2: Explain credit use with T2 Standard

In this example, you see how a t2.nano instance launched as standard earns, accrues, and spends launch and earned credits. You see how the credit balance reflects not only accrued earned credits, but also accrued launch credits.

A t2.nano instance gets 30 launch credits when it is launched, and earns 72 credits every 24 hours. Its credit balance limit is 72 earned credits; launch credits do not count towards the limit. After the limit is reached, new credits that are earned are discarded. For more information about the number of credits that can be earned and accrued, see the credit table. For more information about limits, see Launch credit limits.

You might launch a T2 Standard instance and use it immediately. Or, you might launch a T2 Standard instance and leave it idle for a few days before running applications on it. Whether an instance is used or remains idle determines if credits are spent or accrued. If an instance remains idle for 24 hours from the time it is launched, the credit balance appears to exceed its limit because the balance reflects both accrued earned credits and accrued launch credits. However, after CPU is used, the launch credits are spent first. Thereafter, the limit always reflects the maximum number of earned credits that can be accrued.

This example describes an instance that remains idle for 24 hours from the time it is launched, and walks you through seven periods of time over a 96-hour period, showing the rate at which credits are earned, accrued, spent, and discarded, and the value of the credit balance at the end of each period.
**Period 1: 1 – 24 hours**

At 0 hours on the graph, the T2 instance is launched as standard and immediately gets 30 launch credits. It earns credits while in the running state. The instance remains idle from the time it is launched—CPU utilization is 0%—and no credits are spent. All unspent credits are accrued in the credit balance. At approximately 14 hours after launch, the credit balance is 72 (30 launch credits + 42 earned credits), which is equivalent to what the instance can earn in 24 hours. At 24 hours after launch, the credit balance exceeds 72 credits because the unspent launch credits are accrued in the credit balance—the credit balance is 102 credits: 30 launch credits + 72 earned credits.

<table>
<thead>
<tr>
<th>Credit Spend Rate</th>
<th>0 credits per 24 hours (0% CPU utilization)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Credit Earn Rate</td>
<td>72 credits per 24 hours</td>
</tr>
<tr>
<td>Credit Discard Rate</td>
<td>0 credits per 24 hours</td>
</tr>
<tr>
<td>Credit Balance</td>
<td>102 credits (30 launch credits + 72 earned credits)</td>
</tr>
</tbody>
</table>

**Conclusion**

If there is no CPU utilization after launch, the instance accrues more credits than what it can earn in 24 hours (30 launch credits + 72 earned credits = 102 credits).

In a real-world scenario, an EC2 instance consumes a small number of credits while launching and running, which prevents the balance from reaching the maximum theoretical value in this example.
**Period 2: 25 – 36 hours**

For the next 12 hours, the instance continues to remain idle and earn credits, but the credit balance does not increase. It plateaus at 102 credits (30 launch credits + 72 earned credits). The credit balance has reached its limit of 72 accrued earned credits, so newly earned credits are discarded.

<table>
<thead>
<tr>
<th>Credit Spend Rate</th>
<th>0 credits per 24 hours (0% CPU utilization)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Credit Earn Rate</td>
<td>72 credits per 24 hours (3 credits per hour)</td>
</tr>
<tr>
<td>Credit Discard Rate</td>
<td>72 credits per 24 hours (100% of credit earn rate)</td>
</tr>
<tr>
<td>Credit Balance</td>
<td>102 credits (30 launch credits + 72 earned credits)—balance is unchanged</td>
</tr>
</tbody>
</table>

**Conclusion**

An instance constantly earns credits, but it cannot accrue more earned credits if the credit balance has reached its limit. After the limit is reached, newly earned credits are discarded. Launch credits do not count towards the credit balance limit. If the balance includes accrued launch credits, the balance appears to be over the limit.
**Period 3: 37 – 61 hours**

For the next 25 hours, the instance uses 2% CPU, which requires 30 credits. In the same period, it earns 75 credits, but the credit balance decreases. The balance decreases because the accrued *launch* credits are spent first, while newly earned credits are discarded because the credit balance is already at its limit of 72 earned credits.

<table>
<thead>
<tr>
<th>Credit Spend Rate</th>
<th>28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—30 credits over 25 hours</th>
</tr>
</thead>
<tbody>
<tr>
<td>Credit Earn Rate</td>
<td>72 credits per 24 hours</td>
</tr>
<tr>
<td>Credit Discard Rate</td>
<td>72 credits per 24 hours (100% of credit earn rate)</td>
</tr>
<tr>
<td>Credit Balance</td>
<td>72 credits (30 launch credits were spent; 72 earned credits remain unspent)</td>
</tr>
</tbody>
</table>

**Conclusion**

An instance spends launch credits first, before spending earned credits. Launch credits do not count towards the credit limit. After the launch credits are spent, the balance can never go higher than what can be earned in 24 hours. Furthermore, while an instance is running, it cannot get more launch credits.
Period 4: 62 – 72 hours

For the next 11 hours, the instance uses 2% CPU, which requires 13.2 credits. This is the same CPU utilization as in the previous period, but the balance does not decrease. It stays at 72 credits.

The balance does not decrease because the credit earn rate is higher than the credit spend rate. In the time that the instance spends 13.2 credits, it also earns 33 credits. However, the balance limit is 72 credits, so any earned credits that exceed the limit are discarded. The balance plateaus at 72 credits, which is different from the plateau of 102 credits during Period 2, because there are no accrued launch credits.

| Credit Spend Rate | 28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—13.2 credits over 11 hours |
| Credit Earn Rate  | 72 credits per 24 hours |
| Credit Discard Rate | 43.2 credits per 24 hours (60% of credit earn rate) |
| Credit Balance    | 72 credits (0 launch credits, 72 earned credits)—balance is at its limit |

Conclusion

Burstable performance instances
After launch credits are spent, the credit balance limit is determined by the number of credits that an instance can earn in 24 hours. If the instance earns more credits than it spends, newly earned credits over the limit are discarded.

**Period 5: 73 – 75 hours**

For the next three hours, the instance bursts at 20% CPU utilization, which requires 36 credits. The instance earns nine credits in the same three hours, which results in a net balance decrease of 27 credits. At the end of three hours, the credit balance is 45 accrued earned credits.

<table>
<thead>
<tr>
<th>Credit Spend Rate</th>
<th>288 credits per 24 hours (12 credits per hour, 20% CPU utilization, 400% of credit earn rate) —36 credits over 3 hours</th>
</tr>
</thead>
<tbody>
<tr>
<td>Credit Earn Rate</td>
<td>72 credits per 24 hours (9 credits over 3 hours)</td>
</tr>
<tr>
<td>Credit Discard Rate</td>
<td>0 credits per 24 hours</td>
</tr>
<tr>
<td>Credit Balance</td>
<td>45 credits (previous balance (72) - spent credits (36) + earned credits (9))—balance decreases at a rate of 216 credits per 24 hours (spend rate 288/24 + earn rate 72/24 = balance decrease rate 216/24)</td>
</tr>
</tbody>
</table>

**Conclusion**
If an instance spends more credits than it earns, its credit balance decreases.

**Period 6: 76 – 90 hours**

For the next 15 hours, the instance uses 2% CPU, which requires 18 credits. This is the same CPU utilization as in Periods 3 and 4. However, the balance increases in this period, whereas it decreased in Period 3 and plateaued in Period 4.

In Period 3, the accrued launch credits were spent, and any earned credits that exceeded the credit limit were discarded, resulting in a decrease in the credit balance. In Period 4, the instance spent fewer credits than it earned. Any earned credits that exceeded the limit were discarded, so the balance plateaued at its maximum of 72 credits.

In this period, there are no accrued launch credits, and the number of accrued earned credits in the balance is below the limit. No earned credits are discarded. Furthermore, the instance earns more credits than it spends, resulting in an increase in the credit balance.

| Credit Spend Rate | 28.8 credits per 24 hours (1.2 credits per hour, 2% CPU utilization, 40% of credit earn rate)—18 credits over 15 hours |
| Credit Earn Rate  | 72 credits per 24 hours (45 credits over 15 hours) |
| Credit Discard Rate | 0 credits per 24 hours |
Credit Balance | 72 credits (balance increases at a rate of 43.2 credits per 24 hours—change rate = spend rate 28.8/24 + earn rate 72/24)

Conclusion

If an instance spends fewer credits than it earns, its credit balance increases.

Period 7: 91 – 96 hours

For the next six hours, the instance remains idle—CPU utilization is 0%—and no credits are spent. This is the same CPU utilization as in Period 2, but the balance does not plateau at 102 credits—it plateaus at 72 credits, which is the credit balance limit for the instance.

In Period 2, the credit balance included 30 accrued launch credits. The launch credits were spent in Period 3. A running instance cannot get more launch credits. After its credit balance limit is reached, any earned credits that exceed the limit are discarded.

Credit Spend Rate | 0 credits per 24 hours (0% CPU utilization)
Credit Earn Rate | 72 credits per 24 hours
Credit Discard Rate | 72 credits per 24 hours (100% of credit earn rate)
Credit Balance | 72 credits (0 launch credits, 72 earned credits)
Conclusion

An instance constantly earns credits, but cannot accrue more earned credits if the credit balance limit has been reached. After the limit is reached, newly earned credits are discarded. The credit balance limit is determined by the number of credits that an instance can earn in 24 hours. For more information about credit balance limits, see the credit table.

Work with burstable performance instances

The steps for launching, monitoring, and modifying burstable performance instances (T instances) are similar. The key difference is the default credit specification when they launch.

Each T instance family comes with the following default credit specification:

- T4g, T3a and T3 instances launch as unlimited
- T3 instances on a Dedicated Host can only launch as standard
- T2 instances launch as standard

You can change the default credit specification for the account.

Contents

- Launch a burstable performance instance as Unlimited or Standard
- Use an Auto Scaling group to launch a burstable performance instance as Unlimited
- View the credit specification of a burstable performance instance
- Modify the credit specification of a burstable performance instance
- Set the default credit specification for the account
- View the default credit specification

Launch a burstable performance instance as Unlimited or Standard

You can launch your T instances as unlimited or standard using the Amazon EC2 console, an AWS SDK, a command line tool, or with an Auto Scaling group.

The following procedures describe how to use the EC2 console or the AWS CLI. For information about using an Auto Scaling group, see Use an Auto Scaling group to launch a burstable performance instance as Unlimited.
To launch a T instance as Unlimited or Standard

1. Follow the procedure to launch an instance.
2. Under Instance type, select a T instance type.
3. Expand Advanced details, and for Credit specification, select a credit specification. If you do not make a selection, the default is used, which is standard for T2, and unlimited for T4g, T3a and T3.
4. In the Summary panel, review your instance configuration, and then choose Launch instance. For more information, see Launch an instance using the new launch instance wizard.

AWS CLI

To launch a T instance as Unlimited or Standard

Use the run-instances command to launch your instances. Specify the credit specification using the --credit-specification CpuCredits= parameter. Valid credit specifications are unlimited and standard.

- For T4g, T3a and T3, if you do not include the --credit-specification parameter, the instance launches as unlimited by default.
- For T2, if you do not include the --credit-specification parameter, the instance launches as standard by default.

```
aws ec2 run-instances \
   --image-id ami-abc12345 \
   --count 1 \
   --instance-type t3.micro \
   --key-name MyKeyPair \
   --credit-specification "CpuCredits=unlimited"
```

Use an Auto Scaling group to launch a burstable performance instance as Unlimited

When T instances are launched or started, they require CPU credits for a good bootstrapping experience. If you use an Auto Scaling group to launch your instances, we recommend that you
configure your instances as unlimited. If you do, the instances use surplus credits when they are automatically launched or restarted by the Auto Scaling group. Using surplus credits prevents performance restrictions.

**Create a launch template**

You must use a *launch template* for launching instances as unlimited in an Auto Scaling group. A launch configuration does not support launching instances as unlimited.

⚠️ **Note**

unlimited mode is not supported for T3 instances that are launched on a Dedicated Host.

**Console**

*To create a launch template that launches instances as Unlimited*

1. Follow the [Create a launch template using advanced settings](https://docs.aws.amazon.com/autoscaling/ec2/userguide/create-launch-template.html) procedure in the *Amazon EC2 Auto Scaling User Guide*.

2. In **Launch template contents**, for **Instance type**, choose an instance size.

3. To launch instances as unlimited in an Auto Scaling group, under **Advanced details**, for **Credit specification**, choose **Unlimited**.

4. When you've finished defining the launch template parameters, choose **Create launch template**.

**AWS CLI**

*To create a launch template that launches instances as Unlimited*

Use the `create-launch-template` command and specify unlimited as the credit specification.

- For T4g, T3a and T3, if you do not include the `CreditSpecification={CpuCredits=unlimited}` value, the instance launches as unlimited by default.

- For T2, if you do not include the `CreditSpecification={CpuCredits=unlimited}` value, the instance launches as `standard` by default.
aws ec2 create-launch-template \
  --launch-template-name MyLaunchTemplate \
  --version-description FirstVersion \
  --launch-template-data
ImageId=ami-8c1be5f6,InstanceType=t3.medium,CreditSpecification={CpuCredits=unlimited}

**Associate an Auto Scaling group with a launch template**

To associate the launch template with an Auto Scaling group, create the Auto Scaling group using the launch template, or add the launch template to an existing Auto Scaling group.

**Console**

**To create an Auto Scaling group using a launch template**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. On the navigation bar at the top of the screen, select the same Region that you used when you created the launch template.
3. In the navigation pane, choose **Auto Scaling Groups, Create Auto Scaling group**.
4. Choose **Launch Template**, select your launch template, and then choose **Next Step**.
5. Complete the fields for the Auto Scaling group. When you've finished reviewing your configuration settings on the **Review page**, choose **Create Auto Scaling group**. For more information, see [Creating an Auto Scaling Group Using a Launch Template](https://docs.aws.amazon.com/autoscaling/ec2/userguide/launch-template.html) in the [Amazon EC2 Auto Scaling User Guide](https://docs.aws.amazon.com/autoscaling/ec2/userguide/creating-auto-scaling-group-launch-template.html).

**AWS CLI**

**To create an Auto Scaling group using a launch template**

Use the `create-auto-scaling-group` AWS CLI command and specify the `--launch-template` parameter.

**Console**

**To add a launch template to an existing Auto Scaling group**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. On the navigation bar at the top of the screen, select the same Region that you used when you created the launch template.

3. In the navigation pane, choose **Auto Scaling Groups**.

4. From the Auto Scaling group list, select an Auto Scaling group, and choose **Actions, Edit**.

5. On the **Details** tab, for **Launch Template**, choose a launch template, and then choose **Save**.

**AWS CLI**

To add a launch template to an existing Auto Scaling group

Use the `update-auto-scaling-group` AWS CLI command and specify the `--launch-template` parameter.

View the credit specification of a burstable performance instance

You can view the credit specification (unlimited or standard) of a running or stopped T instance.

**Console**

To view the credit specification of a T instance

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the left navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Details** and view the **Credit specification** field. The value is either unlimited or standard.

**AWS CLI**

To describe the credit specification of a T instance

Use the `describe-instance-credit-specifications` command. If you do not specify one or more instance IDs, all instances with the credit specification of unlimited are returned, as well as instances that were previously configured with the unlimited credit specification. For example, if you resize a T3 instance to an M4 instance, while it is configured as unlimited, Amazon EC2 returns the M4 instance.
Modify the credit specification of a burstable performance instance

You can switch the credit specification of a running or stopped T instance at any time between unlimited and standard.

Note that in unlimited mode, an instance can spend surplus credits, which might incur an additional charge. For more information, see Surplus credits can incur charges.

Console

To modify the credit specification of a T instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose Instances.
3. Select the instance. To modify the credit specification for several instances at one time, select all applicable instances.
4. Choose Actions, Instance settings, Change credit specification. This option is enabled only if you selected a T instance.
5. To change the credit specification to unlimited, select the check box next to the instance ID. To change the credit specification to standard, clear the check box next to the instance ID.

AWS CLI

To modify the credit specification of a T instance
Use the `modify-instance-credit-specification` command. Specify the instance and its credit specification using the `--instance-credit-specification` parameter. Valid credit specifications are unlimited and standard.

```bash
aws ec2 modify-instance-credit-specification \
   --region us-east-1 \
   --instance-credit-specification
   "InstanceId=i-1234567890abcdef0,CpuCredits=unlimited"
```

Example output

```json
{
   "SuccessfulInstanceCreditSpecifications": [
   {
      "InstanceId": "i-1234567890abcdef0"
   }
   ],
   "UnsuccessfulInstanceCreditSpecifications": []
}
```

**Set the default credit specification for the account**

Each T instance family comes with a default credit specification. You can change the default credit specification for each T instance family at the account level per AWS Region.

If you use the launch instance wizard in the EC2 console to launch instances, the value you select for the credit specification overrides the account-level default credit specification. If you use the AWS CLI to launch instances, all new T instances in the account launch using the default credit specification. The credit specification for existing running or stopped instances is not affected.

**Consideration**

The default credit specification for an instance family can be modified only once in a rolling 5-minute period, and up to four times in a rolling 24-hour period.

**Console**

**To set the default credit specification at the account level per Region**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. On the left navigation pane, choose **EC2 Dashboard**.
4. From **Account attributes**, choose **Default credit specification**.
5. Choose **Manage**.
6. For each instance family, choose **Unlimited** or **Standard**, and then choose **Update**.

**AWS CLI**

**To set the default credit specification at the account level (AWS CLI)**

Use the `modify-default-credit-specification` command. Specify the AWS Region, instance family, and the default credit specification using the `-cpu-credits` parameter. Valid default credit specifications are unlimited and standard.

```
aws ec2 modify-default-credit-specification
  --region us-east-1 \
  --instance-family t2 \
  --cpu-credits unlimited
```

**View the default credit specification**

You can view the default credit specification of a T instance family at the account level per AWS Region.

**Console**

**To view the default credit specification at the account level**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. On the left navigation pane, choose **EC2 Dashboard**.
4. From **Account attributes**, choose **Default credit specification**.

**AWS CLI**

**To view the default credit specification at the account level**

Use the `get-default-credit-specification` command. Specify the AWS Region and instance family.
Monitor your CPU credits for burstable performance instances

EC2 sends metrics to Amazon CloudWatch. You can see the CPU credit metrics in the Amazon EC2 per-instance metrics of the CloudWatch console or by using the AWS CLI to list the metrics for each instance. For more information, see List metrics using the console and List metrics using the AWS CLI.

Contents

• Additional CloudWatch metrics for burstable performance instances
• Calculate CPU credit usage

Additional CloudWatch metrics for burstable performance instances

Burstable performance instances have these additional CloudWatch metrics, which are updated every five minutes:

• CPUCreditUsage – The number of CPU credits spent during the measurement period.
• CPUCreditBalance – The number of CPU credits that an instance has accrued. This balance is depleted when the CPU bursts and CPU credits are spent more quickly than they are earned.
• CPUSurplusCreditBalance – The number of surplus CPU credits spent to sustain CPU utilization when the CPUCreditBalance value is zero.
• CPUSurplusCreditsCharged – The number of surplus CPU credits exceeding the maximum number of CPU credits that can be earned in a 24-hour period, and thus attracting an additional charge.

The last two metrics apply only to instances configured as unlimited.

The following table describes the CloudWatch metrics for burstable performance instances. For more information, see List the available CloudWatch metrics for your instances.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUCreditUsage</td>
<td>The number of CPU credits spent by the instance for CPU utilization. One CPU credit equals one vCPU running at 100%</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>utilization for one minute or an equivalent combination of vCPUs, utilization, and time (for example, one vCPU running at 50% utilization for two minutes or two vCPUs running at 25% utilization for two minutes).</td>
</tr>
<tr>
<td></td>
<td>CPU credit metrics are available at a five-minute frequency only. If you specify a period greater than five minutes, use the Sum statistic instead of the Average statistic.</td>
</tr>
<tr>
<td></td>
<td>Units: Credits (vCPU-minutes)</td>
</tr>
<tr>
<td>CPUCreditBalance</td>
<td>The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the CPUCreditBalance also includes the number of launch credits that have been accrued.</td>
</tr>
<tr>
<td></td>
<td>Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits do not count towards the limit.</td>
</tr>
<tr>
<td></td>
<td>The credits in the CPUCreditBalance are available for the instance to spend to burst beyond its baseline CPU utilization.</td>
</tr>
<tr>
<td></td>
<td>When an instance is running, credits in the CPUCreditBalance do not expire. When a T4g, T3a or T3 instance stops, the CPUCreditBalance value persists for seven days. Thereafter, all accrued credits are lost. When a T2 instance stops, the CPUCreditBalance value does not persist, and all accrued credits are lost.</td>
</tr>
<tr>
<td></td>
<td>CPU credit metrics are available at a five-minute frequency only.</td>
</tr>
<tr>
<td></td>
<td>Units: Credits (vCPU-minutes)</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>

</tr>
</tbody>
</table>

**Calculate CPU credit usage**

The CPU credit usage of instances is calculated using the instance CloudWatch metrics described in the preceding table.

Amazon EC2 sends the metrics to CloudWatch every five minutes. A reference to the *prior* value of a metric at any point in time implies the previous value of the metric, sent *five minutes ago*. 
Calculate CPU credit usage for Standard instances

- The CPU credit balance increases if CPU utilization is below the baseline, when the credits spent are less than the credits earned in the prior five-minute interval.
- The CPU credit balance decreases if CPU utilization is above the baseline, when the credits spent are more than the credits earned in the prior five-minute interval.

Mathematically, this is captured by the following equation:

Example

\[
\text{CPUCreditBalance} = \text{prior CPUCreditBalance} + [\text{Credits earned per hour} \times (5/60) - \text{CPUCreditUsage}]
\]

The size of the instance determines the number of credits that the instance can earn per hour and the number of earned credits that it can accrue in the credit balance. For information about the number of credits earned per hour, and the credit balance limit for each instance size, see the [credit table](#).

Example

This example uses a `t3.nano` instance. To calculate the `CPUCreditBalance` value of the instance, use the preceding equation as follows:

- `CPUCreditBalance` – The current credit balance to calculate.
- `prior CPUCreditBalance` – The credit balance five minutes ago. In this example, the instance had accrued two credits.
- `Credits earned per hour` – A `t3.nano` instance earns six credits per hour.
- `5/60` – Represents the five-minute interval between CloudWatch metric publication. Multiply the credits earned per hour by 5/60 (five minutes) to get the number of credits that the instance earned in the past five minutes. A `t3.nano` instance earns 0.5 credits every five minutes.
- `CPUCreditUsage` – How many credits the instance spent in the past five minutes. In this example, the instance spent one credit in the past five minutes.

Using these values, you can calculate the `CPUCreditBalance` value:
Example

\[
\text{CPUCreditBalance} = 2 + [0.5 - 1] = 1.5
\]

**Calculate CPU credit usage for Unlimited instances**

When a burstable performance instance needs to burst above the baseline, it always spends accrued credits before spending surplus credits. When it depletes its accrued CPU credit balance, it can spend surplus credits to burst CPU for as long as it needs. When CPU utilization falls below the baseline, surplus credits are always paid down before the instance accrues earned credits.

We use the term Adjusted balance in the following equations to reflect the activity that occurs in this five-minute interval. We use this value to arrive at the values for the CPUCreditBalance and CPUSurplusCreditBalance CloudWatch metrics.

Example

\[
\text{Adjusted balance} = \text{prior CPUCreditBalance} - \text{prior CPUSurplusCreditBalance} + [\text{Credits earned per hour} \times (5/60) - \text{CPUCreditUsage}]
\]

A value of 0 for Adjusted balance indicates that the instance spent all its earned credits for bursting, and no surplus credits were spent. As a result, both CPUCreditBalance and CPUSurplusCreditBalance are set to 0.

A positive Adjusted balance value indicates that the instance accrued earned credits, and previous surplus credits, if any, were paid down. As a result, the Adjusted balance value is assigned to CPUCreditBalance, and the CPUSurplusCreditBalance is set to 0. The instance size determines the maximum number of credits that it can accrue.

Example

\[
\text{CPUCreditBalance} = \min [\max \text{earned credit balance}, \text{Adjusted balance}]
\]
\[
\text{CPUSurplusCreditBalance} = 0
\]

A negative Adjusted balance value indicates that the instance spent all its earned credits that it accrued and, in addition, also spent surplus credits for bursting. As a result, the Adjusted balance value is assigned to CPUSurplusCreditBalance and CPUCreditBalance is set to 0. Again, the instance size determines the maximum number of credits that it can accrue.
Example

\[
\text{CPUSurplusCreditBalance} = \min [\max \text{ earned credit balance}, -\text{Adjusted balance}]
\]
\[
\text{CPUCreditBalance} = 0
\]

If the surplus credits spent exceed the maximum credits that the instance can accrue, the surplus credit balance is set to the maximum, as shown in the preceding equation. The remaining surplus credits are charged as represented by the CPUSurplusCreditsCharged metric.

Example

\[
\text{CPUSurplusCreditsCharged} = \max [-\text{Adjusted balance} - \max \text{ earned credit balance}, 0]
\]

Finally, when the instance terminates, any surplus credits tracked by the CPUSurplusCreditBalance are charged. If the instance is switched from unlimited to standard, any remaining CPUSurplusCreditBalance is also charged.

Performance acceleration with GPU instances

GPU-based instances provide access to NVIDIA GPUs with thousands of compute cores. You can use these instances to accelerate scientific, engineering, and rendering applications by leveraging the CUDA or Open Computing Language (OpenCL) parallel computing frameworks. You can also use them for graphics applications, including game streaming, 3-D application streaming, and other graphics workloads.

Before you can activate or optimize a GPU-based instance, you must install the appropriate drivers, as follows:

- To install NVIDIA drivers on an instance with an attached NVIDIA GPU, such as a P3 or G4dn instance, see NVIDIA drivers.
- To install AMD drivers on an instance with an attached AMD GPU, such as a G4ad instance, see AMD drivers.

Contents

- Activate NVIDIA GRID Virtual Applications on your Amazon EC2 GPU-based instances
- Optimize GPU settings on Amazon EC2 instances
- Set up Dual 4K displays on G4ad Linux instances
• Get started with P5 instances for Linux

Activate NVIDIA GRID Virtual Applications on your Amazon EC2 GPU-based instances

To activate the GRID Virtual Applications on GPU-based instances that have NVIDIA GPUs (NVIDIA GRID Virtual Workstation is enabled by default), you must define the product type for the driver, as follows.

Activate GRID Virtual Applications on Linux instances

1. Create the /etc/nvidia/gridd.conf file from the provided template file.

   ```bash
   [ec2-user ~]$ sudo cp /etc/nvidia/gridd.conf.template /etc/nvidia/gridd.conf
   ```

2. Open the /etc/nvidia/gridd.conf file in your favorite text editor.

3. Find the FeatureType line, and set it equal to 0. Then add a line with IgnoreSP=TRUE.

   ```
   FeatureType=0 IgnoreSP=TRUE
   ```

4. Save the file and exit.

5. Reboot the instance to pick up the new configuration.

   ```bash
   [ec2-user ~]$ sudo reboot
   ```

Activate GRID Virtual Applications on Windows instances

1. Run regedit.exe to open the registry editor.

2. Navigate to HKEY_LOCAL_MACHINE\SOFTWARE\NVIDIA Corporation\Global \GridLicensing.

3. Open the context (right-click) menu on the right pane and choose New, DWORD.

4. For Name, enter FeatureType and type Enter.

5. Open the context (right-click) menu on FeatureType and choose Modify.

6. For Value data, enter 0 for NVIDIA GRID Virtual Applications and choose OK.
7. Open the context (right-click) menu on the right pane and choose New, DWORD.
8. For Name, enter IgnoreSP and type Enter.
9. Open the context (right-click) menu on IgnoreSP and choose Modify.
10. For Value data, type 1 and choose OK.
11. Close the registry editor.

**Optimize GPU settings on Amazon EC2 instances**

There are several GPU setting optimizations that you can perform to achieve the best performance on NVIDIA GPU instances. With some of these instance types, the NVIDIA driver uses an autoboost feature, which varies the GPU clock speeds. By disabling autoboost and setting the GPU clock speeds to their maximum frequency, you can consistently achieve the maximum performance with your GPU instances.

**Optimize GPU settings on Linux**

1. Configure the GPU settings to be persistent. This command can take several minutes to run.

   `[ec2-user ~]$ sudo nvidia-persistenced`

2. [G3, and P2 instances only] Disable the autoboost feature for all GPUs on the instance.

   `[ec2-user ~]$ sudo nvidia-smi --auto-boost-default=0`

3. Set all GPU clock speeds to their maximum frequency. Use the memory and graphics clock speeds specified in the following commands.

   Some versions of the NVIDIA driver do not support setting the application clock speed, and display the error "Setting applications clocks is not supported for GPU...", which you can ignore.

   • G3 instances:

   `[ec2-user ~]$ sudo nvidia-smi -ac 2505,1177`

   • G4dn instances:

   `[ec2-user ~]$ sudo nvidia-smi -ac 5001,1590`
• G5 instances:

[ec2-user ~]$ sudo nvidia-smi -ac 6250,1710

• G6 and Gr6 instances:

[ec2-user ~]$ sudo nvidia-smi -ac 6251,2040

• P2 instances:

[ec2-user ~]$ sudo nvidia-smi -ac 2505,875

• P3 and P3dn instances:

[ec2-user ~]$ sudo nvidia-smi -ac 877,1530

• P4d instances:

[ec2-user ~]$ sudo nvidia-smi -ac 1215,1410

• P4de instances:

[ec2-user ~]$ sudo nvidia-smi -ac 1593,1410

• P5 instances:

[ec2-user ~]$ sudo nvidia-smi -ac 2619,1980

Optimize GPU settings on Windows

1. Open a PowerShell window and navigate to the NVIDIA installation folder.

   cd "C:\Windows\System32\DriverStore\FileRepository\nv_dispswi.inf_*"

2. [G3, and P2 instances only] Disable the autoboost feature for all GPUs on the instance.

   \nvidia-smi --auto-boost-default=0

3. Set all GPU clock speeds to their maximum frequency. Use the memory and graphics clock speeds specified in the following commands.

   [ec2-user ~]$ sudo nvidia-smi -ac 6250,1710
Some versions of the NVIDIA driver do not support setting the application clock speed, and display the error "Setting applications clocks is not supported for GPU...", which you can ignore.

- G3 instances:
  ```bash
  ./nvidia-smi -ac "2505,1177"
  ```

- G4dn instances:
  ```bash
  ./nvidia-smi -ac "5001,1590"
  ```

- G5 instances:
  ```bash
  ./nvidia-smi -ac "6250,1710"
  ```

- G6 and Gr6 instances:
  ```bash
  ./nvidia-smi -ac "6251,2040"
  ```

- P2 instances:
  ```bash
  ./nvidia-smi -ac "2505,875"
  ```

- P3 and P3dn instances:
  ```bash
  ./nvidia-smi -ac "877,1530"
  ```

- P4d instances:
  ```bash
  [ec2-user ~]$ sudo nvidia-smi -ac 1215,1410
  ```

- P4de instances:
  ```bash
  [ec2-user ~]$ sudo nvidia-smi -ac 1593,1410
  ```

- P5 instances:
  ```bash
  [ec2-user ~]$ sudo nvidia-smi -ac 2619,1980
  ```
Set up Dual 4K displays on G4ad Linux instances

Launch a G4ad instance

1. Connect to your Linux instance to get the PCI Bus address of the GPU you want to target for dual 4K (2x4k):

   ```bash
   lspci -vv | grep -i amd
   ```

   You will get output similar to the following:

   ```
   00:1e.0 Display controller: Advanced Micro Devices, Inc. [*AMD*/ATI] Device 7362 (rev c3)
   Subsystem: Advanced Micro Devices, Inc. [AMD/ATI] Device 0a34
   ```

2. Note the PCI bus address is 00:1e.0 in the above output. Create a file named `/etc/modprobe.d/amdgpu.conf` and add:

   ```
   options amdgpu virtual_display=0000:00:1e.0,2
   ```

3. To install the AMD drivers on Linux, see AMD drivers for your EC2 instance. If you already have the AMD GPU driver installed, you will need to rebuild the amdgpu kernel modules through dkms.

4. Use the below xorg.conf file to define the dual (2x4K) screen topology and save the file in `/etc/X11/xorg.conf`:

   ```
   ~$ cat /etc/X11/xorg.conf
   Section "ServerLayout"
     Identifier     "Layout0"
     Screen          0 "Screen0"
     Screen        1 "Screen1"
     InputDevice     "Keyboard0" "CoreKeyboard"
     InputDevice     "Mouse0" "CorePointer"
     Option          "Xinerama" "1"
   EndSection
   Section "Files"
     ModulePath "/opt/amdgpu/lib64/xorg/modules/drivers"
     ModulePath "/opt/amdgpu/lib/xorg/modules"
     ModulePath "/opt/amdgpu-pro/lib/xorg/modules/extensions"
     ModulePath "/opt/amdgpu-pro/lib64/xorg/modules/extensions"
     ModulePath "/usr/lib64/xorg/modules"
   ```
ModulePath "/usr/lib/xorg/modules"
EndSection
Section "InputDevice"
  # generated from default
  Identifier     "Mouse0"
  Driver         "mouse"
  Option         "Protocol" "auto"
  Option         "Device" "/dev/psaux"
  Option         "Emulate3Buttons" "no"
  Option         "ZAxisMapping" "4 5"
EndSection
Section "InputDevice"
  # generated from default
  Identifier     "Keyboard0"
  Driver         "kbd"
EndSection

Section "Monitor"
  Identifier     "Virtual"
  VendorName     "Unknown"
  ModelName      "Unknown"
  Option         "Primary" "true"
EndSection

Section "Monitor"
  Identifier     "Virtual-1"
  VendorName     "Unknown"
  ModelName      "Unknown"
  Option         "RightOf" "Virtual"
EndSection

Section "Device"
  Identifier     "Device0"
  Driver         "amdgpu"
  VendorName     "AMD"
  BoardName      "Radeon MxGPU V520"
  BusID          "PCI:0:30:0"
EndSection

Section "Device"
  Identifier     "Device1"
  Driver         "amdgpu"
  VendorName     "AMD"
  BoardName      "Radeon MxGPU V520"
5. Set up DCV by following the instructions in setting up an interactive desktop.

6. After the DCV set up is complete, reboot.

7. Confirm that the driver is functional:

   dmesg | grep amdgpu

The response should look like the following:

   Initialized amdgpu
8. You should see in the output for `DISPLAY=:0 xrandr -q` that you have 2 virtual displays connected:

```
~$ DISPLAY=:0 xrandr -q
Screen 0: minimum 320 x 200, current 3840 x 1080, maximum 16384 x 16384

 1440x900  59.99
 1280x960  59.99
 1280x854  59.95
```

GPU instances
9. When you connect into DCV, change the resolution to 2x4K, confirming the dual monitor support is registered by DCV.

![3840x2160 @0x0 - Display 1
3840x2160 @3840x0 - Display 2]

Set up an interactive desktop for Linux

After you confirm that your Linux instance has the AMD GPU driver installed and amdgpu is in use, you can install an interactive desktop manager. We recommend the MATE desktop environment for the best compatibility and performance.

Prerequisite

Open a text editor and save the following as a file named `xorg.conf`. You'll need this file on your instance.

```plaintext
Section "ServerLayout"
  Identifier     "Layout0"
  Screen 0 "Screen0"
  InputDevice "Keyboard0" "CoreKeyboard"
  InputDevice "Mouse0" "CorePointer"
EndSection
Section "Files"
  ModulePath "/opt/amdgpu/lib64/xorg/modules/drivers"
  ModulePath "/opt/amdgpu/lib/xorg/modules"
  ModulePath "/opt/amdgpu-pro/lib/xorg/modules/extensions"
  ModulePath "/opt/amdgpu-pro/lib64/xorg/modules/extensions"
  ModulePath "/usr/lib64/xorg/modules"
  ModulePath "/usr/lib/xorg/modules"
EndSection
Section "InputDevice"
  # generated from default
```
To set up an interactive desktop on Amazon Linux 2

1. Install the EPEL repository.
2. Install the MATE desktop.

```
$ C:\> sudo amazon-linux-extras install epel -y
$ C:\> sudo amazon-linux-extras install mate-desktop1.x -y
$ C:\> sudo yum groupinstall "MATE Desktop" -y
$ C:\> sudo systemctl disable firewalld
```

3. Copy the `xorg.conf` file to `/etc/X11/xorg.conf`.

4. Reboot the instance.

```
$ C:\> sudo reboot
```

5. (Optional) Install the NICE DCV server to use NICE DCV as a high-performance display protocol, and then connect to a NICE DCV session using your preferred client.

To set up an interactive desktop on Ubuntu

1. Install the MATE desktop.

```
$ sudo apt install xorg-dev ubuntu-mate-desktop -y
$ C:\> sudo apt purge ifupdown -y
```

2. Copy the `xorg.conf` file to `/etc/X11/xorg.conf`.

3. Reboot the instance.

```
$ sudo reboot
```

4. Install the AMF encoder for the appropriate version of Ubuntu.

```
$ sudo apt install ./amdgpu-pro-20.20-*/amf-amdgpu-pro_20.20-*/amd64.deb
```

5. (Optional) Install the NICE DCV server to use NICE DCV as a high-performance display protocol, and then connect to a NICE DCV session using your preferred client.

6. After the DCV installation give the DCV User video permissions:

```
$ sudo usermod -aG video dcv
```
To set up an interactive desktop on CentOS

1. Install the EPEL repository.

   $ sudo yum update -y
   $ C:> sudo yum install epel-release -y

2. Install the MATE desktop.

   $ sudo yum groupinstall "MATE Desktop" -y
   $ C:> sudo systemctl disable firewalld

3. Copy the xorg.conf file to /etc/X11/xorg.conf.

4. Reboot the instance.

   $ sudo reboot

5. (Optional) Install the NICE DCV server to use NICE DCV as a high-performance display protocol, and then connect to a NICE DCV session using your preferred client.

Get started with P5 instances for Linux

P5 instances provide 8 NVIDIA H100 GPUs with 640 GB of high-bandwidth GPU memory. They feature 3rd generation AMD EPYC processors and provide 2 TB of system memory, 30 TB of local NVMe instance storage, 3,200 Gbps aggregated network bandwidth, and GPUDirect RDMA support. P5 instances also support Amazon EC2 UltraCluster technology, which provides lower latency and improved network performance using EFA.

The following table provides a summary of the p5.48xlarge specifications.

<table>
<thead>
<tr>
<th>vCPUs</th>
<th>System memory</th>
<th>GPUs</th>
<th>GPU memory</th>
<th>Network bandwidth</th>
<th>GPUDirect RDMA</th>
<th>GPU peer to peer</th>
<th>Instance storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>192</td>
<td>2 TiB</td>
<td>8 NVIDIA H100 GPUs</td>
<td>640 GB HBM3</td>
<td>3200 Gbps with EFAv2</td>
<td>Supported</td>
<td>900 GB/</td>
<td>8 x 3,800 GB NVMe</td>
</tr>
</tbody>
</table>
Software configuration

The easiest way to get started with P5 instances is to launch an instance using an AWS Deep Learning AMI that is preconfigured with all of the required software. For the latest AWS Deep Learning AMI for use with P5 instances, see the AWS Deep Learning Base GPU AMI (Ubuntu 20.04).

If you need to build a custom AMI for use with P5 instances, we recommend installing the following minimum software versions:

- NVIDIA driver 535.54.03 or later
- CUDA 12.1 or later
- NVIDIA GDRCopy 2.3 or later
- EFA installer 1.24.1 or later
- NCCL 2.18.3 or later
- aws-ofi-nccl plugin 1.7.2-aws or later

We also recommend that you configure the instance to not use deeper C-states. For more information, see High performance and low latency by limiting deeper C-states in the Amazon Linux 2 User Guide. The latest AWS Deep Learning Base GPU AMI is preconfigured to not use deeper C-states.

Ubuntu 20.04 specific recommendations

The following recommendations for Ubuntu 20.04 help prevent unpredictable interface naming on boot:

- Ensure you are running systemd 245.4-4ubuntu3.19 or later with the following command:

  ```bash
  systemctl --version
  ```
Ensure you have configured GRUB:

- Open the `/etc/default/grub` configuration file in a text editor.
- Edit the `GRUB_CMDLINE_LINUX_DEFAULT` entry to include `net.naming-scheme=v247`.
- Reboot your instance by running `sudo update-grub`.

**Networking and EFA configuration**

P5 instances deliver 3200 Gbps of networking bandwidth by using multiple EFA interfaces. P5 instances support 32 network cards. We recommend that you define a single EFA network interface per network card. To configure these interfaces at launch we recommend the following settings:

- For network interface 0, specify device index 0
- For network interfaces 1 through 31, specify device index 1

For more information about how to configure your P5 instances for EFA see [Get started with P5 instances and EFA](#).

**Amazon EC2 Mac instances**

EC2 Mac instances are ideal for developing, building, testing, and signing applications for Apple platforms, such as iPhone, iPad, Mac, Vision Pro, Apple Watch, Apple TV, and Safari. You can connect to your Mac instance using SSH or Apple Remote Desktop (ARD).

**Note**

The **unit of billing** is the **dedicated host**. The instances running on that host have no additional charge.

Amazon EC2 Mac instances natively support the macOS operating system.

- EC2 x86 Mac instances (mac1.metal) are built on 2018 Mac mini hardware powered by 3.2 GHz Intel eighth-generation (Coffee Lake) Core i7 processors.
- EC2 M1 Mac instances (mac2.metal) are built on 2020 Mac mini hardware powered by Apple silicon M1 processors.
EC2 M1 Ultra Mac instances (mac2-m1ultra.metal) are built on 2022 Mac Studio hardware powered by Apple silicon M1 Ultra processors.

EC2 M2 Mac instances (mac2-m2.metal) are built on 2023 Mac mini hardware powered by Apple silicon M2 processors.

EC2 M2 Pro Mac instances (mac2-m2pro.metal) are built on 2023 Mac mini hardware powered by Apple silicon M2 Pro processors.

Considerations

The following considerations apply to Mac instances:

- Mac instances are available only as bare metal instances on Dedicated Hosts, with a minimum allocation period of 24 hours before you can release the Dedicated Host. You can launch one Mac instance per Dedicated Host. You can share the Dedicated Host with the AWS accounts or organizational units within your AWS organization, or the entire AWS organization.
• Mac instances are available in different AWS Regions. For a list of Mac instance availability in each of the AWS Regions, see Amazon EC2 instance types by Region.

• Mac instances are available only as On-Demand Instances. They are not available as Spot Instances or Reserved Instances. You can save money on Mac instances by purchasing a Savings Plan.

• Mac instances can run one of the following operating systems:
  • macOS Mojave (version 10.14) (x86 Mac instances only)
  • macOS Catalina (version 10.15) (x86 Mac instances only)
  • macOS Big Sur (version 11) (x86 and M1 Mac instances)
  • macOS Monterey (version 12) (x86 and M1 Mac instances)
  • macOS Ventura (version 13) (all Mac instances, M2 and M2 Pro Mac instances support macOS Ventura version 13.2 or later)
  • macOS Sonoma (version 14) (all Mac instances)

• EBS hotplug is supported.

• AWS does not manage or support the internal SSD on the Apple hardware. We strongly recommend that you use Amazon EBS volumes instead. EBS volumes provide the same elasticity, availability, and durability benefits on Mac instances as they do on any other EC2 instance.

• We recommend using General Purpose SSD (gp2 and gp3) and Provisioned IOPS SSD (io1 and io2) with Mac instances for optimal EBS performance.

• Mac instances support Amazon EC2 Auto Scaling.

• On x86 Mac instances, automatic software updates are disabled. We recommend that you apply updates and test them on your instance before you put the instance into production. For more information, see Update the operating system and software on Mac instances.

• When you stop or terminate a Mac instance, a scrubbing workflow is performed on the Dedicated Host. For more information, see Stop or terminate your Amazon EC2 Mac instance.

⚠️ **Warning**

Do not use FileVault. Enabling FileVault will result in the host failing to boot due to the partitions being locked. If data encryption is required, use Amazon EBS encryption to avoid boot issues and performance impact. With Amazon EBS encryption, encryption operations occur on the servers that host instances, ensuring the security of both data-at-rest and
data-in-transit between an instance and its attached EBS storage. For more information, see Amazon EBS encryption in the Amazon EBS User Guide

### Instance readiness

After you launch a Mac instance, you'll need to wait until the instance is ready before you can connect to it. For an AWS vended AMI with a x86 Mac instance or a Apple silicon Mac instance, the launch time can range from approximately 6 minutes to 20 minutes. Depending on the chosen Amazon EBS volume sizes, the inclusion of additional scripts to user data, or additional loaded software on a custom macOS AMI, the launch time might increase.

You can use a small shell script, like the one below, to poll the describe-instance-status API to know when the instance is ready to be connected to. In the following command, replace the example instance ID with your own.

```bash
for i in $(seq 1 200); do aws ec2 describe-instance-status --instance-ids=i-0123456789example --query='InstanceStatuses[0].InstanceStatus.Status'; sleep 5; done;
```

### EC2 macOS AMIs

Amazon EC2 macOS is designed to provide a stable, secure, and high-performance environment for developer workloads running on Amazon EC2 Mac instances. EC2 macOS AMIs includes packages that enable easy integration with AWS, such as launch configuration tools and popular AWS libraries and tools.

For more information about EC2 macOS AMIs, see Amazon EC2 macOS AMIs release notes.

AWS provides updated EC2 macOS AMIs on a regular basis that include updates to packages owned by AWS and the latest fully-tested macOS version. Additionally, AWS provides updated AMIs with the latest minor version updates or major version updates as soon as they can be fully tested and vetted. If you do not need to preserve data or customizations to your Mac instances, you can get the latest updates by launching a new instance using the current AMI and then terminating the previous instance. Otherwise, you can choose which updates to apply to your Mac instances.

For information about how to subscribe to macOS AMI notifications, see Subscribe to macOS AMI notifications.
EC2 macOS Init

EC2 macOS Init is used to initialize EC2 Mac instances at launch. It uses priority groups to run logical groups of tasks at the same time.

The launchd plist file is `/Library/LaunchDaemons/com.amazon.ec2.macos-init.plist`. The files for EC2 macOS Init are located in `/usr/local/aws/ec2-macos-init`.

For more information, see [https://github.com/aws/ec2-macos-init](https://github.com/aws/ec2-macos-init).

Amazon EC2 System Monitor for macOS

Amazon EC2 System Monitor for macOS provides CPU utilization metrics to Amazon CloudWatch. It sends these metrics to CloudWatch over a custom serial device in 1-minute periods. You can enable or disable this agent as follows. It is enabled by default.

```
sudo setup-ec2monitoring [enable | disable]
```

*Note*

Amazon EC2 System Monitor for macOS is not currently supported on Apple silicon Mac instances.

For information about pricing, see [Pricing](#).

For more information about Mac instances, see [Amazon EC2 Mac Instances](#).

For more information about hardware specifications and network performance of Mac instances, see [General purpose instances](#).

Launch a Mac instance using the AWS Management Console or the AWS CLI

EC2 Mac instances require a [Dedicated Host](#). You first need to allocate a host to your account, and then launch the instance onto the host.

You can launch a Mac instance using the AWS Management Console or the AWS CLI.
Launch a Mac instance using the console

To launch a Mac instance onto a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. Allocate the Dedicated Host, as follows:
   a. In the navigation pane, choose **Dedicated Hosts**.
   b. Choose **Allocate Dedicated Host** and then do the following:
      i. For **Instance family**, choose `mac1`, `mac2`, `mac2-m2`, `mac2-m2pro`, or `mac2-m1ultra`. If the instance family doesn't appear in the list, it's not supported in the currently selected Region.
      ii. For **Instance type**, choose `mac1.metal`, `mac2.metal`, `mac2-m2.metal`, `mac2-m2pro.metal`, or `mac2-m1ultra.metal` based on the instance family chosen.
      iii. For **Availability Zone**, choose the Availability Zone for the Dedicated Host.
      iv. For **Quantity**, keep 1.
      v. Choose **Allocate**.

3. Launch the instance on the host, as follows:
   a. Select the Dedicated Host that you created and then do the following:
      i. Choose **Actions**, **Launch instance(s) onto host**.
      ii. Under **Application and OS Images (Amazon Machine Image)**, select a macOS AMI.
      iii. Under **Instance type**, select the appropriate instance type (`mac1.metal`, `mac2.metal`, `mac2-m2.metal`, `mac2-m2pro.metal`, or `mac2-m1ultra.metal`).
      iv. Under **Advanced details**, verify that Tenancy, Tenancy host by, and Tenancy host ID are preconfigured based on the Dedicated Host you created. Update **Tenancy affinity** as needed.
      v. Complete the wizard, specifying EBS volumes, security groups, and key pairs as needed.
      vi. In the **Summary** panel, choose **Launch instance**.
   b. A confirmation page lets you know that your instance is launching. Choose **View all instances** to close the confirmation page and return to the console. The initial state of an instance is pending. The instance is ready when its state changes to running and it passes status checks.
Launch a Mac instance using the AWS CLI

Allocate the Dedicated Host

Use the following `allocate-hosts` command to allocate a Dedicated Host for your Mac instance, replacing the instance-type with either `mac1.metal`, `mac2.metal`, `mac2-m2.metal`, `mac2-m2pro.metal`, or `mac2-m1ultra.metal`, and the region and availability-zone with the appropriate ones for your environment.

```bash
aws ec2 allocate-hosts --region us-east-1 --instance-type mac1.metal --availability-zone us-east-1b --auto-placement "on" --quantity 1
```

Launch the instance on the host

Use the following `run-instances` command to launch a Mac instance, again replacing the instance-type with either `mac1.metal`, `mac2.metal`, `mac2-m2.metal`, `mac2-m2pro.metal`, or `mac2-m1ultra.metal`, and the region and availability-zone with the ones used previously.

```bash
aws ec2 run-instances --region us-east-1 --instance-type mac1.metal --placement Tenancy=host --image-id ami_id --key-name my-key-pair
```

The initial state of an instance is pending. The instance is ready when its state changes to `running` and it passes status checks. Use the following `describe-instance-status` command to display status information for your instance.

```bash
aws ec2 describe-instance-status --instance-ids i-017f8354e2dc69c4f
```

The following is example output for an instance that is running and has passed status checks.

```json
{
    "InstanceStatuses": [
        {
            "AvailabilityZone": "us-east-1b",
            "InstanceId": "i-017f8354e2dc69c4f",
            "InstanceState": {
                "Code": 16,
                "Name": "running"
            },
            "InstanceStatus": {
                "Details": [
```
Connect to your Mac instance using SSH or a GUI

You can connect to your Mac instance using SSH or a graphical user interface (GUI).

Connect to your instance using SSH

⚠️ **Important**

Multiple users can access the OS simultaneously. Typically there is a 1:1 user:GUI session due to the built-in Screen Sharing service on port 5900. Using SSH within macOS supports multiple sessions up until the "Max Sessions" limit in the sshd_config file.

Amazon EC2 Mac instances do not allow remote root SSH by default. Password authentication is disabled to prevent brute-force password attacks. The ec2-user account is configured to log in remotely using SSH. The ec2-user account also has `sudo` privileges. After you connect to your instance, you can add other users.

To support connecting to your instance using SSH, launch the instance using a key pair and a security group that allows SSH access, and ensure that the instance has internet connectivity. You provide the .pem file for the key pair when you connect to the instance.
Use the following procedure to connect to your Mac instance using an SSH client. If you receive an error while attempting to connect to your instance, see Troubleshoot issues connecting to your Amazon EC2 Linux instance.

**To connect to your instance using SSH**

1. Verify that your local computer has an SSH client installed by entering `ssh` at the command line. If your computer doesn't recognize the command, search for an SSH client for your operating system and install it.

2. Get the public DNS name of your instance. Using the Amazon EC2 console, you can find the public DNS name on both the **Details** and the **Networking** tabs. Using the AWS CLI, you can find the public DNS name using the `describe-instances` command.

3. Locate the `.pem` file for the key pair that you specified when you launched the instance.

4. Connect to your instance using the following `ssh` command, specifying the public DNS name of the instance and the `.pem` file.

   ```bash
   ssh -i /path/key-pair-name.pem ec2-user@instance-public-dns-name
   ```

**Connect to your instance's graphical user interface (GUI)**

Use the following procedure to connect to your instance's GUI using VNC, Apple Remote Desktop (ARD), or the Apple Screen Sharing application (included with macOS).

**Note**

macOS 10.14 and later only allows control if Screen Sharing is enabled through System Preferences.

**To connect to your instance using ARD client or VNC client**

1. Verify that your local computer has an ARD client or a VNC client that supports ARD installed. On macOS, you can leverage the built-in Screen Sharing application. Otherwise, search for ARD for your operating system and install it.

2. From your local computer, connect to your instance using SSH.

3. Set up a password for the ec2-user account using the `passwd` command as follows.
Install and start macOS Screen Sharing using the following command.

```
[ec2-user ~]$ sudo launchctl enable system/com.apple.screensharing
sudo launchctl load -w /System/Library/LaunchDaemons/com.apple.screensharing.plist
```

5. Disconnect from your instance by typing `exit` and pressing Enter.

6. From your computer, connect to your instance using the following `ssh` command. In addition to the options shown in the previous section, use the `-L` option to enable port forwarding and forward all traffic on local port 5900 to the ARD server on the instance.

```
ssh -L 5900:localhost:5900 -i /path/key-pair-name.pem ec2-user@instance-public-dns-name
```

7. From your local computer, use the ARD client or VNC client that supports ARD to connect to `localhost:5900`. For example, use the Screen Sharing application on macOS as follows:

   a. Open Finder and select Go.
   b. Select Connect to Server.
   c. In the Server Address field, enter `vnc://localhost:5900`.
   d. Log in as prompted, using `ec2-user` as the user name and the password that you created for the ec2-user account.

Modify macOS screen resolution on Mac instances

After you connect to your EC2 Mac instance using ARD or a VNC client that supports ARD, you can modify the screen resolution of your macOS environment using any of the publicly available macOS tools or utilities, such as displayplacer.

To modify the screen resolution using displayplacer

1. Install displayplacer.

   ```
   [ec2-user ~]$ brew tap jakehilborn/jakehilborn && brew install displayplacer
   ```

2. Show the current screen information and possible screen resolutions.
3. Apply the desired screen resolution.

For example:

```
RES="2560x1600"
displayplacer "id:69784AF1-CD7D-B79B-E5D4-60D937407F68 res:${RES} scaling:off origin:(0,0) degree:0"
```

## Update the operating system and software on Mac instances

**Warning**

Installation of beta or preview macOS versions is only available on Apple silicon Mac instances. Amazon EC2 doesn't qualify beta or preview macOS versions and doesn't ensure instances will remain functional after an update to a pre-production macOS version. Attempting to install beta or preview macOS versions on Amazon EC2 x86 Mac instances will lead to degradation of your Amazon EC2 Mac Dedicated Host when you stop or terminate your instances, and will prevent you from starting or launching a new instance on that host.

---

**Steps to update software on x86 Mac instances and Apple silicon Mac instances.**

- [Update software on x86 Mac instances](#)
- [Update software on Apple silicon Mac instances](#)

**Update software on x86 Mac instances**

On x86 Mac instances, you can install operating system updates from Apple using the `softwareupdate` command.
To install operating system updates from Apple on x86 Mac instances

1. List the packages with available updates using the following command.

   ![Command]
   
   ```
   [ec2-user ~]$ softwareupdate --list
   ```

2. Install all updates or only specific updates. To install specific updates, use the following command.

   ![Command]
   
   ```
   [ec2-user ~]$ sudo softwareupdate --install label
   ```

   To install all updates instead, use the following command.

   ![Command]
   
   ```
   [ec2-user ~]$ sudo softwareupdate --install --all --restart
   ```

System administrators can use AWS Systems Manager to roll out pre-approved operating system updates on x86 Mac instances. For more information, see the AWS Systems Manager User Guide.

You can use Homebrew to install updates to packages in the EC2 macOS AMIs, so that you have the latest version of these packages on your instances. You can also use Homebrew to install and run common macOS applications on Amazon EC2 macOS. For more information, see the Homebrew Documentation.

To install updates using Homebrew

1. Update Homebrew using the following command.

   ![Command]
   
   ```
   [ec2-user ~]$ brew update
   ```

2. List the packages with available updates using the following command.

   ![Command]
   
   ```
   [ec2-user ~]$ brew outdated
   ```

3. Install all updates or only specific updates. To install specific updates, use the following command.

   ![Command]
   
   ```
   [ec2-user ~]$ brew upgrade package name
   ```

   To install all updates instead, use the following command.
Update software on Apple silicon Mac instances

Considerations

Elastic Network Adapter (ENA) driver

Due to an update in the network driver configuration, ENA driver version 1.0.2 isn't compatible with macOS 13.3 or greater. If you want to install any beta, preview, or production macOS version 13.3 or later and have not installed the latest ENA driver, use the following procedure to install a new version of the driver.

To install a new version of the ENA driver

1. In a Terminal window, connect to your Apple silicon Mac instance using **SSH**.
2. Download the ENA application into the **Applications** file using the following command.

   ```
   [ec2-user ~]$ brew install amazon-ena-ethernet-dext
   ```

3. **Troubleshooting tip**
   
   If you receive the warning No available formula with the name amazon-ena-ethernet-dext, run the following command.

   ```
   [ec2-user ~]$ brew update
   ```

4. Disconnect from your instance by typing **exit** and pressing return.

5. Use the VNC client to activate the ENA application.
   
   a. Setup the VNC client using [Connect to your instance's graphical user interface (GUI)](https://aws.amazon.com/resources/elastic-socket-service).
   
   b. Once you have connected to your instance using the Screen Sharing application, go to the **Applications** folder and open the ENA application.
   
   c. Choose **Activate**
d. To confirm the driver was activated correctly, run the following command in the Terminal window. The output of the command shows that the old driver is in the terminating state and the new driver is in the activated state.

```
systemextensionsctl list;
```

e. After you restart the instance, only the new driver will be present.

**Software update on Apple silicon Mac instances**

On Apple silicon Mac instances, you must complete several steps to perform an in-place operating system update. First, access the internal disk of the instance using the GUI with a VNC (Virtual Network Computing) client. This procedure uses macOS Screen Sharing, the built in VNC client. Then, delegate ownership to the administrative user (`ec2-user`) by signing in as `aws-managed-user` on the Amazon EBS volume.

As you work through this procedure, you create two passwords. One password is for the administrative user (`ec2-user`) and the other password is for a special administrative user (`aws-managed-user`). Remember these passwords since you will use them as you work through the procedure.

**Note**

With this procedure on macOS Big Sur, you can only perform minor updates such as updating from macOS Big Sur 11.7.3 to macOS Big Sur 11.7.4. For macOS Monterey or above, you can perform major software updates.

**To access the internal disk**

1. From your local computer, in the Terminal, connect to your Apple silicon Mac instance using SSH with the following command. For more information, see [Connect to your instance using SSH](#).

```
ssh -i /path/key-pair-name.pem ec2-user@instance-public-dns-name
```

2. Install and start macOS Screen Sharing using the following command.
3. Set a password for `ec2-user` with the following command. Remember the password as you will use it later.

```
[ec2-user ~]$ sudo /usr/bin/dscl . -passwd /Users/ec2-user
```

4. Disconnect from the instance by typing `exit` and pressing return.

5. From your local computer, in the Terminal, reconnect to your instance with an SSH tunnel to the VNC port using the following command.

```
ssh -i /path/key-pair-name.pem -L 5900:localhost:5900 ec2-user@instance-public-dns-name
```

Note

Do not exit this SSH session until the following VNC connection and GUI steps are completed. When the instance is restarted, the connection will close automatically.

6. From your local computer, connect to `localhost:5900` using the following steps:
   a. Open Finder and select Go.
   b. Select Connect to Server.
   c. In the Server Address field, enter vnc://localhost:5900.

7. In the macOS window, connect to the remote session of the Apple silicon Mac instance as `ec2-user` with the password you created in Step 3.

8. Access the internal disk, named InternalDisk, using one of the following options.
   a. For macOS Ventura or above: Open System Settings, select General in the left pane, then Startup Disk at the lower right of the pane.
   b. For macOS Monterey or below: Open System Preferences, select Startup Disk, then unlock the pane by choosing the lock icon in the lower left of the window.
Troubleshooting tip

If you need to mount the internal disk, run the following command in the Terminal.

```bash
APFSVolumeName="InternalDisk" ; SSDContainer=$(diskutil list | grep "Physical Store disk0" -B 3 | grep "/dev/disk" | awk '{print $1}');
diskutil apfs addVolume $SSDContainer APFS $APFSVolumeName
```

9. Choose the internal disk, named **InternalDisk**, and select **Restart**. Select **Restart** again when prompted.

Important

If the internal disk is named **Macintosh HD** instead of **InternalDisk**, your instance needs to be stopped and restarted so the dedicated host can be updated. For more information, see [Stop or terminate your Amazon EC2 Mac instance](#).

Use the following procedure to delegate ownership to the administrative user. When you reconnect to your instance with SSH, you boot from the internal disk using the special administrative user (aws-managed-user). The initial password for aws-managed-user is blank, so you need to overwrite it on your first connection. Then, you need to repeat the steps to install and start macOS Screen Sharing since the boot volume has changed.

**To delegate ownership to the administrator on an Amazon EBS volume**

1. From your local computer, in the Terminal, connect to your Apple silicon Mac instance using the following command.

   ```bash
   ssh -i /path/key-pair-name.pem aws-managed-user@instance-public-dns-name
   ```

2. When you receive the warning `WARNING: REMOTE HOST IDENTIFICATION HAS CHANGED!`, use one of the following commands to resolve this issue.

   a. Clear out the known hosts using the following command. Then, repeat the previous step.
rm ~/.ssh/known_hosts

b. Add the following to the SSH command in the previous step.

-o UserKnownHostsFile=/dev/null -o StrictHostKeyChecking=no

3. Set the password for aws-managed-user with the following command. The aws-managed-user initial password is blank, so you need to overwrite it on your first connection.

a. [aws-managed-user ~]$ sudo /usr/bin/dscl . -passwd /Users/aws-managed-user password

b. When you receive the prompt, Permission denied. Please enter user's old password:, press enter.

Troubleshooting tip
If you get the error passwd: DS error: eDSAuthFailed, use the following command.

[aws-managed-user ~]$ sudo passwd aws-managed-user

4. Install and start macOS Screen Sharing using the following command.

[aws-managed-user ~]$ sudo launchctl enable system/com.apple.screensharing
sudo launchctl load -w /System/Library/LaunchDaemons/com.apple.screensharing.plist

5. Disconnect from the instance by typing exit and pressing return.

6. From your local computer, in the Terminal, reconnect to your instance with an SSH tunnel to the VNC port using the following command.

ssh -i /path/key-pair-name.pem -L 5900:localhost:5900 aws-managed-user@instance-public-dns-name

7. From your local computer, connect to localhost:5900 using the following steps:

a. Open Finder and select Go.

b. Select Connect to Server.
c. In the **Server Address** field, enter `vnc://localhost:5900`.

8. In the macOS window, connect to the remote session of the Apple silicon Mac instance as `aws-managed-user` with the password you created in [Step 3](#).

   > **Note**
   > When prompted to sign in with your Apple ID, select **Set Up Later**.

9. Access the Amazon EBS volume using one of the following options.

   a. For macOS Ventura or later: Open **System Settings**, select **General** in the left pane, then **Startup Disk** at the lower right of the pane.

   b. For macOS Monterey or earlier: Open **System Preferences**, select **Startup Disk**, then unlock the pane using the lock icon in the lower left of the window.

   > **Note**
   > Until the reboot takes place, when prompted for an administrator password, use the password you set above for `aws-managed-user`. This password might be different from the one you set for `ec2-user` or the default administrator account on your instance. The following instructions specify when to use your instance's administrator password.

10. Select the Amazon EBS volume (the volume not named **InternalDisk** in the **Startup Disk** window) and choose **Restart**.

   > **Note**
   > If you have multiple bootable Amazon EBS volumes attached to your Apple silicon Mac instance, be sure to use a unique name for each volume.

11. Confirm the restart, then choose **Authorize Users** when prompted.

12. On the **Authorize user on this volume** pane, verify that the administrative user (`ec2-user` by default) is selected, then select **Authorize**.

13. Enter the `ec2-user` password you created in [Step 3](#) of the previous procedure, then select **Continue**.
14. Enter the password for the special administrative user (aws-managed-user) when prompted.

15. From your local computer, in the Terminal, reconnect to your instance using SSH with user name ec2-user.

**Troubleshooting tip**

If you get the warning WARNING: REMOTE HOST IDENTIFICATION HAS CHANGED!, run the following command and reconnect to your instance using SSH.

```
rm ~/.ssh/known_hosts
```

16. To perform the software update, use the commands under [Update software on x86 Mac instances](#).

### Increase the size of an EBS volume on your Mac instance

You can increase the size of your Amazon EBS volumes on your Mac instance. For more information, see [Amazon EBS Elastic Volumes](#) in the *Amazon EBS User Guide*.

After you increase the size of the volume, you must increase the size of your APFS container as follows.

#### Make increased disk space available for use

1. Determine if a restart is required. If you resized an existing EBS volume on a running Mac instance, you must **reboot** the instance to make the new size available. If disk space modification was done during launch time, a reboot will not be required.

View current status of disk sizes:

```
[ec2-user ~]$ diskutil list external physical
/dev/disk0 (external, physical):                      SIZE IDENTIFIER
#: TYPE_NAME                                   SIZE IDENTIFIER
 0: GUID_partition_scheme                    *322.1 GB disk0
 1: EFI EFI                                  209.7 MB disk0s1
 2: Apple_APFS Container disk2               321.9 GB disk0s2
```

2. Copy and paste the following command.
3. Copy and paste the following command.

```
[ec2-user ~]$ PDISK=$(diskutil list physical external | head -n1 | cut -d" " -f1)
APFSCONT=$(diskutil list physical external | grep "Apple_APFS" | tr -s " " | cut -d" " -f8)
yes | sudo diskutil repairDisk $PDISK
```

```
[ec2-user ~]$ sudo diskutil apfs resizeContainer $APFSCONT 0
```

Stop or terminate your Amazon EC2 Mac instance

When you stop a Mac instance, the instance remains in the stopping state for about 15 minutes before it enters the stopped state.

When you stop or terminate a Mac instance, Amazon EC2 performs a scrubbing workflow on the underlying Dedicated Host to erase the internal SSD, to clear the persistent NVRAM variables, and to update to the latest device firmware. This ensures that Mac instances provide the same security and data privacy as other EC2 Nitro instances. It also allows you to run the latest macOS AMIs. During the scrubbing workflow, the Dedicated Host temporarily enters the pending state. On x86 Mac instances, the scrubbing workflow might take up to 50 minutes to complete. On Apple silicon Mac instances, the scrubbing workflow might take up to 110 minutes to complete. Additionally, on x86 Mac instances, if the device firmware needs to be updated, the scrubbing workflow might take up to 3 hours to complete.

You can't start the stopped Mac instance or launch a new Mac instance until after the scrubbing workflow completes, at which point the Dedicated Host enters the available state.

Metering and billing is paused when the Dedicated Host enters the pending state. You are not charged for the duration of the scrubbing workflow.

Release the Dedicated Host for your Mac instance

When you are finished with your Mac instance, you can release the Dedicated Host. Before you can release the Dedicated Host, you must stop or terminate the Mac instance. You cannot release the host until the allocation period exceeds the 24-hour minimum.

To release the Dedicated Host

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Instance state**, then choose either **Stop instance** or **Terminate instance**.
4. In the navigation pane, choose **Dedicated Hosts**.
5. Select the Dedicated Host and choose **Actions, Release host**.
6. When prompted for confirmation, choose **Release**.

**Find supported macOS versions for your Amazon EC2 Mac Dedicated Host**

You can view the latest macOS versions supported by your Amazon EC2 Mac Dedicated Host. With this functionality, you can validate whether your Dedicated Host can support instance launches with your preferred macOS versions.

Each macOS version requires a minimum firmware version on the underlying Apple Mac to successfully boot. The Apple Mac firmware version can become outdated if an allocated Mac Dedicated Host has remained idle for an extended period of time or if it has a long running instance on it.

To ensure supportability for the latest macOS versions, you can stop or terminate instances on your allocated Mac Dedicated Host. This triggers the host scrubbing workflow and updates the firmware on the underlying Apple Mac to support the latest macOS versions. A Dedicated Host with a long running instance will automatically be updated when you stop or terminate a running instance.

For more information about the scrubbing workflow, see [Stop or terminate your Amazon EC2 Mac instance](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/mac-dh.html).

For more information about launching Mac instances, see [Launch a Mac instance using the AWS Management Console or the AWS CLI](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/mac-dh.html).

You can view information about the latest macOS versions supported on your allocated Dedicated Host using the Amazon EC2 console or the AWS CLI.

**Console**

**To view Dedicated Host firmware information using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Dedicated Hosts**.

3. On the **Dedicated Hosts details** page, under **Latest supported macOS versions**, you can see the latest macOS versions that the host can support.

**AWS CLI**

**To view Dedicated Host firmware information using the AWS CLI**

Use the `describe-mac-hosts` command, replacing `region` with the appropriate AWS Region.

```
$ aws ec2 describe-mac-hosts --region us-east-1
{
   "MacHosts": [
   {
      "HostId": "h-07879acf49EXAMPLE",
      "MacOSLatestSupportedVersions": [
         "14.3",
         "13.6.4",
         "12.7.3"
      ]
   }
   ]
}
```

**Subscribe to macOS AMI notifications**

To be notified when new AMIs are released or when bridgeOS has been updated, subscribe for notifications using Amazon SNS.

For more information about EC2 macOS AMIs, see [Amazon EC2 macOS AMIs release notes](https://aws.amazon.com/documentation/ec2/macos-amis/).

**To subscribe to macOS AMI notifications**

2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must use this Region because the SNS notifications that you are subscribing to were created in this Region.

3. In the navigation pane, choose **Subscriptions**.

4. Choose **Create subscription**.
5. For the Create subscription dialog box, do the following:

   a. For Topic ARN, copy and paste one of the following Amazon Resource Names (ARNs):
      
      - `arn:aws:sns:us-east-1:898855652048:amazon-ec2-bridgeos-updates`

   b. For Protocol, choose one of the following:
      
      - **Email:**
        
        For Endpoint, type an email address that you can use to receive the notifications. After you create your subscription you'll receive a confirmation message with the subject line AWS Notification - Subscription Confirmation. Open the email and choose Confirm subscription to complete your subscription.

      - **SMS:**
        
        For Endpoint, type a phone number that you can use to receive the notifications.

      - **AWS Lambda, Amazon SQS, Amazon Data Firehose (Notifications come in JSON format):**
        
        For Endpoint, enter the ARN for the Lambda function, SQS queue, or Firehose stream you can use to receive the notifications.

   c. Choose Create subscription.

Whenever macOS AMIs are released, we send notifications to the subscribers of the `amazon-ec2-macos-ami-updates` topic. Whenever bridgeOS is updated, we send notifications to the subscribers of the `amazon-ec2-bridgeos-updates` topic. If you no longer want to receive these notifications, use the following procedure to unsubscribe.

**To unsubscribe from macOS AMI notifications**

2. In the navigation bar, change the Region to **US East (N. Virginia)**, if necessary. You must use this Region because the SNS notifications were created in this Region.

3. In the navigation pane, choose Subscriptions.

4. Select the subscriptions and then choose Actions, Delete subscriptions. When prompted for confirmation, choose Delete.
Retrieve macOS AMI IDs using AWS Systems Manager Parameter Store API

You can view all of the macOS AMIs in an AWS Region and retrieve the latest macOS AMI by querying the AWS Systems Manager Parameter Store API. Using these public parameters, you don’t need to manually look up macOS AMI IDs. Public parameters are available for both x86 and ARM64 macOS AMIs and can be integrated with existing AWS CloudFormation templates.

Permissions

The IAM principal that you use must have the ssm:GetParameter IAM permission.

To view a list of all macOS AMIs in the current AWS Region using the AWS CLI

Use the following `get-parameters-by-path` command to view a list of all macOS AMIs in the current Region.

```
aws ssm get-parameters-by-path --path /aws/service/ec2-macos --query "Parameters[].Name"
```

To retrieve the AMI ID of the latest major macOS AMI using the AWS CLI

Use the following `get-parameter` command with the sub-parameter `image_id`. In the following example, replace sonoma with a macOS supported major version, x86_64_mac with the processor, and region-code with a supported AWS Region for which you want the latest macOS AMI ID.

```
aws ssm get-parameter --name /aws/service/ec2-macos/sonoma/x86_64_mac/latest/image_id --region region-code
```

For more information, see Calling AMI public parameters for macOS in the AWS Systems Manager User Guide.

Amazon EC2 macOS AMIs release notes

The following information provides details about the packages included by default in the EC2 macOS AMIs and summarizes the changes for each EC2 macOS AMI release.

For information about how to subscribe to macOS AMI notifications, see Subscribe to macOS AMI notifications.
## Default packages included in Amazon EC2 macOS AMIs

The following table describes packages that are included by default in the EC2 macOS AMIs.

<table>
<thead>
<tr>
<th>Packages</th>
<th>Release notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>EC2 macOS Init</td>
<td><a href="https://github.com/aws/ec2-macos-init/tags">https://github.com/aws/ec2-macos-init/tags</a></td>
</tr>

## Amazon EC2 macOS AMI updates

The following table describes changes included in the EC2 macOS AMI releases. Note that some changes apply to all EC2 macOS AMIs, whereas others apply to only a subset of these AMIs.

### EC2 macOS AMI updates

<table>
<thead>
<tr>
<th>Release</th>
<th>Changes</th>

Release of macOS Sonoma 14.4.1 (all Mac instances)

• Security content of macOS Sonoma 14.4.1

Release of macOS Ventura 13.6.6 (all Mac instances)

• Security content of macOS Ventura 13.6.6

• Updated Safari to 17.4.1
  • Security content of Safari 17.4.1

For macOS Monterey (all Mac instances)

• Updated Safari to 17.4.1
  • Security content of Safari 17.4.1

Amazon EBS–optimized instance types

Amazon EBS–optimized instances use an optimized configuration stack and provide additional, dedicated bandwidth for Amazon EBS I/O. This optimization provides the best performance for your EBS volumes by minimizing contention between Amazon EBS I/O and other traffic from your instance.

When attached to an EBS–optimized instance, General Purpose SSD (gp2 and gp3) volumes are designed to deliver at least 90 percent of their provisioned IOPS performance 99 percent of the time in a given year, and Provisioned IOPS SSD (io1 and io2) volumes are designed to deliver at least 90 percent of their provisioned IOPS performance 99.9 percent of the time in a given year. Throughput Optimized HDD (st1) and Cold HDD (sc1) deliver at least 90 percent of their expected throughput performance 99 percent of the time in a given year. Non-compliant periods
are approximately uniformly distributed, targeting 99 percent of expected total throughput each hour. For more information, see Amazon EBS volume types in the Amazon EBS User Guide.

Some instance types are EBS-optimized by default, and there is no need to enable it and no effect if you attempt to disable it. Other instance types optionally support EBS optimization and you can enable it during or after launch for an additional hourly fee. Some instance types do not support EBS optimization.

The Amazon EC2 Instance Types Guide indicates which instance types are EBS-optimized by default and which instance types optionally support EBS optimization, along with their Amazon EBS optimized performance. For more information, see the following:

- Amazon EBS specifications — General purpose instances
- Amazon EBS specifications — Compute optimized instances
- Amazon EBS specifications — Memory optimized instances
- Amazon EBS specifications — Storage optimized instances
- Amazon EBS specifications — Accelerated computing instances
- Amazon EBS specifications — High-performance computing instances
- Amazon EBS specifications — Previous generation instances

Topics

- Get the maximum Amazon EBS optimized performance
- Find Amazon EBS-optimized Amazon EC2 instance types
- Enable Amazon EBS optimization for an Amazon EC2 instance

Get the maximum Amazon EBS optimized performance

An instance's EBS performance is bounded by the instance type's performance limits, or the aggregated performance of its attached volumes, whichever is smaller. To achieve maximum EBS performance, an instance must have attached volumes that provide a combined performance equal to or greater than the maximum instance performance. For example, to achieve 80,000 IOPS for r6i.16xlarge, the instance must have at least 5 gp3 volumes provisioned with 16,000 IOPS each (5 volumes x 16,000 IOPS = 80,000 IOPS). We recommend that you choose an instance type that provides more dedicated Amazon EBS throughput than your application needs; otherwise, the connection between Amazon EBS and Amazon EC2 can become a performance bottleneck.
You can use the EBSI0Balance% and EBSByteBalance% metrics to help you determine whether your instances are sized correctly. You can view these metrics in the CloudWatch console and set an alarm that is triggered based on a threshold you specify. These metrics are expressed as a percentage. Instances with a consistently low balance percentage are candidates to size up. Instances where the balance percentage never drops below 100% are candidates for downsizing. For more information, see Monitor your instances using CloudWatch.

The high memory instances are designed to run large in-memory databases, including production deployments of the SAP HANA in-memory database, in the cloud. To maximize EBS performance, use high memory instances with an even number of io1 or io2 volumes with identical provisioned performance. For example, for IOPS heavy workloads, use four io1 or io2 volumes with 40,000 provisioned IOPS to get the maximum 160,000 instance IOPS. Similarly, for throughput heavy workloads, use six io1 or io2 volumes with 48,000 provisioned IOPS to get the maximum 4,750 MB/s throughput. For additional recommendations, see Storage Configuration for SAP HANA.

Considerations

- G4dn, I3en, Inf1, M5a, M5ad, R5a, R5ad, T3, T3a, and Z1d instances launched after February 26, 2020 provide the maximum performance listed in the table above. To get the maximum performance from an instance launched before February 26, 2020, stop and start it.
- C5, C5d, C5n, M5, M5d, M5n, M5dn, R5, R5d, R5n, R5dn, and P3dn instances launched after December 3, 2019 provide the maximum performance listed in the table above. To get the maximum performance from an instance launched before December 3, 2019, stop and start it.
- u-6tb1.metal, u-9tb1.metal, and u-12tb1.metal instances launched after March 12, 2020 provide the performance in the table above. Instances of these types launched before March 12, 2020 might provide lower performance. To get the maximum performance from an instance launched before March 12, 2020, contact your account team to upgrade the instance at no additional cost.

Find Amazon EBS-optimized Amazon EC2 instance types

You can use the AWS CLI to view the instances types in the current Region that support EBS optimization.

To find instance types that are Amazon EBS-optimized by default

Use the following describe-instance-types command. If running this command at a Windows Command Prompt, replace the \ line continuation characters with the ^ character.
To find instance types that optionally support Amazon EBS optimization

Use the following `describe-instance-types` command.

```bash
aws ec2 describe-instance-types \
--filters Name=ebs-info.ebs-optimized-support,Values=supported --output=table
```

Example output for eu-west-1:

```
+-------------------------------+-------------------+----------+---------------------+
| InstanceType                  | MaxBandwidth(Mb/s) | MaxIOPS  | MaxThroughput(MB/s)  |
+-------------------------------+-------------------+----------+---------------------+
| i2.2xlarge                    | 1000              | 8000     | 125.0               |
| m2.4xlarge                    | 1000              | 8000     | 125.0               |
| m2.2xlarge                    | 500               | 4000     | 62.5                |
| c1.xlarge                     | 1000              | 8000     | 125.0               |
| i2.xlarge                     | 500               | 4000     | 62.5                |
```

Find EBS-optimized instance types
Enable Amazon EBS optimization for an Amazon EC2 instance

You can manually enable Amazon EBS optimization only for instances types that optionally support Amazon EBS optimization, but are not Amazon EBS-optimized by default. For these instance types you can enable Amazon EBS optimization during or after launch for an additional hourly fee.

Console

To enable Amazon EBS optimization during launch

In the Launch instances wizard, select the required instance type. Expand the Advanced details section, then for EBS-optimized instance, select Enable.

If the selected instance type does not support Amazon EBS optimization, the drop-down is disabled. If the instance type is Amazon EBS-optimized by default, Enable is already selected.

To enable Amazon EBS optimization after launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and select the instance.
3. Stop the instance. Choose Actions, Instance state, Stop instance.

⚠️ Warning

When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.
4. With the instance still selected, choose Actions, Instance settings, Change instance type.

5. Select EBS-optimized and then choose Apply.

   If the instance type is Amazon EBS-optimized by default, or if it does not support Amazon EBS optimization, the checkbox is disabled.

6. Restart the instance. Choose Instance state, Start instance.

Command line

To enable Amazon EBS optimization during launch

You can use one of the following commands with the corresponding option.

- run-instances with --ebs-optimized (AWS CLI)
- New-EC2Instance with -EbsOptimized (AWS Tools for Windows PowerShell)

To enable Amazon EBS optimization after launch

1. If the instance is running, stop it using one of the following commands.

   - stop-instances (AWS CLI)
   - Stop-EC2Instance (AWS Tools for Windows PowerShell)

   **Warning**

   When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

2. Enable EBS optimization using one of the following commands with the corresponding option:

   - modify-instance-attribute with --ebs-optimized (AWS CLI)
   - Edit-EC2InstanceAttribute with -EbsOptimized (AWS Tools for Windows PowerShell)
Instance purchasing options

Amazon EC2 provides the following purchasing options to enable you to optimize your costs based on your needs:

- **On-Demand Instances** – Pay, by the second, for the instances that you launch.
- **Savings Plans** – Reduce your Amazon EC2 costs by making a commitment to a consistent amount of usage, in USD per hour, for a term of 1 or 3 years.
- **Reserved Instances** – Reduce your Amazon EC2 costs by making a commitment to a consistent instance configuration, including instance type and Region, for a term of 1 or 3 years.
- **Spot Instances** – Request unused EC2 instances, which can reduce your Amazon EC2 costs significantly.
- **Dedicated Hosts** – Pay for a physical host that is fully dedicated to running your instances, and bring your existing per-socket, per-core, or per-VM software licenses to reduce costs.
- **Dedicated Instances** – Pay, by the hour, for instances that run on single-tenant hardware.
- **Capacity Reservations** – Reserve capacity for your EC2 instances in a specific Availability Zone.

If you can't make a commitment to a specific instance configuration, but you can commit to a usage amount, purchase Savings Plans to reduce your On-Demand Instance costs. If you require a capacity reservation, purchase Reserved Instances or Capacity Reservations for a specific Availability Zone. Capacity Blocks can be used to reserve a cluster of GPU instances. Spot Instances are a cost-effective choice if you can be flexible about when your applications run and if they can be interrupted. Dedicated Hosts or Dedicated Instances can help you address compliance requirements and reduce costs by using your existing server-bound software licenses. For more information, see [Amazon EC2 Pricing](https://aws.amazon.com/ec2/pricing/).

Contents

- Determine the instance lifecycle
- Purchasing On-Demand Instances for Amazon EC2
- Reserved Instances for Amazon EC2 overview
- Spot Instances
- Amazon EC2 Dedicated Hosts
- Amazon EC2 Dedicated Instances
Determine the instance lifecycle

The lifecycle of an instance starts when it is launched and ends when it is terminated. The purchasing option that you choose affects the lifecycle of the instance. For example, an On-Demand Instance runs when you launch it and ends when you terminate it. A Spot Instance runs as long as capacity is available and your maximum price is higher than the Spot price.

Use one of the following methods to determine the lifecycle of an instance.

To determine the instance lifecycle using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance.
4. On the Details tab, under Instance details, find Lifecycle. If the value is spot, the instance is a Spot Instance. If the value is normal, the instance is either an On-Demand Instance or a Reserved Instance.
5. On the Details tab, under Host and placement group, find Tenancy. If the value is host, the instance is running on a Dedicated Host. If the value is dedicated, the instance is a Dedicated Instance.

To determine the instance lifecycle using the AWS CLI

Use the following describe-instances command:

```bash
aws ec2 describe-instances --instance-ids i-1234567890abcdef0
```

If the instance is running on a Dedicated Host, the output contains the following information:

```json
"Tenancy": "host"
```

If the instance is a Dedicated Instance, the output contains the following information:

```json
"Tenancy": "dedicated"
```

If the instance is a Spot Instance, the output contains the following information:

```json
"Tenancy": "spot"
```
Otherwise, the output does not contain InstanceLifecycle.

**Purchasing On-Demand Instances for Amazon EC2**

With On-Demand Instances, you pay for compute capacity by the second with no long-term commitments. You have full control over the instance's lifecycle—you decide when to launch, stop, hibernate, start, reboot, or terminate it.

There is no long-term commitment required when you purchase On-Demand Instances. You pay only for the seconds that your On-Demand Instances are in the running state, with a 60-second minimum. The price per second for a running On-Demand Instance is fixed, and is listed on the Amazon EC2 Pricing, On-Demand Pricing page.

We recommend that you use On-Demand Instances for applications with short-term, irregular workloads that cannot be interrupted.

For significant savings over On-Demand Instances, use AWS Savings Plans, Spot Instances, or Reserved Instances for Amazon EC2 overview.

**Contents**
- On-Demand Instance quotas
  - Monitor On-Demand Instance quotas and usage
  - Request a quota increase
- Query the prices of On-Demand Instances

**On-Demand Instance quotas**

There are quotas for the number of running On-Demand Instances per AWS account per Region. On-Demand Instance quotas are managed in terms of the number of virtual central processing units (vCPUs) that your running On-Demand Instances are using, regardless of the instance type. Each quota type specifies the maximum number of vCPUs for one or more instance families.

Your account includes the following quotas for On-Demand Instances. Instances that are in the pending, stopping, stopped, and hibernated states do not count towards your On-Demand Instance quotas. Capacity Reservations count toward your On-Demand Instance quotas, even if they are unused.
### On-Demand Instances

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Running On-Demand DL instances</td>
<td>0</td>
<td>Yes</td>
</tr>
<tr>
<td>Running On-Demand F instances</td>
<td>0</td>
<td>Yes</td>
</tr>
<tr>
<td>Running On-Demand G and VT instances</td>
<td>0</td>
<td>Yes</td>
</tr>
<tr>
<td>Running On-Demand HPC instances</td>
<td>0</td>
<td>Yes</td>
</tr>
<tr>
<td>Running On-Demand High Memory instances</td>
<td>0</td>
<td>Yes</td>
</tr>
<tr>
<td>Running On-Demand Inf instances</td>
<td>0</td>
<td>Yes</td>
</tr>
<tr>
<td>Running On-Demand P instances</td>
<td>0</td>
<td>Yes</td>
</tr>
<tr>
<td>Running On-Demand Standard (A, C, D, H, I, M, R, T, Z) instances</td>
<td>5</td>
<td>Yes</td>
</tr>
<tr>
<td>Running On-Demand Trn instances</td>
<td>0</td>
<td>Yes</td>
</tr>
<tr>
<td>Running On-Demand X instances</td>
<td>0</td>
<td>Yes</td>
</tr>
</tbody>
</table>

For information about the different instance families, generations, and sizes, see the [Amazon EC2 Instance Types Guide](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/instance-types.html).

You can launch any combination of instance types that meet your changing application needs, as long as the number of vCPUs does not exceed your account quota. For example, with a Standard instance quota of 256 vCPUs, you could launch 32 m5.2xlarge instances (32 x 8 vCPUs) or 16 c5.4xlarge instances (16 x 16 vCPUs). For more information, see [EC2 On-Demand Instance limits](https).

### Tasks

- Monitor On-Demand Instance quotas and usage
- Request a quota increase

### Monitor On-Demand Instance quotas and usage

You can view and manage your On-Demand Instance quotas for each Region using the following methods.
To view your current quotas using the Service Quotas console

2. From the navigation bar, select a Region.
3. In the filter field, enter **On-Demand**.
4. The **Applied quota value** column displays the maximum number of vCPUs for each On-Demand Instance quota type for your account.

To view your current quotas using the AWS Trusted Advisor console

Open [Service limits page](https://console.aws.amazon.com/trustedadvisor/features/limits) in the AWS Trusted Advisor console.

To configure CloudWatch alarms

With Amazon CloudWatch metrics integration, you can monitor your EC2 usage against your quotas. You can also configure alarms to warn about approaching quotas. For more information, see [Service Quotas and Amazon CloudWatch alarms](https://docs.aws.amazon.com/servicequotas/latest/userguide/service_quotas.html) in the [Service Quotas User Guide](https://docs.aws.amazon.com/servicequotas/latest/userguide/service_quotas.html).

Request a quota increase

Even though Amazon EC2 automatically increases your On-Demand Instance quotas based on your usage, you can request a quota increase if necessary. For example, if you intend to launch more instances than your current quota allows, you can request a quota increase by using the Service Quotas console described in [Amazon EC2 service quotas](https://docs.aws.amazon.com/servicequotas/latest/userguide/service_quotas.html).

Query the prices of On-Demand Instances

You can use the Price List Service API or the AWS Price List API to query the prices of On-Demand Instances. For more information, see [Using the AWS Price List API](https://docs.aws.amazon.com/pricing/latest/userguide/using_price_list_api.html) in the [AWS Billing User Guide](https://docs.aws.amazon.com/pricing/latest/userguide/aws-billing.html).

Reserved Instances for Amazon EC2 overview

⚠️ **Important**

We recommend Savings Plans over Reserved Instances. Saving Plans are the easiest and most flexible way to save money on your AWS compute costs and offer lower prices (up to 72% off On-Demand pricing), just like Reserved Instances. However, Savings Plans...
Reserved Instances provide you with significant savings on your Amazon EC2 costs compared to On-Demand Instance pricing. Reserved Instances are not physical instances, but rather a billing discount applied to the use of On-Demand Instances in your account. These On-Demand Instances must match certain attributes, such as instance type and Region, in order to benefit from the billing discount.

Reserved Instances topics

- Reserved Instance example scenario
- Key variables that determine Reserved Instance pricing
- Regional and zonal Reserved Instances (scope)
- Types of Reserved Instances (offering classes)
- How Reserved Instance discounts are applied
- Use your Reserved Instances
- How you are billed
- Buy Reserved Instances
- Sell in the Reserved Instance Marketplace
- Modify Reserved Instances
- Exchange Convertible Reserved Instances
- Reserved Instance quotas

Reserved Instance example scenario

The following diagram shows a basic scenario of purchasing and using Reserved Instances.
In this scenario, you have a running On-Demand Instance (T2) in your account, for which you're currently paying On-Demand rates. You purchase a Reserved Instance that matches the attributes of your running instance, and the billing benefit is immediately applied. Next, you purchase a Reserved Instance for a C4 instance. You do not have any running instances in your account that match the attributes of this Reserved Instance. In the final step, you launch an instance that matches the attributes of the C4 Reserved Instance, and the billing benefit is immediately applied.

**Key variables that determine Reserved Instance pricing**

The Reserved Instance pricing is determined by the following key variables.

**Instance attributes**

A Reserved Instance has four instance attributes that determine its price.

- **Instance type**: For example, `m4.large`. This is composed of the instance family (for example, `m4`) and the instance size (for example, `large`).
- **Region**: The Region in which the Reserved Instance is purchased.
- **Tenancy**: Whether your instance runs on shared (default) or single-tenant (dedicated) hardware. For more information, see [Amazon EC2 Dedicated Instances](https://aws.amazon.com/ec2/).  
- **Platform**: The operating system; for example, Windows or Linux/Unix. For more information, see [Choosing a platform](https://aws.amazon.com/ec2/platform/).
Term commitment

You can purchase a Reserved Instance for a one-year or three-year commitment, with the three-year commitment offering a bigger discount.

- **One-year**: A year is defined as 31536000 seconds (365 days).
- **Three-year**: Three years is defined as 94608000 seconds (1095 days).

Reserved Instances do not renew automatically; when they expire, you can continue using the EC2 instance without interruption, but you are charged On-Demand rates. In the above example, when the Reserved Instances that cover the T2 and C4 instances expire, you go back to paying the On-Demand rates until you terminate the instances or purchase new Reserved Instances that match the instance attributes.

⚠️ Important

After you purchase a Reserved Instance, you cannot cancel your purchase. However, you might be able to modify, exchange, or sell your Reserved Instance if your needs change.

Payment options

The following payment options are available for Reserved Instances:

- **All Upfront**: Full payment is made at the start of the term, with no other costs or additional hourly charges incurred for the remainder of the term, regardless of hours used.
- **Partial Upfront**: A portion of the cost must be paid upfront and the remaining hours in the term are billed at a discounted hourly rate, regardless of whether the Reserved Instance is being used.
- **No Upfront**: You are billed a discounted hourly rate for every hour within the term, regardless of whether the Reserved Instance is being used. No upfront payment is required.

❗ Note

No Upfront Reserved Instances are based on a contractual obligation to pay monthly for the entire term of the reservation. For this reason, a successful billing history is required before you can purchase No Upfront Reserved Instances.
Generally speaking, you can save more money making a higher upfront payment for Reserved Instances. You can also find Reserved Instances offered by third-party sellers at lower prices and shorter term lengths on the Reserved Instance Marketplace. For more information, see [Sell in the Reserved Instance Marketplace](#).

### Offering class

If your computing needs change, you might be able to modify or exchange your Reserved Instance, depending on the offering class.

- **Standard**: These provide the most significant discount, but can only be modified. Standard Reserved Instances can't be exchanged.

- **Convertible**: These provide a lower discount than Standard Reserved Instances, but can be exchanged for another Convertible Reserved Instance with different instance attributes. Convertible Reserved Instances can also be modified.

For more information, see [Types of Reserved Instances (offering classes)](#).

⚠️ **Important**

After you purchase a Reserved Instance, you cannot cancel your purchase. However, you might be able to [modify], [exchange], or [sell] your Reserved Instance if your needs change.

For more information, see the [Amazon EC2 Reserved Instances Pricing page](#).

### Regional and zonal Reserved Instances (scope)

When you purchase a Reserved Instance, you determine the scope of the Reserved Instance. The scope is either regional or zonal.

- **Regional**: When you purchase a Reserved Instance for a Region, it's referred to as a *regional* Reserved Instance.

- **Zonal**: When you purchase a Reserved Instance for a specific Availability Zone, it's referred to as a *zonal* Reserved Instance.
The scope does not affect the price. You pay the same price for a regional or zonal Reserved Instance. For more information about Reserved Instance pricing, see Key variables that determine Reserved Instance pricing and Amazon EC2 Reserved Instances Pricing.

For more information about how to specify the scope of a Reserved Instance, see RI Attributes, specifically the Availability Zone bullet.

**Differences between regional and zonal Reserved Instances**

The following table highlights some key differences between regional Reserved Instances and zonal Reserved Instances:

<table>
<thead>
<tr>
<th></th>
<th>Regional Reserved Instances</th>
<th>Zonal Reserved Instances</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ability to reserve capacity</td>
<td>A regional Reserved Instance does <em>not</em> reserve capacity.</td>
<td>A zonal Reserved Instance reserves capacity in the specified Availability Zone.</td>
</tr>
<tr>
<td>Availability Zone flexibility</td>
<td>The Reserved Instance discount applies to instance usage in any Availability Zone in the specified Region.</td>
<td>No Availability Zone flexibility—the Reserved Instance discount applies to instance usage in the specified Availability Zone only.</td>
</tr>
<tr>
<td>Instance size flexibility</td>
<td>The Reserved Instance discount applies to instance usage within the instance family, regardless of size. Only supported on Amazon Linux/Unix Reserved Instances with default tenancy. For more information, see Instance size flexibility determined by normalization factor.</td>
<td>No instance size flexibility—the Reserved Instance discount applies to instance usage for the specified instance type and size only.</td>
</tr>
</tbody>
</table>
Regional Reserved Instances | Zonal Reserved Instances
---|---
Queuing a purchase | You can queue purchases for regional Reserved Instances. | You can't queue purchases for zonal Reserved Instances.

For more information and examples, see [How Reserved Instance discounts are applied](#).

**Types of Reserved Instances (offering classes)**

The offering class of a Reserved Instance is either Standard or Convertible. A Standard Reserved Instance provides a more significant discount than a Convertible Reserved Instance, but you can't exchange a Standard Reserved Instance. You can exchange Convertible Reserved Instances. You can modify Standard and Convertible Reserved Instances.

The configuration of a Reserved Instance comprises a single instance type, platform, scope, and tenancy over a term. If your computing needs change, you might be able to modify or exchange your Reserved Instance.

**Differences between Standard and Convertible Reserved Instances**

The following are the differences between Standard and Convertible Reserved Instances.

<table>
<thead>
<tr>
<th></th>
<th>Standard Reserved Instance</th>
<th>Convertible Reserved Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modify Reserved Instances</td>
<td>Some attributes can be modified. For more information, see <a href="#">Modify Reserved Instances</a>.</td>
<td>Some attributes can be modified. For more information, see <a href="#">Modify Reserved Instances</a>.</td>
</tr>
<tr>
<td>Exchange Reserved Instances</td>
<td>Can't be exchanged.</td>
<td>Can be exchanged during the term for another Convertible Reserved Instance with new attributes, including instance family, instance type, platform, scope, or tenancy. For more informati</td>
</tr>
</tbody>
</table>
### How Reserved Instance discounts are applied

Reserved Instances are not physical instances, but rather a billing discount that is applied to the running On-Demand Instances in your account. The On-Demand Instances must match certain specifications of the Reserved Instances in order to benefit from the billing discount.

If you purchase a Reserved Instance and you already have a running On-Demand Instance that matches the specifications of the Reserved Instance, the billing discount is applied immediately and automatically. You do not have to restart your instances. If you do not have an eligible running On-Demand Instance, launch an On-Demand Instance with the same specifications as your Reserved Instance. For more information, see [Use your Reserved Instances](#).

The offering class (Standard or Convertible) of the Reserved Instance does not affect how the billing discount is applied.

### Topics

- [How zonal Reserved Instances are applied](#)
- [How regional Reserved Instances are applied](#)
- [Instance size flexibility](#)
- [Examples of applying Reserved Instances](#)

### How zonal Reserved Instances are applied

A Reserved Instance that is purchased to reserve capacity in a specific Availability Zone is called a zonal Reserved Instance.

<table>
<thead>
<tr>
<th></th>
<th>Standard Reserved Instance</th>
<th>Convertible Reserved Instance</th>
</tr>
</thead>
</table>
• The Reserved Instance discount applies to matching instance usage in that Availability Zone.
• The attributes (tenancy, platform, Availability Zone, instance type, and instance size) of the running instances must match that of the Reserved Instances.

For example, if you purchase two \texttt{c4.xlarge} default tenancy Linux/Unix Standard Reserved Instances for Availability Zone us-east-1a, then up to two \texttt{c4.xlarge} default tenancy Linux/Unix instances running in the Availability Zone us-east-1a can benefit from the Reserved Instance discount.

\textbf{How regional Reserved Instances are applied}

A Reserved Instance that is purchased for a Region is called a regional Reserved Instance, and provides Availability Zone and instance size flexibility.

• The Reserved Instance discount applies to instance usage in any Availability Zone in that Region.
• The Reserved Instance discount applies to instance usage within the instance family, regardless of size—this is known as \textit{instance size flexibility}.

\textbf{Instance size flexibility}

With instance size flexibility, the Reserved Instance discount applies to instance usage for instances that have the same \textit{family, generation, and attribute}. The Reserved Instance is applied from the smallest to the largest instance size within the instance family based on the normalization factor. For an example of how the Reserved Instance discount is applied, see \textit{Scenario 2: Reserved Instances in a single account using the normalization factor}.

\textbf{Limitations}

• \textbf{Supported}: Instance size flexibility is only supported for Regional Reserved Instances.
• \textbf{Not supported}: Instance size flexibility is \textit{not supported} for the following Reserved Instances:
  • Reserved Instances that are purchased for a specific Availability Zone (zonal Reserved Instances)
  • Reserved Instances for G4ad, G4dn, G5, G5g, G6, Gr6, hpc7a, P5, Inf1, and Inf2 instances
  • Reserved Instances for Windows Server, Windows Server with SQL Standard, Windows Server with SQL Server Enterprise, Windows Server with SQL Server Web, RHEL, and SUSE Linux Enterprise Server
  • Reserved Instances with dedicated tenancy
Instance size flexibility determined by normalization factor

Instance size flexibility is determined by the normalization factor of the instance size. The discount applies either fully or partially to running instances of the same instance family, depending on the instance size of the reservation, in any Availability Zone in the Region. The only attributes that must be matched are the instance family, tenancy, and platform.

The following table lists the different sizes within an instance family, and the corresponding normalization factor. This scale is used to apply the discounted rate of Reserved Instances to the normalized usage of the instance family.

<table>
<thead>
<tr>
<th>Instance size</th>
<th>Normalization factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>nano</td>
<td>0.25</td>
</tr>
<tr>
<td>micro</td>
<td>0.5</td>

<tr>
<td>112xlarge</td>
<td>896</td>
</tr>
</tbody>
</table>

For example, a `t2.medium` instance has a normalization factor of 2. If you purchase a `t2.medium` default tenancy Amazon Linux/Unix Reserved Instance in the US East (N. Virginia) and you have two running `t2.small` instances in your account in that Region, the billing benefit is applied in full to both instances.

Or, if you have one `t2.large` instance running in your account in the US East (N. Virginia) Region, the billing benefit is applied to 50% of the usage of the instance.
The normalization factor is also applied when modifying Reserved Instances. For more information, see Modify Reserved Instances.

### Normalization factor for bare metal instances

Instance size flexibility also applies to bare metal instances within the instance family. If you have regional Amazon Linux/Unix Reserved Instances with shared tenancy on bare metal instances, you can benefit from the Reserved Instance savings within the same instance family. The opposite is also true: if you have regional Amazon Linux/Unix Reserved Instances with shared tenancy on instances in the same family as a bare metal instance, you can benefit from the Reserved Instance savings on the bare metal instance.

The metal instance size does not have a single normalization factor. A bare metal instance has the same normalization factor as the equivalent virtualized instance size within the same instance family. For example, an `i3.metal` instance has the same normalization factor as an `i3.16xlarge` instance.

<table>
<thead>
<tr>
<th>Instance size</th>
<th>Normalization factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>a1.metal</td>
<td>32</td>
</tr>
<tr>
<td>m5zn.metal</td>
<td>x2iezn.metal</td>
</tr>
<tr>
<td>c6g.metal</td>
<td>c6gd.metal</td>
</tr>
<tr>
<td>c5n.metal</td>
<td>144</td>
</tr>
</tbody>
</table>
### Instance size | Normalization factor
--- | ---
c5.metal | 192
c5d.metal |
i3en.metal |
m5.metal |
m5d.metal |
m5dn.metal |
m5n.metal |
r5.metal |
r5b.metal |

r5n.metal |
c6i.metal |
c6id.metal |
m6i.metal |
m6id.metal |
r6d.metal |
r6id.metal |
u-*.metal |

For example, an `i3.metal` instance has a normalization factor of 128. If you purchase an `i3.metal` default tenancy Amazon Linux/Unix Reserved Instance in the US East (N. Virginia), the billing benefit can apply as follows:

- If you have one running `i3.16xlarge` in your account in that Region, the billing benefit is applied in full to the `i3.16xlarge` instance (`i3.16xlarge` normalization factor = 128).
- Or, if you have two running `i3.8xlarge` instances in your account in that Region, the billing benefit is applied in full to both `i3.8xlarge` instances (`i3.8xlarge` normalization factor = 64).
- Or, if you have four running `i3.4xlarge` instances in your account in that Region, the billing benefit is applied in full to all four `i3.4xlarge` instances (`i3.4xlarge` normalization factor = 32).

The opposite is also true. For example, if you purchase two `i3.8xlarge` default tenancy Amazon Linux/Unix Reserved Instances in the US East (N. Virginia), and you have one running `i3.metal` instance in that Region, the billing benefit is applied in full to the `i3.metal` instance.

### Examples of applying Reserved Instances

The following scenarios cover the ways in which Reserved Instances are applied.

- **Scenario 1: Reserved Instances in a single account**
- **Scenario 2: Reserved Instances in a single account using the normalization factor**
- **Scenario 3: Regional Reserved Instances in linked accounts**
- **Scenario 4: Zonal Reserved Instances in a linked account**
**Scenario 1: Reserved Instances in a single account**

You are running the following On-Demand Instances in account A:

- 4 x m3.large Linux, default tenancy instances in Availability Zone us-east-1a
- 2 x m4.xlarge Amazon Linux, default tenancy instances in Availability Zone us-east-1b
- 1 x c4.xlarge Amazon Linux, default tenancy instances in Availability Zone us-east-1c

You purchase the following Reserved Instances in account A:

- 4 x m3.large Linux, default tenancy Reserved Instances in Availability Zone us-east-1a (capacity is reserved)
- 4 x m4.large Amazon Linux, default tenancy Reserved Instances in Region us-east-1
- 1 x c4.large Amazon Linux, default tenancy Reserved Instances in Region us-east-1

The Reserved Instance benefits are applied in the following way:

- The discount and capacity reservation of the four m3.large zonal Reserved Instances is used by the four m3.large instances because the attributes (instance size, Region, platform, tenancy) between them match.
- The m4.large regional Reserved Instances provide Availability Zone and instance size flexibility, because they are regional Amazon Linux Reserved Instances with default tenancy.

An m4.large is equivalent to 4 normalized units/hour.

You’ve purchased four m4.large regional Reserved Instances, and in total, they are equal to 16 normalized units/hour (4x4). Account A has two m4.xlarge instances running, which is equivalent to 16 normalized units/hour (2x8). In this case, the four m4.large regional Reserved Instances provide the full billing benefit to the usage of the two m4.xlarge instances.

- The c4.large regional Reserved Instance in us-east-1 provides Availability Zone and instance size flexibility, because it is a regional Amazon Linux Reserved Instance with default tenancy, and applies to the c4.xlarge instance. A c4.large instance is equivalent to 4 normalized units/hour and a c4.xlarge is equivalent to 8 normalized units/hour.

In this case, the c4.large regional Reserved Instance provides partial benefit to c4.xlarge usage. This is because the c4.large Reserved Instance is equivalent to 4 normalized units/hour of usage, but the c4.xlarge instance requires 8 normalized units/hour. Therefore,
the `c4.large` Reserved Instance billing discount applies to 50% of `c4.xlarge` usage. The remaining `c4.xlarge` usage is charged at the On-Demand rate.

**Scenario 2: Reserved Instances in a single account using the normalization factor**

You are running the following On-Demand Instances in account A:

- 2 x `m3.xlarge` Amazon Linux, default tenancy instances in Availability Zone `us-east-1a`
- 2 x `m3.large` Amazon Linux, default tenancy instances in Availability Zone `us-east-1b`

You purchase the following Reserved Instance in account A:

- 1 x `m3.2xlarge` Amazon Linux, default tenancy Reserved Instance in Region `us-east-1`

The Reserved Instance benefits are applied in the following way:

- The `m3.2xlarge` regional Reserved Instance in `us-east-1` provides Availability Zone and instance size flexibility, because it is a regional Amazon Linux Reserved Instance with default tenancy. It applies first to the `m3.large` instances and then to the `m3.xlarge` instances, because it applies from the smallest to the largest instance size within the instance family based on the normalization factor.

An `m3.large` instance is equivalent to 4 normalized units/hour.

An `m3.xlarge` instance is equivalent to 8 normalized units/hour.

An `m3.2xlarge` instance is equivalent to 16 normalized units/hour.

The benefit is applied as follows:

The `m3.2xlarge` regional Reserved Instance provides full benefit to 2 x `m3.large` usage, because together these instances account for 8 normalized units/hour. This leaves 8 normalized units/hour to apply to the `m3.xlarge` instances.

With the remaining 8 normalized units/hour, the `m3.2xlarge` regional Reserved Instance provides full benefit to 1 x `m3.xlarge` usage, because each `m3.xlarge` instance is equivalent to 8 normalized units/hour. The remaining `m3.xlarge` usage is charged at the On-Demand rate.
Scenario 3: Regional Reserved Instances in linked accounts

Reserved Instances are first applied to usage within the purchasing account, followed by qualifying usage in any other account in the organization. For more information, see Reserved Instances and consolidated billing. For regional Reserved Instances that offer instance size flexibility, the benefit is applied from the smallest to the largest instance size within the instance family.

You're running the following On-Demand Instances in account A (the purchasing account):

• 2 x m4.xlarge Linux, default tenancy instances in Availability Zone us-east-1a
• 1 x m4.2xlarge Linux, default tenancy instances in Availability Zone us-east-1b
• 2 x c4.xlarge Linux, default tenancy instances in Availability Zone us-east-1a
• 1 x c4.2xlarge Linux, default tenancy instances in Availability Zone us-east-1b

Another customer is running the following On-Demand Instances in account B—a linked account:

• 2 x m4.xlarge Linux, default tenancy instances in Availability Zone us-east-1a

You purchase the following regional Reserved Instances in account A:

• 4 x m4.xlarge Linux, default tenancy Reserved Instances in Region us-east-1
• 2 x c4.xlarge Linux, default tenancy Reserved Instances in Region us-east-1

The regional Reserved Instance benefits are applied in the following way:

• The discount of the four m4.xlarge Reserved Instances is used by the two m4.xlarge instances and the single m4.2xlarge instance in account A (purchasing account). All three instances match the attributes (instance family, Region, platform, tenancy). The discount is applied to instances in the purchasing account (account A) first, even though account B (linked account) has two m4.xlarge that also match the Reserved Instances. There is no capacity reservation because the Reserved Instances are regional Reserved Instances.
• The discount of the two c4.xlarge Reserved Instances applies to the two c4.xlarge instances, because they are a smaller instance size than the c4.2xlarge instance. There is no capacity reservation because the Reserved Instances are regional Reserved Instances.
Scenario 4: Zonal Reserved Instances in a linked account

In general, Reserved Instances that are owned by an account are applied first to usage in that account. However, if there are qualifying, unused Reserved Instances for a specific Availability Zone (zonal Reserved Instances) in other accounts in the organization, they are applied to the account before regional Reserved Instances owned by the account. This is done to ensure maximum Reserved Instance utilization and a lower bill. For billing purposes, all the accounts in the organization are treated as one account. The following example might help explain this.

You're running the following On-Demand Instance in account A (the purchasing account):

- 1 x m4.xlarge Linux, default tenancy instance in Availability Zone us-east-1a

A customer is running the following On-Demand Instance in linked account B:

- 1 x m4.xlarge Linux, default tenancy instance in Availability Zone us-east-1b

You purchase the following regional Reserved Instances in account A:

- 1 x m4.xlarge Linux, default tenancy Reserved Instance in Region us-east-1

A customer also purchases the following zonal Reserved Instances in linked account C:

- 1 x m4.xlarge Linux, default tenancy Reserved Instances in Availability Zone us-east-1a

The Reserved Instance benefits are applied in the following way:

- The discount of the m4.xlarge zonal Reserved Instance owned by account C is applied to the m4.xlarge usage in account A.
- The discount of the m4.xlarge regional Reserved Instance owned by account A is applied to the m4.xlarge usage in account B.
- If the regional Reserved Instance owned by account A was first applied to the usage in account A, the zonal Reserved Instance owned by account C remains unused and usage in account B is charged at On-Demand rates.

For more information, see Reserved Instances in the Billing and Cost Management Report.
Note

Zonal Reserved Instances reserve capacity only for the owning account and cannot be shared with other AWS accounts. If you need to share capacity with other AWS accounts, use On-Demand Capacity Reservations.

Use your Reserved Instances

Reserved Instances are automatically applied to running On-Demand Instances provided that the specifications match. If you have no running On-Demand Instances that match the specifications of your Reserved Instance, the Reserved Instance is unused until you launch an instance with the required specifications.

If you're launching an On-Demand Instance to take advantage of the billing benefit of a Reserved Instance, ensure that you specify the following information when you configure your On-Demand Instance:

Platform

You must specify an Amazon Machine Image (AMI) that matches the platform (product description) of your Reserved Instance. For example, if you specified Linux/UNIX for your Reserved Instance, you can launch an instance from an Amazon Linux AMI or an Ubuntu AMI.

Instance type

If you purchased a zonal Reserved Instance, you must specify the same instance type as your Reserved Instance; for example, t3.large. For more information, see How zonal Reserved Instances are applied.

If you purchased a regional Reserved Instance, you must specify an instance type from the same instance family as the instance type of your Reserved Instance. For example, if you specified t3.xlarge for your Reserved Instance, you must launch your instance from the T3 family, but you can specify any size, for example, t3.medium. For more information, see How regional Reserved Instances are applied.

Availability Zone

If you purchased a zonal Reserved Instance for a specific Availability Zone, you must launch the instance into the same Availability Zone.
If you purchased a regional Reserved Instance, you can launch the instance into any Availability Zone in the Region that you specified for the Reserved Instance.

**Tenancy**

The tenancy (dedicated or shared) of the instance must match the tenancy of your Reserved Instance. For more information, see [Amazon EC2 Dedicated Instances](https://docs.aws.amazon.com/ec2/latest/userguide/amt topology.html).

For examples of how Reserved Instances are applied to your running On-Demand Instances, see [How Reserved Instance discounts are applied](https://docs.aws.amazon.com/ReservedInstances/latest/UserGuide/rir-buy.html). For more information, see [Why aren’t my Amazon EC2 Reserved Instances applying to my AWS billing in the way that I expected?](https://docs.aws.amazon.com/Reservations/latest/UserGuide/why-not-applying-reservation.html)

You can use various methods to launch the On-Demand Instances that use your Reserved Instance discount. For information about the different launch methods, see [Launch your instance](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/using-instances.html). You can also use Amazon EC2 Auto Scaling to launch an instance. For more information, see the [Amazon EC2 Auto Scaling User Guide](https://docs.aws.amazon.com/autoscaling/ec2/latest/userguide/)

**How you are billed**

All Reserved Instances provide you with a discount compared to On-Demand pricing. With Reserved Instances, you pay for the entire term regardless of actual use. You can choose to pay for your Reserved Instance upfront, partially upfront, or monthly, depending on the payment option specified for the Reserved Instance.

When Reserved Instances expire, you are charged On-Demand rates for EC2 instance usage. You can queue a Reserved Instance for purchase up to three years in advance. This can help you ensure that you have uninterrupted coverage. For more information, see [Queue your purchase](https://docs.aws.amazon.com/Reservations/latest/UserGuide/queue-purchase.html).

The AWS Free Tier is available for new AWS accounts. If you are using the AWS Free Tier to run Amazon EC2 instances, and you purchase a Reserved Instance, you are charged the standard pricing. For information, see [AWS Free Tier](https://aws.amazon.com/free/).
**Usage billing**

Reserved Instances are billed for every clock-hour during the term that you select, regardless of whether an instance is running. Each clock-hour starts on the hour (zero minutes and zero seconds past the hour) of a standard 24-hour clock. For example, 1:00:00 to 1:59:59 is one clock-hour. For more information about instance states, see [Instance lifecycle](#).

A Reserved Instance billing benefit can be applied to a running instance on a per-second basis. Per-second billing is available for instances using an open-source Linux distribution, such as Amazon Linux and Ubuntu. Per-hour billing is used for commercial Linux distributions, such as Red Hat Enterprise Linux and SUSE Linux Enterprise Server.

A Reserved Instance billing benefit can apply to a maximum of 3600 seconds (one hour) of instance usage per clock-hour. You can run multiple instances concurrently, but can only receive the benefit of the Reserved Instance discount for a total of 3600 seconds per clock-hour; instance usage that exceeds 3600 seconds in a clock-hour is billed at the On-Demand rate.

For example, if you purchase one m4.xlarge Reserved Instance and run four m4.xlarge instances concurrently for one hour, one instance is charged at one hour of Reserved Instance usage and the other three instances are charged at three hours of On-Demand usage.

However, if you purchase one m4.xlarge Reserved Instance and run four m4.xlarge instances for 15 minutes (900 seconds) each within the same hour, the total running time for the instances is one hour, which results in one hour of Reserved Instance usage and 0 hours of On-Demand usage.

If multiple eligible instances are running concurrently, the Reserved Instance billing benefit is applied to all the instances at the same time up to a maximum of 3600 seconds in a clock-hour; thereafter, On-Demand rates apply.
Cost Explorer on the Billing and Cost Management console enables you to analyze the savings against running On-Demand Instances. The Reserved Instances FAQ includes an example of a list value calculation.

If you close your AWS account, On-Demand billing for your resources stops. However, if you have any Reserved Instances in your account, you continue to receive a bill for these until they expire.

Viewing your bill

You can find out about the charges and fees to your account by viewing the AWS Billing and Cost Management console.

- The Dashboard displays a spend summary for your account.
- On the Bills page, under Details expand the Elastic Compute Cloud section and the Region to get billing information about your Reserved Instances.

You can view the charges online, or you can download a CSV file.

You can also track your Reserved Instance utilization using the AWS Cost and Usage Report. For more information, see Reserved Instances under Cost and Usage Report in the AWS Billing User Guide.

Reserved Instances and consolidated billing

The pricing benefits of Reserved Instances are shared when the purchasing account is part of a set of accounts billed under one consolidated billing payer account. The instance usage across all member accounts is aggregated in the payer account every month. This is typically useful for companies in which there are different functional teams or groups; then, the normal Reserved Instance logic is applied to calculate the bill. For more information, see Consolidated billing for AWS Organizations.
If you close the account that purchased the Reserved Instance, the payer account is charged for the Reserved Instance until the Reserved Instance expires. After the closed account is permanently deleted in 90 days, the member accounts no longer benefit from the Reserved Instance billing discount.

Note
Zonal Reserved Instances reserve capacity only for the owning account and cannot be shared with other AWS accounts. If you need to share capacity with other AWS accounts, use On-Demand Capacity Reservations.

Reserved Instance discount pricing tiers

If your account qualifies for a discount pricing tier, it automatically receives discounts on upfront and instance usage fees for Reserved Instance purchases that you make within that tier level from that point on. To qualify for a discount, the list value of your Reserved Instances in the Region must be $500,000 USD or more.

The following rules apply:

- Pricing tiers and related discounts apply only to purchases of Amazon EC2 Standard Reserved Instances.
- Pricing tiers do not apply to Reserved Instances for Windows with SQL Server Standard, SQL Server Web, and SQL Server Enterprise.
- Pricing tiers do not apply to Reserved Instances for Linux with SQL Server Standard, SQL Server Web, and SQL Server Enterprise.
- Pricing tier discounts only apply to purchases made from AWS. They do not apply to purchases of third-party Reserved Instances.
- Discount pricing tiers are currently not applicable to Convertible Reserved Instance purchases.

Topics
- Calculate Reserved Instance pricing discounts
- Buy with a discount tier
- Crossing pricing tiers
- Consolidated billing for pricing tiers
Calculate Reserved Instance pricing discounts

You can determine the pricing tier for your account by calculating the list value for all of your Reserved Instances in a Region. Multiply the hourly recurring price for each reservation by the total number of hours for the term and add the undiscounted upfront price (also known as the fixed price) at the time of purchase. Because the list value is based on undiscounted (public) pricing, it is not affected if you qualify for a volume discount or if the price drops after you buy your Reserved Instances.

\[
\text{List value} = \text{fixed price} + (\text{undiscounted recurring hourly price} \times \text{hours in term})
\]

For example, for a 1-year Partial Upfront \texttt{t2.small} Reserved Instance, assume the upfront price is $60.00 and the hourly rate is $0.007. This provides a list value of $121.32.

\[
121.32 = 60.00 + (0.007 \times 8760)
\]

New console

To view the fixed price values for Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Reserved Instances.
3. To display the Upfront price column, choose settings ( ) in the top-right corner, turn on Upfront price, and choose Confirm.

Old console

To view the fixed price values for Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Reserved Instances.
3. To display the Upfront Price column, choose settings ( ) in the top-right corner, select Upfront Price, and choose Close.

To view the fixed price values for Reserved Instances using the command line
When you buy Reserved Instances, Amazon EC2 automatically applies any discounts to the part of your purchase that falls within a discount pricing tier. You don't need to do anything differently, and you can buy Reserved Instances using any of the Amazon EC2 tools. For more information, see Buy Reserved Instances.

After the list value of your active Reserved Instances in a Region crosses into a discount pricing tier, any future purchase of Reserved Instances in that Region are charged at a discounted rate. If a single purchase of Reserved Instances in a Region takes you over the threshold of a discount tier, then the portion of the purchase that is above the price threshold is charged at the discounted rate. For more information about the temporary Reserved Instance IDs that are created during the purchase process, see Crossing pricing tiers.

If your list value falls below the price point for that discount pricing tier—for example, if some of your Reserved Instances expire—future purchases of Reserved Instances in the Region are not discounted. However, you continue to get the discount applied against any Reserved Instances that were originally purchased within the discount pricing tier.

When you buy Reserved Instances, one of four possible scenarios occurs:

- **No discount**—Your purchase within a Region is still below the discount threshold.
- **Partial discount**—Your purchase within a Region crosses the threshold of the first discount tier. No discount is applied to one or more reservations and the discounted rate is applied to the remaining reservations.
- **Full discount**—Your entire purchase within a Region falls within one discount tier and is discounted appropriately.
- **Two discount rates**—Your purchase within a Region crosses from a lower discount tier to a higher discount tier. You are charged two different rates: one or more reservations at the lower discounted rate, and the remaining reservations at the higher discounted rate.
Crossing pricing tiers

If your purchase crosses into a discounted pricing tier, you see multiple entries for that purchase: one for that part of the purchase charged at the regular price, and another for that part of the purchase charged at the applicable discounted rate.

The Reserved Instance service generates several Reserved Instance IDs because your purchase crossed from an undiscounted tier, or from one discounted tier to another. There is an ID for each set of reservations in a tier. Consequently, the ID returned by your purchase CLI command or API action is different from the actual ID of the new Reserved Instances.

Consolidated billing for pricing tiers

A consolidated billing account aggregates the list value of member accounts within a Region. When the list value of all active Reserved Instances for the consolidated billing account reaches a discount pricing tier, any Reserved Instances purchased after this point by any member of the consolidated billing account are charged at the discounted rate (as long as the list value for that consolidated account stays above the discount pricing tier threshold). For more information, see Reserved Instances and consolidated billing.

Buy Reserved Instances

To purchase a Reserved Instance, search for Reserved Instance offerings from AWS and third-party sellers, adjusting your search parameters until you find the exact match that you're looking for.

When you search for Reserved Instances to buy, you receive a quote on the cost of the returned offerings. When you proceed with the purchase, AWS automatically places a limit price on the purchase price. The total cost of your Reserved Instances won't exceed the amount that you were quoted.

If the price rises or changes for any reason, the purchase is not completed. When you are purchasing a third-party seller's Reserved Instance from the EC2 Reserved Instance Marketplace, if there are offerings similar to your choice but at a lower upfront price, AWS sells you the offerings at the lower upfront price.

Before you confirm your purchase, review the details of the Reserved Instance that you plan to buy, and make sure that all the parameters are accurate. After you purchase a Reserved Instance (either from a third-party seller in the Reserved Instance Marketplace or from AWS), you cannot cancel your purchase.
To purchase and modify Reserved Instances, ensure that your user has the appropriate permissions, such as the ability to describe Availability Zones. For information, see the section called “Work with Reserved Instances” (API) or the section called “Work with Reserved Instances” (console).

Topics

- Choosing a platform
- Queue your purchase
- Buy Standard Reserved Instances
- Buy Convertible Reserved Instances
- Buy from the Reserved Instance Marketplace
- View your Reserved Instances
- Cancel a queued purchase
- Renew a Reserved Instance

Choosing a platform

Amazon EC2 supports the following platforms for Reserved Instances:

- Linux/UNIX
- Linux with SQL Server Standard
- Linux with SQL Server Web
- Linux with SQL Server Enterprise
- SUSE Linux
- Red Hat Enterprise Linux
- Red Hat Enterprise Linux with HA
- Windows
- Windows with SQL Server Standard
- Windows with SQL Server Web
- Windows with SQL Server Enterprise

When you purchase a Reserved Instance, you must choose an offering for a platform that represents the operating system for your instance.
Linux instances

• For SUSE Linux and RHEL distributions, you must choose offerings for those specific platforms, i.e., for the SUSE Linux or Red Hat Enterprise Linux platforms.

• For all other Linux distributions (including Ubuntu), choose an offering for the Linux/UNIX platform.

• If you bring your existing RHEL subscription, you must choose an offering for the Linux/UNIX platform, not an offering for the Red Hat Enterprise Linux platform.

Windows instances

• For Windows with SQL Standard, Windows with SQL Server Enterprise, and Windows with SQL Server Web, you must choose offerings for those specific platforms.

• For all other Windows versions, choose an offering for the Windows platform.

Note

Ubuntu Pro is not available as a Reserved Instance. For significant savings compared to On-Demand Instance pricing, we recommend that you use Ubuntu Pro with Savings Plans. For more information, see the Savings Plans User Guide.

Important

If you plan to purchase a Reserved Instance to apply to an On-Demand Instance that was launched from an AWS Marketplace AMI, first check the PlatformDetails field of the AMI. The PlatformDetails field indicates which Reserved Instance to purchase. The platform details of the AMI must match the platform of the Reserved Instance, otherwise the Reserved Instance will not be applied to the On-Demand Instance. For information about how to view the platform details of the AMI, see Understand AMI billing information.

Queue your purchase

By default, when you purchase a Reserved Instance, the purchase is made immediately. Alternatively, you can queue your purchases for a future date and time. For example, you can
queue a purchase for around the time that an existing Reserved Instance expires. This can help you ensure that you have uninterrupted coverage.

You can queue purchases for regional Reserved Instances, but not zonal Reserved Instances or Reserved Instances from other sellers. You can queue a purchase up to three years in advance. On the scheduled date and time, the purchase is made using the default payment method. After the payment is successful, the billing benefit is applied.

You can view your queued purchases in the Amazon EC2 console. The status of a queued purchase is queued. You can cancel a queued purchase any time before its scheduled time. For details, see Cancel a queued purchase.

**Buy Standard Reserved Instances**

You can buy Standard Reserved Instances in a specific Availability Zone and get a capacity reservation. Alternatively, you can forego the capacity reservation and purchase a regional Standard Reserved Instance.

New console

**To buy Standard Reserved Instances using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Reserved Instances, and then choose Purchase Reserved Instances.
3. For Offering class, choose Standard to display Standard Reserved Instances.
4. To purchase a capacity reservation, toggle on Only show offerings that reserve capacity in the top-right corner of the purchase screen. When you toggle on this setting, the Availability Zone field appears.

   To purchase a regional Reserved Instance, toggle off this setting. When you toggle off this setting, the Availability Zone field disappears.
5. Select other configurations as needed, and then choose Search.
6. For each Reserved Instance that you want to purchase, enter the desired quantity, and choose Add to cart.

   To purchase a Standard Reserved Instance from the Reserved Instance Marketplace, look for 3rd party in the Seller column in the search results. The Term column displays non-standard terms. For more information, see Buy from the Reserved Instance Marketplace.
7. To see a summary of the Reserved Instances that you selected, choose **View cart**.

8. If **Order on** is **Now**, the purchase is completed immediately after you choose **Order all**. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.

9. To complete the order, choose **Order all**.

If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from **Payment-pending** to **Active**. When the Reserved Instance is **Active**, it is ready to use.

**Note**

If the status goes to **Retired**, AWS might not have received your payment.

---

**Old console**

**To buy Standard Reserved Instances using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.

3. For **Offering Class**, choose **Standard** to display Standard Reserved Instances.

4. To purchase a capacity reservation, choose **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. To purchase a regional Reserved Instance, leave the check box unselected.

5. Select other configurations as needed and choose **Search**.

To purchase a Standard Reserved Instance from the Reserved Instance Marketplace, look for **3rd Party** in the **Seller** column in the search results. The **Term** column displays non-standard terms.
6. For each Reserved Instance that you want to purchase, enter the quantity, and choose **Add to Cart**.

7. To see a summary of the Reserved Instances that you selected, choose **View Cart**.

8. If **Order On** is **Now**, the purchase is completed immediately. To queue a purchase, choose **Now** and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.

9. To complete the order, choose **Order**.

   If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

    The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from payment-pending to active. When the Reserved Instance is active, it is ready to use.

    **Note**

    If the status goes to retired, AWS might not have received your payment.

**To buy a Standard Reserved Instance using the AWS CLI**

1. Find available Reserved Instances using the `describe-reserved-instances-offerings` command. Specify `standard` for the --offering-class parameter to return only Standard Reserved Instances. You can apply additional parameters to narrow your results. For example, if you want to purchase a regional `t2.large` Reserved Instance with a default tenancy for Linux/UNIX for a 1-year term only:

    ```bash
    aws ec2 describe-reserved-instances-offerings \
      --instance-type t2.large \
      --offering-class standard \
      --product-description "Linux/UNIX" \
      --instance-tenancy default \
      --filters Name=duration,Values=31536000 Name=scope,Values=Region
    ```
To find Reserved Instances on the Reserved Instance Marketplace only, use the `marketplace` filter and do not specify a duration in the request, as the term might be shorter than a 1- or 3-year term.

```
aws ec2 describe-reserved-instances-offerings \
   --instance-type t2.large \n   --offering-class standard \n   --product-description "Linux/UNIX" \n   --instance-tenancy default \n   --filters Name=marketplace,Values=true
```

When you find a Reserved Instance that meets your needs, take note of the offering ID. For example:

```
"ReservedInstancesOfferingId": "bec624df-a8cc-4aad-a72f-4f8abc34caf2"
```

2. Use the `purchase-reserved-instances-offering` command to buy your Reserved Instance. You must specify the Reserved Instance offering ID you obtained the previous step and you must specify the number of instances for the reservation.

```
aws ec2 purchase-reserved-instances-offering \
   --reserved-instances-offering-id be624df-a8cc-4aad-a72f-4f8abc34caf2 \
   --instance-count 1
```

By default, the purchase is completed immediately. Alternatively, to queue the purchase, add the following parameter to the previous call.

```
--purchase-time "2020-12-01T00:00:00Z"
```

3. Use the `describe-reserved-instances` command to get the status of your Reserved Instance.

```
aws ec2 describe-reserved-instances
```

Alternatively, use the following AWS Tools for Windows PowerShell commands:

- [Get-EC2ReservedInstancesOffering](#)
- [New-EC2ReservedInstance](#)
After the purchase is complete, if you already have a running instance that matches the specifications of the Reserved Instance, the billing benefit is immediately applied. You do not have to restart your instances. If you do not have a suitable running instance, launch an instance and ensure that you match the same criteria that you specified for your Reserved Instance. For more information, see Use your Reserved Instances.

For examples of how Reserved Instances are applied to your running instances, see How Reserved Instance discounts are applied.

**Buy Convertible Reserved Instances**

You can buy Convertible Reserved Instances in a specific Availability Zone and get a capacity reservation. Alternatively, you can forego the capacity reservation and purchase a regional Convertible Reserved Instance.

New console

**To buy Convertible Reserved Instances using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Reserved Instances**, and then choose **Purchase Reserved Instances**.
3. For **Offering class**, choose **Convertible** to display Convertible Reserved Instances.
4. To purchase a capacity reservation, toggle on **Only show offerings that reserve capacity** in the top-right corner of the purchase screen. When you toggle on this setting, the **Availability Zone** field appears.

To purchase a regional Reserved Instance, toggle off this setting. When you toggle off this setting, the **Availability Zone** field disappears.
5. Select other configurations as needed and choose **Search**.
6. For each Convertible Reserved Instance that you want to purchase, enter the quantity, and choose **Add to cart**.
7. To see a summary of your selection, choose **View cart**.
8. If Order on is Now, the purchase is completed immediately after you choose Order all. To queue a purchase, choose Now and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.

9. To complete the order, choose Order all.

If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose Close.

The status of your order is listed in the State column. When your order is complete, the State value changes from Payment-pending to Active. When the Reserved Instance is Active, it is ready to use.

**Note**

If the status goes to Retired, AWS might not have received your payment.

Old console

**To buy Convertible Reserved Instances using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Reserved Instances, and then choose Purchase Reserved Instances.
3. For Offering Class, choose Convertible to display Convertible Reserved Instances.
4. To purchase a capacity reservation, choose Only show offerings that reserve capacity in the top-right corner of the purchase screen. To purchase a regional Reserved Instance, leave the check box unselected.
5. Select other configurations as needed and choose Search.
6. For each Convertible Reserved Instance that you want to purchase, enter the quantity, and choose Add to Cart.
7. To see a summary of your selection, choose View Cart.
8. If Order On is Now, the purchase is completed immediately. To queue a purchase, choose Now and select a date. You can select a different date for each eligible offering in the cart. The purchase is queued until 00:00 UTC on the selected date.
9. To complete the order, choose **Order**.

   If, at the time of placing the order, there are offerings similar to your choice but with a lower price, AWS sells you the offerings at the lower price.

10. Choose **Close**.

   The status of your order is listed in the **State** column. When your order is complete, the **State** value changes from payment-pending to active. When the Reserved Instance is active, it is ready to use.

   **Note**

   If the status goes to retired, AWS might not have received your payment.

---

**To buy a Convertible Reserved Instance using the AWS CLI**

1. Find available Reserved Instances using the `describe-reserved-instances-offerings` command. Specify `convertible` for the `--offering-class` parameter to return only Convertible Reserved Instances. You can apply additional parameters to narrow your results; for example, if you want to purchase a regional `t2.large` Reserved Instance with a default tenancy for Linux/UNIX:

   ```
   aws ec2 describe-reserved-instances-offerings \
     --instance-type t2.large \
     --offering-class convertible \
     --product-description "Linux/UNIX" \
     --instance-tenancy default \
     --filters Name=scope,Values=Region
   ```

   When you find a Reserved Instance that meets your needs, take note of the offering ID. For example:

   ```
   "ReservedInstancesOfferingId": "bec624df-a8cc-4aad-a72f-4f8abc34caf2"
   ```

2. Use the `purchase-reserved-instances-offering` command to buy your Reserved Instance. You must specify the Reserved Instance offering ID you obtained the previous step and you must specify the number of instances for the reservation.
By default, the purchase is completed immediately. Alternatively, to queue the purchase, add the following parameter to the previous call.

```
--purchase-time "2020-12-01T00:00:00Z"
```

3. Use the `describe-reserved-instances` command to get the status of your Reserved Instance.

```
aws ec2 describe-reserved-instances
```

Alternatively, use the following AWS Tools for Windows PowerShell commands:

- `Get-EC2ReservedInstancesOffering`
- `New-EC2ReservedInstance`
- `Get-EC2ReservedInstance`

If you already have a running instance that matches the specifications of the Reserved Instance, the billing benefit is immediately applied. You do not have to restart your instances. If you do not have a suitable running instance, launch an instance and ensure that you match the same criteria that you specified for your Reserved Instance. For more information, see "Use your Reserved Instances".

For examples of how Reserved Instances are applied to your running instances, see "How Reserved Instance discounts are applied".

**Buy from the Reserved Instance Marketplace**

You can purchase Reserved Instances from third-party sellers who own Reserved Instances that they no longer need from the Reserved Instance Marketplace. You can do this using the Amazon EC2 console or a command line tool. The process is similar to purchasing Reserved Instances from AWS. For more information, see "Buy Standard Reserved Instances".

There are a few differences between Reserved Instances purchased in the Reserved Instance Marketplace and Reserved Instances purchased directly from AWS:
• **Term** – Reserved Instances that you purchase from third-party sellers have less than a full standard term remaining. Full standard terms from AWS run for one year or three years.

• **Upfront price** – Third-party Reserved Instances can be sold at different upfront prices. The usage or recurring fees remain the same as the fees set when the Reserved Instances were originally purchased from AWS.

• **Types of Reserved Instances** – Only Amazon EC2 Standard Reserved Instances can be purchased from the Reserved Instance Marketplace. Convertible Reserved Instances, Amazon RDS, and Amazon ElastiCache Reserved Instances are not available for purchase on the Reserved Instance Marketplace.

Basic information about you is shared with the seller, for example, your ZIP code and country information.

This information enables sellers to calculate any necessary transaction taxes that they have to remit to the government (such as sales tax or value-added tax) and is provided as a disbursement report. In rare circumstances, AWS might have to provide the seller with your email address, so that they can contact you regarding questions related to the sale (for example, tax questions).

For similar reasons, AWS shares the legal entity name of the seller on the buyer's purchase invoice. If you need additional information about the seller for tax or related reasons, contact [AWS Support](https://aws.amazon.com/support/).

**View your Reserved Instances**

You can view the Reserved Instances you've purchased using the Amazon EC2 console, or a command line tool.

**To view your Reserved Instances in the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

2. In the navigation pane, choose **Reserved Instances**.

3. Your queued, active, and retired Reserved Instances are listed. The **State** column displays the state.

4. If you are a seller in the Reserved Instance Marketplace, the **My Listings** tab displays the status of a reservation that's listed in the [Reserved Instance Marketplace](https://aws.amazon.com/marketplace/). For more information, see [Reserved Instance listing states](https://aws.amazon.com/marketplace/).
To view your Reserved Instances using the command line

- `describe-reserved-instances` (AWS CLI)
- `Get-EC2ReservedInstance` (Tools for Windows PowerShell)

Cancel a queued purchase

You can queue a purchase up to three years in advance. You can cancel a queued purchase any time before its scheduled time.

New console

To cancel a queued purchase

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose `Reserved Instances`.
3. Select one or more Reserved Instances.
4. Choose `Actions, Delete queued Reserved Instances`.
5. When prompted for confirmation, choose `Delete`, and then `Close`.

Old console

To cancel a queued purchase

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose `Reserved Instances`.
3. Select one or more Reserved Instances.
4. Choose `Actions, Delete Queued Reserved Instances`.
5. When prompted for confirmation, choose `Yes, Delete`.

To cancel a queued purchase using the command line

- `delete-queued-reserved-instances` (AWS CLI)
- `Remove-EC2QueuedReservedInstance` (Tools for Windows PowerShell)
Renew a Reserved Instance

You can renew a Reserved Instance before it is scheduled to expire. Renewing a Reserved Instance queues the purchase of a Reserved Instance with the same configuration until the current Reserved Instance expires.

New console

To renew a Reserved Instance using a queued purchase

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Reserved Instances.
3. Select the Reserved Instance to renew.
5. To complete the order, choose Order all, and then Close.

Old console

To renew a Reserved Instance using a queued purchase

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Reserved Instances.
3. Select the Reserved Instance to renew.
5. To complete the order, choose Order.

Sell in the Reserved Instance Marketplace

The Reserved Instance Marketplace is a platform that supports the sale of third-party and AWS customers' unused Standard Reserved Instances, which vary in term lengths and pricing options. For example, you might want to sell Reserved Instances after moving instances to a new AWS Region, changing to a new instance type, ending projects before the term expiration, when your business needs change, or if you have unneeded capacity.

As soon as you list your Reserved Instances in the Reserved Instance Marketplace, they are available for potential buyers to find. All Reserved Instances are grouped according to the duration of the term remaining and the hourly price.
To fulfill a buyer's request to purchase a third-party seller's Reserved Instance via the EC2 Reserved Instance Marketplace, AWS first sells the Reserved Instance with the lowest upfront price in the specified grouping. Then, AWS sells the Reserved Instance with the next lowest price, until the buyer's entire order is fulfilled. AWS then processes the transactions and transfers ownership of the Reserved Instances to the buyer.

You own your Reserved Instance until it's sold. After the sale, you've given up the capacity reservation and the discounted recurring fees. If you continue to use your instance, AWS charges you the On-Demand price starting from the time that your Reserved Instance was sold.

If you want to sell your unused Reserved Instances on the Reserved Instance Marketplace, you must meet certain eligibility criteria.

For information about buying Reserved Instances on the Reserved Instance Marketplace, see Buy from the Reserved Instance Marketplace.

- Information shared with the buyer

Restrictions and limitations

Before you can sell your unused reservations, you must register as a seller in the Reserved Instance Marketplace. For information, see Register as a seller.

The following limitations and restrictions apply when selling Reserved Instances:
• Only Amazon EC2 Standard regional and zonal Reserved Instances can be sold in the Reserved Instance Marketplace.

• Amazon EC2 Convertible Reserved Instances cannot be sold in the Reserved Instance Marketplace.

• Reserved Instances for other AWS services, such as Amazon RDS and Amazon ElastiCache, cannot be sold in the Reserved Instance Marketplace.

• There must be at least one month remaining in the term of the Standard Reserved Instance.

• You cannot sell a Standard Reserved Instance in a Region that is disabled by default.

• The minimum price allowed in the Reserved Instance Marketplace is $0.00.

• You can sell No Upfront, Partial Upfront, or All Upfront Reserved Instances in the Reserved Instance Marketplace as long as they have been active in your account for at least 30 days. Additionally, if there is an upfront payment on a Reserved Instance, it can only be sold after AWS has received the upfront payment.

• You cannot modify your listing in the Reserved Instance Marketplace directly. However, you can change your listing by first canceling it and then creating another listing with new parameters. For information, see Price your Reserved Instances. You can also modify your Reserved Instances before listing them. For information, see Modify Reserved Instances.

• AWS charges a service fee of 12 percent of the total upfront price of each Standard Reserved Instance you sell in the Reserved Instance Marketplace. The upfront price is the price the seller is charging for the Standard Reserved Instance.

• When you register as a seller, the bank you specify must have a US address. For more information, see Additional seller requirements for paid products in the AWS Marketplace Seller Guide.

• Amazon Web Services India Private Limited (AWS India) customers can’t sell Reserved Instances in the Reserved Instance Marketplace even if they have a US bank account. For more information, see What are the differences between AWS accounts and AWS India accounts?

Register as a seller

⚠️ Note

Only the AWS account root user can register an account as a seller.
To sell in the Reserved Instance Marketplace, you must first register as a seller. During registration, you provide the following information:

- **Bank information**—AWS must have your bank information in order to disburse funds collected when you sell your reservations. The bank you specify must have a US address. For more information, see [Bank account for disbursement](#).

- **Tax information**—All sellers are required to complete a tax information interview to determine any necessary tax reporting obligations. For more information, see [Tax information](#).

After AWS receives your completed seller registration, you receive an email confirming your registration and informing you that you can get started selling in the Reserved Instance Marketplace.

### Bank account for disbursement

AWS must have your bank information in order to disburse funds collected when you sell your Reserved Instance. The bank you specify must have a US address. For more information, see Additional seller requirements for paid products in the AWS Marketplace Seller Guide.

### To register a default bank account for disbursements

1. Open the [Reserved Instance Marketplace Seller Registration](#) page and sign in using your AWS credentials.

2. On the Manage Bank Account page, provide the following information about the bank through to receive payment:
   - Bank account holder name
   - Routing number
   - Account number
   - Bank account type

   **Note**

   If you are using a corporate bank account, you are prompted to send the information about the bank account via fax (1-206-765-3424).
After registration, the bank account provided is set as the default, pending verification with the bank. It can take up to two weeks to verify a new bank account, during which time you can't receive disbursements. For an established account, it usually takes about two days for disbursements to complete.

To change the default bank account for disbursement

1. On the Reserved Instance Marketplace Seller Registration page, sign in with the account that you used when you registered.
2. On the Manage Bank Account page, add a new bank account or modify the default bank account as needed.

Tax information

Your sale of Reserved Instances might be subject to a transaction-based tax, such as sales tax or value-added tax. You should check with your business's tax, legal, finance, or accounting department to determine if transaction-based taxes are applicable. You are responsible for collecting and sending the transaction-based taxes to the appropriate tax authority.

As part of the seller registration process, you must complete a tax interview in the Seller Registration Portal. The interview collects your tax information and populates an IRS form W-9, W-8BEN, or W-8BEN-E, which is used to determine any necessary tax reporting obligations.

The tax information you enter as part of the tax interview might differ depending on whether you operate as an individual or business, and whether you or your business are a US or non-US person or entity. As you fill out the tax interview, keep in mind the following:

- Information provided by AWS, including the information in this topic, does not constitute tax, legal, or other professional advice. To find out how the IRS reporting requirements might affect your business, or if you have other questions, contact your tax, legal, or other professional advisor.
- To fulfill the IRS reporting requirements as efficiently as possible, answer all questions and enter all information requested during the interview.
- Check your answers. Avoid misspellings or entering incorrect tax identification numbers. They can result in an invalidated tax form.

Based on your tax interview responses and IRS reporting thresholds, Amazon might file Form 1099-K. Amazon mails a copy of your Form 1099-K on or before January 31 in the year following
the year that your tax account reaches the threshold levels. For example, if your account reaches the threshold in 2018, your Form 1099-K is mailed on or before January 31, 2019.

For more information about IRS requirements and Form 1099-K, see the IRS website.

Price your Reserved Instances

When setting the price for your Reserved Instances, consider the following:

- **Upfront price** – The upfront price is the only price that you can specify for the Reserved Instance that you're selling. The upfront price is the one-time price that the buyer pays when they purchase a Reserved Instance.

Because the value of Reserved Instances decreases over time, by default, AWS can set prices to decrease in equal increments month over month. However, you can set different upfront prices based on when your reservation sells. For example, if your Reserved Instance has nine months of its term remaining, you can specify the amount that you would accept if a customer were to purchase that Reserved Instance with nine months remaining. You could set another price with five months remaining, and yet another price with one month remaining.

The minimum allowed price in the Reserved Instance Marketplace is $0.00.

- **Limits** – The following limits for selling Reserved Instances apply to the *lifetime* of your AWS account. They are not annual limits.
  
  - You can sell up to $50,000 in Reserved Instances.
  - You can sell up to 5,000 Reserved Instances.

These limits typically can't be increased, but will be evaluated on a case-by-case basis if requested. To request a limit increase, complete the Service limit increase form. For Limit type, choose EC2 Reserved Instance Sales.

- **Can't modify** – You cannot modify your listing directly. However, you can change your listing by first canceling it and then creating another listing with new parameters.

- **Can cancel** – You can cancel your listing at any time, as long as it's in the active state. You cannot cancel the listing if it's already matched or being processed for a sale. If some of the instances in your listing are matched and you cancel the listing, only the remaining unmatched instances are removed from the listing.
**List your Reserved Instances**

As a registered seller, you can choose to sell one or more of your Reserved Instances. You can choose to sell all of them in one listing or in portions. In addition, you can list Reserved Instances with any configuration of instance type, platform, and scope.

The console determines a suggested price. It checks for offerings that match your Reserved Instance and matches the one with the lowest price. Otherwise, it calculates a suggested price based on the cost of the Reserved Instance for its remaining time. If the calculated value is less than $1.01, the suggested price is $1.01.

If you cancel your listing and a portion of that listing has already been sold, the cancellation is not effective on the portion that has been sold. Only the unsold portion of the listing is no longer available in the Reserved Instance Marketplace.

To list a Reserved Instance in the Reserved Instance Marketplace using the AWS Management Console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Reserved Instances.
3. Select the Reserved Instances to list, and choose Actions, Sell Reserved Instances.
4. On the **Configure Your Reserved Instance Listing** page, set the number of instances to sell and the upfront price for the remaining term in the relevant columns. See how the value of your reservation changes over the remainder of the term by selecting the arrow next to the **Months Remaining** column.
5. If you are an advanced user and you want to customize the pricing, you can enter different values for the subsequent months. To return to the default linear price drop, choose **Reset**.
6. Choose **Continue** when you are finished configuring your listing.
7. Confirm the details of your listing, on the **Confirm Your Reserved Instance Listing** page and if you're satisfied, choose **List Reserved Instance**.

To view your listings in the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Reserved Instances.
3. Select the Reserved Instance that you've listed and choose the **My Listings** tab near the bottom of the page.
To manage Reserved Instances in the Reserved Instance Marketplace using the AWS CLI

1. Get a list of your Reserved Instances by using the `describe-reserved-instances` command.
2. Note the ID of the Reserved Instance you want to list and call `create-reserved-instances-listing`. You must specify the ID of the Reserved Instance, the number of instances, and the pricing schedule.
3. To view your listing, use the `describe-reserved-instances-listings` command.
4. To cancel your listing, use the `cancel-reserved-instances-listings` command.

Reserved Instance listing states

**Listing State** on the **My Listings** tab of the Reserved Instances page displays the current status of your listings:

The information displayed by **Listing State** is about the status of your listing in the Reserved Instance Marketplace. It is different from the status information that is displayed by the **State** column in the **Reserved Instances** page. This **State** information is about your reservation.

- **active**—The listing is available for purchase.
- **canceled**—The listing is canceled and isn't available for purchase in the Reserved Instance Marketplace.
- **closed**—The Reserved Instance is not listed. A Reserved Instance might be closed because the sale of the listing was completed.

Lifecycle of a listing

When all the instances in your listing are matched and sold, the **My Listings** tab shows that the **Total instance count** matches the count listed under **Sold**. Also, there are no **Available** instances left for your listing, and its **Status** is closed.

When only a portion of your listing is sold, AWS retires the Reserved Instances in the listing and creates the number of Reserved Instances equal to the Reserved Instances remaining in the count. So, the listing ID and the listing that it represents, which now has fewer reservations for sale, is still active.

Any future sales of Reserved Instances in this listing are processed this way. When all the Reserved Instances in the listing are sold, AWS marks the listing as closed.
For example, you create a listing *Reserved Instances listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample* with a listing count of 5.

The **My Listings** tab in the **Reserved Instance** console page displays the listing this way:

*Reserved Instance listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample*

- Total reservation count = 5
- Sold = 0
- Available = 5
- Status = active

A buyer purchases two of the reservations, which leaves a count of three reservations still available for sale. Because of this partial sale, AWS creates a new reservation with a count of three to represent the remaining reservations that are still for sale.

This is how your listing looks in the **My Listings** tab:

*Reserved Instance listing ID 5ec28771-05ff-4b9b-aa31-9e57dexample*

- Total reservation count = 5
- Sold = 2
- Available = 3
- Status = active

If you cancel your listing and a portion of that listing has already sold, the cancelation is not effective on the portion that has been sold. Only the unsold portion of the listing is no longer available in the Reserved Instance Marketplace.

**After your Reserved Instance is sold**

When your Reserved Instance is sold, AWS sends you an email notification. Each day that there is any kind of activity, you receive one email notification capturing all the activities of the day. Activities can include when you create or sell a listing, or when AWS sends funds to your account.

**To track the status of a Reserved Instance listing in the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation page, choose **Reserved Instances**.
3. Choose the **My Listings** tab.

   The **My Listings** tab contains the **Listing State** value. It also contains information about the term, listing price, and a breakdown of how many instances in the listing are available, pending, sold, and canceled.

   You can also use the `describe-reserved-instances-listings` command with the appropriate filter to obtain information about your listings.

**Getting paid**

As soon as AWS receives funds from the buyer, a message is sent to the registered owner account email for the sold Reserved Instance.

AWS sends an Automated Clearing House (ACH) wire transfer to your specified bank account. Typically, this transfer occurs between one to three days after your Reserved Instance has been sold. Disbursements take place once a day. You will receive an email with a disbursement report after the funds are released. Keep in mind that you can't receive disbursements until AWS receives verification from your bank. This can take up to two weeks.

The Reserved Instance that you sold continues to appear when you describe your Reserved Instances.

You receive a cash disbursement for your Reserved Instances through a wire transfer directly into your bank account. AWS charges a service fee of 12 percent of the total upfront price of each Reserved Instance you sell in the Reserved Instance Marketplace.

**Information shared with the buyer**

When you sell in the Reserved Instance Marketplace, AWS shares your company's legal name on the buyer's statement in accordance with US regulations. In addition, if the buyer calls AWS Support because the buyer needs to contact you for an invoice or for some other tax-related reason, AWS might need to provide the buyer with your email address so that the buyer can contact you directly.

For similar reasons, the buyer's ZIP code and country information are provided to the seller in the disbursement report. As a seller, you might need this information to accompany any necessary transaction taxes that you remit to the government (such as sales tax and value-added tax).

AWS cannot offer tax advice, but if your tax specialist determines that you need specific additional information, [contact AWS Support](https://aws.amazon.com).
Modify Reserved Instances

When your needs change, you can modify your Standard or Convertible Reserved Instances and continue to benefit from the billing benefit. You can modify attributes such as the Availability Zone, instance size (within the same instance family and generation), and scope of your Reserved Instance.

**Note**

You can also exchange a Convertible Reserved Instance for another Convertible Reserved Instance with a different configuration. For more information, see [Exchange Convertible Reserved Instances](#).

You can modify all or a subset of your Reserved Instances. You can separate your original Reserved Instances into two or more new Reserved Instances. For example, if you have a reservation for 10 instances in `us-east-1a` and decide to move 5 instances to `us-east-1b`, the modification request results in two new reservations: one for 5 instances in `us-east-1a` and the other for 5 instances in `us-east-1b`.

You can also *merge* two or more Reserved Instances into a single Reserved Instance. For example, if you have four `t2.small` Reserved Instances of one instance each, you can merge them to create one `t2.large` Reserved Instance. For more information, see [Support for modifying instance sizes](#).

After modification, the benefit of the Reserved Instances is applied only to instances that match the new parameters. For example, if you change the Availability Zone of a reservation, the capacity reservation and pricing benefits are automatically applied to instance usage in the new Availability Zone. Instances that no longer match the new parameters are charged at the On-Demand rate, unless your account has other applicable reservations.

If your modification request succeeds:

- The modified reservation becomes effective immediately and the pricing benefit is applied to the new instances beginning at the hour of the modification request. For example, if you successfully modify your reservations at 9:15PM, the pricing benefit transfers to your new instance at 9:00PM. You can get the effective date of the modified Reserved Instances by using the `describe-reserved-instances` command.
- The original reservation is retired. Its end date is the start date of the new reservation, and the end date of the new reservation is the same as the end date of the original Reserved Instance. If
you modify a three-year reservation that had 16 months left in its term, the resulting modified reservation is a 16-month reservation with the same end date as the original one.

- The modified reservation lists a $0 fixed price and not the fixed price of the original reservation.
- The fixed price of the modified reservation does not affect the discount pricing tier calculations applied to your account, which are based on the fixed price of the original reservation.

If your modification request fails, your Reserved Instances maintain their original configuration, and are immediately available for another modification request.

There is no fee for modification, and you do not receive any new bills or invoices.

You can modify your reservations as frequently as you like, but you cannot change or cancel a pending modification request after you submit it. After the modification has completed successfully, you can submit another modification request to roll back any changes you made, if needed.

<td>Instance size flexibility is not available for Reserved Instances on the other platforms, which include Linux with SQL Server Standard, Linux with SQL Server Web, Linux with SQL Server Enterprise, Red Hat Enterprise Linux, SUSE Linux, Windows, Windows with SQL Standard, Windows with SQL Server Enterprise, and Windows with SQL Server Web.</td>
<td></td>
</tr>
</tbody>
</table>

**Requirements**

Amazon EC2 processes your modification request if there is sufficient capacity for your new configuration (if applicable), and if the following conditions are met:

- The Reserved Instance cannot be modified before or at the same time that you purchase it
- The Reserved Instance must be active
- There cannot be a pending modification request
- The Reserved Instance is not listed in the Reserved Instance Marketplace
- There must be a match between the instance size footprint of the original reservation and the new configuration. For more information, see [Support for modifying instance sizes](#).
- The original Reserved Instances are all Standard Reserved Instances or all Convertible Reserved Instances, not some of each type
- The original Reserved Instances must expire within the same hour, if they are Standard Reserved Instances
The Reserved Instance must support instance size flexibility. For the list of Reserved Instances that don't support instance size flexibility, see Instance size flexibility.

Support for modifying instance sizes

You can modify the instance size of a Reserved Instance if the following requirements are met.

Requirements

- The platform is Linux/UNIX.
- You must select another instance size in the same instance family (indicated by a letter, for example, T) and generation (indicated by a number, for example, 2).

  For example, you can modify a Reserved Instance from t2.small to t2.large because they're both in the same T2 family and generation. But you can't modify a Reserved Instance from T2 to M2 or from T2 to T3, because in both these examples, the target instance family and generation are not the same as the original Reserved Instance.

- You can modify the instance size of a Reserved Instance only if it supports instance size flexibility. For the list of Reserved Instances that don't support instance size flexibility, see Instance size flexibility.

- You can't modify the instance size of Reserved Instances for t1.micro instances, because t1.micro has only one size.

- The original and new Reserved Instance must have the same instance size footprint.

Contents

- Instance size footprint
- Normalization factors for bare metal instances

Instance size footprint

Each Reserved Instance has an instance size footprint, which is determined by the normalization factor of the instance size and the number of instances in the reservation. When you modify the instance sizes in an Reserved Instance, the footprint of the new configuration must match that of the original configuration, otherwise the modification request is not processed.

To calculate the instance size footprint of a Reserved Instance, multiply the number of instances by the normalization factor. In the Amazon EC2 console, the normalization factor is measured in units.
The following table describes the normalization factor for the instance sizes in an instance family. For example, t2.medium has a normalization factor of 2, so a reservation for four t2.medium instances has a footprint of 8 units.

<table>
<thead>
<tr>
<th>Instance size</th>
<th>Normalization factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>nano</td>
<td>0.25</td>
</tr>
<tr>
<td>micro</td>
<td>0.5</td>
</tr>
<tr>
<td>small</td>
<td>1</td>

<tr>
<td>2xlarge</td>
<td>16</td>
</tr>
<tr>
<td>3xlarge</td>
<td>24</td>
</tr>
<tr>
<td>4xlarge</td>
<td>32</td>
</tr>
<tr>
<td>6xlarge</td>
<td>48</td>
</tr>
<tr>
<td>8xlarge</td>
<td>64</td>
</tr>
<tr>
<td>9xlarge</td>
<td>72</td>
</tr>
<tr>
<td>10xlarge</td>
<td>80</td>
</tr>
<tr>
<td>12xlarge</td>
<td>96</td>
</tr>
<tr>
<td>16xlarge</td>
<td>128</td>
</tr>
<tr>
<td>18xlarge</td>
<td>144</td>
</tr>
<tr>
<td>24xlarge</td>
<td>192</td>
</tr>
<tr>
<td>32xlarge</td>
<td>256</td>
</tr>
</tbody>
</table>
### Instance size

<table>
<thead>
<tr>
<th>Instance size</th>
<th>Normalization factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>48xlarge</td>
<td>384</td>
</tr>
<tr>
<td>56xlarge</td>
<td>448</td>
</tr>
<tr>
<td>112xlarge</td>
<td>896</td>
</tr>
</tbody>
</table>

You can allocate your reservations into different instance sizes across the same instance family as long as the instance size footprint of your reservation remains the same. For example, you can divide a reservation for one `t2.large` (1 @ 4 units) instance into four `t2.small` (4 @ 1 unit) instances. Similarly, you can combine a reservation for four `t2.small` instances into one `t2.large` instance. However, you cannot change your reservation for two `t2.small` instances into one `t2.large` instance because the footprint of the new reservation (4 units) is larger than the footprint of the original reservation (2 units).

In the following example, you have a reservation with two `t2.micro` instances (1 unit) and a reservation with one `t2.small` instance (1 unit). If you merge both of these reservations to a single reservation with one `t2.medium` instance (2 units), the footprint of the new reservation equals the footprint of the combined reservations.

You can also modify a reservation to divide it into two or more reservations. In the following example, you have a reservation with a `t2.medium` instance (2 units). You can divide the reservation into two reservations, one with two `t2.nano` instances (.5 units) and the other with three `t2.micro` instances (1.5 units).
Normalization factors for bare metal instances

You can modify a reservation with metal instances using other sizes within the same instance family. Similarly, you can modify a reservation with instances other than bare metal instances using the metal size within the same instance family. Generally, a bare metal instance is the same size as the largest available instance size within the same instance family. For example, an i3.metal instance is the same size as an i3.16xlarge instance, so they have the same normalization factor.

The following table describes the normalization factor for the bare metal instance sizes in the instance families that have bare metal instances. The normalization factor for metal instances depends on the instance family, unlike the other instance sizes.

<table>
<thead>
<tr>
<th>Instance size</th>
<th>Normalization factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>a1.metal</td>
<td>32</td>
</tr>
<tr>
<td>m5zn.metal</td>
<td>x2iezn.metal  z1d.metal</td>
</tr>
<tr>
<td>c6g.metal</td>
<td>c6gd.metal  i3.metal</td>
</tr>
<tr>
<td>c5n.metal</td>
<td>144</td>
</tr>
<tr>
<td>c5.metal</td>
<td>c5d.metal</td>
</tr>
</tbody>
</table>
### Instance size

<table>
<thead>
<tr>
<th>Instance size</th>
<th>Normalization factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>c6i.metal</td>
<td>256</td>
</tr>
<tr>
<td>c6id.metal</td>
<td>256</td>
</tr>
<tr>
<td>m6i.metal</td>
<td>256</td>
</tr>
<tr>
<td>m6id.metal</td>
<td>256</td>
</tr>
<tr>
<td>r6d.metal</td>
<td>256</td>
</tr>
<tr>
<td>r6id.metal</td>
<td>256</td>
</tr>
<tr>
<td>u-*.metal</td>
<td>896</td>
</tr>
</tbody>
</table>

For example, an `i3.metal` instance has a normalization factor of 128. If you purchase an `i3.metal` default tenancy Amazon Linux/Unix Reserved Instance, you can divide the reservation as follows:

- An `i3.16xlarge` is the same size as an `i3.metal` instance, so its normalization factor is 128 (128/1). The reservation for one `i3.metal` instance can be modified into one `i3.16xlarge` instance.

- An `i3.8xlarge` is half the size of an `i3.metal` instance, so its normalization factor is 64 (128/2). The reservation for one `i3.metal` instance can be divided into two `i3.8xlarge` instances.

- An `i3.4xlarge` is a quarter the size of an `i3.metal` instance, so its normalization factor is 32 (128/4). The reservation for one `i3.metal` instance can be divided into four `i3.4xlarge` instances.

### Submit modification requests

Before you modify your Reserved Instances, ensure that you have read the applicable restrictions. Before you modify the instance size, calculate the total instance size footprint of the original reservations that you want to modify and ensure that it matches the total instance size footprint of your new configurations.

**New console**

**To modify your Reserved Instances using the AWS Management Console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

2. On the **Reserved Instances** page, select one or more Reserved Instances to modify, and choose **Actions, Modify Reserved Instances**.
3. The first entry in the modification table displays attributes of the selected Reserved Instances, and at least one target configuration beneath it. The Units column displays the total instance size footprint. Choose Add for each new configuration to add. Modify the attributes as needed for each configuration.

- **Scope**: Choose whether the configuration applies to an Availability Zone or to the whole Region.
- **Availability Zone**: Choose the required Availability Zone. Not applicable for regional Reserved Instances.
- **Instance type**: Select the required instance type. The combined configurations must equal the instance size footprint of your original configurations.
- **Count**: Specify the number of instances. To split the Reserved Instances into multiple configurations, reduce the count, choose Add, and specify a count for the additional configuration. For example, if you have a single configuration with a count of 10, you can change its count to 6 and add a configuration with a count of 4. This process retires the original Reserved Instance after the new Reserved Instances are activated.

4. Choose Continue.

5. To confirm your modification choices when you finish specifying your target configurations, choose Submit modifications.

6. You can determine the status of your modification request by looking at the State column in the Reserved Instances screen. The following are the possible states.

- **active (pending modification)** — Transition state for original Reserved Instances
- **retired (pending modification)** — Transition state for original Reserved Instances while new Reserved Instances are being created
- **retired** — Reserved Instances successfully modified and replaced
- **active** — One of the following:
  - New Reserved Instances created from a successful modification request
  - Original Reserved Instances after a failed modification request
To modify your Reserved Instances using the AWS Management Console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the Reserved Instances page, select one or more Reserved Instances to modify, and choose Actions, Modify Reserved Instances.

   **Note**
   
   If your Reserved Instances are not in the active state or cannot be modified, Modify Reserved Instances is disabled.

3. The first entry in the modification table displays attributes of selected Reserved Instances, and at least one target configuration beneath it. The Units column displays the total instance size footprint. Choose Add for each new configuration to add. Modify the attributes as needed for each configuration, and then choose Continue:
   
   - **Scope**: Choose whether the configuration applies to an Availability Zone or to the whole Region.
   - **Availability Zone**: Choose the required Availability Zone. Not applicable for regional Reserved Instances.
   - **Instance Type**: Select the required instance type. The combined configurations must equal the instance size footprint of your original configurations.
   - **Count**: Specify the number of instances. To split the Reserved Instances into multiple configurations, reduce the count, choose Add, and specify a count for the additional configuration. For example, if you have a single configuration with a count of 10, you can change its count to 6 and add a configuration with a count of 4. This process retires the original Reserved Instance after the new Reserved Instances are activated.

4. To confirm your modification choices when you finish specifying your target configurations, choose Submit Modifications.

5. You can determine the status of your modification request by looking at the State column in the Reserved Instances screen. The following are the possible states.

   - **active (pending modification)** — Transition state for original Reserved Instances
   - **retired (pending modification)** — Transition state for original Reserved Instances while new Reserved Instances are being created
To modify your Reserved Instances using the command line

1. To modify your Reserved Instances, you can use one of the following commands:
   - `modify-reserved-instances` (AWS CLI)
   - `Edit-EC2ReservedInstance` (AWS Tools for Windows PowerShell)

2. To get the status of your modification request (processing, fulfilled, or failed), use one of the following commands:
   - `describe-reserved-instances-modifications` (AWS CLI)
   - `Get-EC2ReservedInstancesModification` (AWS Tools for Windows PowerShell)

Troubleshoot modification requests

If the target configuration settings that you requested were unique, you receive a message that your request is being processed. At this point, Amazon EC2 has only determined that the parameters of your modification request are valid. Your modification request can still fail during processing due to unavailable capacity.

In some situations, you might get a message indicating incomplete or failed modification requests instead of a confirmation. Use the information in such messages as a starting point for resubmitting another modification request. Ensure that you have read the applicable restrictions before submitting the request.

Not all selected Reserved Instances can be processed for modification

Amazon EC2 identifies and lists the Reserved Instances that cannot be modified. If you receive a message like this, go to the Reserved Instances page in the Amazon EC2 console and check the information for the Reserved Instances.

Error in processing your modification request
You submitted one or more Reserved Instances for modification and none of your requests can be processed. Depending on the number of reservations you are modifying, you can get different versions of the message.

Amazon EC2 displays the reasons why your request cannot be processed. For example, you might have specified the same target configuration—a combination of Availability Zone and platform—for one or more subsets of the Reserved Instances you are modifying. Try submitting the modification requests again, but ensure that the instance details of the reservations match, and that the target configurations for all subsets being modified are unique.

**Exchange Convertible Reserved Instances**

You can exchange one or more Convertible Reserved Instances for another Convertible Reserved Instance with a different configuration, including instance family, operating system, and tenancy. There are no limits to how many times you perform an exchange, as long as the new Convertible Reserved Instance is of an equal or higher value than the Convertible Reserved Instances that you are exchanging.

When you exchange your Convertible Reserved Instance, the number of instances for your current reservation is exchanged for a number of instances that cover the equal or higher value of the configuration of the new Convertible Reserved Instance. Amazon EC2 calculates the number of Reserved Instances that you can receive as a result of the exchange.

You can't exchange Standard Reserved Instances, but you can modify them. For more information, see [Modify Reserved Instances](#).

**Contents**

- Requirements for exchanging Convertible Reserved Instances
- Calculate Convertible Reserved Instances exchanges
- Merge Convertible Reserved Instances
- Exchange a portion of a Convertible Reserved Instance
- Submit exchange requests

**Requirements for exchanging Convertible Reserved Instances**

If the following conditions are met, Amazon EC2 processes your exchange request. Your Convertible Reserved Instance must be:
• Active
• Not pending a previous exchange request
• Have at least 24 hours remaining before it expires

The following rules apply:

• Convertible Reserved Instances can only be exchanged for other Convertible Reserved Instances currently offered by AWS.
• Convertible Reserved Instances are associated with a specific Region, which is fixed for the duration of the reservation's term. You cannot exchange a Convertible Reserved Instance for a Convertible Reserved Instance in a different Region.
• You can exchange one or more Convertible Reserved Instances at a time for one Convertible Reserved Instance only.
• To exchange a portion of a Convertible Reserved Instance, you can modify it into two or more reservations, and then exchange one or more of the reservations for a new Convertible Reserved Instance. For more information, see Exchange a portion of a Convertible Reserved Instance. For more information about modifying your Reserved Instances, see Modify Reserved Instances.
• All Upfront Convertible Reserved Instances can be exchanged for Partial Upfront Convertible Reserved Instances, and vice versa.

Note
If the total upfront payment required for the exchange (true-up cost) is less than $0.00, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that true-up cost is $0.00 or more.

Note
If the total value (upfront price + hourly price * number of remaining hours) of the new Convertible Reserved Instance is less than the total value of the exchanged Convertible Reserved Instance, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that the total value is the same or higher than that of the exchanged Convertible Reserved Instance.
• To benefit from better pricing, you can exchange a No Upfront Convertible Reserved Instance for an All Upfront or Partial Upfront Convertible Reserved Instance.

• You cannot exchange All Upfront and Partial Upfront Convertible Reserved Instances for No Upfront Convertible Reserved Instances.

• You can exchange a No Upfront Convertible Reserved Instance for another No Upfront Convertible Reserved Instance only if the new Convertible Reserved Instance's hourly price is the same or higher than the exchanged Convertible Reserved Instance's hourly price.

⚠️ **Note**

If the total value (hourly price * number of remaining hours) of the new Convertible Reserved Instance is less than the total value of the exchanged Convertible Reserved Instance, AWS automatically gives you a quantity of instances in the Convertible Reserved Instance that ensures that the total value is the same or higher than that of the exchanged Convertible Reserved Instance.

• If you exchange multiple Convertible Reserved Instances that have different expiration dates, the expiration date for the new Convertible Reserved Instance is the date that's furthest in the future.

• If you exchange a single Convertible Reserved Instance, it must have the same term (1-year or 3-years) as the new Convertible Reserved Instance. If you merge multiple Convertible Reserved Instances with different term lengths, the new Convertible Reserved Instance has a 3-year term. For more information, see [Merge Convertible Reserved Instances](#).

• When Amazon EC2 exchanges a Convertible Reserved Instance, it retires the associated reservation, and transfers the end date to the new reservation. After the exchange, Amazon EC2 sets both the end date for the old reservation and the start date for the new reservation equal to the date of the exchange. For example, if you exchange a three-year reservation that had 16 months left in its term, the new reservation is a 16-month reservation with the same end date as the reservation from the Convertible Reserved Instance that you exchanged.

### Calculate Convertible Reserved Instances exchanges

Exchanging Convertible Reserved Instances is free. However, you might be required to pay a true-up cost, which is a prorated upfront cost of the difference between the Convertible Reserved Instances that you had and the new Convertible Reserved Instances that you receive from the exchange.
Each Convertible Reserved Instance has a list value. This list value is compared to the list value of the Convertible Reserved Instances that you want in order to determine how many instance reservations you can receive from the exchange.

For example: You have 1 x $35-list value Convertible Reserved Instance that you want to exchange for a new instance type with a list value of $10.

\[
\frac{35}{10} = 3.5
\]

You can exchange your Convertible Reserved Instance for three $10 Convertible Reserved Instances. It's not possible to purchase half reservations; therefore you must purchase an additional Convertible Reserved Instance to cover the remainder:

\[
3.5 = 3 \text{ whole Convertible Reserved Instances} + 1 \text{ additional Convertible Reserved Instance}
\]

The fourth Convertible Reserved Instance has the same end date as the other three. If you are exchanging Partial or All Upfront Convertible Reserved Instances, you pay the true-up cost for the fourth reservation. If the remaining upfront cost of your Convertible Reserved Instances is $500, and the new reservation would normally cost $600 on a prorated basis, you are charged $100.

\[
600 \text{ prorated upfront cost of new reservations} - 500 \text{ remaining upfront cost of old reservations} = 100 \text{ difference}
\]

**Merge Convertible Reserved Instances**

If you merge two or more Convertible Reserved Instances, the term of the new Convertible Reserved Instance must be the same as the old Convertible Reserved Instances, or the highest of the Convertible Reserved Instances. The expiration date for the new Convertible Reserved Instance is the expiration date that's furthest in the future.

For example, you have the following Convertible Reserved Instances in your account:

<table>
<thead>
<tr>
<th>Reserved Instance ID</th>
<th>Term</th>
<th>Expiration date</th>
</tr>
</thead>
<tbody>
<tr>
<td>aaaa1111</td>
<td>1-year</td>
<td>2018-12-31</td>
</tr>
<tr>
<td>bbbb2222</td>
<td>1-year</td>
<td>2018-07-31</td>
</tr>
<tr>
<td>Reserved Instance ID</td>
<td>Term</td>
<td>Expiration date</td>
</tr>
<tr>
<td>----------------------</td>
<td>--------</td>
<td>-----------------</td>
</tr>
<tr>
<td>cccc3333</td>
<td>3-year</td>
<td>2018-06-30</td>
</tr>
<tr>
<td>dddd4444</td>
<td>3-year</td>
<td>2019-12-31</td>
</tr>
</tbody>
</table>

• You can merge aaaa1111 and bbbb2222 and exchange them for a 1-year Convertible Reserved Instance. You cannot exchange them for a 3-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2018-12-31.

• You can merge bbbb2222 and cccc3333 and exchange them for a 3-year Convertible Reserved Instance. You cannot exchange them for a 1-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2018-07-31.

• You can merge cccc3333 and dddd4444 and exchange them for a 3-year Convertible Reserved Instance. You cannot exchange them for a 1-year Convertible Reserved Instance. The expiration date of the new Convertible Reserved Instance is 2019-12-31.

**Exchange a portion of a Convertible Reserved Instance**

You can use the modification process to split your Convertible Reserved Instance into smaller reservations, and then exchange one or more of the new reservations for a new Convertible Reserved Instance. The following examples demonstrate how you can do this.

**Example Example: Convertible Reserved Instance with multiple instances**

In this example, you have a t2.micro Convertible Reserved Instance with four instances in the reservation. To exchange two t2.micro instances for an m4.xlarge instance:

1. Modify the t2.micro Convertible Reserved Instance by splitting it into two t2.micro Convertible Reserved Instances with two instances each.
2. Exchange one of the new t2.micro Convertible Reserved Instances for an m4.xlarge Convertible Reserved Instance.
**Example Example: Convertible Reserved Instance with a single instance**

In this example, you have a `t2.large` Convertible Reserved Instance. To change it to a smaller `t2.medium` instance and a `m3.medium` instance:

1. Modify the `t2.large` Convertible Reserved Instance by splitting it into two `t2.medium` Convertible Reserved Instances. A single `t2.large` instance has the same instance size footprint as two `t2.medium` instances.
2. Exchange one of the new `t2.medium` Convertible Reserved Instances for an `m3.medium` Convertible Reserved Instance.

For more information, see [Support for modifying instance sizes](#) and [Submit exchange requests](#).

**Submit exchange requests**

You can exchange your Convertible Reserved Instances using the Amazon EC2 console or a command line tool.

**Exchange a Convertible Reserved Instance using the console**

You can search for Convertible Reserved Instances offerings and select your new configuration from the choices provided.
New console

To exchange Convertible Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Reserved Instances, select the Convertible Reserved Instances to exchange, and choose Actions, Exchange Reserved Instance.
3. Select the attributes of the desired configuration, and choose Find offering.
4. Select a new Convertible Reserved Instance. At the bottom of the screen, you can view the number of Reserved Instances that you receive for the exchange, and any additional costs.
5. When you have selected a Convertible Reserved Instance that meets your needs, choose Review.
6. Choose Exchange, and then Close.

Old console

To exchange Convertible Reserved Instances using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Reserved Instances, select the Convertible Reserved Instances to exchange, and choose Actions, Exchange Reserved Instance.
3. Select the attributes of the desired configuration, and choose Find Offering.
4. Select a new Convertible Reserved Instance. The Instance Count column displays the number of Reserved Instances that you receive for the exchange. When you have selected a Convertible Reserved Instance that meets your needs, choose Exchange.

The Reserved Instances that were exchanged are retired, and the new Reserved Instances are displayed in the Amazon EC2 console. This process can take a few minutes to propagate.

Exchange a Convertible Reserved Instance using the command line interface

To exchange a Convertible Reserved Instance, first find a new Convertible Reserved Instance that meets your needs:

- describe-reserved-instances-offerings (AWS CLI)
- Get-EC2ReservedInstancesOffering (Tools for Windows PowerShell)
Get a quote for the exchange, which includes the number of Reserved Instances you get from the exchange, and the true-up cost for the exchange:

- get-reserved-instances-exchange-quote (AWS CLI)
- GetEC2-ReservedInstancesExchangeQuote (Tools for Windows PowerShell)

Finally, perform the exchange:

- accept-reserved-instances-exchange-quote (AWS CLI)
- Confirm-EC2ReservedInstancesExchangeQuote (Tools for Windows PowerShell)

**Reserved Instance quotas**

You can purchase new Reserved Instances each month. The number of new Reserved Instances that you can purchase each month is determined by your monthly quota, as follows:

<table>
<thead>
<tr>
<th>Quota description</th>
<th>Default quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>New <strong>regional</strong> Reserved Instances</td>
<td>20 per Region per month</td>
</tr>
<tr>
<td>New <strong>zonal</strong> Reserved Instances</td>
<td>20 per Availability Zone per month</td>
</tr>
</tbody>
</table>

For example, in a Region with three Availability Zones, the default quota is 80 new Reserved Instances per month, calculated as follows:

- 20 regional Reserved Instances for the Region
- Plus 60 zonal Reserved Instances (20 for each of the three Availability Zones)

Instances in the running state count toward your quota. Instances that are in the pending, stopping, stopped, and hibernated states do not count towards your quota.

**View the number of Reserved Instances you have purchased**

The number of Reserved Instances that you purchase is indicated by the **Instance count** field (console) or the InstanceCount parameter (AWS CLI). When you purchase new Reserved Instances, the quota is measured against the total instance count. For example, if you purchase a
single Reserved Instance configuration with an instance count of 10, the purchase counts towards your quota as 10, not 1.

You can view how many Reserved Instances you have purchased by using the Amazon EC2 or the AWS CLI.

**Console**

**To view the number of Reserved Instances you have purchased**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Reserved Instances**.
3. Select a Reserved Instance configuration from the table, and check the **Instance count** field.

In the following screenshot, the selected line represents a single Reserved Instance configuration for a t3.micro instance type. The **Instance count** column in the table view and the **Instance count** field in the detail view (outlined in the screenshot) indicate that there are 10 Reserved Instances for this configuration.

![EC2 Reserved Instances](image)

**AWS CLI**

**To view the number of Reserved Instances you have purchased**
Use the **describe-reserved-instances** CLI command and specify the ID of the Reserved Instance configuration.

```bash
aws ec2 describe-reserved-instances \
  --reserved-instances-ids 2fbf16dd-98b6-4a3a-955f-83f87790f04b \
  --output table
```

Example output – The **InstanceCount** field indicates that there are 10 Reserved Instances for this configuration.

**Considerations**

A regional Reserved Instance applies a discount to a running On-Demand Instance. The default On-Demand Instance limit is 20. You cannot exceed your running On-Demand Instance limit by
purchasing regional Reserved Instances. For example, if you already have 20 running On-Demand
Instances, and you purchase 20 regional Reserved Instances, the 20 regional Reserved Instances are
used to apply a discount to the 20 running On-Demand Instances. If you purchase more regional
Reserved Instances, you will not be able to launch more instances because you have reached your
On-Demand Instance limit.

Before purchasing regional Reserved Instances, make sure your On-Demand Instance limit matches
or exceeds the number of regional Reserved Instances you intend to own. If required, make sure
you request an increase to your On-Demand Instance limit before purchasing more regional
Reserved Instances.

A zonal Reserved Instance—a Reserved Instance that is purchased for a specific Availability Zone
—provides a capacity reservation as well as a discount. You can exceed your running On-Demand
Instance limit by purchasing zonal Reserved Instances. For example, if you already have 20 running
On-Demand Instances, and you purchase 20 zonal Reserved Instances, you can launch a further 20
On-Demand Instances that match the specifications of your zonal Reserved Instances, giving you a
total of 40 running instances.

**View your Reserved Instance quotas and request a quota increase**

The Amazon EC2 console provides quota information. You can also request an increase in your
quotas. For more information, see [View your current quotas](#) and [Request an increase](#).
Spot Instances

A Spot Instance is an instance that uses spare EC2 capacity that is available for less than the On-Demand price. Because Spot Instances enable you to request unused EC2 instances at steep discounts, you can lower your Amazon EC2 costs significantly. The hourly price for a Spot Instance is called a Spot price. The Spot price of each instance type in each Availability Zone is set by Amazon EC2, and is adjusted gradually based on the long-term supply of and demand for Spot Instances. Your Spot Instance runs whenever capacity is available.

Spot Instances are a cost-effective choice if you can be flexible about when your applications run and if your applications can be interrupted. For example, Spot Instances are well-suited for data analysis, batch jobs, background processing, and optional tasks. For more information, see Amazon EC2 Spot Instances.

For a comparison of the different purchasing options for EC2 instances, see Instance purchasing options.

- Related services
- Pricing and savings

Concepts

Before you get started with Spot Instances, you should be familiar with the following concepts:

- **Spot capacity pool** – A set of unused EC2 instances with the same instance type (for example, m5.large) and Availability Zone.
- **Spot price** – The current price of a Spot Instance per hour.
- **Spot Instance request** – Requests a Spot Instance. When capacity is available, Amazon EC2 fulfills your request. A Spot Instance request is either one-time or persistent. Amazon EC2 automatically resubmits a persistent Spot Instance request after the Spot Instance associated with the request is interrupted.
- **EC2 instance rebalance recommendation** – Amazon EC2 emits an instance rebalance recommendation signal to notify you that a Spot Instance is at an elevated risk of interruption.
This signal provides an opportunity to proactively rebalance your workloads across existing or new Spot Instances without having to wait for the two-minute Spot Instance interruption notice.

- **Spot Instance interruption** – Amazon EC2 terminates, stops, or hibernates your Spot Instance when Amazon EC2 needs the capacity back. Amazon EC2 provides a Spot Instance interruption notice, which gives the instance a two-minute warning before it is interrupted.

### Key differences between Spot Instances and On-Demand Instances

The following table lists the key differences between Spot Instances and On-Demand Instances.

<table>
<thead>
<tr>
<th></th>
<th>Spot Instances</th>
<th>On-Demand Instances</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Launch time</strong></td>
<td>Can only be launched immediately if the Spot Instance request is active and capacity is available.</td>
<td>Can only be launched immediately if you make a manual launch request and capacity is available.</td>
</tr>
<tr>
<td><strong>Available capacity</strong></td>
<td>If capacity is not available, the Spot Instance request continues to automatically make the launch request until capacity becomes available.</td>
<td>If capacity is not available when you make a launch request, you get an insufficient capacity error (ICE).</td>
</tr>
<tr>
<td><strong>Hourly price</strong></td>
<td>The hourly price for Spot Instances varies based on long-term supply and demand.</td>
<td>The hourly price for On-Demand Instances is static.</td>
</tr>
<tr>
<td><strong>Rebalance recommendation</strong></td>
<td>The signal that Amazon EC2 emits for a running Spot Instance when the instance is at an elevated risk of interruption.</td>
<td>You determine when an On-Demand Instance is interrupted (stopped, hibernated, or terminated).</td>
</tr>
<tr>
<td><strong>Instance interruption</strong></td>
<td>You can stop and start an Amazon EBS-backed Spot Instance. In addition, Amazon EC2 can interrupt an individual Spot Instance if capacity is no longer available.</td>
<td>You determine when an On-Demand Instance is interrupted (stopped, hibernated, or terminated).</td>
</tr>
</tbody>
</table>
How to get started

The first thing that you need to do is get set up to use Amazon EC2. It can also be helpful to have experience launching On-Demand Instances before launching Spot Instances.

Spot basics

• [How Spot Instances work](#)

Working with Spot Instances

• [Create a Spot Instance request](#)
• [Get request status information](#)
• [Spot Instance interruptions](#)

Related services

You can provision Spot Instances directly using Amazon EC2. You can also provision Spot Instances using other services in AWS. For more information, see the following documentation.

Amazon EC2 Auto Scaling and Spot Instances

You can create launch templates or configurations so that Amazon EC2 Auto Scaling can launch Spot Instances. For more information, see Requesting Spot Instances for fault-tolerant and flexible applications and Auto Scaling groups with multiple instance types and purchase options in the [Amazon EC2 Auto Scaling User Guide](#).

Amazon EMR and Spot Instances

There are scenarios where it can be useful to run Spot Instances in an Amazon EMR cluster. For more information, see [Spot Instances](#) and When Should You Use Spot Instances in the [Amazon EMR Management Guide](#).

AWS CloudFormation templates

AWS CloudFormation enables you to create and manage a collection of AWS resources using a template in JSON format. For more information, see [EC2 Spot Instance Updates - Auto Scaling and CloudFormation Integration](#).
AWS SDK for Java

You can use the Java programming language to manage your Spot Instances. For more information, see [Tutorial: Amazon EC2 Spot Instances](#) and [Tutorial: Advanced Amazon EC2 Spot Request Management](#).

AWS SDK for .NET

You can use the .NET programming environment to manage your Spot Instances. For more information, see [Tutorial: Amazon EC2 Spot Instances](#).

**Pricing and savings**

You pay the Spot price for Spot Instances, which is set by Amazon EC2 and adjusted gradually based on the long-term supply of and demand for Spot Instances. Your Spot Instances run until you terminate them, capacity is no longer available, or your Amazon EC2 Auto Scaling group terminates them during scale in.

If you or Amazon EC2 interrupts a running Spot Instance, you are charged for the seconds used or the full hour, or you receive no charge, depending on the operating system used and who interrupted the Spot Instance. For more information, see [Billing for interrupted Spot Instances](#).

Spot Instances are not covered by Savings Plans. If you have a Savings Plan, it does not provide additional savings on top of the savings that you already get from using Spot Instances. Furthermore, your spend on Spot Instances does not apply the commitments in your Compute Savings Plans.

**View prices**

To view the current (updated every five minutes) lowest Spot price per AWS Region and instance type, see the [Amazon EC2 Spot Instances Pricing](#) page.

To view the Spot price history for the past three months, use the Amazon EC2 console or the `describe-spot-price-history` command (AWS CLI). For more information, see [Spot Instance pricing history](#).

We independently map Availability Zones to codes for each AWS account. Therefore, you can get different results for the same Availability Zone code (for example, us-west-2a) between different accounts.
View savings

You can view the savings made from using Spot Instances for a single Spot Fleet or for all Spot Instances. You can view the savings made in the last hour or the last three days, and you can view the average cost per vCPU hour and per memory (GiB) hour. Savings are estimated and may differ from actual savings because they do not include the billing adjustments for your usage. For more information about viewing savings information, see Savings from purchasing Spot Instances.

View billing

Your bill provides details about your service usage. For more information, see Viewing your bill in the AWS Billing User Guide.

Best practices for EC2 Spot

Amazon EC2 Spot Instances are spare EC2 compute capacity in the AWS Cloud that are available to you at savings of up to 90% off compared to On-Demand prices. The only difference between On-Demand Instances and Spot Instances is that Spot Instances can be interrupted by Amazon EC2, with two minutes of notification, when Amazon EC2 needs the capacity back.

Spot Instances are recommended for stateless, fault-tolerant, flexible applications. For example, Spot Instances work well for big data, containerized workloads, CI/CD, stateless web servers, high performance computing (HPC), and rendering workloads.

While running, Spot Instances are exactly the same as On-Demand Instances. However, Spot does not guarantee that you can keep your running instances long enough to finish your workloads. Spot also does not guarantee that you can get immediate availability of the instances that you are looking for, or that you can always get the aggregate capacity that you requested. Moreover, Spot Instance interruptions and capacity can change over time because Spot Instance availability varies based on supply and demand, and past performance isn’t a guarantee of future results.

Spot Instances are not suitable for workloads that are inflexible, stateful, fault-intolerant, or tightly coupled between instance nodes. We do not recommend Spot Instances for workloads that are intolerant of occasional periods when the entire target capacity is not completely available. While following Spot best practices to be flexible about instance types and Availability Zones provides the best chance for high availability, there are no guarantees that capacity will be available, because surges in demand for On-Demand Instances can disrupt workloads on Spot Instances.

We strongly discourage using Spot Instances for these workloads or attempting to fail over to On-Demand Instances to handle interruptions or periods of unavailability. Failing over to On-Demand
Instances can inadvertently drive interruptions for your other Spot Instances. In addition if Spot Instances for a combination of instance type and Availability Zone get interrupted, it might become difficult for you to get On-Demand Instances with that same combination.

Regardless of whether you're an experienced Spot user or new to Spot Instances, if you are currently experiencing issues with Spot Instance interruptions or availability, we recommend that you follow these best practices to have the best experience using the Spot service.

**Spot best practices**

- [Prepare individual instances for interruptions](#)
- [Be flexible about instance types and Availability Zones](#)
- [Use EC2 Auto Scaling groups or EC2 Fleet to manage your aggregate capacity](#)
- [Use the price and capacity optimized allocation strategy](#)
- [Use integrated AWS services to manage your Spot Instances](#)
- [Which is the best Spot request method to use?](#)

**Prepare individual instances for interruptions**

The best way for you to gracefully handle Spot Instance interruptions is to architect your application to be fault-tolerant. To accomplish this, you can take advantage of EC2 instance rebalance recommendations and Spot Instance interruption notices.

An EC2 Instance rebalance recommendation is a signal that notifies you when a Spot Instance is at an elevated risk of interruption. The signal gives you the opportunity to proactively manage the Spot Instance in advance of the two-minute Spot Instance interruption notice. You can decide to rebalance your workload to new or existing Spot Instances that are not at an elevated risk of interruption. We've made it easy for you to use this signal by using the Capacity Rebalancing feature in Auto Scaling groups and EC2 Fleet.

A Spot Instance interruption notice is a warning that is issued two minutes before Amazon EC2 interrupts a Spot Instance. If your workload is "time-flexible," you can configure your Spot Instances to be stopped or hibernated, instead of being terminated, when they are interrupted. Amazon EC2 automatically stops or hibernates your Spot Instances on interruption, and automatically resumes the instances when we have available capacity.

We recommend that you create a rule in [Amazon EventBridge](https://aws.amazon.com/eventbridge/) that captures the rebalance recommendations and interruption notifications, and then triggers a checkpoint for the progress of your workload or gracefully handles the interruption. For more information, see [Monitor rebalance](https://docs.aws.amazon.com/spot/latest/userguide/monitor-rebalances.html)
recommendation signals. For a detailed example that walks you through how to create and use event rules, see Taking Advantage of Amazon EC2 Spot Instance Interruption Notices.

For more information, see EC2 instance rebalance recommendations and Spot Instance interruptions.

**Be flexible about instance types and Availability Zones**

A Spot capacity pool is a set of unused EC2 instances with the same instance type (for example, `m5.large`) and Availability Zone (for example, `us-east-1a`). You should be flexible about which instance types you request and in which Availability Zones you can deploy your workload. This gives Spot a better chance to find and allocate your required amount of compute capacity. For example, don't just ask for `c5.large` if you'd be willing to use larges from the c4, m5, and m4 families.

Depending on your specific needs, you can evaluate which instance types you can be flexible across to fulfill your compute requirements. If a workload can be vertically scaled, you should include larger instance types (more vCPUs and memory) in your requests. If you can only scale horizontally, you should include older generation instance types because they are less in demand from On-Demand customers.

A good rule of thumb is to be flexible across at least 10 instance types for each workload. In addition, make sure that all Availability Zones are configured for use in your VPC and selected for your workload.

**Use EC2 Auto Scaling groups or EC2 Fleet to manage your aggregate capacity**

Spot enables you to think in terms of aggregate capacity—in units that include vCPUs, memory, storage, or network throughput—rather than thinking in terms of individual instances. Auto Scaling groups and EC2 Fleet enable you to launch and maintain a target capacity, and to automatically request resources to replace any that are disrupted or manually terminated. When you configure an Auto Scaling group or an EC2 Fleet, you need only specify the instance types and target capacity based on your application needs. For more information, see Auto Scaling groups in the Amazon EC2 Auto Scaling User Guide and Create an EC2 Fleet in this user guide.

**Use the price and capacity optimized allocation strategy**

Allocation strategies in Auto Scaling groups help you to provision your target capacity without the need to manually look for the Spot capacity pools with spare capacity. We recommend using the price-capacity-optimized strategy because this strategy automatically provisions instances from the most-available Spot capacity pools that also have the lowest possible price. You
can also take advantage of the price-capacity-optimized allocation strategy in EC2 Fleet. Because your Spot Instance capacity is sourced from pools with optimal capacity, this decreases the possibility that your Spot Instances are reclaimed. For more information about allocation strategies, see Spot Instances in the Amazon EC2 Auto Scaling User Guide and When workloads have a high cost of interruption in this user guide.

Use integrated AWS services to manage your Spot Instances

Other AWS services integrate with Spot to reduce overall compute costs without the need to manage the individual instances or fleets. We recommend that you consider the following solutions for your applicable workloads: Amazon EMR, Amazon Elastic Container Service, AWS Batch, Amazon Elastic Kubernetes Service, Amazon SageMaker, AWS Elastic Beanstalk, and Amazon GameLift. To learn more about Spot best practices with these services, see the Amazon EC2 Spot Instances Workshops Website.

Which is the best Spot request method to use?

Use the following table to determine which API to use when requesting Spot Instances.

<table>
<thead>
<tr>
<th>API</th>
<th>When to use?</th>
<th>Use case</th>
<th>Should I use this API?</th>
</tr>
</thead>
</table>
| CreateAutoScalingGroup | • You need multiple instances with either a single configuration or a mixed configuration.  
• You want to automate the lifecycle management through a configurable API. | Create an Auto Scaling group that manages the lifecycle of your instances while maintaining the desired number of instances. Supports horizontal scaling (adding more instances) between specified minimum and maximum limits. | Yes                    |
<p>| CreateFleet         | •                                                                                 | Create a fleet of both On-Demand Instances                                                                                              |                        |</p>
<table>
<thead>
<tr>
<th>API</th>
<th>When to use?</th>
<th>Use case</th>
<th>Should I use this API?</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>You need multiple instances with either a single configuration or a mixed configuration.</td>
<td>and Spot Instances in a single request, with multiple launch specifications that vary by instance type, AMI, Availability Zone, or subnet. The Spot Instance allocation strategy defaults to lowest-price per unit, but you can change it to price-capacity-optimized, capacity-optimized, or diversified.</td>
<td>Yes – in instant mode if you don’t need auto scaling</td>
</tr>
<tr>
<td>API</td>
<td>When to use?</td>
<td>Use case</td>
<td>Should I use this API?</td>
</tr>
<tr>
<td>------------</td>
<td>------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------</td>
<td>------------------------</td>
</tr>
</tbody>
</table>
| RunInstances | • You're already using the RunInstances API to launch On-Demand Instances, and you simply want to change to launching Spot Instances by changing a single parameter.  
  • You do not need multiple instances with different instance types. | Launch a specified number of instances using an AMI and one instance type. | No – because RunInstances does not allow mixed instance types in a single request |
<table>
<thead>
<tr>
<th>API</th>
<th>When to use</th>
<th>Use case</th>
<th>Should I use this API?</th>

</thead>
</table>
| RequestSpotFleet | • We strongly discourage using the RequestSpotFleet API because it is a legacy API with no planned investment.  
• If you want to manage your instance lifecycle, use the CreateFleet API.  
• If you don't want to manage your instance lifecycle, use the CreateAutoScalingGroup API. | DO NOT USE. RequestSpotFleet is legacy API with no planned investment.     | No                     |
| RequestSpotInstances | • We strongly discourage using the RequestSpotInstances API because it is a legacy API with no planned investment. | DO NOT USE. RequestSpotInstances is legacy API with no planned investment. | No                     |
How Spot Instances work

To launch a Spot Instance, either you create a Spot Instance request, or Amazon EC2 creates a Spot Instance request on your behalf. The Spot Instance launches when the Spot Instance request is fulfilled.

You can launch a Spot Instance using several different services. For more information, see Getting Started with Amazon EC2 Spot Instances. In this user guide, we describe the following ways to launch a Spot Instance using EC2:

- You can create a Spot Instance request by using the launch instance wizard in the Amazon EC2 console or the run-instances AWS CLI command. For more information, see Create a Spot Instance request.
- You can create an EC2 Fleet, in which you specify the desired number of Spot Instances. Amazon EC2 creates a Spot Instance request on your behalf for every Spot Instance that is specified in the EC2 Fleet. For more information, see Create an EC2 Fleet.
- You can create a Spot Fleet request, in which you specify the desired number of Spot Instances. Amazon EC2 creates a Spot Instance request on your behalf for every Spot Instance that is specified in the Spot Fleet request. For more information, see Create a Spot Fleet request.

Your Spot Instance launches if there is available capacity.

Your Spot Instance runs until you stop or terminate it, or until Amazon EC2 interrupts it (known as a Spot Instance interruption).

When you use Spot Instances, you must be prepared for interruptions. Amazon EC2 can interrupt your Spot Instance when the demand for Spot Instances rises or when the supply of Spot Instances decreases. When Amazon EC2 interrupts a Spot Instance, it provides a Spot Instance interruption notice, which gives the instance a two-minute warning before Amazon EC2 interrupts it. You can't enable termination protection for Spot Instances. For more information, see Spot Instance interruptions.

You can stop, start, reboot, or terminate an Amazon EBS-backed Spot Instance. The Spot service can stop, terminate, or hibernate a Spot Instance when it interrupts it.

Contents

- Launch Spot Instances in a launch group
- Launch Spot Instances in an Availability Zone group
Launch Spot Instances in a VPC

Launch Spot Instances in a launch group

Specify a launch group in your Spot Instance request to tell Amazon EC2 to launch a set of Spot Instances only if it can launch them all. In addition, if the Spot service must terminate one of the instances in a launch group, it must terminate them all. However, if you terminate one or more of the instances in a launch group, Amazon EC2 does not terminate the remaining instances in the launch group.

Although this option can be useful, adding this constraint can decrease the chances that your Spot Instance request is fulfilled and increase the chances that your Spot Instances are terminated. For example, your launch group includes instances in multiple Availability Zones. If capacity in one of these Availability Zones decreases and is no longer available, then Amazon EC2 terminates all instances for the launch group.

If you create another successful Spot Instance request that specifies the same (existing) launch group as an earlier successful request, then the new instances are added to the launch group. Subsequently, if an instance in this launch group is terminated, all instances in the launch group are terminated, which includes instances launched by the first and second requests.

Launch Spot Instances in an Availability Zone group

Specify an Availability Zone group in your Spot Instance request to tell Amazon EC2 to launch a set of Spot Instances in the same Availability Zone. Amazon EC2 need not interrupt all instances in an Availability Zone group at the same time. If Amazon EC2 must interrupt one of the instances in an Availability Zone group, the others remain running.

Although this option can be useful, adding this constraint can lower the chances that your Spot Instance request is fulfilled.

If you specify an Availability Zone group but don't specify an Availability Zone in the Spot Instance request, the result depends on the network you specified.

Default VPC

Amazon EC2 uses the Availability Zone for the specified subnet. If you don't specify a subnet, it selects an Availability Zone and its default subnet, but not necessarily the lowest-priced zone. If you deleted the default subnet for an Availability Zone, then you must specify a different subnet.

Nondefault VPC
Amazon EC2 uses the Availability Zone for the specified subnet.

Launch Spot Instances in a VPC

You specify a subnet for your Spot Instances the same way that you specify a subnet for your On-Demand Instances.

- [Default VPC] If you want your Spot Instance launched in a specific low-priced Availability Zone, you must specify the corresponding subnet in your Spot Instance request. If you do not specify a subnet, Amazon EC2 selects one for you, and the Availability Zone for this subnet might not have the lowest Spot price.
- [Nondefault VPC] You must specify the subnet for your Spot Instance.

Spot Instance pricing history

Spot Instance prices are set by Amazon EC2 and adjust gradually based on long-term trends in supply and demand for Spot Instance capacity.

When your Spot request is fulfilled, your Spot Instances launch at the current Spot price, not exceeding the On-Demand price. You can view the Spot price history for the last 90 days, filtering by instance type, operating system, and Availability Zone.

To view the current Spot prices

For the current Spot Instance prices, see Amazon EC2 Spot Instances Pricing.

To view the Spot price history using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Choose Pricing history.
4. For Graph, choose to compare the price history by Availability Zones or by Instance Types.

   - If you choose Availability Zones, then choose the Instance type, operating system (Platform), and Date range for which to view the price history.
   - If you choose Instance Types, then choose up to five Instance type(s), the Availability Zone, operating system (Platform), and Date range for which to view the price history.

The following screenshot shows a price comparison for different instance types.
5. Hover (move your pointer) over the graph to display the prices at specific times in the selected date range. The prices are displayed in the information blocks above the graph. The price displayed in the top row shows the price on a specific date. The price displayed in the second row shows the average price over the selected date range.

6. To display the price per vCPU, toggle on Display normalized prices. To display the price for the instance type, toggle off Display normalized prices.

To view the Spot price history using the command line

You can use one of the following commands. For more information, see Access Amazon EC2.

- `describe-spot-price-history` (AWS CLI)
- `Get-EC2SpotPriceHistory` (AWS Tools for Windows PowerShell)

Savings from purchasing Spot Instances

You can view the usage and savings information for Spot Instances at the per-fleet level, or for all running Spot Instances. At the per-fleet level, the usage and savings information includes all instances launched and terminated by the fleet. You can view this information from the last hour or the last three days.

The following screenshot from the Savings section shows the Spot usage and savings information for a Spot Fleet.
You can view the following usage and savings information:

- **Spot Instances** – The number of Spot Instances launched and terminated by the Spot Fleet. When viewing the savings summary, the number represents all your running Spot Instances.
- **vCPU-hours** – The number of vCPU hours used across all the Spot Instances for the selected time frame.
- **Mem(GiB)-hours** – The number of GiB hours used across all the Spot Instances for the selected time frame.
- **On-Demand total** – The total amount you would've paid for the selected time frame had you launched these instances as On-Demand Instances.
- **Spot total** – The total amount to pay for the selected time frame.
- **Savings** – The percentage that you are saving by not paying the On-Demand price.
- **Average cost per vCPU-hour** – The average hourly cost of using the vCPUs across all the Spot Instances for the selected time frame, calculated as follows: \( \text{Average cost per vCPU-hour} = \frac{\text{Spot total}}{\text{vCPU-hours}} \).
- **Average cost per mem(GiB)-hour** – The average hourly cost of using the GiBs across all the Spot Instances for the selected time frame, calculated as follows: \( \text{Average cost per mem(GiB)-hour} = \frac{\text{Spot total}}{\text{Mem(GiB)-hours}} \).
• **Details** table – The different instance types (the number of instances per instance type is in parentheses) that comprise the Spot Fleet. When viewing the savings summary, these comprise all your running Spot Instances.

Savings information can only be viewed using the Amazon EC2 console.

**To view the savings information for a Spot Fleet using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. On the navigation pane, choose **Spot Requests**.
3. Select the ID of a Spot Fleet request and scroll to the **Savings** section.

   Alternatively, select the check box next to the Spot Fleet request ID and choose the **Savings** tab.
4. By default, the page displays usage and savings information for the last three days. You can choose **last hour** or the **last three days**. For Spot Fleets that were launched less than an hour ago, the page shows the estimated savings for the hour.

**To view the savings information for all running Spot Instances using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. On the navigation pane, choose **Spot Requests**.
3. Choose **Savings summary**.

**Work with Spot Instances**

To use Spot Instances, you create a Spot Instance request that includes the desired number of instances, the instance type, and the Availability Zone. If capacity is available, Amazon EC2 fulfills your request immediately. Otherwise, Amazon EC2 waits until your request can be fulfilled or until you cancel the request.

The following illustration shows how Spot Instance requests work. Notice that the request type (one-time or persistent) determines whether the request is opened again when Amazon EC2 interrupts a Spot Instance or if you stop a Spot Instance. If the request is persistent, the request is opened again after your Spot Instance is interrupted. If the request is persistent and you stop your Spot Instance, the request only opens after you start your Spot Instance.

- Cancel a Spot Instance request
- Stop a Spot Instance
- Start a Spot Instance
- Terminate a Spot Instance
- Spot Instance request example launch specifications
Spot Instance request states

A Spot Instance request can be in one of the following states:

- open – The request is waiting to be fulfilled.
- active – The request is fulfilled and has an associated Spot Instance.
- failed – The request has one or more bad parameters.
- closed – The Spot Instance was interrupted or terminated.
- disabled – You stopped the Spot Instance.
- cancelled – You canceled the request, or the request expired.

The following illustration represents the transitions between the request states. Notice that the transitions depend on the request type (one-time or persistent).
A one-time Spot Instance request remains active until Amazon EC2 launches the Spot Instance, the request expires, or you cancel the request. If capacity is not available, your Spot Instance is terminated and the Spot Instance request is closed.
A persistent Spot Instance request remains active until it expires or you cancel it, even if the request is fulfilled. If capacity is not available, your Spot Instance is interrupted. After your instance is interrupted, when capacity becomes available again, the Spot Instance is started if stopped or resumed if hibernated. You can stop a Spot Instance and start it again if capacity is available. If the Spot Instance is terminated (irrespective of whether the Spot Instance is in a stopped or running state), the Spot Instance request is opened again and Amazon EC2 launches a new Spot Instance. For more information, see Stop a Spot Instance, Start a Spot Instance, and Terminate a Spot Instance.

You can track the status of your Spot Instance requests, as well as the status of the Spot Instances launched, through the status. For more information, see Spot request status.

Specify a tenancy for your Spot Instances

You can run a Spot Instance on single-tenant hardware. Dedicated Spot Instances are physically isolated from instances that belong to other AWS accounts. For more information, see Amazon EC2 Dedicated Instances and the Amazon EC2 Dedicated Instances product page.

To run a Dedicated Spot Instance, do one of the following:

- Specify a tenancy of dedicated when you create the Spot Instance request. For more information, see Create a Spot Instance request.
- Request a Spot Instance in a VPC with an instance tenancy of dedicated. For more information, see Launch Dedicated Instances into a VPC with default tenancy. You cannot request a Spot Instance with a tenancy of default if you request it in a VPC with an instance tenancy of dedicated.

All instance families support Dedicated Spot Instances except T instances. For each supported instance family, only the largest instance size or metal size supports Dedicated Spot Instances.

Service-linked role for Spot Instance requests

Amazon EC2 uses service-linked roles for the permissions that it requires to call other AWS services on your behalf. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles provide a secure way to delegate permissions to AWS services because only the linked service can assume a service-linked role. For more information, see Using Service-Linked Roles in the IAM User Guide.
Amazon EC2 uses the service-linked role named **AWSServiceRoleForEC2Spot** to launch and manage Spot Instances on your behalf.

**Permissions granted by AWSServiceRoleForEC2Spot**

Amazon EC2 uses **AWSServiceRoleForEC2Spot** to complete the following actions:

- ec2:DescribeInstances – Describe Spot Instances
- ec2:StopInstances – Stop Spot Instances
- ec2:StartInstances – Start Spot Instances

**Create the service-linked role**

Under most circumstances, you don't need to manually create a service-linked role. Amazon EC2 creates the **AWSServiceRoleForEC2Spot** service-linked role the first time you request a Spot Instance using the console.

If you had an active Spot Instance request before October 2017, when Amazon EC2 began supporting this service-linked role, Amazon EC2 created the **AWSServiceRoleForEC2Spot** role in your AWS account. For more information, see **A New Role Appeared in My Account** in the **IAM User Guide**.

If you use the AWS CLI or an API to request a Spot Instance, you must first ensure that this role exists.

**To create AWSServiceRoleForEC2Spot using the console**

2. In the navigation pane, choose Roles.
3. Choose Create role.
4. On the Select type of trusted entity page, choose EC2, EC2 - Spot Instances, Next: Permissions.
5. On the next page, choose Next:Review.

**To create AWSServiceRoleForEC2Spot using the AWS CLI**
Use the `create-service-linked-role` command as follows.

```
aws iam create-service-linked-role --aws-service-name spot.amazonaws.com
```

If you no longer need to use Spot Instances, we recommend that you delete the `AWSServiceRoleForEC2Spot` role. After this role is deleted from your account, Amazon EC2 will create the role again if you request Spot Instances.

**Grant access to customer managed keys for use with encrypted AMIs and EBS snapshots**

If you specify an [encrypted AMI](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/spot-instances-encrypted.html) or an encrypted Amazon EBS snapshot for your Spot Instances and you use a customer managed key for encryption, you must grant the `AWSServiceRoleForEC2Spot` role permission to use the customer managed key so that Amazon EC2 can launch Spot Instances on your behalf. To do this, you must add a grant to the customer managed key, as shown in the following procedure.

When providing permissions, grants are an alternative to key policies. For more information, see [Using Grants](https://docs.aws.amazon.com/kms/latest/developerguide/grants.html) and [Using Key Policies in AWS KMS](https://docs.aws.amazon.com/kms/latest/developerguide/key-policies.html) in the *AWS Key Management Service Developer Guide*.

**To grant the AWSServiceRoleForEC2Spot role permissions to use the customer managed key**

- Use the `create-grant` command to add a grant to the customer managed key and to specify the principal (the `AWSServiceRoleForEC2Spot` service-linked role) that is given permission to perform the operations that the grant permits. The customer managed key is specified by the key-id parameter and the ARN of the customer managed key. The principal is specified by the grantee-principal parameter and the ARN of the `AWSServiceRoleForEC2Spot` service-linked role.

```
aws kms create-grant \
  --region us-east-1 \n  --key-id arn:aws:kms:us-east-1:444455556666:key/1234abcd-12ab-34cd-56ef-1234567890ab \n  --grantee-principal arn:aws:iam::111122223333:role/aws-service-role/spot.amazonaws.com/AWSServiceRoleForEC2Spot \
  --operations "Decrypt" "Encrypt" "GenerateDataKey" "GenerateDataKeyWithoutPlaintext" "CreateGrant" "DescribeKey" "ReEncryptFrom" "ReEncryptTo"
```
Create a Spot Instance request

You can use the launch instance wizard in the Amazon EC2 console or the run-instances AWS CLI command to request a Spot Instance in the same way that you can launch an On-Demand Instance. This method is only recommended for the following reasons:

- You're already using the launch instance wizard or run-instances command to launch On-Demand Instances, and you simply want to change to launching Spot Instances by changing a single parameter.
- You do not need multiple instances with different instance types.

This method is generally not recommended for launching Spot Instances because you can't specify multiple instance types, and you can't launch Spot Instances and On-Demand Instances in the same request. For the preferred methods for launching Spot Instances, which include launching a fleet that includes Spot Instances and On-Demand Instances with multiple instance types, see Which is the best Spot request method to use?

If you request multiple Spot Instances at one time, Amazon EC2 creates separate Spot Instance requests so that you can track the status of each request separately. For more information about tracking Spot Instance requests, see Spot request status.

New console

To create a Spot Instance request using the launch instance wizard

Steps 1–9 are the same steps you'd use to launch an On-Demand Instance. At Step 10, you configure the Spot Instance request.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, select a Region.
3. From the Amazon EC2 console dashboard, choose Launch instance.
4. (Optional) Under Name and tags, you can name your instance, and tag the Spot Instance request, the instance, the volumes, and the elastic graphics. For information about tags, see Tag your Amazon EC2 resources.
   a. For Name, enter a descriptive name for your instance.
The instance name is a tag, where the key is Name, and the value is the name that you specify. If you don't specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.

b. To tag the Spot Instance request, the instance, the volumes, and the elastic graphics, choose Add additional tags. Choose Add tag, and then enter a key and value, and select the resource type to tag. Choose Add tag again for each additional tag to add.

5. Under Application and OS Images (Amazon Machine Image), choose the operating system (OS) for your instance, and then select an AMI. For more information, see Application and OS Images (Amazon Machine Image).

6. Under Instance type, select the instance type that meets your requirements for the hardware configuration and size of your instance. For more information, see Instance type.

7. Under Key pair (login), choose an existing key pair, or choose Create new key pair to create a new one. For more information, see Amazon EC2 key pairs and Amazon EC2 instances.

⚠️ Important

If you choose the Proceed without key pair (Not recommended) option, you won’t be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

8. Under Network settings, use the default settings, or choose Edit to configure the network settings as necessary.

Security groups form part of the network settings, and define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance.

For more information, see Network settings.

9. The AMI you selected includes one or more volumes of storage, including the root device volume. Under Configure storage, you can specify additional volumes to attach to the instance by choosing Add new volume. For more information, see Configure storage.

10. Under Advanced details, configure the Spot Instance request as follows:

a. Under Purchasing option, select the Request Spot Instances check box.

b. You can either keep the default configuration for the Spot Instance request, or choose Customize (at the right) to specify custom settings for your Spot Instance request.
When you choose **Customize**, the following fields appear.

i. **Maximum price**: You can request Spot Instances at the Spot price, capped at the On-Demand price, or you can specify the maximum amount you're willing to pay.

   - **Warning**: If you specify a maximum price, your instances will be interrupted more frequently than if you choose **No maximum price**.

   - **No maximum price**: Your Spot Instance will launch at the current Spot price. The price will never exceed the On-Demand price. (Recommended)
   - **Set your maximum price (per instance/hour)**: You can specify the maximum amount you're willing pay.
     - If you specify a maximum price that is less than the current Spot price, your Spot Instance will not launch.
     - If you specify a maximum price that is more than the current Spot price, your Spot Instance will launch and be charged at the current Spot price. After your Spot Instance is running, if the Spot price rises above your maximum price, Amazon EC2 interrupts your Spot Instance.
     - Regardless of the maximum price you specify, you will always be charged the current Spot price.
   
   To review Spot price trends, see [Spot Instance pricing history](#).

ii. **Request type**: The Spot Instance request type that you choose determines what happens if your Spot Instance is interrupted.

   - **One-time**: Amazon EC2 places a one-time request for your Spot Instance. If your Spot Instance is interrupted, the request is not resubmitted.
   - **Persistent request**: Amazon EC2 places a persistent request for your Spot Instance. If your Spot Instance is interrupted, the request is resubmitted to replenish the interrupted Spot Instance.

   If you do not specify a value, the default is a one-time request.
iii. **Valid to**: The expiration date of a *persistent* Spot Instance request.

This field is not supported for one-time requests. A *one-time* request remains active until all the instances in the request launch or you cancel the request.

- **No request expiry date**: The request remains active until you cancel it.
- **Set your request expiry date**: The persistent request remains active until the date that you specify, or until you cancel it.

iv. **Interruption behavior**: The behavior that you choose determines what happens when a Spot Instance is interrupted.

- For persistent requests, valid values are **Stop** and **Hibernate**. When an instance is stopped, charges for EBS volume storage apply.

  ![Note](image)

  Spot Instances now use the same hibernation functionality as On-Demand Instances. To enable hibernation, you can either choose **Hibernate** here, or you can choose **Enable** from the **Stop - Hibernate behavior** field, which appears lower down in the launch instance wizard. For the hibernation prerequisites, see [Prerequisites for Amazon EC2 instance hibernation](#).

- For one-time requests, only **Terminate** is valid.

If you do not specify a value, the default is **Terminate**, which is not valid for a persistent Spot Instance request. If you keep the default and try to launch a persistent Spot Instance request, you'll get an error.

For more information, see [Behavior of Spot Instance interruptions](#).

11. On the **Summary** panel, for **Number of instances**, enter the number of instances to launch.

  ![Note](image)

  Amazon EC2 creates a separate request for each Spot Instance.

12. On the **Summary** panel, review the details of your instance, and make any necessary changes. After you submit your Spot Instance request, you can't change the parameters
of the request. You can navigate directly to a section in the launch instance wizard by choosing its link in the Summary panel. For more information, see Summary.

13. When you're ready to launch your instance, choose Launch instance.

If the instance fails to launch or the state immediately goes to terminated instead of running, see Troubleshoot Amazon EC2 instance launch issues.

Old console

To create a Spot Instance request using the launch instance wizard

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, select a Region.
3. From the Amazon EC2 console dashboard, choose Launch Instance.
4. On the Choose an Amazon Machine Image (AMI) page, choose an AMI. For more information, see Step 1: Choose an Amazon Machine Image (AMI).
5. On the Choose an Instance Type page, select the hardware configuration and size of the instance to launch, and then choose Next: Configure Instance Details. For more information, see Step 2: Choose an Instance Type.
6. On the Configure Instance Details page, configure the Spot Instance request as follows:

   • Number of instances: Enter the number of instances to launch.

   Note
   Amazon EC2 creates a separate request for each Spot Instance.

   • (Optional) To help ensure that you maintain the correct number of instances to handle demand on your application, you can choose Launch into Auto Scaling Group to create a launch configuration and an Auto Scaling group. Auto Scaling scales the number of instances in the group according to your specifications. For more information, see the Amazon EC2 Auto Scaling User Guide.

   • Purchasing option: Choose Request Spot instances to launch a Spot Instance. When you choose this option, the following fields appear.

   • Current price: The current Spot price in each Availability Zone is displayed for the instance type that you selected.
• (Optional) **Maximum price:** You can leave the field empty, or you can specify the maximum amount you're willing to pay.

⚠️ **Warning**

If you specify a maximum price, your instances will be interrupted more frequently than if you leave the field empty.

• If you specify a maximum price that is less than the Spot price, your Spot Instance will not launched.

• If you specify a maximum price that is more than the current Spot price, your Spot Instance will launch and be charged at the current Spot price. After your Spot Instance is running, if the Spot price rises above your maximum price, Amazon EC2 interrupts your Spot Instance.

• Regardless of the maximum price you specify, you will always be charged the current Spot price.

• If you leave the field empty, you'll pay the current Spot price.

• **Persistent request:** Choose **Persistent request** to resubmit the Spot Instance request if your Spot Instance is interrupted.

• **Interruption behavior:** By default, the Spot service terminates a Spot Instance when it is interrupted. If you choose **Persistent request**, you can then specify that the Spot service stops or hibernates your Spot Instance when it's interrupted. For more information, see *Behavior of Spot Instance interruptions*.

• (Optional) **Request valid to:** Choose **Edit** to specify when the Spot Instance request expires.

For more information about configuring your Spot Instance, see *Step 3: Configure Instance Details*.

7. The AMI you selected includes one or more volumes of storage, including the root device volume. On the **Add Storage** page, you can specify additional volumes to attach to the instance by choosing **Add New Volume**. For more information, see *Step 4: Add Storage*.

8. On the **Add Tags** page, specify **tags** by providing key and value combinations. For more information, see *Step 5: Add Tags*.
9. On the **Configure Security Group** page, use a security group to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other traffic is ignored. (For more information about security groups, see [Amazon EC2 security groups for your EC2 instances](#).) Select or create a security group, and then choose **Review and Launch**. For more information, see [Step 6: Configure Security Group](#).

10. On the **Review Instance Launch** page, check the details of your instance, and make any necessary changes by choosing the appropriate **Edit** link. When you are ready, choose **Launch**. For more information, see [Step 7: Review Instance Launch and Select Key Pair](#).

11. In the **Select an existing key pair or create a new key pair** dialog box, you can choose an existing key pair, or create a new one. For example, choose **Choose an existing key pair**, then select the key pair that you created when getting set up. For more information, see [Amazon EC2 key pairs and Amazon EC2 instances](#).

    **Important**
    
    If you choose the **Proceed without key pair** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

12. To launch your instance, select the acknowledgment check box, then choose **Launch Instances**.

    If the instance fails to launch or the state immediately goes to **terminated** instead of **running**, see [Troubleshoot Amazon EC2 instance launch issues](#).

**AWS CLI**

**To create a Spot Instance request using** `run-instances`

Use the `run-instances` command and specify the Spot Instance options in the `--instance-market-options` parameter.

```
aws ec2 run-instances 
    --image-id ami-0abcdef1234567890 
    --instance-type t2.micro 
    --count 5 
    --subnet-id subnet-08fc749671b2d077c 
```
The following is the data structure to specify in the JSON file for `--instance-market-options`. You can also specify `ValidUntil` and `InstanceInterruptionBehavior`. If you do not specify a field in the data structure, the default value is used.

The following example creates a persistent request.

```json
{
   "MarketType": "spot",
   "SpotOptions": {
      "SpotInstanceType": "persistent"
   }
}
```

To create a Spot Instance request using `request-spot-instances`

**Note**

We strongly discourage using the `request-spot-instances` command to request a Spot Instance because it is a legacy API with no planned investment. For more information, see [Which is the best Spot request method to use?](#)

Use the `request-spot-instances` command to create a one-time request.

```
aws ec2 request-spot-instances \
   --instance-count 5 \
   --type "one-time" \
   --launch-specification file://specification.json
```

Use the `request-spot-instances` command to create a persistent request.

```
aws ec2 request-spot-instances \
   --instance-count 5 \
   --type "persistent" \
   --launch-specification file://specification.json
```
For example launch specification files to use with these commands, see Spot Instance request example launch specifications. If you download a launch specification file from the Spot Requests console, you must use the request-spot-fleet command instead (the Spot Requests console specifies a Spot Instance request using a Spot Fleet).

**Find your Spot Instances**

Amazon EC2 launches a Spot Instance when capacity is available. A Spot Instance runs until it is interrupted or you terminate it yourself.

A Spot Instance appears in the **Instances** page in the console, along with On-Demand Instances. Use the following procedure to find your Spot Instances.

**Console**

**To find your Spot Instances using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. To find all Spot Instances, in the search pane, choose **Instance lifecycle=spot**.
4. To verify that an instance is a Spot Instance, select the instance, choose the **Details** tab, and check the value of **Lifecycle**. The value for a Spot Instance is **spot** and the value for an On-Demand Instance is **normal**.

**AWS CLI**

**To find your Spot Instances using the AWS CLI**

Use the **describe-instances** command with the --filters option.

```bash
aws ec2 describe-instances \   
  --filters "Name=instance-lifecycle,Values=spot"
```

**To determine whether an instance is a Spot Instance**

Use the **describe-instances** command, using the --query option to check the lifecycle value.

```bash
aws ec2 describe-instances \   
  --query 'Reservations[0].Instances[0].Lifecycle'
```
If the output is `spot`, the instance is a Spot Instance. If there is no output, the instance is an On-Demand Instance.

Use the following procedure to find the Spot Instances launched from a specific Spot Instance or Spot Fleet request.

**Console**

**To find the Spot Instances for a request using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Spot Requests**. The list contains both Spot Instance requests and Spot Fleet requests.
3. If a Spot Instance request is fulfilled, **Capacity** is the ID of the Spot Instance. For a Spot Fleet, **Capacity** indicates how much of the requested capacity has been fulfilled. To view the IDs of the instances in a Spot Fleet, choose the expand arrow, or select the fleet and choose **Instances**.
4. For a Spot Fleet, **Capacity** indicates how much of the requested capacity is fulfilled. To view the IDs of the instances in a Spot Fleet, choose the fleet ID to open its details page and locate the **Instances** pane.

**AWS CLI**

**To find the Spot Instances for a request using the AWS CLI**

Use the `describe-spot-instance-requests` command with the `--query` option.

```bash
aws ec2 describe-spot-instance-requests \
    --query "SpotInstanceRequests[*].{ID:InstanceId}"
```

The following is example output:

```
[
    {
```
Tag Spot Instance requests

To help categorize and manage your Spot Instance requests, you can tag them with custom metadata. You can assign a tag to a Spot Instance request when you create it, or afterward. You can assign tags using the Amazon EC2 console or a command line tool.

When you tag a Spot Instance request, the instances and volumes that are launched by the Spot Instance request are not automatically tagged. You need to explicitly tag the instances and volumes launched by the Spot Instance request. You can assign a tag to a Spot Instance and volumes during launch, or afterward.

For more information about how tags work, see Tag your Amazon EC2 resources.

Contents

• Prerequisites
• Tag a new Spot Instance request
• Tag an existing Spot Instance request
• View Spot Instance request tags

Prerequisites

Grant the user the permission to tag resources. For more information about IAM policies and example policies, see Example: Tag resources.

The IAM policy you create is determined by which method you use for creating a Spot Instance request.

• If you use the launch instance wizard or run-instances to request Spot Instances, see To grant a user the permission to tag resources when using the launch instance wizard or run-instances.
• If you use the request-spot-instances command to request Spot Instances, see To grant a user the permission to tag resources when using request-spot-instances.
To grant a user the permission to tag resources when using the launch instance wizard or run-instances

Create a IAM policy that includes the following:

- The `ec2:RunInstances` action. This grants the user permission to launch an instance.
- For Resource, specify `spot-instances-request`. This allows users to create Spot Instance requests, which request Spot Instances.
- The `ec2:CreateTags` action. This grants the user permission to create tags.
- For Resource, specify `*`. This allows users to tag all resources that are created during instance launch.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowLaunchInstances",
         "Effect": "Allow",
         "Action": [
            "ec2:RunInstances"
         ],
         "Resource": [
            "arn:aws:ec2:us-east-1::image/*",
            "arn:aws:ec2:us-east-1:*:subnet/*",
            "arn:aws:ec2:us-east-1:*:network-interface/*",
            "arn:aws:ec2:us-east-1:*:security-group/*",
            "arn:aws:ec2:us-east-1:*:key-pair/*",
            "arn:aws:ec2:us-east-1:*:volume/*",
            "arn:aws:ec2:us-east-1:*:instance/*",
            "arn:aws:ec2:us-east-1:*:spot-instances-request/*"
         ]
      },
      {
         "Sid": "TagSpotInstanceRequests",
         "Effect": "Allow",
         "Action": "ec2:CreateTags",
         "Resource": "*"
      }
   ]
}
```
When you use the RunInstances action to create Spot Instance requests and tag the Spot Instance requests on create, you need to be aware of how Amazon EC2 evaluates the `spot-instances-request` resource in the RunInstances statement it is evaluated in the IAM policy as follows:

- If you don't tag a Spot Instance request on create, Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement.
- If you tag a Spot Instance request on create, Amazon EC2 evaluates the `spot-instances-request` resource in the RunInstances statement.

Therefore, for the `spot-instances-request` resource, the following rules apply to the IAM policy:

- If you use RunInstances to create a Spot Instance request and you don't intend to tag the Spot Instance request on create, you don't need to explicitly allow the `spot-instances-request` resource; the call will succeed.
- If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must include the `spot-instances-request` resource in the RunInstances allow statement, otherwise the call will fail.
- If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must specify the `spot-instances-request` resource or include a * wildcard in the CreateTags allow statement, otherwise the call will fail.

For example IAM policies, including policies that are not supported for Spot Instance requests, see "Work with Spot Instances."

**To grant a user the permission to tag resources when using request-spot-instances**

Create a IAM policy that includes the following:

- The `ec2:RequestSpotInstances` action. This grants the user permission to create a Spot Instance request.
- The `ec2:CreateTags` action. This grants the user permission to create tags.
- For Resource, specify `spot-instances-request`. This allows users to tag only the Spot Instance request.
Tag a new Spot Instance request

Console

To tag a new Spot Instance request using the console

1. Follow the Create a Spot Instance request procedure.
2. To add a tag, on the Add Tags page, choose Add Tag, and enter the key and value for the tag. Choose Add another tag for each additional tag.

   For each tag, you can tag the Spot Instance request, the Spot Instances, and the volumes with the same tag. To tag all three, ensure that Instances, Volumes, and Spot Instance Requests are selected. To tag only one or two, ensure that the resources you want to tag are selected, and the other resources are cleared.
3. Complete the required fields to create a Spot Instance request, and then choose Launch. For more information, see Create a Spot Instance request.

AWS CLI

To tag a new Spot Instance request using the AWS CLI

To tag a Spot Instance request when you create it, configure the Spot Instance request configuration as follows:

- Specify the tags for the Spot Instance request using the --tag-specification parameter.
- For ResourceType, specify spot-instances-request. If you specify another value, the Spot Instance request will fail.
- For Tags, specify the key-value pair. You can specify more than one key-value pair.
In the following example, the Spot Instance request is tagged with two tags: Key=Environment and Value=Production, and Key=Cost-Center and Value=123.

```
aws ec2 request-spot-instances \
    --instance-count 5 \
    --type "one-time" \
    --launch-specification file://specification.json \
    --tag-specification 'ResourceType=spot-instances-request,Tags=[{Key=Environment,Value=Production},{Key=Cost-Center,Value=123}]
```

### Tag an existing Spot Instance request

**Console**

**To tag an existing Spot Instance request using the console**

After you have created a Spot Instance request, you can add tags to the Spot Instance request using the console.

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Instance request.
4. Choose the **Tags** tab and choose **Create Tag**.

**To tag an existing Spot Instance using the console**

After your Spot Instance request has launched your Spot Instance, you can add tags to the instance using the console. For more information, see [Add and remove tags using the console](#).

**AWS CLI**

**To tag an existing Spot Instance request or Spot Instance using the AWS CLI**

Use the `create-tags` command to tag existing resources. In the following example, the existing Spot Instance request and the Spot Instance are tagged with Key=purpose and Value=test.

```
aws ec2 create-tags \
    --resources sir-08b93456 i-1234567890abcdef0 \
    --tags Key=purpose,Value=test
```
View Spot Instance request tags

Console

To view Spot Instance request tags using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Select your Spot Instance request and choose the Tags tab.

AWS CLI

To describe Spot Instance request tags

You can view the tags of a Spot Instance request by describing the Spot Instance request. Use the describe-spot-instance-requests command to view the configuration of the specified Spot Instance request, which includes any tags that were specified for the request.

```bash
aws ec2 describe-spot-instance-requests \
    --spot-instance-request-ids sir-EXAMPLE1 \
    --query "SpotInstanceRequests[*].Tags"
```

The following is example output.

```json
[
  [

Cancel a Spot Instance request

If you no longer want your Spot Instance request, you can cancel it. You can only cancel Spot Instance requests that are open, active, or disabled.

- Your Spot Instance request is open when your request has not yet been fulfilled and no instances have been launched.
- Your Spot Instance request is active when your request has been fulfilled and Spot Instances have launched as a result.
- Your Spot Instance request is disabled when you stop your Spot Instance.

If your Spot Instance request is active and has an associated running Spot Instance, canceling the request does not terminate the instance. For more information about terminating a Spot Instance, see Terminate a Spot Instance.

Console

To cancel a Spot Instance request using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Select the Spot Instance request.
4. Choose Actions, Cancel request.
5. (Optional) If you are finished with the associated Spot Instances, you can terminate them. In the Cancel Spot request dialog box, select Terminate instances, and then choose Confirm.

AWS CLI

To cancel a Spot Instance request using the AWS CLI

Use the cancel-spot-instance-requests command to cancel the specified Spot Instance request.

```
aws ec2 cancel-spot-instance-requests --spot-instance-request-ids sir-08b93456
```
Stop a Spot Instance

If you don’t need your Spot Instances now, but you want to restart them later without losing the data persisted in the Amazon EBS volume, you can stop them. The steps for stopping a Spot Instance are similar to the steps for stopping an On-Demand Instance.

Note

While a Spot Instance is stopped, you can modify some of its instance attributes, but not the instance type.

We don’t charge usage for a stopped Spot Instance, or data transfer fees, but we do charge for the storage for any Amazon EBS volumes.

Limitations

• You can only stop a Spot Instance if the Spot Instance was launched from a persistent Spot Instance request.

• You can’t stop a Spot Instance if the associated Spot Instance request is cancelled. When the Spot Instance request is cancelled, you can only terminate the Spot Instance.

• You can’t stop a Spot Instance if it is part of a fleet or launch group, or Availability Zone group.

Console

To stop a Spot Instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the Spot Instance. If you didn't save the instance ID of the Spot Instance, see the section called “Find your Spot Instances”.
4. Choose Instance state, Stop instance.
5. When prompted for confirmation, choose Stop.

AWS CLI

To stop a Spot Instance using the AWS CLI
Use the `stop-instances` command to manually stop your Spot Instances.

```bash
aws ec2 stop-instances --instance-ids i-1234567890abcdef0
```

**Start a Spot Instance**

You can start a Spot Instance that you previously stopped.

**Prerequisites**

You can only start a Spot Instance if:

- You manually stopped the Spot Instance.
- The Spot Instance is an EBS-backed instance.
- Spot Instance capacity is available.
- The Spot price is lower than your maximum price.

**Limitations**

- You can't start a Spot Instance if it is part of fleet or launch group, or Availability Zone group.

The steps for starting a Spot Instance are similar to the steps for starting an On-Demand Instance.

**Console**

**To start a Spot Instance using the console**

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose **Instances**.
3. Select the Spot Instance. If you didn't save the instance ID of the Spot Instance, see the section called “Find your Spot Instances”.
4. Choose **Instance state, Start instance**.

**AWS CLI**

**To start a Spot Instance the AWS CLI**

Use the `start-instances` command to manually start your Spot Instances.
**Terminate a Spot Instance**

If you terminate a running or stopped Spot Instance that was launched by a persistent Spot Instance request, the Spot Instance request transitions to the open state so that a new Spot Instance can be launched. To ensure that no new Spot Instance is launched, you must first cancel the Spot Instance request.

If you cancel an active Spot Instance request that has a running Spot Instance, the running Spot Instance is not automatically terminated; you must manually terminate the Spot Instance.

If you cancel a disabled Spot Instance request that has a stopped Spot Instance, the stopped Spot Instance is automatically terminated by the Amazon EC2 Spot service. There might be a short lag between when you cancel the Spot Instance request and when the Spot service terminates the Spot Instance.

For more information, see [Cancel a Spot Instance request](#).  

**Console**

To manually terminate a Spot Instance using the console

1. Before you terminate an instance, verify that you won't lose any data by checking that your Amazon EBS volumes won't be deleted on termination and that you've copied any data that you need from your instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.
2. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
3. In the navigation pane, choose **Instances**.
4. Select the Spot Instance. If you didn't save the instance ID of the Spot Instance, see [the section called “Find your Spot Instances”](#).
5. Choose **Instance state**, **Terminate instance**.
6. Choose **Terminate** when prompted for confirmation.

**AWS CLI**

To manually terminate a Spot Instance using the AWS CLI

```bash
aws ec2 start-instances --instance-ids i-1234567890abcdef0
```

```bash
aws ec2 start-instances --instance-ids i-1234567890abcdef0
```
Use the `terminate-instances` command to manually terminate your Spot Instances.

```
aws ec2 terminate-instances --instance-ids i-1234567890abcdef0 i-0598c7d356eba48d7
```

### Spot Instance request example launch specifications

The following examples show launch configurations that you can use with the `request-spot-instances` command to create a Spot Instance request. For more information, see [Create a Spot Instance request](#).

⚠️ **Important**

We strongly discourage using the `request-spot-instances` command to request a Spot Instance because it is a legacy API with no planned investment. For more information, see [Which is the best Spot request method to use?](#).

#### Examples

- [Example 1: Launch Spot Instances](#)
- [Example 2: Launch Spot Instances in the specified Availability Zone](#)
- [Example 3: Launch Spot Instances in the specified subnet](#)
- [Example 4: Launch a Dedicated Spot Instance](#)

#### Example 1: Launch Spot Instances

The following example does not include an Availability Zone or subnet. Amazon EC2 selects an Availability Zone for you. Amazon EC2 launches the instances in the default subnet of the selected Availability Zone.

```json
{
   "ImageId": "ami-0abcdef1234567890",
   "KeyName": "my-key-pair",
   "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],
   "InstanceType": "m5.medium",
   "IamInstanceProfile": {
      "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
   }
}
```
Example 2: Launch Spot Instances in the specified Availability Zone

The following example includes an Availability Zone. Amazon EC2 launches the instances in the default subnet of the specified Availability Zone.

```json
{
  "ImageId": "ami-0abcdef1234567890",
  "KeyName": "my-key-pair",
  "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],
  "InstanceType": "m5.medium",
  "Placement": {
    "AvailabilityZone": "us-west-2a"
  },
  "IamInstanceProfile": {
    "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
  }
}
```

Example 3: Launch Spot Instances in the specified subnet

The following example includes a subnet. Amazon EC2 launches the instances in the specified subnet. If the VPC is a nondefault VPC, the instance does not receive a public IPv4 address by default.

```json
{
  "ImageId": "ami-0abcdef1234567890",
  "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],
  "InstanceType": "m5.medium",
  "SubnetId": "subnet-1a2b3c4d",
  "IamInstanceProfile": {
    "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
  }
}
```

To assign a public IPv4 address to an instance in a nondefault VPC, specify the `AssociatePublicIpAddress` field as shown in the following example. When you specify a network interface, you must include the subnet ID and security group ID using the network interface, rather than using the `SubnetId` and `SecurityGroupIds` fields shown in the previous code block.
Example 4: Launch a Dedicated Spot Instance

The following example requests Spot Instance with a tenancy of dedicated. A Dedicated Spot Instance must be launched in a VPC.

```
{
  "ImageId": "ami-0abcdef1234567890",
  "KeyName": "my-key-pair",
  "SecurityGroupIds": [ "sg-1a2b3c4d5e6f7g8h9" ],
  "InstanceType": "c5.8xlarge",
  "SubnetId": "subnet-1a2b3c4d5e6f7g8h9",
  "Placement": {
    "Tenancy": "dedicated"
  }
}
```

Spot request status

To help you track your Spot Instance requests and plan your use of Spot Instances, use the request status provided by Amazon EC2. For example, the request status can provide the reason why your Spot request isn't fulfilled yet, or list the constraints that are preventing the fulfillment of your Spot request.

At each step of the process—also called the Spot request lifecycle—specific events determine successive request states.
Lifecycle of a Spot request

The following diagram shows you the paths that your Spot request can follow throughout its lifecycle, from submission to termination. Each step is depicted as a node, and the status code for each node describes the status of the Spot request and Spot Instance.
Pending evaluation

As soon as you create a Spot Instance request, it goes into the pending-evaluation state unless one or more request parameters are not valid (bad-parameters).
### Holding

If one or more request constraints are valid but can't be met yet, or if there is not enough capacity, the request goes into a holding state waiting for the constraints to be met. The request options affect the likelihood of the request being fulfilled. For example, if there is no capacity, your request stays in a holding state until there is available capacity. If you specify an Availability Zone group, the request stays in a holding state until the Availability Zone constraint is met.

In the event of an outage of one of the Availability Zones, there is a chance that the spare EC2 capacity available for Spot Instance requests in other Availability Zones can be affected.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Request state</th>
<th>Instance state</th>
</tr>
</thead>
<tbody>
<tr>
<td>pending-evaluation</td>
<td>open</td>
<td>Not applicable</td>
</tr>
<tr>
<td>bad-parameters</td>
<td>closed</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Status code</th>
<th>Request state</th>
<th>Instance state</th>
</tr>
</thead>
<tbody>
<tr>
<td>capacity-not-available</td>
<td>open</td>
<td>Not applicable</td>
</tr>
<tr>
<td>price-too-low</td>
<td>open</td>
<td>Not applicable</td>
</tr>
<tr>
<td>not-scheduled-yet</td>
<td>open</td>
<td>Not applicable</td>
</tr>
<tr>
<td>launch-group-constraint</td>
<td>open</td>
<td>Not applicable</td>
</tr>
<tr>
<td>az-group-constraint</td>
<td>open</td>
<td>Not applicable</td>
</tr>
<tr>
<td>placement-group-constraint</td>
<td>open</td>
<td>Not applicable</td>
</tr>
<tr>
<td>constraint-not-fillable</td>
<td>open</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>
Pending evaluation/fulfillment-terminal

Your Spot Instance request can go to a terminal state if you create a request that is valid only during a specific time period and this time period expires before your request reaches the pending fulfillment phase. It might also happen if you cancel the request, or if a system error occurs.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Request state</th>
<th>Instance state</th>
</tr>
</thead>
<tbody>
<tr>
<td>schedule-expired</td>
<td>cancelled</td>
<td>Not applicable</td>
</tr>
<tr>
<td>canceled-before-fulfillment</td>
<td>cancelled</td>
<td>Not applicable</td>
</tr>
<tr>
<td>bad-parameters</td>
<td>failed</td>
<td>Not applicable</td>
</tr>
<tr>
<td>system-error</td>
<td>closed</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>

¹ If you cancel the request.

Pending fulfillment

When the constraints you specified (if any) are met, your Spot request goes into the pending-fulfillment state.

At this point, Amazon EC2 is getting ready to provision the instances that you requested. If the process stops at this point, it is likely to be because it was canceled by the user before a Spot Instance was launched. It might also be because an unexpected system error occurred.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Request state</th>
<th>Instance state</th>
</tr>
</thead>
<tbody>
<tr>
<td>pending-fulfillment</td>
<td>open</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>

Fulfilled

When all the specifications for your Spot Instances are met, your Spot request is fulfilled. Amazon EC2 launches the Spot Instances, which can take a few minutes. If a Spot Instance is hibernated
or stopped when interrupted, it remains in this state until the request can be fulfilled again or the request is canceled.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Request state</th>
<th>Instance state</th>
</tr>
</thead>
<tbody>
<tr>
<td>fulfilled</td>
<td>active</td>
<td>pending → running</td>
</tr>
<tr>
<td>fulfilled</td>
<td>active</td>
<td>stopped → running</td>
</tr>
</tbody>
</table>

If you stop a Spot Instance, your Spot request goes into the marked-for-stop or instance-stopped-by-user state until the Spot Instance can be started again or the request is cancelled.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Request state</th>
<th>Instance state</th>
</tr>
</thead>
<tbody>
<tr>
<td>marked-for-stop</td>
<td>active</td>
<td>stopping</td>
</tr>
<tr>
<td>instance-stopped-by-user¹</td>
<td>disabled or cancelled²</td>
<td>stopped</td>
</tr>
</tbody>
</table>

¹ A Spot Instance goes into the instance-stopped-by-user state if you stop the instance or run the shutdown command from the instance. After you've stopped the instance, you can start it again. On restart, the Spot Instance request returns to the pending-evaluation state and then Amazon EC2 launches a new Spot Instance when the constraints are met.

² The Spot request state is disabled if you stop the Spot Instance but do not cancel the request. The request state is cancelled if your Spot Instance is stopped and the request expires.

**Fulfilled-terminal**

Your Spot Instances continue to run as long as there is available capacity for your instance type, and you don't terminate the instance. If Amazon EC2 must terminate your Spot Instances, the Spot request goes into a terminal state. A request also goes into the terminal state if you cancel the Spot request or terminate the Spot Instances.
<table>
<thead>
<tr>
<th>Status code</th>
<th>Request state</th>
<th>Instance state</th>
</tr>
</thead>
<tbody>
<tr>
<td>request-canceled-and-instance-running</td>
<td>cancelled</td>
<td>running</td>
</tr>
<tr>
<td>marked-for-stop</td>
<td>active</td>
<td>running</td>
</tr>
<tr>
<td>marked-for-termination</td>
<td>active</td>
<td>running</td>
</tr>
<tr>
<td>instance-stopped-by-price</td>
<td>disabled</td>
<td>stopped</td>
</tr>
<tr>
<td>instance-stopped-by-user</td>
<td>disabled</td>
<td>stopped</td>
</tr>
<tr>
<td>instance-stopped-no-capacity</td>
<td>disabled</td>
<td>stopped</td>
</tr>
<tr>
<td>instance-terminated-by-price</td>
<td>closed (one-time), open (persistent)</td>
<td>terminated</td>
</tr>
<tr>
<td>instance-terminated-by-schedule</td>
<td>closed</td>
<td>terminated</td>
</tr>
<tr>
<td>instance-terminated-by-service</td>
<td>cancelled</td>
<td>terminated</td>
</tr>
<tr>
<td>instance-terminated-by-user</td>
<td>closed or cancelled (^1)</td>
<td>terminated</td>
</tr>
<tr>
<td>instance-terminated-no-capacity</td>
<td>closed (one-time), open (persistent)</td>
<td>running (†)</td>
</tr>
<tr>
<td>instance-terminated-no-capacity</td>
<td>closed (one-time), open (persistent)</td>
<td>terminated</td>
</tr>
</tbody>
</table>
The request state is closed if you terminate the instance but do not cancel the request. The request state is cancelled if you terminate the instance and cancel the request. Even if you terminate a Spot Instance before you cancel its request, there might be a delay before Amazon EC2 detects that your Spot Instance was terminated. In this case, the request state can either be closed or cancelled.

† When Amazon EC2 interrupts a Spot Instance if it needs the capacity back and the instance is configured to terminate on interruption, the status is immediately set to instance-terminated-no-capacity (it is not set to marked-for-termination). However, the instance remains in the running state for 2 minutes to reflect the 2-minute period when the instance receives the Spot Instance interruption notice. After 2 minutes, the instance state is set to terminated.

**Interruption experiments**

You can use AWS Fault Injection Service to initiate a Spot Instance interruption so that you can test how the applications on your Spot Instances respond. If AWS FIS stops a Spot Instance, your Spot request enters the marked-for-stop-by-experiment state and then the instance-stopped-by-experiment state. If AWS FIS terminates a Spot Instance, your Spot request enters the instance-terminated-by-experiment state. For more information, see the section called “Initiate an interruption”.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Request state</th>
<th>Instance state</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance-terminated-launch-group-constraint</td>
<td>closed (one-time), open (persistent)</td>
<td>terminated</td>
</tr>
<tr>
<td>marked-for-stop-by-experiment</td>
<td>active</td>
<td>running</td>
</tr>
<tr>
<td>instance-stopped-by-experiment</td>
<td>disabled</td>
<td>stopped</td>
</tr>
<tr>
<td>instance-terminated-by-experiment</td>
<td>closed</td>
<td>terminated</td>
</tr>
</tbody>
</table>
Persistent requests

When your Spot Instances are terminated (either by you or Amazon EC2), if the Spot request is a persistent request, it returns to the pending-evaluation state and then Amazon EC2 can launch a new Spot Instance when the constraints are met.

Get request status information

You can get request status information using the AWS Management Console or a command line tool.

To get request status information using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests and select the Spot request.
3. To check the status, on the Description tab, check the Status field.

To get request status information using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2.

- describe-spot-instance-requests (AWS CLI)
- Get-EC2SpotInstanceRequest (AWS Tools for Windows PowerShell)

Spot request status codes

Spot request status information is composed of a status code, the update time, and a status message. Together, these help you determine the disposition of your Spot request.

The following are the Spot request status codes:

az-group-constraint

Amazon EC2 cannot launch all the instances you requested in the same Availability Zone.

bad-parameters

One or more parameters for your Spot request are not valid (for example, the AMI you specified does not exist). The status message indicates which parameter is not valid.
canceled-before-fulfillment

The user canceled the Spot request before it was fulfilled.

capacity-not-available

There is not enough capacity available for the instances that you requested.

constraint-not-fulfillable

The Spot request can't be fulfilled because one or more constraints are not valid (for example, the Availability Zone does not exist). The status message indicates which constraint is not valid.

fulfilled

The Spot request is active, and Amazon EC2 is launching your Spot Instances.

instance-stopped-by-price

Your instance was stopped because the Spot price exceeded your maximum price.

instance-stopped-by-user

Your instance was stopped because a user stopped the instance or ran the shutdown command from the instance.

instance-stopped-no-capacity

Your instance was stopped due to EC2 capacity management needs.

instance-terminated-by-price

Your instance was terminated because the Spot price exceeded your maximum price. If your request is persistent, the process restarts, so your request is pending evaluation.

instance-terminated-by-schedule

Your Spot Instance was terminated at the end of its scheduled duration.

instance-terminated-by-service

Your instance was terminated from a stopped state.

instance-terminated-by-user or spot-instance-terminated-by-user

You terminated a Spot Instance that had been fulfilled, so the request state is closed (unless it's a persistent request) and the instance state is terminated.
instance-terminated-launch-group-constraint

One or more of the instances in your launch group was terminated, so the launch group constraint is no longer fulfilled.

instance-terminated-no-capacity

Your instance was terminated due to standard capacity management processes.

launch-group-constraint

Amazon EC2 cannot launch all the instances that you requested at the same time. All instances in a launch group are started and terminated together.

limit-exceeded

The limit on the number of EBS volumes or total volume storage was exceeded. For more information about these limits and how to request an increase, see Amazon EBS Limits in the Amazon Web Services General Reference.

marked-for-stop

The Spot Instance is marked for stopping.

marked-for-termination

The Spot Instance is marked for termination.

not-scheduled-yet

The Spot request is not evaluated until the scheduled date.

pending-evaluation

After you make a Spot Instance request, it goes into the pending-evaluation state while the system evaluates the parameters of your request.

pending-fulfillment

Amazon EC2 is trying to provision your Spot Instances.

placement-group-constraint

The Spot request can't be fulfilled yet because a Spot Instance can't be added to the placement group at this time.
price-too-low

The request can't be fulfilled yet because your maximum price is below the Spot price. In this case, no instance is launched and your request remains open.

request-canceled-and-instance-running

You canceled the Spot request while the Spot Instances are still running. The request is cancelled, but the instances remain running.

schedule-expired

The Spot request expired because it was not fulfilled before the specified date.

system-error

There was an unexpected system error. If this is a recurring issue, please contact AWS Support for assistance.

EC2 Spot Instance Request Fulfillment event

When a Spot Instance request is fulfilled, Amazon EC2 sends an EC2 Spot Instance Request Fulfillment event to Amazon EventBridge. You can create a rule to take an action whenever this event occurs, such as invoking a Lambda function or notifying an Amazon SNS topic.

The following is example data for this event.

```
{
  "version": "0",
  "id": "01234567-1234-0123-1234-012345678901",
  "detail-type": "EC2 Spot Instance Request Fulfillment",
  "source": "aws.ec2",
  "account": "123456789012",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-2",
  "resources": ["arn:aws:ec2:us-east-2:123456789012:instance/i-1234567890abcdef0"],
  "detail": {
    "spot-instance-request-id": "sir-1a2b3c4d",
    "instance-id": "i-1234567890abcdef0"
  }
}
```

For more information, see the Amazon EventBridge User Guide.
EC2 instance rebalance recommendations

An EC2 instance rebalance recommendation is a signal that notifies you when a Spot Instance is at elevated risk of interruption. The signal can arrive sooner than the two-minute Spot Instance interruption notice, giving you the opportunity to proactively manage the Spot Instance. You can decide to rebalance your workload to new or existing Spot Instances that are not at an elevated risk of interruption.

It is not always possible for Amazon EC2 to send the rebalance recommendation signal before the two-minute Spot Instance interruption notice. Therefore, the rebalance recommendation signal can arrive along with the two-minute interruption notice.

Rebalance recommendations are made available as a EventBridge event and as an item in the instance metadata on the Spot Instance. Events are emitted on a best effort basis.

⚠️ Note

Rebalance recommendations are only supported for Spot Instances that are launched after November 5, 2020 00:00 UTC.

Topics

- Rebalance actions you can take
- Monitor rebalance recommendation signals
- Services that use the rebalance recommendation signal

Rebalance actions you can take

These are some of the possible rebalancing actions that you can take:

Graceful shutdown

When you receive the rebalance recommendation signal for a Spot Instance, you can start your instance shutdown procedures, which might include ensuring that processes are completed before stopping them. For example, you can upload system or application logs to Amazon Simple Storage Service (Amazon S3), you can shut down Amazon SQS workers, or you can complete deregistration from the Domain Name System (DNS). You can also save your work in external storage and resume it at a later time.
Prevent new work from being scheduled

When you receive the rebalance recommendation signal for a Spot Instance, you can prevent new work from being scheduled on the instance, while continuing to use the instance until the scheduled work is completed.

Proactively launch new replacement instances

You can configure Auto Scaling groups, EC2 Fleet, or Spot Fleet to automatically launch replacement Spot Instances when a rebalance recommendation signal is emitted. For more information, see Use Capacity Rebalancing to handle Amazon EC2 Spot interruptions in the Amazon EC2 Auto Scaling User Guide, and Capacity Rebalancing for EC2 Fleet and Capacity Rebalancing for Spot Fleet in this user guide.

Monitor rebalance recommendation signals

You can monitor the rebalance recommendation signal so that, when it is emitted, you can take the actions that are specified in the preceding section. The rebalance recommendation signal is made available as an event that is sent to Amazon EventBridge (formerly known as Amazon CloudWatch Events) and as instance metadata on the Spot Instance.

Monitor rebalance recommendation signals:

- Use Amazon EventBridge
- Use instance metadata

Use Amazon EventBridge

When the rebalance recommendation signal is emitted for a Spot Instance, the event for the signal is sent to Amazon EventBridge. If EventBridge detects an event pattern that matches a pattern defined in a rule, EventBridge invokes a target (or targets) specified in the rule.

The following is an example event for the rebalance recommendation signal.

```json
{
    "version": "0",
    "id": "12345678-1234-1234-1234-123456789012",
    "detail-type": "EC2 Instance Rebalance Recommendation",
    "source": "aws.ec2",
    "account": "123456789012",
}```
The following fields form the event pattern that is defined in the rule:

"detail-type": "EC2 Instance Rebalance Recommendation"

Identifies that the event is a rebalance recommendation event

"source": "aws.ec2"

Identifies that the event is from Amazon EC2

Create an EventBridge rule

You can write an EventBridge rule and automate what actions to take when the event pattern matches the rule.

The following example creates an EventBridge rule to send an email, text message, or mobile push notification every time Amazon EC2 emits a rebalance recommendation signal. The signal is emitted as an EC2 Instance Rebalance Recommendation event, which triggers the action defined by the rule.

Before creating the EventBridge rule, you must create the Amazon SNS topic for the email, text message, or mobile push notification.

To create an EventBridge rule for a rebalance recommendation event

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. Choose Create rule.
3. For Define rule detail, do the following:
   a. Enter a Name for the rule, and, optionally, a description.

   A rule can't have the same name as another rule in the same Region and on the same event bus.
b. For **Event bus**, choose **default**. When an AWS service in your account generates an event, it always goes to your account's default event bus.

c. For **Rule type**, choose **Rule with an event pattern**.

d. Choose **Next**.

4. For **Build event pattern**, do the following:

   a. For **Event source**, choose **AWS events or EventBridge partner events**.

   b. For **Event pattern**, for this example you’ll specify the following event pattern to match the EC2 Instance Rebalance Recommendation event, and then choose **Save**.

   ```json
   {
     "source": ["aws.ec2"],
     "detail-type": ["EC2 Instance Rebalance Recommendation"]
   }
   ```

   To add the event pattern, you can either use a template by choosing **Event pattern form**, or specify your own pattern by choosing **Custom pattern (JSON editor)**, as follows:

   i. To use a template to create the event pattern, do the following:

      A. Choose **Event pattern form**.

      B. For **Event source**, choose **AWS services**.

      C. For **AWS Service**, choose **EC2 Spot Fleet**.

      D. For **Event type**, choose **EC2 Instance Rebalance Recommendation**.

      E. To customize the template, choose **Edit pattern** and make your changes to match the example event pattern.

   ii. (Alternative) To specify a custom event pattern, do the following:

      A. Choose **Custom pattern (JSON editor)**.

      B. In the **Event pattern** box, add the event pattern for this example.

   c. Choose **Next**.

5. For **Select target(s)**, do the following:

   a. For **Target types**, choose **AWS service**.

   b. For **Select a target**, choose **SNS topic** to send an email, text message, or mobile push notification when the event occurs.
c. For **Topic**, choose an existing topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see [Using Amazon SNS for application-to-person (A2P) messaging](https://docs.aws.amazon.com/AmazonSNS/latest/dg/sms-messaging.html) in the *Amazon Simple Notification Service Developer Guide*.

d. (Optional) Under **Additional settings**, you can optionally configure additional settings. For more information, see [Creating Amazon EventBridge rules that react to events](https://docs.aws.amazon.com/AmazonEventBridge/latest/userguide/creating-rules.html) (step 16) in the *Amazon EventBridge User Guide*.

e. Choose **Next**.

6. (Optional) For **Tags**, you can optionally assign one or more tags to your rule, and then choose **Next**.

7. For **Review and create**, do the following:

   a. Review the details of the rule and modify them as necessary.

   b. Choose **Create rule**.

For more information, see [Amazon EventBridge rules](https://docs.aws.amazon.com/AmazonEventBridge/latest/userguide/create-rule.html) and [Amazon EventBridge event patterns](https://docs.aws.amazon.com/AmazonEventBridge/latest/userguide/patterns.html) in the *Amazon EventBridge User Guide*

**Use instance metadata**

The instance metadata category `events/recommendations/rebalance` provides the approximate time, in UTC, when the rebalance recommendation signal was emitted for a Spot Instance.

We recommend that you check for rebalance recommendation signals every 5 seconds so that you don't miss an opportunity to act on the rebalance recommendation.

If a Spot Instance receives a rebalance recommendation, the time that the signal was emitted is present in the instance metadata. You can retrieve the time that the signal was emitted as follows.

Use the command for your operating system.

**Linux**

**IMDSv2**

```
```
IMDSv1

```bash
```

**Windows**

```powershell
```

The following is example output, which indicates the time, in UTC, that the rebalance recommendation signal was emitted for the Spot Instance.

```json
{"noticeTime": "2020-10-27T08:22:00Z"}
```

If the signal has not been emitted for the instance, events/recommendations/rebalance is not present and you receive an HTTP 404 error when you try to retrieve it.

**Services that use the rebalance recommendation signal**

Amazon EC2 Auto Scaling, EC2 Fleet, and Spot Fleet use the rebalance recommendation signal to make it easy for you to maintain workload availability by proactively augmenting your fleet with a new Spot Instance before a running instance receives the two-minute Spot Instance interruption notice. You can have these services monitor and respond proactively to changes affecting the availability of your Spot Instances. For more information, see the following:

- [Use Capacity Rebalancing to handle Amazon EC2 Spot interruptions](#) in the *Amazon EC2 Auto Scaling User Guide*
- [Capacity Rebalancing](#) in the EC2 Fleet topic in this user guide
- [Capacity Rebalancing](#) in the Spot Fleet topic in this user guide

**Spot Instance interruptions**

You can launch Spot Instances on spare EC2 capacity for steep discounts in exchange for returning them when Amazon EC2 needs the capacity back. When Amazon EC2 reclaims a Spot Instance, we call this event a *Spot Instance interruption*. 
When Amazon EC2 interrupts a Spot Instance, it either terminates, stops, or hibernates the instance, depending on what you specified when you created the Spot request.

Demand for Spot Instances can vary significantly from moment to moment, and the availability of Spot Instances can also vary significantly depending on how many unused EC2 instances are available. It is always possible that your Spot Instance might be interrupted.

An On-Demand Instance specified in an EC2 Fleet or Spot Fleet cannot be interrupted.

Reasons for Spot Instance interruption

The following are the possible reasons that Amazon EC2 might interrupt your Spot Instances:

Capacity

Amazon EC2 can interrupt your Spot Instance when it needs it back. EC2 reclaims your instance mainly to repurpose capacity, but it can also occur for other reasons such as host maintenance or hardware decommission.

Price

The Spot price is higher than your maximum price.

You can specify the maximum price in your Spot request. However, if you specify a maximum price, your instances will be interrupted more frequently than if you do not specify it.
Constraints

If your Spot request includes a constraint such as a launch group or an Availability Zone group, the Spot Instances are terminated as a group when the constraint can no longer be met.

You can see the historical interruption rates for your instance type in the Spot Instance Advisor.

Behavior of Spot Instance interruptions

You can specify that Amazon EC2 must do one of the following when it interrupts a Spot Instance:

- **Stop interrupted Spot Instances**
- **Hibernate interrupted Spot Instances**
- **Terminate interrupted Spot Instances** (this is the default behavior)

Specify the interruption behavior

You can specify the interruption behavior when you create a Spot request. If you do not specify an interruption behavior, the default is that Amazon EC2 terminates Spot Instances when they are interrupted.

The way in which you specify the interruption behavior is different depending on how you request Spot Instances.

- If you request Spot Instances using the launch instance wizard, you can specify the interruption behavior as follows: In the launch instance wizard, expand Advanced details and select the Request Spot Instances check box. Choose Customize. From Interruption behavior, choose an interruption behavior. If the interruption behavior is hibernation, you can alternatively choose Enable for Stop - Hibernate behavior.
- If you request Spot Instances using the run-instances CLI, you can specify the interruption behavior as follows: In the request configuration, (--instance-market-options), for InstanceInterruptionBehavior, specify an interruption behavior. If the interruption behavior is hibernate, you can alternatively enable hibernation using the --hibernation-options Configured=true parameter.
- If you configure Spot Instances in a launch template, you can specify the interruption behavior as follows: In the launch template, expand Advanced details and select the Request Spot Instances check box. Choose Customize and then, from Interruption behavior, choose an interruption behavior.
If you request Spot Instances using the Spot console, you can specify the interruption behavior as follows: Select the Maintain target capacity check box and then, from Interruption behavior, choose an interruption behavior.

If you configure Spot Instances in the request configuration when using the create-fleet CLI, you can specify the interruption behavior as follows: For InstanceInterruptionBehavior, specify an interruption behavior.

If you configure Spot Instances in the request configuration when using the request-spot-fleet CLI, you can specify the interruption behavior as follows: For InstanceInterruptionBehavior, specify an interruption behavior.

If you configure Spot Instances using the request-spot-instances CLI, you can specify the interruption behavior as follows: For --instance-interruption-behavior, specify an interruption behavior.

Note

We strongly discourage using the request-spot-fleet and request-spot-instances commands to request Spot Instances because they are legacy APIs with no planned investment. For more information, see Which is the best Spot request method to use?

Stop interrupted Spot Instances

You can specify that Amazon EC2 stops your Spot Instances when they are interrupted. For more information, see Specify the interruption behavior.

Considerations

• Only Amazon EC2 can restart an interrupted stopped Spot Instance.

• For a Spot Instance launched by a persistent Spot Instance request: Amazon EC2 restarts the stopped instance when capacity is available in the same Availability Zone and for the same instance type as the stopped instance (the same launch specification must be used).

• For Spot Instances launched by an EC2 Fleet or Spot Fleet of type maintain: After a Spot Instance is interrupted, Amazon EC2 launches a replacement instance to maintain the target capacity. Amazon EC2 finds the best Spot capacity pools based on the specified allocation strategy (lowestPrice, diversified, or InstancePoolsToUseCount); it does not prioritize the pool with the earlier stopped instance. Later, if the allocation strategy leads to a pool
containing the earlier stopped instance, Amazon EC2 restarts the stopped instance to meet the target capacity.

For example, consider a Spot Fleet with the `lowestPrice` allocation strategy. At initial launch, a `c3.large` pool meets the `lowestPrice` criteria for the launch specification. Later, when the `c3.large` instances are interrupted, Amazon EC2 stops the instances and replenishes capacity from another pool that fits the `lowestPrice` strategy. This time, the pool happens to be a `c4.large` pool and Amazon EC2 launches `c4.large` instances to meet the target capacity. Similarly, Spot Fleet could move to a `c5.large` pool the next time. In each of these transitions, Amazon EC2 does not prioritize pools with earlier stopped instances, but rather prioritizes purely on the specified allocation strategy. The `lowestPrice` strategy can lead back to pools with earlier stopped instances. For example, if instances are interrupted in the `c5.large` pool and the `lowestPrice` strategy leads it back to the `c3.large` or `c4.large` pools, the earlier stopped instances are restarted to fulfill target capacity.

- While a Spot Instance is stopped, you can modify some of its instance attributes, but not the instance type. If you detach or delete an EBS volume, it is not attached when the Spot Instance is started. If you detach the root volume and Amazon EC2 attempts to start the Spot Instance, the instance will fail to start and Amazon EC2 will terminate the stopped instance.
- You can terminate a Spot Instance while it is stopped.
- If you cancel a Spot Instance request, an EC2 Fleet, or a Spot Fleet, Amazon EC2 terminates any associated Spot Instances that are stopped.
- While an interrupted Spot Instance is stopped, you are charged only for the EBS volumes, which are preserved. With EC2 Fleet and Spot Fleet, if you have many stopped instances, you can exceed the limit on the number of EBS volumes for your account. For more information about how you're charged when a Spot Instance is interrupted, see [Billing for interrupted Spot Instances](#).
- Make sure that you are familiar with the implications of stopping an instance. For information about what happens when an instance is stopped, see [Differences between reboot, stop, hibernate, and terminate](#).

**Prerequisites**

To stop an interrupted Spot Instance, the following prerequisites must be in place:
Spot request type

Spot Instance request type – Must be persistent. You can't specify a launch group in the Spot Instance request.

EC2 Fleet or Spot Fleet request type – Must be maintain.

Root volume type

Must be an EBS volume, not an instance store volume.

Hibernate interrupted Spot Instances

You can specify that Amazon EC2 hibernates your Spot Instances when they are interrupted. For more information, see Hibernate your Amazon EC2 instance.

Amazon EC2 now offers the same hibernation experience for Spot Instances as is currently available for On-Demand Instances. It offers more extensive support, where the following is now supported for Spot Instance hibernation:

- More supported AMIs
- More supported instance families
- User-initiated hibernation

Terminate interrupted Spot Instances

When Amazon EC2 interrupts a Spot Instance, it terminates the instance by default, unless you specify a different interruption behavior, such as stop or hibernate. For more information, see Specify the interruption behavior.

Prepare for Spot Instance interruptions

Demand for Spot Instances can vary significantly from moment to moment, and the availability of Spot Instances can also vary significantly depending on how many unused EC2 instances are available. It is always possible that your Spot Instance might be interrupted. Therefore, you must ensure that your application is prepared for a Spot Instance interruption.

We recommend that you follow these best practices so that you're prepared for a Spot Instance interruption.
• Create your Spot request using an Auto Scaling group. If your Spot Instances are interrupted, the Auto Scaling group will automatically launch replacement instances. For more information, see Auto Scaling groups with multiple instance types and purchase options in the Amazon EC2 Auto Scaling User Guide.

• Ensure that your instance is ready to go as soon as the request is fulfilled by using an Amazon Machine Image (AMI) that contains the required software configuration. You can also use user data to run commands at startup.

• Data on instance store volumes is lost when the instance is stopped or terminated. Back up any important data on instance store volumes to a more persistent storage, such as Amazon S3, Amazon EBS, or Amazon DynamoDB.

• Store important data regularly in a place that isn't affected if the Spot Instance terminates. For example, you can use Amazon S3, Amazon EBS, or DynamoDB.

• Divide the work into small tasks (using a Grid, Hadoop, or queue-based architecture) or use checkpoints so that you can save your work frequently.

• Amazon EC2 emits a rebalance recommendation signal to the Spot Instance when the instance is at an elevated risk of interruption. You can rely on the rebalance recommendation to proactively manage Spot Instance interruptions without having to wait for the two-minute Spot Instance interruption notice. For more information, see EC2 instance rebalance recommendations.

• Use the two-minute Spot Instance interruption notices to monitor the status of your Spot Instances. For more information, see Spot Instance interruption notices.

• While we make every effort to provide these warnings as soon as possible, it is possible that your Spot Instance is interrupted before the warnings can be made available. Test your application to ensure that it handles an unexpected instance interruption gracefully, even if you are monitoring for rebalance recommendation signals and interruption notices. You can do this by running the application using an On-Demand Instance and then terminating the On-Demand Instance yourself.

• Run a controlled fault injection experiment with AWS Fault Injection Service to test how your application responds when your Spot Instance is interrupted. For more information, see the Tutorial: Test Spot Instance interruptions using AWS FIS in the AWS Fault Injection Service User Guide.

Initiate a Spot Instance interruption

You can select a Spot Instance request or a Spot Fleet request in the Amazon EC2 console and initiate a Spot Instance interruption so that you can test how the applications on your Spot
Instances handle being interrupted. When you initiate a Spot Instance interruption, Amazon EC2 notifies you that your Spot Instance will be interrupted in two minutes, and then, after two minutes, the instance is interrupted.

The underlying service that performs the Spot Instance interruption is AWS Fault Injection Service (AWS FIS). For information about AWS FIS, see [AWS Fault Injection Service](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/AWS-FI-Introduction.html).

**Note**

Interruption behaviors are `terminate`, `stop`, and `hibernate`. If you set the interruption behavior to `hibernate`, when you initiate a Spot Instance interruption, the hibernation process will begin immediately.

Initiating a Spot Instance interruption is supported in all AWS Regions except Asia Pacific (Jakarta), Asia Pacific (Osaka), China (Beijing), China (Ningxia), and Middle East (UAE).

**Topics**

- [Initiate a Spot Instance interruption](#)
- [Verify the Spot Instance interruption](#)
- [Quotas](#)

**Initiate a Spot Instance interruption**

You can use the EC2 console to quickly initiate a Spot Instance interruption. When you select a Spot Instance request, you can initiate the interruption of one Spot Instance. When you select a Spot Fleet request, you can initiate the interruption of multiple Spot Instances at once.

For more advanced experiments to test Spot Instance interruptions, you can create your own experiments using the AWS FIS console.

**To initiate the interruption of one Spot Instance in a Spot Instance request using the EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. From the navigation pane, choose **Spot Requests**.
3. Select a Spot Instance request, and then choose **Actions, Initiate interruption**. You can’t select multiple Spot Instance requests to initiate an interruption.
4. In the **Initiate Spot Instance interruption** dialog box, under **Service access**, either use the default role, or choose an existing role. To choose an existing role, choose **Use an existing service role**, and then, for **IAM role**, select the role to use.

5. When you're ready to initiate the Spot Instance interruption, choose **Initiate interruption**.

**To initiate the interruption of one or more Spot Instances in a Spot Fleet request using the EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

2. From the navigation pane, choose **Spot Requests**.

3. Select a Spot Fleet request, and then choose **Actions, Initiate interruption**. You can’t select multiple Spot Fleet requests to initiate an interruption.

4. In the **Specify number of Spot Instances** dialog box, for **Number of instances to interrupt**, enter the number of Spot Instances to interrupt, and then choose **Confirm**.

   **Note**
   
   The number can't exceed the number of Spot Instances in the fleet or your **quota** for the number of Spot Instances that AWS FIS can interrupt per experiment.

5. In the **Initiate Spot Instance interruption** dialog box, under **Service access**, either use the default role, or choose an existing role. To choose an existing role, choose **Use an existing service role**, and then, for **IAM role**, select the role to use.

6. When you're ready to initiate the Spot Instance interruption, choose **Initiate interruption**.

**To create more advanced experiments to test Spot Instance interruptions using the AWS FIS console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

2. From the navigation pane, choose **Spot Requests**.

3. Choose **Actions, Create advanced experiments**.

   The AWS FIS console opens. For more information, see [Tutorial: Test Spot Instance interruptions using AWS FIS](https://docs.aws.amazon.com/service-quotas/latest/userguide/quotas-tutorial-test-spot-instance-interruptions.html) in the *AWS Fault Injection Service User Guide*. 

---

*Spot Instances*
Verify the Spot Instance interruption

After you initiate the interruption, the following occurs:

• The Spot Instance receives an instance rebalance recommendation.

• A Spot Instance interruption notice is issued two minutes before AWS FIS interrupts your instance.

• After two minutes, the Spot Instance is interrupted.

• A Spot Instance that was stopped by AWS FIS remains stopped until you restart it.

To verify that the instance was interrupted after you initiated the interruption

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. From the navigation pane, open Spot Requests and Instances in separate browser tabs or windows.

3. For Spot Requests, select the Spot Instance request or Spot Fleet request. The initial status is fulfilled. After the instance is interrupted, the status changes as follows, depending on the interruption behavior:
   • terminate – The status changes to instance-terminated-by-experiment.
   • stop – The status changes to marked-for-stop-by-experiment and then instance-stopped-by-experiment.

4. For Instances, select the Spot Instance. The initial status is Running. Two minutes after you receive the Spot Instance interruption notice, the status changes as follows, depending on the interruption behavior:
   • stop – The status changes to Stopping and then Stopped.
   • terminate – The status changes to Shutting-down and then Terminated.

Quotas

Your AWS account has the following default quota for the number of Spot Instances that AWS FIS can interrupt per experiment.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spot Instances</td>
<td>532</td>
<td>Yes</td>
<td></td>
</tr>
</tbody>
</table>
### Amazon Elastic Compute Cloud

#### User Guide

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target SpotInstances for <code>aws:ec2:send-spot-instance-interruptions</code></td>
<td>Each supported Region: 5</td>
<td></td>
<td>The maximum number of Spot Instances that <code>aws:ec2:send-spot-instance-interruptions</code> can target when you identify targets using tags, per experiment.</td>
</tr>
</tbody>
</table>

You can request a quota increase. For more information, see [Requesting a quota increase](#) in the [Service Quotas User Guide](#).

To view all the quotas for AWS FIS, open the [Service Quotas console](#). In the navigation pane, choose [AWS services](#) and select [AWS Fault Injection Service](#). You can also view all the quotas for [AWS Fault Injection Service](#) in the [AWS Fault Injection Service User Guide](#).

### Spot Instance interruption notices

A *Spot Instance interruption notice* is a warning that is issued two minutes before Amazon EC2 stops or terminates your Spot Instance. If you specify hibernation as the interruption behavior, you receive an interruption notice, but you do not receive a two-minute warning because the hibernation process begins immediately.

The best way for you to gracefully handle Spot Instance interruptions is to architect your application to be fault-tolerant. To accomplish this, you can take advantage of Spot Instance interruption notices. We recommend that you check for these interruption notices every 5 seconds.

The interruption notices are made available as a EventBridge event and as items in the [instance metadata](#) on the Spot Instance. Interruption notices are emitted on a best effort basis.

### EC2 Spot Instance interruption notice

When Amazon EC2 is going to interrupt your Spot Instance, it emits an event two minutes prior to the actual interruption (except for hibernation, which gets the interruption notice, but not two minutes in advance, because hibernation begins immediately). This event can be detected by Amazon EventBridge. For more information about EventBridge events, see the [Amazon](#).
EventBridge User Guide. For a detailed example that walks you through how to create and use event rules, see Taking Advantage of Amazon EC2 Spot Instance Interruption Notices.

The following is an example of the event for Spot Instance interruption. The possible values for instance-action are hibernate, stop, or terminate.

```json
{
  "version": "0",
  "id": "12345678-1234-1234-1234-123456789012",
  "detail-type": "EC2 Spot Instance Interruption Warning",
  "source": "aws.ec2",
  "account": "123456789012",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-2",
  "resources": ["arn:aws:ec2:us-east-2a:instance/i-1234567890abcdef0"],
  "detail": {
    "instance-id": "i-1234567890abcdef0",
    "instance-action": "action"
  }
}
```

Note

The ARN format of the Spot Instance interruption event is `arn:aws:ec2:availability-zone:instance/instance-id`. This format differs from the EC2 resource ARN format.

instance-action

If your Spot Instance is marked to be stopped or terminated by Amazon EC2, the instance-action item is present in your instance metadata. Otherwise, it is not present. You can retrieve the instance-action using Instance Metadata Service Version 2 (IMDSv2) as follows.

Use the command for your operating system.

Linux

```
```
The instance-action item specifies the action and the approximate time, in UTC, when the action will occur.

The following example output indicates the time at which this instance will be stopped.

```json
{"action": "stop", "time": "2017-09-18T08:22:00Z"}
```

The following example output indicates the time at which this instance will be terminated.

```json
{"action": "terminate", "time": "2017-09-18T08:22:00Z"}
```

If Amazon EC2 is not preparing to stop or terminate the instance, or if you terminated the instance yourself, instance-action is not present in the instance metadata and you receive an HTTP 404 error when you try to retrieve it.

**termination-time**

This item is maintained for backward compatibility; you should use instance-action instead.

If your Spot Instance is marked for termination by Amazon EC2 (either due to a Spot Instance interruption where the interruption behavior is set to terminate, or due to the cancellation of a persistent Spot Instance request), the termination-time item is present in your instance metadata. Otherwise, it is not present. You can retrieve the termination-time using IMDSv2 as follows.

Use the command for your operating system.

**Linux**

```bash
```
Windows

```powershell
```

The `termination-time` item specifies the approximate time in UTC when the instance will receive the shutdown signal. The following is example output.

```
2015-01-05T18:02:00Z
```

If Amazon EC2 is not preparing to terminate the instance (either because there is no Spot Instance interruption or because your interruption behavior is set to stop or hibernate), or if you terminated the Spot Instance yourself, the `termination-time` item is either not present in the instance metadata (so you receive an HTTP 404 error) or contains a value that is not a time value.

If Amazon EC2 fails to terminate the instance, the request status is set to fulfilled. The `termination-time` value remains in the instance metadata with the original approximate time, which is now in the past.

**Find interrupted Spot Instances**

In the console, the **Instances** pane displays all instances, including Spot Instances. The instance lifecycle of a Spot Instance is spot. The instance state of a Spot Instance is either stopped or terminated, depending on the interruption behavior that you configured. For a hibernated Spot Instance, the instance state is stopped.

**To find an interrupted Spot Instance using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Apply the following filter: **Instance lifecycle=spot**.
4. Apply the **Instance state=stopped** or **Instance state=terminated** filter depending on the interruption behavior that you configured.
5. For each Spot Instance, on the **Details** tab, under **Instance details**, find **State transition message**. The following codes indicate that the Spot Instance was interrupted.
   - `Server.SpotInstanceShutdown`
For additional details about the reason for the interruption, check the Spot request status code. For more information, see the section called “Spot request status”.

To find interrupted Spot Instances using the AWS CLI

You can list your interrupted Spot Instances using the `describe-instances` command with the --filters parameter. To list only the instance IDs in the output, include the --query parameter.

If the instance interruption behavior is to terminate the Spot Instances, use the following command:

```bash
aws ec2 describe-instances \
  --filters Name=instance-lifecycle,Values=spot Name=instance-state-name,Values=terminated Name=state-reason-code,Values=Server.SpotInstanceTermination \
  --query "Reservations[*].Instances[*].InstanceId"
```

If the instance interruption behavior is to stop the Spot Instances, use the following command:

```bash
aws ec2 describe-instances \
  --filters Name=instance-lifecycle,Values=spot Name=instance-state-name,Values=stopped Name=state-reason-code,Values=Server.SpotInstanceShutdown \
  --query "Reservations[*].Instances[*].InstanceId"
```

Determine whether Amazon EC2 terminated a Spot Instance

If a Spot Instance is terminated, you can use CloudTrail to see whether Amazon EC2 terminated the Spot Instance. In AWS CloudTrail, the event name `BidEvictedEvent` indicates that Amazon EC2 terminated the Spot Instance.

To view `BidEvictedEvent` events in CloudTrail

1. Open the CloudTrail console at https://console.aws.amazon.com/cloudtrail/.
2. In the navigation pane, choose Event history.
3. In the filter drop-down, choose Event name, and then in the filter field to the right, enter BidEvictedEvent.
4. Choose BidEvictedEvent in the resulting list to view its details. Under Event record, you can find the instance ID.
For more information about using CloudTrail, see Log Amazon EC2 API calls using AWS CloudTrail.

Billing for interrupted Spot Instances

When a Spot Instance is interrupted, you’re charged for instance and EBS volume usage, and you might incur other charges, as follows.

Instance usage

<table>
<thead>
<tr>
<th>Who interrupts the Spot Instance</th>
<th>Operating system</th>
<th>Interrupted in the first hour</th>
<th>Interrupted in any hour after the first hour</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you stop or terminate the Spot Instance</td>
<td>Windows and Linux (excluding SUSE)</td>
<td>Charged for the seconds used</td>
<td>Charged for the seconds used</td>
</tr>
<tr>
<td></td>
<td>SUSE</td>
<td>Charged for the full hour even if you used a partial hour</td>
<td>Charged for the full hours used, and charged a full hour for the interrupted partial hour</td>
</tr>
<tr>
<td>If the Amazon EC2 interrupts the Spot Instance</td>
<td>Windows and Linux (excluding SUSE)</td>
<td>No charge</td>
<td>Charged for the seconds used</td>
</tr>
<tr>
<td></td>
<td>SUSE</td>
<td>No charge</td>
<td>Charged for the full hours used, but no charge for the interrupted partial hour</td>
</tr>
</tbody>
</table>

EBS volume usage

While an interrupted Spot Instance is stopped, you are charged only for the EBS volumes, which are preserved.

With EC2 Fleet and Spot Fleet, if you have many stopped instances, you can exceed the limit on the number of EBS volumes for your account.
Other charges

If your running Spot Instance incurs charges for other services, such as for data transfer, Elastic IP addresses, or usage of other AWS managed services, you will be billed for their usage. This is regardless of who interrupts the Spot Instance or when it was interrupted. Even if you're not charged for Spot Instance usage when Amazon EC2 interrupts your Spot Instance in the first hour, you can incur other charges.

For more information about other charges, see Amazon EC2 On-Demand Pricing.
Spot placement score

The Spot placement score feature can recommend an AWS Region or Availability Zone based on your Spot capacity requirements. Spot capacity fluctuates, and you can't be sure that you'll always get the capacity that you need. A Spot placement score indicates how likely it is that a Spot request will succeed in a Region or Availability Zone.

⚠️ Note

A Spot placement score does not provide any guarantees in terms of available capacity or risk of interruption. A Spot placement score serves only as a recommendation.

Benefits

You can use the Spot placement score feature for the following:

- To relocate and scale Spot compute capacity in a different Region, as needed, in response to increased capacity needs or decreased available capacity in the current Region.
- To identify the most optimal Availability Zone in which to run single-Availability Zone workloads.
- To simulate future Spot capacity needs so that you can pick an optimal Region for the expansion of your Spot-based workloads.
- To find an optimal combination of instance types to fulfill your Spot capacity needs.

Topics

- Costs
- How Spot placement score works
- Limitations
- Required IAM permission
- Calculate a Spot placement score
- Example configurations

Costs

There is no additional charge for using the Spot placement score feature.
How Spot placement score works

When you use the Spot placement score feature, you first specify your compute requirements for your Spot Instances, and then Amazon EC2 returns the top 10 Regions or Availability Zones where your Spot request is likely to succeed. Each Region or Availability Zone is scored on a scale from 1 to 10, with 10 indicating that your Spot request is highly likely to succeed, and 1 indicating that your Spot request is not likely to succeed.

To use the Spot placement score feature, follow these steps:

- **Step 1: Specify your Spot requirements**
- **Step 2: Filter the Spot placement score response**
- **Step 3: Review the recommendations**
- **Step 4: Use the recommendations**

### Step 1: Specify your Spot requirements

First, you specify your desired target Spot capacity and your compute requirements, as follows:

1. **Specify the target Spot capacity, and optionally the target capacity unit.**

   You can specify your desired target Spot capacity in terms of the number of instances or vCPUs, or in terms of the amount of memory in MiB. To specify the target capacity in number of vCPUs or amount of memory, you must specify the target capacity unit as vcpu or memory-mib. Otherwise, it defaults to number of instances.

   By specifying your target capacity in terms of the number of vCPUs or the amount of memory, you can use these units when counting the total capacity. For example, if you want to use a mix of instances of different sizes, you can specify the target capacity as a total number of vCPUs. The Spot placement score feature then considers each instance type in the request by its number of vCPUs, and counts the total number of vCPUs rather than the total number of instances when totaling up the target capacity.

   For example, say you specify a total target capacity of 30 vCPUs, and your instance type list consists of c5.xlarge (4 vCPUs), m5.2xlarge (8 vCPUs), and r5.large (2 vCPUs). To achieve a total of 30 vCPUs, you could get a mix of 2 c5.xlarge (2*4 vCPUs), 2 m5.2xlarge (2*8 vCPUs), and 3 r5.large (3*2 vCPUs).

2. **Specify instance types or instance attributes.**

Spot Instances
You can either specify the instance types to use, or you can specify the instance attributes that you need for your compute requirements, and then let Amazon EC2 identify the instance types that have those attributes. This is known as attribute-based instance type selection.

You can't specify both instance types and instance attributes in the same Spot placement score request.

If you specify instance types, you must specify at least three different instance types, otherwise Amazon EC2 will return a low Spot placement score. Similarly, if you specify instance attributes, they must resolve to at least three different instance types.

For examples of different ways to specify your Spot requirements, see [Example configurations](#).

**Step 2: Filter the Spot placement score response**

Amazon EC2 calculates the Spot placement score for each Region or Availability Zone, and returns either the top 10 Regions or the top 10 Availability Zones where your Spot request is likely to succeed. The default is to return a list of scored Regions. If you plan to launch all of your Spot capacity into a single Availability Zone, then it's useful to request a list of scored Availability Zones.

You can specify a Region filter to narrow down the Regions that will be returned in the response.

You can combine the Region filter and a request for scored Availability Zones. In this way, the scored Availability Zones are confined to the Regions for which you've filtered. To find the highest-scored Availability Zone in a Region, specify only that Region, and the response will return a scored list of all of the Availability Zones in that Region.

**Step 3: Review the recommendations**

The Spot placement score for each Region or Availability Zone is calculated based on the target capacity, the composition of the instance types, the historical and current Spot usage trends, and the time of the request. Because Spot capacity is constantly fluctuating, the same Spot placement score request can yield different scores when calculated at different times.

Regions and Availability Zones are scored on a scale from 1 to 10. A score of 10 indicates that your Spot request is highly likely—but not guaranteed—to succeed. A score of 1 indicates that your Spot request is not likely to succeed at all. The same score might be returned for different Regions or Availability Zones.
If low scores are returned, you can edit your compute requirements and recalculate the score. You can also request Spot placement score recommendations for the same compute requirements at different times of the day.

**Step 4: Use the recommendations**

A Spot placement score is only relevant if your Spot request has exactly the same configuration as the Spot placement score configuration (target capacity, target capacity unit, and instance types or instance attributes), and is configured to use the capacity-optimized allocation strategy. Otherwise, the likelihood of getting available Spot capacity will not align with the score.

While a Spot placement score serves as a guideline, and no score guarantees that your Spot request will be fully or partially fulfilled, you can use the following information to get the best results:

- **Use the same configuration** – The Spot placement score is relevant only if the Spot request configuration (target capacity, target capacity unit, and instance types or instance attributes) in your Auto Scaling group, EC2 Fleet, or Spot Fleet is the same as what you entered to get the Spot placement score.

  If you used attribute-based instance type selection in your Spot placement score request, you can use attribute-based instance type selection to configure your Auto Scaling group, EC2 Fleet, or Spot Fleet. For more information, see [Creating an Auto Scaling group with a set of requirements on the instance types used](#), [Attribute-based instance type selection for EC2 Fleet](#), and [Attribute-based instance type selection for Spot Fleet](#).

  Note

  If you specified your target capacity in terms of the number of vCPUs or the amount of memory, and you specified instance types in your Spot placement score configuration, note that you can’t currently create this configuration in your Auto Scaling group, EC2 Fleet, or Spot Fleet. Instead, you must manually set the instance weighting by using the `WeightedCapacity` parameter.

- **Use the capacity-optimized allocation strategy** – Any score assumes that your fleet request will be configured to use all Availability Zones (for requesting capacity across Regions) or a single Availability Zone (if requesting capacity in one Availability Zone) and the capacity-optimized Spot allocation strategy for your request for Spot capacity to succeed. If you use other allocation
strategies, such as lowest-price, the likelihood of getting available Spot capacity will not align with the score.

- **Act on a score immediately** – The Spot placement score recommendation reflects the available Spot capacity at the time of the request, and the same configuration can yield different scores when calculated at different times due to Spot capacity fluctuations. While a score of 10 means that your Spot capacity request is highly likely—but not guaranteed—to succeed, for best results we recommend that you act on a score immediately. We also recommend that you get a fresh score each time you attempt a capacity request.

**Limitations**

- **Target capacity limit** – Your Spot placement score target capacity limit is based on your recent Spot usage, while accounting for potential usage growth. If you have no recent Spot usage, we provide you with a low default limit aligned with your Spot request limit.

- **Request configurations limit** – We can limit the number of new request configurations within a 24-hour period if we detect patterns not associated with the intended use of the Spot placement score feature. If you reach the limit, you can retry the request configurations that you've already used, but you can't specify new request configurations until the next 24-hour period.

- **Minimum number of instance types** – If you specify instance types, you must specify at least three different instance types, otherwise Amazon EC2 will return a low Spot placement score. Similarly, if you specify instance attributes, they must resolve to at least three different instance types. Instance types are considered different if they have a different name. For example, m5.8xlarge, m5a.8xlarge, and m5.12xlarge are all considered different.

**Required IAM permission**

By default, IAM identities (users, roles, or groups) don't have permission to use the Spot placement score feature. To allow IAM identities to use the Spot placement score feature, you must create an IAM policy that grants permission to use the `ec2:GetSpotPlacementScores` EC2 API action. You then attach the policy to the IAM identities that require this permission.

The following is an example IAM policy that grants permission to use the `ec2:GetSpotPlacementScores` EC2 API action.

```json
{
    "Version": "2012-10-17",
    "Statement": [
```
For information about editing an IAM policy, see Editing IAM policies in the IAM User Guide.

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:
  
  Create a permission set. Follow the instructions in Create a permission set in the AWS IAM Identity Center User Guide.

- Users managed in IAM through an identity provider:
  
  Create a role for identity federation. Follow the instructions in Creating a role for a third-party identity provider (federation) in the IAM User Guide.

- IAM users:
  
  - Create a role that your user can assume. Follow the instructions in Creating a role for an IAM user in the IAM User Guide.
  
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the IAM User Guide.

### Calculate a Spot placement score

You can calculate a Spot placement score by using the Amazon EC2 console or the AWS CLI.

#### Topics

- [Calculate a Spot placement score by specifying instance attributes (console)](#)
- [Calculate a Spot placement score by specifying instance types (console)](#)
- [Calculate the Spot placement score (AWS CLI)](#)
Calculate a Spot placement score by specifying instance attributes (console)

To calculate a Spot placement score by specifying instance attributes

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Choose Spot placement score.
4. Choose Enter requirements.
5. For Target capacity, enter your desired capacity in terms of the number of instances or vCPUs, or the amount of memory (MiB).
6. For Instance type requirements, to specify your compute requirements and let Amazon EC2 identify the optimal instance types with these requirements, choose Specify instance attributes that match your compute requirements.
7. For vCPUs, enter the desired minimum and maximum number of vCPUs. To specify no limit, select No minimum, No maximum, or both.
8. For Memory (GiB), enter the desired minimum and maximum amount of memory. To specify no limit, select No minimum, No maximum, or both.
9. For CPU architecture, select the required instance architecture.
10. (Optional) For Additional instance attributes, you can optionally specify one or more attributes to express your compute requirements in more detail. Each additional attribute adds a further constraint to your request. You can omit the additional attributes; when omitted, the default values are used. For a description of each attribute and their default values, see get-spot-placement-scores in the Amazon EC2 Command Line Reference.
11. (Optional) To view the instance types with your specified attributes, expand Preview matching instance types. To exclude instance types from being used in the placement evaluation, select the instances and then choose Exclude selected instance types.
12. Choose Load placement scores, and review the results.
13. (Optional) To display the Spot placement score for specific Regions, for Regions to evaluate, select the Regions to evaluate, and then choose Calculate placement scores.
14. (Optional) To display the Spot placement score for the Availability Zones in the displayed Regions, select the Provide placement scores per Availability Zone check box. A list of scored Availability Zones is useful if you want to launch all of your Spot capacity into a single Availability Zone.
15. (Optional) To edit your compute requirements and get a new placement score, choose Edit, make the necessary adjustments, and then choose Calculate placement scores.

Calculate a Spot placement score by specifying instance types (console)

To calculate a Spot placement score by specifying instance types

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Choose Spot placement score.
4. Choose Enter requirements.
5. For Target capacity, enter your desired capacity in terms of the number of instances or vCPUs, or the amount of memory (MiB).
6. For Instance type requirements, to specify the instance types to use, choose Manually select instance types.
7. Choose Select instance types, select the instance types to use, and then choose Select. To quickly find instance types, you can use the filter bar to filter the instance types by different properties.
8. Choose Load placement scores, and review the results.
9. (Optional) To display the Spot placement score for specific Regions, for Regions to evaluate, select the Regions to evaluate, and then choose Calculate placement scores.
10. (Optional) To display the Spot placement score for the Availability Zones in the displayed Regions, select the Provide placement scores per Availability Zone check box. A list of scored Availability Zones is useful if you want to launch all of your Spot capacity into a single Availability Zone.
11. (Optional) To edit the list of instance types and get a new placement score, choose Edit, make the necessary adjustments, and then choose Calculate placement scores.

Calculate the Spot placement score (AWS CLI)

To calculate the Spot placement score

1. (Optional) To generate all of the possible parameters that can be specified for the Spot placement score configuration, use the get-spot-placement-scores command and the --generate-cli-skeleton parameter.
aws ec2 get-spot-placement-scores
  --region us-east-1
  --generate-cli-skeleton

Expected output

```json
{
  "InstanceTypes": [
    ""
  ],
  "TargetCapacity": 0,
  "TargetCapacityUnitType": "vcpu",
  "SingleAvailabilityZone": true,
  "RegionNames": [

"AcceleratorTotalMemoryMiB": {
  "Min": 0,
  "Max": 0
}
"DryRun": true,
2. Create a JSON configuration file using the output from the previous step, and configure it as follows:

   a. For TargetCapacity, enter your desired Spot capacity in terms of the number of instances or vCPUs, or the amount of memory (MiB).

   b. For TargetCapacityUnitType, enter the unit for the target capacity. If you omit this parameter, it defaults to units.

      Valid values: units (which translates to number of instances) | vcpu | memory-mib

   c. For SingleAvailabilityZone, specify true for a response that returns a list of scored Availability Zones. A list of scored Availability Zones is useful if you want to launch all of your Spot capacity into a single Availability Zone. If you omit this parameter, it defaults to false, and the response returns a list of scored Regions.

   d. (Optional) For RegionNames, specify the Regions to use as a filter. You must specify the Region code, for example, us-east-1.

      With a Region filter, the response returns only the Regions that you specify. If you specified true for SingleAvailabilityZone, the response returns only the Availability Zones in the specified Regions.

   e. You can include either InstanceTypes or InstanceRequirements, but not both in the same configuration.

      Specify one of the following in your JSON configuration:

      • To specify a list of instance types, specify the instance types in the InstanceTypes parameter. Specify at least three different instance types. If you specify only one or two instance types, Spot placement score returns a low score. For the list of instance types, see Amazon EC2 Instance Types.

      • To specify the instance attributes so that Amazon EC2 will identify the instance types that match those attributes, specify the attributes that are located in the InstanceRequirements structure.

      You must provide values for VcpuCount, MemoryMiB, and CpuManufacturers. You can omit the other attributes; when omitted, the default values are used. For a
description of each attribute and their default values, see `get-spot-placement-scores` in the *Amazon EC2 Command Line Reference*.

For example configurations, see [Example configurations](#).

3. To get the Spot placement score for the requirements that you specified in the JSON file, use the `get-spot-placement-scores` command, and specify the name and path to your JSON file by using the `--cli-input-json` parameter.

```bash
aws ec2 get-spot-placement-scores \
  --region us-east-1 \
  --cli-input-json file://file_name.json
```

Example output if `SingleAvailabilityZone` is set to `false` or omitted (if omitted, it defaults to `false`) – a scored list of Regions is returned

```json
"SpotPlacementScores": [
  {
    "Region": "us-east-1",
    "Score": 7
  },
  {
    "Region": "us-west-1",
    "Score": 5
  },
  ...
]
```

Example output if `SingleAvailabilityZone` is set to `true` – a scored list of Availability Zones is returned

```json
"SpotPlacementScores": [
  {
    "Region": "us-east-1",
    "AvailabilityZoneId": "use1-az1",
    "Score": 8
  },
  {
    "Region": "us-east-1",
    "AvailabilityZoneId": "usw2-az3",
    "Score": 6
  },
  ...
]
```
Example configurations

When using the AWS CLI, you can use the following example configurations.

Example configurations

- Example: Specify instance types and target capacity
- Example: Specify instance types, and target capacity in terms of memory
- Example: Specify attributes for attribute-based instance type selection
- Example: Specify attributes for attribute-based instance type selection and return a scored list of Availability Zones

Example: Specify instance types and target capacity

The following example configuration specifies three different instance types and a target Spot capacity of 500 Spot Instances.

```json
{
    "InstanceTypes": [
        "m5.4xlarge",
        "r5.2xlarge",
        "m4.4xlarge"
    ],
    "TargetCapacity": 500
}
```

Example: Specify instance types, and target capacity in terms of memory

The following example configuration specifies three different instance types and a target Spot capacity of 500,000 MiB of memory, where the number of Spot Instances to launch must provide a total of 500,000 MiB of memory.

```json
{
    "InstanceTypes": [
        "m5.4xlarge",
        "r5.2xlarge",
        "m4.4xlarge"
    ]
}
```
Example: Specify attributes for attribute-based instance type selection

The following example configuration is configured for attribute-based instance type selection, and is followed by a text explanation of the example configuration.

```json
{
  "TargetCapacity": 5000,
  "TargetCapacityUnitType": "vcpu",
  "InstanceRequirementsWithMetadata": {
    "ArchitectureTypes": ["arm64"],
    "VirtualizationTypes": ["hvm"],
    "InstanceRequirements": {
      "VCpuCount": {
        "Min": 1,
        "Max": 12
      },
      "MemoryMiB": {
        "Min": 512
      }
    }
  }
}
```

**InstanceRequirementsWithMetadata**

To use attribute-based instance type selection, you must include the `InstanceRequirementsWithMetadata` structure in your configuration, and specify the desired attributes for the Spot Instances.

In the preceding example, the following required instance attributes are specified:

- **ArchitectureTypes** – The architecture type of the instance types must be `arm64`.
- **VirtualizationTypes** – The virtualization type of the instance types must be `hvm`.
- **VCpuCount** – The instance types must have a minimum of 1 and a maximum of 12 vCPUs.
- **MemoryMiB** – The instance types must have a minimum of 512 MiB of memory. By omitting the `Max` parameter, you are indicating that there is no maximum limit.
Note that there are several other optional attributes that you can specify. For the list of attributes, see `get-spot-placement-scores` in the Amazon EC2 Command Line Reference.

**TargetCapacityUnitType**

The `TargetCapacityUnitType` parameter specifies the unit for the target capacity. In the example, the target capacity is 5000 and the target capacity unit type is `vcpu`, which together specify a desired target capacity of 5000 vCPUs, where the number of Spot Instances to launch must provide a total of 5000 vCPUs.

**Example: Specify attributes for attribute-based instance type selection and return a scored list of Availability Zones**

The following example configuration is configured for attribute-based instance type selection. By specifying "SingleAvailabilityZone": true, the response will return a list of scored Availability Zones.

```json
{
  "TargetCapacity": 1000,
  "TargetCapacityUnitType": "vcpu",
  "SingleAvailabilityZone": true,
  "InstanceRequirementsWithMetadata": {
    "ArchitectureTypes": ["arm64"],
    "VirtualizationTypes": ["hvm"],
    "InstanceRequirements": {
      "VCpuCount": {
        "Min": 1,
        "Max": 12
      },
      "MemoryMiB": {
        "Min": 512
      }
    }
  }
}
```

**Track your Spot Instance costs by subscribing to a data feed**

To help you understand the charges for your Spot Instances, Amazon EC2 provides a data feed that describes your Spot Instance usage and pricing. This data feed is sent to an Amazon S3 bucket that you specify when you subscribe to the data feed.
Data feed files arrive in your bucket typically once an hour. If you don't have a Spot Instance running during a certain hour, you don't receive a data feed file for that hour.

Each hour of Spot Instance usage is typically covered in a single data file. These files are compressed (gzip) before they are delivered to your bucket. Amazon EC2 can write multiple files for a given hour of usage where files are large (for example, when file contents for the hour exceed 50 MB before compression).

**Note**

You can create only one Spot Instance data feed per AWS account.

Spot Instance data feed is supported in all AWS Regions except China (Beijing), China (Ningxia), AWS GovCloud (US), and the Regions that are disabled by default.

**Contents**

- Data feed file name and format
- Amazon S3 bucket requirements
- Subscribe to your Spot Instance data feed
- Describe your Spot Instance data feed
- View the data in your data feed
- Delete your Spot Instance data feed

**Data feed file name and format**

The Spot Instance data feed file name uses the following format (with the date and hour in UTC):

```
bucket-name.s3.amazonaws.com/optional-prefix/aws-account-id.YYYY-MM-DD-HH.n.unique-id.gz
```

For example, if your bucket name is **DOC-EXAMPLE-BUCKET** and your prefix is **my-prefix**, your file names are similar to the following:

```
DOC-EXAMPLE-BUCKET.s3.amazonaws.com/my-prefix/111122223333.2023-12-09-07.001.b959dbc6.gz
```

For more information about bucket names, see [Bucket naming rules](#) in the *Amazon S3 User Guide*. 
The Spot Instance data feed files are tab-delimited. Each line in the data file corresponds to one instance hour and contains the fields listed in the following table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timestamp</td>
<td>The timestamp used to determine the price charged for this instance usage.</td>
</tr>
<tr>
<td>UsageType</td>
<td>The type of usage and instance type being charged for. For m1.small Spot Instances, this field is set to SpotUsage. For all other instance types, this field is set to SpotUsage: {instance-type}. For example, SpotUsage:c1.medium.</td>
</tr>
<tr>
<td>Operation</td>
<td>The product being charged for. For Linux Spot Instances, this field is set to RunInstances. For Windows Spot Instances, this field is set to RunInstances:0002. Spot usage is grouped according to Availability Zone.</td>
</tr>
<tr>
<td>InstanceID</td>
<td>The ID of the Spot Instance that generated this instance usage.</td>
</tr>
<tr>
<td>MyBidID</td>
<td>The ID for the Spot Instance request that generated this instance usage.</td>
</tr>
<tr>
<td>MyMaxPrice</td>
<td>The maximum price specified for this Spot request.</td>
</tr>
<tr>
<td>MarketPrice</td>
<td>The Spot price at the time specified in the Timestamp field.</td>
</tr>
<tr>
<td>Charge</td>
<td>The price charged for this instance usage.</td>
</tr>
<tr>
<td>Version</td>
<td>The data feed version. The possible version is 1.0.</td>
</tr>
</tbody>
</table>

**Amazon S3 bucket requirements**

When you subscribe to the data feed, you must specify an Amazon S3 bucket to store the data feed files.
Before you choose an Amazon S3 bucket for the data feed, consider the following:

- You must have FULL_CONTROL permission to the bucket. If you're the bucket owner, you have this permission by default. Otherwise, the bucket owner must grant your AWS account this permission.

- When you subscribe to a data feed, these permissions are used to update the bucket ACL to give the AWS data feed account FULL_CONTROL permission. The AWS data feed account writes data feed files to the bucket. If your account doesn't have the required permissions, the data feed files cannot be written to the bucket. For more information, see Logs sent to Amazon S3 in the Amazon CloudWatch Logs User Guide.

  **Note**
  
  If you update the ACL and remove the permissions for the AWS data feed account, the data feed files cannot be written to the bucket. You must resubscribe to the data feed to receive the data feed files.

- Each data feed file has its own ACL (separate from the ACL for the bucket). The bucket owner has FULL_CONTROL permission to the data files. The AWS data feed account has read and write permissions.

- If you disabled ACLs for your buckets, add a bucket policy that allows full control for users to write to the bucket. For more information, see Review and update bucket policies that use ACL-related condition keys.

- If you delete your data feed subscription, Amazon EC2 doesn't remove the read and write permissions for the AWS data feed account on either the bucket or the data files. You must remove these permissions yourself.

- You must use a customer managed key if you encrypt your Amazon S3 bucket using server-side encryption with a AWS KMS key stored in AWS Key Management Service (SSE-KMS). For more information, see Amazon S3 bucket server-side encryption in the Amazon CloudWatch Logs User Guide.

  **Note**
  
  For Spot Instance data feed, the resource that generates the S3 files is no longer Amazon CloudWatch Logs. Therefore, you must remove the aws:SourceArn section from the S3 bucket permission policy and from the KMS policy.
Subscribe to your Spot Instance data feed

To subscribe to your data feed, use the `create-spot-datafeed-subscription` AWS CLI command.

```bash
aws ec2 create-spot-datafeed-subscription \
   --bucket DOC-EXAMPLE-BUCKET \
   [--prefix my-prefix]
```

Example output

```json
{
   "SpotDatafeedSubscription": {
      "OwnerId": "111122223333",
      "Bucket": "DOC-EXAMPLE-BUCKET",
      "Prefix": "my-prefix",
      "State": "Active"
   }
}
```

Describe your Spot Instance data feed

To describe your data feed subscription, use the `describe-spot-datafeed-subscription` AWS CLI command.

```bash
aws ec2 describe-spot-datafeed-subscription
```

Example output

```json
{
   "SpotDatafeedSubscription": {
      "OwnerId": "123456789012",
      "Prefix": "spotdata",
      "Bucket": "DOC-EXAMPLE-BUCKET",
      "State": "Active"
   }
}
```

View the data in your data feed

In the AWS Management Console, open AWS CloudShell. Use the following `s3 sync` command to get the .gz files from the S3 bucket for your data feed and store them in the folder that you specify.
aws s3 sync s3://DOC-EXAMPLE-BUCKET ./data-feed

To display the contents of a .gz file, change to the folder where you stored the contents of the S3 bucket.

cd data-feed

Use the `ls` command to view the names of the files. Use the `zcat` command with the name of the file to display the contents of the compressed file. The following is an example command.

`zcat 111122223333.2023-12-09-07.001.b959dbc6.gz`

The following is example output.

```
#Version: 1.0
#Fields: Timestamp UsageType Operation InstanceID MyBidID MyMaxPrice MarketPrice Charge
Version
2023-12-09 07:13:47 UTC USE2-SpotUsage:c7a.medium       RunInstances:SV050
i-0c3e0c0b046e050df sir-pwq6nmfp 0.0510000000 USD        0.0142000000 USD
0.0142000000 USD        1
```

Delete your Spot Instance data feed

To delete your data feed, use the `delete-spot-datafeed-subscription` AWS CLI command.

`aws ec2 delete-spot-datafeed-subscription`

Spot Instance quotas

There are quotas for the number of running Spot Instances and pending Spot Instance requests per AWS account per Region. Once a pending Spot Instance request is fulfilled, the request no longer counts towards the quota because the running instance is counted towards the quota.

Spot Instance quotas are managed in terms of the *number of virtual central processing units (vCPUs)* that your running Spot Instances are either using or will use pending the fulfillment of open Spot Instance requests. If you terminate your Spot Instances but do not cancel the Spot Instance requests, the requests count against your Spot Instance vCPU quota until Amazon EC2 detects the Spot Instance terminations and closes the requests.
We provide the following quota types for Spot Instances:

- All DL Spot Instance Requests
- All F Spot Instance Requests
- All G and VT Spot Instance Requests
- All Inf Spot Instance Requests
- All P Spot Instance Requests
- All Standard (A, C, D, H, I, M, R, T, Z) Spot Instance Requests
- All Trn Spot Instance Requests
- All X Spot Instance Requests

Each quota type specifies the maximum number of vCPUs for one or more instance families. For information about the different instance families, generations, and sizes, see Amazon EC2 Instance Types.

You can launch any combination of instance types that meet your changing application needs. For example, with an All Standard Spot Instance Requests quota of 256 vCPUs, you could request 32 m5.2xlarge Spot Instances (32 x 8 vCPUs) or 16 c5.4xlarge Spot Instances (16 x 16 vCPUs).

Tasks

- Monitor Spot Instance quotas and usage
- Request a quota increase

Monitor Spot Instance quotas and usage

You can view and manage your Spot Instance quotas using the following:

- The Amazon EC2 Services quotas page in the Service Quotas console
- The get-service-quota AWS CLI

For more information, see Amazon EC2 service quotas and Viewing service quotas in the Service Quotas User Guide.

With Amazon CloudWatch metrics integration, you can monitor EC2 usage against your quotas. You can also configure alarms to warn about approaching quotas. For more information, see Service Quotas and Amazon CloudWatch alarms in the Service Quotas User Guide.
Request a quota increase

Even though Amazon EC2 automatically increases your Spot Instance quotas based on your usage, you can request a quota increase if necessary. For example, if you intend to launch more Spot Instances than your current quota allows, you can request a quota increase. You can also request a quota increase if you submit a Spot Instance request and you receive the error **Max spot instance count exceeded**. To request a quota increase, use the Service Quotas console described in [Amazon EC2 service quotas](#).

Burstable performance instances

The T instance types are **burstable performance instances**. If you launch your Spot Instances using a burstable performance instance type, and if you plan to use your burstable performance Spot Instances immediately and for a short duration, with no idle time for accruing CPU credits, we recommend that you launch them in [Standard mode](#) to avoid paying higher costs. If you launch burstable performance Spot Instances in [Unlimited mode](#) and burst CPU immediately, you’ll spend surplus credits for bursting. If you use the instance for a short duration, the instance doesn't have time to accrue CPU credits to pay down the surplus credits, and you are charged for the surplus credits when you terminate the instance.

Unlimited mode is suitable for burstable performance Spot Instances only if the instance runs long enough to accrue CPU credits for bursting. Otherwise, paying for surplus credits makes burstable performance Spot Instances more expensive than using other instances. For more information, see [When to use unlimited mode versus fixed CPU](#).

T2 instances, when configured in [Standard mode](#), get **launch credits**. T2 instances are the only burstable performance instances that get launch credits. Launch credits are meant to provide a productive initial launch experience for T2 instances by providing sufficient compute resources to configure the instance. Repeated launches of T2 instances to access new launch credits is not permitted. If you require sustained CPU, you can earn credits (by idling over some period), use [Unlimited mode](#) for T2 Spot Instances, or use an instance type with dedicated CPU.

Amazon EC2 Dedicated Hosts

An Amazon EC2 Dedicated Host is a physical server that is fully dedicated for your use. You can optionally choose to share the instance capacity with other AWS accounts. For more information, see [Cross-account Amazon EC2 Dedicated Host sharing](#).

Dedicated Hosts provide visibility and control over instance placement and they support host affinity. This means that you can launch and run instances on specific hosts, and you can ensure
that instances run only on specific hosts. For more information, see Amazon EC2 Dedicated Host auto-placement and host affinity.

Dedicated Hosts provide comprehensive Bring Your Own License (BYOL) support. They allow you to use your existing per-socket, per-core, or per-VM software licenses, including Windows Server, SQL Server, SUSE Linux Enterprise Server, Red Hat Enterprise Linux, or other software licenses that are bound to VMs, sockets, or physical cores, subject to your license terms.

If you require your instances to run on dedicated hardware, but you do not need visibility or control over instance placement, and you do not need to use per-socket or per-core software licenses, you can consider using Dedicated Instances instead. Dedicated Instances and Dedicated Hosts can both be used to launch Amazon EC2 instances onto dedicated physical servers. There are no performance, security, or physical differences between Dedicated Instances and instances on Dedicated Hosts. However, there are some key differences between them. The following table highlights some of the key differences between Dedicated Instances and Dedicated Hosts:

<table>
<thead>
<tr>
<th>Dedicated Host</th>
<th>Dedicated Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dedicated physical server</td>
<td>Physical server with instance capacity fully dedicated to your use.</td>
</tr>
<tr>
<td>Instance capacity sharing</td>
<td>Can share instance capacity with other accounts.</td>
</tr>
<tr>
<td>Billing</td>
<td>Per-host billing</td>
</tr>
<tr>
<td>Visibility of sockets, cores, and host ID</td>
<td>Provides visibility of the number of sockets and physical cores</td>
</tr>
<tr>
<td>Host and instance affinity</td>
<td>Allows you to consistently deploy your instances to the same physical server over time</td>
</tr>
</tbody>
</table>
Dedicated Hosts restrictions

Before you allocate Dedicated Hosts, take note of the following limitations and restrictions:

- To run RHEL, SUSE Linux, and SQL Server on Dedicated Hosts, you must bring your own AMIs. RHEL, SUSE Linux, and SQL Server AMIs that are offered by AWS or that are available on AWS Marketplace can't be used with Dedicated Hosts. For more information on how to create your own AMI, see [Bring your own software licenses to Amazon EC2 Dedicated Hosts](#).

  This restriction does not apply to hosts allocated for high memory instances (u-6tb1.metal, u-9tb1.metal, u-12tb1.metal, u-18tb1.metal, and u-24tb1.metal). RHEL and SUSE Linux AMIs that are offered by AWS or that are available on AWS Marketplace can be used with these hosts.

- There is a limit on the number of running Dedicated Hosts per instance family per AWS account per Region. Quotas apply to running instances only. If your instance is pending, stopping, or
stopped, it does not count towards your quota. To view the quotas for your account, or to request a quota increase, use the Service Quotas console.

- The instances that run on a Dedicated Host can only be launched in a VPC.
- Auto Scaling groups are supported when using a launch template that specifies a host resource group. For more information, see Create a launch template using advanced settings in the Amazon EC2 Auto Scaling User Guide.
- Amazon RDS instances are not supported.
- The AWS Free Usage tier is not available for Dedicated Hosts.
- Instance placement control refers to managing instance launches onto Dedicated Hosts. You cannot launch Dedicated Hosts into placement groups.
- If you allocate a host for a virtualized instance type, you can't modify the instance type to a .metal instance type after the host is allocated. For example, if you allocate a host for the m5.large instance type, you can't modify the instance type to m5.metal.

Similarly, if you allocate a host for a .metal instance type, you can't modify the instance type to a virtualized instance type after the host is allocated. For example, if you allocate a host for the m5.metal instance type, you can't modify the instance type to m5.large.

Amazon EC2 Dedicated Host pricing and billing

The price for a Dedicated Host varies by payment option.

Payment Options
- On-Demand Dedicated Hosts
- Dedicated Host Reservations
- Savings Plans
- Pricing for Windows Server on Dedicated Hosts

On-Demand Dedicated Hosts

On-Demand billing is automatically activated when you allocate a Dedicated Host to your account.

The On-Demand price for a Dedicated Host varies by instance family and Region. You pay per second (with a minimum of 60 seconds) for active Dedicated Host, regardless of the quantity or the size of instances that you choose to launch on it. For more information about On-Demand pricing, see Amazon EC2 Dedicated Hosts On-Demand Pricing.

You can release an On-Demand Dedicated Host at any time to stop accruing charges for it. For information about releasing a Dedicated Host, see Release an Amazon EC2 Dedicated Host.

Dedicated Host Reservations

Dedicated Host Reservations provide a billing discount compared to running On-Demand Dedicated Hosts. Reservations are available in three payment options:
• **No Upfront**—No Upfront Reservations provide you with a discount on your Dedicated Host usage over a term and do not require an upfront payment. Available in one-year and three-year terms. Only some instance families support the three-year term for No Upfront Reservations.

• **Partial Upfront**—A portion of the reservation must be paid upfront and the remaining hours in the term are billed at a discounted rate. Available in one-year and three-year terms.

• **All Upfront**—Provides the lowest effective price. Available in one-year and three-year terms and covers the entire cost of the term upfront, with no additional future charges.

You must have active Dedicated Hosts in your account before you can purchase reservations. Each reservation can cover one or more hosts that support the same instance family in a single Availability Zone. Reservations are applied to the instance family on the host, not the instance size. If you have three Dedicated Hosts with different instances sizes (\texttt{m4.xlarge}, \texttt{m4.medium}, and \texttt{m4.large}) you can associate a single \texttt{m4} reservation with all those Dedicated Hosts. The instance family and Availability Zone of the reservation must match that of the Dedicated Hosts you want to associate it with.

When a reservation is associated with a Dedicated Host, the Dedicated Host can't be released until the reservation's term is over.

For more information about reservation pricing, see [Amazon EC2 Dedicated Hosts Pricing](#).

**Savings Plans**

Savings Plans are a flexible pricing model that offers significant savings over On-Demand Instances. With Savings Plans, you make a commitment to a consistent amount of usage, in USD per hour, for a term of one or three years. This provides you with the flexibility to use the Dedicated Hosts that best meet your needs and continue to save money, instead of making a commitment to a specific Dedicated Host. For more information, see the [AWS Savings Plans User Guide](#).

**Note**

Savings Plans are not supported with \texttt{u-6tb1.metal}, \texttt{u-9tb1.metal}, \texttt{u-12tb1.metal}, \texttt{u-18tb1.metal}, and \texttt{u-24tb1.metal} Dedicated Hosts.
Pricing for Windows Server on Dedicated Hosts

Subject to Microsoft licensing terms, you can bring your existing Windows Server and SQL Server licenses to Dedicated Hosts. There is no additional charge for software usage if you choose to bring your own licenses.

In addition, you can also use Windows Server AMIs provided by Amazon to run the latest versions of Windows Server on Dedicated Hosts. This is common for scenarios where you have existing SQL Server licenses eligible to run on Dedicated Hosts, but need Windows Server to run the SQL Server workload. Windows Server AMIs provided by Amazon are supported on current generation instance types only. For more information, see Amazon EC2 Dedicated Hosts Pricing.

Amazon EC2 Dedicated Host instance capacity configurations

Dedicated Hosts support different configurations (physical cores, sockets, and VCPUs) that allow you to run instances of different families and sizes.

When you allocate a Dedicated Host in your account, you can choose a configuration that supports either a single instance type, or multiple instance types within the same instance family. The number of instances that you can run on a host depends on the configuration you choose.

Contents

- Single instance type support
- Multiple instance type support

Single instance type support

You can allocate a Dedicated Host that supports only one instance type. With this configuration, every instance that you launch on the Dedicated Host must be of the same instance type, which you specify when you allocate the host.

For example, you can allocate a host that supports only the m5.4xlarge instance type. In this case, you can run only m5.4xlarge instances on that host.

The number of instances that you can launch onto the host depends on the number of physical cores provided by the host, and the number of cores consumed by the specified instance type. For example, if you allocate a host for m5.4xlarge instances, the host provides 48 physical cores, and each m5.4xlarge instance consumes 8 physical cores. This means that you can launch up to 6 instances on that host (48 physical cores / 8 cores per instance = 6 instances).
Multiple instance type support

You can allocate a Dedicated Host that supports multiple instance types within the same instance family. This allows you to run different instance types on the same host, as long as they're in the same instance family and the host has sufficient instance capacity.

For example, you can allocate a host that supports different instance types within the R5 instance family. In this case, you can launch any combination of R5 instance types, such as r5.large, r5.xlarge, r5.2xlarge, and r5.4xlarge, on that host, up to the host's physical core capacity.

The following instance families support Dedicated Hosts with multiple instance type support:

- **General purpose:** A1, M5, M5n, M6i, and T3
- **Compute optimized:** C5, C5n, and C6i
- **Memory optimized:** R5, R5n, and R6i

The number of instances you can run on the host depends on the number of physical cores provided by the host, and the number of cores consumed by each instance type that you run on the host. For example, if you allocate an R5 host, which provides 48 physical cores, and you run two r5.2xlarge instances (4 cores x 2 instances) and three r5.4xlarge instances (8 cores x 3 instances), those instances consume a total of 32 cores, and you can run any combination of R5 instances as long as they do not exceed the remaining 16 cores.

However, for each instance family, there is a limit on the number of instances that can be run for each instance size. For example, an R5 Dedicated Host supports a maximum of 2 r5.8xlarge instances, which uses 32 of the physical cores. In this case, additional R5 instances of smaller sizes can then be used to fill the host to core capacity. For the supported number of instance sizes for each instance family, see the [Dedicated Hosts Configuration Table](#).

The following table shows example instance type combinations:

<table>
<thead>
<tr>
<th>Instance family</th>
<th>Example instance size combinations</th>
</tr>
</thead>
<tbody>
<tr>
<td>R5</td>
<td>Example 1: 4 x r5.4xlarge + 4 x r5.2xlarge</td>
</tr>
<tr>
<td></td>
<td>Example 2: 3 x r5.4xlarge + 1 x r5.2xlarge</td>
</tr>
<tr>
<td>Instance family</td>
<td>Example instance size combinations</td>
</tr>
<tr>
<td>-----------------</td>
<td>----------------------------------</td>
</tr>
<tr>
<td></td>
<td>Example 2: 1 x r5.12xlarge + 1 x r5.4xlarge + 1 x r5.2xlarge + 5 x r5.xlarge + 2 x r5.large</td>
</tr>
</tbody>
</table>

| C5 | Example 1: 1 x c5.9xlarge + 2 x c5.4xlarge + 1 x c5.xlarge |
|    | Example 2: 4 x c5.4xlarge + 1 x c5.xlarge + 2 x c5.large |

| M5 | Example 1: 4 x m5.4xlarge + 4 x m5.2xlarge |
|    | Example 2: 1 x m5.12xlarge + 1 x m5.4xlarge + 1 x m5.2xlarge + 5 x m5.xlarge + 2 x m5.large |

**Considerations**

Keep the following in mind when working with Dedicated Hosts that support multiple instance types:

- With N-type Dedicated Hosts, such as C5n, M5n, and R5n, you can't mix smaller instance sizes (2xlarge and smaller) with larger instance sizes (4xlarge and larger, including metal). If you require smaller and larger instance sizes on N-type Dedicated Hosts at the same time, you must allocate separate hosts for the smaller and larger instance sizes.
- We recommend that you launch larger instance types first, and then fill the remaining instance capacity with smaller instance types as needed.

**Burstable T3 instances on Amazon EC2 Dedicated Hosts**

Dedicated Hosts support burstable performance T3 instances. T3 instances provide a cost-efficient way of using your eligible BYOL license software on dedicated hardware. The smaller vCPU
footprint of T3 instances enables you to consolidate your workloads on fewer hosts and maximize your per-core license utilization.

T3 Dedicated Hosts are best suited for running BYOL software with low to moderate CPU utilization. This includes eligible per-socket, per-core, or per-VM software licenses, such as Windows Server, Windows Desktop, SQL Server, SUSE Enterprise Linux Server, Red Hat Enterprise Linux, and Oracle Database. Examples of workloads suited for T3 Dedicated Hosts are small and medium databases, virtual desktops, development and test environments, code repositories, and product prototypes. T3 Dedicated Hosts are not recommended for workloads with sustained high CPU utilization or for workloads that experience correlated CPU bursts simultaneously.

T3 instances on Dedicated Hosts use the same credit model as T3 instances on shared tenancy hardware. However, they support the standard credit mode only; they do not support the unlimited credit mode. In standard mode, T3 instances on Dedicated Hosts earn, spend, and accrue credits in the same way as burstable instances on shared tenancy hardware. They provide a baseline CPU performance with the ability to burst above the baseline level. To burst above the baseline, the instance spends credits that it has accrued in its CPU credit balance. When the accrued credits are depleted, CPU utilization is lowered to the baseline level. For more information about standard mode, see How standard burstable performance instances work.

T3 Dedicated Hosts support all of the features offered by Amazon EC2 Dedicated Hosts, including multiple instance sizes on a single host, Host resource groups, and BYOL.

**Supported T3 instance sizes and configurations**

T3 Dedicated Hosts run general purpose burstable T3 instances that share CPU resources of the host by providing a baseline CPU performance and the ability to burst to a higher level when needed. This enables T3 Dedicated Hosts, which have 48 cores, to support up to a maximum of 192 instances per host. In order to efficiently utilize the host’s resources and to provide the best instance performance, the Amazon EC2 instance placement algorithm automatically calculates the supported number of instances and instance size combinations that can be launched on the host.

T3 Dedicated Hosts support multiple instance types on the same host. All T3 instance sizes are supported on Dedicated Hosts. You can run different combinations of T3 instances up to the CPU limit of the host.

The following table lists the supported instance types, summarizes the performance of each instance type, and indicates the maximum number of instances of each size that can be launched.
<table>
<thead>
<tr>
<th>Instance type</th>
<th>vCPUs</th>
<th>Memory (GiB)</th>
<th>Baseline CPU utilization per vCPU</th>

</table>

Monitor CPU utilization for T3 Dedicated Hosts

You can use the DedicatedHostCPUUtilization Amazon CloudWatch metric to monitor the vCPU utilization of a Dedicated Host. The metric is available in the EC2 namespace and Per-Host-Metrics dimension. For more information, see Dedicated Host metrics.

Bring your own software licenses to Amazon EC2 Dedicated Hosts

Dedicated Hosts allow you to use your existing per-socket, per-core, or per-VM software licenses. When you bring your own license, you are responsible for managing your own licenses. However, Amazon EC2 has features that help you maintain license compliance, such as instance affinity and targeted placement.

These are the general steps to follow in order to bring your own volume licensed machine image into Amazon EC2.

1. Verify that the license terms controlling the use of your machine images allow usage in a virtualized cloud environment. For more information about Microsoft Licensing, see Amazon Web Services and Microsoft Licensing.
2. After you have verified that your machine image can be used within Amazon EC2, import it using VM Import/Export. For information about how to import your machine image, see the VM Import/Export User Guide.

3. After you import your machine image, you can launch instances from it onto active Dedicated Hosts in your account.

4. When you run these instances, depending on the operating system, you might be required to activate these instances against your own KMS server (for example, Windows Server or Windows SQL Server). You can't activate your imported Windows AMI against the Amazon Windows KMS server.

Note
To track how your images are used in AWS, enable host recording in AWS Config. You can use AWS Config to record configuration changes to a Dedicated Host and use the output as a data source for license reporting. For more information, see Track Amazon EC2 Dedicated Host configuration changes using AWS Config.

Amazon EC2 Dedicated Host auto-placement and host affinity

Placement control for Dedicated Hosts happens on both the instance level and host level.

Auto-placement

Auto-placement is configured at the host level. It allows you to manage whether instances that you launch are launched onto a specific host, or onto any available host that has matching configurations.

When the auto-placement of a Dedicated Host is disabled, it only accepts Host tenancy instance launches that specify its unique host ID. This is the default setting for new Dedicated Hosts.

When the auto-placement of a Dedicated Host is enabled, it accepts any untargeted instance launches that match its instance type configuration.

When launching an instance, you need to configure its tenancy. Launching an instance onto a Dedicated Host without providing a specific Host Id enables it to launch on any Dedicated Host that has auto-placement enabled and that matches its instance type.
Host affinity

Host affinity is configured at the instance level. It establishes a launch relationship between an instance and a Dedicated Host.

When affinity is set to Host, an instance launched onto a specific host always restarts on the same host if stopped. This applies to both targeted and untargeted launches.

When affinity is set to Default, and you stop and restart the instance, it can be restarted on any available host. However, it tries to launch back onto the last Dedicated Host on which it ran (on a best-effort basis).

Allocate an Amazon EC2 Dedicated Host for use in your account

To begin using a Dedicated Host, you must first allocate it in your account. After you allocate the Dedicated Host, the Dedicated Host capacity is made available in your account immediately and you can start launching instances onto the Dedicated Host.

When you allocate a Dedicated Host in your account, you can choose a configuration that supports either a single instance type, or multiple instance types within the same instance family. The number of instances that you can run on the host depends on the configuration you choose. For more information see Amazon EC2 Dedicated Host instance capacity configurations.

Console

To allocate a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts and then choose Allocate Dedicated Host.
3. For Instance family, choose the instance family for the Dedicated Host.
4. Specify whether the Dedicated Host supports multiple instance sizes within the selected instance family, or a specific instance type only. Do one of the following.

   • To configure the Dedicated Host to support multiple instance types in the selected instance family, for Support multiple instance types, choose Enable. Enabling this allows you to launch different instance sizes from the same instance family onto the Dedicated Host. For example, if you choose the m5 instance family and choose this option, you can launch m5.xlarge and m5.4xlarge instances onto the Dedicated Host.

   • To configure the Dedicated Host to support a single instance type within the selected instance family, clear Support multiple instance types, and then for Instance type,
choose the instance type to support. This allows you to launch a single instance type on the Dedicated Host. For example, if you choose this option and specify m5.4xlarge as the supported instance type, you can launch only m5.4xlarge instances onto the Dedicated Host.

5. For **Availability Zone**, choose the Availability Zone in which to allocate the Dedicated Host.

6. To allow the Dedicated Host to accept untargeted instance launches that match its instance type, for **Instance auto-placement**, choose **Enable**. For more information about auto-placement, see Amazon EC2 Dedicated Host auto-placement and host affinity.

7. To enable host recovery for the Dedicated Host, for **Host recovery**, choose **Enable**. For more information, see Amazon EC2 Dedicated Host recovery.

8. For **Quantity**, enter the number of Dedicated Hosts to allocate.

9. (Optional) Choose **Add new tag** and enter a tag key and a tag value.

10. Choose **Allocate**.

**AWS CLI**

**To allocate a Dedicated Host**

Use the `allocate-hosts` AWS CLI command. The following command allocates a Dedicated Host that supports multiple instance types from the m5 instance family in us-east-1a Availability Zone. The host also has host recovery enabled and it has auto-placement disabled.

```
aws ec2 allocate-hosts --instance-family "m5" --availability-zone "us-east-1a" --auto-placement "off" --host-recovery "on" --quantity 1
```

The following command allocates a Dedicated Host that supports untargeted m4.large instance launches in the eu-west-1a Availability Zone, enables host recovery, and applies a tag with a key of purpose and a value of production.

```
aws ec2 allocate-hosts --instance-type "m4.large" --availability-zone "eu-west-1a" --auto-placement "on" --host-recovery "on" --quantity 1 --tag-specifications 'ResourceType=dedicated-host,Tags=[{{Key=purpose,Value=production}}]'
```

**PowerShell**

**To allocate a Dedicated Host**
Use the **New-EC2Host** AWS Tools for Windows PowerShell command. The following command allocates a Dedicated Host that supports multiple instance types from the m5 instance family in us-east-1a Availability Zone. The host also has host recovery enabled and it has auto-placement disabled.

```powershell
PS C:\> New-EC2Host -InstanceFamily m5 -AvailabilityZone us-east-1a -AutoPlacement Off -HostRecovery On -Quantity 1
```

The following commands allocate a Dedicated Host that supports *untargeted* m4.large instance launches in the eu-west-1a Availability Zone, enable host recovery, and apply a tag with a key of purpose and a value of production.

The `TagSpecification` parameter used to tag a Dedicated Host on creation requires an object that specifies the type of resource to be tagged, the tag key, and the tag value. The following commands create the required object.

```powershell
PS C:\> $tag = @{ Key="purpose"; Value="production" };
PS C:\> $tagspec = new-object Amazon.EC2.Model.TagSpecification
PS C:\> $tagspec.ResourceType = "dedicated-host"
PS C:\> $tagspec.Tags.Add($tag)
```

The following command allocates the Dedicated Host and applies the tag specified in the `$tagspec` object.

```powershell
PS C:\> New-EC2Host -InstanceType m4.large -AvailabilityZone eu-west-1a -AutoPlacement On -HostRecovery On -Quantity 1 -TagSpecification $tagspec
```

## Launch Amazon EC2 instances on an Amazon EC2 Dedicated Host

After you have allocated a Dedicated Host, you can launch instances onto it. You can't launch instances with host tenancy if you do not have active Dedicated Hosts with enough available capacity for the instance type that you are launching.

**Tip**

For Dedicated Hosts that support multiple instance sizes, we recommend that you launch the larger instance sizes first, and then fill the remaining instance capacity with the smaller instance sizes as needed.
Before you launch your instances, take note of the limitations. For more information, see Dedicated Hosts restrictions.

You can launch an instance onto a Dedicated Host using the following methods.

Console

To launch an instance onto a specific Dedicated Host from the Dedicated Hosts page

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Dedicated Hosts in the navigation pane.
3. On the Dedicated Hosts page, select a host and choose Actions, Launch Instance(s) onto host.
4. In the Application and OS Images section, select an AMI from the list.

   Note
   SQL Server, SUSE, and RHEL AMIs provided by Amazon EC2 can't be used with Dedicated Hosts.

5. In the Instance type section, select the instance type to launch.

   Note
   If the Dedicated Host supports a single instance type only, the supported instance type is selected by default and can't be changed.
   If the Dedicated Host supports multiple instance types, you must select an instance type within the supported instance family based on the available instance capacity of the Dedicated Host. We recommend that you launch the larger instance sizes first, and then fill the remaining instance capacity with the smaller instance sizes as needed.

6. In the Key pair section, select the key pair to associate with the instance.
7. In the Advanced details section, for Tenancy affinity, choose one of the following:
   - Off — Host affinity disabled. The instance launches onto the specified host, but it is not guaranteed to restart on the same Dedicated Host if stopped.
• A Dedicated Host ID — Host affinity enabled. If stopped, the instance always restarts on this specified host if it has capacity. If the host does not have capacity, the instance can't be restarted; you must establish affinity with a different host.

For more information about Affinity, see Amazon EC2 Dedicated Host auto-placement and host affinity.

**Note**
The Tenancy and Host options are pre-configured based on the host that you selected.

8. Configure the remaining instance options as needed. For more information, see Launch an instance using defined parameters.

9. Choose Launch instance.

**To launch an instance onto a Dedicated Host using the Launch Instance wizard**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the navigation pane, choose Instances, Launch instance.

3. In the Application and OS Images section, select an AMI from the list.

**Note**
SQL Server, SUSE, and RHEL AMIs provided by Amazon EC2 can't be used with Dedicated Hosts.

4. In the Instance type section, select the instance type to launch.

5. In the Key pair section, select the key pair to associate with the instance.

6. In the Advanced details section, do the following:

   a. For Tenancy, select Dedicated Host.
   
   b. For Target host by, select Host ID.
   
   c. For Target host ID, select the host onto which to launch the instance.
   
   d. For Tenancy affinity, choose one of the following:
• **Off** — Host affinity disabled. The instance launches onto the specified host, but it is not guaranteed to restart on the same Dedicated Host if stopped.

• A Dedicated Host ID — Host affinity enabled. If stopped, the instance always restarts on this specified host if it has capacity. If the host does not have capacity, the instance can’t be restarted; you must establish affinity with a different host.

For more information about Affinity, see Amazon EC2 Dedicated Host auto-placement and host affinity.

7. Configure the remaining instance options as needed. For more information, see Launch an instance using defined parameters.

8. Choose **Launch instance**.

**AWS CLI**

**To launch an instance onto a Dedicated Host**

Use the `run-instances` AWS CLI command and specify the instance affinity, tenancy, and host in the `Placement` request parameter.

**PowerShell**

**To launch an instance onto a Dedicated Host**

Use the `New-EC2Instance` AWS Tools for Windows PowerShell command and specify the instance affinity, tenancy, and host in the `Placement` request parameter.

**Launch Amazon EC2 instances into a host resource group**

Dedicated Hosts are also integrated with AWS License Manager. With License Manager, you can create a host resource group, which is a collection of Dedicated Hosts that are managed as a single entity. When creating a host resource group, you specify the host management preferences, such as auto-allocate and auto-release, for the Dedicated Hosts. This allows you to launch instances onto Dedicated Hosts without manually allocating and managing those hosts. For more information, see **Host Resource Groups** in the **AWS License Manager User Guide**.

When you launch an instance into a host resource group that has a Dedicated Host with available instance capacity, Amazon EC2 launches the instance onto that host. If the host resource group does not have a host with available instance capacity, Amazon EC2 automatically allocates a
new host in the host resource group, and then launches the instance onto that host. For more information, see [Host Resource Groups](#) in the [AWS License Manager User Guide](#).

**Requirements and limits**

- You must associate a core- or socket-based license configuration with the AMI.
- You can't use SQL Server, SUSE, or RHEL AMIs provided by Amazon EC2 with Dedicated Hosts.
- You can't target a specific host by choosing a host ID, and you can't enable instance affinity when launching an instance into a host resource group.

You can launch an instance into a host resource group using the following methods.

**Console**

**To launch an instance into a host resource group**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances, Launch instance**.
3. In the **Application and OS Images** section, select an AMI from the list.

   **Note**

   SQL Server, SUSE, and RHEL AMIs provided by Amazon EC2 can't be used with Dedicated Hosts.

4. In the **Instance type** section, select the instance type to launch.
5. In the **Key pair** section, select the key pair to associate with the instance.
6. In the **Advanced details** section, do the following:

   a. For **Tenancy**, select **Dedicated Host**.
   b. For **Target host by**, select **Host resource group**.
   c. For **Tenancy host resource group**, select the host resource group into which to launch the instance.
   d. For **Tenancy affinity**, do one of the following:

      - Select **Off** — The instance launches onto the specified host, but it is not guaranteed to restart on the same Dedicated Host if stopped.
• Select the Dedicated Host ID — If stopped, the instance always restarts on this specific host.

For more information about Affinity, see Amazon EC2 Dedicated Host auto-placement and host affinity.

7. Configure the remaining instance options as needed. For more information, see Launch an instance using defined parameters.

8. Choose Launch instance.

AWS CLI

To launch an instance into a host resource group

Use the run-instances AWS CLI command, and in the Placement request parameter, omit the Tenancy option and specify the host resource group ARN.

PowerShell

To launch an instance into a host resource group

Use the New-EC2Instance AWS Tools for Windows PowerShell command, and in the Placement request parameter, omit the Tenancy option and specify the host resource group ARN.

Modify the auto-placement setting for an existing Amazon EC2 Dedicated Host

You can modify the auto-placement settings of a Dedicated Host after you have allocated it to your AWS account, using one of the following methods.

Console

To modify the auto-placement of a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts.
3. Select a host and choose Actions, Modify host.
4. For Instance auto-placement, choose Enable to enable auto-placement, or clear Enable to disable auto-placement. For more information, see Amazon EC2 Dedicated Host auto-placement and host affinity.
5. Choose Save.

AWS CLI

**To modify the auto-placement of a Dedicated Host**

Use the `modify-hosts` AWS CLI command. The following example enables auto-placement for the specified Dedicated Host.

```bash
aws ec2 modify-hosts --auto-placement on --host-ids h-012a3456b7890cdef
```

PowerShell

**To modify the auto-placement of a Dedicated Host**

Use the `Edit-EC2Host` AWS Tools for Windows PowerShell command. The following example enables auto-placement for the specified Dedicated Host.

```powershell
PS C:\> Edit-EC2Host --AutoPlacement 1 --HostId h-012a3456b7890cdef
```

**Modify supported instance types for an existing Amazon EC2 Dedicated Host**

You can modify a Dedicated Host to change the instance types that it supports. If it currently supports a single instance type, you can modify it to support multiple instance types within that instance family. Similarly, if it currently supports multiple instance types, you can modify it to support a specific instance type only.

To modify a Dedicated Host to support multiple instance types, you must first stop all running instances on the host. The modification takes approximately 10 minutes to complete. The Dedicated Host transitions to the pending state while the modification is in progress. You can't start stopped instances or launch new instances on the Dedicated Host while it is in the pending state.

To modify a Dedicated Host that supports multiple instance types to support only a single instance type, the host must either have no running instances, or the running instances must be of the instance type that you want the host to support. For example, to modify a host that supports multiple instance types in the m5 instance family to support only m5.large instances, the Dedicated Host must either have no running instances, or it must have only m5.large instances running on it.
If you allocate a host for a virtualized instance type, you can't modify the instance type to a .metal instance type after the host is allocated. For example, if you allocate a host for the m5.large instance type, you can't modify the instance type to m5.metal. Similarly, if you allocate a host for a .metal instance type, you can't modify the instance type to a virtualized instance type after the host is allocated. For example, if you allocate a host for the m5.metal instance type, you can't modify the instance type to m5.large.

You can modify the supported instance types using one of the following methods.

Console

To modify the supported instance types for a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the Navigation pane, choose Dedicated Host.
3. Select the Dedicated Host to modify and choose Actions, Modify host.
4. Do one of the following, depending on the current configuration of the Dedicated Host:

   - If the Dedicated Host currently supports a specific instance type, Support multiple instance types is not enabled, and Instance type lists the supported instance type. To modify the host to support multiple types in the current instance family, for Support multiple instance types, choose Enable.

     You must first stop all instances running on the host before modifying it to support multiple instance types.

   - If the Dedicated Host currently supports multiple instance types in an instance family, Enabled is selected for Support multiple instance types. To modify the host to support a specific instance type, for Support multiple instance types, clear Enable, and then for Instance type, select the specific instance type to support.

     You can't change the instance family supported by the Dedicated Host.

5. Choose Save.

AWS CLI

To modify the supported instance types for a Dedicated Host

Use the modify-hosts AWS CLI command.
The following command modifies a Dedicated Host to support multiple instance types within the m5 instance family.

```
aws ec2 modify-hosts --instance-family m5 --host-ids h-012a3456b7890cdef
```

The following command modifies a Dedicated Host to support m5.xlarge instances only.

```
aws ec2 modify-hosts --instance-type m5.xlarge --instance-family --host-ids h-012a3456b7890cdef
```

**PowerShell**

To modify the supported instance types for a Dedicated Host

The following command modifies a Dedicated Host to support multiple instance types within the m5 instance family.

```
PS C:\> Edit-EC2Host --InstanceFamily m5 --HostId h-012a3456b7890cdef
```

The following command modifies a Dedicated Host to support m5.xlarge instances only.

```
PS C:\> Edit-EC2Host --InstanceType m5.xlarge --HostId h-012a3456b7890cdef
```

**Modify Amazon EC2 Dedicated Host tenancy and affinity for an Amazon EC2 instance**

You can change the tenancy of an instance after you have launched it. You can also modify the affinity for your instance to target a specific host or allow it to launch on any available dedicated host with matching attributes in your account. To modify either instance tenancy or affinity, the instance must be in the stopped state.

The operating system details of your instance—and whether SQL Server is installed—affect what conversions are supported. For more information about the tenancy conversion paths available to your instance, see [Tenancy conversion](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/using-sqlserver-tenancy-conversion.html) in the [License Manager User Guide](https://docs.aws.amazon.com/license-manager/latest/userguide/).
Note

For T3 instances, you must launch the instance on a Dedicated Host to use a tenancy of host. For T3 instances, you can't change the tenancy from host to dedicated or default. Attempting to make one of these unsupported tenancy changes results in an InvalidRequest error code.

You can modify an instance's tenancy and affinity using the following methods.

Console

To modify instance tenancy or affinity

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Instances, and select the instance to modify.
3. Choose Instance state, Stop.
4. With the instance selected, choose Actions, Instance settings, Modify instance placement.
5. On the Modify instance placement page, configure the following:
   - Tenancy—Choose one of the following:
     - Run a dedicated hardware instance—Launches the instance as a Dedicated Instance. For more information, see Amazon EC2 Dedicated Instances.
     - Launch the instance on a Dedicated Host—Launches the instance onto a Dedicated Host with configurable affinity.
   - Affinity—Choose one of the following:
     - This instance can run on any one of my hosts—The instance launches onto any available Dedicated Host in your account that supports its instance type.
     - This instance can only run on the selected host—The instance is only able to run on the Dedicated Host selected for Target Host.
   - Target Host—Select the Dedicated Host that the instance must run on. If no target host is listed, you might not have available, compatible Dedicated Hosts in your account.

For more information, see Amazon EC2 Dedicated Host auto-placement and host affinity.
6. Choose Save.
AWS CLI

To modify instance tenancy or affinity

Use the modify-instance-placement AWS CLI command. The following example changes the specified instance's affinity from default to host, and specifies the Dedicated Host that the instance has affinity with.

```
aws ec2 modify-instance-placement --instance-id i-1234567890abcdef0 --affinity host --tenancy host --host-id h-012a34567890cdef
```

PowerShell

To modify instance tenancy or affinity

Use the Edit-EC2InstancePlacement AWS Tools for Windows PowerShell command. The following example changes the specified instance's affinity from default to host, and specifies the Dedicated Host that the instance has affinity with.

```
PS C:\> Edit-EC2InstancePlacement -InstanceId i-1234567890abcdef0 -Affinity host -Tenancy host -HostId h-012a34567890cdef
```

Release an Amazon EC2 Dedicated Host

If you no longer need Dedicated Host, you can stop the instances running on the host, direct them to launch on a different host, and then release the host.

Any running instances on the Dedicated Host must be stopped before you can release the host. These instances can be migrated to other Dedicated Hosts in your account so that you can continue to use them. These steps apply only to On-Demand Dedicated Hosts.

You can release a Dedicated Host using the following methods.

Console

To release a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts.
3. On the Dedicated Hosts page, select the Dedicated Host to release.

5. To confirm, choose Release.

AWS CLI

**To release a Dedicated Host**

Use the `release-hosts` AWS CLI command.

```bash
aws ec2 release-hosts --host-ids h-012a3456b7890cdef
```

**PowerShell**

**To release a Dedicated Host**

```powershell
PS C:\> Remove-EC2Hosts -HostId h-012a3456b7890cdef
```

After you release a Dedicated Host, you can't reuse the same host or host ID again, and you are no longer charged On-Demand billing rates for it. The state of the Dedicated Host is changed to released, and you are not able to launch any instances onto that host.

**Note**

If you have recently released Dedicated Hosts, it can take some time for them to stop counting towards your limit. During this time, you might experience LimitExceeded errors when trying to allocate new Dedicated Hosts. If this is the case, try allocating new hosts again after a few minutes.

The instances that were stopped are still available for use and are listed on the **Instances** page. They retain their host tenancy setting.

**Purchase Dedicated Host Reservations for Dedicated Host billing discounts**

Dedicated Host Reservations provide you with a discount of up to 70 percent compared to On-Demand Dedicated Host pricing. You must have active Dedicated Hosts allocated in your account...
before you can purchase Dedicated Host Reservations. For more information, see Dedicated Host Reservations.

You can purchase Dedicated Host Reservations using the following methods:

Console

**To purchase reservations**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Dedicated Hosts, Dedicated Host Reservations, Purchase Dedicated Host Reservation.
3. On the Find offerings screen, do the following:
   a. For Instance family, select the instance family of the Dedicated Host for which to purchase the Dedicated Host Reservation.
   b. For Payment option, select and configure your preferred payment option.
4. Choose Next.
5. Select the Dedicated Hosts with which to associate the Dedicated Host Reservation, and then choose Next.
6. *(Optional)* Assign tags to the Dedicated Host Reservation.
7. Review your order and choose Purchase.

AWS CLI

**To purchase reservations**

1. Use the describe-host-reservation-offerings AWS CLI command to list the available offerings that match your needs. The following example lists the offerings that support instances in the m4 instance family and have a one-year term.

   ```
   Note
   The term is specified in seconds. A one-year term includes 31,536,000 seconds, and a three-year term includes 94,608,000 seconds.
   ```
aws ec2 describe-host-reservation-offerings --filter Name=instance-family,Values=m4 --max-duration 31536000

The command returns a list of offerings that match your criteria. Note the offeringId of the offering to purchase.

2. Use the purchase-host-reservation AWS CLI command to purchase the offering and provide the offeringId noted in the previous step. The following example purchases the specified reservation and associates it with a specific Dedicated Host that is already allocated in the AWS account, and it applies a tag with a key of purpose and a value of production.

aws ec2 purchase-host-reservation --offering-id hro-03f707bf363b6b324 --host-id-set h-013abcd2a00cbd123 --tag-specifications 'ResourceType=host-reservation,Tags={Key=purpose,Value=production}'

PowerShell

To purchase reservations

1. Use the Get-EC2HostReservationOffering AWS Tools for Windows PowerShell command to list the available offerings that match your needs. The following examples list the offerings that support instances in the m4 instance family and have a one-year term.

    $filter = @{Name="instance-family"; Value="m4"}

    Get-EC2HostReservationOffering -filter $filter -MaxDuration 31536000

    The command returns a list of offerings that match your criteria. Note the offeringId of the offering to purchase.

    Note

    The term is specified in seconds. A one-year term includes 31,536,000 seconds, and a three-year term includes 94,608,000 seconds.
2. Use the `New-EC2HostReservation` AWS Tools for Windows PowerShell command to purchase the offering and provide the `offeringId` noted in the previous step. The following example purchases the specified reservation and associates it with a specific Dedicated Host that is already allocated in the AWS account.

```
PS C:\> New-EC2HostReservation -OfferingId hro-03f707bf363b6b324 -HostIdSet h-013abcd2a00cbd123
```

Cross-account Amazon EC2 Dedicated Host sharing

Dedicated Host sharing enables Dedicated Host owners to share their Dedicated Hosts with other AWS accounts or within an AWS organization. This enables you to create and manage Dedicated Hosts centrally, and share the Dedicated Host across multiple AWS accounts or within your AWS organization.

In this model, the AWS account that owns the Dedicated Host (owner) shares it with other AWS accounts (consumers). Consumers can launch instances onto Dedicated Hosts that are shared with them in the same way that they would launch instances onto Dedicated Hosts that they allocate in their own account. The owner is responsible for managing the Dedicated Host and the instances that they launch onto it. Owners can't modify instances that consumers launch onto shared Dedicated Hosts. Consumers are responsible for managing the instances that they launch onto Dedicated Hosts shared with them. Consumers can't view or modify instances owned by other consumers or by the Dedicated Host owner, and they can't modify Dedicated Hosts that are shared with them.

A Dedicated Host owner can share a Dedicated Host with:

- Specific AWS accounts inside or outside of its AWS organization
- An organizational unit inside its AWS organization
- Its entire AWS organization

Contents

- Prerequisites for sharing Dedicated Hosts
- Limitations for sharing Dedicated Hosts
- Related services
- Share across Availability Zones
Prerequisites for sharing Dedicated Hosts

To share a Dedicated Host, you must own it in your AWS account. You can't share a Dedicated Host that has been shared with you.

To share a Dedicated Host with your AWS organization or an organizational unit in your AWS organization, you must enable sharing with AWS Organizations. For more information, see Enable Sharing with AWS Organizations in the AWS RAM User Guide.

Limitations for sharing Dedicated Hosts

You can't share Dedicated Hosts that have been allocated for the following instance types: u-6tb1.metal, u-9tb1.metal, u-12tb1.metal, u-18tb1.metal, and u-24tb1.metal.

Related services

AWS Resource Access Manager

Dedicated Host sharing integrates with AWS Resource Access Manager (AWS RAM). AWS RAM is a service that enables you to share your AWS resources with any AWS account or through AWS Organizations. With AWS RAM, you share resources that you own by creating a resource share. A resource share specifies the resources to share, and the consumers with whom to share them. Consumers can be individual AWS accounts, or organizational units or an entire organization from AWS Organizations.

For more information about AWS RAM, see the AWS RAM User Guide.

Share across Availability Zones

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each account. This could lead to Availability

Dedicated Hosts
Zone naming differences across accounts. For example, the Availability Zone us-east-1a for your AWS account might not have the same location as us-east-1a for another AWS account.

To identify the location of your Dedicated Hosts relative to your accounts, you must use the Availability Zone ID (AZ ID). The Availability Zone ID is a unique and consistent identifier for an Availability Zone across all AWS accounts. For example, use1-az1 is an Availability Zone ID for the us-east-1 Region and it is the same location in every AWS account.

**To view the Availability Zone IDs for the Availability Zones in your account**

2. The Availability Zone IDs for the current Region are displayed in the **Your AZ ID** panel on the right-hand side of the screen.

**Shared Dedicated Host permissions**

**Permissions for owners**

Owners are responsible for managing their shared Dedicated Hosts and the instances that they launch onto them. Owners can view all instances running on the shared Dedicated Host, including those launched by consumers. However, owners can't take any action on running instances that were launched by consumers.

**Permissions for consumers**

Consumers are responsible for managing the instances that they launch onto a shared Dedicated Host. Consumers can't modify the shared Dedicated Host in any way, and they can't view or modify instances that were launched by other consumers or the Dedicated Host owner.

**Billing and metering**

There are no additional charges for sharing Dedicated Hosts.

Owners are billed for Dedicated Hosts that they share. Consumers are not billed for instances that they launch onto shared Dedicated Hosts.

Dedicated Host Reservations continue to provide billing discounts for shared Dedicated Hosts. Only Dedicated Host owners can purchase Dedicated Host Reservations for shared Dedicated Hosts that they own.
Dedicated Host limits

Shared Dedicated Hosts count towards the owner's Dedicated Hosts limits only. Consumer's Dedicated Hosts limits are not affected by Dedicated Hosts that have been shared with them. Similarly, instances that consumers launch onto shared Dedicated Hosts do not count towards their instance limits.

Host recovery and Dedicated Host sharing

Host recovery recovers instances launched by the Dedicated Host owner and the consumers with whom it has been shared. The replacement Dedicated Host is allocated to the owner's account. It is added to the same resource shares as the original Dedicated Host, and it is shared with the same consumers.

For more information, see Amazon EC2 Dedicated Host recovery.

Share an Amazon EC2 Dedicated Host across AWS accounts

When an owner shares a Dedicated Host, it enables consumers to launch instances on the host. Consumers can launch as many instances onto the shared host as its available capacity allows.

⚠️ Important

Note that you are responsible for ensuring that you have appropriate license rights to share any BYOL licenses on your Dedicated Hosts.

If you share a Dedicated Host with auto-placement enabled, keep the following in mind as it could lead to unintended Dedicated Host usage:

- If consumers launch instances with Dedicated Host tenancy and they do not have capacity on a Dedicated Host that they own in their account, the instance is automatically launched onto the shared Dedicated Host.

To share a Dedicated Host, you must add it to a resource share. A resource share is an AWS RAM resource that lets you share your resources across AWS accounts. A resource share specifies the resources to share, and the consumers with whom they are shared. You can add the Dedicated Host to an existing resource, or you can add it to a new resource share.
If you are part of an organization in AWS Organizations and sharing within your organization is enabled, consumers in your organization are automatically granted access to the shared Dedicated Host. Otherwise, consumers receive an invitation to join the resource share and are granted access to the shared Dedicated Host after accepting the invitation.

**Note**

After you share a Dedicated Host, it could take a few minutes for consumers to have access to it.

You can share a Dedicated Host that you own by using one of the following methods.

**Amazon EC2 console**

**To share a Dedicated Host that you own using the Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose *Dedicated Hosts*.
3. Choose the Dedicated Host to share and choose *Actions, Share host*.
4. Select the resource share to which to add the Dedicated Host and choose *Share host*.

   It could take a few minutes for consumers to get access to the shared host.

**AWS RAM console**

**To share a Dedicated Host that you own using the AWS RAM console**

**AWS CLI**

**To share a Dedicated Host that you own using the AWS CLI**

Use the `create-resource-share` command.

**Unshare a Dedicated Host that is shared with other AWS accounts**

The Dedicated Host owner can unshare a shared Dedicated Host at any time. When you unshare a shared Dedicated Host, the following rules apply:
• Consumers with whom the Dedicated Host was shared can no longer launch new instances onto it.
• Instances owned by consumers that were running on the Dedicated Host at the time of unsharing continue to run but are scheduled for retirement. Consumers receive retirement notifications for the instances and they have two weeks to take action on the notifications. However, if the Dedicated Host is resharred with the consumer within the retirement notice period, the instance retirements are cancelled.

To unshare a shared Dedicated Host that you own, you must remove it from the resource share. You can do this by using one of the following methods.

Amazon EC2 console

To unshare a shared Dedicated Host that you own using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts.
3. Choose the Dedicated Host to unshare and choose the Sharing tab.
4. The Sharing tab lists the resource shares to which the Dedicated Host has been added. Select the resource share from which to remove the Dedicated Host and choose Remove host from resource share.

AWS RAM console

To unshare a shared Dedicated Host that you own using the AWS RAM console

See Updating a Resource Share in the AWS RAM User Guide.

Command line

To unshare a shared Dedicated Host that you own using the AWS CLI

Use the disassociate-resource-share command.

View shared Amazon EC2 Dedicated Hosts in your AWS account

You can view Dedicated Host that you are sharing with other accounts, and Dedicated Hosts that are shared with you. If you own the Dedicated Host, you can see all of the instances running on the
host, including instances launched by consumers. If the Dedicated Host is shared with you, you can see only the instances that you launched onto the shared host, and not those launched by other consumers.

Owners and consumers can identify shared Dedicated Hosts using one of the following methods.

**Amazon EC2 console**

To identify a shared Dedicated Host using the Amazon EC2 console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Dedicated Hosts**. The screen lists Dedicated Hosts that you own and Dedicated Hosts that are shared with you. The **Owner** column shows the AWS account ID of the Dedicated Host owner. To view the instances running on the hosts, select the **Instances** tab.

**Command line**

To identify a shared Dedicated Host using the AWS CLI

Use the `describe-hosts` command. The command returns the Dedicated Hosts that you own and Dedicated Hosts that are shared with you.

**Amazon EC2 Dedicated Hosts on AWS Outposts**

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to your premises. By providing local access to AWS managed infrastructure, AWS Outposts enables you to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs.

An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region.

You can allocate Dedicated Hosts on Outposts that you own in your account. This makes it easier for you to bring your existing software licenses and workloads that require a dedicated physical server to AWS Outposts. You can also target specific hardware assets on an Outpost to help minimize latency between your workloads.
Dedicated Hosts allow you to use your eligible software licenses on Amazon EC2, so that you get the flexibility and cost effectiveness of using your own licenses. Other software licenses that are bound to virtual machines, sockets, or physical cores, can also be used on Dedicated Hosts, subject to their license terms. While Outposts have always been a single-tenant environments that are eligible for BYOL workloads, Dedicated Hosts allows you to limit the needed licenses to a single host as opposed to the entire Outpost deployment.

Additionally, using Dedicated Hosts on an Outpost gives you greater flexibility in instance type deployment, and more granular control over instance placement. You can target a specific host for instance launches and use host affinity to ensure that the instance always runs on that host, or you can use auto-placement to launch an instance onto any available host that has matching configurations and available capacity.

Contents

- Prerequisites
- Supported features
- Considerations
- Allocate an Amazon EC2 Dedicated Host on AWS Outposts

Prerequisites

You must have an Outpost installed at your site. For more information, see Create an Outpost and order Outpost capacity in the AWS Outposts User Guide.

Supported features

- The following instance families are supported: C5, M5, R5, C5d, M5d, R5d, G4dn, and i3en.
- Dedicated Hosts on Outposts can be configured to support multiple instance sizes. Support for multiple instance sizes is available for the following instance families: C5, M5, R5, C5d, M5d, and R5d. For more information, see Amazon EC2 Dedicated Host instance capacity configurations.
- Dedicated Hosts on Outposts support auto-placement and targeted instance launches. For more information, see Amazon EC2 Dedicated Host auto-placement and host affinity.
- Dedicated Hosts on Outposts support host affinity. For more information, see Amazon EC2 Dedicated Host auto-placement and host affinity.
- Dedicated Hosts on Outposts support sharing with AWS RAM. For more information, see Cross-account Amazon EC2 Dedicated Host sharing.
Considerations

- Dedicated Host Reservations are not supported on Outposts.
- Host resource groups and AWS License Manager are not supported on Outposts.
- Dedicated Hosts on Outposts do not support burstable T3 instances.
- Dedicated Hosts on Outposts do not support host recovery.
- Simplified automatic recovery is not supported for instances with Dedicated Host tenancy on Outposts.

Allocate an Amazon EC2 Dedicated Host on AWS Outposts

You allocate and use Dedicated Hosts on Outposts in the same way that would with Dedicated Hosts in an AWS Region.

Prerequisites

Create a subnet on the Outpost. For more information, see Create a subnet in the AWS Outposts User Guide.

To allocate a Dedicated Host on an Outpost, use one of the following methods:

AWS Outposts console

1. Open the AWS Outposts console at https://console.aws.amazon.com/outposts/.
2. In the navigation pane, choose Outposts. Select the Outpost and then choose Actions, Allocate Dedicated Host.
3. Configure the Dedicated Host as needed. For more information, see Allocate an Amazon EC2 Dedicated Host for use in your account.

Note

Availability Zone and Outpost ARN should be pre-populated with the Availability Zone and ARN of the selected Outpost.

4. Choose Allocate.
Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts, and then choose Allocate Dedicated Host.
3. For Availability Zone, select the Availability Zone associated with the Outpost.
4. For Outpost ARN, enter the ARN of the Outpost.
5. To target specific hardware assets on the Outpost, for Target specific hardware assets on Outpost, select Enable. For each hardware asset to target, choose Add asset ID, and then enter the ID of the hardware asset.

Note
The value that you specify for Quantity must be equal to the number of asset IDs that you specify. For example, if you specify 3 asset IDs, then Quantity must also be 3.

6. Configure the remaining Dedicated Host settings as needed. For more information, see Allocate an Amazon EC2 Dedicated Host for use in your account.
7. Choose Allocate.

AWS CLI

Use the allocate-hosts AWS CLI command. For --availability-zone, specify the Availability Zone associated with the Outpost. For --outpost-arn, specify the ARN of the Outpost. Optionally, for --asset-ids, specify the IDs of the Outpost hardware assets to target.

aws ec2 allocate-hosts --availability-zone "us-east-1a" --outpost-arn "arn:aws:outposts:us-east-1a:11112223333:outpost/op-4fe3dc21baEXAMPLE" --asset-ids asset_id --instance-family "m5" --auto-placement "off" --quantity 1

To launch an instance onto a Dedicated Host on an Outpost

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts. Select the Dedicated Host that you allocated in the previous step and choose Actions, Launch instance onto host.
3. Configure the instance as needed and then launch the instance. For more information, see Launch Amazon EC2 instances on an Amazon EC2 Dedicated Host.

Amazon EC2 Dedicated Host recovery

Dedicated Host auto recovery restarts your instances on to a new replacement host when certain problematic conditions are detected on your Dedicated Host. Host recovery reduces the need for manual intervention and lowers the operational burden if there is an unexpected Dedicated Host failure concerning system power or network connectivity events. Other Dedicated Host issues will require manual intervention to recover from.

Contents

- How Amazon EC2 Dedicated Host works
- Supported instance types
- Pricing
- Enable Amazon EC2 Dedicated Host recovery
- Disable Amazon EC2 Dedicated Host recovery
- View the host recovery setting for your Amazon EC2 Dedicated Host
- Manually recover instances that are not supported by Amazon EC2 Dedicated Host recovery

How Amazon EC2 Dedicated Host works

Dedicated Hosts and the host resource groups recovery process use host-level health checks to assess Dedicated Host availability and to detect underlying system failures. The type of Dedicated Host failure determines if Dedicated Host auto recovery is possible. Examples of problems that can cause host-level health checks to fail include:

- Loss of network connectivity
- Loss of system power
- Hardware or software issues on the physical host

⚠️ Important

Dedicated Host auto recovery does not occur when the host is scheduled for retirement.
Dedicated Host auto recovery

When a system power or network connectivity failure is detected on your Dedicated Host, Dedicated Host auto recovery is initiated and Amazon EC2 automatically allocates a replacement Dedicated Host in the same Availability Zone as the original Dedicated Host. The replacement Dedicated Host receives a new host ID, but retains the same attributes as the original Dedicated Host, including:

- Availability Zone
- Instance type
- Tags
- Auto placement settings
- Reservation

When the replacement Dedicated Host is allocated, the instances are recovered on to the replacement Dedicated Host. The recovered instances retain the same attributes as the original instances, including:

- Instance ID
- Private IP addresses
- Elastic IP addresses
- EBS volume attachments
- All instance metadata

Additionally, the built-in integration with AWS License Manager automates the tracking and management of your licenses.

**Note**

AWS License Manager integration is supported only in Regions in which AWS License Manager is available.

If instances have a host affinity relationship with the impaired Dedicated Host, the recovered instances establish host affinity with the replacement Dedicated Host.
When all of the instances have been recovered on to the replacement Dedicated Host, the impaired Dedicated Host is released, and the replacement Dedicated Host becomes available for use.

When host recovery is initiated, the AWS account owner is notified by email and by an AWS Health Dashboard event. A second notification is sent after the host recovery has been successfully completed.

If you are using AWS License Manager to track your licenses, AWS License Manager allocates new licenses for the replacement Dedicated Host based on the license configuration limits. If the license configuration has hard limits that will be breached as a result of the host recovery, the recovery process is not allowed and you are notified of the host recovery failure through an Amazon SNS notification (if notification settings have been configured for AWS License Manager). If the license configuration has soft limits that will be breached as a result of the host recovery, the recovery is allowed to continue and you are notified of the limit breach through an Amazon SNS notification. For more information, see Using License Configurations and Settings in License Manager in the AWS License Manager User Guide.

**Host recovery states**

When a Dedicated Host failure is detected, the impaired Dedicated Host enters the under-assessment state, and all of the instances enter the impaired state. You can't launch instances on to the impaired Dedicated Host while it is in the under-assessment state.

After the replacement Dedicated Host is allocated, it enters the pending state. It remains in this state until the host recovery process is complete. You can't launch instances on to the replacement Dedicated Host while it is in the pending state. Recovered instances on the replacement Dedicated Host remain in the impaired state during the recovery process.

After the host recovery is complete, the replacement Dedicated Host enters the available state, and the recovered instances return to the running state. You can launch instances on to the replacement Dedicated Host after it enters the available state. The original impaired Dedicated Host is permanently released and it enters the released-permanent-failure state.

If the impaired Dedicated Host has instances that do not support host recovery, such as instances with instance store-backed volumes, the Dedicated Host is not released. Instead, it is marked for retirement and enters the permanent-failure state.
Scenarios without Dedicated Host auto recovery

**Dedicated Host auto recovery does not occur when the host is scheduled for retirement.** You will receive a retirement notification in the AWS Health Dashboard, an Amazon CloudWatch event, and the AWS account owner email address receives a message regarding the Dedicated Host failure. Follow the remedial steps described in the retirement notification within the specified time period to manually recover the instances on the retiring host.

**Stopped instances are not recovered** on to the replacement Dedicated Host. If you attempt to start a stopped instance that targets the impaired Dedicated Host, the instance start fails. We recommend that you modify the stopped instance to either target a different Dedicated Host, or to launch on any available Dedicated Host with matching configurations and auto-placement enabled.

**Instances with instance storage are not recovered** on to the replacement Dedicated Host. As a remedial measure, the impaired Dedicated Host is marked for retirement and you receive a retirement notification after the host recovery is complete. Follow the remedial steps described in the retirement notification within the specified time period to manually recover the remaining instances on the impaired Dedicated Host.

**Supported instance types**

Host recovery is supported for the following instance families: A1, C3, C4, C5, C5n, C6a, C6g, C6i, Inf1, G3, G5g, M3, M4, M5, M5n, M5zn, M6a, M6g, M6i, P2, P3, R3, R4, R5, R5b, R5n, R6g, R6i, T3, X1, X1e, X2iezn, u-6tb1, u-9tb1, u-12tb1, u-18tb1, and u-24tb1.

To recover instances that are not supported, see [Manually recover instances that are not supported by Amazon EC2 Dedicated Host recovery](#).

**Note**

Dedicated Host auto recovery of supported metal instance types will take longer to detect and recover from than non-metal instance types.

**Pricing**

There are no additional charges for using host recovery, but the usual Dedicated Host charges apply. For more information, see [Amazon EC2 Dedicated Hosts Pricing](#).

As soon as host recovery is initiated, you are no longer billed for the impaired Dedicated Host. Billing for the replacement Dedicated Host begins only after it enters the available state.
If the impaired Dedicated Host was billed using the On-Demand rate, the replacement Dedicated Host is also billed using the On-Demand rate. If the impaired Dedicated Host had an active Dedicated Host Reservation, it is transferred to the replacement Dedicated Host.

Enable Amazon EC2 Dedicated Host recovery

You can enable host recovery at the time of Dedicated Host allocation or after allocation.

For more information about enabling host recovery at the time of Dedicated Host allocation, see Allocate an Amazon EC2 Dedicated Host for use in your account.

To enable host recovery after allocation using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts.
3. Select the Dedicated Host for which to enable host recovery, and then choose Actions, Modify Host Recovery.
4. For Host recovery, choose Enable, and then choose Save.

To enable host recovery after allocation using the AWS CLI

Use the modify-hosts command and specify the host-recovery parameter.

```
$ aws ec2 modify-hosts --host-recovery on --host-ids h-012a3456b7890cdef
```

Disable Amazon EC2 Dedicated Host recovery

You can disable host recovery at any time after the Dedicated Host has been allocated.

To disable host recovery after allocation using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts.
3. Select the Dedicated Host for which to disable host recovery, and then choose Actions, Modify Host Recovery.
4. For Host recovery, choose Disable, and then choose Save.

To disable host recovery after allocation using the AWS CLI
Use the `modify-hosts` command and specify the host-recovery parameter.

```
$ aws ec2 modify-hosts --host-recovery off --host-ids h-012a3456b7890cdef
```

**View the host recovery setting for your Amazon EC2 Dedicated Host**

You can view the host recovery configuration for a Dedicated Host at any time.

**To view the host recovery configuration for a Dedicated Host using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host, and in the **Description** tab, review the **Host Recovery** field.

**To view the host recovery configuration for a Dedicated Host using the AWS CLI**

Use the `describe-hosts` command.

```
$ aws ec2 describe-hosts --host-ids h-012a3456b7890cdef
```

The `HostRecovery` response element indicates whether host recovery is enabled or disabled.

**Manually recover instances that are not supported by Amazon EC2 Dedicated Host recovery**

Host recovery does not support recovering instances that use instance store volumes. Follow the instructions below to manually recover any of your instances that could not be automatically recovered.

⚠️ **Warning**

Data on instance store volumes is lost when an instance is stopped, hibernated, or terminated. This includes instance store volumes that are attached to an instance that has an EBS volume as the root device. To protect data from instance store volumes, back it up to persistent storage before the instance is stopped or terminated.

**Manually recover EBS-backed instances**

For EBS-backed instances that could not be automatically recovered, we recommend that you manually stop and start the instances to recover them onto a new Dedicated Host. For more
information about stopping your instance, and about the changes that occur in your instance configuration when it's stopped, see Stop and start Amazon EC2 instances.

Manually recover instance store-backed instances

For instance store-backed instances that could not be automatically recovered, we recommend that you do the following:

1. Launch a replacement instance on a new Dedicated Host from your most recent AMI.
2. Migrate all of the necessary data to the replacement instance.
3. Terminate the original instance on the impaired Dedicated Host.

Host maintenance for Amazon EC2 Dedicated Host

With host maintenance, your Amazon EC2 instances on the degraded Dedicated Host are automatically rebooted on a replacement Dedicated Host during a scheduled maintenance event. This helps reduce application downtime and offloads the undifferentiated heavy-lift of maintenance to AWS. Host maintenance is also performed for planned and routine Amazon EC2 maintenance.

Host maintenance is supported on all new Dedicated Host allocations made through Amazon EC2 console. For any Dedicated Host in your AWS account or any new Dedicated Host allocated through AllocateHosts API, you can configure host maintenance for supported Dedicated Hosts. For more information, see the section called “Configure host maintenance”.

Contents

- Pricing
- How host maintenance works for Amazon EC2 Dedicated Hosts
- Configure the host maintenance setting for an Amazon EC2 Dedicated Host

Host maintenance versus host recovery

The following table shows the main differences between host recovery and host maintenance.
Host recovery | Host maintenance
---|---
Accessibility | Unreachable | Reachable
State | under-assessment | permanent-failure
Action | Recovery is immediate | Maintenance is scheduled
Scheduling flexibility | Cannot be rescheduled | Can be rescheduled
Host Resource Group | Supported | Not supported

For more information about host recovery, see [Host recovery](#).

**Supported instance types**

Host maintenance is supported for the following instance families:

- General purpose: A1 | M4 | M5 | M5a | M5n | M5zn | M6a | M6g | M6i | M6in | M7a | M7g | M7i | T3
- Compute optimized: C4 | C5 | C5a | C5n | C6a | C6g | C6i | C6in | C7g | C7gn | C7i
- Memory optimized: R4 | R5 | R5a | R5b | R5n | R6a | R6i | R6in | R7a | R7g | R7iz | u-12tb1 | u-18tb1 | u-24tb1 | u-3tb1 | u-6tb1 | u-9tb1 | X2iezn
- Accelerated computing: G3 | G5g | Inf1 | P2 | P3

**Limitations**

- Host maintenance is not supported in AWS Outposts, AWS Local Zones, and AWS Wavelength Zones.
- Host maintenance cannot be turned on or off for hosts already within a host resource group. Hosts added to a host resource group retain their host maintenance setting. For more information, see [Host resource groups](#).
- Host maintenance is only supported on specific instance types. For more information, see [the section called “Supported instance types”](#).
Related services

Dedicated Host integrates with AWS License Manager—Tracks licenses across your Amazon EC2 Dedicated Hosts (supported only in Regions in which AWS License Manager is available). For more information, see the AWS License Manager User Guide.

You must have sufficient licenses in your AWS account for your new Dedicated Host. The licenses associated with your degraded host are released when the host is released after the completion of the scheduled maintenance event.

Pricing

There are no additional charges for using host maintenance, but the usual Dedicated Host charges apply. For more information, see Amazon EC2 Dedicated Hosts Pricing.

As soon as host maintenance is initiated, you are no longer billed for the degraded Dedicated Host. Billing for the replacement Dedicated Host begins only after it enters the available state.

If the degraded Dedicated Host was billed using the On-Demand rate, the replacement Dedicated Host is also billed using the On-Demand rate. If the degraded Dedicated Host had an active Dedicated Host Reservation, it is transferred to the new Dedicated Host.

How host maintenance works for Amazon EC2 Dedicated Hosts

When degradation is detected on a Dedicated Host, a new Dedicated Host is allocated. Degradation can be caused by degradation of the underlying hardware or detection of certain problematic conditions. Your instances on the degraded Dedicated Host are scheduled to be automatically rebooted on the replacement Dedicated Host.

The replacement Dedicated Host receives a new host ID, but retains the same attributes as the original Dedicated Host. These attributes include the following.

- Auto placement settings
- Availability Zone
- Reservation
- Host affinity
- Host maintenance settings
- Host recovery settings
- Instance type
Host maintenance is available in all AWS Regions for all supported Dedicated Hosts. For more information about Dedicated Hosts where host maintenance is not supported, see the section called “Limitations”.

Your degraded Dedicated Host is released after all of your instances have been rebooted to a new Dedicated Host or stopped. You can access your instances on the degraded Dedicated Host before the scheduled maintenance event, but launching instances on the degraded Dedicated Host is not supported.

You can use the replacement Dedicated Host to launch new instances on the host before the scheduled maintenance event. However, some instance capacity on the replacement host is reserved for the instances that must be migrated from the degraded host. You can't launch new instances into this reserved capacity. For more information, see the section called “Instances on Dedicated Host”.

**Instances on Dedicated Host**

Amazon EC2 automatically reserves capacity on the replacement host for the instances that will be automatically migrated from the degraded host. Amazon EC2 does not reserve capacity on the replacement host for instances that can't be automatically migrated, such as instances with instance store root volumes. The reserved capacity can't be used to launch new instances.

**Note**

The Amazon EC2 console shows the reserved capacity as used capacity. It could appear that the instances are running on both the degraded host and the replacement host. However, the instances will continue to run only on the degraded host until they are stopped or they are migrated into the reserved capacity on the replacement host.

If you manually stop an instance on the degraded host that can be automatically migrated, the capacity that was reserved for that instance on the replacement host is released and becomes available for use.

During the scheduled maintenance event, the instances on the degraded host are rebooted and migrated into the reserved capacity on the replacement Dedicated Host. The migrated instances retain the same attributes as the ones on your degraded host, including the following.
• Amazon EBS volume attachments
• Elastic IP addresses
• Instance ID
• Instance metadata
• Private IP address

You can **stop and start an instance** on the degraded host at any point before the scheduled maintenance event is initiated. Doing this reboots your instance on to another host, and your instance won't undergo scheduled maintenance. You must update your instance's host affinity to the new host where you want to reboot your instance. If you stop all instances on the degraded host before the maintenance event is initiated, the degraded host is released and the maintenance event is canceled. For more information, see [Stop and start Amazon EC2 instances](#).

**Note**

The data on any local store volume is not preserved when you stop and start your instance.

Instances with an **instance store volume** as the root device are terminated after the specified termination date. Any data on the instance store volumes is deleted when the instances are terminated. Terminated instances are permanently deleted, and cannot be started again. For instances with instance store volumes as the root device, we recommend launching replacement instances on a different Dedicated Host using the most recent Amazon Machine Image, and migrating all available data to the replacement instances before the specified termination date. For more information, see [Actions to take for instance retirement](#).

Instances that **cannot be rebooted** automatically are stopped after the specified date. You can start these instances again on a different host. Instances using an Amazon EBS volume as a root device continue to use the same Amazon EBS volume after being started on a new host.

You can set the **order of instance reboot** by rescheduling the start time of an instance reboot in [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

**Maintenance event**

On detection of degradation, a maintenance event is scheduled 14 days later, to reboot your instances on a new Dedicated Host. You receive an email notification providing details about the
degraded host, scheduled maintenance event, and maintenance time slots. For more information, see View scheduled events.

You can reschedule the maintenance event for any day up to seven days after the date of the scheduled event. For more information about rescheduling, see Reschedule a scheduled event.

The maintenance event usually takes a few minutes to complete. In the rare case of an unsuccessful event, you receive an email notification to evict the instances on the degraded host within a specified time frame.

**Host maintenance states**

Your Dedicated Host is set to permanent-failure state when degradation is detected. You cannot launch instances on a Dedicated Host in the state of permanent-failure. On completion of maintenance event, the degraded host is released and put in the state of released, permanent-failure.

After detecting degradation on a Dedicated Host and before scheduling a maintenance event, host maintenance automatically allocates a replacement Dedicated Host in your account. This replacement host stays in a pending state until a maintenance event is scheduled. After the maintenance event is scheduled, the replacement Dedicated Host moves to the available state.

You can use the replacement Dedicated Host to launch new instances on the host before the scheduled maintenance event. However, some instance capacity on the replacement host is reserved for the instances that must be migrated from the degraded host. You can't launch new instances into this reserved capacity. For more information, see the section called “Instances on Dedicated Host”.

**Configure the host maintenance setting for an Amazon EC2 Dedicated Host**

You can configure host maintenance for all supported Dedicated Hosts via AWS Management Console or AWS CLI. See the following table for more details.

**AWS Management Console**

**To enable host maintenance for your Dedicated Host using AWS Management Console.**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts.
3. Select the Dedicated Host > Actions > Modify host.
4. Select _on_ in the **Host maintenance** field.

**To disable host maintenance for your Dedicated Host using AWS Management Console.**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host > **Actions** > **Modify host**.
4. Select _off_ in the **Host maintenance** field.

**To view the host maintenance configuration for your Dedicated Host using AWS Management Console.**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Dedicated Hosts**.
3. Select the Dedicated Host, and in the **Description** tab, review the **Host maintenance** field.

**AWS CLI**

**To enable or disable host maintenance for your new Dedicated Host during allocation using AWS CLI.**

Use the `allocate-hosts` command.

**Enable**

```
aws ec2 allocate-hosts --region us-east-1 --quantity 1 --instance-type m3.large --availability-zone us-east-1b --host-maintenance on
```

**Disable**

```
aws ec2 allocate-hosts --region us-east-1 --quantity 1 --instance-type m3.large --availability-zone us-east-1b --host-maintenance off
```

**To enable or disable host maintenance for your existing Dedicated Host using AWS CLI.**

Use the `modify-hosts` command.
Enable

aws ec2 modify-hosts --region us-east-1 --host-maintenance on --host-ids h-0d123456bbf78910d

Disable

aws ec2 modify-hosts --region us-east-1 --host-maintenance off --host-ids h-0d123456bbf78910d

To view the host maintenance configuration for your Dedicated Host using AWS CLI.

Use the describe-hosts command.

aws ec2 describe-hosts --region us-east-1 --host-ids h-0d123456bbf78910d

Note

If you disable host maintenance, you receive an email notification to evict the degraded host and manually migrate your instances to another host within 28 days. A replacement host is allocated if you have Dedicated Host reservation. After 28 days, the instances running on the degraded host are terminated, and the host is released automatically.

Monitor the state of your Amazon EC2 Dedicated Hosts

Amazon EC2 constantly monitors the state of your Dedicated Hosts. Updates are communicated on the Amazon EC2 console. You can view information about a Dedicated Host using the following methods.

Console

To view the state of a Dedicated Host

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Dedicated Hosts.
3. Locate the Dedicated Host in the list and review the value in the State column.
To view the state of a Dedicated Host

Use the `describe-hosts` AWS CLI command and then review the state property in the hostSet response element.

```
aws ec2 describe-hosts --host-id h-012a3456b7890cdef
```

The following table explains the possible Dedicated Host states.

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>available</td>
<td>AWS hasn't detected an issue with the Dedicated Host. No maintenance or repairs are scheduled. Instances can be launched onto this Dedicated Host.</td>
</tr>
<tr>
<td>released</td>
<td>The Dedicated Host has been released. The host ID is no longer in use. Released hosts can't be reused.</td>
</tr>
<tr>
<td>under-assessment</td>
<td>AWS is exploring a possible issue with the Dedicated Host. If action must be taken, you are notified via the AWS Management Console or email. Instances can't be launched onto a Dedicated Host in this state.</td>
</tr>
<tr>
<td>pending</td>
<td>The Dedicated Host cannot be used for new instance launches. It is either being <a href="#">modified to support multiple instance types</a>, or a <a href="#">host recovery</a> is in progress.</td>
</tr>
<tr>
<td>permanent-failure</td>
<td>An unrecoverable failure has been detected. You receive an eviction notice through your instances and by email. Your instances might</td>
</tr>
<tr>
<td>State</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>continue to run.</td>
<td>If you stop or terminate all instances on a Dedicated Host with this state, AWS retires the host. AWS does not restart instances in this state. Instances can't be launched onto Dedicated Hosts in this state.</td>
</tr>
<tr>
<td>released-permanent-failure</td>
<td>AWS permanently releases Dedicated Hosts that have failed and no longer have running instances on them. The Dedicated Host ID is no longer available for use.</td>
</tr>
</tbody>
</table>

**Track Amazon EC2 Dedicated Host configuration changes using AWS Config**

You can use AWS Config to record configuration changes for Dedicated Hosts, and for instances that are launched, stopped, or terminated on them. You can then use the information captured by AWS Config as a data source for license reporting.

AWS Config records configuration information for Dedicated Hosts and instances individually, and pairs this information through relationships. There are three reporting conditions:

- **AWS Config recording status**—When **On**, AWS Config is recording one or more AWS resource types, which can include Dedicated Hosts and Dedicated Instances. To capture the information required for license reporting, verify that hosts and instances are being recorded with the following fields.

- **Host recording status**—When **Enabled**, the configuration information for Dedicated Hosts is recorded.

- **Instance recording status**—When **Enabled**, the configuration information for Dedicated Instances is recorded.

If any of these three conditions are disabled, the icon in the **Edit Config Recording** button is red. To derive the full benefit of this tool, ensure that all three recording methods are enabled. When all three are enabled, the icon is green. To edit the settings, choose **Edit Config Recording**. You are directed to the **Set up AWS Config** page in the AWS Config console, where you can set up AWS Config and start recording for your hosts, instances, and other supported resource types. For more information, see **Setting up AWS Config using the Console** in the **AWS Config Developer Guide**.
After AWS Config starts recording configuration changes to your hosts and instances, you can get the configuration history of any host that you have allocated or released and any instance that you have launched, stopped, or terminated. For example, at any point in the configuration history of a Dedicated Host, you can look up how many instances are launched on that host, along with the number of sockets and cores on the host. For any of those instances, you can also look up the ID of its Amazon Machine Image (AMI). You can use this information to report on licensing for your own server-bound software that is licensed per-socket or per-core.

You can view configuration histories in any of the following ways:

- By using the AWS Config console. For each recorded resource, you can view a timeline page, which provides a history of configuration details. To view this page, choose the gray icon in the **Config Timeline** column of the **Dedicated Hosts** page. For more information, see [Viewing Configuration Details in the AWS Config Console](#) in the *AWS Config Developer Guide*.

- By running AWS CLI commands. First, you can use the `list-discovered-resources` command to get a list of all hosts and instances. Then, you can use the `get-resource-config-history` command to get the configuration details of a host or instance for a specific time interval. For more information, see [View Configuration Details Using the CLI](#) in the *AWS Config Developer Guide*.

- By using the AWS Config API in your applications. First, you can use the `ListDiscoveredResources` action to get a list of all hosts and instances. Then, you can use the `GetResourceConfigHistory` action to get the configuration details of a host or instance for a specific time interval.

For example, to get a list of all of your Dedicated Hosts from AWS Config, run a CLI command such as the following.

```
aws configservice list-discovered-resources --resource-type AWS::EC2::Host
```

To obtain the configuration history of a Dedicated Host from AWS Config, run a CLI command such as the following.
aws configservice get-resource-config-history --resource-type AWS::EC2::Instance --resource-id i-1234567890abcdef0

To manage AWS Config settings using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the Dedicated Hosts page, choose Edit Config Recording.
3. In the AWS Config console, follow the steps provided to turn on recording. For more information, see Setting up AWS Config using the Console.

For more information, see Viewing Configuration Details in the AWS Config Console.

To activate AWS Config using the command line or API

- AWS CLI: Viewing Configuration Details (AWS CLI) in the AWS Config Developer Guide.
- Amazon EC2 API: GetResourceConfigHistory.

Amazon EC2 Dedicated Instances

By default, EC2 instances run on shared tenancy hardware. This means that multiple AWS accounts might share the same physical hardware.

Dedicated Instances are EC2 instances that run on hardware that's dedicated to a single AWS account. This means that Dedicated Instances are physically isolated at the host hardware level from instances that belong to other AWS accounts, even if those accounts are linked to a single payer account. However, Dedicated Instances might share hardware with other instances from the same AWS account that are not Dedicated Instances.

Dedicated Instances provide no visibility or control over instance placement, and they do not support host affinity. If you stop and start a Dedicated Instance, it might not run on the same host. Similarly, you cannot target a specific host on which to launch or run an instance. Additionally, Dedicated Instances provide limited support for Bring Your Own License (BYOL).

If you require visibility and control over instance placement and more comprehensive BYOL support, consider using a Dedicated Host instead. Dedicated Instances and Dedicated Hosts can both be used to launch Amazon EC2 instances onto dedicated physical servers. There are no performance, security, or physical differences between Dedicated Instances and instances on...
Dedicated Hosts. However, there are some key differences between them. The following table highlights some of the key differences between Dedicated Instances and Dedicated Hosts:

<table>
<thead>
<tr>
<th></th>
<th>Dedicated Host</th>
<th>Dedicated Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dedicated physical server</td>
<td>Physical server with instance capacity fully dedicated to your use.</td>
<td>Physical server that's dedicated to a single customer account.</td>
</tr>
<tr>
<td>Instance capacity sharing</td>
<td>Can share instance capacity with other accounts.</td>
<td>Not supported</td>
</tr>
<tr>
<td>Billing</td>
<td>Per-host billing</td>
<td>Per-instance billing</td>
</tr>
<tr>
<td>Visibility of sockets, cores, and host ID</td>
<td>Provides visibility of the number of sockets and physical cores</td>
<td>No visibility</td>
</tr>
<tr>
<td>Host and instance affinity</td>
<td>Allows you to consistently deploy your instances to the same physical server over time</td>
<td>Not supported</td>
</tr>
<tr>
<td>Targeted instance placement</td>
<td>Provides additional visibility and control over how instances are placed on a physical server</td>
<td>Not supported</td>
</tr>
<tr>
<td>Automatic instance recovery</td>
<td>Supported. For more information, see Amazon EC2 Dedicated Host recovery.</td>
<td>Supported</td>
</tr>
<tr>
<td>Bring Your Own License (BYOL)</td>
<td>Supported</td>
<td>Partial support *</td>

<tr>
<td>Capacity Reservations</td>
<td>Not supported</td>
<td>Supported</td>
</tr>
</tbody>
</table>
* Microsoft SQL Server with License Mobility through Software Assurance, and Windows Virtual Desktop Access (VDA) licenses can be used with Dedicated Instance.

For more information about Dedicated Instances, see Amazon EC2 Dedicated Hosts.

**Topics**

- Dedicated Instance basics
- Supported features
- Dedicated Instances limitations
- Pricing for Dedicated Instances
- Launch Dedicated Instances into a VPC with default tenancy
- Change the tenancy of an Amazon EC2 instance
- Change the tenancy of a Amazon VPC

**Dedicated Instance basics**

A VPC can have a tenancy of either default or dedicated. By default, your VPCs have default tenancy and instances launched into a default tenancy VPC have default tenancy. To launch Dedicated Instances, do the following:

- Create a VPC with a tenancy of dedicated, so that all instances in the VPC run as Dedicated Instances. For more information, see Launch Dedicated Instances into a VPC with default tenancy.
- Create a VPC with a tenancy of default and manually specify a tenancy of dedicated for the instances to run as Dedicated Instances. For more information, see Launch Dedicated Instances into a VPC with default tenancy.

**Supported features**

Dedicated Instances support the following features and AWS service integrations:

**Topics**

- Reserved Instances
- Automatic scaling
- Automatic recovery
• **Dedicated Spot Instances**

• **Burstable performance instances**

### Reserved Instances

To reserve capacity for your Dedicated Instances, you can purchase Dedicated ReservedInstances or Capacity Reservations. For more information, see [Reserved Instances for Amazon EC2 overview](#) and [On-Demand Capacity Reservations](#).

When you purchase a Dedicated Reserved Instance, you are purchasing the capacity to launch a Dedicated Instance into a VPC at a much reduced usage fee; the price break in the usage charge applies only if you launch an instance with dedicated tenancy. When you purchase a Reserved Instance with default tenancy, it applies only to a running instance with default tenancy; it does not apply to a running instance with dedicated tenancy.

You can't use the modification process to change the tenancy of a Reserved Instance after you've purchased it. However, you can exchange a Convertible Reserved Instance for a new Convertible Reserved Instance with a different tenancy.

### Automatic scaling

You can use Amazon EC2 Auto Scaling to launch Dedicated Instances. For more information, see [Launching Auto Scaling Instances in a VPC](#) in the *Amazon EC2 Auto Scaling User Guide*.

### Automatic recovery

You can configure automatic recovery for a Dedicated Instance if it becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair. For more information, see [Instance resiliency](#).

### Dedicated Spot Instances

You can run a Dedicated Spot Instance by specifying a tenancy of dedicated when you create a Spot Instance request. For more information, see [Specify a tenancy for your Spot Instances](#).

### Burstable performance instances

You can leverage the benefits of running on dedicated tenancy hardware with the section called “Burstable performance instances”. T3 Dedicated Instances launch in unlimited mode by default, and they provide a baseline level of CPU performance with the ability to burst to a higher CPU
level when required by your workload. The T3 baseline performance and ability to burst are governed by CPU credits. Because of the burstable nature of the T3 instance types, we recommend that you monitor how your T3 instances use the CPU resources of the dedicated hardware for the best performance. T3 Dedicated Instances are intended for customers with diverse workloads that display random CPU behavior, but that ideally have average CPU usage at or below the baseline usages. For more information, see the section called “Key concepts”.

Amazon EC2 has systems in place to identify and correct variability in performance. However, it is still possible to experience short-term variability if you launch multiple T3 Dedicated Instances that have correlated CPU usage patterns. For these more demanding or correlated workloads, we recommend using M5 or M5a Dedicated Instances rather than T3 Dedicated Instances.

**Dedicated Instances limitations**

Keep the following in mind when using Dedicated Instances:

- Some AWS services or their features are not supported with a VPC with the instance tenancy set to dedicated. Refer to the respective service's documentation to confirm if there are any limitations.
- Some instance types can't be launched into a VPC with the instance tenancy set to dedicated. For more information about supported instance types, see Amazon EC2 Dedicated Instances.
- When you launch a Dedicated Instance backed by Amazon EBS, the EBS volume doesn't run on single-tenant hardware.

**Pricing for Dedicated Instances**

Pricing for Dedicated Instances is different from pricing for On-Demand Instances. For more information, see the Amazon EC2 Dedicated Instances product page.

**Launch Dedicated Instances into a VPC with default tenancy**

When you create a VPC, you have the option of specifying its instance tenancy. If you launch an instance into a VPC that has an instance tenancy of dedicated, the instance will always run as a Dedicated Instance on hardware that's dedicated for your use.

For more information about creating a VPC and choosing the tenancy options, see Create a VPC in the Amazon VPC User Guide.

You can launch a Dedicated Instance using the Amazon EC2 launch instance wizard.
Console

To launch a Dedicated Instance into a default tenancy VPC using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, Launch instance.
3. In the Application and OS Images section, select an AMI from the list.
4. In the Instance type section, select the instance type to launch.

   Note
   
   Ensure that you choose an instance type that's supported as a Dedicated Instance. For more information, see Amazon EC2 Dedicated Instances.

5. In the Key pair section, select the key pair to associate with the instance.
6. In the Advanced details section, for Tenancy, select Dedicated.
7. Configure the remaining instance options as needed. For more information, see Launch an instance using defined parameters.
8. Choose Launch instance.

Command line

To set the tenancy option for an instance during launch using the command line

- run-instances (AWS CLI)
- New-EC2Instance (AWS Tools for Windows PowerShell)

For more information about launching an instance with a tenancy of host, see Launch Amazon EC2 instances on an Amazon EC2 Dedicated Host.

Change the tenancy of an Amazon EC2 instance

You can change the tenancy of a stopped instance after launch. The changes that you make take effect the next time the instance starts.

The operating system details of your instance—and whether SQL Server is installed—affect what conversions are supported. For more information about the tenancy conversion paths available to your instance, see Tenancy conversion in the License Manager User Guide.
Note

For T3 instances, you must launch the instance on a Dedicated Host to use a tenancy of host. You can't change the tenancy from host to dedicated or default. Attempting to make one of these unsupported tenancy changes results in an InvalidRequest error code.

Console

To change the tenancy of an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and select your instance.
3. Choose Instance state, Stop instance, Stop.
5. For Tenancy, choose whether to run your instance on dedicated hardware or on a Dedicated Host. Choose Save.

Command line

To modify the tenancy value of an instance using the command line

- modify-instance-placement (AWS CLI)
- Edit-EC2InstancePlacement (AWS Tools for Windows PowerShell)

Change the tenancy of a Amazon VPC

You can change the instance tenancy of a VPC from dedicated to default after you create it. Modifying the instance tenancy of the VPC does not affect the tenancy of any existing instances in the VPC. The next time you launch an instance in the VPC, it has a tenancy of default, unless you specify otherwise during launch.
Note
You cannot change the instance tenancy of a VPC from default to dedicated after it is created.

You can modify the instance tenancy of a VPC using the AWS CLI, an AWS SDK, or the Amazon EC2 API only.

Command line

To modify the instance tenancy attribute of a VPC using the AWS CLI

Use the modify-vpc-tenancy command and specify the ID of the VPC and instance tenancy value. The only supported value is default.

```
aws ec2 modify-vpc-tenancy --vpc-id vpc-1a2b3c4d --instance-tenancy default
```

On-Demand Capacity Reservations and Capacity Blocks for ML

Capacity Reservations allow you to reserve compute capacity for Amazon EC2 instances in a specific Availability Zone. There are two types of Capacity Reservations serving different use cases.

Types of Capacity Reservations

• On-Demand Capacity Reservations
• Capacity Blocks for ML

The following are some common use cases for On-Demand Capacity Reservations:

• **Scaling events** – Create On-Demand Capacity Reservations ahead of your business-critical events to ensure that you can scale when you need to.
• **Regulatory requirements and disaster recovery** – Use On-Demand Capacity Reservations to satisfy regulatory requirements for high availability, and reserve capacity in a different Availability Zone or Region for disaster recovery.

The following are some common use cases for Capacity Blocks for ML:
• **Machine learning (ML) model training and fine-tuning** – Get uninterrupted access to the GPU instances that you reserved to complete ML model training and fine-tuning.

• **ML experiments and prototypes** – Run experiments and build prototypes that require GPU instances for short durations.

**When to use On-Demand Capacity Reservation**

Use On-Demand Capacity Reservations if you have strict capacity requirements, and are running business-critical workloads that require capacity assurance. With On-Demand Capacity Reservations, you can ensure that you'll always have access to the Amazon EC2 capacity you've reserved for as long as you need it.

**When to use Capacity Blocks for ML**

Use Capacity Blocks for ML when you need to ensure that you have uninterrupted access to GPU instances for a defined period of time starting on a future date. Capacity Blocks are ideal for training and fine-tuning ML models, short experimentation runs, and handling temporary surges in inference demand in the future. With Capacity Blocks, you can ensure that you'll have access to GPU resources on a specific date to run your ML workloads.

**On-Demand Capacity Reservations**

On-Demand Capacity Reservations enable you to reserve compute capacity for your Amazon EC2 instances in a specific Availability Zone for any duration. Capacity Reservations mitigate against the risk of being unable to get On-Demand capacity in case there are capacity constraints. If you have strict capacity requirements, and are running business-critical workloads that require a certain level of long or short-term capacity assurance, we recommend that you create a Capacity Reservation to ensure that you always have access to Amazon EC2 capacity when you need it, for as long as you need it.

You can create Capacity Reservations at any time, without entering into a one-year or three-year term commitment. The capacity becomes available and billing starts as soon as the Capacity Reservation is provisioned in your account. When you no longer need the capacity assurance, cancel the Capacity Reservation to release the capacity and to stop incurring charges. You can also use the billing discounts offered by Savings Plans and Regional Reserved Instances to reduce the cost of a Capacity Reservation.

When you create a Capacity Reservation, you specify:
• The Availability Zone in which to reserve the capacity
• The number of instances for which to reserve capacity
• The instance attributes, including the instance type, platform, Availability Zone, and tenancy

Capacity Reservations can only be used by instances that match their attributes. By default, they are automatically used by running instances that match the attributes. If you don't have any running instances that match the attributes of the Capacity Reservation, it remains unused until you launch an instance with matching attributes.

Differences between Capacity Reservations, Reserved Instances, and Savings Plans

The following table highlights key differences between Capacity Reservations, Reserved Instances, and Savings Plans:
<table>
<thead>
<tr>
<th></th>
<th>Capacity Reservations</th>
<th>Zonal Reserved Instances</th>
<th>Regional Reserved Instances</th>
<th>Savings Plans</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Term</strong></td>
<td>No commitment required. Can be created and canceled as needed.</td>
<td>Requires a fixed one-year or three-year commitment</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Capacity benefit</strong></td>
<td>Capacity reserved in a specific Availability Zone.</td>
<td></td>
<td>No capacity reserved.</td>
<td></td>
</tr>
<tr>
<td><strong>Billing discount</strong></td>
<td>No billing discount. †</td>
<td>Provides a billing discount.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Instance Limits</strong></td>
<td>Your On-Demand Instance limits per Region apply.</td>
<td>Default is 20 per Availability Zone. You can request a limit increase.</td>
<td>Default is 20 per Region. You can request a limit increase.</td>
<td>No limit.</td>
</tr>
</tbody>
</table>

† You can combine Capacity Reservations with Savings Plans or Regional Reserved Instances to receive a discount.

For more information, see the following:

- [Reserved Instances for Amazon EC2 overview](#)
- [Savings Plans User Guide](#)

**Supported platforms**

You must create the Capacity Reservation with the correct platform to ensure that it properly matches with your instances. Capacity Reservations support the following platforms:

- Linux/UNIX
- Linux with SQL Server Standard
- Linux with SQL Server Web
- Linux with SQL Server Enterprise
• SUSE Linux
• Red Hat Enterprise Linux
• RHEL with SQL Server Standard
• RHEL with SQL Server Enterprise
• RHEL with SQL Server Web
• RHEL with HA
• RHEL with HA and SQL Server Standard
• RHEL with HA and SQL Server Enterprise
• Ubuntu Pro
• Windows
• Windows with SQL Server
• Windows with SQL Server Web
• Windows with SQL Server Standard
• Windows with SQL Server Enterprise

When you purchase a Capacity Reservation, you must specify the *platform* that represents the operating system for your instance.

• For SUSE Linux and RHEL distributions, excluding BYOL, you must choose the specific platform. For example, the **SUSE Linux** or **Red Hat Enterprise Linux** platform.
• For all other Linux distributions (including Ubuntu), choose the **Linux/UNIX** platform.
• If you bring your existing RHEL subscription (BYOL), you must choose the **Linux/UNIX** platform.
• For Windows with SQL Standard, Windows with SQL Server Enterprise, and Windows with SQL Server Web, you must choose the specific platform.
• For all other Windows versions, excluding BYOL which is not supported, choose the **Windows** platform.

**Quotas**

The number of instances for which you are allowed to reserve capacity is based on your account’s On-Demand Instance quota. You can reserve capacity for as many instances as that quota allows, minus the number of instances that are already running.
Quotas apply to running instances only. If your instance is pending, stopping, stopped, or hibernated, it does not count towards your quota.

Limitations

Before you create Capacity Reservations, take note of the following limitations and restrictions.

- Active and unused Capacity Reservations count toward your On-Demand Instance limits.
- Capacity Reservations are not transferable from one AWS account to another. However, you can share Capacity Reservations with other AWS accounts. For more information, see Work with shared Capacity Reservations.
- Zonal Reserved Instance billing discounts do not apply to Capacity Reservations.
- Capacity Reservations can be created in cluster placement groups. Spread and partition placement groups are not supported.
- Capacity Reservations can't be used with Dedicated Hosts. Capacity Reservations can be used with Dedicated Instances.
- [Windows instances] Capacity Reservations can't be used with Bring Your Own License (BYOL).
- Capacity Reservations do not ensure that a hibernated instance can resume after you try to start it.

Capacity Reservation pricing and billing

The topics in this section provide an overview of pricing and billing for Capacity Reservations

Topics

- Pricing
- Billing
- Billing discounts
- Viewing your bill

Pricing

Capacity Reservations are charged at the equivalent On-Demand rate whether you run instances in reserved capacity or not. If you do not use the reservation, this shows up as unused reservation on your Amazon EC2 bill. When you run an instance that matches the attributes of a reservation,
you just pay for the instance and nothing for the reservation. There are no upfront or additional charges.

For example, if you create a Capacity Reservation for 20 m4.large Linux instances and run 15 m4.large Linux instances in the same Availability Zone, you will be charged for 15 active instances and for 5 unused instances in the reservation.

Billing discounts for Savings Plans and Regional Reserved Instances apply to Capacity Reservations. For more information, see Billing discounts.

For more information, see Amazon EC2 Pricing.

Billing

Billing starts as soon as the Capacity Reservation is provisioned in your account, and it continues while the Capacity Reservation remains provisioned in your account.

Capacity Reservations are billed at per-second granularity. This means that you are charged for partial hours. For example, if a Capacity Reservation remains provisioned in your account for 24 hours and 15 minutes, you are billed for 24.25 reservation hours.

The following example shows how a Capacity Reservation is billed. The Capacity Reservation is created for one m4.large Linux instance, which has an On-Demand rate of $0.10 per usage hour. In this example, the Capacity Reservation is provisioned in the account for five hours. The Capacity Reservation is unused for the first hour, so it is billed for one unused hour at the m4.large instance type's standard On-Demand rate. In hours two through five, the Capacity Reservation is occupied by an m4.large instance. During this time, the Capacity Reservation accrues no charges, and the account is instead billed for the m4.large instance occupying it. In the sixth hour, the Capacity Reservation is canceled and the m4.large instance runs normally outside of the reserved capacity. For that hour, it is charged at the On-Demand rate of the m4.large instance type.

<table>
<thead>
<tr>
<th>Hour</th>

<td>$0.10</td>
<td>$0.10</td>
<td>$0.10</td>
<td>$0.10</td>
<td>$0.10</td>
<td>$0.10</td>
<td>$0.60</td>
</tr>
</tbody>
</table>

Billing discounts

Billing discounts for Savings Plans and Regional Reserved Instances apply to Capacity Reservations. AWS automatically applies these discounts to Capacity Reservations that have matching
attributes. When a Capacity Reservation is used by an instance, the discount is applied to the instance. Discounts are preferentially applied to instance usage before covering unused Capacity Reservations.

Billing discounts for zonal Reserved Instances do not apply to Capacity Reservations.

For more information, see the following:

- [Reserved Instances for Amazon EC2 overview](#)
- [Savings Plans User Guide](#)
- [Billing and purchase options](#)

### Viewing your bill

You can review the charges and fees to your account on the AWS Billing and Cost Management console.

- The **Dashboard** displays a spend summary for your account.
- On the **Bills** page, under **Details**, expand the **Elastic Compute Cloud** section and the **Region** to get billing information about your Capacity Reservations.

You can view the charges online, or you can download a CSV file. For more information, see [Capacity Reservation Line Items](#) in the *AWS Billing and Cost Management User Guide*.

### Work with Capacity Reservations

To start using Capacity Reservations, you create the capacity reservation in the required Availability Zone. Then, you can launch instances into the reserved capacity, view its capacity utilization in real time, and increase or decrease its capacity as needed.

By default, Capacity Reservations automatically match new instances and running instances that have matching attributes (instance type, platform, Availability Zone, and tenancy). This means that any instance with matching attributes automatically runs in the Capacity Reservation. However, you can also target a Capacity Reservation for specific workloads. This enables you to explicitly control which instances are allowed to run in that reserved capacity.

You can specify how the reservation ends. You can choose to cancel the Capacity Reservation or end it automatically at a specified time. If you specify an end time, the Capacity Reservation is canceled within an hour of the specified time. For example, if you specify 5/31/2019, 13:30:55,
the Capacity Reservation is guaranteed to end between 13:30:55 and 14:30:55 on 5/31/2019. After a reservation ends, you can no longer target instances to the Capacity Reservation. Instances running in the reserved capacity continue to run uninterrupted. If instances targeting a Capacity Reservation are stopped, you cannot restart them until you remove their Capacity Reservation targeting preference or configure them to target a different Capacity Reservation.

Contents

- Create a Capacity Reservation
- Launch instances into an existing Capacity Reservation
- Modify a Capacity Reservation
- Modify an instance's Capacity Reservation settings
- View a Capacity Reservation
- Cancel a Capacity Reservation

Create a Capacity Reservation

If your request to create a Capacity Reservation succeeds, the capacity is available immediately. The capacity remains reserved for your use as long as the Capacity Reservation is active, and you can launch instances into it at any time. If the Capacity Reservation is open, new instances and existing instances that have matching attributes automatically run in the capacity of the Capacity Reservation. If the Capacity Reservation is targeted, instances must specifically target it to run in the reserved capacity.

Your request to create a Capacity Reservation could fail if one of the following is true:

- Amazon EC2 does not have sufficient capacity to fulfill the request. Either try again at a later time, try a different Availability Zone, or try a smaller request. If your application is flexible across instance types and sizes, try different instance attributes.
- The requested quantity exceeds your On-Demand Instance limit for the selected instance family. Increase your On-Demand Instance limit for the instance family and try again. For more information, see On-Demand Instance quotas.

To create a Capacity Reservation using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Capacity Reservations, and then choose Create Capacity Reservation.
3. On the Create a Capacity Reservation page, configure the following settings in the **Instance details** section. The instance type, platform, Availability Zone, and tenancy of the instances that you launch must match the instance type, platform, Availability Zone, and tenancy that you specify here or the Capacity Reservation is not applied. For example, if an open Capacity Reservation doesn't match, an instance launch that targets that Capacity Reservation explicitly will fail.

   a. **Instance Type**—The type of instance to launch into the reserved capacity.
   b. **Launch EBS-optimized instances**—Specify whether to reserve the capacity for EBS-optimized instances. This option is selected by default for some instance types. For more information, see the section called “Amazon EBS optimization”.
   c. **Platform**—The operating system for your instances. For more information, see Supported platforms.
   d. **Availability Zone**—The Availability Zone in which to reserve the capacity.
   e. **Tenancy**—Specify whether to run on shared hardware (default) or a dedicated instance.
   f. **(Optional) Placement group ARN** —The ARN of the cluster placement group in which to create the Capacity Reservation.

   For more information, see Capacity Reservations in cluster placement groups.
   g. **Quantity**—The number of instances for which to reserve capacity. If you specify a quantity that exceeds your remaining On-Demand Instance limit for the selected instance type, the request is denied.

4. Configure the following settings in the **Reservation details** section:

   a. **Reservation Ends**—Choose one of the following options:

      - **Manually**—Reserve the capacity until you explicitly cancel it.
      - **Specific time**—Cancel the capacity reservation automatically at the specified date and time.

   b. **Instance eligibility**—Choose one of the following options:

      - **open**—(Default) The Capacity Reservation matches any instance that has matching attributes (instance type, platform, Availability Zone, and tenancy). If you launch an instance with matching attributes, it is placed into the reserved capacity automatically.
• **targeted**—The Capacity Reservation only accepts instances that have matching attributes (instance type, platform, Availability Zone, and tenancy), and that explicitly target the reservation.

5. Choose **Request reservation**.

**To create a Capacity Reservation using the AWS CLI**

Use the `create-capacity-reservation` command. For more information, see Supported platforms.

The following command creates a Capacity Reservation that reserves capacity for three `m5.2xlarge` instances running Red Hat Enterprise Linux AMIs in the `us-east-1a` Availability Zone.

```bash
aws ec2 create-capacity-reservation --instance-type m5.2xlarge --instance-platform Red Hat Enterprise Linux --availability-zone us-east-1a --instance-count 3
```

The following command creates a Capacity Reservation that reserves capacity for three `m5.2xlarge` instances running Windows with SQL Server AMIs in the `us-east-1a` Availability Zone.

```bash
aws ec2 create-capacity-reservation --instance-type m5.2xlarge --instance-platform Windows with SQL Server --availability-zone us-east-1a --instance-count 3
```

**Launch instances into an existing Capacity Reservation**

When you launch an instance, you can specify whether to launch the instance into any open Capacity Reservation, into a specific Capacity Reservation, or into a group of Capacity Reservations. You can only launch an instance into a Capacity Reservation that has matching attributes (instance type, platform, Availability Zone, and tenancy) and sufficient capacity. Alternatively, you can configure the instance to avoid running in a Capacity Reservation, even if you have an open Capacity Reservation that has matching attributes and available capacity.

Launching an instance into a Capacity Reservation reduces its available capacity by the number of instances launched. For example, if you launch three instances, the available capacity of the Capacity Reservation is reduced by three.
To launch instances into an existing Capacity Reservation using the console

1. Follow the procedure to [launch an instance](#), but don't launch the instance until you've completed the following steps to specify the settings for the placement group and Capacity Reservation.

2. Expand **Advanced details** and do the following:
   
   a. For **Placement group**, select the cluster placement group in which to launch the instance.
   
   b. For **Capacity Reservation**, choose one of the following options depending on the configuration of the Capacity Reservation:
      
      - **None** – Prevents the instances from launching into a Capacity Reservation. The instances run in On-Demand capacity.
      
      - **Open** – Launches the instances into any Capacity Reservation that has matching attributes and sufficient capacity for the number of instances you selected. If there is no matching Capacity Reservation with sufficient capacity, the instance uses On-Demand capacity.
      
      - **Target by ID** – Launches the instances into the selected Capacity Reservation. If the selected Capacity Reservation does not have sufficient capacity for the number of instances you selected, the instance launch fails.
      
      - **Target by group** – Launches the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group. If the selected group does not have a Capacity Reservation with matching attributes and available capacity, the instances launch into On-Demand capacity.

3. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see [Launch an instance using the new launch instance wizard](#).

To launch an instance into an existing Capacity Reservation using the AWS CLI

Use the `run-instances` command and specify the `--capacity-reservation-specification` parameter.

The following example launches a `t2.micro` instance into any open Capacity Reservation that has matching attributes and available capacity:
The following example launches a t2.micro instance into a targeted Capacity Reservation:

```
aws ec2 run-instances --image-id ami-abc12345 --count 1 --instance-type t2.micro --key-name MyKeyPair --subnet-id subnet-1234567890abcdef1 --capacity-reservation-specification CapacityReservationPreference=open
```

The following example launches a t2.micro instance into a Capacity Reservation group:

```
aws ec2 run-instances --image-id ami-abc12345 --count 1 --instance-type t2.micro --key-name MyKeyPair --subnet-id subnet-1234567890abcdef1 --capacity-reservation-specification CapacityReservationTarget={CapacityReservationId=cr-a1234567}
```

**Modify a Capacity Reservation**

You can change the attributes of an active Capacity Reservation after you have created it. You cannot modify a Capacity Reservation after it has expired or after you have explicitly canceled it.

When modifying a Capacity Reservation, you can only increase or decrease the quantity and change the way in which it is released. You cannot change the instance type, EBS optimization, platform, Availability Zone, or instance eligibility of a Capacity Reservation. If you need to modify any of these attributes, we recommend that you cancel the reservation, and then create a new one with the required attributes.

If you specify a new quantity that exceeds your remaining On-Demand Instance limit for the selected instance type, the update fails.

**To modify a Capacity Reservation using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. Choose **Capacity Reservations**, select the Capacity Reservation to modify, and then choose **Edit**.
3. Modify the **Quantity** or **Reservation ends** options as needed, and choose **Save changes**.
To modify a Capacity Reservation using the AWS CLI

Use the `modify-capacity-reservation` command:

For example, the following command modifies a Capacity Reservation to reserve capacity for eight instances.

```
aws ec2 modify-capacity-reservation --capacity-reservation-id cr-1234567890abcdef0 --instance-count 8
```

Modify an instance's Capacity Reservation settings

You can modify the following Capacity Reservation settings for a stopped instance at any time:

- Start in any Capacity Reservation that has matching attributes (instance type, platform, Availability Zone, and tenancy) and available capacity.
- Start the instance in a specific Capacity Reservation.
- Start in any Capacity Reservation that has matching attributes and available capacity in a Capacity Reservation group
- Prevent the instance from starting in a Capacity Reservation.

To modify an instance's Capacity Reservation settings using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Instances and select the instance to modify. Stop the instance if it is not already stopped.
3. Choose Actions, Instance settings, Modify Capacity Reservation Settings.
4. For Capacity Reservation, choose one of the following options:

   - **Open** — Launches the instances into any Capacity Reservation that has matching attributes and sufficient capacity for the number of instances you selected. If there is no matching Capacity Reservation with sufficient capacity, the instance uses On-Demand capacity.
   - **None** — Prevents the instances from launching into a Capacity Reservation. The instances run in On-Demand capacity.
   - **Specify Capacity Reservation** — Launches the instances into the selected Capacity Reservation. If the selected Capacity Reservation does not have sufficient capacity for the number of instances you selected, the instance launch fails.
• **Specify Capacity Reservation group** — Launches the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group. If the selected group does not have a Capacity Reservation with matching attributes and available capacity, the instances launch into On-Demand capacity.

**To modify an instance's Capacity Reservation settings using the AWS CLI**

Use the `modify-instance-capacity-reservation-attributes` command.

For example, the following command changes an instance's Capacity Reservation setting to open or none.

```
aws ec2 modify-instance-capacity-reservation-attributes --instance-id i-1234567890abcdef0 --capacity-reservation-specification CapacityReservationPreference=none|open
```

For example, the following command modifies an instance to target a specific Capacity Reservation.

```
aws ec2 modify-instance-capacity-reservation-attributes --instance-id i-1234567890abcdef0 --capacity-reservation-specification CapacityReservationTarget={CapacityReservationId=cr-1234567890abcdef0}
```

For example, the following command modifies an instance to target a specific Capacity Reservation group.

```
```

**View a Capacity Reservation**

Capacity Reservations have the following possible states:

- **active**—The capacity is available for use.
- **expired**—The Capacity Reservation expired automatically at the date and time specified in your reservation request. The reserved capacity is no longer available for your use.
• cancelled—The Capacity Reservation was canceled. The reserved capacity is no longer available for your use.

• pending—The Capacity Reservation request was successful but the capacity provisioning is still pending.

• failed—The Capacity Reservation request has failed. A request can fail due to request parameters that are not valid, capacity constraints, or instance limit constraints. You can view a failed request for 60 minutes.

**Note**

Due to the eventual consistency model followed by the Amazon EC2 APIs, after you create a Capacity Reservation, it can take up to 5 minutes for the console and the `describe-capacity-reservations` response to indicate that the Capacity Reservation is in the active state. During this time, the console and the `describe-capacity-reservations` response might indicate that the Capacity Reservation is in the pending state. However, the Capacity Reservation might already be available for use and you can attempt to launch instances into it.

To view your Capacity Reservations using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. Choose **Capacity Reservations** and select a Capacity Reservation to view.
3. Choose **View launched instances for this reservation**.

To view your Capacity Reservations using the AWS CLI

Use the `describe-capacity-reservations` command:

For example, the following command describes all Capacity Reservations.

```
aws ec2 describe-capacity-reservations
```

Example output.

```json
{

```
Cancel a Capacity Reservation

You can cancel a Capacity Reservation at any time if you no longer need the reserved capacity. When you cancel a Capacity Reservation, the capacity is released immediately, and it is no longer reserved for your use.
You can cancel empty Capacity Reservations and Capacity Reservations that have running instances. If you cancel a Capacity Reservation that has running instances, the instances continue to run normally outside of the capacity reservation at standard On-Demand Instance rates or at a discounted rate if you have a matching Savings Plan or Regional Reserved Instance.

After you cancel a Capacity Reservation, instances that target it can no longer launch. Modify these instances so that they either target a different Capacity Reservation, launch into any open Capacity Reservation with matching attributes and sufficient capacity, or avoid launching into a Capacity Reservation. For more information, see Modify an instance's Capacity Reservation settings.

**To cancel a Capacity Reservation using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Capacity Reservations** and select the Capacity Reservation to cancel.
3. Choose **Cancel reservation**, Cancel reservation.

**To cancel a Capacity Reservation using the AWS CLI**

Use the `cancel-capacity-reservation` command:

For example, the following command cancels a Capacity Reservation with an ID of `cr-1234567890abcdef0`.

```bash
aws ec2 cancel-capacity-reservation --capacity-reservation-id cr-1234567890abcdef0
```

**Work with Capacity Reservation groups**

You can use AWS Resource Groups to create logical collections of Capacity Reservations, called resource groups. A resource group is a logical grouping of AWS resources that are all in the same AWS Region. For more information about resource groups, see What are resource groups? in the AWS Resource Groups User Guide.

You can include Capacity Reservations that you own in your account, and Capacity Reservations that are shared with you by other AWS accounts in a single resource group. You can also include Capacity Reservations that have different attributes (instance type, platform, Availability Zone, and tenancy) in a single resource group.

When you create resource groups for Capacity Reservations, you can target instances to a group of Capacity Reservations instead of an individual Capacity Reservation. Instances that target a group
of Capacity Reservations match with any Capacity Reservation in the group that has matching attributes (instance type, platform, Availability Zone, and tenancy) and available capacity. If the group does not have a Capacity Reservation with matching attributes and available capacity, the instances run using On-Demand capacity. If a matching Capacity Reservation is added to the targeted group at a later stage, the instance is automatically matched with and moved into its reserved capacity.

To prevent unintended use of Capacity Reservations in a group, configure the Capacity Reservations in the group to accept only instances that explicitly target the capacity reservation. To do this, set **Instance eligibility to targeted** (old console) or **Only instances that specify this reservation** (new console) when creating the Capacity Reservation using the Amazon EC2 console. When using the AWS CLI, specify `--instance-match-criteria targeted` when creating the Capacity Reservation. Doing this ensures that only instances that explicitly target the group, or a Capacity Reservation in the group, can run in the group.

If a Capacity Reservation in a group is canceled or expires while it has running instances, the instances are automatically moved to another Capacity Reservation in the group that has matching attributes and available capacity. If there are no remaining Capacity Reservations in the group that have matching attributes and available capacity, the instances run in On-Demand capacity. If a matching Capacity Reservation is added to the targeted group at a later stage, the instance is automatically moved into its reserved capacity.

**Topics**

- [Create a Capacity Reservation group](#)
- [Add a Capacity Reservation to a group](#)

- [Remove a Capacity Reservation from a group](#)
- [Delete a Capacity Reservation group](#)

**Create a Capacity Reservation group**

**To create a group for Capacity Reservations**

Use the `create-group` AWS CLI command. For name, provide a descriptive name for the group, and for configuration, specify two Type request parameters:
- AWS::EC2::CapacityReservationPool to ensure that the resource group can be targeted for instance launches
- AWS::ResourceGroups::Generic with allowed-resource-types set to AWS::EC2::CapacityReservation to ensure that the resource group accepts Capacity Reservations only

For example, the following command creates a group named MyCRGroup.

```bash
aws resource-groups create-group --name MyCRGroup --configuration
'{"Type":"AWS::EC2::CapacityReservationPool"}
'{"Type":"AWS::ResourceGroups::Generic", "Parameters": [{"Name": "allowed-resource-types", "Values": ["AWS::EC2::CapacityReservation"]}]}'
```

The following shows example output.

```json
{
  "GroupConfiguration": {
    "Status": "UPDATE_COMPLETE",
    "Configuration": [
      {
        "Type": "AWS::EC2::CapacityReservationPool"
      },
      {
        "Type": "AWS::ResourceGroups::Generic",
        "Parameters": [
          {
            "Values": [
              "AWS::EC2::CapacityReservation"
            ],
            "Name": "allowed-resource-types"
          }
        ]
      }
    ],
    "Group": {
      "GroupArn": "arn:aws:resource-groups:sa-east-1:123456789012:group/MyCRGroup",
      "Name": "MyCRGroup"
    }
  }
}
```
Add a Capacity Reservation to a group

If you add a Capacity Reservation that is shared with you to a group, and that Capacity Reservation is unshared, it is automatically removed from the group.

To add a Capacity Reservation to a group

Use the `group-resources` AWS CLI command. For `group`, specify the name of the group to which to add the Capacity Reservations, and for `resources`, specify ARNs of the Capacity Reservations to add. To add multiple Capacity Reservations, separate the ARNs with a space. To get the ARNs of the Capacity Reservations to add, use the `describe-capacity-reservations` AWS CLI command and specify the IDs of the Capacity Reservations.

For example, the following command adds two Capacity Reservations to a group named `MyCRGroup`.

```
```

The following shows example output.

```
{
   "Failed": [],
   "Succeeded": [
   ]
}
```

View Capacity Reservations in a group

To view the Capacity Reservations in a specific group

Use the `list-group-resources` AWS CLI command. For `group`, specify the name of the group.

For example, the following command lists the Capacity Reservations in a group named `MyCRGroup`.

```
aws resource-groups list-group-resources --group MyCRGroup
```

The following shows example output.
Note
The command output includes Capacity Reservations that you own and Capacity Reservations that are shared with you.

View the groups to which a Capacity Reservation belongs

AWS CLI

To view the groups to which a specific Capacity Reservation has been added

Use the `get-groups-for-capacity-reservation` AWS CLI command.

For example, the following command lists the groups to which Capacity Reservation `cr-1234567890abcdef1` has been added.

```
aws ec2 get-groups-for-capacity-reservation --capacity-reservation-id cr-1234567890abcdef1
```

The following shows example output.

```
{
   "CapacityReservationGroups": [
   {
   
```
Note

If you specify a Capacity Reservation that is shared with you, the command returns only Capacity Reservation groups that you own.

Amazon EC2 console

To view the groups to which a specific Capacity Reservation has been added

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Capacity Reservations, select the Capacity Reservation to view, and then choose View.

The groups to which the Capacity Reservation has been added are listed in the Groups card.

Note

If you choose a Capacity Reservation that is shared with you, the console displays only Capacity Reservation groups that you own.

Remove a Capacity Reservation from a group

To remove a Capacity Reservation from a group

Use the ungroup-resources AWS CLI command. For group, specify the ARN of the group from which to remove the Capacity Reservation, and for resources specify the ARNs of the Capacity Reservations to remove. To remove multiple Capacity Reservations, separate the ARNs with a space.

The following example removes two Capacity Reservations from a group named MyCRGroup.

The following shows example output.

```
{
    "Failed": [],
    "Succeeded": [
        "arn:aws:ec2:sa-east-1:123456789012:capacity-reservation/cr-0e154d26a16094dd",
    ]
}
```

**Delete a Capacity Reservation group**

**To delete a group**

Use the [delete-group](#) AWS CLI command. For group, provide the name of the group to delete.

For example, the following command deletes a group named MyCRGroup.

aws resource-groups delete-group --group MyCRGroup

The following shows example output.

```
{
    "Group": {
        "GroupArn": "arn:aws:resource-groups:sa-east-1:123456789012:group/MyCRGroup",
        "Name": "MyCRGroup"
    }
}
```

**Capacity Reservations in cluster placement groups**

You can create Capacity Reservations in a cluster placement group to reserve Amazon EC2 compute capacity for your workloads. Cluster placement groups offer the benefit of low network latency and high network throughput.

Creating a Capacity Reservation in a cluster placement group ensures that you have access to compute capacity in your cluster placement groups when you need it, for as long as you need it.
This is ideal for reserving capacity for high-performance (HPC) workloads that require compute scaling. It allows you to scale your cluster down while ensuring that the capacity remains available for your use so that you can scale back up when needed.

Topics

• Limitations
• Work with Capacity Reservations in cluster placement groups

Limitations

Keep the following in mind when creating Capacity Reservations in cluster placement groups:

• If an existing Capacity Reservation is not in a placement group, you can't modify the Capacity Reservation to reserve capacity in a placement group. To reserve capacity in a placement group, you must create the Capacity Reservation in the placement group.

• After you create a Capacity Reservation in a placement group, you can't modify it to reserve capacity outside of the placement group.

• You can increase your reserved capacity in a placement group by modifying an existing Capacity Reservation in the placement group, or by creating additional Capacity Reservations in the placement group. However, you increase your chances of getting an insufficient capacity error.

• You can't share Capacity Reservations that have been created in a cluster placement group.

• You can't delete a cluster placement group that has active Capacity Reservations. You must cancel all Capacity Reservations in the cluster placement group before you can delete it.

Work with Capacity Reservations in cluster placement groups

To start using Capacity Reservations with cluster placement groups, perform the following steps.

Note

If you want to create a Capacity Reservation in an existing cluster placement group, skip Step 1. Then for Steps 2 and 3, specify the ARN of the existing cluster placement group. For information about how to find the ARN of your existing cluster placement group, see View placement group information.

Topics
• **Step 1: (Conditional) Create a cluster placement group for use with a Capacity Reservation**

• **Step 2: Create a Capacity Reservation in a cluster placement group**

• **Step 3: Launch instances into the cluster placement group**

**Step 1: (Conditional) Create a cluster placement group for use with a Capacity Reservation**

Perform this step only if you need to create a new cluster placement group. To use an existing cluster placement group, skip this step and then for Steps 2 and 3, use the ARN of that cluster placement group. For information about how to find the ARN of your existing cluster placement group, see [View placement group information](#).

You can create the cluster placement group using one of the following methods.

**Console**

**To create a cluster placement group using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Placement Groups**, and then choose **Create placement group**.
3. For **Name**, specify a descriptive name for the placement group.
4. For **Placement strategy**, choose **Cluster**.
5. Choose **Create group**.
6. In the **Placement groups** table, in the **Group ARN** column, make a note of the ARN of the cluster placement group that you created. You'll need it for the next step.

**AWS CLI**

**To create a cluster placement group using the AWS CLI**

Use the `create-placement-group` command. For **--group-name**, specify a descriptive name for the placement group, and for **--strategy**, specify **cluster**.

The following example creates a placement group named `MyPG` that uses the **cluster** placement strategy.

```
aws ec2 create-placement-group
   --group-name MyPG
```
Make a note of the placement group ARN returned in the command output, because you'll need it for the next step.

**Step 2: Create a Capacity Reservation in a cluster placement group**

You create a Capacity Reservation in a cluster placement group in the same way that you create any Capacity Reservation. However, you must also specify the ARN of the cluster placement group in which to create the Capacity Reservation. For more information, see [Create a Capacity Reservation](#).

**Considerations**

- The specified cluster placement group must be in the available state. If the cluster placement group is in the pending, deleting, or deleted state, the request fails.

- The Capacity Reservation and the cluster placement group must be in the same Availability Zone. If the request to create the Capacity Reservation specifies an Availability Zone that is different from that of the cluster placement group, the request fails.

- You can create Capacity Reservations only for instance types that are supported by cluster placement groups. If you specify an unsupported instance type, the request fails. For more information, see [Cluster placement group rules and limitations](#).

- If you create an open Capacity Reservation in a cluster placement group and there are existing running instances that have matching attributes (placement group ARN, instance type, Availability Zone, platform, and tenancy), those instances automatically run in the Capacity Reservation.

- Your request to create a Capacity Reservation could fail if one of the following is true:
  - Amazon EC2 does not have sufficient capacity to fulfill the request. Either try again at a later time, try a different Availability Zone, or try a smaller capacity. If your workload is flexible across instance types and sizes, try different instance attributes.
  - The requested quantity exceeds your On-Demand Instance limit for the selected instance family. Increase your On-Demand Instance limit for the instance family and try again. For more information, see [On-Demand Instance quotas](#).

You can create the Capacity Reservation in the cluster placement group using one of the following methods.
Console

To create a Capacity Reservation using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Capacity Reservations, and then choose Create Capacity Reservation.
3. On the Create a Capacity Reservation page, specify the instance type, platform, Availability Zone, Tenancy, quantity, and end date as needed.
4. For Placement group, select the ARN of the cluster placement group in which to create the Capacity Reservation.
5. Choose Create.

For more information, see Create a Capacity Reservation.

AWS CLI

To create a Capacity Reservation using the AWS CLI

Use the create-capacity-reservation command. For --placement-group-arn, specify the ARN of the cluster placement group in which to create the Capacity Reservation.

```
$ aws ec2 create-capacity-reservation \
   --instance-type instance_type \
   --instance-platform platform \
   --availability-zone az \
   --instance-count quantity \
   --placement-group-arn placement_group_ARN
```

For more information, see Create a Capacity Reservation.

Step 3: Launch instances into the cluster placement group

You launch an instance into a Capacity Reservation in a cluster placement group in the same way that you launch an instance into any Capacity Reservation. However, you must also specify the ARN of the cluster placement group in which to launch the instance. For more information, see Create a Capacity Reservation.
Considerations

- If the Capacity Reservation is open, you do not need to specify the Capacity Reservation in the instance launch request. If the instance has attributes (placement group ARN, instance type, Availability Zone, platform, and tenancy) that match a Capacity Reservation in the specified placement group, the instance automatically runs in the Capacity Reservation.

- If the Capacity Reservation accepts only targeted instance launches, you must specify the target Capacity Reservation in addition to the cluster placement group in the request.

- If the Capacity Reservation is in a Capacity Reservation group, you must specify the target Capacity Reservation group in addition to the cluster placement group in the request. For more information, see [Work with Capacity Reservation groups](#).

You can launch an instance into a Capacity Reservation in a cluster placement group using one of the following methods.

**Console**

**To launch instances into an existing Capacity Reservation using the console**

1. Follow the procedure to [launch an instance](#), but don't launch the instance until you've completed the following steps to specify the settings for the placement group and Capacity Reservation.

2. Expand **Advanced details** and do the following:

   a. For **Placement group**, select the cluster placement group in which to launch the instance.

   b. For **Capacity Reservation**, choose one of the following options depending on the configuration of the Capacity Reservation:

      - **Open** – To launch the instances into any open Capacity Reservation in the cluster placement group that has matching attributes and sufficient capacity.

      - **Target by ID** – To launch the instances into a Capacity Reservation that accepts only targeted instance launches.

      - **Target by group** – To launch the instances into any Capacity Reservation with matching attributes and available capacity in the selected Capacity Reservation group.
3. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see [Launch an instance using the new launch instance wizard](#).

   For more information, see [Launch instances into an existing Capacity Reservation](#).

### AWS CLI

**To launch instances into an existing Capacity Reservation using the AWS CLI**

Use the `run-instances` command. If you need to target a specific Capacity Reservation or a Capacity Reservation group, specify the `--capacity-reservation-specification` parameter. For `--placement`, specify the `GroupName` parameter and then specify the name of the placement group that you created in the previous steps.

The following command launches an instance into a targeted Capacity Reservation in a cluster placement group.

```
$ aws ec2 run-instances \
  --image-id ami_id \
  --count quantity \
  --instance-type instance_type \
  --key-name key_pair_name \
  --subnet-id subnetid \
  --capacity-reservation-specification CapacityReservationTarget={CapacityReservationId=capacityReservationId} \
  --placement "GroupName=cluster_placement_group_name"
```

For more information, see [Launch instances into an existing Capacity Reservation](#).

### Capacity Reservations in Local Zones

A Local Zone is an extension of an AWS Region that is geographically close to your users. Resources created in a Local Zone can serve local users with very low-latency communications. For more information, see [AWS Local Zones](#).

You can extend a VPC from its parent AWS Region into a Local Zone by creating a new subnet in that Local Zone. When you create a subnet in a Local Zone, your VPC is extended to that Local Zone. The subnet in the Local Zone operates the same as the other subnets in your VPC.
By using Local Zones, you can place Capacity Reservations in multiple locations that are closer to your users. You create and use Capacity Reservations in Local Zones in the same way that you create and use Capacity Reservations in regular Availability Zones. The same features and instance matching behavior apply. For more information about the pricing models that are supported in Local Zones, see AWS Local Zones FAQs.

**Considerations**

You can't use Capacity Reservation groups in a Local Zone.

**To use a Capacity Reservation in a Local Zone**

1. Enable the Local Zone for use in your AWS account. For more information, see Opt in to Local Zones.
2. Create a Capacity Reservation in the Local Zone. For Availability Zone, choose the Local Zone. The Local Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example us-west-2-lax-1a. For more information, see Create a Capacity Reservation.
3. Create a subnet in the Local Zone. For Availability Zone, choose the Local Zone. For more information, see Create a subnet in your VPC in the Amazon VPC User Guide.
4. Launch an instance. For Subnet, choose the subnet in the Local Zone (for example subnet-123abc | us-west-2-lax-1a), and for Capacity Reservation, choose the specification (either open or target it by ID) that's required for the Capacity Reservation that you created in the Local Zone. For more information, see Launch instances into an existing Capacity Reservation.

**Capacity Reservations in Wavelength Zones**

AWS Wavelength enables developers to build applications that deliver ultra-low latencies to mobile devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks. You can extend an Amazon Virtual Private Cloud (VPC) to one or more Wavelength Zones. You can then use AWS resources like Amazon EC2 instances to run applications that require ultra-low latency and a connection to AWS services in the Region. For more information, see AWS Wavelength Zones.

When you create On-Demand Capacity Reservations, you can choose the Wavelength Zone and you can launch instances into a Capacity Reservation in a Wavelength Zone by specifying the subnet.
associated with the Wavelength Zone. A Wavelength Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example us-east-1-wl1-bos-wlz-1.

Wavelength Zones are not available in every Region. For information about the Regions that support Wavelength Zones, see [Available Wavelength Zones](#) in the [AWS Wavelength Developer Guide](#).

**Considerations**

You can't use Capacity Reservation groups in a Wavelength Zone.

**To use a Capacity Reservation in a Wavelength Zone**

1. Enable the Wavelength Zone for use in your AWS account. For more information, see the section called “Enable Wavelength Zones”.

2. Create a Capacity Reservation in the Wavelength Zone. For **Availability Zone**, choose the Wavelength. The Wavelength is represented by an AWS Region code followed by an identifier that indicates the location, for example us-east-1-wl1-bos-wlz-1. For more information, see [Create a Capacity Reservation](#).

3. Create a subnet in the Wavelength Zone. For **Availability Zone**, choose the Wavelength Zone. For more information, see [Create a subnet in your VPC](#) in the [Amazon VPC User Guide](#).

4. Launch an instance. For **Subnet**, choose the subnet in the Wavelength Zone (for example subnet-123abc | us-east-1-wl1-bos-wlz-1), and for **Capacity Reservation**, choose the specification (either open or target it by ID) that's required for the Capacity Reservation that you created in the Wavelength. For more information, see [Launch instances into an existing Capacity Reservation](#).

**Capacity Reservations on AWS Outposts**

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to customer premises. By providing local access to AWS managed infrastructure, AWS Outposts enables customers to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs.

An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region.
You can create Capacity Reservations on Outposts that you have created in your account. This allows you to reserve compute capacity on an Outpost at your site. You create and use Capacity Reservations on Outposts in the same way that you create and use Capacity Reservations in regular Availability Zones. The same features and instance matching behavior apply.

You can also share Capacity Reservations on Outposts with other AWS accounts within your organization using AWS Resource Access Manager. For more information about sharing Capacity Reservations, see Work with shared Capacity Reservations.

Prerequisite

You must have an Outpost installed at your site. For more information, see Create an Outpost and order Outpost capacity in the AWS Outposts User Guide.

Considerations

- You can't use Capacity Reservation groups on an Outpost.

To use a Capacity Reservation on an Outpost

1. Create a subnet on the Outpost. For more information, see Create a subnet in the AWS Outposts User Guide.
2. Create a Capacity Reservation on the Outpost.
   a. Open the AWS Outposts console at https://console.aws.amazon.com/outposts/.
   b. In the navigation pane, choose Outposts, and then choose Actions, Create Capacity Reservation.
   c. Configure the Capacity Reservation as needed and then choose Create. For more information, see Create a Capacity Reservation.

   **Note**
   The Instance Type drop-down lists only instance types that are supported by the selected Outpost, and the Availability Zone drop-down lists only the Availability Zone with which the selected Outpost is associated.

3. Launch an instance into the Capacity Reservation. For Subnet choose the subnet that you created in Step 1, and for Capacity Reservation, select the Capacity Reservation that you
Work with shared Capacity Reservations

Capacity Reservation sharing enables Capacity Reservation owners to share their reserved capacity with other AWS accounts or within an AWS organization. This enables you to create and manage Capacity Reservations centrally, and share the reserved capacity across multiple AWS accounts or within your AWS organization.

In this model, the AWS account that owns the Capacity Reservation (owner) shares it with other AWS accounts (consumers). Consumers can launch instances into Capacity Reservations that are shared with them in the same way that they launch instances into Capacity Reservations that they own in their own account. The Capacity Reservation owner is responsible for managing the Capacity Reservation and the instances that they launch into it. Owners cannot modify instances that consumers launch into Capacity Reservations that they have shared. Consumers are responsible for managing the instances that they launch into Capacity Reservations shared with them. Consumers cannot view or modify instances owned by other consumers or by the Capacity Reservation owner.

A Capacity Reservation owner can share a Capacity Reservation with:

- Specific AWS accounts inside or outside of its AWS organization
- An organizational unit inside its AWS organization
- Its entire AWS organization

Prerequisites for sharing Capacity Reservations

- To share a Capacity Reservation, you must own it in your AWS account. You cannot share a Capacity Reservation that has been shared with you.
- You can only share Capacity Reservations for shared tenancy instances. You cannot share Capacity Reservations for dedicated tenancy instances.
- Capacity Reservation sharing is not available to new AWS accounts or AWS accounts that have a limited billing history.
- To share a Capacity Reservation with your AWS organization or an organizational unit in your AWS organization, you must enable sharing with AWS Organizations. For more information, see Enable Sharing with AWS Organizations in the AWS RAM User Guide.
Related services

Capacity Reservation sharing integrates with AWS Resource Access Manager (AWS RAM). AWS RAM is a service that enables you to share your AWS resources with any AWS account or through AWS Organizations. With AWS RAM, you share resources that you own by creating a resource share. A resource share specifies the resources to share, and the consumers with whom to share them. Consumers can be individual AWS accounts, or organizational units or an entire organization from AWS Organizations.

For more information about AWS RAM, see the AWS RAM User Guide.

Share across Availability Zones

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each account. This could lead to Availability Zone naming differences across accounts. For example, the Availability Zone us-east-1a for your AWS account might not have the same location as us-east-1a for another AWS account.

To identify the location of your Capacity Reservations relative to your accounts, you must use the Availability Zone ID (AZ ID). The AZ ID is a unique and consistent identifier for an Availability Zone across all AWS accounts. For example, use1-az1 is an AZ ID for the us-east-1 Region and it is the same location in every AWS account.

To view the AZ IDs for the Availability Zones in your account

2. The AZ IDs for the current Region are displayed in the Your AZ ID panel on the right-hand side of the screen.

Share a Capacity Reservation

When you share a Capacity Reservation that you own with other AWS accounts, you enable them to launch instances into your reserved capacity. If you share an open Capacity Reservation, keep the following in mind as it could lead to unintended Capacity Reservation usage:

- If consumers have running instances that match the attributes of the Capacity Reservation, have the CapacityReservationPreference parameter set to open, and are not yet running in reserved capacity, they automatically use the shared Capacity Reservation.
• If consumers launch instances that have matching attributes (instance type, platform, Availability Zone, and tenancy) and have the CapacityReservationPreference parameter set to open, they automatically launch into the shared Capacity Reservation.

To share a Capacity Reservation, you must add it to a resource share. A resource share is an AWS RAM resource that lets you share your resources across AWS accounts. A resource share specifies the resources to share, and the consumers with whom they are shared. When you share a Capacity Reservation using the Amazon EC2 console, you add it to an existing resource share. To add the Capacity Reservation to a new resource share, you must create the resource share using the AWS RAM console.

If you are part of an organization in AWS Organizations and sharing within your organization is enabled, consumers in your organization are granted access to the shared Capacity Reservation if the prerequisites for sharing are met. If the Capacity Reservation is shared with external accounts, they receive an invitation to join the resource share and are granted access to the shared Capacity Reservation after accepting the invitation.

⚠️ Important

Before launching instances into a Capacity Reservation that is shared with you, verify that you have access to the shared Capacity Reservation by viewing it in the console or by describing it using the describe-capacity-reservations AWS CLI command. If you can view the shared Capacity Reservation in the console or describe it using the AWS CLI, it is available for your use and you can launch instances into it. If you attempt to launch instances into the Capacity Reservation and it is not accessible due to a sharing failure, the instances will launch into On-Demand capacity.

You can share a Capacity Reservation that you own using the Amazon EC2 console, AWS RAM console, or the AWS CLI.

**To share a Capacity Reservation that you own using the Amazon EC2 console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Capacity Reservations.
3. Choose the Capacity Reservation to share and choose Actions, Share reservation.
4. Select the resource share to which to add the Capacity Reservation and choose **Share Capacity Reservation**.

   It could take a few minutes for consumers to get access to the shared Capacity Reservation.

**To share a Capacity Reservation that you own using the AWS RAM console**

See [Creating a Resource Share](#) in the *AWS RAM User Guide*.

**To share a Capacity Reservation that you own using the AWS CLI**

Use the `create-resource-share` command.

**Stop sharing a Capacity Reservation**

The Capacity Reservation owner can stop sharing a Capacity Reservation at any time. The following rules apply:

- Instances owned by consumers that were running in the shared capacity at the time sharing stops continue to run normally outside of the reserved capacity, and the capacity is restored to the Capacity Reservation subject to Amazon EC2 capacity availability.
- Consumers with whom the Capacity Reservation was shared can no longer launch new instances into the reserved capacity.

To stop sharing a Capacity Reservation that you own, you must remove it from the resource share. You can do this using the Amazon EC2 console, AWS RAM console, or the AWS CLI.

**To stop sharing a Capacity Reservation that you own using the Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Capacity Reservations**.
3. Select the Capacity Reservation and choose the **Sharing** tab.
4. The **Sharing** tab lists the resource shares to which the Capacity Reservation has been added. Select the resource share from which to remove the Capacity Reservation and choose **Remove from resource share**.

**To stop sharing a Capacity Reservation that you own using the AWS RAM console**
See [Updating a Resource Share](#) in the *AWS RAM User Guide*.

**To stop sharing a Capacity Reservation that you own using the AWS CLI**

Use the `disassociate-resource-share` command.

**Identify and view a shared Capacity Reservation**

⚠️ **Important**

Before launching instances into a Capacity Reservation that is shared with you, verify that you have access to the shared Capacity Reservation by viewing it in the console or by describing it using the AWS CLI. If you can view the shared Capacity Reservation in the console or describe it using the AWS CLI, it is available for your use and you can launch instances into it. If you attempt to launch instances into the Capacity Reservation and it is not accessible due to a sharing failure, the instance will launch into On-Demand capacity.

Owners and consumers can identify and view shared Capacity Reservations using the Amazon EC2 console and AWS CLI.

**To identify a shared Capacity Reservation using the Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Capacity Reservations**. The screen lists Capacity Reservations that you own and Capacity Reservations that are shared with you. The **Owner** column shows the AWS account ID of the Capacity Reservation owner. *(me)* next to the AWS account ID indicates that you are the owner.

**To identify a shared Capacity Reservation using the AWS CLI**

Use the `describe-capacity-reservations` command. The command returns the Capacity Reservations that you own and Capacity Reservations that are shared with you. `OwnerId` shows the AWS account ID of the Capacity Reservation owner.

**View shared Capacity Reservation usage**

The owner of a shared Capacity Reservation can view its usage at any time using the Amazon EC2 console and the AWS CLI.
To view Capacity Reservation usage using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Capacity Reservations.
3. Select the Capacity Reservation for which to view the usage and choose the Usage tab.

   The AWS account ID column shows the account IDs of the consumers currently using the Capacity Reservation. The Launched instances column shows the number of instances each consumer currently has running in the reserved capacity.

To view Capacity Reservation usage using the AWS CLI

Use the get-capacity-reservation-usage command. AccountId shows the account ID of the account using the Capacity Reservation. UsedInstanceCount shows the number of instances the consumer currently has running in the reserved capacity.

Shared Capacity Reservation permissions

Permissions for owners

Owners are responsible for managing and canceling their shared Capacity Reservations. Owners cannot modify instances running in the shared Capacity Reservation that are owned by other accounts. Owners remain responsible for managing instances that they launch into the shared Capacity Reservation.

Permissions for consumers

Consumers are responsible for managing their instances that are running the shared Capacity Reservation. Consumers cannot modify the shared Capacity Reservation in any way, and they cannot view or modify instances that are owned by other consumers or the Capacity Reservation owner.

Billing and metering

There are no additional charges for sharing Capacity Reservations.

The Capacity Reservation owner is billed for instances that they run inside the Capacity Reservation and for unused reserved capacity. Consumers are billed for the instances that they run inside the shared Capacity Reservation.
If the Capacity Reservation owner belongs to a different payer account and the Capacity Reservation is covered by a Regional Reserved Instance or a Savings Plan, the Capacity Reservation owner continues to be billed for the Regional Reserved Instance or Savings Plan. In these cases, the Capacity Reservation owner pays for the Regional Reserved Instance or Savings Plan, and consumers are billed for the instances that the run in the shared Capacity Reservation.

Instance limits

All Capacity Reservation usage counts toward the Capacity Reservation owner's On-Demand Instance limits. This includes:

- Unused reserved capacity
- Usage by instances owned by the Capacity Reservation owner
- Usage by instances owned by consumers

Instances launched into the shared capacity by consumers count towards the Capacity Reservation owner's On-Demand Instance limit. Consumers' instance limits are a sum of their own On-Demand Instance limits and the capacity available in the shared Capacity Reservations to which they have access.

Capacity Reservation Fleets

An On-Demand Capacity Reservation Fleet is a group of Capacity Reservations.

A Capacity Reservation Fleet request contains all of the configuration information that's needed to launch a Capacity Reservation Fleet. Using a single request, you can reserve large amounts of Amazon EC2 capacity for your workload across multiple instance types, up to a target capacity that you specify.

After you create a Capacity Reservation Fleet, you can manage the Capacity Reservations in the fleet collectively by modifying or canceling the Capacity Reservation Fleet.

- Work with Capacity Reservation Fleets
How Capacity Reservation Fleets work

When you create a Capacity Reservation Fleet, the Fleet attempts to create individual Capacity Reservations to meet the total target capacity that you specified in the Fleet request.

The number of instances for which the Fleet reserves capacity depends on the total target capacity and the instance type weights that you specify. The instance type for which it reserves capacity depends on the allocation strategy and instance type priorities that you use.

If there is insufficient capacity at the time the Fleet is created, and it is unable to immediately meet its total target capacity, the Fleet asynchronously attempts to create Capacity Reservations until it has reserved the requested amount of capacity.

When the Fleet reaches its total target capacity, it attempts to maintain that capacity. If a Capacity Reservation in the Fleet is cancelled, the Fleet automatically creates one or more Capacity Reservations, depending on your Fleet configuration, to replace the lost capacity and to maintain its total target capacity.

The Capacity Reservations in the Fleet can't be managed individually. They must be managed collectively by modifying the Fleet. When you modify a Fleet, the Capacity Reservations in the Fleet are automatically updated to reflect the changes.

Currently, Capacity Reservation Fleets support the open instance matching criteria, and all Capacity Reservations launched by a Fleet automatically use this instance matching criteria. With this criteria, new instances and existing instances that have matching attributes (instance type, platform, Availability Zone, and tenancy) automatically run in the Capacity Reservations created by a Fleet. Capacity Reservation Fleets do not support target instance matching criteria.

Considerations

Keep the following in mind when working with Capacity Reservation Fleets:

- A Capacity Reservation Fleet can be created, modified, viewed, and cancelled using the AWS CLI and AWS API.
- The Capacity Reservations in a Fleet can't be managed individually. They must be managed collectively by modifying or cancelling the Fleet.
- A Capacity Reservation Fleet can't span across Regions.
• A Capacity Reservation Fleet can't span across Availability Zones.

• Capacity Reservations created by a Capacity Reservation Fleet are automatically tagged with the following AWS generated tag:
  • Key — aws:ec2-capacity-reservation-fleet
  • Value — fleet_id

  You can use this tag to identify Capacity Reservations that were created by a Capacity Reservation Fleet.

**Pricing**

There are no additional charges for using Capacity Reservation Fleets. You are billed for the individual Capacity Reservations that are created by your Capacity Reservation Fleets. For more information about how Capacity Reservations are billed, see [Capacity Reservation pricing and billing](#).

**Capacity Reservation Fleet concepts**

This topic describes some of the concepts of Capacity Reservation Fleets.

**Topics**

• [Total target capacity](#)
• [Allocation strategy](#)
• [Instance type weight](#)
• [Instance type priority](#)

**Total target capacity**

The *total target capacity* defines the total amount of compute capacity that the Capacity Reservation Fleet reserves. You specify the total target capacity when you create the Capacity Reservation Fleet. After the Fleet has been created, Amazon EC2 automatically creates Capacity Reservations to reserve capacity up to the total target capacity.

The number of instances for which the Capacity Reservation Fleet reserves capacity is determined by the total target capacity and the *instance type weight* that you specify for each instance type in the Capacity Reservation Fleet (total target capacity/instance type weight=number of instances).
You can assign a total target capacity based on units that are meaningful to your workload. For example, if your workload requires a certain number of vCPUs, you can assign the total target capacity based on the number of vCPUs required. If your workload requires 2048 vCPUs, specify a total target capacity of 2048 and then assign instance type weights based on the number of vCPUs provided by the instance types in the Fleet. For an example, see Instance type weight.

**Allocation strategy**

The allocation strategy for your Capacity Reservation Fleet determines how it fulfills your request for reserved capacity from the instance type specifications in the Capacity Reservation Fleet configuration.

Currently, only the prioritized allocation strategy is supported. With this strategy, the Capacity Reservation Fleet creates Capacity Reservations using the priorities that you have assigned to each of the instance type specifications in the Capacity Reservation Fleet configuration. Lower priority values indicate higher priority for use. For example, say you create a Capacity Reservation Fleet that uses the following instance types and priorities:

- m4.16xlarge — priority = 1
- m5.16xlarge — priority = 3
- m5.24xlarge — priority = 2

The Fleet first attempts to create Capacity Reservations for m4.16xlarge. If Amazon EC2 has insufficient m4.16xlarge capacity, the Fleet attempts to create Capacity Reservations for m5.24xlarge. If Amazon EC2 has insufficient m5.24xlarge capacity, the Fleet creates Capacity Reservations for m5.16xlarge.

**Instance type weight**

The instance type weight is a weight that you assign to each instance type in the Capacity Reservation Fleet. The weight determines how many units of capacity each instance of that specific instance type counts toward the Fleet's total target capacity.

You can assign weights based on units that are meaningful to your workload. For example, if your workload requires a certain number of vCPUs, you can assign weights based on the number of vCPUs provided by each instance type in the Capacity Reservation Fleet. In this case, if you create a Capacity Reservation Fleet using m4.16xlarge and m5.24xlarge instances, you would assign weights that correspond to the number of vCPUs for each instance as follows:
- m4.16xlarge — 64 vCPUs, weight = 64 units
- m5.24xlarge — 96 vCPUs, weight = 96 units

The instance type weight determines the number of instances for which the Capacity Reservation Fleet reserves capacity. For example, if a Capacity Reservation Fleet with a total target capacity of 384 units uses the instance types and weights in the preceding example, the Fleet could reserve capacity for 6 m4.16xlarge instances (384 total target capacity / 64 instance type weight = 6 instances), or 4 m5.24xlarge instances (384 / 96 = 4).

If you do not assign instance type weights, or if you assign an instance type weight of 1, the total target capacity is based purely on instance count. For example, if a Capacity Reservation Fleet with a total target capacity of 384 units uses the instance types in the preceding example, but omits the weights or specifies a weight of 1 for both instance types, the Fleet could reserve capacity for either 384 m4.16xlarge instances or 384 m5.24xlarge instances.

Instance type priority

The instance type priority is a value that you assign to the instance types in the Fleet. The priorities are used to determine which of the instance types specified for the Fleet should be prioritized for use.

Lower priority values indicate a higher priority for use.

Work with Capacity Reservation Fleets

Topics
- Before you begin
- Capacity Reservation Fleet states
- Create a Capacity Reservation Fleet
- View a Capacity Reservation Fleet
- Modify a Capacity Reservation Fleet
- Cancel a Capacity Reservation Fleet

Before you begin

Before you create a Capacity Reservation Fleet:
1. Determine the amount of compute capacity that is needed by your workload.

2. Decide on the instance types and Availability Zones that you want to use.

3. Assign each instance type a priority based on your needs and preferences. For more information, see Instance type priority.

4. Create a capacity weighting system that makes sense for your workload. Assign a weight to each instance type and determine your total target capacity. For more information, see Instance type weight and Total target capacity.

5. Determine whether you need the Capacity Reservation indefinitely or only for a specific period of time.

**Capacity Reservation Fleet states**

A Capacity Reservation Fleet can be in one of the following states:

- **submitted** — The Capacity Reservation Fleet request has been submitted and Amazon EC2 is preparing to create the Capacity Reservations.
- **modifying** — The Capacity Reservation Fleet is being modified. The Fleet remains in this state until the modification is complete.
- **active** — The Capacity Reservation Fleet has fulfilled its total target capacity and it is attempting to maintain this capacity. The Fleet remains in this state until it is modified or deleted.
- **partially_fulfilled** — The Capacity Reservation Fleet has partially fulfilled its total target capacity. There is insufficient Amazon EC2 capacity to fulfill the total target capacity. The Fleet is attempting to asynchronously fulfill its total target capacity.
- **expiring** — The Capacity Reservation Fleet has reached its end date and it is in the process of expiring. One or more of its Capacity Reservations might still be active.
- **expired** — The Capacity Reservation Fleet has reached its end date. The Fleet and its Capacity Reservations are expired. The Fleet can't create new Capacity Reservations.
- **cancelling** — The Capacity Reservation Fleet is in the process of being cancelled. One or more of its Capacity Reservations might still be active.
- **cancelled** — The Capacity Reservation Fleet has been manually cancelled. The Fleet and its Capacity Reservations are cancelled and the Fleet can't create new Capacity Reservations.
- **failed** — The Capacity Reservation Fleet failed to reserve capacity for the specified instance types.
Create a Capacity Reservation Fleet

When you create a Capacity Reservation Fleet it automatically creates Capacity Reservations for the instance types specified in the Fleet request, up to the specified total target capacity. The number of instances for which the Capacity Reservation Fleet reserves capacity depends on the total target capacity and instance type weights that you specify in the request. For more information, see Instance type weight and Total target capacity.

When you create the Fleet, you must specify the instance types to use and a priority for each of those instance types. For more information, see Allocation strategy and Instance type priority.

Note

The AWSServiceRoleForEC2CapacityReservationFleet service-linked role is automatically created in your account the first time that you create a Capacity Reservation Fleet. For more information, see Using service-linked roles for Capacity Reservation Fleet.

Currently, Capacity Reservation Fleets support the open instance matching criteria only.

You can create a Capacity Reservation Fleet using the command line only.

To create a Capacity Reservation Fleet

Use the create-capacity-reservation-fleet AWS CLI command.

```bash
aws ec2 create-capacity-reservation-fleet \
--total-target-capacity capacity_units \
--allocation-strategy prioritized \
--instance-match-criteria open \
--tenancy dedicated|default \
--end-date yyyy-mm-ddThh:mm:ss.000Z \
--instance-type-specifications file://instanceTypeSpecification.json
```

The following is the contents of instanceTypeSpecification.json.

```json
[
  {
    "InstanceType": "instance_type",
    "InstancePlatform": "platform",
    "Weight": "instance_type_weight",
  }
]
```
"AvailabilityZone":"availability_zone",
"AvailabilityZoneId" : "az_id",
"EbsOptimized": true|false,
"Priority" : instance_type_priority
}
]

Expected output.
{
  "Status": "status",
  "TotalFulfilledCapacity": fulfilled_capacity,
  "CapacityReservationFleetId": "cr_fleet_id",
  "TotalTargetCapacity": capacity_units
}

Example
aws ec2 create-capacity-reservation-fleet \
--total-target-capacity 24 \
--allocation-strategy prioritized \
--instance-match-criteria open \
--tenancy default \
--end-date 2021-12-31T23:59:59.000Z \
--instance-type-specifications file://instanceTypeSpecification.json

instanceTypeSpecification.json
[
  {
    "InstanceType": "m5.xlarge",
    "InstancePlatform": "Linux/UNIX",
    "Weight": 3.0,
    "AvailabilityZone":"us-east-1a",
    "EbsOptimized": true,
    "Priority" : 1
  }
]

Example output.
{

View a Capacity Reservation Fleet

You can view configuration and capacity information for a Capacity Reservation Fleet at any time. Viewing a Fleet also provides details about the individual Capacity Reservations that are inside the Fleet.

You can view a Capacity Reservation Fleet using the command line only.

To view a Capacity Reservation Fleet

Use the `describe-capacity-reservation-fleets` AWS CLI command.

```
aws ec2 describe-capacity-reservation-fleets \
--capacity-reservation-fleet-ids cr_fleet_ids
```

Expected output

```json
{
  "CapacityReservationFleets": [
    {
      "Status": "status",
      "EndDate": "yyyy-mm-ddThh:mm:ss.000Z",
      "InstanceMatchCriteria": "open",
      "Tags": [],
      "CapacityReservationFleetId": "cr_fleet_id",
      "Tenancy": "dedicated|default",
      "InstanceTypeSpecifications": [
        {
          "CapacityReservationId": "cr1_id",
          "AvailabilityZone": "cr1_availability_zone",
          "FulfilledCapacity": cr1_used_capacity,
          "Weight": cr1_instance_type_weight,
          "CreateDate": "yyyy-mm-ddThh:mm:ss.000Z",
          "InstancePlatform": "cr1_platform",
          "TotalInstanceCount": cr1_number_of_instances,
          "Priority": cr1_instance_type_priority,
          "EbsOptimized": true|false,
        }
      ]
    }
  ]
}
```
"InstanceType": "cr1_instance_type"
],
{
  "CapacityReservationId": "cr2_id",
  "AvailabilityZone": "cr2_availability_zone",
  "FulfilledCapacity": "cr2_used_capacity",
  "Weight": "cr2_instance_type_weight",
  "CreateDate": "yyyy-mm-ddThh:mm:ss.000Z",
  "InstancePlatform": "cr2_platform",
  "TotalInstanceCount": "cr2_number_of_instances",
  "Priority": "cr2_instance_type_priority",
  "EbsOptimized": true|false,
  "InstanceType": "cr2_instance_type"
},
],
"TotalTargetCapacity": total_target_capacity,
"TotalFulfilledCapacity": total_target_capacity,
"CreateTime": "yyyy-mm-ddThh:mm:ss.000Z",
"AllocationStrategy": "prioritized"
]

Example

```bash
aws ec2 describe-capacity-reservation-fleets \
   --capacity-reservation-fleet-ids crf-abcdef01234567890
```

Example output

```json
{
  "CapacityReservationFleets": [
    {
      "Status": "active",
      "EndDate": "2021-12-31T23:59:59.000Z",
      "InstanceMatchCriteria": "open",
      "Tags": [],
      "CapacityReservationFleetId": "crf-abcdef01234567890",
      "Tenancy": "default",
      "InstanceTypeSpecifications": [
        {
          "CapacityReservationId": "cr-1234567890abcdef0",
          "AvailabilityZone": "us-east-1a",
```
Modify a Capacity Reservation Fleet

You can modify the total target capacity and date of a Capacity Reservation Fleet at any time. When you modify the total target capacity of a Capacity Reservation Fleet, the Fleet automatically creates new Capacity Reservations, or modifies or cancels existing Capacity Reservations in the Fleet to meet the new total target capacity. When you modify the end date for the Fleet, the end dates for all of the individual Capacity Reservations are updated accordingly.

After you modify a Fleet, its status transitions to modifying. You can't attempt additional modifications to a Fleet while it is in the modifying state.

You can't modify the tenancy, Availability Zone, instance types, instance platforms, priorities, or weights used by a Capacity Reservation Fleet. If you need to change any of these parameters, you might need to cancel the existing Fleet and create a new one with the required parameters.

You can modify a Capacity Reservation Fleet using the command line only.

To modify a Capacity Reservation Fleet

Use the `modify-capacity-reservation-fleet` AWS CLI command.

⚠️ Note

You can't specify `--end-date` and `--remove-end-date` in the same command.
aws ec2 modify-capacity-reservation-fleet \
   --capacity-reservation-fleet-id cr_fleet_ids \
   --total-target-capacity capacity_units \
   --end-date yyyy-mm-ddT.hh:mm:ss.000Z \
   --remove-end-date

Expected output

```

{  
   "Return": true  
}
```

Example: Modify total target capacity

```

aws ec2 modify-capacity-reservation-fleet \
   --capacity-reservation-fleet-id crf-01234567890abcedf \
   --total-target-capacity 160
```

Example: Modify end date

```

aws ec2 modify-capacity-reservation-fleet \
   --capacity-reservation-fleet-id crf-01234567890abcedf \
   --end-date 2021-07-04T23:59:59.000Z
```

Example: Remove end date

```

aws ec2 modify-capacity-reservation-fleet \
   --capacity-reservation-fleet-id crf-01234567890abcedf \
   --remove-end-date
```

Example output

```

{  
    "Return": true  
}
```

Cancel a Capacity Reservation Fleet

When you no longer need a Capacity Reservation Fleet and the capacity it reserves, you can cancel it. When you cancel a Fleet, its status changes to cancelled and it can no longer create new Capacity Reservations.
Capacity Reservations. Additionally, all of the individual Capacity Reservations in the Fleet are cancelled and the instances that were previously running in the reserved capacity continue to run normally in shared capacity.

You can cancel a Capacity Reservation Fleet using the command line only.

**To cancel a Capacity Reservation Fleet**

Use the `cancel-capacity-reservation-fleet` AWS CLI command.

```bash
aws ec2 cancel-capacity-reservation-fleets \
--capacity-reservation-fleet-ids cr_fleet_ids
```

**Expected output**

```json
{
  "SuccessfulFleetCancellations": [
    {
      "CurrentFleetState": "state",
      "PreviousFleetState": "state",
      "CapacityReservationFleetId": "cr_fleet_id_1"
    },
    {
      "CurrentFleetState": "state",
      "PreviousFleetState": "state",
      "CapacityReservationFleetId": "cr_fleet_id_2"
    }
  ],
  "FailedFleetCancellations": [
    {
      "CapacityReservationFleetId": "cr_fleet_id_3",
      "CancelCapacityReservationFleetError": [
        {
          "Code": "code",
          "Message": "message"
        }
      ]
    }
  ]
}
```

**Example: Successful cancellation**
aws ec2 cancel-capacity-reservation-fleets \
--capacity-resolution-fleet-ids crf-abcdef01234567890

Example output

```javascript
{
   "SuccessfulFleetCancellations": [
      {
         "CurrentFleetState": "cancelling",
         "PreviousFleetState": "active",
         "CapacityReservationFleetId": "crf-abcdef01234567890"
      }
   ],
   "FailedFleetCancellations": []
}
```

Example Capacity Reservation Fleet configurations

Topics

- **Example 1: Reserve capacity based on vCPUs**

**Example 1: Reserve capacity based on vCPUs**

The following example creates a Capacity Reservation Fleet that uses two instance types: m5.4xlarge and m5.12xlarge.

It uses a weighting system based on the number of vCPUs provided by the specified instance types. The total target capacity is 480 vCPUs. The m5.4xlarge provides 16 vCPUs and gets a weight of 16, while the m5.12xlarge provides 48 vCPUs and gets a weight of 48. This weighting system configures the Capacity Reservation Fleet to reserve capacity for either 30 m5.4xlarge instances (480/16=30), or 10 m5.12xlarge instances (480/48=10).

The Fleet is configured to prioritize the m5.12xlarge capacity and gets priority of 1, while the m5.4xlarge gets a lower priority of 2. This means that the fleet will attempt to reserve the m5.12xlarge capacity first, and only attempt to reserve the m5.4xlarge capacity if Amazon EC2 has insufficient m5.12xlarge capacity.

The Fleet reserves the capacity for Windows instances and the reservation automatically expires on October 31, 2021 at 23:59:59 UTC.
The following is the contents of `instanceTypeSpecification.json`.

```
[
    {
        "InstanceType": "m5.4xlarge",
        "InstancePlatform": "Windows",
        "Weight": 16,
        "AvailabilityZone": "us-east-1a",
        "EbsOptimized": true,
        "Priority": 2
    },
    {
        "InstanceType": "m5.12xlarge",
        "InstancePlatform": "Windows",
        "Weight": 48,
        "AvailabilityZone": "us-east-1a",
        "EbsOptimized": true,
        "Priority": 1
    }
]
```

### Using service-linked roles for Capacity Reservation Fleet

On-Demand Capacity Reservation Fleet uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Capacity Reservation Fleet. Service-linked roles are predefined by Capacity Reservation Fleet and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Capacity Reservation Fleet easier because you don’t have to manually add the necessary permissions. Capacity Reservation Fleet defines the permissions of its service-linked roles, and unless defined otherwise, only Capacity Reservation Fleet can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.
You can delete a service-linked role only after first deleting their related resources. This protects your Capacity Reservation Fleet resources because you can't inadvertently remove permission to access the resources.

**Service-linked role permissions for Capacity Reservation Fleet**

Capacity Reservation Fleet uses the service-linked role named `AWSServiceRoleForEC2CapacityReservationFleet` to create, describe, modify, and cancel Capacity Reservations that were previously created by a Capacity Reservation Fleet, on your behalf.

The `AWSServiceRoleForEC2CapacityReservationFleet` service-linked role trusts the following entity to assume the role: `capacity-reservation-fleet.amazonaws.com`.

The role uses the `AWSSEC2CapacityReservationFleetRolePolicy` policy, which includes the following permissions:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["ec2:DescribeCapacityReservations",
                        "ec2:DescribeInstances"],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": ["ec2:CreateCapacityReservation",
                        "ec2:CancelCapacityReservation",
                        "ec2:ModifyCapacityReservation"],
            "Resource": ["arn:aws:ec2:***:capacity-reservation/**"],
            "Condition": {
                "StringLike": {
                    "ec2:CapacityReservationFleet": "arn:aws:ec2:***:capacity-reservation-fleet/crf-***"
                }
            }
        }
    ]
}
```
You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-Linked Role Permissions in the IAM User Guide.

**Create a service-linked role for Capacity Reservation Fleet**

You don't need to manually create a service-linked role. When you create a Capacity Reservation Fleet using the create-capacity-reservation-fleet AWS CLI command or the CreateCapacityReservationFleet API, the service-linked role is automatically created for you.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a Capacity Reservation Fleet, Capacity Reservation Fleet creates the service-linked role for you again.

**Edit a service-linked role for Capacity Reservation Fleet**

Capacity Reservation Fleet does not allow you to edit the AWSServiceRoleForEC2CapacityReservationFleet service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a Service-Linked Role in the IAM User Guide.
Delete a service-linked role for Capacity Reservation Fleet

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don't have an unused entity that is not actively monitored or maintained. However, you must delete the resources for your service-linked role before you can manually delete it.

Note

If the Capacity Reservation Fleet service is using the role when you try to delete the resources, then the deletion might fail. If that happens, wait for a few minutes and try the operation again.

To delete the AWSServiceRoleForEC2CapacityReservationFleet service-linked role

1. Use the delete-capacity-reservation-fleet AWS CLI command or the DeleteCapacityReservationFleet API to delete the Capacity Reservation Fleets in your account.
2. Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForEC2CapacityReservationFleet service-linked role. For more information, see Deleting a Service-Linked Role in the IAM User Guide.

Supported Regions for Capacity Reservation Fleet service-linked roles

Capacity Reservation Fleet supports using service-linked roles in all of the Regions where the service is available. For more information, see AWS Regions and Endpoints.

Monitoring Capacity Reservations

You can use the following features to monitor your Capacity Reservations:

Topics

- Monitor Capacity Reservations using CloudWatch metrics
- Monitor Capacity Reservations using EventBridge
- Utilization notifications
Monitor Capacity Reservations using CloudWatch metrics

With CloudWatch metrics, you can efficiently monitor your Capacity Reservations and identify unused capacity by setting CloudWatch alarms to notify you when usage thresholds are met. This can help you maintain a constant Capacity Reservation volume and achieve a higher level of utilization.

On-Demand Capacity Reservations send metric data to CloudWatch every five minutes. Metrics are not supported for Capacity Reservations that are active for less than five minutes.

For more information about viewing metrics in the CloudWatch console, see Using Amazon CloudWatch Metrics. For more information about creating alarms, see Creating Amazon CloudWatch Alarms.

Contents

- Capacity Reservation usage metrics
- Capacity Reservation metric dimensions
- View CloudWatch metrics for Capacity Reservations

Capacity Reservation usage metrics

The AWS/EC2CapacityReservations namespace includes the following usage metrics you can use to monitor and maintain on-demand capacity within thresholds you specify for your reservation.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UsedInstanceCount</td>
<td>The number of instances that are currently in use.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td>AvailableInstanceCount</td>
<td>The number of instances that are available.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td>TotalInstanceCount</td>
<td>The total number of instances you have reserved.</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>InstanceUtilization</td>
<td>The percentage of reserved capacity instances that are currently in use.</td>
</tr>
</tbody>
</table>

**Capacity Reservation metric dimensions**

You can use the following dimensions to refine the metrics listed in the previous table.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CapacityReservationId</td>
<td>This globally unique dimension filters the data you request for the identified capacity reservation only.</td>
</tr>
</tbody>
</table>

**View CloudWatch metrics for Capacity Reservations**

Metrics are grouped first by the service namespace, and then by the supported dimensions. You can use the following procedures to view the metrics for your Capacity Reservations.

**To view Capacity Reservation metrics using the CloudWatch console**

2. If necessary, change the Region. From the navigation bar, select the Region where your Capacity Reservation resides. For more information, see [Regions and Endpoints](https://aws.amazon.com/regions/

3. In the navigation pane, choose **Metrics**.
4. For **All metrics**, choose **EC2 Capacity Reservations**.
5. Choose the metric dimension **By Capacity Reservation**. Metrics will be grouped by CapacityReservationId.
6. To sort the metrics, use the column heading. To graph a metric, select the check box next to the metric.
To view Capacity Reservation metrics (AWS CLI)

Use the following `list-metrics` command:

```
aws cloudwatch list-metrics --namespace "AWS/EC2CapacityReservations"
```

Monitor Capacity Reservations using EventBridge

AWS Health sends events to Amazon EventBridge when a Capacity Reservation in your account is below 20 percent usage over certain periods. With EventBridge, you can establish rules that trigger programmatic actions in response to such events. For example, you can create a rule that automatically cancels a Capacity Reservation when its utilization drops below 20 percent utilization over a 7-day period.

Events in EventBridge are represented as JSON objects. The fields that are unique to the event are contained in the "detail" section of the JSON object. The "event" field contains the event name. The "result" field contains the completed status of the action that triggered the event. For more information, see Amazon EventBridge event patterns in the Amazon EventBridge User Guide.

For more information, see the Amazon EventBridge User Guide.

This feature is not supported in AWS GovCloud (US).

Contents

- Events
- Create an EventBridge rule

Events

AWS Health sends the following events when capacity usage for a Capacity Reservation is below 20 percent.

Events

- [AWS_EC2_ODCR_UNDERUTILIZATION_NOTIFICATION](#)
- [AWS_EC2_ODCR_UNDERUTILIZATION_NOTIFICATION_SUMMARY](#)
**AWS_EC2_ODCR_UNDERUTILIZATION_NOTIFICATION**

The following is an example of an event that is generated when a newly created Capacity Reservation is below 20 percent capacity usage over a 24-hour period.

```json
{
    "version": "0",
    "id": "b3e00086-f271-12a1-a36c-55e8ddaa130a",

**AWS_EC2_ODCR_UNDERUTILIZATION_NOTIFICATION_SUMMARY**

The following is an example of an event that is generated when one or more Capacity Reservation is below 20 percent capacity usage over a 7-day period.

[Capacity Reservations](#)
A description of the event will be provided here.
Create an EventBridge rule

To receive email notifications when your Capacity Reservation utilization drops below 20 percent, create an Amazon SNS topic, and then create an EventBridge rule for the AWS_EC2_ODCR_UNDERUTILIZATION_NOTIFICATION event.

To create the Amazon SNS topic

2. In the navigation pane, choose Topics, and then choose Create topic.
3. For Type, choose Standard.
4. For Name, enter a name for the new topic.
5. Choose Create topic.
6. Choose Create subscription.
7. For Protocol, choose Email, and then for Endpoint, enter the email address that receives the notifications.
8. Choose Create subscription.
9. The email address entered above will receive email message with the following subject line: AWS Notification - Subscription Confirmation. Follow the directions to confirm your subscription.

To create the EventBridge rule

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. In the navigation pane, choose Rules, and then choose Create rule.
3. For Name, enter a name for the new rule.
4. For Rule type, choose Rule with an event pattern.
5. Choose Next.
6. In the Event pattern, do the following:
   a. For Event source, choose AWS services.
   b. For AWS service, choose AWS Health.
   c. For Event type, choose EC2 ODCR Underutilization Notification.
7. Choose Next.
8. For Target 1, do the following:
a. For **Target types**, choose **AWS service**.

b. For **Select a target**, choose **SNS topic**.

c. For **Topic**, choose the topic that you created earlier.

9. Choose **Next** and then **Next** again.

10. Choose **Create rule**.

**Utilization notifications**

AWS Health sends the following email and AWS Health Dashboard notifications when capacity utilization for Capacity Reservations in your account drops below 20 percent.

- Individual notifications for each newly created Capacity Reservation that has been below 20 percent utilization over the last 24-hour period.
- A summary notification for all Capacity Reservations that have been below 20 percent utilization over the last 7-day period.

The email notifications and AWS Health Dashboard notifications are sent to the email address associated with the AWS account that owns the Capacity Reservations. The notifications include the following information:

- The ID of the Capacity Reservation.
- The Availability Zone of the Capacity Reservation.
- The average utilization rate for the Capacity Reservation.
- The instance type and platform (operating system) of the Capacity Reservation.

Additionally, when capacity utilization for a Capacity Reservation in your account drops below 20 percent over a 24-hour and 7-day period, AWS Health sends events to EventBridge. With EventBridge, you can create rules that activate automatic actions, such as sending email notifications or triggering AWS Lambda functions, in response to such events. For more information, see [Monitor Capacity Reservations using EventBridge](#).

**Capacity Blocks for ML**

Capacity Blocks for ML allow you to reserve highly sought-after GPU instances on a future date to support your short duration machine learning (ML) workloads. Instances that run inside a Capacity
Block are automatically placed close together inside Amazon EC2 UltraClusters, for low-latency, petabit-scale, nonblocking networking.

With Capacity Blocks, you can see when GPU instance capacity is available on future dates, and you can schedule a Capacity Block to start at a time that works best for you. When you reserve a Capacity Block, you get predictable capacity assurance for GPU instances while paying only for the amount of time that you need. We recommend Capacity Blocks when you need GPUs to support your ML workloads for days or weeks at a time and don't want to pay for a reservation while your GPU instances aren't in use.

The following are some common use cases for Capacity Blocks.

- **ML model training and fine-tuning** – Get uninterrupted access to the GPU instances that you reserved to complete ML model training and fine-tuning.

- **ML experiments and prototypes** – Run experiments and build prototypes that require GPU instances for short durations.

Capacity Blocks are currently available for p5.48xlarge and p4d.24xlarge instances. The p5.48xlarge instances are available in the US East (Ohio) and US East (N. Virginia) Regions. The p4d.24xlarge instances are available in the US East (Ohio) and the US West (Oregon) Regions. You can reserve a Capacity Block with a reservation start time up to eight weeks in the future.

You can use Capacity Blocks to reserve p5 and p4d instances with the following reservation duration and instance quantity options.

- Reservation durations for **1-day increments up 14 days and 7-day increments up to 28 days total**
- Reservation instance quantity options of **1, 2, 4, 8, 16, 32, or 64 instances**

To reserve a Capacity Block, you start by specifying your capacity needs, including the instance type, the number of instances, amount of time, earliest start date, and latest end date that you need. Then, you can see an available Capacity Block offering that meets your specifications. The Capacity Block offering includes details such as start time, Availability Zone, and reservation price. The price of a Capacity Block offering depends on available supply and demand at the time the offering was delivered. After you reserve a Capacity Block, the price doesn't change. For more information, see [Capacity Blocks pricing and billing](#).
When you purchase a Capacity Block offering, your reservation is created for the date and number of instances that you selected. When your Capacity Block reservation begins, you can target instance launches by specifying the reservation ID in your launch requests.

You can use all the instances you reserved until 30 minutes before the end time of the Capacity Block. With 30 minutes left in your Capacity Block reservation, we begin terminating any instances that are running in the Capacity Block. We use this time to clean up your instances before delivering the Capacity Block to the next customer. The last 30 minutes of the reservation are not charged in the price of the Capacity Block. We emit an event through EventBridge 10 minutes before the termination process begins. For more information, see Monitor Capacity Blocks with EventBridge.

- Supported platforms
- Considerations
- Related resources
- Capacity Blocks pricing and billing
- Work with Capacity Blocks
- Monitor Capacity Blocks

Supported platforms

Capacity Blocks for ML currently support p5.48xlarge and p4d.24xlarge instances with default tenancy. When you use the AWS Management Console to purchase a Capacity Block, the default platform option is Linux/UNIX. When you use the AWS Command Line Interface (AWS CLI) or AWS SDK to purchase a Capacity Block, the following platform options are available:

- Linux/Unix
- Red Hat Enterprise Linux
- RHEL with HA
- SUSE Linux
- Ubuntu Pro

Considerations

Before you use Capacity Blocks, consider the following details and limitations.
• Capacity Blocks start and end at 11:30AM Coordinated Universal Time (UTC).

• The termination process for instances running in a Capacity Block begins at 11:00AM Coordinated Universal Time (UTC) on the final day of the reservation.

• Capacity Blocks can be reserved with a start time up to 8 weeks in the future.

• Capacity Block modifications and cancellations aren't allowed.

• Capacity Blocks can't be shared across AWS accounts or within your AWS Organization.

• Capacity Blocks can't be used in a capacity reservation group.

• The total number of instances that can be reserved in Capacity Blocks across all accounts in your AWS Organization can't exceed 64 instances on a particular date.

• To use a Capacity Block, instances must specifically target the reservation ID.

• Instances in a Capacity Block don't count against your On-Demand Instances limits.

• For P5 instances using a custom AMI, ensure that you have the required software and configuration for EFA.

• For Amazon EKS managed node groups, see Create a managed node group with Amazon EC2 Capacity Blocks for ML. For Amazon EKS self-managed node groups, see Use Capacity Blocks for ML with self-managed nodes.

Related resources

After you create a Capacity Block, you can do the following with the Capacity Block:

• Launch instances into the Capacity Block. For more information, see Launch instances into Capacity Blocks.

• Create an Amazon EC2 Auto Scaling group. For more information, see Use Capacity Blocks for machine learning workloads in the Amazon EC2 Auto Scaling User Guide.

Note

If you use Amazon EC2 Auto Scaling or Amazon EKS, you can schedule scaling to run at the start of the Capacity Block reservation. With scheduled scaling, AWS automatically handles retries for you, so you don’t need to worry about implementing retry logic to handle transient failures.

• Enhance ML workflows with AWS ParallelCluster. For more information, see Enhancing ML workflows with AWS ParallelCluster and Amazon EC2 Capacity Blocks for ML.
For more information about AWS ParallelCluster, see What is AWS ParallelCluster.

Capacity Blocks pricing and billing

Topics

• Pricing
• Billing

Pricing

With Amazon EC2 Capacity Blocks for ML, you pay only for what you reserve. The price of a Capacity Block depends on available supply and demand for Capacity Blocks at the time of purchase. You can view the price of a Capacity Block offering before you reserve it. The price of the Capacity Block is charged up front at the time the reservation is made. When you search for a Capacity Block across a range of dates, we return the lowest-priced Capacity Block offering available. After you've reserved a Capacity Block, the price doesn't change.

When you use a Capacity Block, you pay for the operating system you use when your instances are running. For more information about operating system prices, see Amazon EC2 Capacity Blocks for ML Pricing.

Billing

The price of a Capacity Block offering is charged up front. Payment is billed to your AWS account within 12 hours after you purchase a Capacity Block. While your payment is processing, your Capacity Block reservation resource remains in a state of payment-pending. If your payment can't be processed within 12 hours, your Capacity Block is released and the reservation state changes to payment-failed.

After your payment is processed successfully, the Capacity Block resource state changes from payment-pending to scheduled. You receive an invoice that reflects the one-time upfront payment. In the invoice, you can associate the paid amount with the Capacity Block reservation ID.

When your Capacity Block reservation begins, you are billed based only on the operating system you use while your instances are running in the reservation. You can view your usage and associated charges in your anniversary bill for the month of usage in your AWS Cost and Usage Report.
Note

Savings Plans and Reserved Instance discounts don't apply to Capacity Blocks.

Viewing your bill

You can view your bill in the AWS Billing and Cost Management console. The upfront payment for your Capacity Block appears in the month that you purchased the reservation.

After your reservation begins, your bill shows separate lines for the block reservation used and unused time. You can use these line items to see how much time was used in your reservation. You will see only a usage charge in the line for used time if you use a premium operating system. For more information, see Pricing. There is no additional charge for unused time.

For more information, see Viewing your bill in the AWS Billing and Cost Management User Guide.

If your Capacity Block starts in a different month then the month you purchased your reservation, the upfront price and reservation usage show up under separate billing months. In your AWS Cost and Usage Report, the Capacity Block reservation ID is listed in the reservation/ReservationARN line item of your upfront fee and the lineitem/ResourceID in your anniversary bill so that you can associate the usage to the corresponding upfront price.

Work with Capacity Blocks

To start using Capacity Blocks, you first find and purchase an available Capacity Block that matches your reservation size, duration, and timing needs. Then, when the reservation begins, you can use the Capacity Block by launching instances that target the reservation ID. Thirty minutes before the reservation expires, we begin to terminate any instances that are still running in the Capacity Block.

Capacity Blocks are delivered as targeted Capacity Reservations in a single Availability Zone. To run instances in a Capacity Block, you must specify the reservation ID when launching your instances. If you stop instances on your own and the Capacity Block expires, you can't restart them until you target another Capacity Block in the active state.

By default, Capacity Blocks deliver low-latency, high-throughput network connectivity between the instances inside the Capacity Block, so there is no need to use a cluster placement group with a Capacity Block.

Topics
• **Prerequisites**

• **Find and purchase Capacity Blocks**

• **Launch instances into Capacity Blocks**

• **View Capacity Blocks**

**Prerequisites**

You must use the corresponding AWS Region for the instance type that you want to use. For more information, see [Regions](#).

Capacity Blocks with p5.48xlarge instances are available in following AWS Regions.

<table>
<thead>
<tr>
<th>Region name</th>
<th>Region code</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
</tr>
</tbody>
</table>

Capacity Blocks with p4d.24xlarge instances are available in following AWS Regions.

<table>
<thead>
<tr>
<th>Region name</th>
<th>Region code</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
</tr>
</tbody>
</table>

**Note**

Capacity Block sizes of 64 instances are not supported for all instance types in all AWS Regions.

**Find and purchase Capacity Blocks**

To reserve a Capacity Block, you first need to find a block of time when capacity is available that matches your needs. To find a Capacity Block that is available to reserve, you specify the following.
• The number of instances that you need
• The duration of time you that you need the instances
• The date range that you need your reservation

To search for an available Capacity Block offering, you specify a reservation duration and instance count. You must select one of the following options.

• **For reservation duration** – Up to 14 days in 1-day increments or up to 28 days in 7-day increments
• **For instance count** – 1, 2, 4, 8, 16, 32, or 64 instances

If a Capacity Block is available that matches your specifications, we return the details of a single Capacity Block offering. The offering details include the start time of the reservation, the Availability Zone for the reservation, and the price of the reservation. For more information, see [Pricing](#).

You can purchase the Capacity Block offering you are shown, or you can modify your search criteria to see the other options that are available. There is no predefined expiration time for the offering, but offerings are only available on a first-come, first-served basis.

When you purchase a Capacity Block offering, you get an immediate response confirming that your Capacity Block was reserved. After confirmation, you will see a new Capacity Reservation in your account with a reservation type of capacity-block and a start-date set to the start time of the offering that you purchased. Your Capacity Block reservation is created with a state of payment-pending. After the upfront payment is successfully processed, the reservation state changes to scheduled. For more information, see [Billing](#).

You can use one of the following methods to find and purchase a Capacity Block.

**Console**

**To find and purchase a Capacity Block using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation bar at the top of the screen, select an AWS Region. This choice is important because Capacity Block sizes of 64 instances are not supported for all instance types in all Regions.
3. In the navigation pane, choose **Capacity Reservations**, **Purchase Capacity Blocks**.

4. Under **Capacity attributes**, you can define your Capacity Block search parameters. By default, the platform is Linux. If you want to select a different operating system, use the AWS CLI. For more information, see [Supported platforms](#).

5. Under **Total capacity**, select the number of instances you want to reserve.

6. Under **Duration**, enter the number of days you need the reservation for.

7. Under **Date range to search for Capacity Blocks**, enter the earliest date that you want your reservation to start.

8. Choose **Find Capacity Blocks**.

9. If a Capacity Block is available that meets your specifications, you see an offering under **Recommended Capacity Blocks**. If there are multiple offerings that meet your specifications, the earliest available Capacity Block offering is shown. To view other Capacity Block offerings, adjust your search inputs and choose **Find Capacity Blocks** again.

10. When you find a Capacity Block offering that you want to purchase, choose **Next**.

11. (Optional) On the **Add tags** page, choose **Add new tag**.

12. The **Review and purchase** page lists the start and end date, duration, total number of instances, and price.

   **Note**

   Capacity Blocks can't be modified or canceled after you reserve them.

13. In the popup window **Purchase a Capacity Block**, type confirm, then choose **Purchase**.

**AWS CLI**

**To find a Capacity Block using the AWS CLI**

Use the `describe-capacity-block-offerings` command.

The following example searches for a Capacity Block that has 16 p5.48xlarge instances with a date range starting 2023-08-14 and ending 2023-10-22 with a duration of 48 hours. The instance count must be an integer from a predefined set of options 1, 2, 4, 8, 16, 32, 64. The capacity duration must be an integer that is a multiple of 24 between 24 and 336 indicating the number of days in hours.
aws ec2 describe-capacity-block-offerings --instance-type p5.48xlarge \ 
  --instance-count 16 --start-date-range 2023-08-14T00:00:00Z \ 
  --end-date-range 2023-10-22T00:00:00Z --capacity-duration 48

To purchase a Capacity Block using the AWS CLI

Use the `purchase-capacity-block` command and specify the offering ID of the Capacity Block that you want to purchase and the instance platform.

aws ec2 purchase-capacity-block \ 
  --capacity-block-offering-id cbr-0123456789abcdefg \ 
  --instance-platform Linux/UNIX

Launch instances into Capacity Blocks

After you reserve a Capacity Block, you can view the Capacity Block reservation in your AWS account. You can view the `start-date` and `end-date` to see when your reservation will begin and end. Before a Capacity Block reservation begins, the available capacity appears as zero. You can see how many instances will be available in your Capacity Block by the tag value for the tag key `aws:ec2capacityreservation:incrementalRequestedQuantity`.

When a Capacity Block reservation begins, the reservation state changes from `scheduled` to `active`. We emit an event through Amazon EventBridge to notify you that the Capacity Block is available to use. For more information, see Monitor Capacity Blocks.

To use your Capacity Block, you must specify the Capacity Block reservation ID when launching instances. Launching an instance into a Capacity Block reduces the available capacity by the number of instances launched. For example, if your purchased instance capacity is eight instances and you launch four instances, the available capacity is reduced by four.

If you terminate an instance running in the Capacity Block before the reservation ends, you can launch a new instance in its place. When you stop or terminate an instance in a Capacity Block, it takes several minutes to clean up your instance before you can launch another instance to replace it. During this time, your instance will be in a stopping or shutting-down state. After this process is complete, your instance state will change to stopped or terminated. Then, the available capacity in your Capacity Block will update to show another instance available to use.

For information about how to set up an EKS managed node group with a Capacity Block, see Create a managed node group with Capacity Blocks for ML in the Amazon EKS User Guide.
For information about how to set up AWS ParallelCluster using a Capacity Block, see ML on AWS ParallelCluster.

For information about how to launch instances into a Capacity Block using EC2 Fleet, see Tutorial: Launch instances into Capacity Blocks.

For information about how to create a Launch Template targeting a Capacity Block, see Launch an instance from a launch template.

The following steps explain how to launch instances into a Capacity Block in the active state using the AWS Management Console or the AWS CLI.

**Console**

**To launch instances into a Capacity Block using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, select the Region for your Capacity Block reservation.
3. From the Amazon EC2 console dashboard, choose Launch instance.
4. (Optional) Under Name and tags, you can name your instance and tag the instance. For information about tags, see Tag your Amazon EC2 resources.
5. Under Application and OS Images, select an Amazon Machine Image (AMI).
6. Under Instance type, select the instance type that matches your Capacity Block reservation.
7. Under Key pair (login), choose an existing key pair or choose Create new key pair to create a new one. For more information, see Amazon EC2 key pairs and Amazon EC2 instances.
8. Under Network settings, use the default settings, or choose Edit to configure the network settings as necessary.

**Important**

Your instance can't launch in a subnet in a different Availability Zone from the Availability Zone where your Capacity Block is located.

9. Under Advanced details, configure the instance as follows.

   a. Under Purchasing option (market type), select Capacity Blocks.
b. Under **Capacity Reservation**, select **Target by ID**.

c. Select the Capacity Reservation ID of your Capacity Block reservation.

10. On the **Summary** panel, for **Number of instances**, enter the number of instances to launch.

11. Choose **Launch instance**.

**AWS CLI**

**To launch instances into a Capacity Block using the AWS CLI**

- Use the `run-instances` command and specify a `MarketType` of `capacity-block` in the `instance-market-options` structure. You must also specify the `capacity-reservation-specification` parameter.

The following example launches a single p5.48xlarge instance into an active Capacity Block that has matching attributes and available capacity.

```bash
aws ec2 run-instances --image-id ami-abc12345 --count 1 \
--instance-type p5.48xlarge --key-name MyKeyPair \
--subnet-id subnet-1234567890abcdef1 \
--instance-market-options MarketType='capacity-block' \
--capacity-reservation-specification \
CapacityReservationTarget={CapacityReservationId=cr-a1234567}
```

**View Capacity Blocks**

Capacity Blocks have the following states:

- **payment-pending** – The upfront payment hasn't been processed yet.
- **payment-failed**—The payment couldn't be processed in the 12 hour time frame. Your Capacity Block was released.
- **scheduled** – The payment was processed and the Capacity Block reservation hasn't started yet.
- **active** – The reserved capacity is available for your use.
- **expired** – The Capacity Block reservation expired automatically at the date and time specified in your reservation request. The reserved capacity is no longer available for your use.

You can use one of the following methods to view your Capacity Block reservation.
Console

To view Capacity Blocks using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Capacity Reservations.
3. On the Capacity Reservations overview page, you see a resource table with details about all of your Capacity Reservation resources. To find your Capacity Blocks reservations, select Capacity Blocks from the dropdown list above Capacity Reservation ID. In the table, you can see information about your Capacity Blocks such as start and end dates, duration, and status.
4. For more details about a Capacity Block, select the reservation ID for the Capacity Block that you want to view. The Capacity Reservation details page displays all the properties of the reservation and the number of instances in use and available in the Capacity Block.

Note

Before a Capacity Block reservation begins, the available capacity appears as zero. You can see how many instances will be available when the Capacity Block reservation starts by using the following tag value for the tag key: aws:ec2capacityreservation:incrementalRequestedQuantity.

AWS CLI

To view Capacity Blocks using the AWS CLI

By default, when you use the describe-capacity-reservations command both On-Demand Capacity Reservations and Capacity Block reservations are listed. To view only your Capacity Block reservations, filter using capacity-block for the capacity-reservation-type parameter.

For example, the following command describes one or more of your Capacity Block reservations in your current AWS Region.

aws ec2 describe-capacity-reservations -reservation-type capacity-block

Example output.
Monitor Capacity Blocks

Topics

- **Monitor Capacity Blocks with EventBridge**
- **Logging Capacity Blocks API calls with AWS CloudTrail**

Monitor Capacity Blocks with EventBridge

When your Capacity Block reservation starts, Amazon EC2 will emit an event through EventBridge that indicates your capacity is ready to use. Forty minutes before your Capacity Block reservation ends, you receive another EventBridge event that tells you that any instances running in the reservation will begin to terminate in 10 minutes. For more information about EventBridge events, see [Amazon EventBridge Events](#).

The following event structures for events emitted for Capacity Blocks:

**Capacity Block Delivered**
The following example shows an event for Capacity Block Delivered.

```json
{
   "customer_event_id": "[Capacity Reservation Id]-delivered",
   "detail_type": "Capacity Block Reservation Delivered",
   "source": "aws.ec2",
   "account": "[Customer Account ID]",
   "time": "[Current time]",
   "resources": [  "[ODCR ARN]"
   ],
   "detail": {  "capacity-reservation-id": "[ODCR ID]",
                 "end-date": "[ODCR End Date]"
   }
}
```

**Capacity Block Expiration Warning**

The following example shows an event for Capacity Block Expiration Warning.

```json
{
   "customer_event_id": "[Capacity Reservation Id]-approaching-expiry",
   "detail_type": "Capacity Block Reservation Expiration Warning",
   "source": "aws.ec2",
   "account": "[Customer Account ID]",
   "time": "[Current time]",
   "resources": [  "[ODCR ARN]"
   ],
   "detail": {  "capacity-reservation-id": "[ODCR ID]",
                 "end-date": "[ODCR End Date]"
   }
}
```

**Logging Capacity Blocks API calls with AWS CloudTrail**

Capacity Blocks is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Capacity Blocks. CloudTrail captures API calls for Capacity Blocks as events. The calls captured include calls from the Capacity Blocks console and code calls to the Capacity Blocks API operations. If you create a trail, you can enable continuous delivery...
of CloudTrail events to an Amazon S3 bucket, including events for Capacity Blocks. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the information collected by CloudTrail, you can determine the request that was made to Capacity Blocks, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the AWS CloudTrail User Guide.

Capacity Blocks information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Capacity Blocks, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing events with CloudTrail Event history.

For an ongoing record of events in your AWS account, including events for Capacity Blocks, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- Overview for creating a trail
- CloudTrail supported services and integrations
- Configuring Amazon SNS notifications for CloudTrail
- Receiving CloudTrail log files from multiple regions and Receiving CloudTrail log files from multiple accounts

All Capacity Blocks actions are logged by CloudTrail and are documented in the Amazon EC2 API Reference. For example, calls to the CapacityBlockScheduled, and CapacityBlockActive actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or AWS Identity and Access Management (IAM) user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
• Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity element.

Understanding Capacity Blocks log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following examples show CloudTrail log entries for:

• TerminateCapacityBlocksInstances
• CapacityBlockPaymentFailed
• CapacityBlockScheduled
• CapacityBlockActive
• CapacityBlockFailed
• CapacityBlockExpired

Note
Some fields have been redacted from the examples for data privacy.

TerminateCapacityBlocksInstances

```json
{
    "eventVersion": "1.05",
    "userIdentity": {
        "accountId": "123456789012",
        "invokedBy": "AWS Internal;"
    },
    "eventTime": "2023-10-02T00:06:08Z",
    "eventSource": "ec2.amazonaws.com",
    "eventName": "TerminateCapacityBlockInstances",
    "awsRegion": "us-east-1",

```
Instance lifecycle

An Amazon EC2 instance transitions through different states from the moment you launch it through to its termination.

The following illustration represents the transitions between instance states. Notice that you can't stop and start an instance store-backed instance. For more information about instance store-backed instances, see Storage for the root device.
The following table provides a brief description of each instance state and indicates whether instance usage is billed. Some AWS resources, such as Amazon EBS volumes and Elastic IP addresses, incur charges regardless of the instance's state. For more information, see Avoiding Unexpected Charges in the AWS Billing User Guide.

<table>

Instance launch

When you launch an instance, it enters the pending state. The instance type that you specified at launch determines the hardware of the host computer for your instance. We use the Amazon Machine Image (AMI) you specified at launch to boot the instance. After the instance is ready for you, it enters the running state. You can connect to your running instance and use it the way that you'd use a computer sitting in front of you.

As soon as your instance transitions to the running state, you're billed for each second, with a one-minute minimum, that you keep the instance running, even if the instance remains idle and you don't connect to it.

Instance stop and start (Amazon EBS-backed instances only)

If your instance fails a status check or is not running your applications as expected, and if the root volume of your instance is an Amazon EBS volume, you can stop and start your instance to try to fix the problem.

When you stop your instance, it enters the stopping state, and then the stopped state. You are not charged for usage or data transfer fees for your instance when it is stopped. Charges are incurred for the storage of any Amazon EBS volumes. While your instance is in the stopped state, you can modify certain attributes of the instance, including the instance type.

When you start your instance, it enters the pending state, and the instance is moved to a new host computer (though in some cases, it remains on the current host). When you stop and start your instance, you lose any data on the instance store volumes attached to the previous host computer.

Your instance retains its private IPv4 address, which means that an Elastic IP address associated with the private IPv4 address or network interface remains associated with your instance. If your instance has an IPv6 address, it retains the IPv6 address.

Each time you transition an instance from stopped to running, you are charged per second when the instance is running, with a minimum of one minute per instance start.

For more details about stopping and starting an instance, see Stop and start Amazon EC2 instances.
Instance hibernate (Amazon EBS-backed instances only)

When you hibernate an instance, we signal the operating system to perform hibernation (suspend-to-disk), which saves the contents from the instance memory (RAM) to your Amazon EBS root volume. We persist the instance's Amazon EBS root volume and any attached Amazon EBS data volumes. When you start your instance, the Amazon EBS root volume is restored to its previous state and the RAM contents are reloaded. Previously attached data volumes are reattached and the instance retains its instance ID.

When you hibernate your instance, it enters the stopping state, and then the stopped state. We don't charge usage for a hibernated instance when it is in the stopped state, but we do charge while it is in the stopping state, unlike when you stop an instance without hibernating it. We don't charge usage for data transfer fees, but we do charge for the storage for any Amazon EBS volumes, including storage for the RAM data.

When you start your hibernated instance, it enters the pending state, and we move the instance to a new host computer (though in some cases, it remains on the current host).

Your instance retains its private IPv4 address, which means that an Elastic IP address associated with the private IPv4 address or network interface is still associated with your instance. If your instance has an IPv6 address, it retains its IPv6 address.

For more information, see Hibernate your Amazon EC2 instance.

Instance reboot

You can reboot your instance using the Amazon EC2 console, a command line tool, and the Amazon EC2 API. We recommend that you use Amazon EC2 to reboot your instance instead of running the operating system reboot command from your instance.

Rebooting an instance is equivalent to rebooting an operating system. The instance remains on the same host computer and maintains its public DNS name, private IP address, and any data on its instance store volumes. It typically takes a few minutes for the reboot to complete, but the time it takes to reboot depends on the instance configuration.

Rebooting an instance doesn't start a new instance billing period; per second billing continues without a further one-minute minimum charge.

For more information, see Reboot your instance.
 Instance termination

When you've decided that you no longer need an instance, you can terminate it. As soon as the status of an instance changes to shutting-down or terminated, you stop incurring charges for that instance.

If you enable termination protection, you can't terminate the instance using the console, CLI, or API.

After you terminate an instance, it remains visible in the console for a short while, and then the entry is automatically deleted. You can also describe a terminated instance using the CLI and API. Resources (such as tags) are gradually disassociated from the terminated instance, therefore may no longer be visible on the terminated instance after a short while. You can't connect to or recover a terminated instance.

Each Amazon EBS-backed instance supports the InstanceInitiatedShutdownBehavior attribute, which controls whether the instance stops or terminates when you initiate shutdown from within the instance itself (for example, by using the `shutdown` command on Linux). The default behavior is to stop the instance. You can modify the setting of this attribute while the instance is running or stopped.

Each Amazon EBS volume supports the DeleteOnTermination attribute, which controls whether the volume is deleted or preserved when you terminate the instance it is attached to. The default is to delete the root device volume and preserve any other EBS volumes.

For more information, see Terminate Amazon EC2 instances.

 Differences between reboot, stop, hibernate, and terminate

The following table summarizes the key differences between rebooting, stopping, hibernating, and terminating your instance.

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Reboot</th>
<th>Stop/start (Amazon EBS-backed instances only)</th>
<th>Hibernate (Amazon EBS-backed instances only)</th>
<th>Terminate</th>
</tr>
</thead>
<tbody>

<tr>
<td>Billing</td>
<td>The instance billing hour doesn't change</td>
<td>You stop incurring charges for an instance as soon as its state changes to stopping. Each time an instance transitions from stopped to running, we start a new instance billing period, billing a minimum of one minute every time you start your instance.</td>
<td>You incur charges while the instance is in the stopping state, but stop incurring charges when the instance is in the stopped state. Each time an instance transitions from stopped to running, we start a new instance billing period, billing a minimum of one minute every time you start your instance.</td>
<td>You stop incurring charges for an instance as soon as its state changes to shutting-down</td>
</tr>
</tbody>
</table>

Operating system shutdown commands always terminate an instance store-backed instance. You can control whether operating system shutdown commands stop or terminate an Amazon EBS-backed instance. For more information, see [Change the instance initiated shutdown behavior](#).

### Launch your instance

An instance is a virtual server in the AWS Cloud. You launch an instance from an Amazon Machine Image (AMI). The AMI provides the operating system, application server, and applications for your instance.
When you sign up for AWS, you can get started with Amazon EC2 for free using the AWS Free Tier. You can use the free tier to launch and use a t2.micro instance for free for 12 months (in Regions where t2.micro is unavailable, you can use a t3.micro instance under the free tier). You incur charges for your instance or usage that counts against your Free Tier limits while the instance is running, even if it remains idle. For more information, see Amazon EC2 pricing.

You can launch an instance using the following methods.

<table>
<thead>
<tr>
<th>Method</th>
<th>Documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Amazon EC2 console] Use the launch instance wizard to specify the launch parameters.</td>
<td>Launch an instance using the old launch instance wizard</td>
</tr>
<tr>
<td>[Amazon EC2 console] Create a launch template and launch the instance from the launch template.</td>
<td>Launch an instance from a launch template</td>
</tr>
<tr>
<td>[Amazon EC2 console] Use an existing instance as the base.</td>
<td>Launch an instance using parameters from an existing instance</td>
</tr>
<tr>
<td>[Amazon EC2 console] Use an AMI that you purchased from the AWS Marketplace.</td>
<td>Launch an AWS Marketplace instance</td>
</tr>
<tr>
<td>[AWS CLI] Use an AMI that you select.</td>
<td>Using Amazon EC2 through the AWS CLI</td>
</tr>
<tr>
<td>[AWS CLI] Use EC2 Fleet to provision capacity across different EC2 instance types and Availability Zones, and across On-Demand Instance, Reserved Instance, and Spot Instance purchase models.</td>

</tr>
</tbody>
</table>

**Note**

To launch an EC2 instance into an IPv6-only subnet, you must use [Instances built on the AWS Nitro System](https://aws.amazon.com/nitro/).  

**Note**

When launching an IPv6-only instance, it is possible that DHCPv6 may not immediately provide the instance with the IPv6 DNS name server. During this initial delay, the instance may not be able to resolve public domains.

For instances running on Amazon Linux 2, if you want to immediately update the `/etc/resolv.conf` file with the IPv6 DNS name server, run the following cloud-init directive at launch:

```
#cloud-config
bootcmd:
  - /usr/bin/sed -i -E 's,^nameserver\s+\[.\[:digit:\]\]+$,nameserver fd00:ec2::253,' /etc/resolv.conf
```

Another option is to change the configuration file and re-image your AMI so that the file has the IPv6 DNS name server address immediately on booting.
When you launch your instance, you can launch your instance in a subnet that is associated with one of the following resources:

- An Availability Zone - This option is the default.
- A Local Zone - To launch an instance in a Local Zone, you must opt in to the Local Zone, and then create a subnet in the zone. For more information, see Get started with Local Zones.
- A Wavelength Zone - To launch an instance in a Wavelength Zone, you must opt in to the Wavelength Zone, and then create a subnet in the zone. For information about how to launch an instance in a Wavelength Zone, see Get started with AWS Wavelength.
- An Outpost - To launch an instance in an Outpost, you must create an Outpost. For information about how to create an Outpost, see Get started with AWS Outposts.

After you launch your instance, you can connect to it and use it. To begin, the instance state is pending. When the instance state is running, the instance has started booting. There might be a short time before you can connect to the instance. Note that bare metal instance types might take longer to launch.

The instance receives a public DNS name that you can use to contact the instance from the internet. The instance also receives a private DNS name that other instances within the same VPC can use to contact the instance.

When you are finished with an instance, be sure to terminate it. For more information, see Terminate Amazon EC2 instances.

Launch an instance using the new launch instance wizard

You can launch an instance using the new launch instance wizard. The launch instance wizard specifies the launch parameters that are required for launching an instance. Where the launch instance wizard provides a default value, you can accept the default or specify your own value. If you accept the default values, then it's possible to launch an instance by selecting only a key pair.

⚠ Important

You incur charges for that instance or usage that counts against your Free Tier limits while the instance is running, even if it remains idle.
Quickly launch an instance

To set up an instance quickly for testing purposes, follow these steps. You'll select the operating system and your key pair, and accept the default values. For information about all of the parameters in the launch instance wizard, see Launch an instance using defined parameters.

To quickly launch an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, US East (Ohio)). Select a Region in which to launch the instance.
3. From the Amazon EC2 console dashboard, choose Launch instance.
4. (Optional) Under Name and tags, for Name, enter a descriptive name for your instance.
5. Under Application and OS Images (Amazon Machine Image), choose Quick Start, and then choose the operating system (OS) for your instance.
6. Under Key pair (login), for Key pair name, choose an existing key pair or create a new one.
7. In the Summary panel, choose Launch instance.

Launch an instance using defined parameters

Except for the key pair, the launch instance wizard provides default values for all of the parameters. You can accept any or all of the defaults, or configure an instance by specifying your own values for each parameter. The parameters are grouped in the launch instance wizard. The following instructions take you through each parameter group.

Parameters for instance configuration

- Initiate instance launch
- Name and tags
- Application and OS Images (Amazon Machine Image)
- Instance type
- Key pair (login)
Initiate instance launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, US East (Ohio)). Select a Region in which to launch the instance.
3. From the Amazon EC2 console dashboard, choose Launch instance.

Name and tags

The instance name is a tag, where the key is Name, and the value is the name that you specify. You can tag the instance, volumes, and network interfaces. For Spot Instances, you can tag the Spot Instance request only. For information about tags, see Tag your Amazon EC2 resources.

Specifying an instance name and additional tags is optional.

- For Name, enter a descriptive name for the instance. If you don't specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.
- To add additional tags, choose Add additional tags. Choose Add tag, and then enter a key and value, and select the resource type to tag. Choose Add tag again for each additional tag to add.

Application and OS Images (Amazon Machine Image)

An Amazon Machine Image (AMI) contains the information required to create an instance. For example, an AMI might contain the software that's required to act as a web server, such as Linux, Apache, and your website.

You can find a suitable AMI as follows. With each option for finding an AMI, you can choose Cancel (at top right) to return to the launch instance wizard without choosing an AMI.

Search bar

To search through all available AMIs, enter a keyword in the AMI search bar and then press Enter. To select an AMI, choose Select.
Recents

The AMIs that you've recently used.

Choose Recently launched or Currently in use, and then, from Amazon Machine Image (AMI), select an AMI.

My AMIs

The private AMIs that you own, or private AMIs that have been shared with you.

Choose Owned by me or Shared with me, and then, from Amazon Machine Image (AMI), select an AMI.

Quick Start

AMIs are grouped by operating system (OS) to help you get started quickly.

First select the OS that you need, and then, from Amazon Machine Image (AMI), select an AMI. To select an AMI that is eligible for the free tier, make sure that the AMI is marked Free tier eligible.

Browse more AMIs

Choose Browse more AMIs to browse the full AMI catalog.

- To search through all available AMIs, enter a keyword in the search bar and then press Enter.
- To find an AMI by using a Systems Manager parameter, choose the arrow button to the right of the search bar, and then choose Search by Systems Manager parameter. For more information, see Find an AMI using a Systems Manager parameter.
- To search by category, choose Quickstart AMIs, My AMIs, AWS Marketplace AMIs, or Community AMIs.

The AWS Marketplace is an online store where you can buy software that runs on AWS, including AMIs. For more information about launching an instance from the AWS Marketplace, see Launch an AWS Marketplace instance. In Community AMIs, you can find AMIs that AWS community members have made available for others to use. AMIs from Amazon or a verified partner are marked Verified provider.

- To filter the list of AMIs, select one or more check boxes under Refine results on the left of the screen. The filter options are different depending on the selected search category.
• Check the **Root device type** listed for each AMI. Notice which AMIs are the type that you need: either **ebs** (backed by Amazon EBS) or **instance-store** (backed by instance store). For more information, see [Storage for the root device](#).

• Check the **Virtualization** type listed for each AMI. Notice which AMIs are the type that you need: either **hvm** or **paravirtual**. For example, some instance types require HVM. For more information about Linux virtualization types, see [AMI virtualization types](#).

• Check the **Boot mode** listed for each AMI. Notice which AMIs use the boot mode that you need: either **legacy-bios**, **uefi**, or **uefi-preferred**. For more information, see [Amazon EC2 boot modes](#).

• Choose an AMI that meets your needs, and then choose **Select**.

**Warning when changing the AMI**

If you modify the configuration of any volumes or security groups associated with the selected AMI, and then you choose a different AMI, a window opens to warn you that some of your current settings will be changed or removed. You can review the changes to the security groups and volumes. Furthermore, you can either view which volumes will be added and deleted, or view only the volumes that will be added.

**Instance type**

The instance type defines the hardware configuration and size of the instance. Larger instance types have more CPU and memory. For more information, see [Amazon EC2 instance types](#).

• For **Instance type**, select the instance type for the instance.

  **Free Tier** – If your AWS account is less than 12 months old, you can use Amazon EC2 under the Free Tier by selecting the **t2.micro** instance type (or the **t3.micro** instance type in Regions where **t2.micro** is unavailable). If an instance type is eligible under the Free Tier, it is labeled **Free tier eligible**.

• **Compare instance types**: You can compare different instance types by the following attributes: number of vCPUs, architecture, amount of memory (GiB), amount of storage (GB), storage type, and network performance.

• **Get advice**: You can get guidance and suggestions for instance types from the Amazon Q EC2 instance type selector. For more information, see [Get instance type recommendations for a new workload](#).
Key pair (login)

For **Key pair name**, choose an existing key pair, or choose **Create new key pair** to create a new one. For more information, see [Amazon EC2 key pairs and Amazon EC2 instances](#).

⚠️ **Important**

If you choose the **Proceed without key pair (Not recommended)** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

Network settings

Configure the network settings, as necessary.

- **VPC**: Choose an existing VPC for your instance. You can choose the default VPC or a VPC that you created. For more information, see the section called “Virtual private clouds”.

- **Subnet**: You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone, or Outpost.

  To launch the instance in an Availability Zone, select the subnet in which to launch your instance. To create a new subnet, choose **Create new subnet** to go to the Amazon VPC console. When you are done, return to the launch instance wizard and choose the Refresh icon to load your subnet in the list.

  To launch the instance in an IPv6-only subnet, the instance must be [built on the Nitro System](#).

  To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

  To launch an instance in an Outpost, select a subnet in a VPC that you associated with the Outpost.

- **Auto-assign Public IP**: Specify whether your instance receives a public IPv4 address. By default, instances in a default subnet receive a public IPv4 address, and instances in a nondefault subnet don't. You can select **Enable** or **Disable** to override the subnet's default setting. For more information, see [Public IPv4 addresses](#).

- **Firewall (security groups)**: Use a security group to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other traffic is
ignored. For more information about security groups, see Amazon EC2 security groups for your EC2 instances.

If you add a network interface, you must specify the same security group in the network interface.

Select or create a security group as follows:

- To select an existing security group for your VPC, choose Select existing security group, and select your security group from Common security groups.

- To create a new security group for your VPC, choose Create security group. The launch instance wizard automatically defines the launch-wizard-x security group and provides the following check boxes for quickly adding security group rules:

  (Linux) Allow SSH traffic from – Creates an inbound rule to allow you to connect to your instance over SSH (port 22).

  (Windows) Allow RDP traffic from – Creates an inbound rule to allow you to connect to your instance over RDP (port 3389).

Specify whether the traffic comes from Anywhere, Custom, or My IP.

Allow HTTPs traffic from the internet – Creates an inbound rule that opens port 443 (HTTPS) to allow internet traffic from anywhere. If your instance will be a web server, you'll need this rule.

Allow HTTP traffic from the internet – Creates an inbound rule that opens port 80 (HTTP) to allow internet traffic from anywhere. If your instance will be a web server, you'll need this rule.

You can edit these rules and add rules to suit your needs.

To edit or add a rule, choose Edit (at top right). To add a rule, choose Add security group rule. For Type, select the network traffic type. The Protocol field is automatically filled in with the protocol to open to network traffic. For Source type, select the source type. To let the launch instance wizard add your computer's public IP address, choose My IP. However, if you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.
Warning

Rules that enable all IP addresses (0.0.0.0/0) to access your instance over SSH or RDP are acceptable if you are briefly launching a test instance and will stop or terminate it soon, but are unsafe for production environments. You should authorize only a specific IP address or range of addresses to access your instance.

- **Advanced network configuration** – Available only if you choose a subnet.

  **Network interface**

  - **Device index**: The index of the network card. The primary network interface must be assigned to network card index 0. Some instance types support multiple network cards.
  
  - **Network interface**: Select **New interface** to let Amazon EC2 create a new interface, or select an existing, available network interface.
  
  - **Description**: (Optional) A description for the new network interface.
  
  - **Subnet**: The subnet in which to create the new network interface. For the primary network interface, this is the subnet in which the instance is launched. If you've entered an existing network interface as the primary network interface, the instance is launched in the subnet in which the network interface is located.
  
  - **Security groups**: The security groups to associate the network interface.
  
  - **Primary IP**: A private IPv4 address from the range of your subnet. Leave blank to let Amazon EC2 choose a private IPv4 address for you.
  
  - **Secondary IP**: Additional private IPv4 addresses from the range of your subnet. Choose **Manually assign** and enter an IPv4 address. Choose **Add IP** to add another IPv4 address. Alternatively, choose **Automatically assign** and enter a value to indicate the number of IPv4 addresses that Amazon EC2 chooses for you.
  
  - (IPv6-only) **IPv6 IPs**: IPv6 addresses from the range of the subnet. Choose **Manually assign** and enter an IPv6 address. Choose **Add IP** to add another IPv6 address. Alternatively, choose **Automatically assign** and enter a value to indicate the number of IPv6 addresses that Amazon EC2 chooses for you.
  
  - **IPv4 Prefixes**: IPv4 prefixes. Choose **Manually assign** and enter an IPv4 prefix. Alternatively, choose **Automatically assign** and enter a value to indicate the number of IPv4 prefixes that Amazon EC2 chooses for you.
• **IPv6 Prefixes**: IPv6 prefixes. Choose **Manually assign** and enter an IPv6 prefix. Alternatively, choose **Automatically assign** and enter a value to indicate the number of IPv6 prefixes that Amazon EC2 chooses for you.

• (Dual-stack and IPv6-only) **Assign Primary IPv6 IP**: When you launch an instance into a dual-stack or IPv6-only subnet, you can indicate whether it would have a primary IPv6 address. This helps prevent disruptions to traffic to the instance or network interface. Choose **Yes** if you rely on the IPv6 address of this instance not changing, and AWS chooses an IPv6 address associated with the network interface to be the primary IPv6 address. You can't remove the primary IPv6 address later on. When you enable an IPv6 GUA address to be a primary IPv6, the first IPv6 GUA becomes the primary IPv6 address until the instance is terminated or the network interface is detached. If you have multiple IPv6 addresses associated with a network interface attached to your instance and you let Amazon EC2 assign a primary IPv6 address, the first IPv6 GUA address associated with the network interface becomes the primary IPv6 address.

• **Delete on termination**: Indicates whether the network interface is deleted when the instance is deleted.

• **Elastic Fabric Adapter**: Indicates whether the network interface is an Elastic Fabric Adapter. For more information, see [Elastic Fabric Adapter](#).

• **ENA Express**: ENA Express is powered by AWS Scalable Reliable Datagram (SRD) technology. SRD technology uses a packet spraying mechanism to distribute load and avoid network congestion. Enabling ENA Express allows supported instances to communicate using SRD on top of regular TCP traffic when possible. The launch instance wizard does not include ENA Express configuration for the instance unless you select **Enable** or **Disable** from the list.

• **ENA Express UDP**: If you've enabled ENA Express, you can optionally use it for UDP traffic. The launch instance wizard does not include ENA Express configuration for the instance unless you select **Enable** or **Disable**.

Choose **Add network interface** to add additional network interfaces. Additional network interfaces can reside in a different subnet of the same VPC or in a subnet in a different VPC that you own (as long as the subnet is in the same Availability Zone as your instance). If you choose to add an additional network interface residing in another VPC subnet, you'll see the **Multi-VPC subnets** option when you select a subnet. If you select a subnet in another VPC, the **Multi-VPC** label appears next to the network interface you've added. This enables you to create multi-homed instances across VPCs with different networking and security configurations. Note that if you attach an additional ENI from another VPC, you must choose a security group for the ENI from that VPC.
For more information, see Elastic network interfaces. If you specify more than one network interface, your instance cannot receive a public IPv4 address. Additionally, if you specify an existing network interface for eth0, you cannot override the subnet's public IPv4 setting using Auto-assign Public IP. For more information, see Assign a public IPv4 address during instance launch.

Configure storage

The AMI you selected includes one or more volumes of storage, including the root volume. You can specify additional volumes to attach to the instance.

You can use the Simple or Advanced view. With the Simple view, you specify the size and type of the volume. To specify all volume parameters, choose the Advanced view (at top right of the card).

By using the Advanced view, you can configure each volume as follows:

- **Storage type**: Select Amazon EBS or instance store volumes to associate with your instance. The volume types available in the list depend on the instance type that you've chosen. For more information, see Amazon EC2 instance store temporary block storage for Amazon EC2 instances and Amazon EBS volumes.

- **Device name**: Select from the list of available device names for the volume.

- **Snapshot**: Select the snapshot from which to restore the volume. You can search for available shared and public snapshots by entering text into the Snapshot field.

- **Size (GiB)**: For EBS volumes, you can specify a storage size. If you have selected an AMI and instance that are eligible for the free tier, keep in mind that to stay within the free tier, you must stay under 30 GiB of total storage.

- **Volume type**: For EBS volumes, select a volume type. For more information, see Amazon EBS volume types in the Amazon EBS User Guide.

- **IOPS**: If you have selected a Provisioned IOPS SSD volume type, then you can enter the number of I/O operations per second (IOPS) that the volume can support.

- **Delete on termination**: For Amazon EBS volumes, choose Yes to delete the volume when the instance is terminated, or choose No to keep the volume. For more information, see Preserve data when an instance is terminated.

- **Encrypted**: If the instance type supports EBS encryption, you can choose Yes to enable encryption for the volume. If you have enabled encryption by default in this Region, encryption
is enabled for you. For more information, see Amazon EBS encryption in the Amazon EBS User Guide.

- **KMS key**: If you selected Yes for Encrypted, then you must select a customer managed key to use to encrypt the volume. If you have enabled encryption by default in this Region, the default customer managed key is selected for you. You can select a different key or specify the ARN of any customer managed key that you created.

- **File systems**: Mount an Amazon EFS or Amazon FSx file system to the instance. For more information about mounting an Amazon EFS file system, see Use Amazon EFS with Amazon EC2 Linux instances. For more information about mounting an Amazon FSx file system, see Use Amazon FSx with Amazon EC2 instances

Advanced details

For Advanced details, expand the section to view the fields and specify any additional parameters for the instance.

- **Domain join directory**: Select the AWS Directory Service directory (domain) to which your instance is joined to after launch. If you select a domain, you must select an IAM role with the required permissions. For more information about domain joining, see Seamlessly join an Amazon EC2 Linux instance to your AWS Managed Microsoft AD directory (Linux instances) and Seamlessly join an Amazon EC2 Windows instance to your AWS Managed Microsoft AD directory (Windows instances).

- **IAM instance profile**: Select an AWS Identity and Access Management (IAM) instance profile to associate with the instance. For more information, see IAM roles for Amazon EC2.

- **Hostname type**: Select whether the guest OS hostname of the instance will include the resource name or the IP name. For more information, see Amazon EC2 instance hostname types.

- **DNS Hostname**: Determines if the DNS queries to the resource name or the IP name (depending on what you selected for Hostname type) will respond with the IPv4 address (A record), IPv6 address (AAAA record), or both. For more information, see Amazon EC2 instance hostname types.

- **Instance auto-recovery**: When enabled, recovers your instance if system status checks fail. This setting is enabled by default at launch for supported instance types. For more information, see Configure simplified automatic recovery.

- **Shutdown behavior**: Select whether the instance should stop or terminate when shut down. For more information, see Change the instance initiated shutdown behavior.
• **Stop - Hibernate behavior**: To enable hibernation, choose **Enable**. This field is available only if your instance meets the hibernation prerequisites. For more information, see [Hibernate your Amazon EC2 instance](#).

• **Termination protection**: To prevent accidental termination, choose **Enable**. For more information, see [Enable termination protection](#).

• **Stop protection**: To prevent accidental stopping, choose **Enable**. For more information, see [Enable stop protection](#).

• **Detailed CloudWatch monitoring**: Choose **Enable** to turn on detailed monitoring of your instance using Amazon CloudWatch. Additional charges apply. For more information, see [Monitor your instances using CloudWatch](#).

• **Elastic GPU**: Amazon Elastic Graphics reached end of life on January 8, 2024. For workloads that require graphics acceleration, we recommend that you use Amazon EC2 G4ad, G4dn, or G5 instances.

• **Elastic inference**: An elastic inference accelerator to attach to your EC2 CPU instance. For more information, see [Working with Amazon Elastic Inference](#) in the *Amazon Elastic Inference Developer Guide*.

**Note**

Starting April 15, 2023, AWS will not onboard new customers to Amazon Elastic Inference (EI), and will help current customers migrate their workloads to options that offer better price and performance. After April 15, 2023, new customers will not be able to launch instances with Amazon EI accelerators in Amazon SageMaker, Amazon ECS, or Amazon EC2. However, customers who have used Amazon EI at least once during the past 30-day period are considered current customers and will be able to continue using the service.

• **Credit specification**: Choose **Unlimited** to enable applications to burst beyond the baseline for as long as needed. This field is only valid for **T** instances. Additional charges may apply. For more information, see [Burstable performance instances](#).

• **Placement group**: Specify a placement group in which to launch the instance. You can select an existing placement group, or create a new one. Not all instance types support launching an instance in a placement group. For more information, see [Placement groups](#).

• **EBS-optimized instance**: An instance that's optimized for Amazon EBS uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. If the
instance type supports this feature, choose **Enable** to enable it. Additional charges apply. For more information, see the section called “Amazon EBS optimization”.

- **Purchasing option**: Choose **Spot Instances** to request Spot Instances at the Spot price, capped at the On-Demand price, and choose **Customize Spot Instance options** to change the default Spot Instance settings. You can set your maximum price (not recommended), and change the request type, request duration, and interruption behavior. If you do not request a Spot Instance, Amazon EC2 launches an On-Demand Instance by default. For more information, see [Create a Spot Instance request](#).

- **Capacity Reservation**: Specify whether to launch the instance into any open Capacity Reservation (**Open**), a specific Capacity Reservation (**Target by ID**), or a Capacity Reservation group (**Target by group**). To specify that a Capacity Reservation should not be used, choose **None**. For more information, see [Launch instances into an existing Capacity Reservation](#).

- **Tenancy**: Choose whether to run your instance on shared hardware (**Shared**), isolated, dedicated hardware (**Dedicated**), or on a Dedicated Host (**Dedicated host**). If you choose to launch the instance onto a Dedicated Host, you can specify whether to launch the instance into a host resource group or you can target a specific Dedicated Host. Additional charges may apply. For more information, see [Amazon EC2 Dedicated Instances](#) and [Amazon EC2 Dedicated Hosts](#).

- **RAM disk ID**: (Only valid for paravirtual (PV) AMIs) Select a RAM disk for the instance. If you have selected a kernel, you might need to select a specific RAM disk with the drivers to support it.

- **Kernel ID**: (Only valid for paravirtual (PV) AMIs) Select a kernel for the instance.

- **Nitro Enclave**: Allows you to create isolated execution environments, called enclaves, from Amazon EC2 instances. Select **Enable** to enable the instance for AWS Nitro Enclaves. For more information, see [What is AWS Nitro Enclaves?](#) in the [AWS Nitro Enclaves User Guide](#).

- **License configurations**: You can launch instances against the specified license configuration to track your license usage. For more information, see [Create a license configuration](#) in the [AWS License Manager User Guide](#).

- **Metadata accessible**: You can enable or disable access to the instance metadata. For more information, see [Configure instance metadata options for new instances](#).

- **Metadata IPv6 endpoint**: You can enable the instance to use the IMDS IPv6 address \[fd00:ec2::254\] to retrieve instance metadata. This option is only available if you are launching instances built on the AWS Nitro System into an IPv6-supported subnet (dual stack or IPv6 only). For more information about retrieving instance metadata, see [Retrieve instance metadata](#).
• **Metadata version**: If you enable access to the instance metadata, you can choose to require the use of Instance Metadata Service Version 2 when requesting instance metadata. For more information, see [Configure instance metadata options for new instances](#).

• **Metadata response hop limit**: If you enable instance metadata, you can set the allowable number of network hops for the metadata token. For more information, see [Configure instance metadata options for new instances](#).

• **Allow tags in metadata**: If you select **Enable**, the instance will allow access to all of its tags from its metadata. If no value is specified, then by default, access to the tags in instance metadata is not allowed. For more information, see [Allow access to tags in instance metadata](#).

• **User data**: You can specify user data to configure an instance during launch, or to run a configuration script. For more information about user data for Linux instances, see [Run commands on your Amazon EC2 instance at launch](#). For more information about user data for Windows instances, see [How Amazon EC2 handles user data for Windows instances](#).

**Summary**

Use the **Summary** panel to specify the number of instances to launch, to review your instance configuration, and to launch your instances.

• **Number of instances**: Enter the number of instances to launch. All of the instances will launch with the same configuration.

**Tip**

To ensure faster instance launches, break up large requests into smaller batches. For example, create five separate launch requests for 100 instances each instead of one launch request for 500 instances.

• (Optional) If you specify more than one instance, to help ensure that you maintain the correct number of instances to handle demand on your application, you can choose **consider EC2 Auto Scaling** to create a launch template and an Auto Scaling group. Auto Scaling scales the number of instances in the group according to your specifications. For more information, see the [Amazon EC2 Auto Scaling User Guide](#).
Note

If Amazon EC2 Auto Scaling marks an instance that is in an Auto Scaling group as unhealthy, the instance is automatically scheduled for replacement where it is terminated and another is launched, and you lose your data on the original instance. An instance is marked as unhealthy if you stop or reboot the instance, or if another event marks the instance as unhealthy. For more information, see Health checks for instances in an Auto Scaling group in the Amazon EC2 Auto Scaling User Guide.

- Review the details of your instance, and make any necessary changes. You can navigate directly to a section by choosing its link in the Summary panel.

- When you're ready to launch your instance, choose Launch instance.

  If the instance fails to launch or the state immediately goes to terminated instead of running, see Troubleshoot Amazon EC2 instance launch issues.

(Optional) You can create a billing alert for the instance. On the confirmation screen, under Next Steps, choose Create billing alerts and follow the directions. Billing alerts can also be created after you launch the instance. For more information, see Creating a billing alarm to monitor your estimated AWS charges in the Amazon CloudWatch User Guide.

Launch an instance using the old launch instance wizard

You can launch an instance using the old launch instance wizard only if your Region supports the old launch experience. The launch instance wizard specifies all the launch parameters required for launching an instance. Where the launch instance wizard provides a default value, you can accept the default or specify your own value. You must specify an AMI and a key pair to launch an instance.

For the instructions to use the new launch instance wizard, see Launch an instance using the new launch instance wizard.

Important

When you launch an instance that's not within the AWS Free Tier, you are charged for the time that the instance is running, even if it remains idle.
Steps to launch an instance:

- **Initiate instance launch**
- **Step 1: Choose an Amazon Machine Image (AMI)**
- **Step 2: Choose an Instance Type**
- **Step 3: Configure Instance Details**
- **Step 4: Add Storage**
- **Step 5: Add Tags**
- **Step 6: Configure Security Group**
- **Step 7: Review Instance Launch and Select Key Pair**

**Initiate instance launch**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation bar at the top of the screen, the current Region is displayed (for example, US East (Ohio)). Select a Region for the instance that meets your needs.
3. From the Amazon EC2 console dashboard, choose **Launch instance**.

**Step 1: Choose an Amazon Machine Image (AMI)**

When you launch an instance, you must select a configuration, known as an Amazon Machine Image (AMI). An AMI contains the information required to create a new instance. For example, an AMI might contain the software required to act as a web server, such as Linux, Apache, and your website.

When you launch an instance, you can either select an AMI from the list, or you can select a Systems Manager parameter that points to an AMI ID. For more information, see the section called “Find an AMI using a Systems Manager parameter”.

On the **Choose an Amazon Machine Image (AMI)** page, use one of two options to choose an AMI. Either search the list of AMIs, or search by Systems Manager parameter.

**By searching the list of AMIs**

1. Select the type of AMI to use in the left pane:
Quick Start

A selection of popular AMIs to help you get started quickly. To select an AMI that is eligible for the free tier, choose **Free tier only** in the left pane. These AMIs are marked **Free tier eligible**.

**My AMIs**

The private AMIs that you own, or private AMIs that have been shared with you. To view AMIs that are shared with you, choose **Shared with me** in the left pane.

**AWS Marketplace**

An online store where you can buy software that runs on AWS, including AMIs. For more information about launching an instance from the AWS Marketplace, see [Launch an AWS Marketplace instance](#).

**Community AMIs**

The AMIs that AWS community members have made available for others to use. To filter the list of AMIs by operating system, choose the appropriate check box under **Operating system**. You can also filter by architecture and root device type.

2. (Linux instances) Check the **Root device type** listed for each AMI. Notice which AMIs are the type that you need, either ebs (backed by Amazon EBS) or instance-store (backed by instance store). For more information, see [Storage for the root device](#).

3. Check the **Virtualization type** listed for each AMI. Notice which AMIs are the type that you need, either hvm or paravirtual. For example, some instance types require HVM. For more information about Linux virtualization types, see [AMI virtualization types](#).

4. Check the **Boot mode** listed for each AMI. Notice which AMIs use the boot mode that you need, either legacy-bios or uefi. For more information, see [Amazon EC2 boot modes](#).

5. Choose an AMI that meets your needs, and then choose **Select**.

**By Systems Manager parameter**

1. Choose **Search by Systems Manager parameter** (at top right).

2. For **Systems Manager parameter**, select a parameter. The corresponding AMI ID appears next to **Currently resolves to**.

3. Choose **Search**. The AMIs that match the AMI ID appear in the list.
4. Select the AMI from the list, and choose **Select**.

---

**Step 2: Choose an Instance Type**

On the **Choose an Instance Type** page, select the hardware configuration and size of the instance to launch. Larger instance types have more CPU and memory. For more information, see [Amazon EC2 instance types](https://aws.amazon.com/ec2/instance-types/).

To remain eligible for the free tier, choose the **t2.micro** instance type (or the **t3.micro** instance type in Regions where **t2.micro** is unavailable). If an instance type is eligible under the Free Tier, it is labeled **Free tier eligible**.

By default, the wizard displays current generation instance types, and selects the first available instance type based on the AMI that you selected. To view previous generation instance types, choose **All generations** from the filter list.

---

**Note**

To set up an instance quickly for testing purposes, choose **Review and Launch** to accept the default configuration settings, and launch your instance. Otherwise, to configure your instance further, choose **Next: Configure Instance Details**.

---

**Step 3: Configure Instance Details**

On the **Configure Instance Details** page, change the following settings as necessary (expand **Advanced Details** to see all the settings), and then choose **Next: Add Storage**:

- **Number of instances**: Enter the number of instances to launch.

---

**Tip**

To ensure faster instance launches, break up large requests into smaller batches. For example, create five separate launch requests for 100 instances each instead of one launch request for 500 instances.

- (Optional) To help ensure that you maintain the correct number of instances to handle demand on your application, you can choose **Launch into Auto Scaling Group** to create a launch configuration and an Auto Scaling group. Auto Scaling scales the number of instances in the
group according to your specifications. For more information, see the Amazon EC2 Auto Scaling User Guide.

Note

If Amazon EC2 Auto Scaling marks an instance that is in an Auto Scaling group as unhealthy, the instance is automatically scheduled for replacement where it is terminated and another is launched, and you lose your data on the original instance. An instance is marked as unhealthy if you stop or reboot the instance, or if another event marks the instance as unhealthy. For more information, see Health checks for Auto Scaling instances in the Amazon EC2 Auto Scaling User Guide.

- Purchasing option: Choose Request Spot instances to launch a Spot Instance. This adds and removes options from this page. You can optionally set your maximum price (not recommended), and optionally change the request type, interruption behavior, and request validity. For more information, see Create a Spot Instance request.

- Network: Select the VPC or to create a new VPC, choose Create new VPC to go the Amazon VPC console. When you have finished, return to the launch instance wizard and choose Refresh to load your VPC in the list.

- Subnet: You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone or Outpost.

To launch the instance in an Availability Zone, select the subnet into which to launch your instance. You can select No preference to let AWS choose a default subnet in any Availability Zone. To create a new subnet, choose Create new subnet to go to the Amazon VPC console. When you are done, return to the wizard and choose Refresh to load your subnet in the list.

To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

To launch an instance in an Outpost, select a subnet in a VPC that you associated with an Outpost.

- Auto-assign Public IP: Specify whether your instance receives a public IPv4 address. By default, instances in a default subnet receive a public IPv4 address and instances in a nondefault subnet don't. You can select Enable or Disable to override the subnet's default setting. For more information, see Public IPv4 addresses.

- Auto-assign IPv6 IP: Specify whether your instance receives an IPv6 address from the range of the subnet. Select Enable or Disable to override the subnet's default setting. This option
is only available if you've associated an IPv6 CIDR block with your VPC and subnet. For more information, see Add an IPv6 CIDR block to your VPC in the Amazon VPC User Guide.

- **Hostname type**: Select whether the guest OS hostname of the instance will include the resource name or the IP name. For more information, see Amazon EC2 instance hostname types.

- **DNS Hostname**: Determines if the DNS queries to the resource name or the IP name (depending on what you selected for Hostname type) will respond with the IPv4 address (A record), IPv6 address (AAAA record), or both. For more information, see Amazon EC2 instance hostname types.

- **Domain join directory**: Select the AWS Directory Service directory (domain) to which your instance is joined after launch. If you select a domain, you must select an IAM role with the required permissions. For more information about domain joining, see Seamlessly join an Amazon EC2 Linux instance to your AWS Managed Microsoft AD directory (Linux instances) and Seamlessly join an Amazon EC2 Windows instance to your AWS Managed Microsoft AD directory (Windows instances).

- **Placement group**: A placement group determines the placement strategy of your instances. Select an existing placement group, or create a new one. This option is only available if you've selected an instance type that supports placement groups. For more information, see Placement groups.

- **Capacity Reservation**: Specify whether to launch the instance into shared capacity, any open Capacity Reservation, a specific Capacity Reservation, or a Capacity Reservation group. For more information, see Launch instances into an existing Capacity Reservation.

- **IAM role**: Select an AWS Identity and Access Management (IAM) role to associate with the instance. For more information, see IAM roles for Amazon EC2.

- **CPU options**: Choose Specify CPU options to specify a custom number of vCPUs during launch. Set the number of CPU cores and threads per core. For more information, see Optimize CPU options.

- **Shutdown behavior**: Select whether the instance should stop or terminate when shut down. For more information, see Change the instance initiated shutdown behavior.

- **Stop - Hibernate behavior**: To enable hibernation, select this check box. This option is only available if your instance meets the hibernation prerequisites. For more information, see Hibernate your Amazon EC2 instance.

- **Enable termination protection**: To prevent accidental termination, select this check box. For more information, see Enable termination protection.

- **Enable stop protection**: To prevent accidental stopping, select this check box. For more information, see Enable stop protection.
• **Monitoring**: Select this check box to turn on detailed monitoring of your instance using Amazon CloudWatch. Additional charges apply. For more information, see Monitor your instances using CloudWatch.

• **EBS-optimized instance**: An Amazon EBS-optimized instance uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. If the instance type supports this feature, select this check box to enable it. Additional charges apply. For more information, see Amazon EBS–optimized instance types.

• **Tenancy**: If you are launching your instance into a VPC, you can choose to run your instance on isolated, dedicated hardware (Dedicated) or on a Dedicated Host (Dedicated host). Additional charges may apply. For more information, see Amazon EC2 Dedicated Instances and Amazon EC2 Dedicated Hosts.

• **T2/T3 Unlimited**: Select this check box to enable applications to burst beyond the baseline for as long as needed. Additional charges may apply. For more information, see Burstable performance instances.

• **File systems**: To create a new file system to mount to your instance, choose Create new file system, enter a name for the new file system, and then choose Create. The file system is created using Amazon EFS Quick Create, which applies the service recommended settings. The security groups required to enable access to the file system are automatically created and attached to the instance and the mount targets of the file system. You can also choose to manually create and attach the required security groups. To mount one or more existing Amazon EFS file systems to your instance, choose Add file system and then choose the file systems to mount and the mount points to use. For more information, see Use Amazon EFS with Amazon EC2 Linux instances.

• **Network interfaces**: If you selected a specific subnet, you can specify up to two network interfaces for your instance:
  
  • For **Network Interface**, select New network interface to let AWS create a new interface, or select an existing, available network interface.
  
  • For **Primary IP**, enter a private IPv4 address from the range of your subnet, or leave Auto-assign to let AWS choose a private IPv4 address for you.
  
  • For **Secondary IP addresses**, choose Add IP to assign more than one private IPv4 address to the selected network interface.
  
  • (IPv6-only) For **IPv6 IPs**, choose Add IP, and enter an IPv6 address from the range of the subnet, or leave Auto-assign to let AWS choose one for you.
  
  • **Network Card Index**: The index of the network card. The primary network interface must be assigned to network card index 0. Some instance types support multiple network cards.
• Choose **Add Device** to add a secondary network interface. A secondary network interface can reside in a different subnet of the VPC, provided it's in the same Availability Zone as your instance.

For more information, see [Elastic network interfaces](#). If you specify more than one network interface, your instance cannot receive a public IPv4 address. Additionally, if you specify an existing network interface for eth0, you cannot override the subnet's public IPv4 setting using **Auto-assign Public IP**. For more information, see [Assign a public IPv4 address during instance launch](#).

• **Kernel ID**: (Only valid for paravirtual (PV) AMIs) Select **Use default** unless you want to use a specific kernel.

• **RAM disk ID**: (Only valid for paravirtual (PV) AMIs) Select **Use default** unless you want to use a specific RAM disk. If you have selected a kernel, you may need to select a specific RAM disk with the drivers to support it.

• **Enclave**: Select **Enable** to enable the instance for AWS Nitro Enclaves. For more information, see [What is AWS Nitro Enclaves?](#) in the [AWS Nitro Enclaves User Guide](#).

• **Metadata accessible**: You can enable or disable access to the Instance Metadata Service (IMDS). For more information, see [Use IMDSv2](#).

• **Metadata IPv6 endpoint**: You can enable the instance to use the IMDS IPv6 address [fd00:ec2::254] to retrieve instance metadata. This option is only available if you are launching instances built on the AWS Nitro System into an IPv6-supported subnet (dual stack or IPv6 only). For more information about retrieving instance metadata, see [Retrieve instance metadata](#).

• **Metadata version**: If you enable access to the IMDS, you can choose to require the use of Instance Metadata Service Version 2 when requesting instance metadata. For more information, see [Configure instance metadata options for new instances](#).

• **Metadata token response hop limit**: If you enable the IMDS, you can set the allowable number of network hops for the metadata token. For more information, see [Use IMDSv2](#).

• **User data**: You can specify user data to configure an instance during launch, or to run a configuration script. To attach a file, select the **As file** option and browse for the file to attach.
Step 4: Add Storage

The AMI you selected includes one or more volumes of storage, including the root device volume. On the Add Storage page, you can specify additional volumes to attach to the instance by choosing Add New Volume. Configure each volume as follows, and then choose Next: Add Tags.

- **Type**: Select instance store or Amazon EBS volumes to associate with your instance. The types of volume available in the list depend on the instance type you've chosen. For more information, see Amazon EC2 instance store temporary block storage for Amazon EC2 instances and Amazon EBS volumes.

- **Device**: Select from the list of available device names for the volume.

- **Snapshot**: Enter the name or ID of the snapshot from which to restore a volume. You can also search for available shared and public snapshots by typing text into the Snapshot field. Snapshot descriptions are case-sensitive.

- **Size**: For EBS volumes, you can specify a storage size. Even if you have selected an AMI and instance that are eligible for the free tier, to stay within the free tier, you must stay under 30 GiB of total storage.

- **Volume Type**: For EBS volumes, select a volume type. For more information, see Amazon EBS volume types in the Amazon EBS User Guide.

- **IOPS**: If you have selected a Provisioned IOPS SSD volume type, then you can enter the number of I/O operations per second (IOPS) that the volume can support.

- **Delete on Termination**: For Amazon EBS volumes, select this check box to delete the volume when the instance is terminated. For more information, see Preserve data when an instance is terminated.

- **Encrypted**: If the instance type supports EBS encryption, you can specify the encryption state of the volume. If you have enabled encryption by default in this Region, the default customer managed key is selected for you. You can select a different key or disable encryption. For more information, see Amazon EBS encryption in the Amazon EBS User Guide.

Step 5: Add Tags

On the Add Tags page, specify tags by providing key and value combinations. You can tag the instance, the volumes, or both. For Spot Instances, you can tag the Spot Instance request only. Choose Add another tag to add more than one tag to your resources. Choose Next: Configure Security Group when you are done.
Step 6: Configure Security Group

On the **Configure Security Group** page, use a security group to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other traffic is ignored. (For more information about security groups, see [Amazon EC2 security groups for your EC2 instances](https://aws.amazon.com/documentation/ec2/security-groups/).) Select or create a security group as follows, and then choose **Review and Launch**.

- To select an existing security group, choose **Select an existing security group**, and select your security group. You can't edit the rules of an existing security group, but you can copy them to a new group by choosing **Copy to new**. Then you can add rules as described in the next step.
- To create a new security group, choose **Create a new security group**. The wizard automatically defines the **launch-wizard-x** security group and creates an inbound rule to allow you to connect to your instance. Linux instances use an inbound rule for SSH (port 22) and Windows instances use an inbound rule for RDP (port 3389).
- You can add rules to suit your needs. For example, if your instance is a web server, open ports 80 (HTTP) and 443 (HTTPS) to allow internet traffic.

To add a rule, choose **Add Rule**, select the protocol to open to network traffic, and then specify the source. Choose **My IP** from the **Source** list to let the wizard add your computer's public IP address. However, if you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

⚠️ **Warning**

Rules that enable all IP addresses (0.0.0.0/0) to access your instance over SSH or RDP are acceptable for this short exercise, but are unsafe for production environments. You should authorize only a specific IP address or range of addresses to access your instance.

Step 7: Review Instance Launch and Select Key Pair

On the **Review Instance Launch** page, check the details of your instance, and make any necessary changes by choosing the appropriate **Edit** link.

When you are ready, choose **Launch**.

In the **Select an existing key pair or create a new key pair** dialog box, you can choose an existing key pair, or create a new one. For example, choose **Choose an existing key pair**, then select the
key pair you created when getting set up. For more information, see Amazon EC2 key pairs and Amazon EC2 instances.

⚠ Important

If you choose the Proceed without key pair option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

To launch your instance, select the acknowledgment check box, then choose Launch Instances.

(Optional) You can create a status check alarm for the instance (additional fees may apply). On the confirmation screen, choose Create status check alarms and follow the directions. Status check alarms can also be created after you launch the instance. For more information, see Create CloudWatch alarms for Amazon EC2 instances that fail status checks.

If the instance fails to launch or the state immediately goes to terminated instead of running, see Troubleshoot Amazon EC2 instance launch issues.

Launch an instance from a launch template

You can use a launch template to store instance launch parameters so that you do not have to specify them every time you launch an instance. For example, you can create a launch template with the AMI ID, instance type, and network settings that you typically use to launch instances. When you launch an instance using the Amazon EC2 console, an AWS SDK, or a command line tool, you can specify the launch template instead of entering the parameters again.

For each launch template, you can create one or more numbered launch template versions. Each version can have different launch parameters. When you launch an instance from a launch template, you can use any version of the launch template. If you do not specify a version, the default version is used. You can set any version of the launch template as the default version—by default, it's the first version of the launch template.

The following diagram shows a launch template with three versions. The first version specifies the instance type, AMI ID, subnet, and key pair to use to launch the instance. The second version is based on the first version and also specifies a security group for the instance. The third version uses different values for some of the parameters. Version 2 is set as the default version. If you launched an instance from this launch template, the launch parameters from version 2 would be used if no other version were specified.
Launch template restrictions

The following rules apply to launch templates and launch template versions:

- **Quotas** – To view the quotas for your launch templates and launch template versions, open the [Service Quotas](https://console.aws.amazon.com/servicequotas/home?region=us-east-1) console or use the `list-service-quotas` AWS CLI command. Each AWS account can have up to a maximum of 5,000 launch templates per Region and up to 10,000 versions per launch template. Your accounts might have different quotas based on their age and usage history.

- **Parameters are optional** – Launch template parameters are optional. However, you must ensure that your request to launch an instance includes all the required parameters. For example, if your launch template does not include an AMI ID, you must specify both the launch template and an AMI ID when you launch an instance.

- **Parameters not validated** – Launch template parameters are not fully validated when you create the launch template. If you specify incorrect values for parameters, or if you do not use supported parameter combinations, no instances can launch using this launch template. Ensure
that you specify the correct values for the parameters and that you use supported parameter combinations. For example, to launch an instance in a placement group, you must specify a supported instance type.

- **Tags** – You can tag a launch template, but you cannot tag a launch template version.
- **Immutable** – Launch templates are immutable. To modify a launch template, you must create a new version of the launch template.
- **Version numbers** – Launch template versions are numbered in the order in which they are created. When you create a launch template version, you cannot specify the version number yourself.

**Control access to launch templates with IAM permissions**

You can use IAM permissions to control which launch template actions users can perform, such as viewing, creating, or deleting launch templates.

When you grant users permission to create launch templates and launch template versions, you can't use resource-level permissions to restrict the resources that they can specify in a launch template. Therefore, ensure that you grant permissions to create launch templates and launch template versions only to appropriate administrators.

You must grant anyone that will use a launch template the permissions required to create and access the resources that are specified in the launch template. For example:

- To launch an instance from a shared private Amazon Machine Image (AMI), the user must have launch permission for the AMI.
- To create EBS volumes with tags from existing snapshots, the user must have read access to the snapshots, and permissions to create and tag volumes.

**Contents**

- ec2:CreateLaunchTemplate
- ec2:DescribeLaunchTemplates
- ec2:DescribeLaunchTemplateVersions
- ec2:DeleteLaunchTemplate
- Control versioning permissions
- Control access to tags on launch templates
**ec2:CreateLaunchTemplate**

To create a launch template in the console or by using the APIs, the principal must have the `ec2:CreateLaunchTemplate` permission in an IAM policy. Whenever possible, use tags to help you control access to the launch templates in your account.

For example, the following IAM policy statement gives the principal permission to create launch templates only if the template uses the specified tag (`purpose=testing`).

```json
{
    "Sid": "IAMPolicyForCreatingTaggedLaunchTemplates",
    "Action": "ec2:CreateLaunchTemplate",
    "Effect": "Allow",
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:ResourceTag/purpose": "testing"
        }
    }
}
```

Principals who create launch templates might need some related permissions, such as:

- **ec2:CreateTags** – To add tags to the launch template during the `CreateLaunchTemplate` operation, the `CreateLaunchTemplate` caller must have the `ec2:CreateTags` permission in an IAM policy.

- **ec2:RunInstances** – To launch EC2 instances from the launch template that they created, the principal must also have the `ec2:RunInstances` permission in an IAM policy.

For resource-creating actions that apply tags, users must have the `ec2:CreateTags` permission. The following IAM policy statement uses the `ec2:CreateAction` condition key to allow users to create tags only in the context of `CreateLaunchTemplate`. Users cannot tag existing launch templates or any other resources. For more information, see [Grant permission to tag Amazon EC2 resources during creation](#).

```json
{
    "Sid": "IAMPolicyForTaggingLaunchTemplatesOnCreation",
    "Action": "ec2:CreateTags",
    "Effect": "Allow",
}
```
The IAM user who creates a launch template doesn't automatically have permission to use the launch template that they created. Like any other principal, the launch template creator needs to get permission through an IAM policy. If an IAM user wants to launch an EC2 instance from a launch template, they must have the `ec2:RunInstances` permission. When granting these permissions, you can specify that users can only use launch templates with specific tags or specific IDs. You can also control the AMI and other resources that anyone using launch templates can reference and use when launching instances by specifying resource-level permissions for the `RunInstances` call. For example policies, see [Launch templates](#).

**ec2:DescribeLaunchTemplates**

To list launch templates in the account, the principal must have the `ec2:DescribeLaunchTemplates` permission in an IAM policy. Because Describe actions do not support resource-level permissions, you must specify them without conditions and the value of the resource element in the policy must be "*".

For example, the following IAM policy statement gives the principal permission to list all launch templates in the account.

```
{  
  "Sid": "IAMPolicyForDescribingLaunchTemplates",  
  "Action": "ec2:DescribeLaunchTemplates",  
  "Effect": "Allow",  
  "Resource": "*"
}
```

**ec2:DescribeLaunchTemplateVersions**

Principals who view launch templates should also have the `ec2:DescribeLaunchTemplateVersions` permission to retrieve the entire set of attributes that make up the launch templates.

To list launch template versions in the account, the principal must have the `ec2:DescribeLaunchTemplateVersions` permission in an IAM policy. Because Describe
actions do not support resource-level permissions, you must specify them without conditions and the value of the resource element in the policy must be "*".

For example, the following IAM policy statement gives the principal permission to list all launch template versions in the account.

```json
{
    "Sid": "IAMPolicyForDescribingLaunchTemplateVersions",
    "Effect": "Allow",
    "Action": "ec2:DescribeLaunchTemplateVersions",
    "Resource": "*"
}
```

**ec2:DeleteLaunchTemplate**

⚠️ **Important**

Use caution when giving principals permission to delete a resource. Deleting a launch template might cause a failure in an AWS resource that relies on the launch template.

To delete a launch template, the principal must have the `ec2:DeleteLaunchTemplate` permission in an IAM policy. Whenever possible, use tag-based condition keys to limit the permissions.

For example, the following IAM policy statement gives the principal permission to delete launch templates only if the template uses the specified tag (**purpose=testing**).

```json
{
    "Sid": "IAMPolicyForDeletingLaunchTemplates",
    "Action": "ec2:DeleteLaunchTemplate",
    "Effect": "Allow",
    "Resource": "*",
    "Condition": {
        "StringEquals": {
            "aws:ResourceTag/purpose": "testing"
        }
    }
}
```

Alternatively, you can use ARNs to identify the launch template that the IAM policy applies to.
A launch template has the following ARN.

```
"Resource": "arn:aws:ec2:region:account-id:launch-template/lt-09477bcd97b0d310e"
```

You can specify multiple ARNs by enclosing them in a list, or you can specify a `Resource` value of "*" without the `Condition` element to allow the principal to delete any launch template in the account.

**Control versioning permissions**

For trusted administrators, you can grant access for creating and deleting versions of a launch template, and for changing the default version of a launch template, by using IAM policies similar to the following examples.

⚠️ **Important**

Be cautious when giving principals permission to create launch template versions or modify launch templates.

- When you create a launch template version, you affect any AWS resources that allow Amazon EC2 to launch instances on your behalf with the `Latest` version.
- When you modify a launch template, you can change which version is the `Default` and therefore affect any AWS resources that allow Amazon EC2 to launch instances on your behalf with this modified version.

You also need to be cautious in how you handle AWS resources that interact with the `Latest` or `Default` launch template version, such as EC2 Fleet and Spot Fleet. When a different launch template version is used for `Latest` or `Default`, Amazon EC2 does not re-check user permissions for actions to be completed when launching new instances to fulfil the fleet's target capacity because there is no user interaction with the AWS resource. By granting a user permission to call the `CreateLaunchTemplateVersion` and `ModifyLaunchTemplate` APIs, the user is effectively also granted the `iam:PassRole` permission if they point the fleet to a different launch template version that contains an instance profile (a container for an IAM role). It means that a user can potentially update a launch template to pass an IAM role to an instance even if they don't have the `iam:PassRole` permission. You can manage this risk by being careful when granting permissions to who can create and manage launch template versions.
**ec2:CreateLaunchTemplateVersion**

To create a new version of a launch template, the principal must have the `ec2:CreateLaunchTemplateVersion` permission for the launch template in an IAM policy.

For example, the following IAM policy statement gives the principal permission to create launch template versions only if the version uses the specified tag (`environment=production`). Alternatively, you can specify one or multiple launch template ARNs, or you can specify a `Resource` value of "*" without the `Condition` element to allow the principal to create versions of any launch template in the account.

```
{
   "Sid": "IAMPolicyForCreatingLaunchTemplateVersions",
   "Action": "ec2:CreateLaunchTemplateVersion",
   "Effect": "Allow",
   "Resource": "*",
   "Condition": {
      "StringEquals": {
         "aws:ResourceTag/environment": "production"
      }
   }
}
```

**ec2>DeleteLaunchTemplateVersion**

⚠️ **Important**

As always, you should exercise caution when giving principals permission to delete a resource. Deleting a launch template version might cause a failure in an AWS resource that relies on the launch template version.

To delete a launch template version, the principal must have the `ec2>DeleteLaunchTemplateVersion` permission for the launch template in an IAM policy.

For example, the following IAM policy statement gives the principal permission to delete launch template versions only if the version uses the specified tag (`environment=production`). Alternatively, you can specify one or multiple launch template ARNs, or you can specify a `Resource` value of "*" without the `Condition` element to allow the principal to delete versions of any launch template in the account.
ec2:ModifyLaunchTemplate

To change the Default version that is associated with a launch template, the principal must have the ec2:ModifyLaunchTemplate permission for the launch template in an IAM policy.

For example, the following IAM policy statement gives the principal permission to modify launch templates only if the launch template uses the specified tag (environment=production). Alternatively, you can specify one or multiple launch template ARNs, or you can specify a Resource value of "*" without the Condition element to allow the principal to modify any launch template in the account.

Control access to tags on launch templates

You can use condition keys to limit tagging permissions when the resource is a launch template. For example, the following IAM policy allows removing only the tag with the temporary key from launch templates in the specified account and Region.
For more information about conditions keys that you can use to control the tag keys and values that can be applied to Amazon EC2 resources, see Control access to specific tags.

**Use launch templates to control launching instances**

You can specify that users can only launch instances if they use a launch template, and that they can only use a specific launch template. You can also control who can create, modify, describe, and delete launch templates and launch template versions.

**Use launch templates to control launch parameters**

A launch template can contain all or some of the parameters to launch an instance. When you launch an instance using a launch template, you can override parameters that are specified in the launch template. Or, you can specify additional parameters that are not in the launch template.

> **Note**
>
> You cannot remove launch template parameters during launch (for example, you can't specify a null value for the parameter). To remove a parameter, create a new version of the launch template without the parameter and use that version to launch the instance.

To launch instances, users must have permissions to use the `ec2:RunInstances` action. Users must also have permissions to create or use the resources that are created or associated with the instance. You can use resource-level permissions for the `ec2:RunInstances` action to control the launch parameters that users can specify. Alternatively, you can grant users permissions to launch an instance using a launch template. This enables you to manage launch parameters in a launch template rather than in an IAM policy, and to use a launch template as an authorization vehicle.
for launching instances. For example, you can specify that users can only launch instances using a launch template, and that they can only use a specific launch template. You can also control the launch parameters that users can override in the launch template. For example policies, see Launch templates.

**Control the use of launch templates**

By default, users do not have permissions to work with launch templates. You can create a policy that grants users permissions to create, modify, describe, and delete launch templates and launch template versions. You can also apply resource-level permissions to some launch template actions to control a user's ability to use specific resources for those actions. For more information, see the following example policies: Example: Work with launch templates.

Take care when granting users permissions to use the ec2:CreateLaunchTemplate and ec2:CreateLaunchTemplateVersion actions. You cannot use resource-level permissions to control which resources users can specify in the launch template. To restrict the resources that are used to launch an instance, ensure that you grant permissions to create launch templates and launch template versions only to appropriate administrators.

**Important security concerns when using launch templates with EC2 Fleet or Spot Fleet**

To use launch templates, you must grant your users permissions to create, modify, describe, and delete launch templates and launch template versions. You can control who can create launch templates and launch template versions by controlling access to the ec2:CreateLaunchTemplate and ec2:CreateLaunchTemplateVersion actions. You can also control who can modify launch templates by controlling access to the ec2:ModifyLaunchTemplate action.

⚠️ **Important**

If an EC2 Fleet or Spot Fleet is configured to use the Latest or Default launch template version, the fleet is not aware if Latest or Default are later changed to point to a different launch template version. When a different launch template version is used for Latest or Default, Amazon EC2 does not re-check permissions for actions to be completed when launching new instances to fulfil the fleet's target capacity. This is an important consideration when granting permissions to who can create and manage launch template versions, particularly the ec2:ModifyLaunchTemplate action that allows a user to change the Default launch template version.
By granting a user permission to use the EC2 actions for the launch template APIs, the user is effectively also granted the `iam:PassRole` permission if they create or update an EC2 Fleet or Spot Fleet to point to a different launch template version that contains an instance profile (a container for an IAM role). It means that a user can potentially update a launch template to pass an IAM role to an instance even if they don’t have the `iam:PassRole` permission. For more information and an example IAM policy, see Using an IAM role to grant permissions to applications running on Amazon EC2 instances in the IAM User Guide.

For more information, see Control the use of launch templates and Example: Work with launch templates.

Create a launch template

Create a launch template using parameters that you define, or use an existing launch template or an instance as the basis for a new launch template.

Tasks

- Create a launch template from parameters
- Create a launch template from an existing launch template
- Create a launch template from an instance
- Use a Systems Manager parameter instead of an AMI ID

Create a launch template from parameters

To create a launch template, you must specify the launch template name and at least one instance configuration parameter.

Console directions

To create a launch template using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Launch Templates, and then choose Create launch template.
3. The launch template parameters are grouped. For details about each group see the sections below.
4. Use the Summary panel to review your launch template configuration. You can navigate to any section by choosing its link and then make any necessary changes.
5. When you're ready to create your launch template, choose **Create launch template**.

### Launch template name, description, and tags

1. For **Launch template name**, enter a descriptive name for the launch template.
2. For **Template version description**, provide a brief description of this version of the launch template.
3. To **tag** the launch template on creation, expand **Template tags**, choose **Add tag**, and then enter a tag key and value pair. Choose **Add tag** again for each additional tag to add.

![Note]

To tag the resources that are created when an instance is launched, you must specify the tags under **Resource tags**. For more information, see [Resource tags](#).

### Application and OS Images (Amazon Machine Image)

An Amazon Machine Image (AMI) contains the information required to create an instance. For example, an AMI might contain the software that's required to act as a web server, such as Linux, Apache, and your website.

You can find a suitable AMI as follows. With each option for finding an AMI, you can choose **Cancel** (at top right) to return to the launch template without choosing an AMI.

**Search bar**

To search through all available AMIs, enter a keyword in the AMI search bar and then press **Enter**. To select an AMI, choose **Select**.

**Recents**

The AMIs that you've recently used.

Choose **Recently launched** or **Currently in use**, and then, from **Amazon Machine Image (AMI)**, select an AMI.

**My AMIs**

The private AMIs that you own, or private AMIs that have been shared with you.
Choose **Owned by me** or **Shared with me**, and then, from **Amazon Machine Image (AMI)**, select an AMI.

**Quick Start**

AMIs are grouped by operating system (OS) to help you get started quickly.

First select the OS that you need, and then, from **Amazon Machine Image (AMI)**, select an AMI. To select an AMI that is eligible for the free tier, make sure that the AMI is marked **Free tier eligible**.

**Browse more AMIs**

Choose **Browse more AMIs** to browse the full AMI catalog.

- To search through all available AMIs, enter a keyword in the search bar and then press **Enter**.
- To find an AMI using a Systems Manager parameter, choose the arrow button to the right of the search bar, and then choose **Search by Systems Manager parameter**. For more information, see [Find an AMI using a Systems Manager parameter](#).
- To specify a Systems Manager parameter that will resolve to an AMI at the time an instance is launched from the launch template, choose the arrow button to the right of the search bar, and then choose **Specify custom value/Systems Manager parameter**. For more information, see [Use a Systems Manager parameter instead of an AMI ID](#).
- To search by category, choose **Quickstart AMIs**, **My AMIs**, **AWS Marketplace AMIs**, or **Community AMIs**.

The AWS Marketplace is an online store where you can buy software that runs on AWS, including AMIs. For more information about launching an instance from the AWS Marketplace, see [Launch an AWS Marketplace instance](#). In **Community AMIs**, you can find AMIs that AWS community members have made available for others to use. AMIs from Amazon or a verified partner are marked **Verified provider**.

- To filter the list of AMIs, select one or more check boxes under **Refine results** on the left of the screen. The filter options are different depending on the selected search category.
- Check the **Root device type** listed for each AMI. Notice which AMIs are the type that you need: either **ebs** (backed by Amazon EBS) or **instance-store** (backed by instance store). For more information, see [Storage for the root device](#).
- Check the **Virtualization** type listed for each AMI. Notice which AMIs are the type that you need: either **hvm** or **paravirtual**. For example, some instance types require HVM. For more information, see [AMI virtualization types](#).
- Check the **Boot mode** listed for each AMI. Notice which AMIs use the boot mode that you need: either **legacy-bios**, **uefi**, or **uefi-preferred**. For more information, see [Amazon EC2 boot modes](#).

- Choose an AMI that meets your needs, and then choose **Select**.

### Instance type

The instance type defines the hardware configuration and size of the instance. Larger instance types have more CPU and memory. For more information, see the [Amazon EC2 instance types](#).

For **Instance type**, you can either select an instance type, or you can specify instance attributes and let Amazon EC2 identify the instance types with those attributes.

**Note**

Specifying instance attributes is supported only when using Auto Scaling groups, EC2 Fleet, and Spot Fleet to launch instances. For more information, see [Creating an Auto Scaling group using attribute-based instance type selection](#), [Attribute-based instance type selection for EC2 Fleet](#), and [Attribute-based instance type selection for Spot Fleet](#).

If you plan to use the launch template in the [launch instance wizard](#) or with the [RunInstances API](#), you must select an instance type.

- **Instance type**: Ensure that the instance type is compatible with the AMI that you've specified. For more information, see [Amazon EC2 instance types](#).

- **Compare instance types**: You can compare different instance types by the following attributes: number of vCPUs, architecture, amount of memory (GiB), amount of storage (GB), storage type, and network performance.

- **Get advice**: You can get guidance and suggestions for instance types from the Amazon Q EC2 instance type selector. For more information, see [Get instance type recommendations for a new workload](#).

- **Advanced**: To specify instance attributes and let Amazon EC2 identify the instance types with those attributes, choose **Advanced**, and then choose **Specify instance type attributes**.

- **Number of vCPUs**: Enter the minimum and maximum number of vCPUs for your compute requirements. To indicate no limits, enter a minimum of 0, and leave the maximum blank.
• **Amount of memory (MiB):** Enter the minimum and maximum amount of memory, in MiB, for your compute requirements. To indicate no limits, enter a minimum of 0, and leave the maximum blank.

• Expand **Optional instance type attributes** and choose **Add attribute** to express your compute requirements in more detail. For information about each attribute, see **InstanceRequirementsRequest** in the *Amazon EC2 API Reference*.

• **Resulting instance types:** You can preview the instance types that match the specified attributes. To exclude instance types, choose **Add attribute**, and from the **Attribute** list, choose **Excluded instance types**. From the **Attribute value** list, select the instance types to exclude.

**Key pair (login)**

The key pair for the instance.

For **Key pair name**, choose an existing key pair, or choose **Create new key pair** to create a new one. For more information, see [Amazon EC2 key pairs and Amazon EC2 instances](https://docs.aws.amazon.com/en_us/AmazonEC2/latest/UserGuide/creating-ebs-volumes.html).

**Network settings**

Configure the network settings, as necessary.

• **Subnet:** You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone, or Outpost.

To launch the instance in an Availability Zone, select the subnet in which to launch your instance. To create a new subnet, choose **Create new subnet** to go to the Amazon VPC console. When you are done, return to the wizard and choose the Refresh icon to load your subnet in the list.

To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

To launch an instance in an Outpost, select a subnet in a VPC that you associated with the Outpost.

• **Firewall (security groups):** Use one or more security groups to define firewall rules for your instance. These rules specify which incoming network traffic is delivered to your instance. All other traffic is ignored. For more information about security groups, see [Amazon EC2 security groups for your EC2 instances](https://docs.aws.amazon.com/en_us/AmazonEC2/latest/UserGuide/creating-ebs-volumes.html).
If you add a network interface, you must specify the same security groups in the network interface.

Select or create a security group as follows:

- To select an existing security group, choose **Select existing security group**, and select your security group from **Common security groups**.
- To create a new security group, choose **Create security group**.

You can add rules to suit your needs. For example, if your instance will be a web server, open ports 80 (HTTP) and 443 (HTTPS) to allow internet traffic.

To add a rule, choose **Add security group rule**. For **Type**, select the network traffic type. The **Protocol** field is automatically filled in with the protocol to open to network traffic. For **Source type**, select the source type. To let the launch template add your computer's public IP address, choose **My IP**. However, if you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.

⚠️ **Warning**

Rules that enable all IP addresses (0.0.0.0/0) to access your instance over SSH or RDP are acceptable if you are briefly launching a test instance and will stop or terminate it soon, but are unsafe for production environments. You should authorize only a specific IP address or range of addresses to access your instance.

- **Advanced network configuration**

**Network interface**

- **Device index**: The device number for the network interface, for example, eth0 for the primary network interface. If you leave the field blank, AWS creates the primary network interface.
- **Network interface**: Select **New interface** to let Amazon EC2 create a new interface, or select an existing, available network interface.
- **Description**: (Optional) A description for the new network interface.
- **Subnet**: The subnet in which to create the new network interface. For the primary network interface (eth0), this is the subnet in which the instance is launched. If you've entered an
existing network interface for eth0, the instance is launched in the subnet in which the network interface is located.

- **Security groups**: One or more security groups in your VPC with which to associate the network interface.

- **Auto-assign public IP**: Specify whether your instance receives a public IPv4 address. By default, instances in a default subnet receive a public IPv4 address and instances in a nondefault subnet do not. You can select **Enable** or **Disable** to override the subnet's default setting. For more information, see **Public IPv4 addresses**.

- **Primary IP**: A private IPv4 address from the range of your subnet. Leave blank to let Amazon EC2 choose a private IPv4 address for you.

- **Secondary IP**: One or more additional private IPv4 addresses from the range of your subnet. Choose **Manually assign** and enter an IP address. Choose **Add IP** to add another IP address. Alternatively, choose **Automatically assign** to let Amazon EC2 choose one for you, and enter a value to indicate the number of IP addresses to add.

- (IPv6-only) **IPv6 IPs**: An IPv6 address from the range of the subnet. Choose **Manually assign** and enter an IP address. Choose **Add IP** to add another IP address. Alternatively, choose **Automatically assign** to let Amazon EC2 choose one for you, and enter a value to indicate the number of IP addresses to add.

- **IPv4 Prefixes**: The IPv4 prefixes for the network interface.

- **IPv6 Prefixes**: The IPv6 prefixes for the network interface.

- (Optional) **Assign Primary IPv6 IP**: If you're launching an instance into a dual-stack or IPv6-only subnet, you have the option to **Assign Primary IPv6 IP**. Assigning a primary IPv6 address enables you to avoid disrupting traffic to instances or ENIs. Choose **Enable** if this instance relies on its IPv6 address not changing. When you launch the instance, AWS will automatically assign an IPv6 address associated with the ENI attached to your instance to be the primary IPv6 address. Once you enable an IPv6 GUA address to be a primary IPv6, you cannot disable it. When you enable an IPv6 GUA address to be a primary IPv6, the first IPv6 GUA will be made the primary IPv6 address until the instance is terminated or the network interface is detached. If you have multiple IPv6 addresses associated with an ENI attached to your instance and you enable a primary IPv6 address, the first IPv6 GUA address associated with the ENI becomes the primary IPv6 address.

- **Delete on termination**: Whether the network interface is deleted when the instance is deleted.

- **Elastic Fabric Adapter**: Indicates whether the network interface is an Elastic Fabric Adapter. For more information, see the section called “Elastic Fabric Adapter”.
• **Network card index:** The index of the network card. The primary network interface must be assigned to network card index 0. Some instance types support multiple network cards.

• **ENA Express:** ENA Express is powered by AWS Scalable Reliable Datagram (SRD) technology. SRD technology uses a packet spraying mechanism to distribute load and avoid network congestion. Enabling ENA Express allows supported instances to communicate using SRD on top of regular TCP traffic when possible. The launch template does not include ENA Express configuration for the instance unless you select **Enable** or **Disable**.

• **ENA Express UDP:** If you've enabled ENA Express, you can optionally use it for UDP traffic. The launch template does not include ENA Express configuration for the instance unless you select **Enable** or **Disable**.

Choose **Add network interface** to add more network interfaces. The number of network interfaces that you can add depends on the number that is supported by the selected instance type. Additional network interfaces can reside in a different subnet of the same VPC or in a subnet in a different VPC that you own (as long as the subnet is in the same Availability Zone as your instance). If you select a subnet in another VPC, the **Multi-VPC** label appears next to the network interface you've added. This enables you to create multi-homed instances across VPCs with different networking and security configurations. Note that if you attach an additional ENI from another VPC, you must choose a security group for the ENI from that VPC.

For more information, see **Elastic network interfaces**. If you specify more than one network interface, your instance cannot receive a public IPv4 address. Additionally, if you specify an existing network interface for eth0, you cannot override the subnet's public IPv4 setting using **Auto-assign Public IP**. For more information, see **Assign a public IPv4 address during instance launch**.

**Configure storage**

If you specify an AMI for the launch template, the AMI includes one or more volumes of storage, including the root volume (**Volume 1 (AMI Root)**). You can specify additional volumes to attach to the instance.

You can use the **Simple** or **Advanced** view. With the **Simple** view, you specify the size and type of volume. To specify all volume parameters, choose the **Advanced** view (at top right of the card).

To add a new volume, choose **Add new volume**.

By using the **Advanced** view, you can configure each volume as follows:
• **Storage type**: The type of volume (EBS or ephemeral) to associate with your instance. The instance store (ephemeral) volume type is only available if you select an instance type that supports it. For more information, see Amazon EC2 instance store temporary block storage for Amazon EC2 instances and Amazon EBS volumes.

• **Device name**: Select from the list of available device names for the volume.

• **Snapshot**: Select the snapshot from which to create the volume. You can search for available shared and public snapshots by entering text into the **Snapshot** field.

• **Size (GiB)**: For EBS volumes, you can specify a storage size. If you have selected an AMI and instance that are eligible for the free tier, keep in mind that to stay within the free tier, you must stay under 30 GiB of total storage.

• **Volume type**: For EBS volumes, select a volume type. For more information, see Amazon EBS volume types in the Amazon EBS User Guide.

• **IOPS**: If you have selected a Provisioned IOPS SSD (io1 and io2) or General Purpose SSD (gp3) volume type, then you can enter the number of I/O operations per second (IOPS) that the volume can support. This is required for io1, io2, and gp3 volumes. It is not supported for gp2, st1, sc1, or standard volumes. If you omit this parameter for the launch template, you must specify a value for it when you launch an instance from the launch template.

• **Delete on termination**: For Amazon EBS volumes, choose **Yes** to delete the volume when the instance is terminated, or choose **No** to keep the volume. For more information, see Preserve data when an instance is terminated.

• **Encrypted**: If the instance type supports EBS encryption, you can choose **Yes** to enable encryption for the volume. If you have enabled encryption by default in this Region, encryption is enabled for you. For more information, see Amazon EBS encryption in the Amazon EBS User Guide.

• **KMS key**: If you selected **Yes** for **Encrypted**, then you must select a customer managed key to use to encrypt the volume. If you have enabled encryption by default in this Region, the default customer managed key is selected for you. You can select a different key or specify the ARN of any customer managed key that you created.

### Resource tags

To **tag** the resources that are created when an instance is launched, under **Resource tags**, choose **Add tag**, and then enter a tag key and value pair. For **Resource types**, specify the resources to tag on creation. You can specify the same tag for all the resources, or specify different tags for different resources. Choose **Add tag** again for each additional tag to add.
You can specify tags for the following resources that are created when a launch template is used:

- Instances
- Volumes
- Spot Instance requests
- Network interfaces

**Note**
To tag the launch template itself, you must specify the tags under Template tags. For more information, see Launch template name, description, and tags.

**Advanced details**

For Advanced details, expand the section to view the fields and specify any additional parameters for the instance.

- **Purchasing option**: Choose Request Spot Instances to request Spot Instances at the Spot price, capped at the On-Demand price, and choose Customize to change the default Spot Instance settings. You can set your maximum price (not recommended), and change the request type, request duration, and interruption behavior. If you do not request a Spot Instance, EC2 launches an On-Demand Instance by default. For more information, see Spot Instances.

- **IAM instance profile**: Select an AWS Identity and Access Management (IAM) instance profile to associate with the instance. For more information, see IAM roles for Amazon EC2.

- **Hostname type**: Select whether the guest OS hostname of the instance will include the resource name or the IP name. For more information, see Amazon EC2 instance hostname types.

- **Instance auto-recovery**: When enabled, recovers your instance if system status checks fail. This setting is enabled by default at launch for supported instance types. For more information, see Configure simplified automatic recovery.

- **DNS Hostname**: Determines if the DNS queries to the resource name or the IP name (depending on what you selected for Hostname type) will respond with the IPv4 address (A record), IPv6 address (AAAA record), or both. For more information, see Amazon EC2 instance hostname types.

- **Shutdown behavior**: Select whether the instance should stop or terminate when shut down. For more information, see Change the instance initiated shutdown behavior.
• **Stop - Hibernate behavior:** To enable hibernation, choose **Enable**. This field is only valid for instances that meet the hibernation prerequisites. For more information, see [Hibernate your Amazon EC2 instance](#).

• **Termination protection:** To prevent accidental termination, choose **Enable**. For more information, see [Enable termination protection](#).

• **Stop protection:** To prevent accidental stopping, choose **Enable**. For more information, see [Enable stop protection](#).

• **Detailed CloudWatch monitoring:** Choose **Enable** to enable detailed monitoring of the instance using Amazon CloudWatch. Additional charges apply. For more information, see [Monitor your instances using CloudWatch](#).

• **Elastic GPU:** Amazon Elastic Graphics reached end of life on January 8, 2024. For workloads that require graphics acceleration, we recommend that you use Amazon EC2 G4ad, G4dn, or G5 instances.

• **Elastic inference:** An elastic inference accelerator to attach to your EC2 CPU instance. For more information, see [Working with Amazon Elastic Inference](#) in the *Amazon Elastic Inference Developer Guide*.

---

**Note**

Starting April 15, 2023, AWS will not onboard new customers to Amazon Elastic Inference (EI), and will help current customers migrate their workloads to options that offer better price and performance. After April 15, 2023, new customers will not be able to launch instances with Amazon EI accelerators in Amazon SageMaker, Amazon ECS, or Amazon EC2. However, customers who have used Amazon EI at least once during the past 30-day period are considered current customers and will be able to continue using the service.

• **Credit specification:** Choose **Unlimited** to enable applications to burst beyond the baseline for as long as needed. This field is only valid for **T** instances. Additional charges may apply. For more information, see [Burstable performance instances](#).

• **Placement group:** Specify a placement group in which to launch the instance. You can select an existing placement group, or create a new one. Not all instance types can be launched in a placement group. For more information, see [Placement groups](#).

• **EBS-optimized instance:** Select **Enable** to provide additional, dedicated capacity for Amazon EBS I/O. Not all instance types support this feature. Additional charges apply. For more information, see the section called “Amazon EBS optimization”.

---
• **Capacity Reservation:** Specify whether to launch the instance into any open Capacity Reservation (**Open**), a specific Capacity Reservation (**Target by ID**), or a Capacity Reservation group (**Target by group**). To specify that a Capacity Reservation should not be used, choose **None**. For more information, see [Launch instances into an existing Capacity Reservation](#).

• **Tenancy:** Choose whether to run your instance on shared hardware (**Shared**), isolated, dedicated hardware (**Dedicated**), or on a Dedicated Host (**Dedicated host**). If you choose to launch the instance onto a Dedicated Host, you can specify whether to launch the instance into a host resource group or you can target a specific Dedicated Host. Additional charges may apply. For more information, see [Amazon EC2 Dedicated Instances](#) and [Amazon EC2 Dedicated Hosts](#).

• **RAM disk ID:** (Only valid for paravirtual (PV) AMIs) Select a RAM disk for the instance. If you have selected a kernel, you might need to select a specific RAM disk with the drivers to support it.

• **Kernel ID:** (Only valid for paravirtual (PV) AMIs) Select a kernel for the instance.

• **Nitro Enclave:** Allows you to create isolated execution environments, called enclaves, from Amazon EC2 instances. Select **Enable** to enable the instance for AWS Nitro Enclaves. For more information, see [What is AWS Nitro Enclaves?](#) in the [AWS Nitro Enclaves User Guide](#).

• **License configurations:** You can launch instances against the specified license configuration to track your license usage. For more information, see [Create a license configuration](#) in the [AWS License Manager User Guide](#).

• **Specify CPU options:** Choose **Specify CPU options** to specify a custom number of vCPUs during launch. Set the number of CPU cores and threads per core. For more information, see [Optimize CPU options](#).

• **Metadata IPv6 endpoint:** You can enable the instance to use the IMDS IPv6 address [fd00:ec2::254] to retrieve instance metadata. This option is only available if you are launching instances built on the AWS Nitro System into an IPv6-supported subnet (dual stack or IPv6 only). For more information, see [Retrieve instance metadata](#).

• **Metadata accessible:** You can enable or disable access to the IMDS. For more information, see [Configure instance metadata options for new instances](#).

• **Metadata version:** If you enable access to the IMDS, you can choose to require the use of Instance Metadata Service Version 2 when requesting instance metadata. For more information, see [Configure instance metadata options for new instances](#).

• **Metadata response hop limit:** If you enable the IMDS, you can set the allowable number of network hops for the metadata token. For more information, see [Configure instance metadata options for new instances](#).
• **Allow tags in metadata**: If you select Enable, the instance will allow access to all of its instance's tags from its metadata. If you do not include this setting in the template, by default, access to the tags in instance metadata is not allowed. For more information, see [Allow access to tags in instance metadata](#).

• **User data**: You can specify user data to configure an instance during launch, or to run a configuration script. For more information, see [Run commands on your Amazon EC2 instance at launch](#).

**AWS CLI example**

The following example uses the `create-launch-template` command to create a launch template with the specified name and instance configuration.

```bash
aws ec2 create-launch-template \
  --launch-template-name TemplateForWebServer \
  --version-description WebVersion1 \
  --tag-specifications 'ResourceType=launch-template,Tags=[{Key=purpose,Value=production}]]' \
  --launch-template-data file://template-data.json
```

The following is example JSON that specifies the launch template data for the instance configuration. Save the JSON to a file and include it in the `--launch-template-data` parameter as shown in the example command.

```json
{
  "NetworkInterfaces": [{
    "AssociatePublicIpAddress": true,
    "DeviceIndex": 0,
    "Ipv6AddressCount": 1,
    "SubnetId": "subnet-7b16de0c"
  }],
  "ImageId": "ami-8c1be5f6",
  "InstanceType": "r4.4xlarge",
  "TagSpecifications": [{
    "ResourceType": "instance",
    "Tags": [{
      "Key": "Name",
      "Value": "webserver"
    }]
  }],
```

---

Launch 764
"CpuOptions": {
  "CoreCount": 4,
  "ThreadsPerCore": 2
}
}

The following is example output.

{
  "LaunchTemplate": {
    "LatestVersionNumber": 1,
    "LaunchTemplateId": "lt-01238c059e3466abc",
    "LaunchTemplateName": "TemplateForWebServer",
    "DefaultVersionNumber": 1,
    "CreatedBy": "arn:aws:iam::123456789012:root",
    "CreateTime": "2017-11-27T09:13:24.000Z"
  }
}

AWS Tools for Windows PowerShell example

The following example uses the `New-EC2LaunchTemplate` cmdlet to create a launch template with the specified name and instance configuration.

```powershell
$launchTemplateData = [Amazon.EC2.Model.RequestLaunchTemplateData]@
{ ImageId = 'ami-8c1be5f6'
  InstanceType = 'r4.4xlarge'
  NetworkInterfaces = @( [Amazon.EC2.Model.LaunchTemplateInstanceNetworkInterfaceSpecificationRequest]@{ AssociatePublicIpAddress = $true
    DeviceIndex = 0
    Ipv6AddressCount = 1
    SubnetId = 'subnet-7b16de0c' })
  TagSpecifications = @( [Amazon.EC2.Model.LaunchTemplateTagSpecificationRequest]@{ ResourceType = 'instance'
    Tags = [Amazon.EC2.Model.Tag]@{ Key = 'Name'
      Value = 'webserver' }) }
}
CpuOptions = [Amazon.EC2.Model.LaunchTemplateCpuOptionsRequest]@{
    CoreCount = 4
    ThreadsPerCore = 2
}

$tagSpecificationData = [Amazon.EC2.Model.TagSpecification]@{
    ResourceType = 'launch-template'
    Tags = [Amazon.EC2.Model.Tag]@{
        Key = 'purpose'
        Value = 'production'
    }
}

New-EC2LaunchTemplate -LaunchTemplateName 'TemplateForWebServer' -VersionDescription 'WebVersion1' -LaunchTemplateData $launchTemplateData -TagSpecification $tagSpecificationData

The following is example output.

<table>
<thead>
<tr>
<th>CreatedBy</th>
<th>arn:aws:iam::123456789012:root</th>
</tr>
</thead>
<tbody>
<tr>
<td>CreateTime</td>
<td>9/19/2023 16:57:55</td>
</tr>
<tr>
<td>DefaultVersionNumber</td>
<td>1</td>
</tr>
<tr>
<td>LatestVersionNumber</td>
<td>1</td>
</tr>
<tr>
<td>LaunchTemplateId</td>
<td>lt-01238c059eEXAMPLE</td>
</tr>
<tr>
<td>LaunchTemplateName</td>
<td>TemplateForWebServer</td>
</tr>
<tr>

<td>{purpose}</td>
</tr>
</tbody>
</table>

Create a launch template from an existing launch template

You can clone an existing launch template and then adjust the parameters to create a new launch template. However, you can only do this when using the Amazon EC2 console; the AWS CLI does not support cloning a template.

Console

To create a launch template from an existing launch template

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Launch Templates, and then choose Create launch template.
3. For Launch template name, enter a descriptive name for the launch template.
4. For **Template version description**, provide a brief description of this version of the launch template.

5. To tag the launch template on creation, expand **Template tags**, choose **Add tag**, and then enter a tag key and value pair.

6. Expand **Source template**, and for **Launch template name** choose a launch template on which to base the new launch template.

7. For **Source template version**, choose the launch template version on which to base the new launch template.

8. Adjust any launch parameters as required, and then choose **Create launch template**.

---

**Create a launch template from an instance**

**Console**

To create a launch template from an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance, and choose **Actions, Create template from instance**.
4. Provide a name, description, and tags, and adjust the launch parameters as required.

> **Note**
>
> When you create a launch template from an instance, the instance's network interface IDs and IP addresses are not included in the template.

5. Choose **Create launch template**.

**AWS CLI**

You can use the AWS CLI to create a launch template from an existing instance by first getting the launch template data from an instance, and then creating a launch template using the launch template data.
To get launch template data from an instance

- Use the `get-launch-template-data` command and specify the instance ID. You can use the output as a base to create a new launch template or launch template version. By default, the output includes a top-level `LaunchTemplateData` object, which cannot be specified in your launch template data. Use the `--query` option to exclude this object.

```
aws ec2 get-launch-template-data \
  --instance-id i-0123d646e8048babc \
  --query "LaunchTemplateData"
```

The following is example output.

```json
{
  "Monitoring": {},
  "ImageId": "ami-8c1be5f6",
  "BlockDeviceMappings": [
    {
      "DeviceName": "/dev/xvda",
      "Ebs": {
        "DeleteOnTermination": true
      }
    }
  ],
  "EbsOptimized": false,
  "Placement": {
    "Tenancy": "default",
    "GroupName": "",
    "AvailabilityZone": "us-east-1a"
  },
  "InstanceType": "t2.micro",
  "NetworkInterfaces": [
    {
      "Description": "",
      "NetworkInterfaceId": "eni-35306abc",
      "PrivateIpAddresses": [
        {
          "Primary": true,
          "PrivateIpAddress": "10.0.0.72"
        }
      ],
      "SubnetId": "subnet-7b16de0c",
    }
  ]
}
```
You can write the output directly to a file, for example:

```bash
aws ec2 get-launch-template-data \  --instance-id i-0123d646e8048babc \  --query "LaunchTemplateData" >> instance-data.json
```

**To create a launch template using launch template data**

- Use the `create-launch-template` command to create a launch template using the output from the previous procedure. For more information about creating a launch template using the AWS CLI, see [Create a launch template from parameters](#).

**Use a Systems Manager parameter instead of an AMI ID**

Instead of specifying an AMI ID in your launch templates, you can specify an AWS Systems Manager parameter. If the AMI ID changes, you can update the AMI ID in one place by updating the Systems Manager parameter in the Systems Manager Parameter Store. Parameters can also be shared with other AWS accounts. You can centrally store and manage AMI parameters in one account and share them with every other account that needs to reference them. By using a Systems Manager parameter, all your launch templates can be updated in a single action.

A Systems Manager parameter is a user-defined key-value pair that you create in the [AWS Systems Manager Parameter Store](#). The Parameter Store provides a central place to store your application configuration values.
In the following diagram, the golden-ami parameter is first mapped to the original AMI ami-aabbccddeeffgghhi in the Parameter Store. In the launch template, the value for the AMI ID is golden-ami. When an instance is launched using this launch template, the AMI ID resolves to ami-aabbccddeeffgghhi. Later, the AMI is updated resulting in a new AMI ID. In the Parameter Store, the golden-ami parameter is mapped to the new ami-00112233445566778. The launch template remains unchanged. When an instance is launched using this launch template, the AMI ID resolves to the new ami-00112233445566778.

![Diagram showing the mapping of the Parameter Store to the launch template and then to the launch instance.](image)

**Systems Manager parameter format for AMI IDs**

Launch templates require that user-defined Systems Manager parameters adhere to the following format when used in place of an AMI ID:

- Parameter type: String
- Parameter data type: aws:ec2:image – This ensures that Parameter Store validates that the value you enter is in the proper format for an AMI ID.

For more information about creating a valid parameter for an AMI ID, see [Creating Systems Manager parameters](https://docs.aws.amazon.com/systems-manager/latest/userguide/systems-manager-parameters-creating.html) in the *AWS Systems Manager User Guide*.

**Systems Manager parameter format in launch templates**

To use a Systems Manager parameter in place of an AMI ID in a launch template, you must use one of the following formats when specifying the parameter in the launch template:

To reference a public parameter:
• resolve:ssm:`public-parameter`

To reference a parameter stored in the same account:

• resolve:ssm:`parameter-name`
• resolve:ssm:`parameter-name:version-number` – The version number itself is a default label
• resolve:ssm:`parameter-name:label`

To reference a parameter shared from another AWS account:

• resolve:ssm:`parameter-ARN`
• resolve:ssm:`parameter-ARN:version-number`
• resolve:ssm:`parameter-ARN:label`

**Parameter versions**

Systems Manager parameters are versioned resources. When you update a parameter, you create new, successive versions of the parameter. Systems Manager supports [parameter labels](link) that you can map to specific versions of a parameter.

For example, the `golden-ami` parameter can have three versions: 1, 2, and 3. You can create a parameter label `beta` that maps to version 2, and a parameter label `prod` that maps to version 3.

In a launch template, you can specify version 3 of the `golden-ami` parameter by using either of the following formats:

• resolve:ssm:`golden-ami:3`
• resolve:ssm:`golden-ami:prod`

Specifying the version or label is optional. If a version or label is not specified, the latest version of the parameter is used.

**Specify a Systems Manager parameter in a launch template**

You can specify a Systems Manager parameter in a launch template instead of an AMI ID when you create a launch template or a new version of a launch template.
To specify a Systems Manager parameter in a launch template

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Launch Templates, and then choose Create launch template.
3. For Launch template name, enter a descriptive name for the launch template.
4. Under Application and OS Images (Amazon Machine Image), choose Browse more AMIs.
5. Choose the arrow button to the right of the search bar, and then choose Specify custom value/Systems Manager parameter.
6. In the Specify custom value or Systems Manager parameter dialog box, do the following:
   a. For AMI ID or Systems Manager parameter string, enter the Systems Manager parameter name using one of the following formats:

      To reference a public parameter:
      
      • resolve:ssm:public-parameter

      To reference a parameter stored in the same account:

      • resolve:ssm:parameter-name
      • resolve:ssm:parameter-name:version-number
      • resolve:ssm:parameter-name:label

      To reference a parameter shared from another AWS account:

      • resolve:ssm:parameter-ARN
      • resolve:ssm:parameter-ARN:version-number
      • resolve:ssm:parameter-ARN:label

   b. Choose Save.
7. Specify any other launch template parameters as needed, and then choose Create launch template.

For more information, see Create a launch template from parameters.
AWS CLI

To specify a Systems Manager parameter in a launch template

- Use the `create-launch-template` command to create the launch template. To specify the AMI to use, enter the Systems Manager parameter name using one of the following formats:

  To reference a public parameter:

  - `resolve:ssm:public-parameter`

  To reference a parameter stored in the same account:

  - `resolve:ssm:parameter-name`
  - `resolve:ssm:parameter-name:version-number`
  - `resolve:ssm:parameter-name:label`

  To reference a parameter shared from another AWS account:

  - `resolve:ssm:parameter-ARN`
  - `resolve:ssm:parameter-ARN:version-number`
  - `resolve:ssm:parameter-ARN:label`

The following example creates a launch template that specifies the following:

- A name for the launch template (`TemplateForWebServer`)
- A tag for the launch template (`purpose=production`)
- The data for the instance configuration, specified in a JSON file:
  - The AMI to use (`resolve:ssm:golden-ami`)
  - The instance type to launch (`m5.4xlarge`)
  - A tag for the instance (`Name=webserver`)

```bash
aws ec2 create-launch-template \ 
  --launch-template-name TemplateForWebServer \ 
```
The following is an example JSON file that contains the launch template data for the instance configuration. The value for ImageId is the Systems Manager parameter name, entered in the required format `resolve:ssm:golden-ami`.

```json
{"LaunchTemplateData": {
    "ImageId": "resolve:ssm:golden-ami",
    "InstanceType": "m5.4xlarge",
    "TagSpecifications": [{
        "ResourceType": "instance",
        "Tags": [{
            "Key": "Name",
            "Value": "webserver"
        }]
    }]
}}
```

**Verify that a launch template gets the correct AMI ID**

**To resolve the Systems Manager parameter to the actual AMI ID**

Use the `describe-launch-template-versions` command and include the `--resolve-alias` parameter.

```
aws ec2 describe-launch-template-versions \
    --launch-template-name my-launch-template \
    --versions $Default \
    --resolve-alias
```

The response includes the AMI ID for ImageId. In this example, when an instance is launched using this launch template, the AMI ID resolves to `ami-0ac394d6a3example`.

```json
{
    "LaunchTemplateVersions": [
        {
            "LaunchTemplateId": "lt-089c023a30example",
```
Related resources

For more information about working with Systems Manager parameters, see the following reference materials in the Systems Manager documentation.

- For information about how to look up the AMI public parameters supported by Amazon EC2, see Calling AMI public parameters.
- For information about sharing parameters with other AWS accounts or through AWS Organizations, see Working with shared parameters.
- For information about monitoring whether your parameters are created successfully, see Native parameter support for Amazon Machine Image IDs.

Limitations

- Currently, EC2 Fleets and Spot Fleets do not support using a launch template that has a Systems Manager parameter specified in place of an AMI ID. For EC2 Fleets and Spot Fleets, if you specify an AMI in the launch template, you must specify the AMI ID.
- Amazon EC2 Auto Scaling provides other restrictions. For more information, see Use AWS Systems Manager parameters instead of AMI IDs in launch templates in the Amazon EC2 Auto Scaling User Guide.

Modify a launch template (manage launch template versions)

Launch templates are immutable; after you create a launch template, you can't modify it. Instead, you can create a new version of the launch template that includes any changes you require.
You can create different versions of a launch template, set the default version, describe a launch template version, and delete versions that you no longer require.

Tasks

- Create a launch template version
- Set the default launch template version
- Describe a launch template version
- Delete a launch template version

Create a launch template version

When you create a launch template version, you can specify new launch parameters or use an existing version as the base for the new version. For more information about the launch parameters, see Create a launch template.

Console

To create a launch template version

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Launch Templates.
3. Select a launch template, and then choose Actions, Modify template (Create new version).
4. For Template version description, enter a description for this version of the launch template.
5. (Optional) Expand Source template and select a version of the launch template to use as a base for the new launch template version. The new launch template version inherits the launch parameters from this launch template version.
6. Modify the launch parameters as required, and choose Create launch template.

AWS CLI

To create a launch template version

- Use the create-launch-template-version command. You can specify a source version on which to base the new version. The new version inherits the launch parameters from this version, and you can override parameters using --launch-template-data.
following example creates a new version based on version 1 of the launch template and specifies a different AMI ID.

```bash
aws ec2 create-launch-template-version \
  --launch-template-id lt-0abcd290751193123 \
  --version-description WebVersion2 \
  --source-version 1 \
  --launch-template-data "ImageId=ami-c998b6b2"
```

Set the default launch template version

You can set the default version for the launch template. When you launch an instance from a launch template and do not specify a version, the instance is launched using the parameters of the default version.

Console

To set the default launch template version

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Launch Templates.
3. Select the launch template and choose Actions, Set default version.
4. For Template version, select the version number to set as the default version and choose Set as default version.

AWS CLI

To set the default launch template version

- Use the `modify-launch-template` command and specify the version that you want to set as the default.

```bash
aws ec2 modify-launch-template \
  --launch-template-id lt-0abcd290751193123 \
  --default-version 2
```
Describe a launch template version

Using the console, you can view all the versions of the selected launch template, or get a list of the launch templates whose latest or default version matches a specific version number. Using the AWS CLI, you can describe all versions, individual versions, or a range of versions of a specified launch template. You can also describe all the latest versions or all the default versions of all the launch templates in your account.

Console

To describe a launch template version

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Launch Templates.
3. You can view a version of a specific launch template, or get a list of the launch templates whose latest or default version matches a specific version number.
   - To view a version of a launch template: Select the launch template. On the Versions tab, from Version, select a version to view its details.
   - To get a list of all the launch templates whose latest version matches a specific version number: From the search bar, choose Latest version, and then choose a version number.
   - To get a list of all the launch templates whose default version matches a specific version number: From the search bar, choose Default version, and then choose a version number.

AWS CLI

To describe a launch template version

- Use the describe-launch-template-versions command and specify the version numbers. In the following example, versions 1 and 3 are specified.

aws ec2 describe-launch-template-versions \
--launch-template-id lt-0abcd290751193123 \
--versions 1 3
To describe all the latest and default launch template versions in your account

- Use the `describe-launch-template-versions` command and specify `$Latest`, `$Default`, or both. You must omit the launch template ID and name in the call. You cannot specify version numbers.

```bash
aws ec2 describe-launch-template-versions 
--versions "$Latest,$Default"
```

Delete a launch template version

If you no longer require a launch template version, you can delete it.

Considerations

- You can't replace the version number after you delete it.
- You can't delete the default version of the launch template; you must first assign a different version as the default. If the default version is the only version for the launch template, you must delete the entire launch template.
- When using the console, you can delete one launch template version at a time. When using the AWS CLI, you can delete up to 200 launch template versions in a single request. To delete more than 200 versions in a single request, you can delete the launch template, which also deletes all of its versions.

Console

To delete a launch template version

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose Launch Templates.
3. Select the launch template and choose Actions, Delete template version.
4. Select the version to delete and choose Delete.
AWS CLI

**To delete a launch template version**

- Use the `delete-launch-template-versions` command and specify the version numbers to delete. You can specify up to 200 launch template versions to delete in a single request.

```bash
aws ec2 delete-launch-template-versions 
   --launch-template-id lt-0abcd290751193123 
   --versions 1
```

**Delete a launch template**

If you no longer require a launch template, you can delete it. Deleting a launch template deletes all of its versions. To delete a specific version of a launch template, see [Delete a launch template version](#).

When you delete a launch template, it doesn't affect any instances that you've launched from the launch template.

**Console**

**To delete a launch template**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions, Delete template**.
4. Enter **Delete** to confirm deletion, and then choose **Delete**.

**AWS CLI**

**To delete a launch template**

Use the `delete-launch-template` (AWS CLI) command and specify the launch template.

```bash
aws ec2 delete-launch-template --launch-template-id lt-01238c059e3466abc
```

**PowerShell**

**To delete a launch template**
Use the `Remove-EC2LaunchTemplate` (AWS Tools for PowerShell) command and specify the launch template. If `-Force` is omitted, PowerShell prompts for a confirmation.

```
Remove-EC2LaunchTemplate -LaunchTemplateId lt-0123456789example -Force
```

**Launch instances from a launch template**

Launch templates are supported by several instance launch services. This topic describes how to use a launch template when launching an instance using the EC2 launch instance wizard, Amazon EC2 Auto Scaling, EC2 Fleet, and Spot Fleet.

**Topics**
- [Launch an instance from a launch template](#)
- [Use launch templates with Amazon EC2 Auto Scaling](#)
- [Use launch templates with EC2 Fleet](#)
- [Use launch templates with Spot Fleet](#)

**Launch an instance from a launch template**

You can use the parameters contained in a launch template to launch an instance. You have the option to override or add launch parameters before you launch the instance.

Instances that are launched using a launch template are automatically assigned two tags with the keys `aws:ec2launchtemplate:id` and `aws:ec2launchtemplate:version`. You cannot remove or edit these tags.

**Console**

**To launch an instance from a launch template using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Launch Templates**.
3. Select the launch template and choose **Actions, Launch instance from template**.
4. For **Source template version**, select the launch template version to use.
5. For **Number of instances**, specify the number of instances to launch.
6. (Optional) You can override or add launch template parameters by changing and adding parameters in the **Instance details** section.
7. Choose **Launch instance from template**.

**AWS CLI**

To launch an instance from a launch template using the AWS CLI

- Use the `run-instances` command and specify the `--launch-template` parameter. Optionally specify the launch template version to use. If you don’t specify the version, the default version is used.

  ```bash
  aws ec2 run-instances \\
  --launch-template LaunchTemplateId=lt-0abcd290751193123,Version=1
  ```

- To override a launch template parameter, specify the parameter in the `run-instances` command. The following example overrides the instance type that’s specified in the launch template (if any).

  ```bash
  aws ec2 run-instances \\
  --launch-template LaunchTemplateId=lt-0abcd290751193123 \\
  --instance-type t2.small
  ```

- If you specify a nested parameter that’s part of a complex structure, the instance is launched using the complex structure as specified in the launch template plus any additional nested parameters that you specify.

  In the following example, the instance is launched with the tag `Owner=TeamA` as well as any other tags that are specified in the launch template. If the launch template has an existing tag with a key of `Owner`, the value is replaced with `TeamA`.

  ```bash
  aws ec2 run-instances \\
  --launch-template LaunchTemplateId=lt-0abcd290751193123 \\
  --tag-specifications "ResourceType=instance,Tags=[{Key=Owner,Value=TeamA}]"
  ```

  In the following example, the instance is launched with a volume with the device name `/dev/xvdb` as well as any other block device mappings that are specified in the launch template. If the launch template has an existing volume defined for `/dev/xvdb`, its values are replaced with the specified values.

  ```bash
  aws ec2 run-instances \\
  ```
If the instance fails to launch or the state immediately goes to terminated instead of running, see Troubleshoot Amazon EC2 instance launch issues.

PowerShell

To launch an instance from a launch template using the AWS Tools for PowerShell

• Use the `New-EC2Instance` command and specify the `-LaunchTemplate` parameter. Optionally specify the launch template version to use. If you don't specify the version, the default version is used.

```powershell
Import-Module AWS.Tools.EC2
New-EC2Instance `-LaunchTemplate ("New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification -Property @{
    LaunchTemplateId = 'lt-0abcd290751193123';
    Version          = '4'
}"
)
```

• To override a launch template parameter, specify the parameter in the `New-EC2Instance` command. The following example overrides the instance type that's specified in the launch template (if any).

```powershell
Import-Module AWS.Tools.EC2
New-EC2Instance `-InstanceType t4g.small` `-LaunchTemplate ("New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification -Property @{
    LaunchTemplateId = 'lt-0abcd290751193123';
    Version          = '4'
}"
)
```
• If you specify a nested parameter that's part of a complex structure, the instance is launched using the complex structure as specified in the launch template plus any additional nested parameters that you specify.

In the following example, the instance is launched with the tag **Owner=TeamA** as well as any other tags that are specified in the launch template. If the launch template has an existing tag with a key of **Owner**, the value is replaced with **TeamA**.

```powershell
Import-Module AWS.Tools.EC2
New-EC2Instance -InstanceType t4g.small -LaunchTemplate (New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification -Property @{LaunchTemplateId = 'lt-0abcd290751193123'; Version = '4'} }
    -TagSpecification (New-Object -TypeName Amazon.EC2.Model.TagSpecification -Property @{ResourceType = 'instance'; Tags = @( @{key = "Owner"; value = "TeamA" }, @{key = "Department"; value = "Operations" } ) })
)

```

In the following example, the instance is launched with a volume with the device name `/dev/xvdb` as well as any other block device mappings that are specified in the launch template. If the launch template has an existing volume defined for `/dev/xvdb`, its values are replaced with the specified values.

```powershell
Import-Module AWS.Tools.EC2
New-EC2Instance -InstanceType t4g.small -LaunchTemplate (New-Object -TypeName Amazon.EC2.Model.LaunchTemplateSpecification -Property @{LaunchTemplateId = 'lt-0abcd290751193123'; Version = '4'} )
```

If the instance fails to launch or the state immediately goes to terminated instead of running, see Troubleshoot Amazon EC2 instance launch issues.

Use launch templates with Amazon EC2 Auto Scaling

You can create an Auto Scaling group and specify a launch template to use for the group. When Amazon EC2 Auto Scaling launches instances in the Auto Scaling group, it uses the launch parameters defined in the associated launch template. For more information, see Create a launch template for an Auto Scaling group and Create a launch template using advanced settings in the Amazon EC2 Auto Scaling User Guide.

Before you can create an Auto Scaling group using a launch template, you must create a launch template that includes the parameters required to launch an instance in an Auto Scaling group, such as the ID of the AMI. The console provides guidance to help you create a template that you can use with Amazon EC2 Auto Scaling.

To create a launch template to use with Auto Scaling using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Launch Templates, and then choose Create launch template.
3. For Launch template name, enter a descriptive name for the launch template.
4. For Template version description, provide a brief description of this version of the launch template.
5. Under **Auto Scaling guidance**, select the check box to have Amazon EC2 provide guidance to help create a template to use with Auto Scaling.

6. Modify the launch parameters as required. Because you selected Auto Scaling guidance, some fields are required and some fields are not available. For information about how to configure the launch parameters for Amazon EC2 Auto Scaling, see [Create a launch template for an Auto Scaling group](#) and [Create a launch template using advanced settings](#) in the *Amazon EC2 Auto Scaling User Guide*.

7. Choose **Create launch template**.

8. (Optional) To create an Auto Scaling group using this launch template, on the **Next steps** page, choose **Create Auto Scaling group**.

For examples that show how to use the AWS CLI to create launch templates with various parameter combinations, see [Examples for creating and managing launch templates with the AWS Command Line Interface (AWS CLI)](#) in the *Amazon EC2 Auto Scaling User Guide*.

**To create or update an Auto Scaling group with a launch template using the AWS CLI**

- Use the `create-auto-scaling-group` or the `update-auto-scaling-group` command and specify the `--launch-template` parameter.

For more information about creating or updating an Auto Scaling group using a launch template, see the following topics in the *Amazon EC2 Auto Scaling User Guide*.

- [Create Auto Scaling groups using launch templates](#)
- [Update an Auto Scaling group](#)

**Use launch templates with EC2 Fleet**

You can create an EC2 Fleet request and specify a launch template in the instance configuration. When Amazon EC2 fulfills the EC2 Fleet request, it uses the launch parameters defined in the associated launch template. You can override some of the parameters that are specified in the launch template.

For more information, see [Create an EC2 Fleet](#).
To create an EC2 Fleet with a launch template using the AWS CLI

- Use the `create-fleet` command. Use the `--launch-template-configs` parameter to specify the launch template and any overrides for the launch template.

Use launch templates with Spot Fleet

You can create a Spot Fleet request and specify a launch template in the instance configuration. When Amazon EC2 fulfills the Spot Fleet request, it uses the launch parameters defined in the associated launch template. You can override some of the parameters that are specified in the launch template.

For more information, see [Create a Spot Fleet request](#).

To create a Spot Fleet request with a launch template using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Choose Request Spot Instances.
4. Under Launch parameters, choose Use a launch template.
5. For Launch template, choose a launch template, and then, from the field to the right, choose the launch template version.
6. Configure your Spot Fleet by selecting different options on this screen. For more information about the options, see [Create a Spot Fleet request using defined parameters (console)](#).
7. When you're ready to create your Spot Fleet, choose Launch.

To create a Spot Fleet request with a launch template using the AWS CLI

- Use the `request-spot-fleet` command. Use the `LaunchTemplateConfigs` parameter to specify the launch template and any overrides for the launch template.

Launch an instance using parameters from an existing instance

The Amazon EC2 console provides a Launch more like this option that enables you to use a current instance as a base for launching other instances. This option automatically populates the Amazon EC2 launch instance wizard with certain configuration details from the selected instance.
Considerations

- We do not clone your instances; we only replicate some of the configuration details. To create a copy of your instance, first create an AMI from it, then launch more instances from the AMI. Create a launch template to ensure that you launch your instances using the same launch details.
- The current instance must be in the running state.

Copied details

The following configuration details are copied from the selected instance into the launch instance wizard:

- AMI ID
- Instance type
- Availability Zone, or the VPC and subnet in which the selected instance is located
- Public IPv4 address. If the selected instance currently has a public IPv4 address, the new instance receives a public IPv4 address - regardless of the selected instance's default public IPv4 address setting. For more information about public IPv4 addresses, see Public IPv4 addresses.
- Placement group, if applicable
- IAM role associated with the instance, if applicable
- Shutdown behavior setting (stop or terminate)
- Termination protection setting (true or false)
- CloudWatch monitoring (enabled or disabled)
- Amazon EBS-optimization setting (true or false)
- Tenancy setting, if launching into a VPC (shared or dedicated)
- Kernel ID and RAM disk ID, if applicable
- User data, if specified
- Tags associated with the instance, if applicable
- Security groups associated with the instance
- [Windows instances] Association information. If the selected instance is associated with a configuration file, the same file is automatically associated with the new instance. If the configuration file includes a joined domain configuration, the new instance is joined to the same domain. For more information about joining a domain, see Seamlessly Join a Windows EC2 Instance in the AWS Directory Service Administration Guide.
Details not copied

The following configuration details are not copied from your selected instance. Instead, the wizard applies their default settings or behavior:

- **Number of network interfaces** – The default is one network interface, which is the primary network interface (eth0).
- **Storage** – The default storage configuration is determined by the AMI and the instance type.

To launch more instances like an existing instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select an instance, and then choose **Actions, Images and templates, Launch more like this**.
4. The launch instance wizard opens. You can make any necessary changes to the instance configuration by selecting different options on this screen.

    When you are ready to launch your instance, choose **Launch instance**.
5. If the instance fails to launch or the state immediately goes to **terminated** instead of **running**, see [Troubleshoot Amazon EC2 instance launch issues](#).

Launch an AWS Marketplace instance

You can subscribe to an AWS Marketplace product and launch an instance from the product’s AMI using the Amazon EC2 launch wizard. For more information about paid AMIs, see [Paid AMIs](#). To cancel your subscription after launch, you first have to terminate all instances running from it. For more information, see [Manage your AWS Marketplace subscriptions](#).

New console

To launch an instance from the AWS Marketplace using the launch wizard

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the Amazon EC2 console dashboard, choose **Launch instance**.
3. (Optional) Under **Name and tags**, for **Name**, enter a descriptive name for your instance.
4. Under **Application and OS Images (Amazon Machine Image)**, choose **Browse more AMIs**, and then choose the **AWS Marketplace AMIs** tab. Find a suitable AMI by browsing the categories or using the search functionality. To choose a product, choose **Select**.

5. A window opens with an overview of the product you've selected. You can view the pricing information, as well as any other information that the vendor has provided. When you're ready, choose one of the following buttons:

- **Subscribe on instance launch** – Your subscription starts when you choose **Launch instance** (at Step 10).
- **Subscribe now** – Your subscription starts immediately. While the subscription is underway, you can configure the instance by continuing with the steps in this procedure. If there are any problems with your credit card details, you will be asked to update your account details.

6. For **Instance type**, select an instance type for your instance. The instance type defines the hardware configuration and size of the instance to launch.

7. Under **Key pair (login)**, for **Key pair name**, choose an existing key pair or create a new one.

8. Under **Network settings, Firewall (security groups)**, take note of the new security group that was created according to the vendor's specifications for the product. The security group might include rules that allow all IPv4 addresses (0.0.0.0/0) access on SSH (port 22) on Linux or RDP (port 3389) on Windows. We recommend that you adjust these rules to allow only a specific address or range of addresses to access your instance over those ports.

9. You can use the other fields on the screen to configure your instance, add storage, and add tags. For information about the different options that you can configure, see **Launch an instance using defined parameters**.

10. In the **Summary** panel, under **Software Image (AMI)**, check the details of the AMI from which you're about to launch the instance. Also check the other configuration details that you specified. When you're ready to launch your instance, choose **Launch instance**.
11. Depending on the product you've subscribed to, the instance might take a few minutes or more to launch. If you chose **Subscribe on instance launch** at Step 5, you are first subscribed to the product before your instance can launch. If there are any problems with your credit card details, you will be asked to update your account details. When the launch confirmation page displays, choose **View all instances** to go to the **Instances** page.

**Note**
You are charged the subscription price as long as your instance is in the **running** state, even if it is idle. If your instance is stopped, you might still be charged for storage.

12. When your instance is in the **running** state, you can connect to it. To do this, select your instance in the list, choose **Connect**, and choose a connection option. For more information about connecting to your instance, see [Connect to your Linux instance](#) [Connect to your Windows instance](#).

**Important**
Check the vendor's usage instructions carefully, as you might need to use a specific user name to connect to your instance. For information about accessing your subscription details, see [Manage your AWS Marketplace subscriptions](#).

13. If the instance fails to launch or the state immediately goes to **terminated** instead of **running**, see [Troubleshoot Amazon EC2 instance launch issues](#).

Old console

**To launch an instance from the AWS Marketplace using the launch wizard**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. From the Amazon EC2 dashboard, choose **Launch instance**.
3. On the **Choose an Amazon Machine Image (AMI)** page, choose the **AWS Marketplace** category on the left. Find a suitable AMI by browsing the categories, or using the search functionality. Choose **Select** to choose your product.
4. A dialog displays an overview of the product you've selected. You can view the pricing information, as well as any other information that the vendor has provided. When you're ready, choose Continue.

Note
You are not charged for using the product until you have launched an instance with the AMI. Take note of the pricing for each supported instance type, as you will be prompted to select an instance type on the next page of the wizard. Additional taxes may also apply to the product.

5. On the **Choose an Instance Type** page, select the hardware configuration and size of the instance to launch. When you're done, choose **Next: Configure Instance Details**.

6. On the next pages of the wizard, you can configure your instance, add storage, and add tags. For more information about the different options you can configure, see **Launch an instance using the old launch instance wizard**. Choose **Next** until you reach the **Configure Security Group** page.

The wizard creates a new security group according to the vendor's specifications for the product. The security group may include rules that allow all IPv4 addresses (0.0.0.0/0) access on SSH (port 22) on Linux or RDP (port 3389) on Windows. We recommend that you adjust these rules to allow only a specific address or range of addresses to access your instance over those ports.

When you are ready, choose **Review and Launch**.

7. On the **Review Instance Launch** page, check the details of the AMI from which you're about to launch the instance, as well as the other configuration details you set up in the wizard. When you're ready, choose **Launch** to select or create a key pair, and launch your instance.

8. Depending on the product you've subscribed to, the instance may take a few minutes or more to launch. You are first subscribed to the product before your instance can launch. If there are any problems with your credit card details, you will be asked to update your account details. When the launch confirmation page displays, choose **View Instances** to go to the Instances page.
9. When your instance is in the running state, you can connect to it. To do this, select your instance in the list and choose Connect. Follow the instructions in the dialog. For more information about connecting to your instance, see Connect to your Linux instanceConnect to your Windows instance.

10. If the instance fails to launch or the state immediately goes to terminated instead of running, see Troubleshoot Amazon EC2 instance launch issues.

Launch an AWS Marketplace AMI instance using the API and CLI

To launch instances from AWS Marketplace products using the API or command line tools, first ensure that you are subscribed to the product. You can then launch an instance with the product's AMI ID using the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS CLI</td>
<td>Use the run-instances command, or see the following topic for more information: Launching an Instance.</td>
</tr>
<tr>
<td>AWS Tools for Windows PowerShell</td>
<td>Use the New-EC2Instance command, or see the following topic for more information: Launch an Amazon EC2 Instance Using Windows PowerShell</td>
</tr>
<tr>
<td>Query API</td>
<td>Use the RunInstances request.</td>
</tr>
</tbody>
</table>
Stop and start Amazon EC2 instances

You can stop and start your instance if it has an Amazon EBS volume as its root device. When you stop an instance, it shuts down. When you start an instance, it is typically migrated to a new underlying host computer and assigned a new public IPv4 address.

When you stop an instance, it is not deleted. If you decide that you no longer need an instance, you can terminate it. For more information, see Terminate Amazon EC2 instances. If you want to hibernate an instance to save the contents from the instance memory (RAM), see Hibernate your Amazon EC2 instance. For distinctions between instance lifecycle actions, see Differences between reboot, stop, hibernate, and terminate.

Contents

• How instance stop and start works
• Manually stop and start your instances
• Automatically stop and start your instances
• Find all running and stopped instances
• Enable stop protection for your instance

How instance stop and start works

When you stop an instance, changes are registered at the OS level of the instance, some resources are lost, and some resources persist. When you start an instance, changes are registered at the instance level.

The following diagram shows what is lost and what persists when an Amazon EC2 instance is stopped. When an instance stops, it loses any attached instance store volumes and the data stored on those volumes, the data stored on the instance RAM, and the assigned public IPv4 address if an Elastic IP address is not associated with the instance. An instance retains assigned private IPv4 addresses, Elastic IP addresses associated with the instance, any IPv6 addresses, and any attached Amazon EBS volumes and the data on those volumes.
What happens when you stop an instance

Changes registered at the OS level

- The API request sends a button press event to the guest.
- Various system services are stopped as a result of the button press event. Graceful shutdown is triggered by the ACPI shutdown button press event from the hypervisor.
- ACPI shutdown is initiated.
- The instance shuts down when the graceful shutdown process exits. There is no configurable OS shutdown time.
- If the instance OS does not cleanly shut down within a few minutes, a hard shutdown is performed.
- The instance stops running.
- The instance status changes to stopping and then stopped.
- **[Auto Scaling]** If your instance is in an Auto Scaling group, when the instance is in any Amazon EC2 state other than running, or if its status for the status checks becomes impaired, Amazon EC2 Auto Scaling considers the instance to be unhealthy and replaces it. For more information, see Health checks for Auto Scaling instances in the Amazon EC2 Auto Scaling User Guide.
- **[Windows instances]** When you stop and start a Windows instance, the launch agent performs tasks on the instance, such as changing the drive letters for any attached Amazon EBS volumes. For more information about these defaults and how you can change them, see the section called “EC2Launch v2”.

---

Stop and start
Resources lost

- Data stored on the RAM.
- Data stored on the instance store volumes.
- The public IPv4 address that Amazon EC2 automatically assigned to the instance upon launch or start. To retain a public IPv4 address that never changes, you can associate an Elastic IP address with your instance.

Resources that persist

- Any attached Amazon EBS volumes.
- Data stored on the attached Amazon EBS volumes.
- Private IPv4 addresses.
- IPv6 addresses.
- Elastic IP addresses associated with the instance. Note that when the instance is stopped, you are charged for the associated Elastic IP addresses.

For information about what happens when you stop a Mac instance, see the section called “Stop or terminate Mac instance”.

What happens when you start an instance

Changes registered at the OS level

- In most cases, the instance is migrated to a new underlying host computer (though in some cases, such as when an instance is allocated to a host in a Dedicated Host configuration, it remains on the current host).
- Amazon EC2 assigns a new public IPv4 address to the instance if the instance is configured to receive a public IPv4 address. To retain a public IPv4 address that never changes, you can associate an Elastic IP address with your instance.

Test application response to stop and start

You can use AWS Fault Injection Service to test how your application responds when your instance is stopped and started. For more information, see the AWS Fault Injection Service User Guide.
Costs related to instance stop and start

The following costs are associated with stopping and starting an instance.

Stopping — As soon as the state of an instance changes to shutting-down or terminated, charges are no longer incurred for the instance. You are not charged for usage or data transfer fees for a stopped instance. Charges are incurred to store Amazon EBS storage volumes.

Starting — Each time you start a stopped instance, you are charged for a minimum of one minute of usage. After one minute, you are charged for only the seconds you use. For example, if you run an instance for 20 seconds and then stop it, you are charged for a minute of usage. If you run an instance for 3 minutes and 40 seconds, you are charged for 3 minutes and 40 seconds of usage.

Manually stop and start your instances

You can stop and start your Amazon EBS-backed instances (instances with EBS root devices). You can't stop and start instances with instance store root device.

⚠️ Warning

When you stop an instance, the data on any instance store volumes is erased. Before you stop an instance, verify that you've copied any data that you need from the instance store volumes to persistent storage, such as Amazon EBS or Amazon S3.

Console

To stop and start an Amazon EBS-backed instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose Instances, and then select the instance.
3. On the Storage tab, verify that Root device type is EBS. Otherwise, you can't stop the instance.
4. Choose Instance state, Stop instance. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.
5. When prompted for confirmation, choose Stop. It can take a few minutes for the instance to stop.
6. To start a stopped instance, select the instance, and choose Instance state, Start instance.
7. It can take a few minutes for the instance to enter the running state.

8. If you stopped an Amazon EBS-backed instance and it appears "stuck" in the stopping state, you can forcibly stop it. For more information, see Troubleshoot Amazon EC2 instance stop issues.

Command line

**Prerequisites**

Verify that the root device of the instance is an EBS volume. For example, run the `describe-instances` AWS CLI command and verify that `RootDeviceType` is `ebs`, not `instance-store`.

**To stop and start an Amazon EBS-backed instance**

Use one of the following commands:

- **AWS CLI**—`stop-instances` and `start-instances`.
- **AWS Tools for PowerShell**—`Stop-EC2Instance` and `Start-EC2Instance`.
- **OS commands**—You can initiate a shutdown using the `shutdown` or `poweroff` commands. When you use an OS command, the instance stops by default. You can change this behavior so that it terminates instead. For more information, see Change the instance initiated shutdown behavior.

[Linux instances] Using the OS `halt` command from an instance does not initiate a shutdown. If you use the `halt` command, the instance does not terminate; instead, it places the CPU into HLT, which suspends CPU operation. The instance remains running.

**Automatically stop and start your instances**

You can automate stopping and starting instances with the following services:

**Instance Scheduler on AWS**

You can use Instance Scheduler on AWS to automate the starting and stopping of EC2 instances. For more information, see How do I use Instance Scheduler with CloudFormation to schedule EC2 instances? Note that additional charges apply.
AWS Lambda and an Amazon EventBridge rule

You can use Lambda and an EventBridge rule to stop and start your instances on a schedule. For more information, see [How do I use Lambda to stop and start Amazon EC2 instances at regular intervals?](#).

Amazon EC2 Auto Scaling

To ensure you have the correct number of Amazon EC2 instances available to handle the load for an application, create Auto Scaling groups. Amazon EC2 Auto Scaling ensures that your application always has the right capacity to handle the traffic demand, and saves costs by launching instances only when they are needed. Note that Amazon EC2 Auto Scaling terminates, rather than stops, unneeded instances. To set up Auto Scaling groups, see [Get started with Amazon EC2 Auto Scaling](#).

Find all running and stopped instances

You can find all of your running and stopped instances across all AWS Regions on a single page using [Amazon EC2 Global View](#). This capability is especially useful for taking inventory and finding forgotten instances. For information about how to use Global View, see [Amazon EC2 Global View](#).

Enable stop protection for your instance

To prevent an instance from being accidentally stopped, you can enable stop protection for the instance. Stop protection also protects your instance from accidental termination.

The `DisableApiStop` attribute of the Amazon EC2 [ModifyInstanceAttribute](#) API controls whether the instance can be stopped by using the Amazon EC2 console, the AWS CLI, or the Amazon EC2 API. You can set the value of this attribute when you launch the instance, while the instance is running, or while the instance is stopped.

**Considerations**

- Enabling stop protection does not prevent you from accidentally stopping an instance by initiating a shutdown from the instance using an operating system command such as `shutdown` or `poweroff`.
- Enabling stop protection does not prevent AWS from stopping the instance when there is a scheduled event to stop the instance.
- Enabling stop protection does not prevent Amazon EC2 Auto Scaling from terminating an instance when the instance is unhealthy or during scale-in events. You can control whether an
Auto Scaling group can terminate a particular instance when scaling in by using `instance scale-in protection`.

- Stop protection not only prevents your instance from being accidentally stopped, but also from accidental termination when using the console, AWS CLI, or API. However, it does not automatically set the `DisableApiTermination` attribute. Note that when the `DisableApiStop` attribute is set to `false`, the `DisableApiTermination` attribute setting determines whether the instance can be terminated using the console, AWS CLI, or API. For more information see [Terminate Amazon EC2 instances](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/stop-running-amazon-ec2-instances.html).

- You can't enable stop protection for instance store-backed instances.

- You can't enable stop protection for Spot Instances.

- The Amazon EC2 API follows an eventual consistency model when you enable or disable stop protection. This means that the result of running commands to set the stop protection attribute might not be immediately visible to all subsequent commands you run. For more information, see [Eventual consistency](https://docs.aws.amazon.com/AWSEC2/latest/EndUserGuide/stop-running-amazon-ec2-instances.html) in the *Amazon EC2 Developer Guide*.

### Stop protection tasks

- [Enable stop protection for an instance at launch](#)
- [Enable stop protection for a running or stopped instance](#)
- [Disable stop protection for a running or stopped instance](#)

## Enable stop protection for an instance at launch

You can enable stop protection for an instance when launching the instance using one of the following methods.

### Console

**To enable stop protection for an instance at launch**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. On the dashboard, choose **Launch instance**.
4. In the wizard, enable stop protection by choosing **Enable** for **Stop protection** under **Advanced details**.
AWS CLI

**To enable stop protection for an instance at launch**

Use the `run-instances` AWS CLI command to launch the instance, and specify the `disable-api-stop` parameter.

```
aws ec2 run-instances \\
   --image-id ami-a1b2c3d4e5example \\
   --instance-type t3.micro \\
   --key-name MyKeyPair \\
   --disable-api-stop \\
   ...
```

**Enable stop protection for a running or stopped instance**

You can enable stop protection for an instance while the instance is running or stopped using one of the following methods.

**Console**

**To enable stop protection for a running or stopped instance**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances**.
3. Select the instance, and then choose **Actions>Instance settings>Change stop protection**.
4. Select the **Enable** check box, and then choose **Save**.

**AWS CLI**

**To enable stop protection for a running or stopped instance**

Use the `modify-instance-attribute` AWS CLI command and specify the `disable-api-stop` parameter.

```
aws ec2 modify-instance-attribute \\
   --instance-id i-1234567890abcdef0 \\
   --disable-api-stop
```

Stop and start 801
Disable stop protection for a running or stopped instance

You can disable stop protection for a running or stopped instance using one of the following methods.

Console

To disable stop protection for a running or stopped instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose Instances.
3. Select the instance, and then choose Actions, Instance settings, Change stop protection.
4. Clear the Enable check box, and then choose Save.

AWS CLI

To disable stop protection for a running or stopped instance

Use the modify-instance-attribute AWS CLI command and specify the no-disable-api-stop parameter.

```
aws ec2 modify-instance-attribute \
--instance-id i-1234567890abcdef0 \n--no-disable-api-stop
```

Hibernate your Amazon EC2 instance

When you hibernate an instance, Amazon EC2 signals the operating system to perform hibernation (suspend-to-disk). Hibernation saves the contents from the instance memory (RAM) to your Amazon Elastic Block Store (Amazon EBS) root volume. Amazon EC2 persists the instance's EBS root volume and any attached EBS data volumes. When your instance is started:

- The EBS root volume is restored to its previous state
- The RAM contents are reloaded
- The processes that were previously running on the instance are resumed
- Previously attached data volumes are reattached and the instance retains its instance ID
You can hibernate an instance only if it's enabled for hibernation and it meets the hibernation prerequisites.

If an instance or application takes a long time to bootstrap and build a memory footprint in order to become fully productive, you can use hibernation to pre-warm the instance. To pre-warm the instance, you:

1. Launch it with hibernation enabled.
2. Bring it to a desired state.
3. Hibernate it so that it's ready to be resumed to the desired state whenever needed.

You're not charged for instance usage for a hibernated instance when it is in the stopped state or for data transfer when the contents of the RAM are transferred to the EBS root volume. You are charged for storage of any EBS volumes, including storage for the RAM contents.

If you no longer need an instance, you can terminate it at any time, including when it is in a stopped (hibernated) state. For more information, see Terminate Amazon EC2 instances.

Contents

- How Amazon EC2 instance hibernation works
- Prerequisites for Amazon EC2 instance hibernation
- Configure a Linux AMI to support hibernation
- Enable hibernation for an Amazon EC2 instance
- Disable KASLR on an instance (Ubuntu only)
- Hibernate an Amazon EC2 instance
- Start a hibernated Amazon EC2 instance
- Troubleshoot Amazon EC2 instance hibernation

**How Amazon EC2 instance hibernation works**

The following diagram shows a basic overview of the hibernation process for EC2 instances.
What happens when you hibernate an instance

When you hibernate an instance, the following happens:

- The instance moves to the \textit{stopping} state. Amazon EC2 signals the operating system to perform hibernation (suspend-to-disk). The hibernation freezes all of the processes, saves the contents of the RAM to the EBS root volume, and then performs a regular shutdown.
- After the shutdown is complete, the instance moves to the \textit{stopped} state.
- Any EBS volumes remain attached to the instance, and their data persists, including the saved contents of the RAM.
- Any Amazon EC2 instance store volumes remain attached to the instance, but the data on the instance store volumes is lost.
- While your instance is in the \textit{stopped} state, you can modify certain attributes of the instance, including the instance type or size.
- In most cases, the instance is migrated to a new underlying host computer when it's started. This is also what happens when you stop and start an instance.
- When the instance is started, the instance boots up and the operating system reads in the contents of the RAM from the EBS root volume, before unfreezing processes to resume its state.
- The instance retains its private IPv4 addresses and any IPv6 addresses. When the instance is started, the instance continues to retain its private IPv4 addresses and any IPv6 addresses.
- Amazon EC2 releases the public IPv4 address. When the instance is started, Amazon EC2 assigns a new public IPv4 address to the instance.
- The instance retains its associated Elastic IP addresses. You're charged for any Elastic IP addresses that are associated with a hibernated instance.
For information about how hibernation differs from reboot, stop, and terminate, see [Differences between reboot, stop, hibernate, and terminate](#).

**Limitations**

- When you hibernate an instance, the data on any instance store volumes is lost.

- (Linux instances) You can't hibernate a Linux instance that has more than 150 GB of RAM.

- (Windows instances) You can't hibernate a Windows instance that has more than 16 GB of RAM.

- If you create a snapshot or AMI from an instance that is hibernated or has hibernation enabled, you might not be able to connect to a new instance that is launched from the AMI or from an AMI that was created from the snapshot.

- (Spot Instances only) If Amazon EC2 hibernates your Spot Instance, only Amazon EC2 can resume your instance. If you hibernate your Spot Instance ([user-initiated hibernation](#)), you can resume your instance. A hibernated Spot Instance can only be resumed if capacity is available and the Spot price is less than or equal to your specified maximum price.

- You can't hibernate an instance that is in an Auto Scaling group or used by Amazon ECS. If your instance is in an Auto Scaling group and you try to hibernate it, the Amazon EC2 Auto Scaling service marks the stopped instance as unhealthy, and might terminate it and launch a replacement instance. For more information, see [Health checks for instances in an Auto Scaling group](#) in the [Amazon EC2 Auto Scaling User Guide](#).

- You can't hibernate an instance that is configured to boot in UEFI mode with [UEFI Secure Boot](#) enabled.

- If you hibernate an instance that was launched into a Capacity Reservation, the Capacity Reservation does not ensure that the hibernated instance can resume after you try to start it.

- You can't hibernate an instance that uses a kernel below 5.10 if Federal Information Processing Standard (FIPS) mode is enabled.

- We do not support keeping an instance hibernated for more than 60 days. To keep the instance for longer than 60 days, you must start the hibernated instance, stop the instance, and start it.

- We constantly update our platform with upgrades and security patches, which can conflict with existing hibernated instances. We notify you about critical updates that require a start for hibernated instances so that we can perform a shutdown or a reboot to apply the necessary upgrades and security patches.
Considerations for hibernating a Spot Instance

- If you hibernate your Spot Instance, you can restart it provided capacity is available and the Spot price is less than or equal to your specified maximum price.

- If Amazon EC2 hibernates your Spot Instance:
  - Only Amazon EC2 can resume your instance.
  - Amazon EC2 resumes the hibernated Spot Instance when capacity becomes available with a Spot price that is less than or equal to your specified maximum price.
  - Before Amazon EC2 hibernates your Spot Instance, you'll receive an interruption notice two minutes before hibernation starts.

For more information, see Spot Instance interruptions.

- There are several ways in which you can enable hibernation for a Spot Instance. For more information, see Specify the interruption behavior.

Prerequisites for Amazon EC2 instance hibernation

You can enable hibernation support for an On-Demand Instance or a Spot Instance when you launch it. You can't enable hibernation on an existing instance, whether it is running or stopped. For more information, see Enable instance hibernation.

Requirements to hibernate an instance

- AWS Regions
- AMIs
- Instance families
- Instance RAM size
- Root volume type
- Root volume size
- Root volume encryption
- EBS volume type
- Spot Instance requests

AWS Regions

You can use hibernation with instances in all AWS Regions.
AMIs

You must use an HVM AMI that supports hibernation. The following AMIs support hibernation:

Linux AMIs

- AL2023 AMI released 2023.09.20 or later
- Amazon Linux 2 AMI released 2019.08.29 or later
- Amazon Linux AMI 2018.03 released 2018.11.16 or later
- CentOS version 8 AMI \(^1\) (Additional configuration is required)
- Fedora version 34 or later AMI \(^1\) (Additional configuration is required)
- Red Hat Enterprise Linux (RHEL) 9 AMI \(^1\) (Additional configuration is required)
- Red Hat Enterprise Linux (RHEL) 8 AMI \(^1\) (Additional configuration is required)
- Ubuntu 22.04.2 LTS (Jammy Jellyfish) AMI released with serial number 20230303 or later \(^2\)
- Ubuntu 20.04 LTS (Focal Fossa) AMI released with serial number 20210820 or later \(^2\)
- Ubuntu 18.04 LTS (Bionic Beaver) AMI released with serial number 20190722.1 or later \(^2\) \(^4\)
- Ubuntu 16.04 LTS (Xenial Xerus) AMI \(^2\) \(^3\) \(^4\) (Additional configuration is required)

\(^1\) For CentOS, Fedora, and Red Hat Enterprise Linux, hibernation is supported on Nitro-based instances only.

\(^2\) We recommend disabling KASLR on instances with Ubuntu 22.04.2 LTS (Jammy Jellyfish), Ubuntu 20.04 LTS (Focal Fossa), Ubuntu 18.04 LTS (Bionic Beaver), and Ubuntu 16.04 LTS (Xenial Xerus). For more information, see Disable KASLR on an instance (Ubuntu only).

\(^3\) For the Ubuntu 16.04 LTS (Xenial Xerus) AMI, hibernation is not supported on t3. nano instance types. No patch will be made available because Ubuntu (Xenial Xerus) ended support in April 2021. If you want to use t3. nano instance types, we recommend that you upgrade to the Ubuntu 22.04.2 LTS (Jammy Jellyfish), Ubuntu 20.04 LTS (Focal Fossa) AMI, or the Ubuntu 18.04 LTS (Bionic Beaver) AMI.

\(^4\) Support for Ubuntu 18.04 LTS (Bionic Beaver) and Ubuntu 16.04 LTS (Xenial Xerus) has reached end of life.

To configure your own AMI to support hibernation, see Configure a Linux AMI to support hibernation.
Support for other versions of Ubuntu and other operating systems is coming soon.

**Windows AMIs**

- Windows Server 2022 AMI released 2023.09.13 or later
- Windows Server 2019 AMI released 2019.09.11 or later
- Windows Server 2016 AMI released 2019.09.11 or later
- Windows Server 2012 R2 AMI released 2019.09.11 or later
- Windows Server 2012 AMI released 2019.09.11 or later

**Instance families**

You must use an instance family that supports hibernation.

- General purpose: M3, M4, M5, M5a, M5ad, M5d, M6g, M6gd, M6i, M6id, M7g, M7gd, M7i, M7i-flex, T2, T3, T3a
- Compute optimized: C3, C4, C5, C5d, C6g, C6gd, C6gn, C6i, C6id, C7a, C7g, C7gd, C7i, C7i-flex
- Memory optimized: R3, R4, R5, R5a, R5ad, R5d, R6g, R6gd, R7a, R7g, R7gd, R7i, R7iz
- Storage optimized: I3, I3en

**Nitro instances** – Bare metal instances are not supported.

**To see the available instance types that support hibernation in a specific Region**

The available instance types vary by Region. To see the available instance types that support hibernation in a Region, use the `describe-instance-types` command with the `--region` parameter. Include the `--filters` parameter to scope the results to the instance types that support hibernation and the `--query` parameter to scope the output to the value of InstanceType.

```
aws ec2 describe-instance-types --filters Name=hibernation-supported,Values=true --query "InstanceTypes[*].[InstanceType]" --output text | sort
```

Example output

```
c3.2xlarge
c3.4xlarge
c3.8xlarge
```
Instance RAM size

**Linux instances** – Must be less than 150 GB.

**Windows instances** – Can be up to 16 GB. For hibernating a T3 or T3a Windows instance, we recommend at least 1 GB of RAM.

Root volume type

The root volume must be an EBS volume, not an instance store volume.

Root volume size

The root volume must be large enough to store the RAM contents and accommodate your expected usage, for example, OS or applications. If you enable hibernation, space is allocated on the root volume at launch to store the RAM.

Root volume encryption

The root volume must be encrypted to ensure the protection of sensitive content that is in memory at the time of hibernation. When RAM data is moved to the EBS root volume, it is always encrypted. Encryption of the root volume is enforced at instance launch.

Use one of the following three options to ensure that the root volume is an encrypted EBS volume:

- **EBS encryption by default** – You can enable EBS encryption by default to ensure that all new EBS volumes created in your AWS account are encrypted. This way, you can enable hibernation for your instances without specifying encryption intent at instance launch. For more information, see [Enable encryption by default](#).

- **EBS "single-step" encryption** – You can launch encrypted EBS-backed EC2 instances from an unencrypted AMI and also enable hibernation at the same time. For more information, see [Use encryption with EBS-backed AMIs](#).

- **Encrypted AMI** – You can enable EBS encryption by using an encrypted AMI to launch your instance. If your AMI does not have an encrypted root snapshot, you can copy it to a new AMI.
and request encryption. For more information, see Encrypt an unencrypted image during copy and Copy an AMI.

**EBS volume type**

The EBS volumes must use one of the following EBS volume types:

- General Purpose SSD (gp2 and gp3)
- Provisioned IOPS SSD (io1 and io2)

If you choose a Provisioned IOPS SSD volume type, you must provision the EBS volume with the appropriate IOPS to achieve optimum performance for hibernation. For more information, see Amazon EBS volume types in the Amazon EBS User Guide.

**Spot Instance requests**

For Spot Instances, the following requirements apply:

- The Spot Instance request type must be persistent.
- You can't specify a launch group in the Spot Instance request.

**Configure a Linux AMI to support hibernation**

The following Linux AMIs support hibernation, but to hibernate an instance that was launched with one of these AMIs, additional configuration is required before you can hibernate the instance.

**Additional configuration required for:**

- Amazon Linux 2 minimal AMI released 2019.08.29 or later
- Amazon Linux 2 released before 2019.08.29
- Amazon Linux released before 2018.11.16
- CentOS version 8 or later
- Fedora version 34 or later
- Red Hat Enterprise Linux version 8 or 9
- Ubuntu 20.04 LTS (Focal Fossa) released before serial number 20210820
- Ubuntu 18.04 (Bionic Beaver) released before serial number 20190722.1
- Ubuntu 16.04 (Xenial Xerus)
For more information, see Update instance software on your Amazon Linux 2 instance.

No additional configuration is required for the following AMIs because they're already configured to support hibernation:

- AL2023 AMI released 2023.09.20 or later
- Amazon Linux 2 full AMI released 2019.08.29 or later
- Amazon Linux AMI 2018.03 released 2018.11.16 or later
- Ubuntu 22.04.2 LTS (Jammy Jellyfish) AMI released with serial number 20230303 or later
- Ubuntu 20.04 LTS (Focal Fossa) AMI released with serial number 20210820 or later
- Ubuntu 18.04 LTS (Bionic Beaver) AMI released with serial number 20190722.1 or later
- Amazon Linux 2 minimal AMI released 2019.08.29 or later

To configure an Amazon Linux 2 minimal AMI released 2019.08.29 or later to support hibernation

1. Install the ec2-hibinit-agent package from the repositories.

   ```
   [ec2-user ~]$ sudo yum install ec2-hibinit-agent
   ```

2. Restart the service.

   ```
   [ec2-user ~]$ sudo systemctl start hibinit-agent
   ```

Amazon Linux 2 released before 2019.08.29

To configure an Amazon Linux 2 AMI released before 2019.08.29 to support hibernation

1. Update the kernel to 4.14.138-114.102 or later.

   ```
   [ec2-user ~]$ sudo yum update kernel
   ```

2. Install the ec2-hibinit-agent package from the repositories.

   ```
   [ec2-user ~]$ sudo yum install ec2-hibinit-agent
   ```

3. Reboot the instance.
4. Confirm that the kernel version is updated to 4.14.138-114.102 or later.

```
[ec2-user ~]$ sudo reboot
```

5. Stop the instance and create an AMI. For more information, see Create an Amazon EBS-backed AMI.

**Amazon Linux released before 2018.11.16**

To configure an Amazon Linux AMI released before 2018.11.16 to support hibernation

1. Update the kernel to 4.14.77-70.59 or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the ec2-hibinit-agent package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibinit-agent
```

3. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

4. Confirm that the kernel version is updated to 4.14.77-70.59 or greater.

```
[ec2-user ~]$ uname -a
```

5. Stop the instance and create an AMI. For more information, see Create an Amazon EBS-backed AMI.

**CentOS version 8 or later**

To configure a CentOS version 8 or later AMI to support hibernation

1. Update the kernel to 4.18.0-305.7.1.el8_4.x86_64 or later.

```
[ec2-user ~]$ sudo yum update kernel
```

```
[ec2-user ~]$ sudo reboot
```

```
[ec2-user ~]$ uname -a
```

5. Stop the instance and create an AMI. For more information, see Create an Amazon EBS-backed AMI.
2. Install the Fedora Extra Packages for Enterprise Linux (EPEL) repository.

```
```

3. Install the `ec2-hibinit-agent` package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibinit-agent
```

4. Enable the hibernate agent to start on boot.

```
[ec2-user ~]$ sudo systemctl enable hibinit-agent.service
```

5. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

6. Confirm that the kernel version is updated to `4.18.0-305.7.1.el8_4.x86_64` or later.

```
[ec2-user ~]$ uname -a
```

**Fedora version 34 or later**

**To configure a Fedora version 34 or later AMI to support hibernation**

1. Update the kernel to `5.12.10-300.fc34.x86_64` or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the `ec2-hibinit-agent` package from the repositories.

```
[ec2-user ~]$ sudo dnf install ec2-hibinit-agent
```

3. Enable the hibernate agent to start on boot.

```
[ec2-user ~]$ sudo systemctl enable hibinit-agent.service
```

4. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```
5. Confirm that the kernel version is updated to `5.12.10-300.fc34.x86_64` or later.

```
[ec2-user ~]$ uname -a
```

Red Hat Enterprise Linux version 8 or 9

To configure a Red Hat Enterprise Linux 8 or 9 AMI to support hibernation

1. Update the kernel to `4.18.0-305.7.1.el8_4.x86_64` or later.

```
[ec2-user ~]$ sudo yum update kernel
```

2. Install the Fedora Extra Packages for Enterprise Linux (EPEL) repository.

   RHEL version 8:

   ```
   ```

   RHEL version 9:

   ```
   ```

3. Install the `ec2-hibinit-agent` package from the repositories.

```
[ec2-user ~]$ sudo yum install ec2-hibinit-agent
```

4. Enable the hibernate agent to start on boot.

```
[ec2-user ~]$ sudo systemctl enable hibinit-agent.service
```

5. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

6. Confirm that the kernel version is updated to `4.18.0-305.7.1.el8_4.x86_64` or later.

```
[ec2-user ~]$ uname -a
```
Ubuntu 20.04 LTS (Focal Fossa) released before serial number 20210820

To configure an Ubuntu 20.04 LTS (Focal Fossa) AMI released before serial number 20210820 to support hibernation

1. Update the linux-aws-kernel to 5.8.0-1038.40 or later, and grub2 to 2.04-1ubuntu26.13 or later.

   [ec2-user ~]$ sudo apt update
   [ec2-user ~]$ sudo apt dist-upgrade

2. Reboot the instance.

   [ec2-user ~]$ sudo reboot

3. Confirm that the kernel version is updated to 5.8.0-1038.40 or later.

   [ec2-user ~]$ uname -a

4. Confirm that the grub2 version is updated to 2.04-1ubuntu26.13 or later.

   [ec2-user ~]$ dpkg --list | grep grub2-common

Ubuntu 18.04 (Bionic Beaver) released before serial number 20190722.1

To configure an Ubuntu 18.04 LTS AMI released before serial number 20190722.1 to support hibernation

1. Update the kernel to 4.15.0-1044 or later.

   [ec2-user ~]$ sudo apt update
   [ec2-user ~]$ sudo apt dist-upgrade

2. Install the ec2-hibinit-agent package from the repositories.

   [ec2-user ~]$ sudo apt install ec2-hibinit-agent

3. Reboot the instance.

   [ec2-user ~]$ sudo reboot
4. Confirm that the kernel version is updated to 4.15.0-1044 or later.

```
[ec2-user ~]$ uname -a
```

Ubuntu 16.04 (Xenial Xerus)

To configure Ubuntu 16.04 LTS to support hibernation, you need to install the linux-aws-hwe kernel package version 4.15.0-1058-aws or later and the ec2-hibinit-agent.

⚠️ Important

The `linux-aws-hwe` kernel package is supported by Canonical. The standard support for Ubuntu 16.04 LTS ended in April 2021, and the package no longer receives regular updates. However, it will receive additional security updates until the Extended Security Maintenance support ends in 2024. For more information, see Amazon EC2 Hibernation for Ubuntu 16.04 LTS now available on the Canonical Ubuntu Blog.

We recommend that you upgrade to the Ubuntu 20.04 LTS (Focal Fossa) AMI or the Ubuntu 18.04 LTS (Bionic Beaver) AMI.

To configure an Ubuntu 16.04 LTS AMI to support hibernation

1. Update the kernel to 4.15.0-1058-aws or later.

```
[ec2-user ~]$ sudo apt update
[ec2-user ~]$ sudo apt install linux-aws-hwe
```

2. Install the `ec2-hibinit-agent` package from the repositories.

```
[ec2-user ~]$ sudo apt install ec2-hibinit-agent
```

3. Reboot the instance.

```
[ec2-user ~]$ sudo reboot
```

4. Confirm that the kernel version is updated to 4.15.0-1058-aws or later.

```
[ec2-user ~]$ uname -a
```
Enable hibernation for an Amazon EC2 instance

To hibernate an instance, you must first enable it for hibernation while launching the instance.

⚠️ Important
You can't enable or disable hibernation for an instance after you launch it.

Topics
- Enable hibernation for On-Demand Instances
- Enable hibernation for Spot Instances
- View if an instance is enabled for hibernation

Enable hibernation for On-Demand Instances

Use one the following methods to enable hibernation for your On-Demand Instances.

New console

To enable hibernation for an On-Demand Instance

1. Follow the procedure to launch an instance, but don't launch the instance until you've completed the following steps to enable hibernation.
2. To enable hibernation, configure the following fields in the launch instance wizard:
   a. Under Application and OS Images (Amazon Machine Image), select an AMI that supports hibernation. For more information, see AMIs.
   b. Under Instance type, select a supported instance type. For more information, see Instance families.
   c. Under Configure storage, choose Advanced (at the right), and specify the following information for the root volume:
      - For Size (GiB), enter the EBS root volume size. The volume must be large enough to store the RAM contents and accommodate your expected usage.
      - For Volume type, select a supported EBS volume type: General Purpose SSD (gp2 and gp3) or Provisioned IOPS SSD (io1 and io2).
For **Encrypted**, choose **Yes**. If you enabled encryption by default in this AWS Region, **Yes** is selected.

- For **KMS key**, select the encryption key for the volume. If you enabled encryption by default in this AWS Region, the default encryption key is selected.

For more information about the prerequisites for the root volume, see [Prerequisites for Amazon EC2 instance hibernation](#).

d. Expand **Advanced details**, and for **Stop - Hibernate behavior**, choose **Enable**.

### 3. In the Summary panel, review your instance configuration, and then choose Launch instance. For more information, see [Launch an instance using the new launch instance wizard](#).

**Old console**

**To enable hibernation for an On-Demand Instance**

1. Follow the [Launch an instance using the old launch instance wizard](#) procedure.

2. On the **Choose an Amazon Machine Image (AMI)** page, select an AMI that supports hibernation. For more information about supported AMIs, see [Prerequisites for Amazon EC2 instance hibernation](#).

3. On the **Choose an Instance Type** page, select a supported instance type, and choose **Next: Configure Instance Details**. For information about supported instance types, see [Prerequisites for Amazon EC2 instance hibernation](#).

4. On the **Configure Instance Details** page, for **Stop - Hibernate Behavior**, select the **Enable hibernation as an additional stop behavior** check box.

5. On the **Add Storage** page, for the root volume, specify the following information:

   - For **Size (GiB)**, enter the EBS root volume size. The volume must be large enough to store the RAM contents and accommodate your expected usage.

   - For **Volume Type**, select a supported EBS volume type, General Purpose SSD (gp2 and gp3) or Provisioned IOPS SSD (io1 and io2).

   - For **Encryption**, select the encryption key for the volume. If you enabled encryption by default in this AWS Region, the default encryption key is selected.
For more information about the prerequisites for the root volume, see Prerequisites for Amazon EC2 instance hibernation.

6. Continue as prompted by the wizard. When you've finished reviewing your options on the Review Instance Launch page, choose Launch. For more information, see Launch an instance using the old launch instance wizard.

AWS CLI

To enable hibernation for an On-Demand Instance

Use the run-instances command to launch an instance. Specify the EBS root volume parameters using the --block-device-mappings file://mapping.json parameter, and enable hibernation using the --hibernation-options Configured=true parameter.

```bash
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --instance-type m5.large \
    --block-device-mappings file://mapping.json \
    --hibernation-options Configured=true \
    --count 1 \
    --key-name MyKeyPair
```

Specify the following in mapping.json.

```
[
    {
        "DeviceName": "/dev/xvda",
        "Ebs": {
            "VolumeSize": 30,
            "VolumeType": "gp2",
            "Encrypted": true
        }
    }
]
```

Note

The value for DeviceName must match the root device name that's associated with the AMI. To find the root device name, use the describe-images command.
aws ec2 describe-images --image-id ami-0abcdef1234567890

If you enabled encryption by default in this AWS Region, you can omit "Encrypted": true.

PowerShell

To enable hibernation for an On-Demand Instance using the AWS Tools for Windows PowerShell

Use the New-EC2Instance command to launch an instance. Specify the EBS root volume by first defining the block device mapping, and then adding it to the command using the -BlockDeviceMappings parameter. Enable hibernation using the -HibernationOptions_Configured $true parameter.

PS C:\> $ebs_encrypt = New-Object Amazon.EC2.Model.BlockDeviceMapping
PS C:\> $ebs_encrypt.DeviceName = "/dev/xvda"
PS C:\> $ebs_encrypt.Ebs = New-Object Amazon.EC2.Model.EbsBlockDevice
PS C:\> $ebs_encrypt.Ebs.VolumeSize = 30
PS C:\> $ebs_encrypt.Ebs.VolumeType = "gp2"
PS C:\> $ebs_encrypt.Ebs.Encrypted = $true

PS C:\> New-EC2Instance \
    -ImageId ami-0abcdef1234567890 \
    -InstanceType m5.large \
    -BlockDeviceMappings $ebs_encrypt \
    -HibernationOptions_Configured $true \
    -MinCount 1 \
    -MaxCount 1 \
    -KeyName MyKeyPair

Note

The value for DeviceName must match the root device name associated with the AMI. To find the root device name, use the Get-EC2Image command.

Get-EC2Image -ImageId ami-0abcdef1234567890
If you enabled encryption by default in this AWS Region, you can omit Encrypted = $true from the block device mapping.

Enable hibernation for Spot Instances

Use one of the following methods to enable hibernation for your Spot Instances. For more information about hibernating a Spot Instance on interruption, see Spot Instance interruptions.

Console

You can use the launch instance wizard in the Amazon EC2 console to enable hibernation for a Spot Instance.

To enable hibernation for a Spot Instance

1. Follow the procedure to request a Spot Instance using the launch instance wizard, but don’t launch the instance until you’ve completed the following steps to enable hibernation.

2. To enable hibernation, configure the following fields in the launch instance wizard:

   a. Under Application and OS Images (Amazon Machine Image), select an AMI that supports hibernation. For more information, see AMIs.

   b. Under Instance type, select a supported instance type. For more information, see Instance families.

   c. Under Configure storage, choose Advanced (at the right), and specify the following information for the root volume:

      • For Size (GiB), enter the EBS root volume size. The volume must be large enough to store the RAM contents and accommodate your expected usage.

      • For Volume type, select a supported EBS volume type: General Purpose SSD (gp2 and gp3) or Provisioned IOPS SSD (io1 and io2).

      • For Encrypted, choose Yes. If you enabled encryption by default in this AWS Region, Yes is selected.

      • For KMS key, select the encryption key for the volume. If you enabled encryption by default in this AWS Region, the default encryption key is selected.
For more information about the prerequisites for the root volume, see Prerequisites for Amazon EC2 instance hibernation.

d. Expand Advanced details, and, in addition to the fields for configuring a Spot Instance, do the following:

i. For Request type, choose Persistent.

ii. For Interruption behavior, choose Hibernate. Alternatively, for Stop - Hibernate behavior, choose Enable. Both fields enable hibernation on your Spot Instance. You need only configure one of them.

3. In the Summary panel, review your instance configuration, and then choose Launch instance. For more information, see Launch an instance using the new launch instance wizard.

AWS CLI

You can enable hibernation for a Spot Instance using the run-instances AWS CLI command.

To enable hibernation for a Spot Instance using the hibernation-options parameter

Use the run-instances command to request a Spot Instance. Specify the EBS root volume parameters using the --block-device-mappings file://mapping.json parameter, and enable hibernation using the --hibernation-options Configured=true parameter. The Spot request type (SpotInstanceType) must be persistent.

```
aws ec2 run-instances \
  --image-id ami-0abcdef1234567890 \
  --instance-type c4.xlarge \
  --block-device-mappings file://mapping.json \
  --hibernation-options Configured=true \
  --count 1 \
  --key-name MyKeyPair \
  --instance-market-options \
  { 
    "MarketType":"spot", 
    "SpotOptions":{ 
      "MaxPrice":"1", 
      "SpotInstanceType":"persistent" 
    } 
```
Specify the EBS root volume parameters in mapping.json as follows.

```json
[
  {
    "DeviceName": "/dev/xvda",
    "Ebs": {
      "VolumeSize": 30,
      "VolumeType": "gp2",
      "Encrypted": true
    }
  }
]
```

**Note**

The value for DeviceName must match the root device name that's associated with the AMI. To find the root device name, use the `describe-images` command.

```bash
aws ec2 describe-images --image-id ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit "Encrypted": true.

---

PowerShell

**To enable hibernation for a Spot Instance using the AWS Tools for Windows PowerShell**

Use the `New-EC2Instance` command to request a Spot Instance. Specify the EBS root volume by first defining the block device mapping, and then adding it to the command using the `-BlockDeviceMappings` parameter. Enable hibernation using the `-HibernationOptions_Configured $true` parameter.

```powershell
PS C:\> $ebs_encrypt = New-Object Amazon.EC2.Model.BlockDeviceMapping
PS C:\> $ebs_encrypt.DeviceName = "/dev/xvda"
PS C:\> $ebs_encrypt.Ebs = New-Object Amazon.EC2.Model.EbsBlockDevice
PS C:\> $ebs_encrypt.Ebs.VolumeSize = 30
PS C:\> $ebs_encrypt.Ebs.VolumeType = "gp2"
```
```powershell
PS C:\> $ebs_encrypt.Ebs.Encrypted = $true
PS C:\> New-EC2Instance `  `-ImageId ami-0abcdef1234567890 `  `-InstanceType m5.large `  `-BlockDeviceMappings $ebs_encrypt `  `-HibernationOptions_Configured $true `  `-MinCount 1 `  `-MaxCount 1 `  `-KeyName MyKeyPair `  `-InstanceMarketOption @(`     `MarketType = spot; `SpotOptions @{$ `MaxPrice = 1; `SpotInstanceType = persistent} `)
```

**Note**

The value for DeviceName must match the root device name associated with the AMI. To find the root device name, use the `Get-EC2Image` command.

```powershell
Get-EC2Image -ImageId ami-0abcdef1234567890
```

If you enabled encryption by default in this AWS Region, you can omit Encrypted = $true from the block device mapping.

There are several ways in which you can enable hibernation for a Spot Instance. For more information, see [Specify the interruption behavior](#).

**View if an instance is enabled for hibernation**

Use the following instructions to view whether an instance is enabled for hibernation.

**Console**

**To view if an instance is enabled for hibernation**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance and, on the Details tab, in the Instance details section, inspect Stop-.hibernate behavior. Enabled indicates that the instance is enabled for hibernation.

AWS CLI

To view if an instance is enabled for hibernation

Use the describe-instances command and specify the --filters "Name=hibernation-options.configured,Values=true" parameter to filter instances that are enabled for hibernation.

```
aws ec2 describe-instances \
--filters "Name=hibernation-options.configured,Values=true"
```

The following field in the output indicates that the instance is enabled for hibernation.

```
"HibernationOptions": {
    "Configured": true
}
```

PowerShell

To view if an instance is enabled for hibernation using the AWS Tools for Windows PowerShell

Use the Get-EC2Instance command and specify the -Filter @{ Name="hibernation-options.configured"; Value="true"} parameter to filter instances that are enabled for hibernation.

```
(Get-EC2Instance -Filter @{Name="hibernation-options.configured"; Value="true"}).Instances
```

The output lists the EC2 instances that are enabled for hibernation.

Disable KASLR on an instance (Ubuntu only)

To run hibernation on a newly launched instance with Ubuntu 16.04 LTS (Xenial Xerus), Ubuntu 18.04 LTS (Bionic Beaver) released with serial number 20190722.1 or later, or Ubuntu 20.04 LTS
(Focal Fossa) released with serial number 20210820 or later, we recommend disabling KASLR (Kernel Address Space Layout Randomization). On Ubuntu 16.04 LTS, Ubuntu 18.04 LTS, or Ubuntu 20.04 LTS, KASLR is enabled by default.

KASLR is a standard Linux kernel security feature that helps to mitigate exposure to and ramifications of yet-undiscovered memory access vulnerabilities by randomizing the base address value of the kernel. With KASLR enabled, there is a possibility that the instance might not resume after it has been hibernated.

To learn more about KASLR, see [Ubuntu Features](https://ubuntu.com/features).

**To disable KASLR on an instance launched with Ubuntu**

1. Connect to your instance using SSH. For more information, see the section called “Connect with SSH from Linux or macOS”.

2. Open the `/etc/default/grub.d/50-cloudimg-settings.cfg` file in your editor of choice. Edit the `GRUB_CMDLINE_LINUX_DEFAULT` line to append the `nokaslr` option to its end, as shown in the following example.

   ```
   GRUB_CMDLINE_LINUX_DEFAULT="console=tty1 console=ttyS0 nvme_core.io_timeout=4294967295 nokaslr"
   ```

3. Save the file and exit your editor.

4. Run the following command to rebuild the grub configuration.

   ```
   [ec2-user ~]$ sudo update-grub
   ```

5. Reboot the instance.

   ```
   [ec2-user ~]$ sudo reboot
   ```

6. Run the following command to confirm that `nokaslr` has been added.

   ```
   [ec2-user ~]$ cat /proc/cmdline
   ```

   The output of the command should include the `nokaslr` option.
Hibernate an Amazon EC2 instance

You can initiate hibernation on an On-Demand Instance or Spot Instance if the instance is an EBS-backed instance, is enabled for hibernation, and meets the hibernation prerequisites. If an instance cannot hibernate successfully, a normal shutdown occurs.

Console

To hibernate an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select an instance, and choose Instance state, Hibernate instance. If Hibernate instance is disabled, the instance is already hibernated or stopped, or it can't be hibernated. For more information, see Prerequisites for Amazon EC2 instance hibernation.
4. When prompted for confirmation, choose Hibernate. It can take a few minutes for the instance to hibernate. The instance state first changes to Stopping, and then changes to Stopped when the instance has hibernated.

AWS CLI

To hibernate an EBS-backed instance

Use the stop-instances command and specify the --hibernate parameter.

```bash
aws ec2 stop-instances \
   --instance-ids i-1234567890abcdef0 \
   --hibernate
```

PowerShell

To hibernate an instance using the AWS Tools for Windows PowerShell

Use the Stop-EC2Instance command and specify the -Hibernate $true parameter.

```powershell
Stop-EC2Instance ` 
   -InstanceId i-1234567890abcdef0 ` 
   -Hibernate $true
```
Console

**To view if hibernation was initiated on an instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance and, on the **Details** tab, in the **Instance details** section, check the value for **State transition message**.

   *Client.UserInitiatedHibernate: User initiated hibernate* indicates that you initiated hibernation on the On-Demand Instance or Spot Instance.

AWS CLI

**To view if hibernation was initiated on an instance**

Use the `describe-instances` command and specify the `state-reason-code` filter to see the instances on which hibernation was initiated.

```
aws ec2 describe-instances \
   --filters "Name=state-reason-code,Values=Client.UserInitiatedHibernate"
```

The following field in the output indicates that hibernation was initiated on the On-Demand Instance or Spot Instance.

```
"StateReason": {
   "Code": "Client.UserInitiatedHibernate"
}
```

PowerShell

**To view if hibernation was initiated on an instance using the AWS Tools for Windows PowerShell**

Use the `Get-EC2Instance` command and specify the `state-reason-code` filter to see the instances on which hibernation was initiated.

```
Get-EC2Instance \
```
The output lists the EC2 instances on which hibernation was initiated.

**Start a hibernated Amazon EC2 instance**

Start a hibernated instance by starting it in the same way that you would start a stopped instance.

**Note**

For Spot Instances, if Amazon EC2 hibernated the instance, then only Amazon EC2 can resume it. You can only resume a hibernated Spot Instance if you hibernated it. Spot Instances can only be resumed if capacity is available and the Spot price is less than or equal to your specified maximum price.

**Console**

**To start a hibernated instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select a hibernated instance, and choose **Instance state, Start instance**. It can take a few minutes for the instance to enter the **running** state. During this time, the instance **status checks** show the instance in a failed state until the instance has started.

**AWS CLI**

**To start a hibernated instance**

Use the **start-instances** command.

```
aws ec2 start-instances \
--instance-ids i-1234567890abcdef0
```

**PowerShell**

**To start a hibernated instance using the AWS Tools for Windows PowerShell**
Use the `Start-EC2Instance` command.

```
Start-EC2Instance ' -InstanceId i-1234567890abcdef0
```

## Troubleshoot Amazon EC2 instance hibernation

Use this information to help diagnose and fix issues that you might encounter when hibernating an instance.

### Hibernation issues

- Can't hibernate immediately after launch
- Takes too long to transition from stopping to stopped, and memory state not restored after start
- Instance "stuck" in the stopping state
- Can’t start Spot Instance immediately after hibernate
- Resume Spot Instances failed

### Can't hibernate immediately after launch

If you try to hibernate an instance too quickly after you've launched it, you get an error.

You must wait for about two minutes for Linux instances and about five minutes for Windows instances after launch before hibernating.

### Takes too long to transition from stopping to stopped, and memory state not restored after start

If it takes a long time for your hibernating instance to transition from the stopping state to stopped, and if the memory state is not restored after you start, this could indicate that hibernation was not properly configured.

### Linux instances

Check the instance system log and look for messages that are related to hibernation. To access the system log, `connect` to the instance or use the `get-console-output` command. Find the log lines from the hibinit-agent. If the log lines indicate a failure or the log lines are missing, there was most likely a failure configuring hibernation at launch.
For example, the following message indicates that the instance root volume is not large enough: hibinit-agent: Insufficient disk space. Cannot create setup for hibernation. Please allocate a larger root device.

If the last log line from the hibinit-agent is hibinit-agent: Running: swapoff /swap, hibernation was successfully configured.

If you do not see any logs from these processes, your AMI might not support hibernation. For information about supported AMIs, see Prerequisites for Amazon EC2 instance hibernation. If you used your own Linux AMI, make sure that you followed the instructions for Configure a Linux AMI to support hibernation.

**Windows Server 2016 and later**

Check the EC2 launch log and look for messages that are related to hibernation. To access the EC2 launch log, connect to the instance and open the C:\ProgramData\Amazon\EC2-Windows\Launch\Log\Ec2Launch.log file in a text editor. If you're using EC2Launch v2, open C:\ProgramData\Amazon\EC2Launch\log\agent.log.

![Note](image)

*By default, Windows hides files and folders under C:\ProgramData. To view EC2 Launch directories and files, enter the path in Windows Explorer or change the folder properties to show hidden files and folders.*

Find the log lines for hibernation. If the log lines indicate a failure or the log lines are missing, there was most likely a failure configuring hibernation at launch.

For example, the following message indicates that hibernation failed to configure: Message: Failed to enable hibernation. If the error message includes decimal ASCII values, you can convert the ASCII values to plain text in order to read the full error message.

If the log line contains HibernationEnabled: true, hibernation was successfully configured.

**Windows Server 2012 R2 and earlier**

Check the EC2 config log and look for messages that are related to hibernation. To access the EC2 config log, connect to the instance and open the C:\Program Files\Amazon\Ec2ConfigService\Logs\Ec2ConfigLog.txt file in a text editor. Find the log lines for...
SetHibernateOnSleep. If the log lines indicate a failure or the log lines are missing, there was most likely a failure configuring hibernation at launch.

For example, the following message indicates that the instance root volume is not large enough:

SetHibernateOnSleep: Failed to enable hibernation: Hibernation failed with the following error: There is not enough space on the disk.

If the log line is SetHibernateOnSleep: HibernationEnabled: true, hibernation was successfully configured.

**Windows instance size**

If you’re using a T3 or T3a Windows instance with less than 1 GB of RAM, try increasing the size of the instance to one that has at least 1 GB of RAM.

**Instance "stuck" in the stopping state**

If you hibernated your instance and it appears "stuck" in the stopping state, you can forcibly stop it. For more information, see [Troubleshoot Amazon EC2 instance stop issues](#).

**Can’t start Spot Instance immediately after hibernate**

If you try to start a Spot Instance within two minutes of hibernating it, you might get the following error:

You failed to start the Spot Instance because the associated Spot Instance request is not in an appropriate state to support start.

Wait for about two minutes for Linux instances and about five minutes for Windows instances and then retry starting the instance.

**Resume Spot Instances failed**

If your Spot Instance was hibernated successfully but failed to resume, and instead rebooted (a fresh restart where the hibernated state is not retained), it might be because the user data contained the following script:

```
/usr/bin/enable-ec2-spot-hibernation
```

Remove this script from the **User data** field in the launch template, and then request a new Spot Instance.
Note that even if the instance failed to resume, without the hibernated state preserved, the instance can still be started in the same way as starting from the stopped state.

**Reboot your instance**

An instance reboot is equivalent to an operating system reboot. In most cases, it takes only a few minutes to reboot your instance.

When you reboot an instance, it keeps the following:

- Public DNS name (IPv4)
- Private IPv4 address
- Public IPv4 address
- IPv6 address (if applicable)
- Any data on its instance store volumes

Rebooting an instance doesn't start a new instance billing period (with a minimum one-minute charge), unlike stopping and starting your instance.

We might schedule your instance for a reboot for necessary maintenance, such as to apply updates that require a reboot. No action is required on your part; we recommend that you wait for the reboot to occur within its scheduled window. For more information, see Scheduled events for Amazon EC2 instances.

We recommend that you use the Amazon EC2 console, a command line tool, or the Amazon EC2 API to reboot your instance instead of running the operating system reboot command from your instance. If you use the Amazon EC2 console, a command line tool, or the Amazon EC2 API to reboot your instance, we perform a hard reboot if the instance does not cleanly shut down within a few minutes. If you use AWS CloudTrail, then using Amazon EC2 to reboot your instance also creates an API record of when your instance was rebooted.

**Windows instances**

If Windows is installing updates on your instance, we recommend that you do not reboot or shut down your instance using the Amazon EC2 console or the command line until all the updates are installed. When you use the Amazon EC2 console or the command line to reboot or shut down your instance, there is a risk that your instance will be hard rebooted. A hard reboot while updates are being installed could throw your instance into an unstable state.
Console

**To reboot an instance using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Instance state, Reboot instance**.

   Alternatively, select the instance and choose **Actions, Manage instance state**. In the screen that opens, choose **Reboot**, and then **Change state**.
4. Choose **Reboot** when prompted for confirmation.

   The instance remains in the **running** state.

Command line

**To reboot an instance**

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](https://docs.aws.amazon.com/cli/latest/userguide/cli-aws.html).

- **reboot-instances** (AWS CLI)
- **Restart-EC2Instance** (AWS Tools for Windows PowerShell)

**To run a controlled fault injection experiment**

You can use AWS Fault Injection Service to test how your application responds when your instance is rebooted. For more information, see the [AWS Fault Injection Service User Guide](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/FaultInjection.html).

**Terminate Amazon EC2 instances**

You can delete your instance when you no longer need it. This is referred to as **terminating** your instance. As soon as the state of an instance changes to shutting-down or terminated, you stop incurring charges for that instance.

You can't connect to or start an instance after you've terminated it. However, you can launch additional instances using the same AMI. If you'd rather stop or hibernate an instance, see [Stop and start Amazon EC2 instances](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/stop-start-instances.html) or [Hibernate your Amazon EC2 instance](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/stop-start-instances.html). For more information, see [Differences between reboot, stop, hibernate, and terminate](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/DifferencesTerminates.html).

- **Terminate an instance**
- **Troubleshoot instance termination**
- **Enable termination protection**
- **Change the instance initiated shutdown behavior**
- **Preserve data when an instance is terminated**

**How instance termination works**

When you terminate an instance, changes are registered at the OS level of the instance, some resources are lost, and some resources persist.

The following diagram shows what is lost and what persists when an Amazon EC2 instance is terminated. When an instance terminates, the data on any instance store volumes and the data stored the instance RAM is erased. Any Elastic IP addresses associated with the instance are detached. For Amazon EBS volumes and the data on those volumes, the outcome depends on the **Delete on termination** setting for the volume. By default, the root volume is deleted and the data volumes are preserved.
Considerations

- When an instance terminates, the data on any instance store volumes associated with that instance is deleted.

- By default, Amazon EBS root device volumes are automatically deleted when the instance terminates. However, any additional EBS volumes that you attach at launch, or any EBS volumes that you attach to an existing instance persist even after the instance terminates. For more information, see [Preserve data when an instance is terminated](#).

  ![Note]
  > Any volumes that are not deleted upon termination of the instance will continue to incur charges.

- To prevent an instance from being accidentally terminated by someone, [enable termination protection](#).

- To control whether an instance stops or terminates when shutdown is initiated from the instance, change the [instance initiated shutdown behavior](#).

- If you run a script on instance termination, your instance might have an abnormal termination, because we have no way to ensure that shutdown scripts run. Amazon EC2 attempts to shut an instance down cleanly and run any system shutdown scripts; however, certain events (such as hardware failure) may prevent these system shutdown scripts from running.

What happens when you terminate an instance

Changes registered at the OS level

- The API request sends a button press event to the guest.

- Various system services are stopped as a result of the button press event. Graceful shutdown of the system is provided by [systemd](#) (Linux) or the System process (Windows). Graceful shutdown is triggered by the ACPI shutdown button press event from the hypervisor.

- ACPI shutdown is initiated.

- The instance will shut down after the graceful shutdown process exits. There is no configurable OS shutdown time. The instance remains visible in the console for a short time, then the entry is automatically deleted.
Resources lost

- Data stored on an instance store volume.
- Data stored on Amazon EBS root device volumes if the DeleteOnTermination attribute is set to true.

Resources that persist

- Data stored on additional Amazon EBS volumes attached at launch or after launch of an instance.

Test application response to instance termination

You can use AWS Fault Injection Service to test how your application responds when your instance is terminated. For more information, see the AWS Fault Injection Service User Guide.

Terminate an instance

You can terminate an instance at any time.

Console

To terminate an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, and choose Instance state, Terminate instance.
4. Choose Terminate when prompted for confirmation.
5. After you terminate an instance, it remains visible for a short while, with a state of terminated.

If termination fails or if a terminated instance is visible for more than a few hours, see Terminated instance still displayed.
Command line

**To terminate an instance using the command line**

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](#).

- `terminate-instances` (AWS CLI)
- `Remove-EC2Instance` (AWS Tools for Windows PowerShell)

**Troubleshoot instance termination**

The requester must have permission to call `ec2:TerminateInstances`. For more information, see [Example policies to work with instances](#).

If you terminate your instance and another instance starts, most likely you have configured automatic scaling through a feature like EC2 Fleet or Amazon EC2 Auto Scaling. For more information, see [Instances automatically launched or terminated](#).

You can't terminate an instance if termination protection is turned on. For more information, see [termination protection](#).

If your instance is in the shutti ng-down state for longer than usual, it should be cleaned up (terminated) by automated processes within the Amazon EC2 service. For more information, see [Delayed instance termination](#).

**Enable termination protection**

To prevent your instance from being accidentally terminated, you can enable *termination protection* for the instance. The `DisableApiTermination` attribute controls whether the instance can be terminated using the AWS Management Console, AWS Command Line Interface (AWS CLI), or API. By default, termination protection is disabled for your instance which means that your instance can be terminated using the AWS Management Console, AWS CLI, or API. You can set the value of this attribute when you launch an instance, while the instance is running, or while the instance is stopped (for Amazon EBS backed instances).

The `DisableApiTermination` attribute doesn't prevent you from terminating an instance by initiating shutdown from the instance (using an operating system command for system shutdown) when the `InstanceInitiatedShutdownBehavior` attribute is set. For more information, see [Change the instance initiated shutdown behavior](#).
Considerations

- Enabling termination protection does not prevent AWS from terminating the instance when there is a scheduled event to terminate the instance.
- Enabling termination protection does not prevent Amazon EC2 Auto Scaling from terminating an instance when the instance is unhealthy or during scale-in events. You can control whether an Auto Scaling group can terminate a particular instance when scaling using instance scale-in protection. You can control whether an Auto Scaling group can terminate unhealthy instances by suspending the ReplaceUnhealthy scaling process.
- You can't enable termination protection for Spot Instances.

To enable termination protection for an instance at launch time

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the dashboard, choose Launch Instance and follow the directions in the wizard.
3. On the Configure Instance Details page, select the Enable termination protection check box.

To enable termination protection for a running or stopped instance

1. Select the instance, and choose Actions, Instance Settings, Change Termination Protection.
2. Choose Yes, Enable.

To disable termination protection for a running or stopped instance

1. Select the instance, and choose Actions, Instance Settings, Change Termination Protection.
2. Choose Yes, Disable.

To enable or disable termination protection using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2.

- modify-instance-attribute (AWS CLI)
- Edit-EC2InstanceAttribute (AWS Tools for Windows PowerShell)
Terminate multiple instances with termination protection

If you terminate multiple instances across multiple Availability Zones in the same request, and one or more of the specified instances are enabled for termination protection, the request fails with the following results:

- The specified instances that are in the same Availability Zone as the protected instance are not terminated.
- The specified instances that are in different Availability Zones, where no other specified instances are protected, are successfully terminated.

Example

Suppose that you have the following four instances across two Availability Zones.

<table>
<thead>
<tr>
<th>Instance</th>
<th>Availability Zone</th>
<th>Terminate protection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instance 1</td>
<td>AZ A</td>
<td>Disabled</td>
</tr>
<tr>
<td>Instance 2</td>
<td></td>
<td>Disabled</td>
</tr>
<tr>
<td>Instance 3</td>
<td>AZ B</td>
<td>Enabled</td>
</tr>
<tr>
<td>Instance 4</td>
<td></td>
<td>Disabled</td>
</tr>
</tbody>
</table>

If you attempt to terminate all of these instances in the same request, the request reports failure with the following results:

- **Instance 1** and **Instance 2** are successfully terminated because neither instance is enabled for termination protection.
- **Instance 3** and **Instance 4** fail to terminate because **Instance 3** is enabled for termination protection.

Change the instance initiated shutdown behavior

By default, when you initiate a shutdown from an Amazon EBS backed instance (using a command such as `shutdown` or `poweroff`), the instance stops. You can change this behavior so that the
instance terminates instead by changing the `InstanceInitiatedShutdownBehavior` attribute for the instance. You can change this attribute while the instance is running or stopped.

The `halt` command doesn't initiate a shutdown. If used, the instance doesn't terminate; instead, it places the CPU into HLT and the instance continues to run.

**Note**

The `InstanceInitiatedShutdownBehavior` attribute only applies when you perform a shutdown from the operating system of the instance itself. It doesn't apply when you stop an instance using the `StopInstances` API or the Amazon EC2 console.

You can change the `InstanceInitiatedShutdownBehavior` attribute using the Amazon EC2 console or the command line.

**Console**

**To change the instance initiated shutdown behavior**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance.
4. Choose **Actions, Instance settings, Change shutdown behavior**.

**Shutdown behavior** displays the current behavior.

5. To change the behavior, for **Shutdown behavior**, choose **Stop** or **Terminate**.
6. Choose **Save**.

**Command line**

**To change the instance initiated shutdown behavior**

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](https://aws.amazon.com/documentation/ec2/using-command-line-interfaces/).

- `modify-instance-attribute` (AWS CLI)
- `Edit-EC2InstanceAttribute` (AWS Tools for Windows PowerShell)
Preserve data when an instance is terminated

Depending on your use case, you might want to preserve the data on your instance store volume or Amazon EBS volume when the Amazon EC2 instance is terminated. The data on an instance store volume doesn't persist when an instance is terminated. If you need to preserve the data stored on an instance store volume beyond the lifetime of the instance, you must manually copy that data to more persistent storage, such as an Amazon EBS volume, an Amazon S3 bucket, or an Amazon EFS file system. For more information, see Storage options for your Amazon EC2 instances.

For data on Amazon EBS volumes, Amazon EC2 uses the value of the DeleteOnTermination attribute for each attached Amazon EBS volume to determine whether to preserve or delete the volume.

The default value for the DeleteOnTermination attribute differs depending on whether the volume is the root volume of the instance or a non-root volume attached to the instance.

Root volume

By default, when you launch an instance the DeleteOnTermination attribute for the root volume of an instance is set to true. Therefore, the default is to delete the root volume of the instance when the instance terminates.

Non-root volume

By default, when you attach a non-root EBS volume to an instance, its DeleteOnTermination attribute is set to false. Therefore, the default is to preserve these volumes.

Note

After the instance terminates, you can take a snapshot of the preserved volume or attach it to another instance. You must delete a volume to avoid incurring further charges.

The DeleteOnTermination attribute can be set by the creator of an AMI as well as by the person who launches an instance. When the attribute is changed by the creator of an AMI or by the person who launches an instance, the new setting overrides the original AMI default setting. We recommend that you verify the default setting for the DeleteOnTermination attribute after you launch an instance with an AMI.
To verify if an Amazon EBS volume will be deleted on instance termination, view the details for volume on the instance's details pane. On the Storage tab, under Block devices, scroll right to view the Delete on termination setting for the volume.

- If Yes, the volume will be deleted when the instance is terminated.
- If No, the volume will not be deleted when the instance is terminated. Any volumes that are not deleted upon termination of the instance will continue to incur charges.

**Change the root volume to persist at launch**

Using the console, you can change the DeleteOnTermination attribute when you launch an instance. To change this attribute for a running instance, you must use the command line.

Use one of the following methods to change the root volume to persist at launch.

**Console**

**To change the root volume of an instance to persist at launch using the console**

1. Follow the procedure to launch an instance, but don't launch the instance until you've completed the following steps to change the root volume to persist.
2. Under Storage (volumes), expand the information under the root volume.
3. For Delete on termination, choose No
4. In the Summary panel, review your instance configuration, and then choose Launch instance. For more information, see Launch an instance using the new launch instance wizard.

**Command line**

**To change the root volume of an instance to persist at launch using the command line**

When you launch an EBS-backed instance, you can use one of the following commands to change the root device volume to persist. For more information about these command line interfaces, see Access Amazon EC2.

- run-instances (AWS CLI)
- New-EC2Instance (AWS Tools for Windows PowerShell)
In the block device mappings for the volumes that you want to persist, include --DeleteOnTermination, and specify false.

For example, to persist a volume add the following option to your run-instances command:

```
--block-device-mappings file://mapping.json
```

In mapping.json, specify the device name, for example /dev/sda1 or /dev/xvda, and for --DeleteOnTermination, specify false.

```
[
  {
    "DeviceName": "device_name",
    "Ebs": {
      "DeleteOnTermination": false
    }
  }
]
```

**Change the root volume of a running instance to persist**

You can use one of the following commands to change the root device volume of a running EBS-backed instance to persist. For more information about these command line interfaces, see [Access Amazon EC2](https://docs.aws.amazon.com/AmazonS3/latest/userguide/using-sdk-console.html).

- `modify-instance-attribute` (AWS CLI)
- `Edit-EC2InstanceAttribute` (AWS Tools for Windows PowerShell)

For example, use the following command:

```
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --block-device-mappings file://mapping.json
```

In mapping.json, specify the device name, for example /dev/sda1 or /dev/xvda, and for --DeleteOnTermination, specify false.

```
[
  {
```

Terminate
Instance retirement

An instance is scheduled to be retired when AWS detects irreparable failure of the underlying hardware that hosts the instance. The instance root device determines the behavior of instance retirement:

- If your instance root device is an Amazon EBS volume, the instance is stopped, and you can start it again at any time. Starting the stopped instance migrates it to new hardware.
- If your instance root device is an instance store volume, the instance is terminated, and can't be used again.

For more information about the types of instance events, see Scheduled events for Amazon EC2 instances.

Contents

- Identify instances scheduled for retirement
- Actions to take for EBS-backed instances scheduled for retirement
- Actions to take for instance-store backed instances scheduled for retirement

Identify instances scheduled for retirement

If your instance is scheduled for retirement, you receive an email prior to the event with the instance ID and retirement date. You can also check for instances that are scheduled for retirement using the Amazon EC2 console or the command line.

⚠️ Important

If an instance is scheduled for retirement, we recommend that you take action as soon as possible because the instance might be unreachable. (The email notification you receive states the following: "Due to this degradation your instance could already be unreachable.")
Ways to identify instances scheduled for retirement

- Email notification
- Console identification

Email notification

If your instance is scheduled for retirement, you receive an email prior to the event with the instance ID and retirement date.

The email is sent to the primary account holder and the operations contact. For more information, see Adding, changing, or removing alternate contacts in the AWS Billing User Guide.

Console identification

If you use an email account that you do not check regularly for instance retirement notifications, you can use the Amazon EC2 console or the command line to determine if any of your instances are scheduled for retirement.

To identify instances scheduled for retirement using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose EC2 Dashboard. Under Scheduled events, you can see the events that are associated with your Amazon EC2 instances and volumes, organized by Region.

### Scheduled events

**US East (N. Virginia)**

- 7 instance(s) have scheduled events
- 1 volume(s) are impaired
3. If you have an instance with a scheduled event listed, select its link below the Region name to go to the **Events** page.

4. The **Events** page lists all resources that have events associated with them. To view instances that are scheduled for retirement, select **Instance resources** from the first filter list, and then **Instance stop or retirement** from the second filter list.

5. If the filter results show that an instance is scheduled for retirement, select it, and note the date and time in the **Start time** field in the details pane. This is your instance retirement date.

**To identify instances scheduled for retirement using the command line**

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](#).

- `describe-instance-status` (AWS CLI)
- `Get-EC2InstanceStatus` (AWS Tools for Windows PowerShell)

**Actions to take for EBS-backed instances scheduled for retirement**

To preserve the data on your retiring instance, you can perform one of the following actions. It's important that you take this action before the instance retirement date to prevent unforeseen downtime and data loss.

For Linux instances, if you are not sure whether your instance is backed by EBS or instance store, see [Root volumes for your Amazon EC2 instances](#).

**Check if your instance is reachable**

When you are notified that your instance is scheduled for retirement, we recommend that you take the following action as soon as possible:

- Check if your instance is reachable by either connecting to or pinging your instance.
- If your instance is reachable, you should plan to stop/start your instance at an appropriate time before the scheduled retirement date, when the impact is minimal. For more information about stopping and starting your instance, and what to expect when your instance is stopped, such as the effect on public, private, and Elastic IP addresses that are associated with your instance, see [Stop and start Amazon EC2 instances](#). Note that data on instance store volumes is lost when you stop and start your instance.
• If your instance is unreachable, you should take immediate action and perform a stop/start to recover your instance.

• Alternatively, if you want to terminate your instance, plan to do so as soon as possible so that you stop incurring charges for the instance.

Create a backup of your instance

Create an EBS-backed AMI from your instance so that you have a backup. To ensure data integrity, stop the instance before you create the AMI. You can wait for the scheduled retirement date when the instance is stopped, or stop the instance yourself before the retirement date. You can start the instance again at any time. For more information, see Create an Amazon EBS-backed AMI.

Launch a replacement instance

After you create an AMI from your instance, you can use the AMI to launch a replacement instance. From the Amazon EC2 console, select your new AMI and then choose Launch instance from AMI. Configure the parameters for your instance and then choose Launch instance. For more information about each field, see Launch an instance using the new launch instance wizard.

Actions to take for instance-store backed instances scheduled for retirement

To preserve the data on your retiring instance, you can perform one of the following actions. It's important that you take this action before the instance retirement date to prevent unforeseen downtime and data loss.

⚠️ Warning

If your instance store-backed instance passes its retirement date, it is terminated and you cannot recover the instance or any data that was stored on it. Regardless of the root device of your instance, the data on instance store volumes is lost when the instance is retired, even if the volumes are attached to an EBS-backed instance.

Check if your instance is reachable

When you are notified that your instance is scheduled for retirement, we recommend that you take the following action as soon as possible:

• Check if your instance is reachable by either connecting to or pinging your instance.
If your instance is unreachable, there is likely very little that can be done to recover your instance. For more information, see Troubleshoot an unreachable Amazon EC2 instance. AWS will terminate your instance on the scheduled retirement date, so, for an unreachable instance, you can immediately terminate the instance yourself.

**Launch a replacement instance**

Create an instance store-backed AMI from your instance using the AMI tools, as described in Create an instance store-backed Linux AMI. From the Amazon EC2 console, select your new AMI and then choose Launch instance from AMI. Configure the parameters for your instance and then choose Launch instance. For more information about each field, see Launch an instance using the new launch instance wizard.

**Convert your instance to an EBS-backed instance**

Transfer your data to an EBS volume, take a snapshot of the volume, and then create AMI from the snapshot. You can launch a replacement instance from your new AMI. For more information, see Convert your instance store-backed AMI to an Amazon EBS-backed AMI.

**Instance resiliency**

⚠️ **Important**

The following information applies to configuring recovery-related capabilities on healthy instances. If you are currently encountering difficulties accessing your instance, see Troubleshoot EC2 instances.

In the event that AWS determines an instance is unavailable due to an underlying hardware issue, there are two mechanisms that you can configure for instance resiliency which can restore availability—simplified automatic recovery and Amazon CloudWatch action based recovery. This process is called instance recovery.

At least one mechanism must be configured or enabled in advance with supported resources for the instance recovery process to occur. By default, simplified automatic recovery is enabled for supported instances when they are launched.

**Topics**
Overview of instance recovery

The following are examples of underlying hardware issues that might require instance recovery:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host that impact network reachability

A recovered instance is identical to the original instance, including its:

- Instance ID
- Public, private, and Elastic IP addresses
- Instance metadata
- Placement group
- Attached EBS volumes
- Availability Zone

A successful instance recovery will appear to the instance as an unplanned reboot. In other words, content stored in volatile memory will be lost, instance store data will be erased, and the operating system’s uptime will start over from zero.

To help protect against data loss, we recommend that you regularly create backups of valuable data. For more information about backup and recovery best practices for Amazon EC2 instances, see Best practices for Amazon EC2.

Instance recovery alternatives

The following alternatives to instance recovery can be considered when they meet the use case of your instances.
Auto Scaling groups

You can use Auto Scaling groups to allow you to group a collection of instances together for the purposes of scaling and availability. In the event an instance within an Auto Scaling group becomes unavailable, the instance will automatically be replaced (not recovered) by the Auto Scaling group. For more information, see *What is Amazon EC2 Auto Scaling?* in the *Amazon EC2 Auto Scaling User Guide*.

Amazon EBS Multi-Attach

You can configure Amazon EBS Multi-Attach for your instances to allow multiple instances to be connected to the same EBS volume. When combined with appropriate software, this allows for high availability clustering to be enabled. For an example configuration with Linux instances, see *Clustered storage simplified: GFS2 on Amazon EBS Multi-Attach enabled volumes* on the AWS Storage Blog.

Configure CloudWatch action based recovery

⚠️ **Important**

- The following information applies to configuring recovery-related capabilities on healthy instances. If you are currently encountering difficulties accessing your instance, see *Troubleshoot EC2 instances*.
- For your workload to function properly after a successful instance recovery, your instance must boot and accept traffic without requiring manual intervention.

You can configure Amazon CloudWatch action based recovery to add recovery actions to Amazon CloudWatch alarms. CloudWatch action based recovery works with the `StatusCheckFailed_System` metric. CloudWatch action based recovery provides to-the-minute recovery response time granularity and Amazon Simple Notification Service (Amazon SNS) notifications of recovery actions and outcomes. These configuration options allow for faster recovery attempts with more granular control over the system status check failure event response compared to simplified automatic recovery. For more information about available CloudWatch options, see *Status checks for your instances*.  

Instance resiliency
Amazon CloudWatch action based recovery doesn't operate during service events in the AWS Health Dashboard. For more information, see the section called “Troubleshooting CloudWatch action based recovery failures”.

**Topics**

- Requirements and limitations for CloudWatch action based recovery
- Configure CloudWatch action based recovery
- Troubleshooting CloudWatch action based recovery failures

**Requirements and limitations for CloudWatch action based recovery**

CloudWatch action based recovery can attempt to recover an instance if it:

- Is in the running state. For more information, see the section called “Instance lifecycle”.
- Uses default (On-Demand) or dedicated instance tenancy. For more information, see the section called “Instance purchasing options”.
- Is of an instance type for which Amazon EC2 has capacity available. In some situations, such as significant outages, not enough capacity will be available and some recovery attempts might fail.
- Doesn't use dedicated instance tenancy. For Amazon EC2 Dedicated Hosts, you can use Dedicated Host Auto Recovery to automatically recover unhealthy instances.
- Doesn't use an Elastic Fabric Adapter.
- Isn't a member of an Auto Scaling group.
- Isn't currently undergoing a scheduled maintenance event.
- Uses one of the following instance types:
  - **General purpose**: A1 | M3 | M4 | M5 | M5a | M5n | M5zn | M6a | M6g | M6i | M6in | M7a | M7g | M7i | M7i-flex | T1 | T2 | T3 | T3a | T4g
  - **Compute optimized**: C3 | C4 | C5 | C5a | C5n | C6a | C6g | C6gn | C6i | C6in | C7a | C7g | C7gn | C7i | C7i-flex
  - **Memory optimized**: R3 | R4 | R5 | R5a | R5b | R5n | R6a | R6g | R6i | R6in | R7a | R7g | R7i | R7iz | R8g | u-3tb1 | u-6tb1 | u-9tb1 | u-12tb1 | u-18tb1 | u-24tb1 | u7i-12tb | u7in-16tb | u7in-24tb | u7in-32tb | X1 | X1e | X2iezn
  - **Accelerated computing**: G3 | G3s | G5g | Inf1 | P2 | P3 | VT1
  - **High-performance computing**: Hpc6a | Hpc7a | Hpc7g
  - **Metal instances**: Any of the above types with the metal instance size.
• Has instance store volumes **and** uses one of the following instance types: M3 | C3 | R3 | X1 | X1e | X2idn | X2iedn

⚠️ **Warning**

- Data on instance store volumes will be lost if the instance is stopped. For more information about stopping an instance, see the section called “Instance stop and start”.
- In the event of a systems status check failure, the instance store and block device mapped data might be lost. For these instance types, you can consider using the section called “Enable termination protection”.

We recommend that you regularly create backups of valuable data. For information about backup and recovery best practices for Amazon EC2, see Best practices for Amazon EC2.

You can also use the AWS Management Console or the AWS CLI to view the instance types that support CloudWatch action based recovery.

**Console**

**To view the instance types that support Amazon CloudWatch action based recovery**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the left navigation pane, choose **Instance Types**.
3. In the filter bar, enter **Auto Recovery support: true**. Alternatively, as you enter the characters and the filter name appears, you can select it.

   The **Instance types** table displays all the instance types that support Amazon CloudWatch action based recovery.

**AWS CLI**

**To view the instance types that support Amazon CloudWatch action based recovery**

Use the `describe-instance-types` command.

```bash
code
aws ec2 describe-instance-types --filters Name=auto-recovery-supported,Values=true
```
Configure CloudWatch action based recovery

CloudWatch action based recovery works with the StatusCheckFailed_System metric. CloudWatch action based recovery is configured through the CloudWatch console. To set up CloudWatch action based recovery, see Adding recover actions to CloudWatch alarms in the Amazon CloudWatch User Guide.

Troubleshooting CloudWatch action based recovery failures

The following issues can cause the recovery of your instance with CloudWatch action based recovery to fail:

- CloudWatch action based recovery does not operate during service events in the AWS Health Dashboard. You might not receive recovery failure notifications for such events. For the latest service availability information, see the Service health status page.
- Temporary, insufficient capacity of replacement hardware.
- The instance has reached the maximum daily allowance for recovery attempts. Your instance might subsequently be retired if automatic recovery fails and a hardware degradation is determined to be the root cause for the original system status check failure.

If the instance's system status check failure persists despite multiple recovery attempts, see Troubleshoot instances with failed status checks for additional guidance.

Configure simplified automatic recovery

⚠️ Important

- The following information applies to configuring recovery-related capabilities on healthy instances. If you are currently encountering difficulties accessing your instance, see Troubleshoot EC2 instances.
- For your workload to function properly after a successful instance recovery, your instance must boot and accept traffic without requiring manual intervention.
By default, simplified automatic recovery monitors all supported running instances. In the event that a system status check failure is detected, simplified automatic recovery attempts to remediate the instance to a healthy state. Simplified automatic recovery doesn't operate during service events in the AWS Health Dashboard. For more information, see the section called “Troubleshooting simplified automatic recovery failures”.

When a simplified automatic recovery event occurs, you will receive an AWS Health Dashboard event. To configure notifications for these events, see the Getting Started with AWS User Notifications in the AWS User Notifications User Guide. You can also use Amazon EventBridge rules to monitor for simplified automatic recovery events using the following event codes:

- AWS_EC2_SIMPLIFIED_AUTO_RECOVERY_SUCCESS — successful events
- AWS_EC2_SIMPLIFIED_AUTO_RECOVERY_FAILURE — failed events

For more information, see Amazon EventBridge rules.

Topics

- Requirements and limitations for simplified automatic recovery
- Configure simplified automatic recovery
- Troubleshooting simplified automatic recovery failures

Requirements and limitations for simplified automatic recovery

Simplified automatic recovery will attempt to recover an instance if it:

- Is in the running state. For more information, see the section called “Instance lifecycle”.
- Uses default (On-Demand) or dedicated tenancy. For more information, see the section called “Instance purchasing options”.
- Is of an instance type for which Amazon EC2 has capacity available. In some situations, such as significant outages, not enough capacity will be available and some recovery attempts might fail.
- Doesn't use host tenancy. For Amazon EC2 Dedicated Hosts, you can use Dedicated Host Auto Recovery to automatically recover unhealthy instances.
- Doesn't use an Elastic Fabric Adapter.
- Isn't a metal instance size.
- Isn't a member of an Auto Scaling group.
• Isn't currently undergoing a scheduled maintenance event.
• Doesn't have instance store volumes.
• Uses one of the following instance types:
  • **General purpose:** A1 | M3 | M4 | M5 | M5a | M5n | M5zn | M6a | M6g | M6i | M6in | M7a | M7g | M7i | M7i-flex | T1 | T2 | T3 | T3a | T4g
  • **Compute optimized:** C3 | C4 | C5 | C5a | C5n | C6a | C6g | C6gn | C6i | C6in | C7a | C7g | C7gn | C7i | C7i-flex
  • **Memory optimized:** R3 | R4 | R5 | R5a | R5b | R5n | R6a | R6g | R6i | R6in | R7a | R7g | R7i | R7iz | R8g | u-3tb1 | u-6tb1 | u-9tb1 | u-12tb1 | u-18tb1 | u-24tb1 | u7i-12tb | u7in-16tb | u7in-24tb | u7in-32tb | X1 | X1e | X2iezn
  • **Accelerated computing:** G3 | G3s | G5g | Inf1 | P2 | P3 | VT1
  • **High-performance computing:** Hpc6a | Hpc7a | Hpc7g

⚠️ **Warning**

• Data on instance store volumes will be lost if the instance is stopped. For more information about stopping an instance, see the section called “Instance stop and start”.

• In the event of a systems status check failure, the instance store and block device mapped data might be lost. For these instance types, you can consider using the section called “Enable termination protection”.

We recommend that you regularly create backups of valuable data. For information about backup and recovery best practices for Amazon EC2, see [Best practices for Amazon EC2](#).

**Configure simplified automatic recovery**

Simplified automatic recovery is enabled by default when you launch a supported instance. You can set the automatic recovery behavior to disabled during or after launching the instance. The default configuration doesn't enable simplified automatic recovery for an unsupported instance type.
Console

To disable simplified automatic recovery during instance launch
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then choose Launch instance.
3. In the Advanced details section, for Instance auto-recovery, select Disabled.
4. Configure the remaining instance launch settings as needed and then launch the instance.

To disable simplified automatic recovery for a running or stopped instance
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, and then choose Actions, Instance settings, Change auto-recovery behavior.
4. Choose Off, and then choose Save.

To set the automatic recovery behavior to default for a running or stopped instance
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, and then choose Actions, Instance settings, Change auto-recovery behavior.
4. Choose Default (On), and then choose Save.

AWS CLI

To disable simplified automatic recovery at launch
Use the run-instances command.

```
aws ec2 run-instances \
--image-id ami-1a2b3c4d \
--instance-type t2.micro \
--key-name MyKeyPair \
--maintenance-options AutoRecovery=Disabled \
[...]
```
To disable simplified automatic recovery for a running or stopped instance

Use the `modify-instance-maintenance-options` command.

```bash
aws ec2 modify-instance-maintenance-options \
--instance-id i-0abcdef1234567890 \
--auto-recovery disabled
```

To set the automatic recovery behavior to default for a running or stopped instance

Use the `modify-instance-maintenance-options` command.

```bash
aws ec2 modify-instance-maintenance-options \
--instance-id i-0abcdef1234567890 \
--auto-recovery default
```

**Troubleshooting simplified automatic recovery failures**

The following issues can cause the recovery of your instance with simplified automatic recovery to fail:

- Simplified automatic recovery does not operate during service events in the AWS Health Dashboard. You might not receive recovery failure notifications for such events. For the latest service availability information, see the [Service health](#) status page.
- Temporary, insufficient capacity of replacement hardware.
- The instance has reached the maximum daily allowance for recovery attempts. Your instance might subsequently be retired if automatic recovery fails and a hardware degradation is determined to be the root cause for the original system status check failure.

If the instance’s system status check failure persists despite multiple recovery attempts, see [Troubleshoot instances with failed status checks](#) for additional guidance.

**Work with instance metadata**

*Instance metadata* is data about your instance that you can use to configure or manage the running instance. Instance metadata is divided into *categories*, for example, host name, events, and security groups.
You can also use instance metadata to access user data that you specified when launching your instance. For example, you can specify parameters for configuring your instance, or include a simple script. You can also build generic AMIs and use user data to modify the configuration files supplied at launch time. For example, if you run web servers for various small businesses, they can all use the same generic AMI and retrieve their content from a Amazon S3 bucket that you specify in the user data at launch. To add a new customer at any time, create a bucket for the customer, add their content, and launch your AMI with the unique bucket name provided to your code in the user data. If you launch multiple instances using the same RunInstances call, the user data is available to all instances in that reservation. Each instance that is part of the same reservation has a unique ami-launch-index number, so that you can write code that controls what the instances do. For example, the first host might elect itself as the original node in a cluster. For a detailed AMI launch example, see Linux example: AMI launch index value.

EC2 instances can also include dynamic data, such as an instance identity document that is generated when the instance is launched. For more information, see Dynamic data categories.

⚠️ Important

Although you can only access instance metadata and user data from within the instance itself, the data is not protected by authentication or cryptographic methods. Anyone who has direct access to the instance, and potentially any software running on the instance, can view its metadata. Therefore, you should not store sensitive data, such as passwords or long-lived encryption keys, as user data.

- Linux example: AMI launch index value
- Instance identity documents for Amazon EC2 instances
Use IMDSv2

You can access instance metadata from a running instance using one of the following methods:

- Instance Metadata Service Version 1 (IMDSv1) – a request/response method
- Instance Metadata Service Version 2 (IMDSv2) – a session-oriented method

By default, you can use either IMDSv1 or IMDSv2, or both.

You can configure the Instance Metadata Service (IMDS) on each instance so that local code or users must use IMDSv2. When you specify that IMDSv2 must be used, IMDSv1 no longer works. For information about how to configure your instance to use IMDSv2, see Configure the instance metadata options.

The PUT or GET headers are unique to IMDSv2. If these headers are present in the request, then the request is intended for IMDSv2. If no headers are present, it is assumed the request is intended for IMDSv1.

For an extensive review of IMDSv2, see Add defense in depth against open firewalls, reverse proxies, and SSRF vulnerabilities with enhancements to the EC2 Instance Metadata Service.

To retrieve instance metadata, see Retrieve instance metadata.

- How Instance Metadata Service Version 2 works
- Transition to using Instance Metadata Service Version 2
- Use a supported AWS SDK

How Instance Metadata Service Version 2 works

IMDSv2 uses session-oriented requests. With session-oriented requests, you create a session token that defines the session duration, which can be a minimum of one second and a maximum of six hours. During the specified duration, you can use the same session token for subsequent requests. After the specified duration expires, you must create a new session token to use for future requests.
The examples in this section use the IPv4 address of the Instance Metadata Service (IMDS): 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: [fd00:ec2::254]. The IPv6 address of the IMDS is compatible with IMDSv2 commands. The IPv6 address is only accessible on instances built on the AWS Nitro System and in an IPv6-supported subnet (dual stack or IPv6 only).

The following examples use a shell script and IMDSv2 to retrieve the top-level instance metadata items. Each example:

- Creates a session token lasting six hours (21,600 seconds) using the PUT request
- Stores the session token header in a variable named TOKEN (Linux instances) or token (Windows instances)
- Requests the top-level metadata items using the token

**Linux example**

You can run two separate commands, or combine them.

**Separate commands**

First, generate a token using the following command.

```bash
```

Then, use the token to generate top-level metadata items using the following command.

```bash
```

**Combined commands**

You can store the token and combine the commands. The following example combines the above two commands and stores the session token header in a variable named TOKEN.
Note
If there is an error in creating the token, instead of a valid token, an error message is stored in the variable, and the command will not work.

After you've created a token, you can reuse it until it expires. In the following example command, which gets the ID of the AMI used to launch the instance, the token that is stored in $TOKEN in the previous example is reused.

Windows example

After you've created a token, you can reuse it until it expires. In the following example command, which gets the ID of the AMI used to launch the instance, the token that is stored in $token in the previous example is reused.

When you use IMDSv2 to request instance metadata, the request must include the following:

1. Use a PUT request to initiate a session to the instance metadata service. The PUT request returns a token that must be included in subsequent GET requests to the instance metadata service. The token is required to access metadata using IMDSv2.
2. Include the token in all GET requests to the IMDS. When token usage is set to required, requests without a valid token or with an expired token receive a 401 - Unauthorized HTTP error code.

- The token is an instance-specific key. The token is not valid on other EC2 instances and will be rejected if you attempt to use it outside of the instance on which it was generated.

- The PUT request must include a header that specifies the time to live (TTL) for the token, in seconds, up to a maximum of six hours (21,600 seconds). The token represents a logical session. The TTL specifies the length of time that the token is valid and, therefore, the duration of the session.

- After a token expires, to continue accessing instance metadata, you must create a new session using another PUT.

- You can choose to reuse a token or create a new token with every request. For a small number of requests, it might be easier to generate and immediately use a token each time you need to access the IMDS. But for efficiency, you can specify a longer duration for the token and reuse it rather than having to write a PUT request every time you need to request instance metadata. There is no practical limit on the number of concurrent tokens, each representing its own session. IMDSv2 is, however, still constrained by normal IMDS connection and throttling limits. For more information, see Query throttling.

HTTP GET and HEAD methods are allowed in IMDSv2 instance metadata requests. PUT requests are rejected if they contain an X-Forwarded-For header.

By default, the response to PUT requests has a response hop limit (time to live) of 1 at the IP protocol level. If you need a bigger hop limit, you can adjust it by using the `modify-instance-metadata-options` AWS CLI command. For example, you might need a bigger hop limit for backward compatibility with container services running on the instance. For more information, see Modify instance metadata options for existing instances.

### Transition to using Instance Metadata Service Version 2

When migrating to IMDSv2, we recommend that you use the following tools and transition path.

**Topics**

- [Tools for helping with the transition to IMDSv2](#)
- [Recommended path to requiring IMDSv2](#)
Tools for helping with the transition to IMDSv2

If your software uses IMDSv1, use the following tools to help reconfigure your software to use IMDSv2.

AWS software

The latest versions of the AWS CLI and AWS SDKs support IMDSv2. To use IMDSv2, make sure that your EC2 instances have the latest versions of the CLI and SDKs. For information about updating the CLI, see [Installing, updating, and uninstalling the AWS CLI](https://docs.aws.amazon.com/cli/latest/userguide/installing.html) in the *AWS Command Line Interface User Guide*.

All Amazon Linux 2 and Amazon Linux 2023 software packages support IMDSv2. In Amazon Linux 2023, IMDSv1 is disabled by default.

For the minimum AWS SDK versions that support IMDSv2, see [Use a supported AWS SDK](https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/imds-supported-versions.html).

IMDS Packet Analyzer

The IMDS Packet Analyzer is an open-sourced tool that identifies and logs IMDSv1 calls from your instance’s boot phase. This can assist in identifying the software making IMDSv1 calls on EC2 instances, allowing you to pinpoint exactly what you need to update to get your instances ready to use IMDSv2 only. You can run IMDS Packet Analyzer from a command line or install it as a service. For more information, see [IMDS Packet Analyzer](https://github.com/aws-imds/imds-packet-analyzer) on GitHub.

CloudWatch

IMDSv2 uses token-backed sessions, while IMDSv1 does not. The MetadataNoToken CloudWatch metric tracks the number of calls to the Instance Metadata Service (IMDS) that are using IMDSv1. By tracking this metric to zero, you can determine if and when all of your software has been upgraded to use IMDSv2.

After you've disabled IMDSv1, you can use the MetadataNoTokenRejected CloudWatch metric to track the number of times an IMDSv1 call was attempted and rejected. By tracking this metric, you can ascertain whether your software call needs to be updated to use IMDSv2.

For more information, see [Instance metrics](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/monitor-instance-metadata.html).

Updates to EC2 APIs and CLIs

For new instances, you can use the RunInstances API to launch new instances that require the use of IMDSv2. For more information, see [Configure instance metadata options for new instances](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/instance-metadata-overview.html#instance-metadata-options).
For existing instances, you can use the `ModifyInstanceMetadataOptions` API to require the use of IMDSv2. For more information, see *Modify instance metadata options for existing instances*.

To require the use of IMDSv2 on all new instances launched by Auto Scaling groups, your Auto Scaling groups can use either a launch template or a launch configuration. When you [create a launch template](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/creating-launch-template.html) or [create a launch configuration](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/creating-launch-configuration.html), you must configure the `MetadataOptions` parameters to require the use of IMDSv2. The Auto Scaling group launches new instances using the new launch template or launch configuration, but existing instances are not affected. For existing instances in an Auto Scaling group, you can use the `ModifyInstanceMetadataOptions` API to require the use of IMDSv2 on the existing instances, or terminate the instances and the Auto Scaling group will launch new replacement instances with the instance metadata options settings that are defined in the new launch template or launch configuration.

**Use an AMI that configures IMDSv2 by default**

When you launch an instance, you can automatically configure it to use IMDSv2 by default (the `HttpTokens` parameter is set to `required`) by launching it with an AMI that is configured with the `ImdsSupport` parameter set to `v2.0`. You can set the `ImdsSupport` parameter to `v2.0` when you register the AMI using the `register-image` CLI command, or you can modify an existing AMI by using the `modify-image-attribute` CLI command. For more information, see *Configure the AMI*.

**IAM policies and SCPs**

You can use an IAM policy or AWS Organizations service control policy (SCP) to control users as follows:

- Can't launch an instance using the `RunInstances` API unless the instance is configured to use IMDSv2.
- Can't modify a running instance using the `ModifyInstanceMetadataOptions` API to re-enable IMDSv1.

The IAM policy or SCP must contain the following IAM condition keys:

- `ec2:MetadataHttpEndpoint`
- `ec2:MetadataHttpPutResponseHopLimit`
- `ec2:MetadataHttpTokens`

If a parameter in the API or CLI call does not match the state specified in the policy that contains the condition key, the API or CLI call fails with an `UnauthorizedOperation` response.
Furthermore, you can choose an additional layer of protection to enforce the change from IMDSv1 to IMDSv2. At the access management layer with respect to the APIs called via EC2 Role credentials, you can use a new condition key in either IAM policies or AWS Organizations service control policies (SCPs). Specifically, by using the condition key `ec2:RoleDelivery` with a value of `2.0` in your IAM policies, API calls made with EC2 Role credentials obtained from IMDSv1 will receive an `UnauthorizedOperation` response. The same thing can be achieved more broadly with that condition required by an SCP. This ensures that credentials delivered via IMDSv1 cannot actually be used to call APIs because any API calls not matching the specified condition will receive an `UnauthorizedOperation` error.

For example IAM policies, see [Work with instance metadata](#). For more information on SCPs, see [Service Control Policies](#) in the *AWS Organizations User Guide*.

**Recommended path to requiring IMDSv2**

Using the above tools, we recommend that you follow this path for transitioning to IMDSv2.

**Step 1: At the start**

Update the SDKs, CLIs, and your software that use Role credentials on their EC2 instances to versions compatible with IMDSv2. For information about updating the CLI, see [Upgrading to the latest version of the AWS CLI](#) in the *AWS Command Line Interface User Guide*.

Then, change your software that directly accesses instance metadata (in other words, that does not use an SDK) using the IMDSv2 requests. You can use the [IMDS Packet Analyzer](#) to identify the software that you need to change to use IMDSv2 requests.

**Step 2: Track your transition progress**

Track your transition progress by using the CloudWatch metric `MetadataNoToken`. This metric shows the number of IMDSv1 calls to the IMDS on your instances. For more information, see [Instance metrics](#).

**Step 3: When there is zero IMDSv1 usage**

When the CloudWatch metric `MetadataNoToken` records zero IMDSv1 usage, your instances are ready to be fully transitioned to using IMDSv2. At this stage, you can do the following:

- **Account default**
You can set IMDSv2 to be required as an account default. When an instance is launched, the instance configuration is automatically set to the account default.

To set the account default, do the following:

- Amazon EC2 console: On the EC2 Dashboard, under **Account attributes, Data protection and security**, for **IMDS defaults**, set **Instance metadata service** to **Enabled** and **Metadata version** to **V2 only (token required)**. For more information, see **Set IMDSv2 as the default for the account**.

**New instances**

When launching a new instance, you can do the following:

- Amazon EC2 console: In the launch instance wizard, set **Metadata accessible** to **Enabled** and **Metadata version** to **V2 only (token required)**. For more information, see **Configure the instance at launch**.

- AWS CLI: Use the **run-instances** CLI command and specify that IMDSv2 is required.

**Existing instances**

For existing instances, you can do the following:

- Amazon EC2 console: On the **Instances** page, select your instance, choose **Actions, Instance settings, Modify instance metadata options**, and for **IMDSv2**, choose **Required**. For more information, see **Require the use of IMDSv2**.

- AWS CLI: Use the **modify-instance-metadata-options** CLI command to specify that only IMDSv2 is to be used.

You can modify the instance metadata options on running instances, and you don't need to restart the instances after modifying the instance metadata options.

**Step 4: Check if your instances are transitioned to IMDSv2**

You can check if any instances are not yet configured to require the use of IMDSv2, in other words, IMDSv2 is still configured as optional1. If any instances are still configured as optional1, you can modify the instance metadata options to make IMDSv2 required by repeating the preceding **Step 3**.
To filter your instances:

- Amazon EC2 console: On the **Instances** page, filter your instances by using the **IMDSv2 = optional** filter. For more information about filtering, see Filter resources using the console. You can also view whether IMDSv2 is required or optional for each instance: In the **Preferences** window, toggle on **IMDSv2** to add the **IMDSv2** column to the **Instances** table.

- AWS CLI: Use the **describe-instances** CLI command and filter by **metadata-options.http-tokens = optional**, as follows:

```
aws ec2 describe-instances --filters "Name=metadata-options.http-tokens,Values=optional" --query "Reservations[*].Instances[*].[InstanceId]" --output text
```

**Step 5: When all of your instances are transitioned to IMDSv2**

The `ec2:MetadataHttpTokens`, `ec2:MetadataHttpPutResponseHopLimit`, and `ec2:MetadataHttpEndpoint` IAM condition keys can be used to control the use of the **RunInstances** and the **ModifyInstanceMetadataOptions** APIs and corresponding CLIs. If a policy is created, and a parameter in the API call does not match the state specified in the policy using the condition key, the API or CLI call fails with an **UnauthorizedOperation** response. For example IAM policies, see Work with instance metadata.

Furthermore, after you've disabled IMDSv1, you can use the MetadataNoTokenRejected CloudWatch metric to track the number of times an IMDSv1 call was attempted and rejected. If, after disabling IMDSv1, you have software that is not working properly and the MetadataNoTokenRejected metric records IMDSv1 calls, it's likely that this software needs to be updated to use IMDSv2.

**Use a supported AWS SDK**

To use IMDSv2, your EC2 instances must use an AWS SDK version that supports using IMDSv2. The latest versions of all the AWS SDKs support using IMDSv2.

⚠️ **Important**

We recommend that you to stay up to date with SDK releases to keep up with the latest features, security updates, and underlying dependencies. Continued use of an unsupported
The following are the minimum versions that support using IMDSv2:

- AWS CLI – 1.16.289
- AWS Tools for Windows PowerShell – 4.0.1.0
- AWS SDK for .NET – 3.3.634.1
- AWS SDK for C++ – 1.7.229
- AWS SDK for Go – 1.25.38
- AWS SDK for Go v2 – 0.19.0
- AWS SDK for Java – 1.11.678
- AWS SDK for Java 2.x – 2.10.21
- AWS SDK for JavaScript in Node.js – 2.722.0
- AWS SDK for PHP – 3.147.7
- AWS SDK for Python (Boto3) – 1.12.6
- AWS SDK for Python (Boto3) – 1.12.6
- AWS SDK for Ruby – 3.79.0

Configure the instance metadata options

The instance metadata service (IMDS) runs locally on every EC2 instance. The instance metadata options refer to a set of configurations that control the accessibility and behavior of the IMDS on an EC2 instance.

You can configure the following instance metadata options on each instance:

**Instance metadata service (IMDS):** enabled | disabled

You can enable or disable the IMDS on an instance. When disabled, you or any code won't be able to access the instance metadata on the instance.

The IMDS has two endpoints on an instance: IPv4 (169.254.169.254) and IPv6 ([fd00:ec2::254]). When you enable the IMDS, the IPv4 endpoint is automatically enabled. If you want to enable the IPv6 endpoint, you need to do so explicitly.
IMDS IPv6 endpoint: enabled | disabled

You can explicitly enable the IPv6 IMDS endpoint on an instance. When the IPv6 endpoint is enabled, the IPv4 endpoint remains enabled. The IPv6 endpoint is only supported on instances built on the AWS Nitro System and in an IPv6-supported subnet (dual stack or IPv6 only).

Metadata version: IMDSv1 or IMDSv2 (token optional) | IMDSv2 only (token required)

When requesting instance metadata, IMDSv2 calls require a token. IMDSv1 calls do not require a token. You can configure an instance to allow either IMDSv1 or IMDSv2 calls (where a token is optional), or to only allow IMDSv2 calls (where a token is required).

Metadata response hop limit: 1–64

The hop limit is the number of network hops that the PUT response is allowed to make. You can set the hop limit to a minimum of 1 and a maximum of 64. In a container environment, we recommend setting the hop limit to 2. For more information, see Considerations.

Access to tags in instance metadata: enabled | disabled

You can enable or disable access to the instance's tags from an instance's metadata. For more information, see View tags for your instances using instance metadata.

Where to configure instance metadata options

Instance metadata options can be configured at different levels, as follows:

- **Account** – You can set default values for the instance metadata options at the account level for each AWS Region. When an instance is launched, the instance metadata options are automatically set to the account-level values. You can change these values at launch. Account-level default values do not affect existing instances.

- **AMI** – You can set the imds-support parameter to v2.0 when you register or modify an AMI. When an instance is launched with this AMI, the instance metadata version is automatically set to IMDSv2 and the hop limit is set to 2.

- **Instance** – You can change all the instance metadata options on an instance at launch, overriding the default settings. You can also change the instance metadata options after launch on a running or stopped instance. Note that changes may be restricted by an IAM or SCP policy.
Order of precedence for instance metadata options

The value for each instance metadata option is determined at instance launch, following a hierarchical order of precedence. The hierarchy, with the highest precedence at the top, is as follows:

- **Precedence 1: Instance configuration at launch** – Values can be specified either in the launch template or in the instance configuration. Any values specified here override values specified at the account level or in the AMI.
- **Precedence 2: Account settings** – If a value is not specified at instance launch, then it is determined by the account-level settings (which are set for each AWS Region). Account-level settings either include a value for each metadata option, or indicate no preference at all.
- **Precedence 3: AMI configuration** – If a value is not specified at instance launch or at the account level, then it is determined by the AMI configuration. This applies only to `HttpTokens` and `HttpPutResponseHopLimit`.

Each metadata option is evaluated separately. The instance can be configured with a mix of direct instance configuration, account-level defaults, and the configuration from the AMI.

You can change the value of any metadata option after launch on a running or stopped instance, unless changes are restricted by an IAM or SCP policy.

**Determine values for metadata options – Example 1**

In this example, an EC2 instance is launched into a Region where the `HttpPutResponseHopLimit` is set to 1 at the account level. The specified AMI has `ImdsSupport` set to `v2.0`. No metadata options are specified directly on the instance at launch. The instance is launched with the following metadata options:

```
"MetadataOptions": {
    ...
    "HttpTokens": "required",
    "HttpPutResponseHopLimit": 1,
    ...
}
```

These values were determined as follows:
• **No metadata options specified at launch:** During the launch of the instance, specific values for the metadata options were not provided either in the instance launch parameters or in the launch template.

• **Account settings take next precedence:** In the absence of specific values specified at launch, the settings at the account level within the Region take precedence. This means that the default values configured at the account level are applied. In this case, the HttpPutResponseHopLimit was set to 1.

• **AMI settings take last precedence:** In the absence of a specific value specified at launch or at the account level for HttpTokens (the instance metadata version), the AMI setting is applied. In this case, the AMI setting ImdsSupport: v2.0 determined that HttpTokens was set to required. Note that while the AMI setting ImdsSupport: v2.0 is designed to set HttpPutResponseHopLimit: 2, it was overridden by the account-level setting HttpPutResponseHopLimit: 1, which has higher precedence.

**Determine values for metadata options – Example 2**

In this example, the EC2 instance is launched with the same settings as in the previous Example 1, but with HttpTokens set to optional directly on the instance at launch. The instance is launched with the following metadata options:

```json
"MetadataOptions": {
  ...
  "HttpTokens": "optional",
  "HttpPutResponseHopLimit": 1,
  ...
}
```

The value for HttpPutResponseHopLimit is determined in the same way as in Example 1. However, the value for HttpTokens is determined as follows: Metadata options configured on the instance at launch take first precedence. Even though the AMI was configured with ImdsSupport: v2.0 (in other words, HttpTokens is set to required), the value specified on the instance at launch (HttpTokens set to optional) took precedence.

**Set the instance metadata version**

When an instance is launched, the value for the instance *metadata version* is either IMDSv1 or IMDSv2 (token optional) or IMDSv2 only (token required).
At instance launch, you can either manually specify the value for the metadata version, or use the default value. If you manually specify the value, it overrides any defaults. If you opt not to manually specify the value, it will be determined by a combination of default settings, as outlined in the following table.

The table shows how the metadata version for an instance at launch (indicated by **Resulting instance configuration** in column 4) is determined by the settings at the different levels of configuration. The order of precedence is from left to right, where the first column takes the highest precedence, as follows:

- **Column 1: Launch parameter** – Represents the setting on the instance that you manually specify at launch.
- **Column 2: Account level default** – Represents the setting for the account.
- **Column 3: AMI default** – Represents the setting on the AMI.

**Use IAM condition keys to restrict instance metadata options**

You can use IAM condition keys in an IAM policy or SCP as follows:

- Allow an instance to launch only if it's configured to require the use of IMDSv2
- Restrict the number of allowed hops
- Turn off access to instance metadata
Tasks

- Configure instance metadata options for new instances
- Modify instance metadata options for existing instances

Note

You should proceed cautiously and conduct careful testing before making any changes. Take note of the following:

- If you enforce the use of IMDSv2, applications or agents that use IMDSv1 for instance metadata access will break.
- If you turn off all access to instance metadata, applications or agents that rely on instance metadata access to function will break.
- For IMDSv2, you must use /latest/api/token when retrieving the token.
- (Windows only) If your PowerShell version is earlier than 4.0, you must update to Windows Management Framework 4.0 to require the use of IMDSv2.

Configure instance metadata options for new instances

You can configure the following instance metadata options for new instances.

Options

- Require the use of IMDSv2
- Enable the IMDS IPv4 and IPv6 endpoints
- Turn off access to instance metadata

Require the use of IMDSv2

You can use the following methods to require the use of IMDSv2 on your new instances.

To require IMDSv2

- Set IMDSv2 as the default for the account
- Configure the instance at launch
- Configure the AMI
Use an IAM policy

Set IMDSv2 as the default for the account

You can set the default version for the instance metadata service (IMDS) at the account level for each AWS Region. This means that when you launch a new instance, the instance metadata version is automatically set to the account-level default. However, you can manually override the value at launch or after launch. For more information about how the account-level settings and manual overrides affect an instance, see Order of precedence for instance metadata options.

Note

Setting the account-level default does not reset existing instances. For example, if you set the account-level default to IMDSv2, any existing instances that are set to IMDSv1 are not affected. If you want to change the value on existing instances, you must manually change the value on the instances themselves.

You can set the account default for the instance metadata version to IMDSv2 so that all new instances in the account launch with IMDSv2 required, and IMDSv1 will be disabled. With this account default, when you launch an instance, the following are the default values for the instance:

- Console: Metadata version is set to V2 only (token required) and Metadata response hop limit is set to 2.
- AWS CLI: HttpTokens is set to required and HttpPutResponseHopLimit is set to 2.

Note

Before setting the account default to IMDSv2, ensure that your instances do not depend on IMDSv1. For more information, see Recommended path to requiring IMDSv2.

Console

To set IMDSv2 as the default for the account for the specified Region

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose EC2 Dashboard.
4. Under Account attributes, choose Data protection and security.
5. Next to IMDS defaults, choose Manage.
6. On the Manage IMDS defaults page, do the following:
   a. For Instance metadata service, choose Enabled.
   b. For Metadata version, choose V2 only (token required).
   c. For Metadata response hop limit, specify 2 if your instances will host containers. Otherwise, select No preference. When no preference is specified, at launch, the value defaults to 2 if the AMI requires IMDSv2; otherwise it defaults to 1.
   d. Choose Update.

AWS CLI

To set IMDSv2 as the default for the account for the specified Region

Use the modify-instance-metadata-defaults command and specify the Region in which to modify the IMDS account level settings. Include --http-tokens set to required and --http-put-response-hop-limit set to 2 if your instances will host containers. Otherwise, specify -1 to indicate no preference. When -1 (no preference) is specified, at launch, the value defaults to 2 if the AMI requires IMDSv2; otherwise it defaults to 1.

```
aws ec2 modify-instance-metadata-defaults \
  --region us-east-1 \n  --http-tokens required \n  --http-put-response-hop-limit 2
```

Expected output

```
{
  "Return": true
}
```

To view the default account settings for the instance metadata options for the specified Region

Use the get-instance-metadata-defaults command and specify the Region.
aws ec2 get-instance-metadata-defaults --region us-east-1

Example output

```json
{
   "AccountLevel": {
      "HttpTokens": "required",
      "HttpPutResponseHopLimit": 2
   }
}
```

PowerShell

To set IMDSv2 as the default for the account for the specified Region

Use the `Edit-EC2InstanceMetadataDefault` command and specify the Region in which to modify the IMDS account level settings. Include `-HttpToken` set to `required` and `-HttpPutResponseHopLimit` set to 2 if your instances will host containers. Otherwise, specify `-1` to indicate no preference. When `-1` (no preference) is specified, at launch, the value defaults to 2 if the AMI requires IMDSv2; otherwise it defaults to 1.

```powershell
Edit-EC2InstanceMetadataDefault `-
   -Region us-east-1 `-
   -HttpToken required `-
   -HttpPutResponseHopLimit 2
```

Expected output

```
True
```

To view the default account settings for the instance metadata options for the specified Region

Use the `Get-EC2InstanceMetadataDefault` command and specify the Region.

```powershell
Get-EC2InstanceMetadataDefault -Region us-east-1 | Format-List
```

Example output

```
HttpEndpoint : 
```
### Configure the instance at launch

When you **launch an instance**, you can configure the instance to require the use of IMDSv2 by configuring the following fields:

- Amazon EC2 console: Set **Metadata version** to **V2 only (token required)**.
- AWS CLI: Set **HttpTokens** to **required**.

When you specify that IMDSv2 is required, you must also enable the Instance Metadata Service (IMDS) endpoint by setting **Metadata accessible** to **Enabled** (console) or **HttpEndpoint** to enabled (AWS CLI).

In a container environment, when IMDSv2 is required, we recommend setting the hop limit to 2. For more information, see [Considerations](#).

#### New console

**To require the use of IMDSv2 on a new instance**

- When launching a new instance in the Amazon EC2 console, expand **Advanced details**, and do the following:
  - For **Metadata accessible**, choose **Enabled**.
  - For **Metadata version**, choose **V2 only (token required)**.
  - (Container environment) For **Metadata response hop limit**, choose **2**.

  For more information, see [Advanced details](#).

#### Old console

**To require the use of IMDSv2 on a new instance**

- When launching a new instance in the Amazon EC2 console, select the following options on the **Configure Instance Details** page:
- Under **Advanced Details**, for **Metadata accessible**, select **Enabled**.

- For **Metadata version**, select **V2 (token required)**.

For more information, see [Step 3: Configure Instance Details](#).

**AWS CLI**

**To require the use of IMDSv2 on a new instance**

The following `run-instances` example launches a `c6i.large` instance with `--metadata-options` set to `HttpTokens=required`. When you specify a value for `HttpTokens`, you must also set `HttpEndpoint` to `enabled`. Because the secure token header is set to `required` for metadata retrieval requests, this requires the instance to use IMDSv2 when requesting instance metadata.

In a container environment, when IMDSv2 is required, we recommend setting the hop limit to 2 with `HttpPutResponseHopLimit=2`.

```
aws ec2 run-instances \
   --image-id ami-0abcdef1234567890 \
   --instance-type c6i.large \
   ... \
   --metadata-options "HttpEndpoint=enabled,HttpTokens=required,HttpPutResponseHopLimit=2"
```

**PowerShell**

**To require the use of IMDSv2 on a new instance**

The following `New-EC2Instance` Cmdlet example launches a `c6i.large` instance with `MetadataOptions_HttpEndpoint` set to `enabled` and the `MetadataOptions_HttpTokens` parameter to `required`. When you specify a value for `HttpTokens`, you must also set `HttpEndpoint` to `enabled`. Because the secure token header is set to `required` for metadata retrieval requests, this requires the instance to use IMDSv2 when requesting instance metadata.

```
New-EC2Instance `\n   -ImageId ami-0abcdef1234567890 `\n   -InstanceType c6i.large `\n```
AWS CloudFormation

To specify the metadata options for an instance using AWS CloudFormation, see the `AWS::EC2::LaunchTemplate MetadataOptions` property in the *AWS CloudFormation User Guide*.

Configure the AMI

When you register a new AMI or modify an existing AMI, you can set the `imds-support` parameter to `v2.0`. Instances launched from this AMI will have `Metadata version` set to **V2 only (token required)** (console) or `HttpTokens` set to `required` (AWS CLI). With these settings, the instance requires that IMDSv2 is used when requesting instance metadata.

Note that when you set `imds-support` to `v2.0`, instances launched from this AMI will also have `Metadata response hop limit` (console) or `http-put-response-hop-limit` (AWS CLI) set to **2**.

> **Important**
> Do not use this parameter unless your AMI software supports IMDSv2. After you set the value to `v2.0`, you can't undo it. The only way to "reset" your AMI is to create a new AMI from the underlying snapshot.

To configure a new AMI for IMDSv2

Use one of the following methods to configure a new AMI for IMDSv2.

AWS CLI

The following `register-image` example registers an AMI using the specified snapshot of an EBS root volume as device `/dev/xvda`. Specify `v2.0` for the `imds-support` parameter so that instances launched from this AMI will require that IMDSv2 is used when requesting instance metadata.

```
aws ec2 register-image \
   --name my-image \
   --root-device-name /dev/xvda 
```
PowerShell

The following `Register-EC2Image` Cmdlet example registers an AMI using the specified snapshot of an EBS root volume as device `/dev/xvda`. Specify v2.0 for the `ImdsSupport` parameter so that instances launched from this AMI will require that IMDSv2 is used when requesting instance metadata.

```
Register-EC2Image 
-Name 'my-image' 
-RootDeviceName /dev/xvda 
-BlockDeviceMapping ( 
    New-Object 
        -TypeName Amazon.EC2.Model.BlockDeviceMapping 
        -Property @{
            DeviceName = '/dev/xvda';
            EBS = (New-Object -TypeName Amazon.EC2.Model.EbsBlockDevice -Property @{
                SnapshotId = 'snap-0123456789example'
                VolumeType = 'gp3'
            })
        } ) 
-Architecture X86_64 
-ImdsSupport v2.0
```

To configure an existing AMI for IMDSv2

Use one of the following methods to configure an existing AMI for IMDSv2.

AWS CLI

The following `modify-image-attribute` example modifies an existing AMI for IMDSv2 only. Specify v2.0 for the `imds-support` parameter so that instances launched from this AMI will require that IMDSv2 is used when requesting instance metadata.

```
aws ec2 modify-image-attribute 
    --image-id ami-0123456789example 
```
PowerShell

The following Edit-EC2ImageAttribute Cmdlet example modifies an existing AMI for IMDSv2 only. Specify v2.0 for the imds-support parameter so that instances launched from this AMI will require that IMDSv2 is used when requesting instance metadata.

```
Edit-EC2ImageAttribute `-
-ImageId ami-0abcdef1234567890 `-
-ImdsSupport 'v2.0'
```

Use an IAM policy

You can create an IAM policy that prevents users from launching new instances unless they require IMDSv2 on the new instance.

To enforce the use of IMDSv2 on all new instances by using an IAM policy

To ensure that users can only launch instances that require the use of IMDSv2 when requesting instance metadata, you can specify that the condition to require IMDSv2 must be met before an instance can be launched. For the example IAM policy, see Work with instance metadata.

Enable the IMDS IPv4 and IPv6 endpoints

The IMDS has two endpoints on an instance: IPv4 (169.254.169.254) and IPv6 ([fd00:ec2::254]). When you enable the IMDS, the IPv4 endpoint is automatically enabled. The IPv6 endpoint remains disabled even if you launch an instance into an IPv6-only subnet. To enable the IPv6 endpoint, you need to do so explicitly. When you enable the IPv6 endpoint, the IPv4 endpoint remains enabled.

You can enable the IPv6 endpoint at instance launch or after.

Requirements for enabling the IPv6 endpoint

- The selected instance type is built on the AWS Nitro System.
- The selected subnet supports IPv6, where the subnet is either dual stack or IPv6 only.

Use any of the following methods to launch an instance with the IMDS IPv6 endpoint enabled.
New console

To enable the IMDS IPv6 endpoint at instance launch

- Launch the instance in the Amazon EC2 console with the following specified under Advanced details:
  - For Metadata IPv6 endpoint, choose Enabled.

For more information, see Advanced details.

AWS CLI

To enable the IMDS IPv6 endpoint at instance launch

The following run-instances example launches a c6i.large instance with the IPv6 endpoint enabled for the IMDS. To enable the IPv6 endpoint, for the --metadata-options parameter, specify HttpProtocolIpv6=enabled. When you specify a value for HttpProtocolIpv6, you must also set HttpEndpoint to enabled.

```
aws ec2 run-instances \
  --image-id ami-0abcdef1234567890 \
  --instance-type c6i.large \
  ... \
  --metadata-options "HttpEndpoint=enabled,HttpProtocolIpv6=enabled"
```

PowerShell

To enable the IMDS IPv6 endpoint at instance launch

The following New-EC2Instance Cmdlet example launches a c6i.large instance with the IPv6 endpoint enabled for the IMDS. To enable the IPv6 endpoint, specify MetadataOptions_HttpProtocolIpv6 as enabled. When you specify a value for MetadataOptions_HttpProtocolIpv6, you must also set MetadataOptions_HttpEndpoint to enabled.

```
New-EC2Instance ` 
  -ImageId ami-0abcdef1234567890 ` 
  -InstanceType c6i.large ` 
  -MetadataOptions_HttpEndpoint enabled ` 
  -MetadataOptions_HttpProtocolIpv6 enabled
```
Turn off access to instance metadata

You can turn off access to the instance metadata by disabling the IMDS when you launch an instance. You can turn on access later by re-enabling the IMDS. For more information, see Turn on access to instance metadata.

⚠️ Important

You can choose to disable the IMDS at launch or after launch. If you disable the IMDS at launch, the following might not work:

- You might not have SSH access to your instance. The public-keys/0/openssh-key, which is your instance's public SSH key, will not be accessible because the key is normally provided and accessed from EC2 instance metadata.
- EC2 user data will not be available and will not run at instance start. EC2 user data is hosted on the IMDS. If you disable the IMDS, you effectively turn off access to user data.

To access this functionality, you can re-enable the IMDS after launch.

New console

To turn off access to instance metadata at launch

- Launch the instance in the Amazon EC2 console with the following specified under Advanced details:
  - For Metadata accessible, choose Disabled.

For more information, see Advanced details.

Old console

To turn off access to instance metadata at launch

- Launch the instance in the Amazon EC2 console with the following option selected on the Configure Instance Details page:
  - Under Advanced Details, for Metadata accessible, select Disabled.
For more information, see Step 3: Configure Instance Details.

AWS CLI

**To turn off access to instance metadata at launch**

Launch the instance with `--metadata-options` set to `HttpEndpoint=disabled`.

```
aws ec2 run-instances  
    --image-id ami-0abcdef1234567890  
    --instance-type c6i.large  
    ...  
    --metadata-options "HttpEndpoint=disabled"
```

PowerShell

**To turn off access to instance metadata at launch**

The following `New-EC2Instance` Cmdlet example launches an instance with `MetadataOptions_HttpEndpoint` set to `disabled`.

```
New-EC2Instance  
    -ImageId ami-0abcdef1234567890  
    -InstanceType c6i.large  
    -MetadataOptions_HttpEndpoint disabled
```

AWS CloudFormation

To specify the metadata options for an instance using AWS CloudFormation, see the `AWS::EC2::LaunchTemplate MetadataOptions` property in the AWS CloudFormation User Guide.

**Modify instance metadata options for existing instances**

You can modify the instance metadata options for existing instances.

You can also create an IAM policy that prevents users from modifying the instance metadata options on existing instances. To control which users can modify the instance metadata options, specify a policy that prevents all users other than users with a specified role to use the `ModifyInstanceMetadataOptions` API. For the example IAM policy, see Work with instance metadata.
Query instance metadata options for existing instances

You can query the instance metadata options for your existing instances by using one of the following methods.

Console

To query the instance metadata options for an existing instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select your instance.
4. Choose Actions, Instance settings, Modify instance metadata options.
5. Review the current instance metadata options in the Modify instance metadata options dialog box.

AWS CLI

To query the instance metadata options for an existing instance using the AWS CLI

Use the describe-instances CLI command.

```
aws ec2 describe-instances \
   --instance-id i-1234567898abcdef0 \
   --query 'Reservations[].Instances[].MetadataOptions'
```

PowerShell

To query the instance metadata options for an existing instance using the Tools for PowerShell

Use the Get-EC2Instance Cmdlet.

```
(Get-EC2Instance `\n   -InstanceId i-1234567898abcdef0).Instances_MetadataOptions
```
Require the use of IMDSv2

Use one of the following methods to modify the instance metadata options on an existing instance to require that IMDSv2 is used when requesting instance metadata. When IMDSv2 is required, IMDSv1 cannot be used.

**Note**

Before requiring that IMDSv2 is used, ensure that the instance isn't making IMDSv1 calls. The `MetadataNoToken` CloudWatch metric tracks IMDSv1 calls. When `MetadataNoToken` records zero IMDSv1 usage for an instance, the instance is then ready to require IMDSv2.

**Console**

**To require the use of IMDSv2 on an existing instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select your instance.
4. Choose **Actions, Instance settings, Modify instance metadata options**.
5. In the **Modify instance metadata options** dialog box, do the following:
   a. For **Instance metadata service**, select **Enable**.
   b. For **IMDSv2**, choose **Required**.
   c. Choose **Save**.

**AWS CLI**

**To require the use of IMDSv2 on an existing instance**

Use the `modify-instance-metadata-options` CLI command and set the `http-tokens` parameter to `required`. When you specify a value for `http-tokens`, you must also set `http-endpoint` to `enabled`.

```bash
aws ec2 modify-instance-metadata-options \
   --instance-id i-1234567898abcdef0 \
   --http-tokens required
```
PowerShell

To require the use of IMDSv2 on an existing instance

Use the Edit-EC2InstanceMetadataOption Cmdlet and set the HttpTokens parameter to required. When you specify a value for HttpTokens, you must also set HttpEndpoint to enabled.

```
(Edit-EC2InstanceMetadataOption `  
  -InstanceId i-1234567898abcdef0 `  
  -HttpTokens required `  
  -HttpEndpoint enabled).InstanceMetadataOptions
```

Restore the use of IMDSv1

When IMDSv2 is required, IMDSv1 will not work when requesting instance metadata. When IMDSv2 is optional, then both IMDSv2 and IMDSv1 will work. Therefore, to restore IMDSv1, make IMDSv2 optional by using one of the following methods.

Console

To restore the use of IMDSv1 on an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select your instance.
4. Choose Actions, Instance settings, Modify instance metadata options.
5. In the Modify instance metadata options dialog box, do the following:
   a. For Instance metadata service, make sure that Enable is selected.
   b. For IMDSv2, choose Optional.
   c. Choose Save.

AWS CLI

To restore the use of IMDSv1 on an instance
You can use the `modify-instance-metadata-options` CLI command with `http-tokens` set to `optional` to restore the use of IMDSv1 when requesting instance metadata.

```
aws ec2 modify-instance-metadata-options \
   --instance-id i-1234567898abcdef0 \
   --http-tokens optional \
   --http-endpoint enabled
```

**PowerShell**

**To restore the use of IMDSv1 on an instance**

You can use the `Edit-EC2InstanceMetadataOption` Cmdlet with `HttpTokens` set to `optional` to restore the use of IMDSv1 when requesting instance metadata.

```
(Edit-EC2InstanceMetadataOption `\`
   -InstanceId i-1234567898abcdef0 `\`
   -HttpTokens optional `\`
   -HttpEndpoint enabled).InstanceMetadataOptions
```

**Change the PUT response hop limit**

For existing instances, you can change the settings of the PUT response hop limit.

Currently only the AWS CLI and AWS SDKs support changing the PUT response hop limit.

**AWS CLI**

**To change the PUT response hop limit**

Use the `modify-instance-metadata-options` CLI command and set the `http-put-response-hop-limit` parameter to the required number of hops. In the following example, the hop limit is set to 3. Note that when specifying a value for `http-put-response-hop-limit`, you must also set `http-endpoint` to `enabled`.

```
aws ec2 modify-instance-metadata-options \
   --instance-id i-1234567898abcdef0 \
   --http-put-response-hop-limit 3 \
   --http-endpoint enabled
```
PowerShell

To change the PUT response hop limit

Use the `Edit-EC2InstanceMetadataOption` Cmdlet and set the `HttpPutResponseHopLimit` parameter to the required number of hops. In the following example, the hop limit is set to 3. Note that when specifying a value for `HttpPutResponseHopLimit`, you must also set `HttpEndpoint` to enabled.

```powershell
(Edit-EC2InstanceMetadataOption
   -InstanceId i-1234567898abcdef0
   -HttpPutResponseHopLimit 3
   -HttpEndpoint enabled).InstanceMetadataOptions
```

Enable the IMDS IPv4 and IPv6 endpoints

The IMDS has two endpoints on an instance: IPv4 (169.254.169.254) and IPv6 ([fd00:ec2::254]). When you enable the IMDS, the IPv4 endpoint is automatically enabled. The IPv6 endpoint remains disabled even if you launch an instance into an IPv6-only subnet. To enable the IPv6 endpoint, you need to do so explicitly. When you enable the IPv6 endpoint, the IPv4 endpoint remains enabled.

You can enable the IPv6 endpoint at instance launch or after.

Requirements for enabling the IPv6 endpoint

- The selected instance type is built on the AWS Nitro System.
- The selected subnet supports IPv6, where the subnet is either dual stack or IPv6 only.

Currently only the AWS CLI and AWS SDKs support enabling the IMDS IPv6 endpoint after instance launch.

AWS CLI

To enable the IMDS IPv6 endpoint for your instance

Use the `modify-instance-metadata-options` CLI command and set the `http-protocol-ipv6` parameter to enabled. Note that when specifying a value for `http-protocol-ipv6`, you must also set `http-endpoint` to enabled.
To enable the IMDS IPv6 endpoint for your instance

Use the `Edit-EC2InstanceMetadataOption` Cmdlet and set the `HttpProtocolIPv6` parameter to enabled. Note that when specifying a value for `HttpProtocolIPv6`, you must also set `HttpEndpoint` to enabled.

```powershell
(Edit-EC2InstanceMetadataOption -InstanceId i-1234567898abcdef0 -HttpProtocolIPv6 enabled -HttpEndpoint enabled).InstanceMetadataOptions
```

Turn on access to instance metadata

You can turn on access to instance metadata by enabling the HTTP endpoint of the IMDS on your instance, regardless of which version of the IMDS you are using. You can reverse this change at any time by disabling the HTTP endpoint.

Use one of the following methods to turn on access to instance metadata on an instance.

Console

**To turn on access to instance metadata**

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose **Instances**.
3. Select your instance.
4. Choose **Actions, Instance settings, Modify instance metadata options**.
5. In the **Modify instance metadata options** dialog box, do the following:
   a. For **Instance metadata service**, select **Enable**.
   b. Choose **Save**.
AWS CLI

To turn on access to instance metadata

Use the `modify-instance-metadata-options` CLI command and set the `http-endpoint` parameter to enabled.

```
aws ec2 modify-instance-metadata-options \
  --instance-id i-1234567898abcdef0 \
  --http-endpoint enabled
```

PowerShell

To turn on access to instance metadata

Use the `Edit-EC2InstanceMetadataOption` Cmdlet and set the `HttpEndpoint` parameter to enabled.

```
(Edit-EC2InstanceMetadataOption `\n  -InstanceId i-1234567898abcdef0 `\n  -HttpEndpoint enabled).InstanceMetadataOptions
```

Turn off access to instance metadata

You can turn off access to instance metadata by disabling the HTTP endpoint of the IMDS on your instance, regardless of which version of the IMDS you are using. You can reverse this change at any time by enabling the HTTP endpoint.

Use one of the following methods to turn off access to instance metadata on an instance.

Console

To turn off access to instance metadata

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose Instances.
3. Select your instance.
4. Choose Actions, Instance settings, Modify instance metadata options.
5. In the Modify instance metadata options dialog box, do the following:
a. For **Instance metadata service**, clear **Enable**.

b. Choose **Save**.

**AWS CLI**

**To turn off access to instance metadata**

Use the `modify-instance-metadata-options` CLI command and set the `http-endpoint` parameter to `disabled`.

```
aws ec2 modify-instance-metadata-options \
    --instance-id i-1234567898abcdef0 \
    --http-endpoint disabled
```

**PowerShell**

**To turn off access to instance metadata**

Use the `Edit-EC2InstanceMetadataOption` Cmdlet and set the `HttpEndpoint` parameter to `disabled`.

```
(Edit-EC2InstanceMetadataOption `\n    -InstanceId i-1234567898abcdef0 `\n    -HttpEndpoint disabled).InstanceMetadataOptions
```

**Retrieve instance metadata**

Because your instance metadata is available from your running instance, you do not need to use the Amazon EC2 console or the AWS CLI. This can be helpful when you’re writing scripts to run from your instance. For example, you can access the local IP address of your instance from instance metadata to manage a connection to an external application.

Instance metadata is divided into categories. For a description of each instance metadata category, see [Instance metadata categories](#).

To view all categories of instance metadata from within a running instance, get the data from the following IPv4 or IPv6 URLs. These IP addresses are link-local addresses and are valid only from the instance. For more information, see [Link-local addresses](#).
IPv4

IPv6

http://[fd00:ec2::254]/latest/meta-data/

Pricing

You are not billed for HTTP requests used to retrieve instance metadata and user data.

Considerations

To avoid problems with instance metadata retrieval, consider the following.

Command format

The command format is different, depending on whether you use IMDSv1 or IMDSv2. By default, you can use both versions of the IMDS. To require the use of IMDSv2, see Use IMDSv2.

(IMDSv2) If IMDSv2 is required, IMDSv1 does not work

To check whether IMDSv2 is required, select the instance to view its details. The value for IMDSv2 is either Required (you must use IMDSv2) or Optional (you can use either IMDSv2 or IMDSv1).

(IMDSv2) Use /latest/api/token to retrieve the token

Issuing PUT requests to any version-specific path, for example /2021-03-23/api/token, results in the metadata service returning 403 Forbidden errors. This behavior is intended.

IPv6 support

To retrieve instance metadata using IPv6 address, ensure that you enable and use [fd00:ec2::254] instead of the IPv4 address. The instance must be built on the AWS Nitro System and launched in a subnet that supports IPv6.

(Windows) Create custom AMIs using Windows Sysprep

To ensure that IMDS works when you launch an instance from a custom Windows AMI, the AMI must be a standardized image created with Windows Sysprep. Otherwise, the IMDS won't work. For more information, see Use EC2 launch agents to create an AMI with Windows Sysprep.
In a container environment, set the hop limit to 2

The AWS SDKs use IMDSv2 calls by default. If the IMDSv2 call receives no response, the SDK retries the call and, if still unsuccessful, uses IMDSv1. This can result in a delay, especially in a container environment. In a container environment, if the hop limit is 1, the IMDSv2 response does not return because going to the container is considered an additional network hop. To avoid the process of falling back to IMDSv1 and the resultant delay, in a container environment we recommend that you set the hop limit to 2. For more information, see Configure the instance metadata options.

Metadata version

To avoid having to update your code every time Amazon EC2 releases a new instance metadata build, we recommend that you use latest in the path, and not the version number.

Responses and error messages

All instance metadata is returned as text (HTTP content type text/plain).

A request for a specific metadata resource returns the appropriate value, or a 404 - Not Found HTTP error code if the resource is not available.

A request for a general metadata resource (the URI ends with a /) returns a list of available resources, or a 404 - Not Found HTTP error code if there is no such resource. The list items are on separate lines, terminated by line feeds (ASCII 10).

For requests made using Instance Metadata Service Version 2, the following HTTP error codes can be returned:

- 400 - Missing or Invalid Parameters – The PUT request is not valid.
- 401 - Unauthorized – The GET request uses an invalid token. The recommended action is to generate a new token.
- 403 - Forbidden – The request is not allowed or the IMDS is turned off.

Examples for IMDSv2

Run the following examples on your Amazon EC2 instance to retrieve the instance metadata for IMDSv2.
On Windows instances, you can use Windows PowerShell or you can install cURL or wget. If you install a third-party tool on a Windows instance, ensure that you read the accompanying documentation carefully, as the calls and the output might be different from what is described here.

Examples

- Get the available versions of the instance metadata
- Get the top-level metadata items
- Get the values for metadata items
- Get the list of available public keys
- Show the formats in which public key 0 is available
- Get public key 0 (in the OpenSSH key format)
- Get the subnet ID for an instance
- Get the instance tags for an instance

Get the available versions of the instance metadata

This example gets the available versions of the instance metadata. Each version refers to an instance metadata build when new instance metadata categories were released. The instance metadata build versions do not correlate with the Amazon EC2 API versions. The earlier versions are available to you in case you have scripts that rely on the structure and information present in a previous version.

Retrieve instance metadata
Retrieve instance metadata

PowerShell

subnet-be9b61d7

Get the subnet ID for an instance

This example gets the subnet ID for an instance.

cURL

subnet-be9b61d7
Get the instance tags for an instance

If access to instance tags in the instance metadata is turned on, you can get the tags for an instance from instance metadata. For more information, see Retrieve tags from instance metadata.

Query throttling

We throttle queries to the IMDS on a per-instance basis, and we place limits on the number of simultaneous connections from an instance to the IMDS.

If you're using the IMDS to retrieve AWS security credentials, avoid querying for credentials during every transaction or concurrently from a high number of threads or processes, as this might lead to throttling. Instead, we recommend that you cache the credentials until they start approaching their expiry time. For more information about IAM role and security credentials associated with the role, see Retrieve security credentials from instance metadata.

If you are throttled while accessing the IMDS, retry your query with an exponential backoff strategy.

Limit IMDS access

You can consider using local firewall rules to disable access from some or all processes to the IMDS.

For instances built on the AWS Nitro System, the IMDS can be reached from your own network when a network appliance within your VPC, such as a virtual router, forwards packets to the IMDS address, and the default source/destination check on the instance is disabled. To prevent a source from outside your VPC reaching the IMDS, we recommend that you modify the configuration of the network appliance to drop packets with the destination IPv4 address of the IMDS 169.254.169.254 and, if you enabled the IPv6 endpoint, the IPv6 address of the IMDS [fd00:ec2::254].

Linux instances

Using iptables to limit access

The following example uses Linux iptables and its owner module to prevent the Apache webserver (based on its default installation user ID of apache) from accessing 169.254.169.254. It uses a deny rule to reject all instance metadata requests (whether IMDSv1 or IMDSv2) from any process running as that user.
$ sudo iptables --append OUTPUT --proto tcp --destination 169.254.169.254 --match owner --uid-owner apache --jump REJECT

Or, you can consider only allowing access to particular users or groups, by using allow rules. Allow rules might be easier to manage from a security perspective, because they require you to make a decision about what software needs access to instance metadata. If you use allow rules, it's less likely you will accidentally allow software to access the metadata service (that you did not intend to have access) if you later change the software or configuration on an instance. You can also combine group usage with allow rules, so that you can add and remove users from a permitted group without needing to change the firewall rule.

The following example prevents access to the IMDS by all processes, except for processes running in the user account trustworthy-user.

$ sudo iptables --append OUTPUT --proto tcp --destination 169.254.169.254 --match owner ! --uid-owner trustworthy-user --jump REJECT

**Note**

- To use local firewall rules, you need to adapt the preceding example commands to suit your needs.
- By default, iptables rules are not persistent across system reboots. They can be made to be persistent by using OS features, not described here.
- The iptables owner module only matches group membership if the group is the primary group of a given local user. Other groups are not matched.

**Using PF or IPFW to limit access**

If you are using FreeBSD or OpenBSD, you can also consider using PF or IPFW. The following examples limit access to the IMDS to just the root user.

**PF**

$ block out inet proto tcp from any to 169.254.169.254

$ pass out inet proto tcp from any to 169.254.169.254 user root
**IPFW**

```
$ allow tcp from any to 169.254.169.254 uid root
```

```
$ deny tcp from any to 169.254.169.254
```

**Note**

The order of the PF and IPFW commands matter. PF defaults to last matching rule and IPFW defaults to first matching rule.

---

**Windows instances**

**Using Windows firewall to limit access**

The following PowerShell example uses the built-in Windows firewall to prevent the Internet Information Server webserver (based on its default installation user ID of NT AUTHORITY\IUSR) from accessing 169.254.169.254. It uses a *deny rule* to reject all instance metadata requests (whether IMDSv1 or IMDSv2) from any process running as that user.

```
PS C:\> $blockPrincipal = New-Object -TypeName System.Security.Principal.NTAccount ("NT AUTHORITY\IUSR")
PS C:\> $BlockPrincipalSID = $blockPrincipal.Translate([System.Security.Principal.SecurityIdentifier]).Value
PS C:\> $BlockPrincipalSDDL = "D:(A;;CC;;;$BlockPrincipalSID)"
PS C:\> New-NetFirewallRule -DisplayName "Block metadata service from IIS" -Action block -Direction out -Protocol TCP -RemoteAddress 169.254.169.254 -LocalUser $BlockPrincipalSDDL
```

Or, you can consider only allowing access to particular users or groups, by using *allow rules*. Allow rules might be easier to manage from a security perspective, because they require you to make a decision about what software needs access to instance metadata. If you use *allow rules*, it's less likely you will accidentally allow software to access the metadata service (that you did not intend to have access) if you later change the software or configuration on an instance. You can also combine group usage with allow rules, so that you can add and remove users from a permitted group without needing to change the firewall rule.
The following example prevents access to instance metadata by all processes running as an OS group specified in the variable `blockPrincipal` (in this example, the Windows group Everyone), except for processes specified in `exceptionPrincipal` (in this example, a group called `trustworthy-users`). You must specify both deny and allow principals because Windows Firewall, unlike the `! --uid-owner trustworthy-user` rule in Linux iptables, does not provide a shortcut mechanism to allow only a particular principal (user or group) by denying all the others.

```powershell
PS C:\> $blockPrincipal = New-Object -TypeName System.Security.Principal.NTAccount("Everyone")
PS C:\> $BlockPrincipalSID = $blockPrincipal.Translate([System.Security.Principal.SecurityIdentifier]).Value
PS C:\> $exceptionPrincipal = New-Object -TypeName System.Security.Principal.NTAccount("trustworthy-users")
PS C:\> $ExceptionPrincipalSID = $exceptionPrincipal.Translate([System.Security.Principal.SecurityIdentifier]).Value
PS C:\> $PrincipalSDDL = "O:LSD:(D;;CC;;;$ExceptionPrincipalSID)(A;;CC;;;$BlockPrincipalSID)"
PS C:\> New-NetFirewallRule -DisplayName "Block metadata service for $($blockPrincipal.Value), exception: $($exceptionPrincipal.Value)" -Action block -Direction out -Protocol TCP -RemoteAddress 169.254.169.254 -LocalUser $PrincipalSDDL
```

**Note**
To use local firewall rules, you need to adapt the preceding example commands to suit your needs.

**Using netsh rules to limit access**
You can consider blocking all software using `netsh` rules, but those are much less flexible.

```powershell
C:\> netsh advfirewall firewall add rule name="Block metadata service altogether" dir=out protocol=TCP remoteip=169.254.169.254 action=block
```

**Note**
- To use local firewall rules, you need to adapt the preceding example commands to suit your needs.
netsh rules must be set from an elevated command prompt, and can't be set to deny or allow particular principals.

Work with instance user data

You can use instance user data to customize your instances. When you launch an instance, you can store parameters or scripts as user data. Any scripts in user data are run when you launch the instance. You can view user data as an instance attribute. You can also view user data from your instance through the Instance Metadata Service (IMDS).

Considerations

- User data is treated as opaque data: what you specify is what you get back upon retrieval. It is up to the instance to interpret and act on user data.
- User data must be base64-encoded. Depending on the tool or SDK that you're using, the base64-encoding might be performed for you. For example:
  - The Amazon EC2 console can perform the base64-encoding for you or accept base64-encoded input.
  - AWS CLI version 2 performs base64-encoding of binary parameters for you by default. AWS CLI version 1 performs the base64-encoding of the --user-data parameter for you.
  - The AWS SDK for Python (Boto3) performs base64-encoding of the UserData parameter for you.
- User data is limited to 16 KB, in raw form, before it is base64-encoded. The size of a string of length \( n \) after base64-encoding is \( \text{ceil}(n/3)\times4 \).
- User data must be base64-decoded when you retrieve it. If you retrieve the data using instance metadata or the console, it's decoded for you automatically.
- If you stop an instance, modify its user data, and start the instance, the updated user data is not run automatically when you start the instance. With Windows instances, you can configure settings so that updated user data scripts are run one time when you start the instance or every time you reboot or start the instance.
- User data is an instance attribute. If you create an AMI from an instance, the instance user data is not included in the AMI.
Specify instance user data at launch

You can specify user data when you launch an instance. For console directions, see Specify instance user data at launch. For a Linux example that uses the AWS CLI, see the section called “User data and the AWS CLI”. For a Windows example that uses the Tools for Windows PowerShell, see the section called “User data and the Tools for Windows PowerShell”.

Modify instance user data

You can modify user data for instances with an EBS root volume. The instance must be in the stopped state. For console directions, see View and update the instance user data. For a Linux example that uses the AWS CLI, see modify-instance-attribute. For a Windows example that uses the Tools for Windows PowerShell, see the section called “User data and the Tools for Windows PowerShell”.

Retrieve instance user data from your instance

To retrieve user data from an instance, use one of the following URIs. To retrieve user data using the IPv6 address, you must enable it, and the instance must be an instance built on the AWS Nitro System in a subnet that supports IPv6.

**IPv4**

http://169.254.169.254/latest/user-data

**IPv6**

http://[fd00:ec2::254]/latest/user-data

A request for user data returns the data as it is (content type application/octet-stream). If the instance does not have any user data, the request returns 404 - Not Found.

Example: Retrieve comma-separated text

This example retrieves user data that was specified as comma-separated text.

cURL

```
IMDSv2
```
IMDSv1

IMDSv2

Example: Retrieve a script

This example retrieves user data that was specified as a script.

cURL

service httpd start
chkconfig httpd on

**IMDSv1**

#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on

**Powershell**

**IMDSv2**

<powershell>
$file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
</powershell>
<persist>true</persist>

**IMDSv1**

<powershell>
$file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
</powershell>
<persist>true</persist>
Retrieve instance user data from your computer

You can retrieve user data for an instance from your own computer. For console directions, see View and update the instance user data. For an example that uses the AWS CLI, see User data and the AWS CLI. For an example that uses the Tools for Windows PowerShell, see User data and the Tools for Windows PowerShell.

Run commands on your Amazon EC2 instance at launch

When you launch an Amazon EC2 instance, you can pass user data to the instance that is used to perform automated configuration tasks, or to run scripts after the instance starts.

If you're interested in more complex automation scenarios, you might consider AWS CloudFormation or AWS OpsWorks. For more information, see the following:

- Deploying applications on Amazon EC2 with AWS CloudFormation in the AWS CloudFormation User Guide.
- AWS OpsWorks User Guide.

On Linux instances, you can pass two types of user data to Amazon EC2: shell scripts and cloud-init directives. You can also pass this data into the launch instance wizard as plain text, as a file (this is useful for launching instances with the command line tools), or as base64-encoded text (for API calls).

On Windows instances, the launch agents handle your user data scripts. The following sections cover the differences in how user data is handled on each operating system.

How Amazon EC2 handles user data for Linux instances

In the following examples, the commands from the Install a LAMP server on Amazon Linux 2 are converted to a shell script and a set of cloud-init directives that run when the instance launches. In each example, the following tasks are performed by the user data:

- The distribution software packages are updated.
- The necessary web server, php, and mariadb packages are installed.
- The httpd service is started and turned on via systemctl.
- The ec2-user is added to the apache group.
The appropriate ownership and file permissions are set for the web directory and the files contained within it.

A simple web page is created to test the web server and PHP engine.

Contents

- Prerequisites
- User data and shell scripts
- User data and the console
- User data and cloud-init directives
- User data and the AWS CLI
- Combine shell scripts and cloud-init directives

Prerequisites

The examples in this topic assume the following:

- Your instance has a public DNS name that is reachable from the internet.
- The security group associated with your instance is configured to allow SSH (port 22) traffic so that you can connect to the instance to view the output log files.
- Your instance is launched with an Amazon Linux 2 AMI. These instructions are intended for use with Amazon Linux 2, and the commands and directives may not work for other Linux distributions. For more information about other distributions, such as their support for cloud-init, see their specific documentation.

User data and shell scripts

If you are familiar with shell scripting, this is the easiest and most complete way to send instructions to an instance at launch. Adding these tasks at boot time adds to the amount of time it takes to boot the instance. You should allow a few minutes of extra time for the tasks to complete before you test that the user script has finished successfully.

⚠️ Important

By default, user data scripts and cloud-init directives run only during the boot cycle when you first launch an instance. You can update your configuration to ensure that your user
User data shell scripts must start with the `#!` characters and the path to the interpreter you want to read the script (commonly `/bin/bash`). For an introduction on shell scripting, see the [Bash Reference Manual](https://www.gnu.org/software/bash/manual/bashref.html) on the [GNU Operating System](https://www.gnu.org/software/bash/) website.

Scripts entered as user data are run as the root user, so do not use the `sudo` command in the script. Remember that any files you create will be owned by the root user; if you need a non-root user to have file access, you should modify the permissions accordingly in the script. Also, because the script is not run interactively, you cannot include commands that require user feedback (such as `yum update` without the `-y` flag).

If you use an AWS API, including the AWS CLI, in a user data script, you must use an instance profile when launching the instance. An instance profile provides the appropriate AWS credentials required by the user data script to issue the API call. For more information, see [Using instance profiles](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_create_for_user.html) in the IAM User Guide. The permissions you assign to the IAM role depend on which services you are calling with the API. For more information, see [IAM roles for Amazon EC2](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_create_for_user.html).

The cloud-init output log file captures console output so it is easy to debug your scripts following a launch if the instance does not behave the way you intended. To view the log file, connect to the instance and open `/var/log/cloud-init-output.log`.

When a user data script is processed, it is copied to and run from `/var/lib/cloud/instances/instance-id/`. The script is not deleted after it is run. Be sure to delete the user data scripts from `/var/lib/cloud/instances/instance-id/` before you create an AMI from the instance. Otherwise, the script will exist in this directory on any instance launched from the AMI.

**User data and the console**

You can specify instance user data when you launch the instance. If the root volume of the instance is an EBS volume, you can also stop the instance and update its user data.
Specify instance user data at launch

Follow the procedure for launching an instance. The User data field is located in the Advanced details section of the launch instance wizard. Enter your shell script in the User data field, and then complete the instance launch procedure.

This example script creates and configures our web server.

```
#!/bin/bash
yum update -y
amazon-linux-extras install -y lamp-mariadb10.2-php7.2 php7.2
yum install -y httpd mariadb-server
systemctl start httpd
systemctl enable httpd
usermod -a -G apache ec2-user
chown -R ec2-user:apache /var/www
chmod 2775 /var/www
find /var/www -type d -exec chmod 2775 {} \;
find /var/www -type f -exec chmod 0664 {} \;
```

Allow enough time for the instance to launch and run the commands in your script, and then check to see that your script has completed the tasks that you intended.

For our example, in a web browser, enter the URL of the PHP test file the script created. This URL is the public DNS address of your instance followed by a forward slash and the file name.

```
http://my.public.dns.amazonaws.com/phpinfo.php
```

You should see the PHP information page. If you are unable to see the PHP information page, check that the security group you are using contains a rule to allow HTTP (port 80) traffic. For more information, see Add rules to a security group.

(Optional) If your script did not accomplish the tasks you were expecting it to, or if you just want to verify that your script completed without errors, connect to the instance, examine the cloud-init output log file (/var/log/cloud-init-output.log), and look for error messages in the output.

For additional debugging information, you can create a Mime multipart archive that includes a cloud-init data section with the following directive:

```
output : { all : '|' tee -a /var/log/cloud-init-output.log' }
```
This directive sends command output from your script to /var/log/cloud-init-output.log. For more information about cloud-init data formats and creating Mime multi part archive, see cloud-init Formats.

View and update the instance user data

To update the instance user data, you must first stop the instance. If the instance is running, you can view the user data but you cannot modify it.

⚠️ Warning
When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

To modify instance user data

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Instance state, Stop instance. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.
4. When prompted for confirmation, choose Stop. It can take a few minutes for the instance to stop.
5. With the instance still selected, choose Actions, Instance settings, Edit user data.
6. Modify the user data as needed, and then choose Save.
7. Start the instance. The new user data is visible on your instance after you start it; however, user data scripts are not run.

User data and cloud-init directives

The cloud-init package configures specific aspects of a new Amazon Linux instance when it is launched; most notably, it configures the .ssh/authorized_keys file for the ec2-user so you can log in with your own private key. For more information about the configuration tasks that the cloud-init package performs for Amazon Linux instances, see Using cloud-init on Amazon Linux 2 in the Amazon Linux 2 User Guide.
The cloud-init user directives can be passed to an instance at launch the same way that a script is passed, although the syntax is different. For more information about cloud-init, see [http://cloudinit.readthedocs.org/en/latest/index.html](http://cloudinit.readthedocs.org/en/latest/index.html).

**Important**

By default, user data scripts and cloud-init directives run only during the boot cycle when you first launch an instance. You can update your configuration to ensure that your user data scripts and cloud-init directives run every time you restart your instance. For more information, see [How can I utilize user data to automatically run a script with every restart of my Amazon EC2 Linux instance?](https://aws.amazon.com/knowledge-center/how-can-i-utilize-user-data-to-automatically-run-a-script-with-every-restart-of-my-amazon-ec2-linux-instance/) in the AWS Knowledge Center.

Adding these tasks at boot time adds to the amount of time it takes to boot an instance. You should allow a few minutes of extra time for the tasks to complete before you test that your user data directives have completed.

**To pass cloud-init directives to an instance with user data**

1. Follow the procedure for launching an instance. The **User data** field is located in the **Advanced details** section of the launch instance wizard. Enter your cloud-init directive text in the **User data** field, and then complete the instance launch procedure.

   In the example below, the directives create and configure a web server on Amazon Linux 2. The `#cloud-config` line at the top is required in order to identify the commands as cloud-init directives.

```text
#cloud-config
repo_update: true
repo_upgrade: all

packages:
  - httpd
  - mariadb-server

runcmd:
  - [ sh, -c, "amazon-linux-extras install -y lamp-mariadb10.2-php7.2 php7.2" ]
  - systemctl start httpd
  - sudo systemctl enable httpd
  - [ sh, -c, "usermod -a -G apache ec2-user" ]
```

Run commands at launch
2. Allow enough time for the instance to launch and run the directives in your user data, and then check to see that your directives have completed the tasks you intended.

For this example, in a web browser, enter the URL of the PHP test file the directives created. This URL is the public DNS address of your instance followed by a forward slash and the file name.

http://my.public.dns.amazonaws.com/phpinfo.php

You should see the PHP information page. If you are unable to see the PHP information page, check that the security group you are using contains a rule to allow HTTP (port 80) traffic. For more information, see Add rules to a security group.

3. (Optional) If your directives did not accomplish the tasks you were expecting them to, or if you just want to verify that your directives completed without errors, connect to the instance, examine the output log file (/var/log/cloud-init-output.log), and look for error messages in the output. For additional debugging information, you can add the following line to your directives:

```bash
output : { all : '| tee -a /var/log/cloud-init-output.log' }
```

This directive sends runcmd output to /var/log/cloud-init-output.log.

User data and the AWS CLI

You can use the AWS CLI to specify, modify, and view the user data for your instance. For information about viewing user data from your instance using instance metadata, see Retrieve instance user data from your instance.

On Windows, you can use the AWS Tools for Windows PowerShell instead of using the AWS CLI. For more information, see User data and the Tools for Windows PowerShell.

Example: Specify user data at launch
To specify user data when you launch your instance, use the `run-instances` command with the `--user-data` parameter. With `run-instances`, the AWS CLI performs base64 encoding of the user data for you.

The following example shows how to specify a script as a string on the command line:

```
aws ec2 run-instances --image-id ami-abcd1234 --count 1 --instance-type m3.medium --key-name my-key-pair --subnet-id subnet-abcd1234 --security-group-ids sg-abcd1234 --user-data echo user data
```

The following example shows how to specify a script using a text file. Be sure to use the `file://` prefix to specify the file.

```
aws ec2 run-instances --image-id ami-abcd1234 --count 1 --instance-type m3.medium --key-name my-key-pair --subnet-id subnet-abcd1234 --security-group-ids sg-abcd1234 --user-data file://my_script.txt
```

The following is an example text file with a shell script.

```
#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on
```

**Example: Modify the user data of a stopped instance**

You can modify the user data of a stopped instance using the `modify-instance-attribute` command. With `modify-instance-attribute`, the AWS CLI does not perform base64 encoding of the user data for you.

- On a **Linux** computer, use the `base64` command to encode the user data.

  ```
  base64 my_script.txt >my_script_base64.txt
  ```

- On a **Windows** computer, use the `certutil` command to encode the user data. Before you can use this file with the AWS CLI, you must remove the first (BEGIN CERTIFICATE) and last (END CERTIFICATE) lines.

  ```
  certutil -encode my_script.txt my_script_base64.txt
  ```
notepad my_script_base64.txt

Use the --attribute and --value parameters to use the encoded text file to specify the user data. Be sure to use the file:// prefix to specify the file.

```bash
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --attribute userData --value file://my_script_base64.txt
```

**Example: Clear the user data of a stopped instance**

To delete the existing user data, use the `modify-instance-attribute` command as follows:

```bash
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --user-data Value=
```

**Example: View user data**

To retrieve the user data for an instance, use the `describe-instance-attribute` command. With `describe-instance-attribute`, the AWS CLI does not perform base64 decoding of the user data for you.

```bash
aws ec2 describe-instance-attribute --instance-id i-1234567890abcdef0 --attribute userData
```

The following is example output with the user data base64 encoded.

```json
{
   "UserData": {
      "Value": "IyEvYmluL2Jhc2gKeXVtIHVwZGF0ZSAteQpzZXJ2aWNlIGh0dHBkIHN0YXJ0CmNoa2NvbmZpZyBodHRwZCBvbpg==",
      "InstanceId": "i-1234567890abcdef0"
   }
}
```

- On a **Linux** computer, use the --query option to get the encoded user data and the base64 command to decode it.

  ```bash
  aws ec2 describe-instance-attribute --instance-id i-1234567890abcdef0 --attribute userData --output text --query "UserData.Value" | base64 --decode
  ```
On a **Windows** computer, use the `--query` option to get the coded user data and the `certutil` command to decode it. Note that the encoded output is stored in a file and the decoded output is stored in another file.

```
aws ec2 describe-instance-attribute --instance-id i-1234567890abcdef0 --attribute userData --output text --query "UserData.Value" >my_output.txt
certutil -decode my_output.txt my_output_decoded.txt
type my_output_decoded.txt
```

The following is example output.

```
#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on
```

**Combine shell scripts and cloud-init directives**

By default, you can include only one content type in user data at a time. However, you can use the `text/cloud-config` and `text/x-shellscript` content-types in a mime-multi part file to include both a shell script and cloud-init directives in your user data.

The following shows the mime-multi part format.

```
Content-Type: multipart/mixed; boundary="//"
MIME-Version: 1.0

--//
Content-Type: text/cloud-config; charset="us-ascii"
MIME-Version: 1.0
Content-Transfer-Encoding: 7bit
Content-Disposition: attachment; filename="cloud-config.txt"

#cloud-config
cloud-init directives

--//
Content-Type: text/x-shellscript; charset="us-ascii"
MIME-Version: 1.0
Content-Transfer-Encoding: 7bit
Content-Disposition: attachment; filename="userdata.txt"
```
For example, the following user data includes cloud-init directives and a bash shell script. The cloud-init directives create a file (/test-cloudinit/cloud-init.txt), and writes Created by cloud-init to that file. The bash shell script creates a file (/test-userscript/userscript.txt) and writes Created by bash shell script to that file.

How Amazon EC2 handles user data for Windows instances

On Windows instances, the default launch agents for your operating system version handle user data as follows.
• **EC2Launch v2** runs user data scripts on Windows Server 2022
• **EC2Launch** runs user data scripts on Windows Server 2016 and 2019
• **EC2Config service** runs user data scripts on Windows Server versions prior to Windows Server 2016

For examples of the assembly of a `UserData` property in a AWS CloudFormation template, see [Base64 Encoded UserData Property](#) and [Base64 Encoded UserData Property with AccessKey and SecretKey](#).

For an example of running commands on an instance within an Auto Scaling group that works with lifecycle hooks, see [Tutorial: Configure user data to retrieve the target lifecycle state through instance metadata](#) in the *Amazon EC2 Auto Scaling User Guide*.

**Contents**

- **User data scripts**
- **User data execution**
- **User data and the console**
- **User data and the Tools for Windows PowerShell**

**User data scripts**

For EC2Config or EC2Launch to run scripts, you must enclose the script within a special tag when you add it to user data. The tag that you use depends on whether the commands run in a Command Prompt window (batch commands) or use Windows PowerShell.

If you specify both a batch script and a Windows PowerShell script, the batch script runs first and the Windows PowerShell script runs next, regardless of the order in which they appear in the instance user data.

If you use an AWS API, including the AWS CLI, in a user data script, you must use an instance profile when launching the instance. An instance profile provides the appropriate AWS credentials required by the user data script to make the API call. For more information, see [Instance profiles](#). The permissions you assign to the IAM role depend on which services you are calling with the API. For more information, see [IAM roles for Amazon EC2](#).

**Script type**
• Syntax for batch scripts
• Syntax for Windows PowerShell scripts
• Syntax for YAML configuration scripts
• Base64 encoding

Syntax for batch scripts

Specify a batch script using the script tag. Separate the commands using line breaks as shown in the following example.

```xml
<script>
    echo Current date and time >> %SystemRoot%\Temp\test.log
    echo %DATE% %TIME% >> %SystemRoot%\Temp\test.log
</script>
```

By default, user data scripts run one time when you launch the instance. To run the user data scripts every time you reboot or start the instance, add `<persist>true</persist>` to the user data.

```xml
<script>
    echo Current date and time >> %SystemRoot%\Temp\test.log
    echo %DATE% %TIME% >> %SystemRoot%\Temp\test.log
</script>
<persist>true</persist>
```

EC2Launch v2 agent

To run an XML user data script as a detached process with the EC2Launch v2 `executeScript` task in the `UserData` stage, add `<detach>true</detach>` to the user data.

```xml
<script>
    echo Current date and time >> %SystemRoot%\Temp\test.log
    echo %DATE% %TIME% >> %SystemRoot%\Temp\test.log
</script>
<detach>true</detach>
```

Note
The detach tag is not supported by previous launch agents.
Syntax for Windows PowerShell scripts

The AWS Windows AMIs include the AWS Tools for Windows PowerShell, so you can specify these cmdlets in user data. If you associate an IAM role with your instance, you don't need to specify credentials to the cmdlets, as applications that run on the instance use the role's credentials to access AWS resources (for example, Amazon S3 buckets).

Specify a Windows PowerShell script using the `<powershell>` tag. Separate the commands using line breaks. The `<powershell>` tag is case-sensitive.

For example:

```powershell
$file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
</powershell>
```

By default, the user data scripts run one time when you launch the instance. To run the user data scripts every time you reboot or start the instance, add `<persist>true</persist>` to the user data.

```powershell
$file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
</powershell>
<persist>true</persist>
```

You can specify one or more PowerShell arguments with the `<powershellArguments>` tag. If no arguments are passed, EC2Launch and EC2Launch v2 add the following argument by default: `-ExecutionPolicy Unrestricted`.

**Example:**

```powershell
$file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
</powershell>
```
<powershellArguments>-ExecutionPolicy Unrestricted -NoProfile -NonInteractive</powershellArguments>

EC2Launch v2 agent

To run an XML user data script as a detached process with the EC2Launch v2 executeScript task in the UserData stage, add <detach>true</detach> to the user data.

<i>Note</i>

The detach tag is not supported by previous launch agents.

<powershell>
    $file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
    New-Item $file -ItemType file
</powershell>
<detach>true</detach>

Syntax for YAML configuration scripts

If you are using EC2Launch v2 to run scripts, you can use the YAML format. To view configuration tasks, details, and examples for EC2Launch v2, see EC2Launch v2 task configuration.

Specify a YAML script with the executeScript task.

Example YAML syntax to run a PowerShell script

```yaml
version: 1.0
  tasks:
    - task: executeScript
      inputs:
        - frequency: always
        type: powershell
        runAs: localSystem
        content: |
            $file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
            New-Item $file -ItemType file
```

Example YAML syntax to run a batch script
version: 1.1
  tasks:
    - task: executeScript
      inputs:
        - frequency: always
          type: batch
          runAs: localSystem
          content: |-
            echo Current date and time >> %SystemRoot%\Temp\test.log
            echo %DATE% %TIME% >> %SystemRoot%\Temp\test.log

Base64 encoding

If you’re using the Amazon EC2 API or a tool that does not perform base64 encoding of the user data, you must encode the user data yourself. If not, an error is logged about being unable to find script or powershell tags to run. The following is an example that encodes using Windows PowerShell.

```powershell
$n = [System.Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($script))
```

The following is an example that decodes using PowerShell.

```powershell
$script = [System.Text.Encoding]::UTF8.GetString([System.Convert]::FromBase64String($n))
```

For more information about base64 encoding, see [https://www.ietf.org/rfc/rfc4648.txt](https://www.ietf.org/rfc/rfc4648.txt).

User data execution

By default, all AWS Windows AMIs have user data execution enabled for the initial launch. You can specify that user data scripts are run the next time the instance reboots or restarts. Alternatively, you can specify that user data scripts are run every time the instance reboots or restarts.

Note

User data is not enabled to run by default after the initial launch. To enable user data to run when you reboot or start the instance, see Subsequent reboots or starts.
User data scripts are run from the local administrator account when a random password is generated. Otherwise, user data scripts are run from the System account.

**Instance launch**

Scripts in the instance user data are run during the initial launch of the instance. If the persist tag is found, user data execution is enabled for subsequent reboots or starts. The log files for EC2Launch v2, EC2Launch, and EC2Config contain the output from the standard output and standard error streams.

**EC2Launch v2**

The log file for EC2Launch v2 is `C:\ProgramData\Amazon\EC2Launch\log\agent.log`.

⚠️ **Note**

The `C:\ProgramData` folder might be hidden. To view the folder, you must show hidden files and folders.

The following information is logged when the user data is run:

- **Info**: Converting user-data to yaml format – If the user data was provided in XML format
- **Info**: Initialize user-data state – The start of user data execution
- **Info**: Frequency is: always – If the user data task is running on every boot
- **Info**: Frequency is: once – If the user data task is running just once
- **Stage**: postReadyUserData execution completed – The end of user data execution

**EC2Launch**

The log file for EC2Launch is `C:\ProgramData\Amazon\EC2-Windows\Launch\Log\UserdataExecution.log`.

The `C:\ProgramData` folder might be hidden. To view the folder, you must show hidden files and folders.

The following information is logged when the user data is run:

Run commands at launch
Userdata execution begins – The start of user data execution

<persist> tag was provided: true – If the persist tag is found

Running userdata on every boot – If the persist tag is found

<powershell> tag was provided. Running powershell content – If the powershell tag is found

<script> tag was provided. Running script content – If the script tag is found

Message: The output from user scripts – If user data scripts are run, their output is logged

EC2Config

The log file for EC2Config is C:\Program Files\Amazon\Ec2ConfigService\Logs\Ec2Config.log. The following information is logged when the user data is run:

Ec2HandleUserData: Message: Start running user scripts – The start of user data execution

Ec2HandleUserData: Message: Re-enabled userdata execution – If the persist tag is found

Ec2HandleUserData: Message: Could not find <persist> and </persist> – If the persist tag is not found

Ec2HandleUserData: Message: The output from user scripts – If user data scripts are run, their output is logged

Subsequent reboots or starts

When you update instance user data, user data scripts are not run automatically when you reboot or start the instance. However, you can enable user data execution so that user data scripts are run one time when you reboot or start the instance, or every time you reboot or start the instance.

If you choose the <strong>Shutdown with Sysprep</strong> option, user data scripts are run the next time the instance starts or reboots, even if you did not enable user data execution for subsequent reboots or starts. The user data scripts will not be executed on subsequent reboots or starts.

To enable user data execution with EC2Launch v2 (Preview AMIs)

To run a task in user data on first boot, set frequency to once.
• To run a task in user data on every boot, set frequency to always.

**To enable user data execution with EC2Launch (Windows Server 2016 or later)**

1. Connect to your Windows instance.
2. Open a PowerShell command window and run the following command:

   ```powershell
   C:\ProgramData\Amazon\EC2-Windows\Launch\Scripts\InitializeInstance.ps1 -Schedule
   ```
3. Disconnect from your Windows instance. To run updated scripts the next time the instance is started, stop the instance and update the user data.

**To enable user data execution with EC2Config (Windows Server 2012 R2 and earlier)**

1. Connect to your Windows instance.
2. Open `C:\Program Files\Amazon\Ec2ConfigService\Ec2ConfigServiceSetting.exe`.
3. For **User Data**, select **Enable UserData execution for next service start**.
4. Disconnect from your Windows instance. To run updated scripts the next time the instance is started, stop the instance and update the user data.

**User data and the console**

You can specify instance user data when you launch the instance. If the root volume of the instance is an EBS volume, you can also stop the instance and update its user data.

**Specify instance user data at launch**

Follow the procedure for [launching an instance](https://docs.aws.amazon.com/elasticloadbalancing/latest/guide/launch-an-instance.html). The **User data** field is located in the **Advanced details** section of the launch instance wizard. Enter your PowerShell script in the **User data** field, and then complete the instance launch procedure.

In the following screenshot of the **User data** field, the example script creates a file in the Windows temporary folder, using the current date and time in the file name. When you include `<persist>true</persist>`, the script is run every time you reboot or start the instance. If you leave the **User data has already been base64 encoded** check box empty, the Amazon EC2 console performs the base64 encoding for you.
User data - optional  info
Enter user data in the field.

```powershell
$file = $env:SystemRoot+"\Temp\"+(Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
</powershell>
<persist>true</persist>
```

- User data has already been base64 encoded

View and update the instance user data

You can view the instance user data for any instance, and you can update the instance user data for a stopped instance.

To update the user data for an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Actions, Instance state, Stop instance.

   Warning
   When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

4. When prompted for confirmation, choose Stop. It can take a few minutes for the instance to stop.
5. With the instance still selected, choose **Actions, Instance settings, Edit user data**. You can’t change the user data if the instance is running, but you can view it.

6. In the **Edit user data** dialog box, update the user data, and then choose **Save**. To run user data scripts every time you reboot or start the instance, add `<persist>true</persist>`, as shown in the following example:

```
<powershell>
$file = $env:SystemRoot+"\Temp\"+(Get-Date).ToString("MM-dd-yy-hh-mm")
New-Item $file -ItemType file
</powershell>
```

7. Start the instance. If you enabled user data execution for subsequent reboots or starts, the updated user data scripts are run as part of the instance start process.
User data and the Tools for Windows PowerShell

You can use the Tools for Windows PowerShell to specify, modify, and view the user data for your instance. For information about viewing user data from your instance using instance metadata, see Retrieve instance user data from your instance. For information about user data and the AWS CLI, see User data and the AWS CLI.

Example: Specify instance user data at launch

Create a text file with the instance user data. To run user data scripts every time you reboot or start the instance, add <persist>true</persist>, as shown in the following example.

```xml
<powershell>
    $file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
    New-Item $file -ItemType file
</powershell>
<persist>true</persist>
```

To specify instance user data when you launch your instance, use the `New-EC2Instance` command.

```powershell
PS C:\> $Script = Get-Content -Raw script.txt
PS C:\> $UserData = [System.Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($Script))
```

Use the `-UserData` parameter to pass the user data to the `New-EC2Instance` command.

```powershell
PS C:\> New-EC2Instance -ImageId ami-abcd1234 -MinCount 1 -MaxCount 1 -InstanceType m3.medium -KeyName my-key-pair -SubnetId subnet-12345678 -SecurityGroupIds sg-1a2b3c4d -UserData $UserData
```

Example: Update instance user data for a stopped instance

You can modify the user data of a stopped instance using the `Edit-EC2InstanceAttribute` command.

Create a text file with the new script. Use the following commands to encode the user data in the text file named `new-script.txt`.

```powershell
PS C:\> $NewScript = Get-Content -Raw new-script.txt
```

Run commands at launch
Use the `-UserData` and `-Value` parameters to specify the user data.

```powershell
PS C:\> $NewUserData = [System.Convert]::ToBase64String([System.Text.Encoding]::ASCII.GetBytes($NewScript))
```

Example: View instance user data

To retrieve the user data for an instance, use the `Get-EC2InstanceAttribute` command.

```powershell
PS C:\> (Get-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -Attribute userData).UserData
```

The following is example output. Note that the user data is encoded.

```
PHBvd2Vyc2hlbGw +DQpSZW5hbWUtQ29tcHV0ZXIgLU5ld05hbWUgdXNlci1kYXRhLXRlc3QNCjwvcG93ZXJzaGVsbD4=
```

Use the following commands to store the encoded user data in a variable and then decode it.

```powershell
PS C:\> $UserData_encoded = (Get-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -Attribute userData).UserData
PS C:\> [System.Text.Encoding]::UTF8.GetString([System.Convert]::FromBase64String($UserData_encoded))
```

The following is example output.

```
<powershell>
  $file = $env:SystemRoot + "\Temp\" + (Get-Date).ToString("MM-dd-yy-hh-mm")
  New-Item $file -ItemType file
</powershell>
<persist>true</persist>
```

Example: Rename the instance to match the tag value

You can use the `Get-EC2Tag` command to read the tag value, rename the instance on first boot to match the tag value, and reboot. To run this command successfully, you must have a role with
ec2:DescribeTags permissions attached to the instance because tag information is retrieved by the API call. For more information on settings permissions by using IAM roles, see [Attach an IAM role to an instance](#).

```powershell
$nameValue = (Get-EC2Tag -filter @{Name="resource-id";Value=$instanceId},@{Name="key";Value="Name"}).Value
$pattern = "^(?!\[0-9\]{1,15}$)[a-zA-Z0-9-]{1,15}$"
#Verify Name Value satisfies best practices for Windows hostnames
if ($nameValue -match $pattern)
{Try
    {Rename-Computer -NewName $nameValue -Restart -ErrorAction Stop}
Catch
    {$ErrorMessage = $_.Exception.Message
     Write-Output "Rename failed: $ErrorMessage"}
}Else
{Throw "Provided name not a valid hostname. Please ensure Name value is between 1 and 15 characters in length and contains only alphanumeric or hyphen characters"}
</powershell>

You can also rename the instance using tags in instance metadata, if your instance is configured to access tags from the instance metadata. For more information, see [View tags for your instances using instance metadata](#).

```powershell
$nameValue = Get-EC2InstanceMetadata -Path /tags/instance/Name
$pattern = "^(?!\[0-9\]{1,15}$)[a-zA-Z0-9-]{1,15}$"
#Verify Name Value satisfies best practices for Windows hostnames
if ($nameValue -match $pattern)
{Try
    {Rename-Computer -NewName $nameValue -Restart -ErrorAction Stop}
Catch
    {$ErrorMessage = $_.Exception.Message
     Write-Output "Rename failed: $ErrorMessage"}
}Else
{Throw "Provided name not a valid hostname. Please ensure Name value is between 1 and 15 characters in length and contains only alphanumeric or hyphen characters"}
</powershell>`
Retrieve dynamic data from your instance

To retrieve dynamic data from within a running instance, use one of the following URIs. To retrieve user data using the IPv6 address, you must enable it and the instance must be an instances built on the AWS Nitro System in a subnet that supports IPv6.

IPv4

IPv6

http://[fd00:ec2::254]/latest/dynamic/

This example retrieves the high-level instance identity categories.

For more information about dynamic data and examples of how to retrieve it, see Instance identity documents for Amazon EC2 instances.

Instance metadata categories

Instance metadata is divided into categories. To retrieve instance metadata, you specify the category in the request, and the metadata is returned in the response.

When new categories are released, a new instance metadata build is created with a new version number. In the following table, the Version when category was released column specifies the build version when an instance metadata category was released. To avoid having to update your code every time Amazon EC2 releases a new instance metadata build, use latest instead of the version number in your metadata requests. For more information, see Get the available versions of the instance metadata.

When Amazon EC2 releases a new instance metadata category, the instance metadata for the new category might not be available for existing instances. With instances built on the Nitro system, you can retrieve instance metadata only for the categories that were available at launch. For instances with the Xen hypervisor, you can stop and then start the instance to update the categories that are available for the instance.
The following table lists the categories of instance metadata. Some of the category names include placeholders for data that is unique to your instance. For example, `mac` represents the MAC address for the network interface. You must replace the placeholders with actual values when you retrieve the instance metadata.

<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>
<th>Version when category was released</th>
</tr>
</thead>
<tbody>
<tr>
<td>ami-id</td>
<td>The AMI ID used to launch the instance.</td>
<td>1.0</td>
</tr>
<tr>
<td>ami-launch-index</td>
<td>If you launch multiple instances using the same RunInstances call, this value indicates the launch order for each instance. The value of the first instance launched is 0. If you launch instances using Auto Scaling or EC2 fleet, this value is always 0.</td>
<td>1.0</td>
</tr>
<tr>
<td>ami-manifest-path</td>
<td>The path to the AMI manifest file in Amazon S3. If you used an Amazon EBS-backed AMI to launch the instance, the returned result is unknown.</td>
<td>1.0</td>
</tr>
<tr>
<td>ancestor-ami-ids</td>
<td>The AMI IDs of any instances that were rebundled to create this AMI. This value will only exist if the AMI manifest file contained an ancestor-amis key.</td>
<td>2007-10-10</td>
</tr>
<tr>
<td>autoscaling/target-lifecycle-state</td>
<td>Value showing the target Auto Scaling lifecycle state that an Auto Scaling instance is transitioning to. Present when the instance transitions to one of the target lifecycle</td>
<td>2021-07-15</td>
</tr>
</tbody>
</table>
### Instance metadata categories

<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>
<th>Version when category was released</th>
</tr>
</thead>
<tbody>
<tr>
<td>block-device-mapping/ami</td>
<td>The virtual device that contains the root/boot file system.</td>
<td>2007-12-15</td>
</tr>
<tr>
<td>block-device-mapping/ebs (N)</td>
<td>The virtual devices associated with any Amazon EBS volumes. Amazon EBS volumes are only available in metadata if they were present at launch time or when the instance was last started. The (N) indicates the index of the Amazon EBS volume (such as ebs1 or ebs2).</td>
<td>2007-12-15</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>
<th>Version when category was released</th>
</tr>
</thead>
<tbody>
<tr>
<td>block-device-mapping/ephemeral N</td>
<td>The virtual devices for any non-NVMe instance store volumes. The $N$ indicates the index of each volume. The number of instance store volumes in the block device mapping might not match the actual number of instance store volumes for the instance. The instance type determines the number of instance store volumes that are available to an instance. If the number of instance store volumes in a block device mapping exceeds the number available to an instance, the additional instance store volumes are ignored.</td>
<td>2007-12-15</td>
</tr>
<tr>
<td>block-device-mapping/root</td>
<td>The virtual devices or partitions associated with the root devices or partitions on the virtual device, where the root (/ or C:) file system is associated with the given instance.</td>
<td>2007-12-15</td>
</tr>
<tr>
<td>block-device-mapping/swap</td>
<td>The virtual devices associated with swap. Not always present.</td>
<td>2007-12-15</td>
</tr>
<tr>
<td>elastic-gpus/associations/elastic-gpu-id</td>

<td>Data that can be used by other parties to verify its origin and authenticity. See Instance identity documents for Amazon EC2 instances.</td>
<td>2009-04-04</td>
</tr>
</tbody>
</table>

**Linux example: AMI launch index value**

This example demonstrates how you can use both user data and instance metadata to configure your Linux instances.

---

**Note**

The examples in this section use the IPv4 address of the IMDS: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: [fd00:ec2::254]. The IPv6 address of the IMDS is compatible with IMDSv2 commands. The IPv6 address is only accessible on instances built on the AWS Nitro System and in an IPv6-supported subnet (dual stack or IPv6 only).
Alice wants to launch four instances of her favorite database AMI, with the first acting as the original instance and the remaining three acting as replicas. When she launches them, she wants to add user data about the replication strategy for each replica. She is aware that this data will be available to all four instances, so she needs to structure the user data in a way that allows each instance to recognize which parts are applicable to it. She can do this using the ami-launch-index instance metadata value, which will be unique for each instance. If she starts more than one instance at the same time, the ami-launch-index indicates the order in which the instances were launched. The value of the first instance launched is 0.

Here is the user data that Alice has constructed.

```
replicate-every=1min | replicate-every=5min | replicate-every=10min
```

The replicate-every=1min data defines the first replica's configuration, replicate-every=5min defines the second replica's configuration, and so on. Alice decides to provide this data as an ASCII string with a pipe symbol (|) delimiting the data for the separate instances.

Alice launches four instances using the `run-instances` command, specifying the user data.

```
aws ec2 run-instances \
   --image-id ami-0abcdef1234567890 \
   --count 4 \
   --instance-type t2.micro \
   --user-data "replicate-every=1min | replicate-every=5min | replicate-every=10min"
```

After they're launched, all instances have a copy of the user data and the common metadata shown here:

- AMI ID: ami-0abcdef1234567890
- Reservation ID: r-1234567890abcabc0
- Public keys: none
- Security group name: default
- Instance type: t2.micro

However, each instance has unique metadata, as shown in the following tables.
<table>
<thead>
<tr>
<th>Metadata</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance-id</td>
<td>i-1234567890abcdef0</td>
</tr>
<tr>

<tr>
<td>public-hostname</td>
<td>ec2-67-202-51-224.compute-1.amazonaws.com</td>
</tr>
<tr>
<td>public-ipv4</td>
<td>67.202.51.224</td>
</tr>
<tr>
<td>local-hostname</td>
<td>ip-10-251-50-36.ec2.internal</td>
</tr>
<tr>
<td>local-ipv4</td>
<td>10.251.50.36</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Metadata</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance-id</td>
<td>i-0ee992212549ce0e7</td>
</tr>
<tr>
<td>ami-launch-index</td>
<td>2</td>
</tr>
<tr>
<td>public-hostname</td>
<td>ec2-67-202-51-225.compute-1.amazonaws.com</td>
</tr>
<tr>
<td>public-ipv4</td>
<td>67.202.51.225</td>
</tr>
</tbody>
</table>
Alice can use the `ami-launch-index` value to determine which portion of the user data is applicable to a particular instance.

1. She connects to one of the instances, and retrieves the `ami-launch-index` for that instance to ensure it is one of the replicas:

   **IMDSv2**

   ```
   2
   ```

   For the following steps, the IMDSv2 requests use the stored token from the preceding IMDSv2 command, assuming the token has not expired.
IMDSv1

```
```

2. She saves the ami-launch-index as a variable.

IMDSv2

```
```

IMDSv1

```
```

3. She saves the user data as a variable.

IMDSv2

```
```

IMDSv1

```
```

4. Finally, Alice uses the `cut` command to extract the portion of the user data that is applicable to that instance.

IMDSv2

```
[ec2-user ~]$ echo $user_data | cut -d"|" -f"$ami_launch_index" replicate-every=5min
```

IMDSv1

```
[ec2-user ~]$ echo $user_data | cut -d"|" -f"$ami_launch_index" replicate-every=5min
```
Instance identity documents for Amazon EC2 instances

Each instance that you launch has an instance identity document that provides information about the instance itself. You can use the instance identity document to validate the attributes of the instance.

The instance identity document is generated when the instance is stopped and started, restarted, or launched. The instance identity document is exposed (in plaintext JSON format) through the Instance Metadata Service (IMDS). The IPv4 address 169.254.169.254 is a link-local address and is valid only from the instance. For more information, see Link-local address on Wikipedia. The IPv6 address [fd00:ec2::254] is a unique local address and is valid only from the instance. For more information, see Unique local address on Wikipedia.

⚠️ Note

The examples in this section use the IPv4 address of the IMDS: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: [fd00:ec2::254]. The IPv6 address of the IMDS is compatible with IMDSv2 commands. The IPv6 address is only accessible on Instances built on the AWS Nitro System and in an IPv6-supported subnet (dual stack or IPv6 only).

You can retrieve the instance identity document from a running instance at any time. The instance identity document includes the following information:

<table>
<thead>
<tr>
<th>Data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>accountId</td>
<td>The ID of the AWS account that launched the instance.</td>
</tr>
<tr>
<td>architecture</td>
<td>The architecture of the AMI used to launch the instance (i386</td>
</tr>
<tr>
<td>availabilityZone</td>
<td>The Availability Zone in which the instance is running.</td>
</tr>
<tr>
<td>billingProducts</td>
<td>The billing products of the instance.</td>
</tr>
<tr>
<td>devpayProductCodes</td>
<td>Deprecated.</td>
</tr>
</tbody>
</table>
### Data

<table>
<thead>
<tr>
<th>Data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageId</td>
<td>The ID of the AMI used to launch the instance.</td>
</tr>
<tr>
<td>instanceId</td>
<td>The ID of the instance.</td>
</tr>
<tr>
<td>instanceType</td>
<td>The instance type of the instance.</td>
</tr>
<tr>
<td>kernelId</td>
<td>The ID of the kernel associated with the instance, if applicable.</td>
</tr>
<tr>
<td>marketplaceProductCodes</td>
<td>The AWS Marketplace product code of the AMI used to launch the instance.</td>
</tr>
<tr>
<td>pendingTime</td>
<td>The date and time that the instance was launched.</td>
</tr>
<tr>
<td>privateIp</td>
<td>The private IPv4 address of the instance.</td>
</tr>
<tr>
<td>ramdiskId</td>
<td>The ID of the RAM disk associated with the instance, if applicable.</td>

<tr>
<td>region</td>
<td>The Region in which the instance is running.</td>
</tr>
<tr>
<td>version</td>
<td>The version of the instance identity document format.</td>
</tr>
</tbody>
</table>

### Retrieve the instance identity document for an Amazon EC2 instance from the Instance Metadata Service

#### To retrieve the plaintext instance identity document

Connect to the instance and run the following command.

**Linux**

IMDSv2

```bash
```
IMDSv1

Windows

IMDSv2

IMDSv1

The following is example output.

{
    "devpayProductCodes" : null,
    "marketplaceProductCodes" : [ "1abc2defghijklm3nopqrs4tu" ],
    "availabilityZone" : "us-west-2b",
    "privateIp" : "10.158.112.84",
    "version" : "2017-09-30",
    "instanceId" : "i-1234567890abcdef0",
    "billingProducts" : null,
    "instanceType" : "t2.micro",
    "accountId" : "123456789012",
    "imageId" : "ami-5fb8c835",
    "pendingTime" : "2016-11-19T16:32:11Z",
    "architecture" : "x86_64",
    "kernelId" : null,
    "ramdiskId" : null,
    "region" : "us-west-2"
}
Verify the instance identity document for an Amazon EC2 instance

If you intend to use the contents of the instance identity document for an important purpose, you should verify its contents and authenticity before using it.

The plaintext instance identity document is accompanied by three hashed and encrypted signatures. You can use these signatures to verify the origin and authenticity of the instance identity document and the information that it includes. The following signatures are provided:

- Base64-encoded signature—This is a base64-encoded SHA256 hash of the instance identity document that is encrypted using an RSA key pair.
- PKCS7 signature—This is a SHA1 hash of the instance identity document that is encrypted using a DSA key pair.
- RSA-2048 signature—This is a SHA256 hash of the instance identity document that is encrypted using an RSA-2048 key pair.

Each signature is available at a different endpoint in the instance metadata. You can use any one of these signatures depending on your hashing and encryption requirements. To verify the signatures, you must use the corresponding AWS public certificate.

Options

- Option 1: Verify instance identity document using the PKCS7 signature
- Option 2: Verify instance identity document using the base64-encoded signature
- Option 3: Verify instance identity document using the RSA-2048 signature
- AWS public certificates

Option 1: Verify instance identity document using the PKCS7 signature

This topic explains how to verify the instance identity document using the PKCS7 signature and the AWS DSA public certificate.

Linux instances

To verify the instance identity document using the PKCS7 signature and the AWS DSA public certificate

1. Connect to the instance.
2. Retrieve the PKCS7 signature from the instance metadata and add it to a new file named pkcs7 along with the required header and footer. Use one of the following commands depending on the IMDS version used by the instance.

**IMDSv2**

```bash
$ echo "-----BEGIN PKCS7-----" >> pkcs7
&& echo "" >> pkcs7
&& echo "-----END PKCS7-----" >> pkcs7
```

**IMDSv1**

```bash
$ echo "-----BEGIN PKCS7-----" >> pkcs7
&& echo "" >> pkcs7
&& echo "-----END PKCS7-----" >> pkcs7
```

3. Find the DSA public certificate for your Region in [AWS public certificates](https://aws.amazon.com/publiccerts/) and add the contents to a new file named certificate.

4. Use the **OpenSSL smime** command to verify the signature. Include the -verify option to indicate that the signature needs to be verified, and the -noverify option to indicate that the certificate does not need to be verified.

   ```bash
   $ openssl smime -verify -in pkcs7 -inform PEM -certfile certificate -noverify | tee document
   ```

   If the signature is valid, the **Verification successful** message appears.

   The command also writes the contents of the instance identity document to a new file named document. You can compare the contents of the of the instance identity document from the instance metadata with the contents of this file using the following commands.

   ```bash
   $ openssl dgst -sha256 < document
   ```
Windows instances

Prerequisites

This procedure requires the `System.Security` Microsoft .NET Core class. To add the class to your PowerShell session, run the following command.

```
PS C:\> Add-Type -AssemblyName System.Security
```

**Note**

The command adds the class to the current PowerShell session only. If you start a new session, you must run the command again.

To verify the instance identity document using the PKCS7 signature and the AWS DSA public certificate

1. Connect to the instance.
2. Retrieve the PKCS7 signature from the instance metadata, convert it to a byte array, and add it to a variable named `$Signature`. Use one of the following commands depending on the IMDS version used by the instance.

**IMDSv2**

```

```
3. Retrieve the plaintext instance identity document from the instance metadata, convert it to a byte array, and add it to a variable named $Document. Use one of the following commands depending on the IMDS version used by the instance.

IMDSv2

```powershell
```

IMDSv1

```powershell
```

4. Find the DSA public certificate for your Region in AWS public certificates and add the contents to a new file named certificate.pem.

5. Extract the certificate from the certificate file and store it in a variable named $Store.

```powershell
```

6. Verify the signature.

```powershell
PS C:\> $SignatureDocument.Decode($Signature)
PS C:\> $SignatureDocument.CheckSignature($Store, $true)
```

If the signature is valid, the command returns no output. If the signature cannot be verified, the command returns Exception calling "CheckSignature" with "2"
argument(s): "Cannot find the original signer. If your signature cannot be verified, contact AWS Support.

7. Validate the content of the instance identity document.

```powershell
PS C:\> [Linq.Enumerable]::SequenceEqual($SignatureDocument.ContentInfo.Content, $Document)
```

If the content of the instance identity document is valid, the command returns True. If instance identity document cannot be validated, contact AWS Support.

**Option 2: Verify instance identity document using the base64-encoded signature**

This topic explains how to verify the instance identity document using the base64-encoded signature and the AWS RSA public certificate.

**Linux instances**

**To validate the instance identity document using the base64-encoded signature and the AWS RSA public certificate**

1. Connect to the instance.
2. Retrieve the base64-encoded signature from the instance metadata, convert it to binary, and add it to a file named `signature`. Use one of the following commands depending on the IMDS version used by the instance.

**IMDSv2**

```bash
```

**IMDSv1**

```bash
```
3. Retrieve the plaintext instance identity document from the instance metadata and add it to a file named `document`. Use one of the following commands depending on the IMDS version used by the instance.

**IMDSv2**

```bash
```

**IMDSv1**

```bash
```

4. Find the RSA public certificate for your Region in [AWS public certificates](https://aws.amazon.com/about-aws(service-certificate)) and add the contents to a new file named `certificate`.

5. Extract the public key from the AWS RSA public certificate and save it to a file named `key`.

```bash
$ openssl x509 -pubkey -noout -in certificate >> key
```

6. Use **OpenSSL dgst** command to verify the instance identity document.

```bash
$ openssl dgst -sha256 -verify key -signature signature document
```

If the signature is valid, the Verification successful message appears.

The command also writes the contents of the instance identity document to a new file named `document`. You can compare the contents of the instance identity document from the instance metadata with the contents of this file using the following commands.

```bash
$ openssl dgst -sha256 < document
```

```bash
```

If the signature cannot be verified, contact AWS Support.
Windows instances

To validate the instance identity document using the base64-encoded signature and the AWS RSA public certificate

1. Connect to the instance.

2. Retrieve the base64-encoded signature from the instance metadata, convert it to a byte array, and add it to variable named $Signature. Use one of the following commands depending on the IMDS version used by the instance.

IMDSv2

```

```

IMDSv1

```
```

3. Retrieve the plaintext instance identity document from the instance metadata, convert it to a byte array, and add it to a variable named $Document. Use one of the following commands depending on the IMDS version used by the instance.

IMDSv2

```
```

IMDSv1

```
```
4. Find the RSA public certificate for your Region in AWS public certificates and add the contents to a new file named certificate.pem.

5. Verify the instance identity document.

   ```powershell
   ```

   If the signature is valid, the command returns True. If the signature cannot be verified, contact AWS Support.

Option 3: Verify instance identity document using the RSA-2048 signature

This topic explains how to verify the instance identity document using the RSA-2048 signature and the AWS RSA-2048 public certificate.

Linux instances

To verify the instance identity document using the RSA-2048 signature and the AWS RSA-2048 public certificate

1. Connect to the instance.
2. Retrieve the RSA-2048 signature from the instance metadata and add it to a file named rsa2048 along the required header and footer. Use one of the following commands depending on the IMDS version used by the instance.

   **IMDSv2**

   ```bash
   $ echo "-----BEGIN PKCS7-----" >> rsa2048
   && echo "" >> rsa2048
   && echo "-----END PKCS7-----" >> rsa2048
   ```

   **IMDSv1**

   ```bash
   $ echo "-----BEGIN PKCS7-----" >> rsa2048
   ```

   ```bash
   && echo "" >> rsa2048
   ```
3. Find the **RSA-2048** public certificate for your Region in AWS public certificates and add the contents to a new file named certificate.

4. Use the **OpenSSL smime** command to verify the signature. Include the -verify option to indicate that the signature needs to be verified, and the -noverify option to indicate that the certificate does not need to be verified.

```bash
$ openssl smime -verify -in rsa2048 -inform PEM -certfile certificate -noverify | tee document
```

If the signature is valid, the **Verification successful** message appears. If the signature cannot be verified, contact AWS Support.

**Windows instances**

**Prerequisites**

This procedure requires the System.Security Microsoft .NET Core class. To add the class to your PowerShell session, run the following command.

```powershell
PS C:\> Add-Type -AssemblyName System.Security
```

**Note**

The command adds the class to the current PowerShell session only. If you start a new session, you must run the command again.

**To verify the instance identity document using the RSA-2048 signature and the AWS RSA-2048 public certificate**

1. Connect to the instance.
2. Retrieve the RSA-2048 signature from the instance metadata, convert it to a byte array, and add it to a variable named $Signature. Use one of the following commands depending on the IMDS version used by the instance.
3. Retrieve the plaintext instance identity document from the instance metadata, convert it to a byte array, and add it to a variable named $Document. Use one of the following commands depending on the IMDS version used by the instance.

**IMDSv2**

```powershell

```

**IMDSv1**

```powershell
```

4. Find the **RSA-2048** public certificate for your Region in [AWS public certificates](https://aws.amazon.com/about-aws/whats-new/aws-public-certificates/) and add the contents to a new file named `certificate.pem`.

5. Extract the certificate from the certificate file and store it in a variable named `$Store`.

```powershell
```

6. Verify the signature.
If the signature is valid, the command returns no output. If the signature cannot be verified, the command returns Exception calling "CheckSignature" with "2" argument(s): "Cannot find the original signer. If your signature cannot be verified, contact AWS Support.

7. Validate the content of the instance identity document.

If the content of the instance identity document is valid, the command returns True. If instance identity document cannot be validated, contact AWS Support.

**AWS public certificates**

The following AWS public certificates can be used to verify the contents of an instance's instance identity document as described in [Verify the instance identity document for an Amazon EC2 instance](link).

Ensure that you use the correct certificate for your Region and for the verification procedure that you're using. If you're verifying the PKCS7 signature, use the DSA certificate. If you're verifying the base6-encoded signature, use the RSA certificate. If you're verifying the RSA-2048 signature, use the RSA-2048 certificate.

Instance identity documents

1028
Instance identity roles for Amazon EC2 instances

Each Amazon EC2 instance that you launch has an instance identity role that represents its identity. An instance identity role is a type of IAM role. AWS services and features that are integrated to use the instance identity role can use it to identify the instance to the service.

The instance identity role credentials are accessible from the Instance Metadata Service (IMDS) at /identity-credentials/ec2/security-credentials/ec2-instance. The credentials consist of an AWS temporary access key pair and a session token. They are used to sign AWS Sigv4 requests to the AWS services that use the instance identity role. The credentials are present in the instance metadata regardless of whether a service or feature that makes use of instance identity roles is enabled on the instance.

Instance identity roles are automatically created when an instance is launched, have no role-trust policy document, and are not subject to any identity or resource policy.
Supported services

The following AWS services use the instance identity role:

- **Amazon EC2** – [EC2 Instance Connect](#) uses the instance identity role to update the host keys for a Linux instance.
- **Amazon GuardDuty** – [Runtime Monitoring](#) uses the instance identity role to allow the runtime agent to send security telemetry to the GuardDuty VPC endpoint.
- **AWS Security Token Service (AWS STS)** – Instance identity role credentials can be used with the AWS STS [GetCallerIdentity](#) action.
- **AWS Systems Manager** – When using [Default Host Management Configuration](#), AWS Systems Manager uses the identity provided by the instance identity role to register EC2 instances. After identifying your instance, Systems Manager can pass your AWSSystemsManagerDefaultEC2InstanceManagementRole IAM role to your instance.

Instance identity roles can’t be used with other AWS services or features because they do not have an integration with instance identity roles.

Instance identity role ARN

The instance identity role ARN takes the following format:

```
arn:aws-partition:iam::account-number:assumed-role/aws:ec2-instance/instance-id
```

For example:

```
arn:aws:iam::0123456789012:assumed-role/aws:ec2-instance/i-0123456789example
```

For more information about ARNs, see [Amazon Resource Names (ARNs)](#) in the IAM User Guide.

Connect to your EC2 instance

This section of the Amazon EC2 User Guide provides information to help you connect to your Amazon EC2 instance after you launch it. It also provides information to help you connect your instance to another AWS resource.

Topics
Connect to your Linux instance

There are many ways to connect to your Linux instance. Some vary depending on the operating system of the local machine that you connect from. Others, like EC2 Instance Connect or AWS Systems Manager Session Manager, don't vary. In this section, you can learn how to connect to your Linux instance and transfer files between your local computer and your instance.

Before you connect to your Linux instance, complete the following prerequisites.

- Get information about your instance
- Locate the private key and set permissions
- (Optional) Get the instance fingerprint

Then, choose from one of the following options to connect to your Linux instance.

Options to connect based on your local operating system

- Connect from a Linux or macOS local machine using SSH
- Connect from a Windows local machine

Options to connect from any local operating system

- Connect using Session Manager
- Connect to your Linux instance with EC2 Instance Connect.

Note

For instance connection troubleshooting tips, see Troubleshoot issues connecting to your Amazon EC2 Linux instance.
To troubleshoot boot, network configuration, and other issues for instances built on the AWS Nitro System, you can use the EC2 Serial Console for Amazon EC2 instances.

Get information about your instance

To prepare to connect to an instance, get the following information from the Amazon EC2 console or by using the AWS CLI.

- Get the public DNS name of the instance.

You can get the public DNS for your instance from the Amazon EC2 console. Check the Public IPv4 DNS column of the Instances pane. If this column is hidden, choose the settings icon ( ) in the top-right corner of the screen, and select Public IPv4 DNS. You can also find the public DNS in the instance information section of the Instances pane. When you select the instance in the Instances pane of the Amazon EC2 console, information about that instance will appear on the lower half of the page. Under the Details tab, look for Public IPv4 DNS.

If you prefer, you can use the describe-instances (AWS CLI) or Get-EC2Instance (AWS Tools for Windows PowerShell) commands.
If no Public IPv4 DNS is displayed, verify that the Instance state is Running, and that you have not launched the instance in a private subnet. If you launched your instance using the launch instance wizard, you may have edited the Auto-assign public IP field under Network settings and changed the value to Disable. If you disable the Auto-assign public IP option, the instance is not assigned a public IP address when it is launched.

- (IPv6 only) Get the IPv6 address of the instance.

If you assigned an IPv6 address to your instance, you can optionally connect to the instance using its IPv6 address instead of a public IPv4 address or public IPv4 DNS hostname. Your local computer must have an IPv6 address and must be configured to use IPv6. You can get the IPv6 address of your instance from the Amazon EC2 console. Check the IPv6 IPs column of the Instances pane. Or, you can find the IPv6 address in the instance information section. When you select the instance in the Instances pane of the Amazon EC2 console, information about that instance will appear on the lower half of the page. Under the Details tab, look for IPv6 address.

If you prefer, you can use the describe-instances (AWS CLI) or Get-EC2Instance (AWS Tools for Windows PowerShell) commands. For more information about IPv6, see IPv6 addresses.

- Get the user name for your instance.

You can connect to your instance using the username for your user account or the default username for the AMI that you used to launch your instance.

- Get the username for your user account.

For more information about how to create a user account, see Manage system users on your Linux instance.

- Get the default username for the AMI that you used to launch your instance:

<table>
<thead>
<tr>
<th>AMI used to launch instance</th>
<th>Default username</th>
</tr>
</thead>
<tbody>
<tr>
<td>AL2023</td>
<td>ec2-user</td>
</tr>
<tr>
<td>Amazon Linux 2</td>
<td></td>
</tr>
<tr>
<td>Amazon Linux</td>
<td></td>
</tr>
<tr>
<td>CentOS</td>
<td>centos or ec2-user</td>
</tr>
</tbody>
</table>
**AMI used to launch instance** | **Default username**
---|---
Debian | admin
Fedora | fedora or ec2-user
RHEL | ec2-user or root
SUSE | ec2-user or root
Ubuntu | ubuntu
Oracle | ec2-user
Bitnami | bitnami
Rocky Linux | rocky
Other | Check with the AMI provider

**Locate the private key and set permissions**

You must know the location of your private key file to connect to your instance. For SSH connections, you must set the permissions so that only you can read the file.

For information about how key pairs work when using Amazon EC2, see [Amazon EC2 key pairs and Amazon EC2 instances](#).

- **Locate the private key**

  Get the fully-qualified path to the location on your computer of the .pem file for the key pair that you specified when you launched the instance. For more information, see [the section called “Identify the public key specified at launch”](#).

  If you can't find your private key file, see [I've lost my private key. How can I connect to my Linux instance?](#).

  If you are connecting to your instance using Putty and need to convert the .pem file to .ppk, see [Convert your private key using PuTTYgen](#) in the [Connect to your Linux instance from Windows with PuTTY](#) topic in this section.
• Set the permissions of your private key so that only you can read it

  Connect from macOS or Linux

  (Linux instances) If you plan to use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

  ```bash
  chmod 400 key-pair-name.pem
  ```

  If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see Error: Unprotected private key file.

• Connect from Windows

  Open File Explorer and right-click on the .pem file. Select Properties > Security tab and choose Advanced. Choose Disable inheritance. Remove access to all users except for the current user.

(Optional) Get the instance fingerprint

To protect yourself from man-in-the-middle attacks, you can verify the authenticity of the instance you're about to connect to by verifying the fingerprint that is displayed. Verifying the fingerprint is useful if you launched your instance from a public AMI provided by a third party.

Task overview

First, get the instance fingerprint from the instance. Then, when you connect to the instance and are prompted to verify the fingerprint, compare the fingerprint you obtained in this procedure with the fingerprint that is displayed. If the fingerprints don't match, someone might be attempting a man-in-the-middle attack. If they match, you can confidently connect to your instance.

Prerequisites to get the instance fingerprint

• The instance must not be in the pending state. The fingerprint is available only after the first boot of the instance is complete.

• You must be the instance owner to get the console output.

• There are various ways to get the instance fingerprint. If you want to use the AWS CLI, it must be installed on your local computer. For information about installing the AWS CLI, see Installing the AWS Command Line Interface in the AWS Command Line Interface User Guide.
To get the instance fingerprint

In Step 1, you get the console output, which includes the instance fingerprint. In Step 2, you find the instance fingerprint in the console output.

1. Get the console output using one of the following methods.

   Console

   1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   2. From the left navigator, choose Instances.
   3. Select your instance, and then choose Actions, Monitor and troubleshoot, Get system log.

   AWS CLI

   On your local computer (not on the instance you’re connecting to), use the `get-console-output` (AWS CLI) command. If the output is large, you can pipe it to a text file, where it might be easier to read. Note that you must specify an AWS Region when you use the AWS CLI, either explicitly or by setting a default Region. For information about how to set or specify a Region, see Configuration basics in the AWS Command Line Interface User Guide.

```
aws ec2 get-console-output --instance-id instance_id --query Output --output text > temp.txt
```

2. In the console output, find the instance (host) fingerprint, which is located under BEGIN SSH HOST KEY FINGERPRINTS. There might be several instance fingerprints. When you connect to your instance, it will display only one of the fingerprints.

The exact output can vary by operating system, AMI version, and whether AWS created the key pairs. The following is example output.

```
ec2:########################################################################################################################
ec2: -----BEGIN SSH HOST KEY FINGERPRINTS-----
ec2: 256 SHA256:l4UB/neBad9tvkgJf1QZWxheQmR59WgrgzEimCG6kZY no comment (ECDSA)
ec2: 256 SHA256:kpEa+rw/Uq3zx YaZN8KT501liBtJ0IdHG52dFi66EEfQ no comment (ED25519)
ec2: 2048 SHA256:L8l6pepcA7iqW/jBecQjVZClUrKY+o2cHLI0iHerbVc no comment (RSA)
ec2: -----END SSH HOST KEY FINGERPRINTS-----
```

You'll reference this fingerprint when you connect to the instance.

**Connect to your Linux instance from Linux or macOS using SSH**

You can use Secure Shell (SSH) to connect to your Linux instance from a local machine that runs a Linux or macOS operating system, or you can use a platform independent connection tool, such as EC2 Instance Connect or AWS Systems Manager Session Manager. For more information about platform independent tools, see [Connect to your Linux instance](#).

This page explains how to connect to your instance with an SSH client. To connect to your Linux instance from Windows, see [Connect from Windows](#).

---

**Note**

If you receive an error while attempting to connect to your instance, make sure that your instance meets all of the [SSH connection prerequisites](#). If it meets all of the prerequisites, and you're still not able to connect to your Linux instance, see [Troubleshoot issues connecting to your Amazon EC2 Linux instance](#).

---

**Contents**

- [SSH connection prerequisites](#)
- [Connect to your Linux instance using an SSH client](#)
- [Transfer files to Linux instances using an SCP client](#)

**SSH connection prerequisites**

Before you connect to your Linux instance, complete the following prerequisites.

**Check your instance status**

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks. You can view this information in the **Status check** column on the **Instances** page.
Get the public DNS name and user name to connect to your instance

To find the public DNS name or IP address of your instance and the user name that you should use to connect to your instance, see Get information about your instance.

Locate the private key and set the permissions

To locate the private key that is required to connect to your instance, and to set the key permissions, see Locate the private key and set permissions.

Install an SSH client on your local computer as needed

Your local computer might have an SSH client installed by default. You can verify this by typing ssh at the command line. If your computer doesn't recognize the command, you can install an SSH client.

- Recent versions of Windows Server 2019 and Windows 10 – OpenSSH is included as an installable component. For more information, see OpenSSH in Windows.

- Earlier versions of Windows – Download and install OpenSSH. For more information, see Win32-OpenSSH.

- Linux and macOS X – Download and install OpenSSH. For more information, see https://www.openssh.com.

Connect to your Linux instance using an SSH client

Use the following procedure to connect to your Linux instance using an SSH client. If you receive an error while attempting to connect to your instance, see Troubleshoot issues connecting to your Amazon EC2 Linux instance.

Connect to your instance using SSH

1. In a terminal window, use the ssh command to connect to the instance. You specify the path and file name of the private key (.pem), the user name for your instance, and the public DNS name or IPv6 address for your instance. For more information about how to find the private key, the user name for your instance, and the DNS name or IPv6 address for an instance, see Locate the private key and set permissions and Get information about your instance. To connect to your instance, use one of the following commands.

   - (Public DNS) To connect using your instance's public DNS name, enter the following command.
ssh -i /path/key-pair-name.pem instance-user-name@instance-public-dns-name

- (IPv6) Alternatively, if your instance has an IPv6 address, to connect using your instance's IPv6 address, enter the following command.

ssh -i /path/key-pair-name.pem instance-user-name@instance-IPv6-address

You see a response like the following:

The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (198-51-100-1)'
can't be established.
ECDSA key fingerprint is 4UB/neBad9tvkgJf1QZxheQmR59WgrgzEimCG6kZY.
Are you sure you want to continue connecting (yes/no)?

2. (Optional) Verify that the fingerprint in the security alert matches the fingerprint that you previously obtained in (Optional) Get the instance fingerprint. If these fingerprints don't match, someone might be attempting a man-in-the-middle attack. If they match, continue to the next step.

3. Enter yes.

You see a response like the following:

Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (ECDSA) to the list of known hosts.

Transfer files to Linux instances using an SCP client

One way to transfer files between your local computer and a Linux instance is to use the secure copy protocol (SCP). This section describes how to transfer files with SCP. The procedure is similar to the procedure for connecting to an instance with SSH.

Prerequisites

- Verify the general prerequisites for transferring files to your instance.

Before you transfer files between your local machine and your instance, take the following actions to ensure that you have all of the information you need.

- Get information about your instance
- Locate the private key and set permissions
- (Optional) Get the instance fingerprint
- Install an SCP client

Most Linux, Unix, and Apple computers include an SCP client by default. If yours doesn’t, the OpenSSH project provides a free implementation of the full suite of SSH tools, including an SCP client. For more information, see https://www.openssh.com.

The following procedure steps you through using SCP to transfer a file using the instance's public DNS name, or the IPv6 address if your instance has one.

**To use SCP to transfer files between your computer and your instance**

1. Determine the location of the source file on your computer and the destination path on the instance. In the following examples, the name of the private key file is key-pair-name.pem, the file to transfer is my-file.txt, the user name for the instance is ec2-user, the public DNS name of the instance is instance-public-dns-name, and the IPv6 address of the instance is instance-IPv6-address.

   - (Public DNS) To transfer a file to the destination on the instance, enter the following command from your computer.

```
scp -i /path/key-pair-name.pem /path/my-file.txt ec2-user@instance-public-dns-name:/path/
```

   - (IPv6) To transfer a file to the destination on the instance if the instance has an IPv6 address, enter the following command from your computer. The IPv6 address must be enclosed in square brackets ([ ]), which must be escaped (\).

```
scp -i /path/key-pair-name.pem /path/my-file.txt ec2-user@[instance-IPv6-address]:/path/
```

2. If you haven’t already connected to the instance using SSH, you see a response like the following:

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (10.254.142.33)' can't be established.
Are you sure you want to continue connecting (yes/no)?
```
(Optional) You can optionally verify that the fingerprint in the security alert matches the instance fingerprint. For more information, see (Optional) Get the instance fingerprint.

Enter yes.

3. If the transfer is successful, the response is similar to the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (RSA) to the list of known hosts.
my-file.txt                                100%   480     24.4KB/s   00:00
```

4. To transfer a file in the other direction (from your Amazon EC2 instance to your computer), reverse the order of the host parameters. For example, you can transfer my-file.txt from your EC2 instance to the a destination on your local computer as my-file2.txt, as shown in the following examples.

   - (Public DNS) To transfer a file to a destination on your computer, enter the following command from your computer.

     ```
     scp -i /path/key-pair-name.pem ec2-user@instance-public-dns-name:path/my-file.txt path/my-file2.txt
     ```

   - (IPv6) To transfer a file to a destination on your computer if the instance has an IPv6 address, enter the following command from your computer. The IPv6 address must be enclosed in square brackets ([ ]), which must be escaped (\).

     ```
     scp -i /path/key-pair-name.pem ec2-user@[instance-IPv6-address]:path/my-file.txt path/my-file2.txt
     ```

**Connect to your Linux instance from Windows**

You can use the following methods to connect to your Linux instance from a local machine that has a Windows operating system.

**Connect to your Linux instance from Windows with OpenSSH**

The following procedures show you how to connect to your Linux instance from Windows using OpenSSH, an open source connectivity tool for remote login with the SSH protocol. OpenSSH is supported on Windows Server 2019 and later operating systems.
Prerequisites

Before you connect to your Linux instance from Windows using OpenSSH, complete the following prerequisites.

Verify that the instance is ready

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks. You can view this information in the Status check column on the Instances page.

Verify the general prerequisites for connecting to your instance

To find the public DNS name or IP address of your instance and the username that you should use to connect to your instance, see Get information about your instance.

Verify your Windows version

To connect to your Linux instance from Windows using OpenSSH, the Windows version must be Windows Server 2019 and later.

Verify PowerShell prerequisites

To install OpenSSH on your Windows OS using PowerShell, you must be running PowerShell version 5.1 or later, and your account must be a member of the built-in Administrators group. Run $PSVersionTable.PSVersion from PowerShell to check your PowerShell version.

To check whether you are a member of the built-in Administrators group, run the following PowerShell command:

```
(New-Object
```

If you are a member of the built-in Administrators group, the output is True.
**Install OpenSSH for Windows using PowerShell**

To install OpenSSH for Windows using PowerShell, run the following PowerShell command:

```
Add-WindowsCapability -Online -Name OpenSSH.Client~~~~0.0.1.0
```

**Expected output:**

<table>
<thead>
<tr>
<th>Path</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Online</td>
<td>True</td>
</tr>
<tr>
<td>RestartNeeded</td>
<td>False</td>
</tr>
</tbody>
</table>

**Connect to your Linux instance from Windows using OpenSSH**

After you install OpenSSH, use the following procedure to connect to your Linux instance from Windows using OpenSSH. If you receive an error while attempting to connect to your instance, see [Troubleshoot issues connecting to your Amazon EC2 Linux instance](#).

**To connect to your instance using OpenSSH**

1. In PowerShell or the Command Prompt, use the `ssh` command to connect to the instance. You specify the path and file name of the private key (.pem), the username for your instance, and the public DNS name or IPv6 address for your instance. For more information about how to find the private key, the username for your instance, and the DNS name or IPv6 address for an instance, see [Locate the private key and set permissions](#) and [Get information about your instance](#). To connect to your instance, use one of the following commands.

   - (Public DNS) To connect using your instance's public DNS name, enter the following command.

     ```
     ssh -i /path/key-pair-name.pem instance-user-name@instance-public-dns-name
     ```

   - (IPv6) Alternatively, if your instance has an IPv6 address, to connect using your instance's IPv6 address, enter the following command.

     ```
     ssh -i /path/key-pair-name.pem instance-user-name@instance-IPv6-address
     ```

   You see a response like the following:

   ```
   The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (198-51-100-1)' can't be established.
   ```
ECDSA key fingerprint is l4UB/neBad9tvkgJf1QZWheQmR59WgrgzEimCG6kZy. Are you sure you want to continue connecting (yes/no/[fingerprint])?

2. (Optional) Verify that the fingerprint in the security alert matches the fingerprint that you previously obtained in (Optional) Get the instance fingerprint. If these fingerprints don't match, someone might be attempting a man-in-the-middle attack. If they match, continue to the next step.

3. Enter yes.

You see a response like the following:

Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (ECDSA) to the list of known hosts.

Uninstall OpenSSH from Windows using PowerShell

To uninstall OpenSSH from Windows using PowerShell, run the following PowerShell command:

```
Remove-WindowsCapability -Online -Name OpenSSH.Client~~~~0.0.1.0
```

Expected output:

```
Path          : 
Online        : True
RestartNeeded : True
```

Connect to your Linux instance from Windows with PuTTY

If you're running Windows Server 2019 or later, we recommend using OpenSSH, which is an open source connectivity tool for remote login with the SSH protocol. For steps to connect to a Linux instance from Windows using OpenSSH, see Connect to your Linux instance from Windows with OpenSSH.

The following instructions explain how to connect to your instance using PuTTY, a free SSH client for Windows. If you receive an error while attempting to connect to your instance, see Troubleshoot issues connecting to your Amazon EC2 Linux instance.

Contents
Prerequisites

Before you connect to your Linux instance using PuTTY, complete the following prerequisites.

Verify that the instance is ready

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks. You can view this information in the Status check column on the Instances page.

Verify the general prerequisites for connecting to your instance

To find the public DNS name or IP address of your instance and the username that you should use to connect to your instance, see Get information about your instance.

Install PuTTY on your local computer

Download and install PuTTY from the PuTTY download page. If you already have an earlier version of PuTTY installed, we recommend that you download the latest version. Be sure to install the entire suite.

Convert your private .pem key to .ppk using PuTTYgen

For the key pair that you specified when you launched the instance, if you chose to create the private key in the .pem format, you must convert it to a .ppk file for use with PuTTY. Locate the private .pem file, and then follow the steps in the next section.

Convert your private key using PuTTYgen

PuTTY does not natively support the PEM format for SSH keys. PuTTY provides a tool named PuTTYgen, which converts PEM keys to the required PPK format for PuTTY. You must convert your private key (.pem file) into this format (.ppk file) as follows in order to connect to your instance using PuTTY.
To convert your private .pem key to .ppk

1. From the Start menu, choose All Programs, PuTTY, PuTTYgen.

2. Under Type of key to generate, choose RSA. If your version of PuTTYgen does not include this option, choose SSH-2 RSA.

3. Choose Load. By default, PuTTYgen displays only files with the extension .ppk. To locate your .pem file, choose the option to display files of all types.

4. Select your .pem file for the key pair that you specified when you launched your instance and choose Open. PuTTYgen displays a notice that the .pem file was successfully imported. Choose OK.

5. To save the key in the format that PuTTY can use, choose Save private key. PuTTYgen displays a warning about saving the key without a passphrase. Choose Yes.

6. Specify the same name for the key that you used for the key pair (for example, key-pair-name) and choose Save. PuTTY automatically adds the .ppk file extension.

Your private key is now in the correct format for use with PuTTY. You can now connect to your instance using PuTTY's SSH client.
Connect to your Linux instance

Use the following procedure to connect to your Linux instance using PuTTY. You need the .ppk file that you created for your private key. For more information, see Convert your private key using PuTTYgen in the preceding section. If you receive an error while attempting to connect to your instance, see Troubleshoot issues connecting to your Amazon EC2 Linux instance.

Last tested version of PuTTY: .78

To connect to your instance using PuTTY

1. Start PuTTY (from the Start menu, search for PuTTY and then choose Open).
2. In the Category pane, choose Session and complete the following fields:
   a. In the Host Name box, do one of the following:
      • (Public DNS) To connect using your instance's public DNS name, enter instance-user-name@instance-public-dns-name.
      • (IPv6) Alternatively, if your instance has an IPv6 address, to connect using your instance's IPv6 address, enter instance-user-name@instance-IPv6-address.
   
      For information about how to get the username for your instance, and the public DNS name or IPv6 address of your instance, see Get information about your instance.
   b. Ensure that the Port value is 22.
   c. Under Connection type, select SSH.
3. (Optional) You can configure PuTTY to automatically send 'keepalive' data at regular intervals to keep the session active. This is useful to avoid disconnecting from your instance due to session inactivity. In the Category pane, choose Connection, and then enter the required interval in Seconds between keepalives. For example, if your session disconnects after 10 minutes of inactivity, enter 180 to configure PuTTY to send keepalive data every 3 minutes.

4. In the Category pane, expand Connection, SSH, and Auth. Choose Credentials.

5. Next to Private key file for authentication, choose Browse. In the Select private key file dialog box, select the .ppk file that you generated for your key pair. You can either double-click the file or choose Open in the Select private key file dialog box.

6. (Optional) If you plan to connect to this instance again after this session, you can save the session information for future use. In the Category pane, choose Session. Enter a name for the session in Saved Sessions, and then choose Save.

7. To connect to the instance, choose Open.

8. If this is the first time you have connected to this instance, PuTTY displays a security alert dialog box that asks whether you trust the host to which you are connecting.
a. (Optional) Verify that the fingerprint in the security alert dialog box matches the fingerprint that you previously obtained in (Optional) Get the instance fingerprint. If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.

b. Choose Accept. A window opens and you are connected to your instance.

**Note**

If you specified a passphrase when you converted your private key to the PuTTY format, you must provide that passphrase when you log in to the instance.

If you receive an error while attempting to connect to your instance, see [Troubleshoot issues connecting to your Amazon EC2 Linux instance](#).

### Transfer files to your Linux instance using the PuTTY Secure Copy client

The PuTTY Secure Copy client (PSCP) is a command line tool that you can use to transfer files between your Windows computer and your Linux instance. If you prefer a graphical user interface (GUI), you can use an open source GUI tool named WinSCP. For more information, see [Transfer files to your Linux instance using WinSCP](#).

To use PSCP, you need the private key you generated in [Convert your private key using PuTTYgen](#). You also need the public DNS name of your Linux instance, or the IPv6 address if your instance has one.

The following example transfers the file `Sample_file.txt` from the C:\ drive on a Windows computer to the `instance-user-name` home directory on an Amazon Linux instance. To transfer a file, use one of the following commands.

- **(Public DNS)** To transfer a file using your instance's public DNS name, enter the following command.

  ```
  pscp -i C:\path\my-key-pair.ppk C:\path\Sample_file.txt instance-user-name@instance-public-dns-name:/home/instance-user-name/Sample_file.txt
  ```

- **(IPv6)** Alternatively, if your instance has an IPv6 address, to transfer a file using your instance's IPv6 address, enter the following command. The IPv6 address must be enclosed in square brackets ([ ]).

  ```
  pscp -i C:\path\my-key-pair.ppk C:\path\Sample_file.txt instance-user-name@[instance-public-dns-name]:/home/instance-user-name/Sample_file.txt
  ```
Transfer files to your Linux instance using WinSCP

WinSCP is a GUI-based file manager for Windows that you can use to upload and transfer files to a remote computer using the SFTP, SCP, FTP, and FTPS protocols. With WinSCP, you can drag and drop files from your Windows computer to your Linux instance or synchronize entire directory structures between the two systems.

Requirements

- You must have the private key that you generated in Convert your private key using PuTTYgen.
- You must have the public DNS name of your Linux instance.
- Your Linux instance must have scp installed. For some operating systems, you install the openssh-clients package. For others, such as the Amazon ECS-optimized AMI, you install the scp package. Check the documentation for your Linux distribution.

To connect to your instance using WinSCP

1. Download and install WinSCP from http://winscp.net/eng/download.php. For most users, the default installation options are OK.
2. Start WinSCP.
3. At the WinSCP login screen, for Host name, enter one of the following:
   - (Public DNS or IPv4 address) To log in using your instance's public DNS name or public IPv4 address, enter the public DNS name or public IPv4 address for your instance.
   - (IPv6) Alternatively, if your instance has an IPv6 address, to log in using your instance's IPv6 address, enter the IPv6 address for your instance.
4. For User name, enter the default username for your AMI.
   - For AL2023, Amazon Linux 2, or the Amazon Linux AMI, the user name is ec2-user.
   - For a CentOS AMI, the user name is centos or ec2-user.
   - For a Debian AMI, the user name is admin.
   - For a Fedora AMI, the user name is fedora or ec2-user.

```bash
pscp -i C:\path\my-key-pair.ppk C:\path\Sample_file.txt instance-user-name@[instance-IPv6-address]:/home/instance-user-name/Sample_file.txt
```
• For a RHEL AMI, the user name is `ec2-user` or `root`.
• For a SUSE AMI, the user name is `ec2-user` or `root`.
• For an Ubuntu AMI, the user name is `ubuntu`.
• For an Oracle AMI, the user name is `ec2-user`.
• For a Bitnami AMI, the user name is `bitnami`.

**Note**
To find the default user name for other Linux distributions, check with the AMI provider.

5. Specify the private key file for your instance.
   
   a. Choose the **Advanced...** button.
   
   b. Under SSH, choose **Authentication**.
   
   c. Specify the path for your private key file, or choose the ... button to browse to the key pair file.
   
   d. Choose **OK**.

Here is a screenshot from WinSCP version 6.1:
WinSCP requires a PuTTY private key file (.ppk). You can convert a .pem security key file to the .ppk format using PuTTYgen. For more information, see Convert your private key using PuTTYgen.

6. (Optional) In the left panel, choose Directories. For Remote directory, enter the path for the directory to which to add files. To open the advanced site settings for newer versions of WinSCP, choose Advanced. To find the Remote directory setting, under Environment, choose Directories.

7. Choose Login. To add the host fingerprint to the host cache, choose Yes.
8. After the connection is established, in the connection window your Linux instance is on the right and your local machine is on the left. You can drag and drop files between the remote file system and your local machine. For more information on WinSCP, see the project documentation at [http://winscp.net/eng/docs/start](http://winscp.net/eng/docs/start).

If you receive an error that you cannot run SCP to start the transfer, verify that you installed `scp` on the Linux instance.

**Connect to your Linux instance from Windows with Windows Subsystem for Linux (WSL)**

After you launch your instance, you can connect to it and use it the way that you'd use a computer sitting in front of you.

The following instructions explain how to connect to your instance with a Linux distribution on the Windows Subsystem for Linux (WSL). WSL is a free download and enables you to run native Linux command line tools directly on Windows, alongside your traditional Windows desktop, without the overhead of a virtual machine.

By installing WSL, you can use a native Linux environment to connect to your Linux EC2 instances instead of using PuTTY or PuTTYgen. The Linux environment makes it easier to connect to your
Amazon Elastic Compute Cloud

Linux instances because it comes with a native SSH client that you can use to connect to your Linux instances and change the permissions of the .pem key file. The Amazon EC2 console provides the SSH command for connecting to the Linux instance, and you can get verbose output from the SSH command for troubleshooting. For more information, see the Windows Subsystem for Linux Documentation.

Note

After you've installed the WSL, all the prerequisites and steps are the same as those described in Connect to your Linux instance from Linux or macOS using SSH, and the experience is just like using native Linux.

If you receive an error while attempting to connect to your instance, see Troubleshoot issues connecting to your Amazon EC2 Linux instance.

Contents

• Prerequisites
• Connect to your Linux instance using WSL
• Transfer files to Linux instances from Linux using SCP
• Uninstall WSL

Prerequisites

Before you connect to your Linux instance, complete the following prerequisites.

Verify that the instance is ready

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check that your instance has passed its status checks. You can view this information in the Status check column on the Instances page.

Verify the general prerequisites for connecting to your instance

To find the public DNS name or IP address of your instance and the user name that you should use to connect to your instance, see Get information about your instance.
Install the Windows Subsystem for Linux (WSL) and a Linux distribution on your local computer

Install the WSL and a Linux distribution using the instructions in the Windows 10 Installation Guide. The example in the instructions installs the Ubuntu distribution of Linux, but you can install any distribution. You are prompted to restart your computer for the changes to take effect.

Copy the private key from Windows to WSL

In a WSL terminal window, copy the .pem file (for the key pair that you specified when you launched the instance) from Windows to WSL. Note the fully-qualified path to the .pem file on WSL to use when connecting to your instance. For information about how to specify the path to your Windows hard drive, see How do I access my C drive?. For more information about key pairs and Windows instances, see Amazon EC2 key pairs and Windows instances.

```bash
cp /mnt/<Windows drive letter>/path/my-key-pair.pem ~/WSL-path/my-key-pair.pem
```

Connect to your Linux instance using WSL

Use the following procedure to connect to your Linux instance using the Windows Subsystem for Linux (WSL). If you receive an error while attempting to connect to your instance, see Troubleshoot issues connecting to your Amazon EC2 Linux instance.

To connect to your instance using SSH

1. In a terminal window, use the ssh command to connect to the instance. You specify the path and file name of the private key (.pem), the user name for your instance, and the public DNS name or IPv6 address for your instance. For more information about how to find the private key, the user name for your instance, and the DNS name or IPv6 address for an instance, see Locate the private key and set permissions and Get information about your instance. To connect to your instance, use one of the following commands.

   • (Public DNS) To connect using your instance's public DNS name, enter the following command.

   ```bash
   ssh -i /path/key-pair-name.pem instance-user-name@my-instance-public-dns-name
   ```

   • (IPv6) Alternatively, if your instance has an IPv6 address, you can connect to the instance using its IPv6 address. Specify the ssh command with the path to the private key (.pem) file, the appropriate user name, and the IPv6 address.
You see a response like the following:

```
The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (10.254.142.33)' can't be established.
Are you sure you want to continue connecting (yes/no)?
```

2. (Optional) Verify that the fingerprint in the security alert matches the fingerprint that you previously obtained in (Optional) Get the instance fingerprint. If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.

3. Enter yes.

You see a response like the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (RSA) to the list of known hosts.
```

**Transfer files to Linux instances from Linux using SCP**

One way to transfer files between your local computer and a Linux instance is to use the secure copy protocol (SCP). This section describes how to transfer files with SCP. The procedure is similar to the procedure for connecting to an instance with SSH.

**Prerequisites**

- **Verify the general prerequisites for transferring files to your instance.**

  Before you transfer files between your local machine and your instance, take the following actions to ensure that you have all of the information you need.

  - [Get information about your instance](#)
  - [Locate the private key and set permissions](#)
  - *(Optional)* Get the instance fingerprint
  - Install an SCP client
Most Linux, Unix, and Apple computers include an SCP client by default. If yours doesn't, the OpenSSH project provides a free implementation of the full suite of SSH tools, including an SCP client. For more information, see https://www.openssh.com.

The following procedure steps you through using SCP to transfer a file. If you've already connected to the instance with SSH and have verified its fingerprints, you can start with the step that contains the SCP command (step 4).

To use SCP to transfer a file

1. Transfer a file to your instance using the instance's public DNS name. For example, if the name of the private key file is key-pair-name, the file to transfer is SampleFile.txt, the user name is instance-user-name, and the public DNS name of the instance is my-instance-public-dns-name or the IPv6 address is my-instance-IPv6-address, use one of the following commands to copy the file to the instance-user-name home directory.

   • (Public DNS) To transfer a file using your instance's public DNS name, enter the following command.

   
   
   scp -i /path/key-pair-name.pem /path/SampleFile.txt instance-user-name@my-instance-public-dns-name:~

   • (IPv6) Alternatively, if your instance has an IPv6 address, you can transfer a file using the instance's IPv6 address. The IPv6 address must be enclosed in square brackets ([ ]), which must be escaped (\). 

   
   scp -i /path/key-pair-name.pem /path/SampleFile.txt instance-user-name@[my-instance-IPv6-address]:~

   You see a response like the following:

   
   The authenticity of host 'ec2-198-51-100-1.compute-1.amazonaws.com (10.254.142.33)' can't be established.
   Are you sure you want to continue connecting (yes/no)?

2. (Optional) Verify that the fingerprint in the security alert matches the fingerprint that you previously obtained in (Optional) Get the instance fingerprint. If these fingerprints don't
match, someone might be attempting a "man-in-the-middle" attack. If they match, continue to the next step.

3. Enter yes.

You see a response like the following:

```
Warning: Permanently added 'ec2-198-51-100-1.compute-1.amazonaws.com' (RSA) to the list of known hosts.
Sending file modes: C0644 20 SampleFile.txt
Sink: C0644 20 SampleFile.txt
 SampleFile.txt                                100%   20     0.0KB/s   00:00
```

If you receive a "bash: scp: command not found" error, you must first install scp on your Linux instance. For some operating systems, this is located in the openssh-clients package. For Amazon Linux variants, such as the Amazon ECS-optimized AMI, use the following command to install scp:

```
[ec2-user ~]$ sudo yum install -y openssh-clients
```

4. To transfer files in the other direction (from your Amazon EC2 instance to your local computer), reverse the order of the host parameters. For example, to transfer the SampleFile.txt file from your EC2 instance back to the home directory on your local computer as SampleFile2.txt, use one of the following commands on your local computer.

- (Public DNS) To transfer a file using your instance's public DNS name, enter the following command.

  `scp -i /path/key-pair-name.pem instance-user-name@ec2-198-51-100-1.compute-1.amazonaws.com:~/SampleFile.txt ~/SampleFile2.txt`

- (IPv6) Alternatively, if your instance has an IPv6 address, to transfer files in the other direction using the instance's IPv6 address, enter the following command.

  `scp -i /path/key-pair-name.pem instance-user-name@[2001:db8:1234:1a00:9691:9503:25ad:1761]:~/SampleFile.txt ~/SampleFile2.txt`
Uninstall WSL

For information about uninstalling Windows Subsystem for Linux, see How do I uninstall a WSL Distribution?

Connect to your Linux instance with EC2 Instance Connect

Amazon EC2 Instance Connect provides a simple and secure way to connect to your Linux instances with Secure Shell (SSH). With EC2 Instance Connect, you use AWS Identity and Access Management (IAM) policies and principals to control SSH access to your instances, removing the need to share and manage SSH keys. All connection requests using EC2 Instance Connect are logged to AWS CloudTrail so that you can audit connection requests.

You can use EC2 Instance Connect to connect to your instances using the Amazon EC2 console or an SSH client of your choice.

When you connect to an instance using EC2 Instance Connect, the Instance Connect API pushes an SSH public key to the instance metadata where it remains for 60 seconds. An IAM policy attached to your user authorizes your user to push the public key to the instance metadata. The SSH daemon uses AuthorizedKeysCommand and AuthorizedKeysCommandUser, which are configured when Instance Connect is installed, to look up the public key from the instance metadata for authentication, and connects you to the instance.

You can use EC2 Instance Connect to connect to instances that have public or private IP addresses. For more information, see Connect using EC2 Instance Connect.

For a blog post that discusses how to improve the security of your bastion hosts using EC2 Instance Connect, see Securing your bastion hosts with Amazon EC2 Instance Connect.

Tip

EC2 Instance Connect is one of the options to connect to your Linux instance. For other options, see Connect to your Linux instance. To connect to a Windows instance, see Connect to your Windows instance.

Contents

• Tutorial: Complete the configuration required to connect to your instance using EC2 Instance Connect
Tutorial: Complete the configuration required to connect to your instance using EC2 Instance Connect

To connect to your instance using EC2 Instance Connect in the Amazon EC2 console, you first need to complete the prerequisite configuration that will allow you to successfully connect to your instance. The purpose of this tutorial is to guide you through the tasks to complete the prerequisite configuration.

Tutorial overview

In this tutorial, you'll complete the following four tasks:

- **Task 1: Grant permissions required to use EC2 Instance Connect**

  First you'll create an IAM policy that contains the IAM permissions that allow you to push a public key to the instance metadata. You'll attach this policy to your IAM identity (user, user group, or role) so that your IAM identity gets these permissions.

- **Task 2: Allow inbound traffic from the EC2 Instance Connect service to your instance**

  Then you'll create a security group that allows traffic from the EC2 Instance Connect service to your instance. This is required when you use EC2 Instance Connect in the Amazon EC2 console to connect to your instance.

- **Task 3: Launch your instance**

  You'll then launch an EC2 instance using an AMI that is pre-installed with EC2 Instance Connect and you'll add the security group that you created in the previous step.

- **Task 4: Connect to your instance**

  Finally, you'll use EC2 Instance Connect in the Amazon EC2 console to connect to your instance. If you can connect, then you can be sure that the prerequisite configuration you completed in Tasks 1, 2, and 3 were successful.
Task 1: Grant permissions required to use EC2 Instance Connect

When you connect to an instance using EC2 Instance Connect, the EC2 Instance Connect API pushes an SSH public key to the instance metadata where it remains for 60 seconds. You need an IAM policy attached to your IAM identity (user, user group, or role) to grant you the required permission to push the public key to the instance metadata.

Task objective

You'll create the IAM policy that grants the permission to push the public key to the instance. The specific action to allow is `ec2-instance-connect:SendSSHPublicKey`. You must also allow the `ec2:DescribeInstances` action so that you can view and select your instance in the Amazon EC2 console.

After you've created the policy, you'll attach the policy to your IAM identity (user, user group, or role) so that your IAM identity gets the permissions.

You'll create a policy that is configured as follows:

```json
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": "ec2-instance-connect:SendSSHPublicKey",
        "Resource": "*"
    },
    {
        "Effect": "Allow",
        "Action": "ec2:DescribeInstances",
        "Resource": "*"
    }
}
```

⚠️ Important

The IAM policy created in this tutorial is a highly permissive policy; it allows you to connect to any instance using any AMI username. We're using this highly permissive policy to keep the tutorial simple and focused on the specific configurations that this tutorial is teaching. However, in a production environment, we recommend that your IAM policy is configured...
To create and attach an IAM policy that allows you to use EC2 Instance Connect to connect to your instances

1. **First create the IAM policy**
   b. In the navigation pane, choose **Policies**.
   c. Choose **Create policy**.
   d. On the **Specify permission** page, do the following:
      i. For **Service**, choose **EC2 Instance Connect**.
      ii. Under **Actions allowed**, in the search field start typing **send** to show the relevant actions, and then select **SendSSHPublicKey**.
      iii. Under **Resources**, choose **All**. For a production environment, we recommend specifying the instance by its ARN, but for this tutorial, you're allowing all instances.
      iv. Choose **Add more permissions**.
      v. For **Service**, choose **EC2**.
      vi. Under **Actions allowed**, in the search field start typing **describein** to show the relevant actions, and then select **DescribeInstances**.
      vii. Choose **Next**.
   e. On the **Review and create** page, do the following:
      i. For **Policy name**, enter a name for the policy.
      ii. Choose **Create policy**.

2. **Then attach the policy to your identity**
   a. In the IAM console, in the navigation pane, choose **Policies**.
   b. In the list of policies, select the option button next to the name of the policy you created. You can use the search box to filter the list of policies.
   c. Choose **Actions, Attach**.
d. Under **IAM entities**, select the check box next to your identity (user, user group, or role). You can use the search box to filter the list of entities.

e. Choose **Attach policy**.

**View an animation: Create an IAM policy**
Task 2: Allow inbound traffic from the EC2 Instance Connect service to your instance

When you use EC2 Instance Connect in the Amazon EC2 console to connect to an instance, the traffic that must be allowed to reach the instance is traffic from the EC2 Instance Connect service. This is different to connecting from your local computer to an instance; in that case, you must allow traffic from your local computer to your instance. To allow traffic from the EC2 Instance Connect service, you must create a security group that allows inbound SSH traffic from the IP address range for the EC2 Instance Connect service.

The IP address ranges for the AWS services are available at https://ip-ranges.amazonaws.com/ip-ranges.json. The EC2 Instance Connect IP address ranges are identified by "service": "EC2_INSTANCE_CONNECT".

Task objective

First you'll find the IP address range for EC2_INSTANCE_CONNECT in the AWS Region in which your instance is located. Then you'll create a security group that allows inbound SSH traffic on port 22 from that IP address range.
To create a security group that allows inbound traffic from the EC2 Instance Connect service to your instance

1. **First get the IP address range for the EC2 Instance Connect service**
   b. Choose Raw Data.
   c. Find the IP address range for EC2_INSTANCE_CONNECT for the AWS Region in which your instance is located. You can use the browser search field to search for the service EC2_INSTANCE_CONNECT, and keep searching until you find the Region in which your instance is located.

   For example, if your instance is located in the US East (N. Virginia) (us-east-1) Region, the IP address range for EC2_INSTANCE_CONNECT in that Region is 18.206.107.24/29.

   ![Note]
   The IP address ranges are different for each AWS Region.

   d. Copy the IP address range that appears next to ip_prefix. You will use this IP address range later in this procedure.

   For more information about downloading the AWS IP address ranges JSON file and filtering by service, see [AWS IP address ranges](https://console.aws.amazon.com/vpc/ipranges) in the *Amazon VPC User Guide*.

2. **Then create the security group with an inbound rule to allow traffic from the copied IP address range**
   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. In the navigation pane, choose Security Groups.
   c. Choose Create security group.
   d. Under Basic details, do the following:
      i. For Security group name, enter a meaningful name for your security group.
      ii. For Description, enter a meaningful description for your security group.
   e. Under Inbound rules, do the following:
i. Choose Add rule.

ii. For Type, choose SSH.

iii. For Source, leave Custom.

iv. In the field next to Source, paste the IP address range for the EC2 Instance Connect service that you copied earlier in this procedure.

For example, if your instance is located in the US East (N. Virginia) (us-east-1) Region, paste the following IP address range into the field: 18.206.107.24/29

f. Choose Create security group.

View an animation: Get the IP address range for EC2 Instance Connect for a specific Region

Connect to your Linux instance
Task 3: Launch your instance

When you launch an instance, you must specify an AMI that contains the information required to launch the instance. You can choose to launch an instance with or without EC2 Instance Connect pre-installed. In this task, we specify an AMI that comes pre-installed with EC2 Instance Connect.

If you launch your instance without EC2 Instance Connect pre-installed, and you want to use EC2 Instance Connect to connect to your instance, you'll need to perform additional configuration steps. These steps are outside the scope of this tutorial.

Task objective

You'll launch an instance with the Amazon Linux 2023 AMI, which comes pre-installed with EC2 Instance Connect. You'll also specify the security group that you created earlier so that you can use EC2 Instance Connect in the Amazon EC2 console to connect to your instance. Because you'll use EC2 Instance Connect to connect to your instance, which pushes a public key to your instance's metadata, you won't need to specify an SSH key when you launch your instance.

To launch an instance that can use EC2 Instance Connect in the Amazon EC2 console for connection

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, Ireland). Select a Region in which to launch your instance. This choice is important because you created a security group that allows traffic for a specific Region, so you must select the same Region in which to launch your instance.

3. From the Amazon EC2 console dashboard, choose Launch instance.

4. (Optional) Under Name and tags, for Name, enter a descriptive name for your instance.

5. Under Application and OS Images (Amazon Machine Image), choose Quick Start. Amazon Linux is selected by default. Under Amazon Machine Image (AMI), Amazon Linux 2023 AMI is selected by default. Keep the default selection for this task.

6. Under Instance type, for Instance type, keep the default selection, or choose a different instance type.

7. Under Key pair (login), for Key pair name, choose Proceed without a key pair (Not recommended). When you use EC2 Instance Connect to connect to an instance, EC2 Instance Connect pushes a key pair to the instance's metadata, and it is this key pair that is used for the connection.

8. Under Network settings, do the following:
   a. For Auto-assign public IP, leave Enable.
   b. For Firewall (security groups), choose Select existing security group.
   c. Under Common security groups, choose the security group that you created earlier.

9. In the Summary panel, choose Launch instance.
Task 4: Connect to your instance

When you connect to an instance using EC2 Instance Connect, the EC2 Instance Connect API pushes an SSH public key to the instance metadata where it remains for 60 seconds. The SSH daemon uses AuthorizedKeysCommand and AuthorizedKeysCommandUser to look up the public key from the instance metadata for authentication, and connects you to the instance.

Task objective

In this task, you'll connect to your instance using EC2 Instance Connect in the Amazon EC2 console. If you completed the prerequisite Tasks 1, 2, and 3, the connection should be successful.

Steps to connect to your instance

Use the following steps to connect to your instance. To view an animation of the steps, see View an animation: Connect to your instance.

To connect an instance using EC2 Instance Connect in the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, Ireland). Select the Region in which your instance is located.

3. In the navigation pane, choose Instances.

4. Select your instance and choose Connect.

5. Choose the EC2 Instance Connect tab.

6. For Connection type, choose Connect using EC2 Instance Connect.

7. Choose Connect.

A terminal window opens in the browser, and you are connected to your instance.

**View an animation: Connect to your instance**

---

**Prerequisites for EC2 Instance Connect**

The following are the prerequisites for installing EC2 Instance Connect and for using EC2 Instance Connect to connect to an instance:

- **AWS Regions**
- **Local Zones**
• AMIs
• Install EC2 Instance Connect
• Network access
• Security group rule
• Grant permissions
• Local computer setup
• Username

AWS Regions

Supported in all AWS Regions.

Local Zones

Not supported.

AMIs

EC2 Instance Connect comes pre-installed on the following AMIs:

• AL2023
• Amazon Linux 2 2.0.20190618 or later
• macOS Sonoma 14.2.1 or later
• macOS Ventura 13.6.3 or later
• macOS Monterey 12.7.2 or later
• Ubuntu 20.04 or later

EC2 Instance Connect is not pre-installed on the following AMIs, but you can install it on instances that are launched using the following AMIs:

• Amazon Linux 2 prior to version 2.0.20190618
• CentOS Stream 8 and 9
• macOS Sonoma prior to 14.2.1, Ventura prior to 13.6.3, and Monterey prior to 12.7.2
• Red Hat Enterprise Linux (RHEL) 8 and 9
• Ubuntu 16.04 or 18.04
Install EC2 Instance Connect

To use EC2 Instance Connect to connect to an instance, the instance must have EC2 Instance Connect installed. You can either launch the instance using an AMI that comes pre-installed with EC2 Instance Connect, or you can install EC2 Instance Connect on instances that are launched with supported AMIs. For the supported AMIs, see the preceding section. For the installation instructions, see Install EC2 Instance Connect on your EC2 instances.

Network access

Instances can be configured to allow users to connect to your instance over the internet or through the instance's private IP address. Depending on how your users will connect to your instance using EC2 Instance Connect, you must configure the following network access:

- If your users will connect to your instance over the internet, then your instance must have a public IP address and be in a public subnet. For more information, see Enable internet access in the Amazon VPC User Guide.
- If your users will connect to your instance through the instance's private IP address, then you must establish private network connectivity to your VPC, such as by using AWS Direct Connect, AWS Site-to-Site VPN, or VPC peering, so that your users can reach the instance's private IP address.

If your instance does not have a public IPv4 address and you prefer not to configure the network access as described above, you can consider EC2 Instance Connect Endpoint as an alternative to EC2 Instance Connect. With EC2 Instance Connect Endpoint, you can connect to an instance using SSH or RDP even if the instance does not have a public IPv4 address. For more information, see Connect to your Linux instance using the Amazon EC2 console.

Security group rule

Ensure that the security group associated with your instance allows inbound SSH traffic on port 22 from your IP address or from your network. The default security group for the VPC does not allow incoming SSH traffic by default. The security group created by the launch instance wizard allows incoming SSH traffic by default. For more information, see Rules to connect to instances from your computer.

EC2 Instance Connect uses specific IP address ranges for browser-based SSH connections to your instance (when users use the Amazon EC2 console to connect to an instance). If your users will use the Amazon EC2 console to connect to an instance, ensure that the security group associated with
your instance allows inbound SSH traffic from the IP address range for EC2_INSTANCE_CONNECT. To identify the address range, download the JSON file provided by AWS and filter for the subset for EC2 Instance Connect, using EC2_INSTANCE_CONNECT as the service value. These IP address ranges differ between AWS Regions. For more information about downloading the JSON file and filtering by service, see AWS IP address ranges in the Amazon VPC User Guide.

Grant permissions

You must grant the required permissions to every IAM user who will use EC2 Instance Connect to connect to an instance. For more information, see Grant IAM permissions for EC2 Instance Connect.

Local computer setup

If your users will connect using SSH, they must ensure that their local computer has an SSH client. A user's local computer most likely has an SSH client installed by default. They can check for an SSH client by typing ssh at the command line. If their local computer doesn't recognize the command, they can install an SSH client. For information about installing an SSH client on Linux or macOS X, see http://www.openssh.com. For information about installing an SSH client on Windows 10, see OpenSSH in Windows.

There is no need to install an SSH client on a local computer if your users use only the Amazon EC2 console to connect to an instance.

Username

When using EC2 Instance Connect to connect to an instance, the username must meet the following prerequisites:

- First character: Must be a letter (A-Z, a-z), a digit (0-9), or an underscore (_)
- Subsequent characters: Can be letters (A-Z, a-z), digits (0-9), or the following characters: @ . _ -
- Minimum length: 1 character
- Maximum length: 31 characters

Grant IAM permissions for EC2 Instance Connect

To connect to an instance using EC2 Instance Connect, you must create an IAM policy that grants your users permissions for the following actions and condition:
• **ec2-instance-connect:SendSSHPublicKey** action – Grants permission to push the public key to an instance.

• **ec2:osuser** condition – Specifies the name of the OS user that can push the public key to an instance. Use the default username for the AMI that you used to launch the instance. The default username for AL2023 and Amazon Linux 2 is **ec2-user**, and for Ubuntu it's **ubuntu**.

• **ec2:DescribeInstances** action – Required when using the EC2 console because the wrapper calls this action. Users might already have permission to call this action from another policy.

Consider restricting access to specific EC2 instances. Otherwise, all IAM principals with permission for the **ec2-instance-connect:SendSSHPublicKey** action can connect to all EC2 instances. You can restrict access by specifying resource ARNs or by using resource tags as [condition keys](#).

For more information, see [Actions, resources, and condition keys for Amazon EC2 Instance Connect](#).

For information about creating IAM policies, see [Creating IAM policies](#) in the [IAM User Guide](#).

**Allow users to connect to specific instances**

The following IAM policy grants permission to connect to specific instances, identified by their resource ARNs.

In the following example IAM policy, the following actions and condition are specified:

• The **ec2-instance-connect:SendSSHPublicKey** action grants users permission to connect to two instances, specified by the resource ARNs. To grant users permission to connect to all EC2 instances, replace the resource ARNs with the * wildcard.

• The **ec2:osuser** condition grants permission to connect to the instances only if the **ami-username** is specified when connecting.

• The **ec2:DescribeInstances** action is specified to grant permission to users who will use the console to connect to your instances. If your users will only use an SSH client to connect to your instances, you can omit **ec2:DescribeInstances**. Note that the **ec2:Describe* API actions do not support resource-level permissions. Therefore, the * wildcard is necessary in the Resource element.

```json
{
    "Version": "2012-10-17",
    "Statement": [
```

**Connect to your Linux instance**

---

1074
Allow users to connect to instances with specific tags

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on tags that can be attached to users and AWS resources. You can use resource tags to control access to an instance. For more information about using tags to control access to your AWS resources, see Controlling access to AWS resources in the IAM User Guide.

In the following example IAM policy, the ec2-instance-connect:SendSSHPublicKey action grants users permission to connect to any instance (indicated by the * wildcard in the resource ARN) on condition that the instance has a resource tag with key=tag-key and value=tag-value.

The ec2:DescribeInstances action is specified to grant permission to users who will use the console to connect to your instances. If your users will use only an SSH client to connect to your instances, you can omit ec2:DescribeInstances. Note that the ec2:Describe* API actions do not support resource-level permissions. Therefore, the * wildcard is necessary in the Resource element.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2-instance-connect:SendSSHPublicKey",
            "Resource": [
                "arn:aws:ec2:region:account-id:instance/i-1234567890abcdef0",
                "arn:aws:ec2:region:account-id:instance/i-0598c7d356eba48d7"
            ],
            "Condition": {
                "StringEquals": {
                    "ec2:osuser": "ami-username"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "ec2:DescribeInstances",
            "Resource": "*
        }
    ]
}
```
Install EC2 Instance Connect on your EC2 instances

To connect to an instance using EC2 Instance Connect, the instance must have EC2 Instance Connect installed.

The following AMIs come pre-installed with EC2 Instance Connect:

- AL2023 standard AMI
- Amazon Linux 2 2.0.20190618 or later
- macOS Sonoma 14.2.1 or later
- macOS Ventura 13.6.3 or later
- macOS Monterey 12.7.2 or later
- Ubuntu 20.04 or later

If your instance was launched with one of the AMIs in the preceding list, you can skip this procedure.

Note

If you configured the AuthorizedKeysCommand and AuthorizedKeysCommandUser settings for SSH authentication, the EC2 Instance Connect installation will not update them. As a result, you cannot use EC2 Instance Connect.
Prerequisites for installing EC2 Instance Connect

• Launch the instance with one of the following supported AMIs:

  Amazon Linux 2 prior to version 2.0.20190618

  AL2023 minimal AMI or Amazon ECS-optimized AMI

  CentOS Stream 8 and 9

  macOS Sonoma prior to 14.2.1, Ventura prior to 13.6.3, and Monterey prior to 12.7.2

  Red Hat Enterprise Linux (RHEL) 8 and 9

  Ubuntu 16.04 and 18.04

  If your instance was launched with a later version of Amazon Linux 2, macOS Sonoma, Ventura, or Monterey, or Ubuntu, it comes pre-installed with EC2 Instance Connect and you can skip this procedure.

• Verify the general prerequisites for EC2 Instance Connect.

  For more information, see Prerequisites for EC2 Instance Connect.

• Verify the prerequisites for connecting to your instance using an SSH client on your local machine.

  If your local machine is Linux or macOS, see Connect to your Linux instance from Linux or macOS using SSH. If your local machine is Windows, see Prerequisites.

  For more information, see SSH connection prerequisites.

• Get the ID of the instance.

  You can get the ID of your instance using the Amazon EC2 console (from the Instance ID column). If you prefer, you can use the describe-instances (AWS CLI) or Get-EC2Instance (AWS Tools for Windows PowerShell) command.

• Install an SSH client on your local computer.

  Your local computer most likely has an SSH client installed by default. You can check for an SSH client by typing ssh at the command line. If your local computer doesn't recognize the command, you can install an SSH client. For information about installing an SSH client on Linux or macOS X,
see http://www.openssh.com. For information about installing an SSH client on Windows 10, see OpenSSH in Windows.

- (Ubuntu) Install the AWS CLI on your instance.

To install EC2 Instance Connect on an Ubuntu instance, you must use the AWS CLI on the instance. For more information about installing the AWS CLI, see Installing the AWS CLI in the AWS Command Line Interface User Guide.

Install EC2 Instance Connect

Installing EC2 Instance Connect configures the SSH daemon on the instance.

Use one of the following procedures for installing EC2 Instance Connect depending on the operating system of your instance.

Amazon Linux 2

To install EC2 Instance Connect on an instance launched with Amazon Linux 2

1. Connect to your instance using SSH.

   Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and the default username of the AMI that you used to launch your instance. For Amazon Linux 2, the default username is ec2-user.

   $ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com

   For more information about connecting to your instance, see Connect to your Linux instance from Linux or macOS using SSH.

2. Install the EC2 Instance Connect package on your instance.

   [ec2-user ~]$ sudo yum install ec2-instance-connect

   You should see three new scripts in the /opt/aws/bin/ folder:

   eic_curlAuthorizedKeys
   eic_parseAuthorizedKeys
3. (Optional) Verify that EC2 Instance Connect was successfully installed on your instance.

    [ec2-user ~]$ sudo less /etc/ssh/sshd_config

EC2 Instance Connect was successfully installed if the AuthorizedKeysCommand and AuthorizedKeysCommandUser lines contain the following values:

    AuthorizedKeysCommand /opt/aws/bin/eic_run_authorized_keys %u %f
    AuthorizedKeysCommandUser ec2-instance-connect

- AuthorizedKeysCommand sets the eic_run_authorized_keys script to look up the keys from the instance metadata
- AuthorizedKeysCommandUser sets the system user as ec2-instance-connect

**Note**

If you previously configured AuthorizedKeysCommand and AuthorizedKeysCommandUser, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

**CentOS**

To install EC2 Instance Connect on an instance launched with CentOS

1. Connect to your instance using SSH.

   Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and the default username of the AMI that you used to launch your instance. For CentOS, the default username is centos or ec2-user.

   $ ssh -i my_ec2_private_key.pem centos@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
For more information about connecting to your instance, see Connect to your Linux instance from Linux or macOS using SSH.

2. If you use an HTTP or HTTPS proxy, you must set the `http_proxy` or `https_proxy` environment variables in the current shell session.

If you're not using a proxy, you can skip this step.

- For an HTTP proxy server, run the following commands:

  ```
  $ export http_proxy=http://hostname:port
  $ export https_proxy=http://hostname:port
  ```

- For an HTTPS proxy server, run the following commands:

  ```
  $ export http_proxy=https://hostname:port
  $ export https_proxy=https://hostname:port
  ```

3. Install the EC2 Instance Connect package on your instance by running the following commands.

The EC2 Instance Connect configuration files for CentOS are provided in a Red Hat Package Manager (RPM) package, with different RPM packages for CentOS 8 and CentOS 9 and for instance types that run on Intel/AMD (x86_64) or ARM (AArch64).

Use the command block for your operating system and CPU architecture.

- CentOS 8

  Intel/AMD (x86_64)

  ```
  [ec2-user ~]$ mkdir /tmp/ec2-instance-connect
  ```
Connect to your Linux instance

ARM (AArch64)

[ec2-user ~]$ mkdir /tmp/ec2-instance-connect

CentOS 9

Intel/AMD (x86_64)

[ec2-user ~]$ mkdir /tmp/ec2-instance-connect

ARM (AArch64)

[ec2-user ~]$ mkdir /tmp/ec2-instance-connect
You should see the following new script in the /opt/aws/bin/ folder:

```
eic_run_authorized_keys
```

4. (Optional) Verify that EC2 Instance Connect was successfully installed on your instance.
   
   - For CentOS 8:
     
     ```
     [ec2-user ~]$ sudo less /lib/systemd/system/ssh.service.d/ec2-instance-connect.conf
     ```
   
   - For CentOS 9:
     
     ```
     [ec2-user ~]$ sudo less /etc/ssh/sshd_config.d/60-ec2-instance-connect.conf
     ```

   EC2 Instance Connect was successfully installed if the AuthorizedKeysCommand and AuthorizedKeysCommandUser lines contain the following values:

   ```
   AuthorizedKeysCommand /opt/aws/bin/eic_run_authorized_keys %u %f
   AuthorizedKeysCommandUser ec2-instance-connect
   ```

   - AuthorizedKeysCommand sets the `eic_run_authorized_keys` script to look up the keys from the instance metadata
   - AuthorizedKeysCommandUser sets the system user as `ec2-instance-connect`

   **Note**

   If you previously configured AuthorizedKeysCommand and AuthorizedKeysCommandUser, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.
To install EC2 Instance Connect on an instance launched with macOS

1. Connect to your instance using SSH.

Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and the default username of the AMI that you used to launch your instance. For macOS instances, the default username is `ec2-user`.

```
$ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see Connect to your Linux instance from Linux or macOS using SSH.

2. Update Homebrew using the following command. The update will list the software that Homebrew knows about. The EC2 Instance Connect package is provided via Homebrew on macOS instances. For more information, see Update the operating system and software on Mac instances.

```
[ec2-user ~]$ brew update
```

3. Install the EC2 Instance Connect package on your instance. This will install the software and configure sshd to use it.

```
[ec2-user ~]$ brew install ec2-instance-connect
```

You should see the following new script in the `/opt/aws/bin/` folder:

```
eic_run_authorized_keys
```

4. (Optional) Verify that EC2 Instance Connect was successfully installed on your instance.

```
[ec2-user ~]$ sudo less /etc/ssh/sshd_config.d/60-ec2-instance-connect.conf
```

EC2 Instance Connect was successfully installed if the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` lines contain the following values:
AuthorizedKeysCommand /opt/aws/bin/eic_run_authorized_keys %u %f
AuthorizedKeysCommandUser ec2-instance-connect

- AuthorizedKeysCommand sets the eic_run_authorized_keys script to look up the keys from the instance metadata
- AuthorizedKeysCommandUser sets the system user as ec2-instance-connect

Note

If you previously configured AuthorizedKeysCommand and AuthorizedKeysCommandUser, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

RHEL

To install EC2 Instance Connect on an instance launched with Red Hat Enterprise Linux (RHEL)

1. Connect to your instance using SSH.

Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and the default username of the AMI that you used to launch your instance. For RHEL, the default username is ec2-user or root.

```
$ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see Connect to your Linux instance from Linux or macOS using SSH.

2. If you use an HTTP or HTTPS proxy, you must set the http_proxy or https_proxy environment variables in the current shell session.

If you’re not using a proxy, you can skip this step.

- For an HTTP proxy server, run the following commands:
$ export http_proxy=http://hostname:port
$ export https_proxy=http://hostname:port

• For an HTTPS proxy server, run the following commands:

$ export http_proxy=https://hostname:port
$ export https_proxy=https://hostname:port

3. Install the EC2 Instance Connect package on your instance by running the following commands.

The EC2 Instance Connect configuration files for RHEL are provided in a Red Hat Package Manager (RPM) package, with different RPM packages for RHEL 8 and RHEL 9 and for instance types that run on Intel/AMD (x86_64) or ARM (AArch64).

Use the command block for your operating system and CPU architecture.

• RHEL 8

Intel/AMD (x86_64)

[ec2-user ~]$ mkdir /tmp/ec2-instance-connect

ARM (AArch64)

[ec2-user ~]$ mkdir /tmp/ec2-instance-connect
[ec2-user ~]$ curl https://amazon-ec2-instance-connect-us-west-2.s3.us-west-2.amazonaws.com/latest/linux_arm64/ec2-instance-connect-
You should see the following new script in the `/opt/aws/bin/` folder:

```
eic_runAuthorizedKeys
```

4. (Optional) Verify that EC2 Instance Connect was successfully installed on your instance.

- For RHEL 8:
EC2 Instance Connect was successfully installed if the ` AuthorizedKeysCommand` and ` AuthorizedKeysCommandUser` lines contain the following values:

- `AuthorizedKeysCommand` sets the `eic_run_authorized_keys` script to look up the keys from the instance metadata
- `AuthorizedKeysCommandUser` sets the system user as `ec2-instance-connect`

**Note**

If you previously configured ` AuthorizedKeysCommand` and ` AuthorizedKeysCommandUser`, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

Ubuntu

**To install EC2 Instance Connect on an instance launched with Ubuntu 16.04 or later**

1. Connect to your instance using SSH.

Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and use the default username of the AMI that you used to launch your instance. For an Ubuntu AMI, the username is `ubuntu`.

```bash
[ec2-user ~]$ sudo less /lib/systemd/system/ssh.service.d/ec2-instance-connect.conf

For RHEL 9:

[ec2-user ~]$ sudo less /etc/ssh/sshd_config.d/60-ec2-instance-connect.conf

[ec2-user ~]$ sudo less /etc/ssh/sshd_config.d/60-ec2-instance-connect.conf
```
2. (Optional) Ensure your instance has the latest Ubuntu AMI.

Run the following commands to update all the packages on your instance.

```
ubuntu:~$ sudo apt-get update
```

```
ubuntu:~$ sudo apt-get upgrade
```

3. Install the EC2 Instance Connect package on your instance.

```
ubuntu:~$ sudo apt-get install ec2-instance-connect
```

You should see three new scripts in the `/usr/share/ec2-instance-connect/` folder:

```
eic_curlAuthorized_keys
eic_parseAuthorized_keys
eic_runAuthorized_keys
```

4. (Optional) Verify that Instance Connect was successfully installed on your instance.

```
ubuntu:~$ sudo less /lib/systemd/system/ssh.service.d/ec2-instance-connect.conf
```

EC2 Instance Connect was successfully installed if the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` lines contain the following values:

```
AuthorizedKeysCommand /usr/share/ec2-instance-connect/eic_runAuthorized_keys %u %f
AuthorizedKeysCommandUser ec2-instance-connect
```

- `AuthorizedKeysCommand` sets the `eic_runAuthorized_keys` script to look up the keys from the instance metadata
- `AuthorizedKeysCommandUser` sets the system user as `ec2-instance-connect`
**Note**

If you previously configured AuthorizedKeysCommand and AuthorizedKeysCommandUser, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

For more information about the EC2 Instance Connect package, see [aws/aws-ec2-instance-connect-config](https://github.com/aws/aws-ec2-instance-connect-config) on the GitHub website.

**Connect using EC2 Instance Connect**

The following instructions explain how to connect to your Linux instance using EC2 Instance Connect through the Amazon EC2 console, the AWS CLI, or an SSH client.

**Requirements**

Before you begin, be sure to review the [prerequisites](#).

**Connection options**

- **Connect using the Amazon EC2 console**
- **Connect using the AWS CLI**
- **Connect using your own key and SSH client**
- **Troubleshoot**

**Connect using the Amazon EC2 console**

You can connect to an instance using EC2 Instance Connect through the Amazon EC2 console. Instance Connect handles the permissions.

**Requirement**

To connect using the Amazon EC2 console, the instance must have a public IPv4 address. If the instance has only an IPv6 address, you can connect using the [ec2-instance-connect AWS CLI commands](https://docs.aws.amazon.com/cli/latest/reference/ec2-instance-connect.html).
To connect to your instance using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Connect.
4. Choose the EC2 Instance Connect tab.
5. For Connection type, choose Connect using EC2 Instance Connect.
6. For Username, verify the username.
7. Choose Connect to open a terminal window.

Connect using the AWS CLI

You can use the ec2-instance-connect AWS CLI commands to connect to your instance using an SSH client.

If you don't specify a connection type, EC2 Instance Connect tries to connect to the instance as follows:

- Connect using the public IPv4 address.
- If there is no public IPv4 address, connect using the private IPv4 address and an EC2 Instance Connect Endpoint.
- If there is no private IPv4 address or no EC2 Instance Connect Endpoint, connect using the IPv6 address.

Requirements

You must prepare to use the AWS CLI version 2. For more information, see Install or update to the latest version of the AWS CLI.

Connection types

auto (default)

The CLI tries to connect using the instance's IP addresses in the following order and with the corresponding connection type:

- Public IPv4: direct
- Private IPv4: eice
The CLI tries to connect using the instance's IP addresses in the following order (it does not connect over an EC2 Instance Connect Endpoint):

- Public IPv4
- IPv6
- Private IPv4

eice

The CLI always uses the instance's private IPv4 address.

### Note

In the future, we might change the behavior of the auto connection type. To ensure that your desired connection type is used, we recommend that you explicitly set the `--connection-type` to either `direct` or `eice`.

When you connect to an instance using EC2 Instance Connect, the EC2 Instance Connect API pushes an SSH public key to the instance metadata where it remains for 60 seconds. An IAM policy attached to your user authorizes your user to push the public key to the instance metadata.

**To connect to an instance using the instance ID**

If you only know the instance ID, and want to let EC2 Instance Connect determine the connection type to use when connecting to your instance, use the `ec2-instance-connect` CLI command and specify the `ssh` parameter and the instance ID.

```
aws ec2-instance-connect ssh --instance-id i-1234567890example
```

### Tip

If you get an error when using this command, make sure that you're using AWS CLI version 2. The `ssh` parameter is only available in AWS CLI version 2. For more information, see About AWS CLI version 2 in the *AWS Command Line Interface User Guide*.
To connect to an instance using the instance ID and an EC2 Instance Connect Endpoint

If you want to connect to your instance over an EC2 Instance Connect Endpoint, use the preceding command and also specify the --connection-type parameter with the eice value.

```bash
aws ec2-instance-connect ssh --instance-id i-1234567890example --connection-type eice
```

To connect to an instance using the instance ID and your own private key file

If you want to connect to your instance over an EC2 Instance Connect Endpoint using your own private key, specify the instance ID and the path to the private key file. Do not include `file://` in the path; the following example will fail: `file:///path/to/key`.

```bash
aws ec2-instance-connect ssh --instance-id i-1234567890example --private-key-file /path/to/key.pem
```

Connect using your own key and SSH client

You can use your own SSH key and connect to your instance from the SSH client of your choice while using the EC2 Instance Connect API. This enables you to benefit from the Instance Connect capability to push a public key to the instance. This connection method works for instances with public and private IP addresses.

Requirements

- Requirements for key pairs
  - Supported types: RSA (OpenSSH and SSH2) and ED25519
  - Supported lengths: 2048 and 4096
  - For more information, see [Create a key pair using a third-party tool and import the public key to Amazon EC2](#).
- When connecting to an instance that has only private IP addresses, the local computer from which you are initiating the SSH session must have connectivity to the EC2 Instance Connect service endpoint (to push your SSH public key to the instance) as well as network connectivity to the instance's private IP address to establish the SSH session. The EC2 Instance Connect service endpoint is reachable over the internet or over an AWS Direct Connect public virtual interface. To connect to the instance's private IP address, you can leverage services such as [AWS Direct Connect](#), [AWS Site-to-Site VPN](#), or [VPC peering](#).
To connect to your instance using your own key and any SSH client

1. **(Optional) Generate new SSH private and public keys**

   You can generate new SSH private and public keys, `my_key` and `my_key.pub`, using the following command:

   ```bash
   ssh-keygen -t rsa -f my_key
   ```

2. **Push your SSH public key to the instance**

   Use the `send-ssh-public-key` command to push your SSH public key to the instance. If you launched your instance using AL2023 or Amazon Linux 2, the default username for the AMI is `ec2-user`. If you launched your instance using Ubuntu, the default username for the AMI is `ubuntu`.

   The following example pushes the public key to the specified instance in the specified Availability Zone, to authenticate `ec2-user`.

   ```bash
   aws ec2-instance-connect send-ssh-public-key \
     --region us-west-2 \
     --availability-zone us-west-2b \
     --instance-id i-001234a4bf70dec41EXAMPLE \
     --instance-os-user ec2-user \
     --ssh-public-key file://my_key.pub
   ```

3. **Connect to the instance using your private key**

   Use the `ssh` command to connect to the instance using the private key before the public key is removed from the instance metadata (you have 60 seconds before it is removed). Specify the private key that corresponds to the public key, the default username for the AMI that you used to launch your instance, and the instance's public DNS name (if connecting over a private network, specify the private DNS name or IP address). Add the `IdentitiesOnly=yes` option to ensure that only the files in the ssh config and the specified key are used for the connection.

   ```bash
   ssh -o "IdentitiesOnly=yes" -i my_key ec2-user@ec2-198-51-100-1.compute-1.amazonaws.com
   ```
Troubleshoot

If you receive an error while attempting to connect to your instance, see the following:

- Troubleshoot issues connecting to your Amazon EC2 Linux instance
- How do I troubleshoot issues connecting to my EC2 instance using EC2 Instance Connect?

Uninstall EC2 Instance Connect

To disable EC2 Instance Connect, connect to your instance and uninstall the `ec2-instance-connect` package that is installed on the OS. If the `sshd` configuration matches what it was set to when you installed EC2 Instance Connect, uninstalling `ec2-instance-connect` also removes the `sshd` configuration. If you modified the `sshd` configuration after installing EC2 Instance Connect, you must update it manually.

Amazon Linux

You can uninstall EC2 Instance Connect on AL2023 and Amazon Linux 2 2.0.20190618 or later, where EC2 Instance Connect is preconfigured.

**To uninstall EC2 Instance Connect on an instance launched using Amazon Linux**

1. Connect to your instance using SSH. Specify the SSH key pair you used for your instance when you launched it and the default username for the AL2023 or Amazon Linux 2 AMI, which is `ec2-user`.

   For example, the following `ssh` command connects to the instance with the public DNS name `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, using the key pair `my_ec2_private_key.pem`.

   ```
   $ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
   ```

2. Uninstall the `ec2-instance-connect` package using the `yum` command.

   ```
   [ec2-user ~]$ sudo yum remove ec2-instance-connect
   ```
To uninstall EC2 Instance Connect on an instance launched using an Ubuntu AMI

1. Connect to your instance using SSH. Specify the SSH key pair you used for your instance when you launched it and the default username for the Ubuntu AMI, which is **ubuntu**.

   For example, the following `ssh` command connects to the instance with the public DNS name `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, using the key pair `my_ec2_private_key.pem`.

   ```
   $ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
   ```

2. Uninstall the `ec2-instance-connect` package using the `apt-get` command.

   ```
   ubuntu:~$ sudo apt-get remove ec2-instance-connect
   ```

Connect to your Windows instance

You can connect to Amazon EC2 instances created from most Windows Amazon Machine Images (AMIs) using Remote Desktop. Remote Desktop uses the **Remote Desktop Protocol (RDP)** to connect to and use your instance in the same way you use a computer sitting in front of you (local computer). It is available on most editions of Windows and is also available for Mac OS.

The license for the Windows Server operating system allows two simultaneous remote connections for administrative purposes. The license for Windows Server is included in the price of your Windows instance. If you require more than two simultaneous remote connections, you must purchase a Remote Desktop Services (RDS) license. If you attempt a third connection, an error occurs.

**Tip**

If you need to connect to your instance in order to troubleshoot boot, network configuration, and other issues for instances built on the **AWS Nitro System**, you can use the **EC2 Serial Console for Amazon EC2 instances**.
Connect to your Windows instance using an RDP client

The following section details the prerequisites and process to connect to your instance using its IPv4 or IPv6 address with an RDP client.

Prerequisites

You must meet the following prerequisites to connect to your Windows instance using an RDP client.

• **Install an RDP client**
  - (Windows) Windows includes an RDP client by default. To verify, type `mstsc` at a Command Prompt window. If your computer doesn't recognize this command, see the [Windows home page](#) and search for the download for the Microsoft Remote Desktop app.
  - (macOS X) Download the [Microsoft Remote Desktop app](#) from the Mac App Store.
  - (Linux) Use Remmina.

• **Locate the private key**

Get the fully-qualified path to the location on your computer of the `.pem` file for the key pair that you specified when you launched the instance. For more information, see the section called “Identify the public key specified at launch”.

If you can't find your private key file, see

> When you connect to a newly-launched Windows instance, you decrypt the password for the Administrator account using the private key for the key pair that you specified when you launched the instance.

If you lose the Administrator password and you no longer have the private key, you must reset the password or create a new instance. For more information, see [Reset the administrator password for an Amazon EC2 Windows instance](#). For steps to reset the password using an Systems Manager document, see [Reset passwords and SSH keys on EC2 instances](#) in the AWS Systems Manager User Guide.
• Enable inbound RDP traffic from your IP address to your instance

Ensure that the security group associated with your instance allows incoming RDP traffic (port 3389) from your IP address. The default security group does not allow incoming RDP traffic by default. For more information, see Rules to connect to instances from your computer.

Tip
You can create an EC2 Instance Connect Endpoint to connect to your Windows instance using RDP without a public IPv4 address.

Connect to a Windows instance using RDP and its IPv4 address

To connect to a Windows instance, you must retrieve the initial administrator password and use this password when you connect to your instance using Remote Desktop. It takes a few minutes after instance launch before this password is available.

The default username for the Administrator account depends on the language of the operating system (OS) contained in the AMI. To ascertain the correct username, identify the language of your AMI’s OS, and then choose the corresponding username. For example, for an English OS, the username is Administrator, for a French OS it's Administrateur, and for a Portuguese OS it's Administrador. If a language version of the OS does not have a username in the same language, choose the username Administrator (Other). For more information, see Localized Names for Administrator Account in Windows in the Microsoft TechNet Wiki.

If you’ve joined your instance to a domain, you can connect to your instance using domain credentials you’ve defined in AWS Directory Service. On the Remote Desktop login screen, instead of using the local computer name and the generated password, use the fully-qualified user name for the administrator (for example, corp.example.com\Admin), and the password for this account.

If you receive an error while attempting to connect to your instance, see the section called “Remote Desktop can't connect to the remote computer”.

To connect to your Windows instance using an RDP client

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and then choose **Connect**.

4. On the **Connect to instance** page, choose the **RDP client** tab.

5. For **Username**, choose the default username for the Administrator account. The username you choose must match the language of the operating system (OS) contained in the AMI that you used to launch your instance. If there is no username in the same language as your OS, choose **Administrator (Other)**.

6. Choose **Get password**.

7. On the **Get Windows password** page, do the following:
   
   a. Choose **Upload private key file** and navigate to the private key (.pem) file that you specified when you launched the instance. Select the file and choose **Open** to copy the entire contents of the file to this window.
   
   b. Choose **Decrypt password**. The **Get Windows password** page closes, and the default administrator password for the instance appears under **Password**, replacing the **Get password** link shown previously.
   
   c. Copy the password and save it in a safe place. This password is required to connect to the instance.

8. Choose **Download remote desktop file**. When you have finished downloading the file, choose **Cancel** to return to the **Instances** page. Navigate to your downloads directory, and open the RDP file.

9. You might get a warning that the publisher of the remote connection is unknown. Choose **Connect** to continue to connect to your instance.

10. The administrator account is chosen by default. Paste the password that you copied previously, and then choose **OK**.

11. Due to the nature of self-signed certificates, you might get a warning that the security certificate could not be authenticated. Do one of the following:
   
   - If you trust the certificate, choose **Yes** to connect to your instance.
   
   - **[Windows]** Before you proceed, compare the thumbprint of the certificate with the value in the system log to confirm the identity of the remote computer. Choose **View certificate** and then choose **Thumbprint** from the **Details** tab. Compare this value to the value of RDP\CERTIFICATE-THUMBPRINT in **Actions, Monitor and troubleshoot, Get system log**.
     
   - **[Mac OS X]** Before you proceed, compare the fingerprint of the certificate with the value in the system log to confirm the identity of the remote computer. Choose **Show Certificate**, expand **Details**, and choose **SHA1 Fingerprints**. Compare this value to the
value of RDPCERTIFICATE-THUMBPRINT in Actions, Monitor and troubleshoot, Get system log.

Connect to a Windows instance using RDP and its IPv6 address

If you've enabled your VPC for IPv6 and assigned an IPv6 address to your Windows instance, you can use an RDP client to connect to your instance using its IPv6 address (for example, 2001:db8:1234:1a00:9691:9503:25ad:1761) instead of using its public IPv4 address or public DNS hostname.

To connect to your Windows instance using its IPv6 address

1. Get the initial administrator password for your instance, as described in Connect to your Windows instance using an RDP client. This password is required to connect to your instance.

2. (Windows) Open the RDP client on your Windows computer, choose Show Options, and do the following:
• For **Computer**, enter the IPv6 address of your Windows instance.
• For **User name**, enter **Administrator**.
• Choose **Connect**.
• When prompted, enter the password that you saved previously.

(macOS X) Open the RDP client on your computer and do the following:

• Choose **New**.
• For **PC Name**, enter the IPv6 address of your Windows instance.
• For **User name**, enter **Administrator**.
• Close the dialog box. Under **My Desktops**, select the connection, and choose **Start**.
• When prompted, enter the password that you saved previously.

3. Due to the nature of self-signed certificates, you may get a warning that the security certificate could not be authenticated. If you trust the certificate, you can choose **Yes** or **Continue**. Otherwise, you can verify the identity of the remote computer, as described in **Connect to your Windows instance using an RDP client**.

### Connect to your Windows instance using Fleet Manager

You can use Fleet Manager, a capability of AWS Systems Manager, to connect to Windows instances using the Remote Desktop Protocol (RDP) and display up to four Windows instances on the same page in the AWS Management Console. You can connect to the first instance in the Fleet Manager Remote Desktop directly from the **Instances** page in the Amazon EC2 console. For more information about Fleet Manager, see **Connect to a managed node using Remote Desktop** in the **AWS Systems Manager User Guide**.

Before attempting to connect to an instance using Fleet Manager, ensure that the necessary setup steps have been completed. For more information, see **Setting up Fleet Manager**.

⚠️ **Note**

You do not need to specifically allow incoming RDP traffic from your IP address if you use Fleet Manager to connect. Fleet Manager handles that for you.
To connect to instances using RDP with Fleet Manager (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation pane, choose Instances.
3. Select the instance and then choose Connect.
4. On the Connect to instance page, choose the option to Connect using Fleet Manager, then choose Fleet Manager Remote Desktop. This opens the Fleet Manager Remote Desktop page in the AWS Systems Manager console.

For more information about connecting to Windows instances from the Fleet Manager Remote Desktop page, see Connect using Remote Desktop in the AWS Systems Manager User Guide.
Configure your accounts

After you connect over RDP, we recommend that you perform the following:

- Change the administrator password from the default value. You can change the password while you are logged on to the instance itself, just as you would on any computer running Windows Server.

- Create another user with administrator privileges on the instance. This is a safeguard in case you forget the administrator password or have a problem with the administrator account. The new user must have permission to access the instance remotely. Open System Properties by right-clicking on the This PC icon on your Windows desktop or File Explorer and selecting Properties. Choose Remote settings, and choose Select Users to add the user to the Remote Desktop Users group.
Transfer files to Windows instances

You can work with your Windows instance in the same way that you would work with any Windows server. For example, you can transfer files between a Windows instance and your local computer using the local file sharing feature of the Microsoft Remote Desktop Connection (RDP) software. You can access local files on hard disk drives, DVD drives, portable media drives, and mapped network drives.

To access your local files from your Windows instances, you must enable the local file sharing feature by mapping the remote session drive to your local drive. The steps are slightly different depending on whether your local computer operating system is Windows or macOS X.

Windows

**To map the remote session drive to your local drive on your local Windows computer**

1. Open the Remote Desktop Connection client.
2. Choose Show Options.
3. Add the instance host name to the **Computer** field and user name to the **User name** field, as follows:
   a. Under **Connection settings**, choose Open..., and browse to the RDP shortcut file that you downloaded from the Amazon EC2 console. The file contains the Public IPv4 DNS host name, which identifies the instance, and the Administrator user name.
   b. Select the file and choose Open. The **Computer** and **User name** fields are populated with the values from the RDP shortcut file.
   c. Choose Save.
4. Choose the **Local Resources** tab.
5. Under **Local devices and resources**, choose More...
6. Open **Drives** and select the local drive to map to your Windows instance.

7. Choose **OK**.
8. Choose **Connect** to connect to your Windows instance.

**macOS X**

To map the remote session drive to your local folder on your local macOS X computer

1. Open the Remote Desktop Connection client.
2. Browse to the RDP file that you downloaded from the Amazon EC2 console (when you initially connected to the instance), and drag it onto the Remote Desktop Connection client.
3. Right-click the RDP file, and choose **Edit**.
4. Choose the **Folders** tab, and select the **Redirect folders** check box.
5. Choose the + icon at bottom left, browse to the folder to map, and choose Open. Repeat this step for every folder to map.

6. Choose Save.

7. Choose Connect to connect to your Windows instance. You'll be prompted for the password.

8. On the instance, in File Explorer, expand This PC, and find the shared folder from which you can access your local files. In the following screenshot, the Desktop folder on the local computer was mapped to the remote session drive on the instance.
For more information on making local devices available to a remote session on a Mac computer, see [Get started with the macOS client](#).

### Connect using Session Manager

Session Manager is a fully-managed AWS Systems Manager capability for managing your Amazon EC2 instances through an interactive, one-click, browser-based shell, or through the AWS CLI. You can use Session Manager to start a session with an instance in your account. After the session is started, you can run interactive commands on the instance as you would for any other connection type. For more information about Session Manager, see [AWS Systems Manager Session Manager](#) in the [AWS Systems Manager User Guide](#).

Before attempting to connect to an instance using Session Manager, ensure that the necessary setup steps have been completed. For more information, see [Setting up Session Manager](#).

**To connect to an Amazon EC2 instance using Session Manager on the Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Connect**.

4. For **Connection method**, choose **Session Manager**.

5. Choose **Connect**.

**Tip**

If you receive an error that you're not authorized to perform one or more Systems Manager actions (ssm: `command-name`), then you must update your policies to allow you to start sessions from the Amazon EC2 console. For more information and instructions, see [Quickstart default IAM policies for Session Manager](https://docs.aws.amazon.com/systems-manager/latest/userguide/) in the AWS Systems Manager User Guide.

### Connect to your instances using EC2 Instance Connect Endpoint

EC2 Instance Connect Endpoint allows you to connect securely to an instance from the internet, without using a bastion host, or requiring that your virtual private cloud (VPC) has direct internet connectivity.
Benefits

• You can connect to your instances without requiring the instances to have a public IPv4 address. AWS charges for all public IPv4 addresses, including public IPv4 addresses associated with running instances and Elastic IP addresses. For more information, see the Public IPv4 Address tab on the Amazon VPC pricing page.

• You can connect to your instances from the internet without requiring that your VPC has direct internet connectivity through an internet gateway.

• You can control access to the creation and use of the EC2 Instance Connect Endpoints to connect to instances using IAM policies and permissions.

• All attempts to connect to your instances, both successful and unsuccessful, are logged to CloudTrail.

Pricing

There is no additional cost for using EC2 Instance Connect Endpoints. If you use an EC2 Instance Connect Endpoint to connect to an instance in a different Availability Zone, there is an additional charge for data transfer across Availability Zones.

Contents

• How it works

• Considerations

• Grant permissions to use EC2 Instance Connect Endpoint

• Security groups for EC2 Instance Connect Endpoint

• Create an EC2 Instance Connect Endpoint

• Connect to an Amazon EC2 instance using EC2 Instance Connect Endpoint

• Log connections established over EC2 Instance Connect Endpoint

• Delete an EC2 Instance Connect Endpoint

• Service-linked role for EC2 Instance Connect Endpoint

• Quotas for EC2 Instance Connect Endpoint
How it works

EC2 Instance Connect Endpoint is an identity-aware TCP proxy. The EC2 Instance Connect Endpoint Service establishes a private tunnel from your computer to the endpoint using the credentials for your IAM entity. Traffic is authenticated and authorized before it reaches your VPC.

You can [configure additional security group rules](#) to restrict inbound traffic to your instances. For example, you can use inbound rules to allow traffic on management ports only from the EC2 Instance Connect Endpoint.

You can configure route table rules to allow the endpoint to connect to any instance in any subnet of the VPC.

The following diagram shows how a user can connect to their instances from the internet using an EC2 Instance Connect Endpoint. First, create an **EC2 Instance Connect Endpoint** in subnet A. We create a network interface for the endpoint in the subnet, which serves as the entry point for traffic destined to your instances in the VPC. If the route table for subnet B allows traffic from subnet A, then you can use the endpoint to reach instances in subnet B.
Considerations

Before you begin, consider the following.

• EC2 Instance Connect Endpoint is intended specifically for management traffic use cases, not for high volume data transfers. High volume data transfers are throttled.

• Your instance must have an IPv4 address (either private or public). EC2 Instance Connect Endpoint does not support connecting to instances using IPv6 addresses.

• (Linux instances) If you use your own key pair, you can use any Linux AMI. Otherwise, your instance must have EC2 Instance Connect installed. For information about which AMIs include EC2 Instance Connect and how to install it on other supported AMIs, see Install EC2 Instance Connect.

• You can assign a security group to an EC2 Instance Connect Endpoint when you create it. Otherwise, we use the default security group for the VPC. The security group for an EC2 Instance Connect Endpoint must allow outbound traffic to the destination instances. For more information, see Security groups for EC2 Instance Connect Endpoint.

• You can configure an EC2 Instance Connect Endpoint to preserve the source IP addresses of clients when routing requests to the instances. Otherwise, the IP address of the network interface becomes the client IP address for all incoming traffic.
  • If you turn on client IP preservation, the security groups for the instances must allow traffic from the clients. Also, the instances must be in the same VPC as the EC2 Instance Connect Endpoint.
  • If you turn off client IP preservation, the security groups for the instances must allow traffic from the VPC. This is the default.

• The following instance types do not support client IP preservation: C1, CG1, CG2, G1, HI1, M1, M2, M3, and T1. If you turn on client IP preservation and attempt to connect to an instance with one of these instance types by using EC2 Instance Connect Endpoint, the connection fails.

• Client IP preservation is not supported when traffic is routed through a transit gateway.

• When you create an EC2 Instance Connect Endpoint, a service-linked role is automatically created for the Amazon EC2 service in AWS Identity and Access Management (IAM). Amazon EC2 uses the service-linked role to provision network interfaces in your account, which are required when creating EC2 Instance Connect Endpoints. For more information, see Service-linked role for EC2 Instance Connect Endpoint.
• You can create only 1 EC2 Instance Connect Endpoint per VPC and per subnet. For more information, see [Quotas for EC2 Instance Connect Endpoint](#). If you need to create another EC2 Instance Connect Endpoint in a different Availability Zone within the same VPC, you must first delete the existing EC2 Instance Connect Endpoint. Otherwise, you'll receive a quota error.

• Each EC2 Instance Connect Endpoint can support up to 20 concurrent connections.

• The maximum duration for an established TCP connection is 1 hour (3,600 seconds). You can specify the maximum allowed duration in an IAM policy, which can be up to 3,600 seconds. For more information, see [Permissions to use EC2 Instance Connect Endpoint to connect to instances](#).

**Grant permissions to use EC2 Instance Connect Endpoint**

By default, IAM entities don't have permission to create, describe, or modify EC2 Instance Connect Endpoints. An IAM administrator can create IAM policies that grant the permissions required to perform specific actions on the resources that they need.

For information about creating IAM policies, see [Creating IAM policies](#) in the IAM User Guide.

The following example policies show how you can control the permissions that users have to EC2 Instance Connect Endpoints.

**Examples**

- [Permissions to create, describe, and delete EC2 Instance Connect Endpoints](#)
- [Permissions to use EC2 Instance Connect Endpoint to connect to instances](#)
- [Permissions to connect only from a specific IP address range](#)

**Permissions to create, describe, and delete EC2 Instance Connect Endpoints**

To create an EC2 Instance Connect Endpoint, users require permissions for the following actions:

- `ec2:CreateInstanceConnectEndpoint`
- `ec2:CreateNetworkInterface`
- `ec2:CreateTags`
- `iam:CreateServiceLinkedRole`
To describe and delete EC2 Instance Connect Endpoints, users require permissions for the following actions:

- `ec2:DescribeInstanceConnectEndpoints`
- `ec2:DeleteInstanceConnectEndpoint`

You can create a policy that grants permission to create, describe, and delete EC2 Instance Connect Endpoints in all subnets. Alternatively, you can restrict actions for specified subnets only by specifying the subnet ARNs as the allowed Resource or by using the `ec2:SubnetID` condition key. You can also use the `aws:ResourceTag` condition key to explicitly allow or deny endpoint creation with certain tags. For more information, see [Policies and permissions in IAM](https://docs.aws.amazon.com/IAM/latest/UserGuide/reference_policies_actions-resources-context-keys.html) in the *IAM User Guide*.

**Example IAM policy**

In the following example IAM policy, the Resource section grants permission to create and delete endpoints in all subnets, specified by the asterisk (*). The `ec2:Describe*` API actions do not support resource-level permissions. Therefore, the * wildcard is necessary in the Resource element.

```json
{

        }
    ]
}
```
Permissions to use EC2 Instance Connect Endpoint to connect to instances

The `ec2-instance-connect:OpenTunnel` action grants permission to establish a TCP connection to an instance to connect over the EC2 Instance Connect Endpoint. You can specify the EC2 Instance Connect Endpoint to use. Alternatively, a `Resource` with an asterisk (*) allows users to use any available EC2 Instance Connect Endpoint. You can also restrict access to instances based on the presence or absence of resource tags as condition keys.

**Conditions**

- `ec2-instance-connect:remotePort` – The port on the instance that can be used to establish a TCP connection. When this condition key is used, attempting to connect to an instance on any other port other than the port specified in the policy results in a failure.

- `ec2-instance-connect:privateIpAddress` – The destination private IP address associated with the instance that you want to establish a TCP connection with. You can specify a single IP address, such as `10.0.0.1/32`, or a range of IPs through CIDRs, such as `10.0.1.0/28`. When this condition key is used, attempting to connect to an instance with a different private IP address or outside the CIDR range results in a failure.

- `ec2-instance-connect:maxTunnelDuration` – The maximum duration for an established TCP connection. The unit is seconds and the duration ranges from a minimum of 1 second to a maximum of 3,600 seconds (1 hour). If the condition is not specified, the default duration is set to 3,600 seconds (1 hour). Attempting to connect to an instance for longer than the specified duration in the IAM policy or for longer than the default maximum results in a failure. The connection is disconnected after the specified duration.

If `maxTunnelDuration` is specified in the IAM policy and the value specified is less than 3,600 seconds (the default), then you must specify `--max-tunnel-duration` in the command when
connecting to an instance. For information about how to connect to an instance, see Connect to an Amazon EC2 instance using EC2 Instance Connect Endpoint.

You can also grant a user access to establish connections to instances based on the presence of resource tags on the EC2 Instance Connect Endpoint. For more information, see Policies and permissions in IAM in the IAM User Guide.

For Linux instances, the ec2-instance-connect:SendSSHPublicKey action grants permission to push the public key to an instance. The ec2:osuser condition specifies the name of the OS (operating system) user that can push the public key to an instance. Use the default username for the AMI that you used to launch the instance. For more information, see Grant IAM permissions for EC2 Instance Connect.

Example IAM policy

The following example IAM policies allow an IAM principal to connect to an instance using only the specified EC2 Instance Connect Endpoint, identified by the specified endpoint ID eice-123456789abcdef. The connection is successfully established only if all the conditions are satisfied.

Note

The ec2:Describe* API actions do not support resource-level permissions. Therefore, the * wildcard is necessary in the Resource element.

Linux

This example evaluates if the connection to the instance is established on —port 22 (SSH), if the private IP address of the instance lies within the range of 10.0.1.0/31 (between 10.0.1.0 and 10.0.1.1), and the maxTunnelDuration is less than or equal to 3600 seconds. The connection is disconnected after 3600 seconds (1 hour).

```json
{
    "Version": "2012-10-17",
    "Statement": [{
        "Sid": "EC2InstanceConnect",
        "Action": "ec2-instance-connect:OpenTunnel",
        "Effect": "Allow",
```
  "Condition": {
    "NumericEquals": {
      "ec2-instance-connect:remotePort": "22"
    },
    "IpAddress": {
      "ec2-instance-connect:privateIpAddress": "10.0.1.0/31"
    },
    "NumericLessThanEquals": {
      "ec2-instance-connect:maxTunnelDuration": "3600"
    }
  }
},
{
  "Sid": "SSHPublickey",
  "Effect": "Allow",
  "Action": "ec2-instance-connect:SendSSHPublicKey",
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "ec2:osuser": "ami-username"
    }
  }
},
{
  "Sid": "Describe",
  "Action": [
    "ec2:DescribeInstances",
    "ec2:DescribeInstanceConnectEndpoints"
  ],
  "Effect": "Allow",
  "Resource": "*"
}
}

Windows

This example evaluates if the connection to the instance is established on port 3389 (RDP), if the private IP address of the instance lies within the range of 10.0.1.0/31 (between 10.0.1.0 and 10.0.1.1), and the maxTunnelDuration is less than or equal to 3600 seconds. The connection is disconnected after 3600 seconds (1 hour).
Permissions to connect only from a specific IP address range

The following example IAM policy allows an IAM principal to connect to an instance on condition they are connecting from an IP address within the IP address range specified in the policy. If the IAM principal calls OpenTunnel from an IP address not within 192.0.2.0/24 (the example IP address range in this policy), the response is Access Denied. For more information, see `aws:SourceIp` in the IAM User Guide.
Security groups for EC2 Instance Connect Endpoint

A security group controls the traffic that is allowed to reach and leave the resources that it is associated with. For example, we deny traffic to and from an Amazon EC2 instance unless it is specifically allowed by the security groups associated with the instance.
The following examples show you how to configure the security group rules for the EC2 Instance Connect Endpoint and the target instances.

**Examples**

- [EC2 Instance Connect Endpoint security group rules](#)
- [Target instance security group rules](#)

**EC2 Instance Connect Endpoint security group rules**

The security group rules for an EC2 Instance Connect Endpoint must allow outbound traffic destined for the target instances to leave the endpoint. You can specify either the instance security group or the IPv4 address range of the VPC as the destination.

Traffic to the endpoint originates from the EC2 Instance Connect Endpoint Service, and it is allowed regardless of the inbound rules for the endpoint security group. To control who can use EC2 Instance Connect Endpoint to connect to an instance, use an IAM policy. For more information, see [Permissions to use EC2 Instance Connect Endpoint to connect to instances](#).

**Example outbound rule: Security group referencing**

The following example uses security group referencing, which means that the destination is a security group associated with the target instances. This rule allows outbound traffic from the endpoint to all instances that use this security group.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Destination</th>
<th>Port range</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td><em>ID of instance security group</em></td>
<td>22</td>
<td>Allows outbound SSH traffic to all instances associated with the instance security group</td>
</tr>
</tbody>
</table>

**Example outbound rule: IPv4 address range**

The following example allows outbound traffic to the specified IPv4 address range. The IPv4 addresses of an instance is assigned from its subnet, so you can use the IPv4 address range of the VPC.
Target instance security group rules

The security group rules for target instances must allow inbound traffic from the EC2 Instance Connect Endpoint. You can specify either the endpoint security group or an IPv4 address range as the source. If you specify an IPv4 address range, the source depends on whether client IP preservation is off or on. For more information, see Considerations.

Because security groups are stateful, the response traffic is allowed to leave the VPC regardless of the outbound rules for the instance security group.

Example inbound rule: Security group referencing

The following example uses security group referencing, which means that the source is the security group associated with the endpoint. This rule allows inbound SSH traffic from the endpoint to all instances that use this security group, whether client IP preservation is on or off. If there are no other inbound security group rules for SSH, then the instances accept SSH traffic only from the endpoint.

Example inbound rule: Client IP preservation off

The following example allows inbound SSH traffic from the specified IPv4 address range. Because client IP preservation is off, the source IPv4 address is the address of the endpoint network interface. The address of the endpoint network interface is assigned from its subnet, so you can use the IPv4 address range of the VPC to allow connections to all instances in the VPC.
### Example inbound rule: Client IP preservation on

The following example allows inbound SSH traffic from the specified IPv4 address range. Because client IP preservation is on, the source IPv4 address is the address of the client.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Source</th>
<th>Port range</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>VPC IPv4 CIDR</td>
<td>22</td>
<td>Allows inbound SSH traffic from the VPC</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Source</th>
<th>Port range</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>Public IPv4 address range</td>
<td>22</td>
<td>Allows inbound traffic from the specified client IPv4 address range</td>
</tr>
</tbody>
</table>

### Create an EC2 Instance Connect Endpoint

You can create an EC2 Instance Connect Endpoint to allow secure connection to your instances.

You can't modify an EC2 Instance Connect Endpoint after you've created it. Instead, you must delete the EC2 Instance Connect Endpoint and create a new one with the settings that you need.

#### Prerequisites

You must have the required IAM permissions to create an EC2 Instance Connect Endpoint. For more information, see [Permissions to create, describe, and delete EC2 Instance Connect Endpoints](#).

#### Shared subnets

You can create an EC2 Instance Connect Endpoint in a subnet that is shared with you. You can't use a EC2 Instance Connect Endpoint that the VPC owner created in a subnet that is shared with you.

#### Create the endpoint using the console

Use the following procedure to create an EC2 Instance Connect Endpoint.

#### To create an EC2 Instance Connect Endpoint

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the left navigation pane, choose **Endpoints**.

3. Choose **Create endpoint**, and then specify the endpoint settings as follows:

   a. (Optional) For **Name tag**, enter a name for the endpoint.
   
   b. For **Service category**, choose **EC2 Instance Connect Endpoint**.
   
   c. For **VPC**, select the VPC that has the target instances.
   
   d. (Optional) To preserve client IP addresses, expand **Additional settings** and select the check box. Otherwise, the default is to use the endpoint network interface as the client IP address.
   
   e. (Optional) For **Security groups**, select the security group to associate with the endpoint. Otherwise, the default is to use the default security group for the VPC. For more information, see [Security groups for EC2 Instance Connect Endpoint](#).
   
   f. For **Subnet**, select the subnet in which to create the endpoint.
   
   g. (Optional) To add a tag, choose **Add new tag** and enter the tag key and the tag value.

4. Review your settings and then choose **Create endpoint**.

   The initial status of the endpoint is **Pending**. Before you can connect to an instance using this endpoint, you must wait until the endpoint status is **Available**. This can take a few minutes.

5. To connect to an instance using your endpoint, see [Connect to an instance](#).

---

### Create the endpoint using the AWS CLI

Use the `create-instance-connect-endpoint` command to create an EC2 Instance Connect Endpoint.

**Prerequisites**

Install AWS CLI version 2 and configure it using your credentials. For more information, see [Install or update to the latest version of the AWS CLI](#) and [Configure the AWS CLI](#) in the **AWS Command Line Interface User Guide**. Alternatively, open AWS CloudShell and run AWS CLI commands in its pre-authenticated shell.

**To create the endpoint**

Use the following command to create an endpoint network interface for your EC2 Instance Connect Endpoint in the specified subnet.

```
aws ec2 create-instance-connect-endpoint --subnet-id subnet-0123456789example
```
The following is example output.

```json
{
  "OwnerId": "111111111111",
  "InstanceConnectEndpointId": "eice-0123456789example",
  "InstanceConnectEndpointArn": "arn:aws:ec2:us-east-1:111111111111:instance-connect-endpoint/eice-0123456789example",
  "State": "create-complete",
  "StateMessage": "",
  "DnsName": "eice-0123456789example.0123abcd.ec2-instance-connect-endpoint.us-east-1.amazonaws.com",
  "FipsDnsName": "eice-0123456789example.0123abcd.fips.ec2-instance-connect-endpoint.us-east-1.amazonaws.com",
  "NetworkInterfaceIds": [
    "eni-0123abcd"
  ],
  "VpcId": "vpc-0123abcd",
  "AvailabilityZone": "us-east-1a",
  "CreatedAt": "2023-04-07T15:43:53.000Z",
  "SubnetId": "subnet-0123abcd",
  "PreserveClientIp": false,
  "SecurityGroupIds": [
    "sg-0123abcd"
  ],
  "Tags": []
}
```

**To monitor the creation status**

The initial value for the State field is create-in-progress. Before you can connect to an instance using this endpoint, wait until the state is create-complete. Use the `describe-instance-connect-endpoints` command to monitor the status of the EC2 Instance Connect Endpoint. The `--query` parameter filters the results to the State field.

```
aws ec2 describe-instance-connect-endpoints --instance-connect-endpoint-ids eice-0123456789example --query InstanceConnectEndpoints[*].State --output text
```

The following is example output.

```
create-complete
```
Connect to an Amazon EC2 instance using EC2 Instance Connect Endpoint

You can use EC2 Instance Connect Endpoint to connect to an Amazon EC2 instance that supports SSH or RDP.

Contents

• Prerequisites
• Troubleshoot

Prerequisites

• You must have the required IAM permission to connect to an EC2 Instance Connect Endpoint. For more information, see Permissions to use EC2 Instance Connect Endpoint to connect to instances.

• The EC2 Instance Connect Endpoint must be in the Available (console) or create-complete (AWS CLI) state. If you do not have an EC2 Instance Connect Endpoint for your VPC, you can create one. For more information, see Create an EC2 Instance Connect Endpoint.

• Your instance must have an IPv4 address (either private or public). EC2 Instance Connect Endpoint does not support connecting to instances using IPv6 addresses.

• (Linux instances) To use the EC2 console to connect to your instance, or to use the CLI to connect and have EC2 Instance Connect handle the ephemeral key, your instance must have EC2 Instance Connect installed. For more information, see Install EC2 Instance Connect.

• Ensure that the security group of the instance allows inbound SSH traffic from the EC2 Instance Connect Endpoint. For more information, see Target instance security group rules.

Connect to your Linux instance using the Amazon EC2 console

You can connect to an instance using the Amazon EC2 console as follows.

To connect to your instance using the browser-based client

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, choose Connect.
4. Choose the EC2 Instance Connect tab.
5. For Connection type, choose Connect using EC2 Instance Connect Endpoint.
6. For **EC2 Instance Connect Endpoint**, choose the ID of the EC2 Instance Connect Endpoint.

7. For **Username**, if the AMI that you used to launch the instance uses a user name other than `ec2-user`, enter the correct user name.

8. For **Max tunnel duration (seconds)**, enter the maximum allowed duration for the SSH connection.

   The duration must comply with any `maxTunnelDuration` condition specified in the IAM policy. If you don’t have access to the IAM policy, contact your administrator.

9. Choose **Connect**. This opens a terminal window for your instance.

**Connect to your Linux instance using SSH**

You can use SSH to connect to your Linux instance, and use the `open-tunnel` command to establish a private tunnel. You can use `open-tunnel` in single connection or multi-connection mode.

For information about using the AWS CLI to connect to your instance using SSH, see [Connect using the AWS CLI](#).

The following examples use **OpenSSH**. You can use any other SSH client that supports a proxy mode.

**Single connection**

**To allow only a single connection to an instance using SSH and the `open-tunnel` command**

Use `ssh` and the **open-tunnel** AWS CLI command as follows. The `-o proxy` command encloses the `open-tunnel` command that creates the private tunnel to the instance.

```
ssh -i my-key-pair.pem ec2-user@i-0123456789example \
   -o ProxyCommand='aws ec2-instance-connect open-tunnel --instance-id i-0123456789example'
```

For:

- `-i` – Specify the key pair that was used to launch the instance.
- `ec2-user@i-0123456789example` – Specify the username of the AMI that was used to launch the instance, and the instance ID.
• **--instance-id** – Specify the ID of the instance to connect to. Alternatively, specify `%h`, which extracts the instance ID from the user.

### Multi-connection

To allow multiple connections to an instance, first run the [open-tunnel](https://docs.aws.amazon.com/cli/latest/userguide/cli-aws-open-tunnel.html) AWS CLI command to start listening for new TCP connections, and then use `ssh` to create a new TCP connection and a private tunnel to your instance.

#### To allow multiple connections to your instance using SSH and the open-tunnel command

1. Run the following command to start listening for new TCP connections on the specified port on your local machine.

   ```bash
   aws ec2-instance-connect open-tunnel \
   --instance-id i-0123456789example \
   --local-port 8888
   ```

   **Expected output**

   ```
   Listening for connections on port 8888.
   ```

2. In a *new terminal window*, run the following `ssh` command to create a new TCP connection and a private tunnel to your instance.

   ```bash
   ssh -i my-key-pair.pem ec2-user@localhost -p 8888
   ```

   **Expected output** – In the *first* terminal window, you'll see the following:

   ```
   [1] Accepted new tcp connection, opening websocket tunnel.
   ```

   You might also see the following:

   ```
   ```
Connect to your Linux instance using the AWS CLI

If you only know your instance ID, you can use the `ec2-instance-connect` AWS CLI command to connect to your instance using an SSH client. For more information about using the `ec2-instance-connect` command, see Connect using the AWS CLI.

Prerequisites

Install AWS CLI version 2 and configure it using your credentials. For more information, see Install or update to the latest version of the AWS CLI and Configure the AWS CLI in the AWS Command Line Interface User Guide. Alternatively, open AWS CloudShell and run AWS CLI commands in its pre-authenticated shell.

To connect to an instance using the instance ID and an EC2 Instance Connect Endpoint

If you only know the instance ID, use the `ec2-instance-connect` CLI command, and specify the `ssh` command, the instance ID, and the `--connection-type` parameter with the `eice` value.

```bash
aws ec2-instance-connect ssh --instance-id i-1234567890example --connection-type eice
```

Tip

If you get an error when using this command, make sure that you're using AWS CLI version 2. The `ssh` parameter is only available in AWS CLI version 2. For more information, see About AWS CLI version 2 in the AWS Command Line Interface User Guide.

Connect to your Windows instance using EC2 Instance Connect Endpoint

You can use Remote Desktop Protocol (RDP) over EC2 Instance Connect Endpoint to connect to a Windows instance without a public IPv4 address or public DNS name.

To connect to your Windows instance using an RDP client

1. Complete Steps 1 – 8 in Connect to your Windows instance using RDP. After downloading the RDP desktop file at Step 8, you'll get an Unable to connect message, which is to be expected because your instance does not have a public IP address.

2. Run the following command to establish a private tunnel to the VPC in which the instance is located. `--remote-port` must be 3389 because RDP uses port 3389 by default.
aws ec2-instance-connect open-tunnel \
   --instance-id i-0123456789example \
   --remote-port 3389 \
   --local-port any-port

3. In your Downloads folder, find the RDP desktop file that you downloaded, and drag it onto the RDP client window.

4. Right-click the RDP desktop file and choose Edit.

5. In the Edit PC window, for PC name (the instance to connect to), enter localhost:local-port, where local-port uses the same value as you specified in Step 2, and then choose Save.

Note that the following screenshot of the Edit PC window is from Microsoft Remote Desktop on a Mac. If you are using a Windows client, the window might be different.
6. In the RDP client, right-click the PC (that you just configured) and choose **Connect** to connect to your instance.

7. At the prompt, enter the decrypted password for the administrator account.
Troubleshoot

Use the following information to help diagnose and fix issues that you might encounter when using EC2 Instance Connect Endpoint to connect an instance.

Can't connect to your instance

The following are common reasons why you might not be able to connect to your instance.

- Security groups – Check the security groups assigned to the EC2 Instance Connect Endpoint and your instance. For more information about the required security group rules, see Security groups for EC2 Instance Connect Endpoint.

- Instance state – Verify that your instance is in the running state.

- Key pair – If the command you're using to connect requires a private key, verify that your instance has a public key and that you have the corresponding private key.

- IAM permissions – Verify that you have the required IAM permissions. For more information, see Grant permissions to use EC2 Instance Connect Endpoint.

For more troubleshooting tips for Linux instances, see Troubleshoot issues connecting to your Amazon EC2 Linux instance. For troubleshooting tips for Windows instances, see the section called “Windows instance RDP issues.”

ErrorCode: AccessDeniedException

If you receive an AccessDeniedException error, and the maxTunnelDuration condition is specified in the IAM policy, be sure to specify the --max-tunnel-duration parameter when connecting to an instance. For more information about this parameter, see open-tunnel in the AWS CLI Command Reference.

Log connections established over EC2 Instance Connect Endpoint

You can log resource operations and audit connections established over the EC2 Instance Connect Endpoint with AWS CloudTrail logs.

For more information about using AWS CloudTrail with Amazon EC2, see Log Amazon EC2 API calls using AWS CloudTrail.
Log EC2 Instance Connect Endpoint API calls with AWS CloudTrail

EC2 Instance Connect Endpoint resource operations are logged to CloudTrail as management events. When the following API calls are made, the activity is recorded as a CloudTrail event in Event history:

- CreateInstanceConnectEndpoint
- DescribeInstanceConnectEndpoints
- DeleteInstanceConnectEndpoint

You can view, search, and download recent events in your AWS account. For more information, see Viewing events with CloudTrail Event history in the AWS CloudTrail User Guide.

Use AWS CloudTrail to audit users who connect to an instance using EC2 Instance Connect Endpoint

Connection attempts to instances via EC2 Instance Connect Endpoint are logged in CloudTrail in Event history. When a connection to an instance is initiated through an EC2 Instance Connect Endpoint, the connection is logged as a CloudTrail management event with the eventName of OpenTunnel.

You can create Amazon EventBridge rules that route the CloudTrail event to a target. For more information, see the Amazon EventBridge User Guide.

The following is an example of an OpenTunnel management event that was logged in CloudTrail.

```json
{
    "eventVersion": "1.08",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "ABCDEFGONGNOMOOCB6XYTQEXAMPLE",
        "arn": "arn:aws:iam::123456789012:user/IAM-friendly-name",
        "accountId": "123456789012",
        "accessKeyId": "ABCDEFGUKZHNAW4OSN2AEXAMPLE",
        "userName": "IAM-friendly-name"
    },
    "eventTime": "2023-04-11T23:50:40Z",
    "eventSource": "ec2-instance-connect.amazonaws.com",
    "eventName": "OpenTunnel",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "1.2.3.4",
}
```
Delete an EC2 Instance Connect Endpoint

When you are finished with an EC2 Instance Connect Endpoint, you can delete it.

You must have the required IAM permissions to create an EC2 Instance Connect Endpoint. For more information, see Permissions to create, describe, and delete EC2 Instance Connect Endpoints.

When you delete an EC2 Instance Connect Endpoint using the console, it enters the Deleting state. If deletion is successful, the deleted endpoint no longer appears. If deletion fails, the state is delete-failed and Status message provides the failure reason.

When you delete an EC2 Instance Connect Endpoint using the AWS CLI, it enters the delete-in-progress state. If deletion is successful, it enters the delete-complete state. If deletion fails, the state is delete-failed and StateMessage provides the failure reason.

Console

To delete an EC2 Instance Connect Endpoint

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the left navigation pane, choose **Endpoints**.
3. Select the endpoint.
4. Choose **Actions, Delete VPC endpoints**.
5. When prompted for confirmation, enter **delete**.
6. Choose **Delete**.

**AWS CLI**

**To delete an EC2 Instance Connect Endpoint**

Use the **delete-instance-connect-endpoint** AWS CLI command and specify the ID of the EC2 Instance Connect Endpoint to delete.

```bash
aws ec2 delete-instance-connect-endpoint --instance-connect-endpoint-id eice-03f5e49b83924bbc7
```

The following is example output.

```json
{
   "InstanceConnectEndpoint": {
      "OwnerId": "111111111111",
      "InstanceConnectEndpointId": "eice-0123456789example",
      "InstanceConnectEndpointArn": "arn:aws:ec2:us-east-1:111111111111:instance-connect-endpoint/eice-0123456789example",
      "State": "delete-in-progress",
      "StateMessage": "",
      "NetworkInterfaceIds": [],
      "VpcId": "vpc-0123abcd",
      "AvailabilityZone": "us-east-1d",
      "CreatedAt": "2023-02-07T12:05:37+00:00",
      "SubnetId": "subnet-0123abcd"
   }
}
```

**Service-linked role for EC2 Instance Connect Endpoint**

Amazon EC2 uses AWS Identity and Access Management (IAM) **service-linked roles**. A service-linked role is a unique type of IAM role that is linked directly to Amazon EC2. Service-linked roles are
predefined by Amazon EC2 and include all the permissions required so that Amazon EC2 can call other AWS services on your behalf. For more information, see Using service-linked roles in the IAM User Guide.

**Service-linked role permissions for EC2 Instance Connect Endpoint**

Amazon EC2 uses AWSServiceRoleForEC2InstanceConnect to create and manage network interfaces in your account that are required by EC2 Instance Connect Endpoint.

The AWSServiceRoleForEC2InstanceConnect service-linked role trusts the following services to assume the role:

- ec2-instance-connect.amazonaws.com

The AWSServiceRoleForEC2InstanceConnect service-linked role uses the managed policy Ec2InstanceConnectEndpoint. To view the permissions for this policy, see Ec2InstanceConnectEndpoint in the AWS Managed Policy Reference.

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see Service-linked role permissions in the IAM User Guide.

**Create a service-linked role for EC2 Instance Connect Endpoint**

You don't need to manually create the service-linked role. When you create an EC2 Instance Connect Endpoint, Amazon EC2 creates the service-linked role for you.

**Edit a service-linked role for EC2 Instance Connect Endpoint**

EC2 Instance Connect Endpoint doesn't allow you to edit the AWSServiceRoleForEC2InstanceConnect service-linked role.

**Delete a service-linked role for EC2 Instance Connect Endpoint**

If you no longer need to use EC2 Instance Connect Endpoint, we recommend that you delete the AWSServiceRoleForEC2InstanceConnect service-linked role.

You must delete all EC2 Instance Connect Endpoint resources before you can delete the service-linked role.

To delete the service-linked role, see Deleting a service-linked role in the IAM User Guide.
Quotas for EC2 Instance Connect Endpoint

Your AWS account has default quotas, formerly referred to as limits, for each AWS service. Unless otherwise noted, each quota is Region-specific.

Your AWS account has the following quotas related to EC2 Instance Connect Endpoint.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Adjustable</th>
</tr>
</thead>
<tbody>

Connect your EC2 instance to an AWS resource

After you launch an instance, you can connect it to one or more AWS resources.

This section describes how to automatically connect an Amazon EC2 instance to an Amazon RDS database.

Automatically connect an EC2 instance to an RDS database

You can use the automatic connection functionality in the Amazon EC2 console to quickly connect one or more EC2 instances to an RDS database to allow traffic between them.

For more information, see How the connection is automatically configured. For a detailed walkthrough, which includes other ways to connect an EC2 instance and an RDS database, see Tutorial: Connect an Amazon EC2 instance to an Amazon RDS database.

Topics

- Costs
Prerequisites

Automatically connect an instance and a database

How the connection is automatically configured

Costs

While there is no charge to automatically connect your EC2 instance to an RDS database, you are charged for the underlying services. Data transfer fees will apply if your EC2 instance and RDS database are in different Availability Zones. For information about data transfer fees, see Data Transfer on the Amazon EC2 On-Demand Pricing page.

Prerequisites

Before you can automatically connect an EC2 instance to an RDS database, check the following:

- The EC2 instances must be in the Running state. You can't connect an EC2 instance if it's in another state.
- The EC2 instances and the RDS database must be in the same virtual private cloud (VPC). The automatic connection feature is not supported if an EC2 instance and RDS database are in different VPCs.

Automatically connect an instance and a database

You can automatically connect an EC2 instance to an RDS database immediately after you've launched your instance, or later.

Automatically connect immediately after launch

Use the following steps to automatically connect an EC2 instance to an RDS database immediately after you've launched the EC2 instance.

To view an animation of these steps, see View an animation: Automatically connect a newly-launched EC2 instance to an RDS database.

To automatically connect a newly-launched EC2 instance to an RDS database using the EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the console dashboard, choose **Launch instances**, and then follow the steps to **launch an instance**.

3. On the instance launch confirmation page, choose **Connect an RDS database**.

4. In the **Connect RDS Database** dialog box, do the following:
   
   a. For **Database role**, choose either **Cluster** or **Instance**.
   
   b. For **RDS database**, select a database to connect to.

   ![Note](image)

   **Note**

   The EC2 instances and the RDS database must be in the same VPC in order to connect to each other.

   c. Choose **Connect**.

**View an animation: Automatically connect a newly-launched EC2 instance to an RDS database**
Automatically connect an existing instance

Use the following steps to automatically connect an existing EC2 instance to an RDS database.

To view an animation of these steps, see View an animation: Automatically connect an existing EC2 instance to an RDS database.

To automatically connect an existing EC2 instance to an RDS database using the EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select one or more EC2 instances to connect to an RDS database, and then choose **Actions**, **Networking**, **Connect RDS database**.
   
   If **Connect RDS database** is not available, check that the EC2 instances are in the **Running** state and that they are in the same VPC.
4. In the **Connect RDS Database** dialog box, do the following:
   a. For **Database role**, choose either **Cluster** or **Instance**.
   b. For **RDS database**, select a database to connect to.
   c. Choose **Connect**.

**Note**

The EC2 instances and the RDS database must be in the same VPC in order to connect to each other.
View an animation: Automatically connect an existing EC2 instance to an RDS database

For information about how to use the Amazon RDS console to automatically connect an EC2 instance to an RDS database, see Configure automatic network connectivity with an EC2 instance in the Amazon RDS User Guide.

How the connection is automatically configured

When you use the EC2 console to automatically configure the connection between an EC2 instance and an RDS database to allow traffic between them, the connection is configured by security groups.

The security groups are automatically created and added to the EC2 instance and RDS database, as follows:

- Amazon EC2 creates a security group called **ec2-rds-x** and adds it to the EC2 instance. It has one outbound rule that allows traffic to the database by specifying **rds-ec2-x** (the database security group) as its destination.

- Amazon RDS creates a security group called **rds-ec2-x** and adds it to the database. It has one inbound rule that allows traffic from the EC2 instance by specifying **ec2-rds-x** (the EC2 instance security group) as its source.
The security groups reference each other as the destination and source, and only allow traffic on the database port. You can reuse these security groups so that any database with the rds-ec2-\textit{x} security group can talk to any EC2 instance with the ec2-rds-\textit{x} security group.

The security group names follow a pattern. For the security groups created by Amazon EC2, the pattern is \texttt{ec2-rds-x}, and for the security groups created by Amazon RDS, the pattern is \texttt{rds-ec2-x}. \textit{x} is a number, which increases by 1 each time a new security group is automatically created.

\textbf{Tutorial: Connect an Amazon EC2 instance to an Amazon RDS database}

\textbf{Tutorial objective}

The objective of this tutorial is to learn how to configure a secure connection between an Amazon EC2 instance and an Amazon RDS database by using the AWS Management Console.

There are different options for configuring the connection. In this tutorial, we explore the following three options:

- \textbf{Option 1: Automatically connect your EC2 instance to your RDS database using the EC2 console}

  Use the automatic connection feature in the EC2 console to automatically configure the connection between your EC2 instance and your RDS database to allow traffic between the EC2 instance and the RDS database.

- \textbf{Option 2: Automatically connect your EC2 instance to your RDS database using the RDS console}

  Use the automatic connection feature in the RDS console to automatically configure the connection between your EC2 instance and your RDS database to allow traffic between the EC2 instance and the RDS database.

- \textbf{Option 3: Manually connect your EC2 instance to your RDS database by mimicking the automatic connection feature}

  Configure the connection between your EC2 instance to your RDS database by manually configuring and assigning the security groups to reproduce the configuration that is automatically created by the automatic connection feature in Option 1 and Option 2.

\textbf{Context}

As context for why you'd want to configure a connection between your EC2 instance and an RDS database, let's consider the following scenario: Your website presents a form to your users to fill in. You need to capture the form data in a database. You can host your website on an EC2 instance...
that's been configured as a web server, and you can capture the form data in an RDS database. The EC2 instance and the RDS database need to be connected to each other so that the form data can go from the EC2 instance to the RDS database. This tutorial explains how to configure that connection. Note that this is just one example of a use case for connecting an EC2 instance and an RDS database.

**Architecture**

The following diagram shows the resources that are created and the architectural configuration that results from completing all the steps in this tutorial.

The diagram illustrates the following resources that you'll create:

- You'll create an EC2 instance and an RDS database in the same AWS Region, VPC, and Availability Zone.
- You'll create the EC2 instance in a public subnet.
- You'll create the RDS database in a private subnet.

When you use the RDS console to create the RDS database and automatically connect the EC2 instance, the VPC, DB subnet group, and public access settings for the database are
automatically selected. The RDS database is automatically created in a private subnet within the same VPC as the EC2 instance.

- Internet users can connect to the EC2 instance by using SSH or HTTP/HTTPS via an Internet gateway.
- Internet users cannot connect directly to the RDS database; only the EC2 instance is connected to the RDS database.
- When you use the automatic connection feature to allow traffic between the EC2 instance and the RDS database, the following security groups are automatically created and added:
  - Security group `ec2-rds-x` is created and added to the EC2 instance. It has one outbound rule that references the `rds-ec2-x` security group as its destination. This allows traffic from the EC2 instance to reach the RDS database with the `rds-ec2-x` security group.
  - Security group `rds-ec2-x` is created and added to the RDS database. It has one inbound rule that references the `ec2-rds-x` security group as its source. This allows traffic from the EC2 instance with the `ec2-rds-x` security group to reach the RDS database.

By using separate security groups (one for the EC2 instance, and one for the RDS database), you have better control over the security of the instance and the database. If you were to use the same security group on both the instance and the database, and then modified the security group to suit, say, only the database, the modification would affect both the instance and the database. In other words, if you were to use one security group, you could unintentionally modify the security of a resource (either the instance or the database) because you'd forgotten that the security group was attached to it.

The security groups that are automatically created also respect least privilege as they only allow the mutual connection for this workload on the database port by creating a workload-specific security group pair.

**Considerations**

Consider the following when you complete the tasks in this tutorial:

- **Two consoles** – You will use the following two consoles for this tutorial:
  - Amazon EC2 console – You will use the EC2 console to launch instances, to automatically connect an EC2 instance to an RDS database, and for the manual option to configure the connection by creating the security groups.
• **Amazon RDS console** – You will use the RDS console to create an RDS database and to automatically connect an EC2 instance to an RDS database.

• **One VPC** – To use the automatic connection feature, your EC2 instance and your RDS database must be in the same VPC.

If you were to manually configure the connection between your EC2 instance and your RDS database, you could launch your EC2 instance in one VPC and your RDS database in another VPC; however, you’d need to set up additional routing and VPC configuration. This scenario is not covered in this tutorial.

• **One AWS Region** – The EC2 instance and RDS database must be located in the same Region.

• **Two security groups** – The connectivity between the EC2 instance and the RDS database is configured by two security groups—a security group for your EC2 instance, and a security group for your RDS database.

When you use the automatic connection feature in the EC2 console or RDS console to configure the connectivity (Option 1 and Option 2 of this tutorial), the security groups are automatically created and assigned to the EC2 instance and RDS database.

If you do not use the automatic connection feature, you'll need to manually create and assign the security groups. You do this in Option 3 of this tutorial.

**Time to complete the tutorial**

30 minutes

You can complete the entire tutorial in one sitting, or you can complete it one task at a time.

**Costs**

By completing this tutorial, you might incur costs for the AWS resources that you create.

You can use Amazon EC2 under the [free tier](#) provided your AWS account is less than 12 months old and you configure your resources according to the free tier requirements.

If your EC2 instance and your RDS database are in different Availability Zones, you will incur data transfer fees. To avoid incurring these fees, the EC2 instance and the RDS database must be in the same Availability Zone. For information about data transfer fees, see [Data Transfer](#) on the Amazon EC2 On-Demand Pricing page.
To prevent incurring costs after you've completed the tutorial, make sure to delete the resources if they are no longer needed. For the steps to delete the resources, see Clean up.

Option 1: Automatically connect your EC2 instance to your RDS database using the EC2 console

Objective

The objective of Option 1 is to explore the automatic connection feature in the EC2 console that automatically configures the connection between your EC2 instance and RDS database to allow traffic from the EC2 instance to the RDS database. In Option 3, you'll learn how to manually configure the connection.

Before you begin

You'll need the following to complete this tutorial:

- An RDS database that is in the same VPC as the EC2 instance. You can either use an existing RDS database or follow the steps in Task 1 to create a new RDS database.
- An EC2 instance that is in the same VPC as the RDS database. You can either use an existing EC2 instance or follow the steps in Task 2 to create a new EC2 instance.
- Permissions to call the following operations:
  - ec2: AssociateRouteTable
  - ec2: AuthorizeSecurityGroupEgress
  - ec2: CreateRouteTable
  - ec2: CreateSecurityGroup
  - ec2: CreateSubnet
  - ec2: DescribeInstances
  - ec2: DescribeNetworkInterfaces
  - ec2: DescribeRouteTables
  - ec2: DescribeSecurityGroups
  - ec2: DescribeSubnets
  - ec2: ModifyNetworkInterfaceAttribute
  - ec2: RevokeSecurityGroupEgress
Tasks to complete Option 1

- **Task 1: Create an RDS database – optional**
- **Task 2: Launch an EC2 instance – optional**
- **Task 3: Automatically connect your EC2 instance to your RDS database**
- **Task 4: Verify the connection configuration**

**Task 1: Create an RDS database – optional**

**Note**

Creating a Amazon RDS database is not the focus of this tutorial. If you already have an RDS database and would like to use it in this tutorial, you can skip this task.

**Task objective**

The objective of this task is to create an RDS database so that you can complete Task 3 where you configure the connection between your EC2 instance and your RDS database. If you have an RDS database that you can use, you can skip this task.

**Important**

If you use an existing RDS database, make sure that it is in the same VPC as your EC2 instance so that you can use the automatic connection feature.

**Steps to create an RDS database**

Use the following steps to create an RDS database.

To view an animation of these steps, see [View an animation: Create an RDS database](#).

**RDS database configuration**

The steps in this task configure the RDS database as follows:

- Engine type: MySQL
- Template: Free tier
• DB instance identifier: tutorial-database-1
• DB instance class: db.t3.micro

⚠️ Important
In a production environment, you should configure your database to meet your specific needs.

To create a MySQL RDS database

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the Region selector (at top right), choose an AWS Region. The database and the EC2 instance must be in the same Region in order to use the automatic connection feature in the EC2 console.
3. On the dashboard, choose Create database.
4. Under Choose a database creation method, check that Standard create is selected. If you choose Easy create, the VPC selector is not available. You must ensure that your database is in the same VPC as your EC2 instance in order to use the automatic connection feature in the EC2 console.
5. Under Engine options, for Engine type, choose MySQL.
6. Under Templates, choose a sample template to meet your needs. For this tutorial, choose Free tier to create a database at no cost. However, note that the free tier is only available if your account is less than 12 months old. Other restrictions apply. You can read more by choosing the Info link in the Free tier box.
7. Under Settings, do the following:
   a. For DB instance identifier, enter a name for the database. For this tutorial, enter tutorial-database-1.
   b. For Master username, leave the default name, which is admin.
   c. For Master password, enter a password that you can remember for this tutorial, and then, for Confirm password, enter the password again.
8. Under Instance configuration, for DB instance class, leave the default, which is db.t3.micro. If your account is less than 12 months, you can use this database class for free. Other restrictions apply. For more information, see AWS Free Tier.
9. Under **Connectivity**, for **Compute resource**, choose **Don't connect to an EC2 compute resource** because you'll connect the EC2 instance and the RDS database later in Task 3.

   (Later, in Option 2 of this tutorial, you'll try out the automatic connection feature in the RDS console by choosing **Connect to an EC2 compute resource**.)

10. For **Virtual private cloud (VPC)**, choose a VPC. The VPC must have a DB subnet group. To use the automatic connection feature, your EC2 instance and RDS database must be in the same VPC.

11. Keep all the default values for the other fields on this page.

12. Choose **Create database**.

   On the **Databases** screen, the **Status** of the new database is **Creating** until the database is ready to use. When the status changes to **Available**, you can connect to the database. Depending on the database class and the amount of storage, it can take up to 20 minutes before the new database is available.
View an animation: Create an RDS database

You're now ready for **Task 2: Launch an EC2 instance – optional**.

**Task 2: Launch an EC2 instance – optional**

**Note**

Launching an instance is not the focus of this tutorial. If you already have an Amazon EC2 instance and would like to use it in this tutorial, you can skip this task.
Task objective

The objective of this task is to launch an EC2 instance so that you can complete Task 3 where you configure the connection between your EC2 instance and your Amazon RDS database. If you have an EC2 instance that you can use, you can skip this task.

⚠️ Important

If you use an existing EC2 instance, make sure that it is in the same VPC as your RDS database so that you can use the automatic connection feature.

Steps to launch an EC2 instance

Use the following steps to launch an EC2 instance for this tutorial.

To view an animation of these steps, see View an animation: Launch an EC2 instance.

EC2 instance configuration

The steps in this task configure the EC2 instance as follows:

- Instance name: tutorial-instance-1
- AMI: Amazon Linux 2
- Instance type: t2.micro
- Auto-assign public IP: Enabled
- Security group with the following three rules:
  - Allow SSH from your IP address
  - Allow HTTPS traffic from anywhere
  - Allow HTTP traffic from anywhere

⚠️ Important

In a production environment, you should configure your instance to meet your specific needs.
To launch an EC2 instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the Region selector (at top right), choose an AWS Region. The instance and the RDS database must be in the same Region in order to use the automatic connection feature in the EC2 console.
3. On the EC2 Dashboard, choose Launch instance.
4. Under Name and tags, for Name, enter a name to identify your instance. For this tutorial, name the instance tutorial-instance-1. While the instance name is not mandatory, when you select your instance in the EC2 console, the name will help you easily identify it.
5. Under Application and OS Images, choose an AMI that meets your web server needs. This tutorial uses Amazon Linux 2.
6. Under Instance type, for Instance type, select an instance type that meets your web server needs. This tutorial uses t2.micro.

Note

You can use Amazon EC2 under the Free tier provided your AWS account is less than 12 months old and you choose a t2.micro instance type (or t3.micro in Regions where t2.micro is not available).

7. Under Key pair (login), for Key pair name, choose your key pair.
8. Under Network settings, do the following:
   a. For Network and Subnet, if you haven’t made changes to your default VPC or subnets, you can keep the default settings.
      If you have made changes to your default VPC or subnets, check the following:
      i. The instance must be in the same VPC as the RDS database to use the automatic connection feature. By default you have only one VPC.
      ii. The VPC that you’re launching your instance into must have an internet gateway attached to it so that you can access your web server from the internet. Your default VPC is automatically set up with an internet gateway.
      iii. To ensure that your instance receives a public IP address, for Auto-assign public IP, check that Enable is selected. If Disable is selected, choose Edit (to the right of Network Settings), and then, for Auto-assign public IP, choose Enable.
b. To connect to your instance by using SSH, you need a security group rule that authorizes SSH (Linux) or RDP (Windows) traffic from your computer's public IPv4 address. By default, when you launch an instance, a new security group is created with a rule that allows inbound SSH traffic from anywhere.

To make sure that only your IP address can connect to your instance, under Firewall (security groups), from the drop-down list next to the Allow SSH traffic from check box, choose My IP.

c. To allow traffic from the internet to your instance, select the following check boxes:

- Allow HTTPS traffic from the internet
- Allow HTTP traffic from the internet

9. In the Summary panel, review your instance configuration and then choose Launch instance.

10. Keep the confirmation page open. You'll need it for the next task when you automatically connect your instance to your database.

   If the instance fails to launch or the state immediately goes to terminated instead of running, see Troubleshoot Amazon EC2 instance launch issues.

For more information about launching an instance, see Launch an instance using the new launch instance wizard.
You're now ready for **Task 3: Automatically connect your EC2 instance to your RDS database**.

**Task 3: Automatically connect your EC2 instance to your RDS database**

**Task objective**

The objective of this task is to use the automatic connection feature in the EC2 console to automatically configure the connection between your EC2 instance and your RDS database.

**Steps to connect your EC2 instance and RDS database**

Use the following steps to connect your EC2 instance and RDS database using the automatic feature in the EC2 console.

To view an animation of these steps, see [View an animation: Automatically connect a newly-launched EC2 instance to an RDS database](#).
To automatically connect an EC2 instance to an RDS database using the EC2 console

1. On the instance launch confirmation page (it should be open from the previous task), choose Connect an RDS database.

   If you closed the confirmation page, follow these steps:

   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. In the navigation pane, choose Instances.
   c. Select the EC2 instance that you just created, and then choose Actions, Networking, Connect RDS database.

      If Connect RDS database is not available, check that the EC2 instance is in the Running state.

2. For Database role, choose Instance. Instance in this case refers to the database instance.
3. For RDS database, choose the RDS database that you created in Task 1.

   Note
   The EC2 instance and the RDS database must be in the same VPC in order to connect to each other.

4. Choose Connect.
You're now ready for **Task 4: Verify the connection configuration**.

**Task 4: Verify the connection configuration**

**Task objective**

The objective of this task is to verify that the two security groups were created and assigned to the instance and database.

When you use the automatic connection feature in the EC2 console to configure the connectivity, the security groups are automatically created and assigned to the instance and database, as follows:

- Security group **rds-ec2-x** is created and added to the RDS database. It has one inbound rule that references the **ec2-rds-x** security group as its source. This allows traffic from the EC2 instance with the **ec2-rds-x** security group to reach the RDS database.
Security group ec2-rds-x is created and added to the EC2 instance. It has one outbound rule that references the rds-ec2-x security group as its destination. This allows traffic from the EC2 instance to reach the RDS database with the rds-ec2-x security group.

Steps to verify the connection configuration

Use the following steps to verify the connection configuration.

To view an animation of these steps, see View an animation: Verify the connection configuration.

To verify the connection configuration using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation page, choose Databases.
3. Choose the RDS database that you created for this tutorial.
4. On the Connectivity & security tab, under Security, VPC security groups, verify that a security group called rds-ec2-x is displayed.
5. Choose the rds-ec2-x security group. The Security Groups screen in the EC2 console opens.
6. Choose the rds-ec2-x security group to open it.
7. Choose the Inbound rules tab.
8. Verify that the following security group rule exists, as follows:
   • Type: MYSQL/Aurora
   • Port range: 3306
   • Source: sg-0987654321example / ec2-rds-x – This is the security group that is assigned to the EC2 instance that you verified in the preceding steps.
   • Description: Rule to allow connections from EC2 instances with sg-1234567890example attached
10. In the navigation pane, choose Instances.
11. Choose the EC2 instance that you selected to connect to the RDS database in the previous task, and choose the Security tab.
12. Under Security details, Security groups, verify that a security group called ec2-rds-x is in the list. x is a number.
13. Choose the `ec2-rds-x` security group to open it.

14. Choose the **Outbound rules** tab.

15. Verify that the following security group rule exists, as follows:

   - **Type**: MySQL/Aurora
   - **Port range**: 3306
   - **Destination**: `sg-1234567890example / rds-ec2-x`
   - **Description**: Rule to allow connections to `database-tutorial` from any instances this security group is attached to

By verifying that these security groups and security group rules exist and that they are assigned to the RDS database and EC2 instance as described in this procedure, you can verify that the connection was automatically configured by using the automatic connection feature.

**View an animation: Verify the connection configuration**
You have completed Option 1 of this tutorial. You can now either complete Option 2, which teaches you how to use the RDS console to automatically connect an EC2 instance to an RDS database, or you can complete Option 3, which teaches you how to manually configure the security groups that were automatically created in Option 1.

**Option 2: Automatically connect your EC2 instance to your RDS database using the RDS console**

**Objective**

The objective of Option 2 is to explore the automatic connect feature in the RDS console that automatically configures the connection between your EC2 instance and RDS database to allow traffic from the EC2 instance to the RDS database. In Option 3, you'll learn how to manually configure the connection.

**Before you begin**

You'll need the following to complete this tutorial:

- An EC2 instance that is in the same VPC as the RDS database. You can either use an existing EC2 instance or follow the steps in Task 1 to create a new instance.
- Permissions to call the following operations:
  - ec2:AssociateRouteTable
  - ec2:AuthorizeSecurityGroupEgress
  - ec2:CreateRouteTable
  - ec2:CreateSecurityGroup
  - ec2:CreateSubnet
  - ec2:DescribeInstances
  - ec2:DescribeNetworkInterfaces
  - ec2:DescribeRouteTables
  - ec2:DescribeSecurityGroups
  - ec2:DescribeSubnets
  - ec2:ModifyNetworkInterfaceAttribute
  - ec2:RevokeSecurityGroupEgress
Tasks to complete Option 2

- **Task 1: Launch an EC2 instance – optional**
- **Task 2: Create an RDS database and automatically connect it to your EC2 instance**
- **Task 3: Verify the connection configuration**

**Task 1: Launch an EC2 instance – optional**

ℹ️ **Note**

Launching an instance is not the focus of this tutorial. If you already have an Amazon EC2 instance and would like to use it in this tutorial, you can skip this task.

**Task objective**

The objective of this task is to launch an EC2 instance so that you can complete Task 2 where you configure the connection between your EC2 instance and your Amazon RDS database. If you have an EC2 instance that you can use, you can skip this task.

**Steps to launch an EC2 instance**

Use the following steps to launch an EC2 instance for this tutorial.

To view an animation of these steps, see [View an animation: Launch an EC2 instance](#).

**EC2 instance configuration**

The steps in this task configure the EC2 instance as follows:

- **Instance name:** `tutorial-instance-2`
- **AMI:** Amazon Linux 2
- **Instance type:** `t2.micro`
- **Auto-assign public IP:** Enabled
- **Security group with the following three rules:**
  - Allow SSH from your IP address
  - Allow HTTPS traffic from anywhere
  - Allow HTTP traffic from anywhere
**Important**

In a production environment, you should configure your instance to meet your specific needs.

---

**To launch an EC2 instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. On the **EC2 Dashboard**, choose **Launch instance**.
3. Under **Name and tags**, for **Name**, enter a name to identify your instance. For this tutorial, name the instance `tutorial-instance-2`. While the instance name is not mandatory, when you select your instance in the RDS console, the name will help you easily identify it.
4. Under **Application and OS Images**, choose an AMI that meets your web server needs. This tutorial uses **Amazon Linux**.
5. Under **Instance type**, for **Instance type**, select an instance type that meets your web server needs. This tutorial uses **t2.micro**.

---

**Note**

You can use Amazon EC2 under the [Free tier](https://aws.amazon.com/free/) provided your AWS account is less than 12 months old and you choose a t2.micro instance type (or t3.micro in Regions where t2.micro is not available).

6. Under **Key pair (login)**, for **Key pair name**, choose your key pair.
7. Under **Network settings**, do the following:
   a. For **Network** and **Subnet**, if you haven’t made changes to your default VPC or subnets, you can keep the default settings.

If you have made changes to your default VPC or subnets, check the following:

   i. The instance must be in the same VPC as the RDS database to use the automatic connection configuration. By default you have only one VPC.
   ii. The VPC that you’re launching your instance into must have an internet gateway attached to it so that you can access your web server from the internet. Your default VPC is automatically set up with an internet gateway.
To ensure that your instance receives a public IP address, for **Auto-assign public IP**, check that **Enable** is selected. If **Disable** is selected, choose **Edit** (to the right of **Network Settings**), and then, for **Auto-assign public IP**, choose **Enable**.

b. To connect to your instance by using SSH, you need a security group rule that authorizes SSH (Linux) or RDP (Windows) traffic from your computer’s public IPv4 address. By default, when you launch an instance, a new security group is created with a rule that allows inbound SSH traffic from anywhere.

   To make sure that only your IP address can connect to your instance, under **Firewall (security groups)**, from the drop-down list next to the **Allow SSH traffic from** check box, choose **My IP**.

c. To allow traffic from the internet to your instance, select the following check boxes:

   - **Allow HTTPS traffic from the internet**
   - **Allow HTTP traffic from the internet**

8. In the **Summary** panel, review your instance configuration and then choose **Launch instance**.

9. Choose **View all instances** to close the confirmation page and return to the console. Your instance will first be in a pending state, and will then go into the **running** state.

   If the instance fails to launch or the state immediately goes to **terminated** instead of **running**, see **Troubleshoot Amazon EC2 instance launch issues**.

For more information about launching an instance, see **Launch an instance using the new launch instance wizard**.
You're now ready for **Task 2: Create an RDS database and automatically connect it to your EC2 instance**.

**Task 2: Create an RDS database and automatically connect it to your EC2 instance**

**Task objective**

The objective of this task is to create an RDS database and use the automatic connection feature in the RDS console to automatically configure the connection between your EC2 instance and your RDS database.

**Steps to create an RDS database**

Use the following steps to create an RDS database and connect it to your EC2 instance using the automatic feature in the RDS console.

To view an animation of these steps, see [View an animation: Create an RDS database and automatically connect it to an EC2 instance](#).
**DB instance configuration**

The steps in this task configure the DB instance as follows:

- Engine type: MySQL
- Template: Free tier
- DB instance identifier: `tutorial-database`
- DB instance class: `db.t3.micro`

⚠️ **Important**

In a production environment, you should configure your instance to meet your specific needs.

---

**To create an RDS database and automatically connect it to an EC2 instance**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. From the Region selector (at top right), choose the AWS Region in which you created the EC2 instance. The EC2 instance and the RDS database must be in the same Region.
3. On the dashboard, choose **Create database**.
4. Under **Choose a database creation method**, check that **Standard create** is selected. If you choose **Easy create**, the automatic connection feature is not available.
5. Under **Engine options**, for **Engine type**, choose **MySQL**.
6. Under **Templates**, choose a sample template to meet your needs. For this tutorial, choose **Free tier** to create an RDS database at no cost. However, note that the free tier is only available if your account is less than 12 months old. Other restrictions apply. You can read more by choosing the **Info** link in the **Free tier** box.
7. Under **Settings**, do the following:
   a. For **DB instance identifier**, enter a name for the database. For this tutorial, enter `tutorial-database`.
   b. For **Master username**, leave the default name, which is **admin**.
   c. For **Master password**, enter a password that you can remember for this tutorial, and then, for **Confirm password**, enter the password again.
8. Under **Instance configuration**, for **DB instance class**, leave the default, which is **db.t3.micro**. If your account is less than 12 months, you can use this instance for free. Other restrictions apply. For more information, see [AWS Free Tier](#).

9. Under **Connectivity**, for **Compute resource**, choose **Connect to an EC2 compute resource**. This is the automatic connection feature in the RDS console.

10. For **EC2 instance**, choose the EC2 instance that you want to connect to. For the purposes of this tutorial, you can either choose the instance that you created in the previous task, which you named **tutorial-instance**, or choose another existing instance. If you don't see your instance in the list, choose the refresh icon to the right of **Connectivity**.

When you use the automatic connection feature, a security group is added to this EC2 instance, and another security group is added to the RDS database. The security groups are automatically configured to allow traffic between the EC2 instance and the RDS database. In the next task, you'll verify that the security groups were created and assigned to the EC2 instance and RDS database.

11. Choose **Create database**.

On the **Databases** screen, the **Status** of the new database is **Creating** until the database is ready to use. When the status changes to **Available**, you can connect to the database. Depending on the database class and the amount of storage, it can take up to 20 minutes before the new database is available.

To learn more, see [Configure automatic network connectivity with an EC2 instance](#) in the Amazon RDS User Guide.
You're now ready for **Task 3: Verify the connection configuration**.

**Task 3: Verify the connection configuration**

**Task objective**

The objective of this task is to verify that the two security groups were created and assigned to the instance and the database.
When you use the automatic connection feature in the RDS console to configure the connectivity, the security groups are automatically created and assigned to the instance and database, as follows:

- Security group `rds-ec2-x` is created and added to the RDS database. It has one inbound rule that references the `ec2-rds-x` security group as its source. This allows traffic from the EC2 instance with the `ec2-rds-x` security group to reach the RDS database.
- Security group `ec2-rds-x` is created and added to the EC2 instance. It has one outbound rule that references the `rds-ec2-x` security group as its destination. This allows traffic from the EC2 instance to reach the RDS database with the `rds-ec2-x` security group.

**Steps to verify the connection configuration**

Use the following steps to verify the connection configuration.

To view an animation of these steps, see [View an animation: Verify the connection configuration](https://console.aws.amazon.com/rds/).

**To verify the connection configuration using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Choose the EC2 instance that you selected to connect to the RDS database in the previous task, and choose the **Security** tab.
4. Under **Security details**, **Security groups**, verify that a security group called `ec2-rds-x` is in the list. `x` is a number.
5. Choose the `ec2-rds-x` security group to open it.
6. Choose the **Outbound rules** tab.
7. Verify that the following security group rule exists, as follows:
   - Type: **MySQL/Aurora**
   - Port range: **3306**
   - Destination: **sg-1234567890example / rds-ec2-x**
   - Description: **Rule to allow connections to database-tutorial from any instances this security group is attached to**
8. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
9. In the navigation page, choose **Databases**.
10. Choose the RDS database that you created for this tutorial.

11. On the **Connectivity & security** tab, under **Security, VPC security groups**, verify that a security group called *rds-ec2-x* is displayed.

12. Choose the *rds-ec2-x* security group. The **Security Groups** screen in EC2 console opens.

13. Choose the *rds-ec2-x* security group and open it.

14. Choose the **Inbound rules** tab.

15. Verify that the following security group rule exists, as follows:
   
   - **Type:** MySQL/Aurora
   - **Port range:** 3306
   - **Source:** *sg-0987654321example / ec2-rds-x* – This is the security group that is assigned to the EC2 instance that you verified in the preceding steps.
   - **Description:** Rule to allow connections from EC2 instances with *sg-1234567890example* attached

By verifying that these security groups and security group rules exist and that they are assigned to the EC2 instance and RDS database as described in this procedure, you can verify that the connection was automatically configured by using the automatic connection feature.
You have completed Option 2 of this tutorial. You can now either complete Option 3, which teaches you how to manually configure the security groups that were automatically created in Option 2.

**Option 3: Manually connect your EC2 instance to your RDS database by mimicking the automatic connection feature**

**Objective**

The objective of Option 3 is to learn how to manually configure the connection between an EC2 instance and an RDS database by manually reproducing the configuration of the automatic connection feature.

**Before you begin**

You'll need the following to complete this tutorial:
• An EC2 instance that is in the same VPC as the RDS database. You can either use an existing EC2 instance or follow the steps in Task 1 to create a new instance.

• An RDS database that is in the same VPC as the EC2 instance. You can either use an existing RDS database or follow the steps in Task 2 to create a new database.

• Permissions to call the following operations. If you have completed Option 1 of this tutorial, you already have these permissions.
  • ec2:AssociateRouteTable
  • ec2:AuthorizeSecurityGroupEgress
  • ec2:CreateRouteTable
  • ec2:CreateSecurityGroup
  • ec2:CreateSubnet
  • ec2:DescribeInstances
  • ec2:DescribeNetworkInterfaces
  • ec2:DescribeRouteTables
  • ec2:DescribeSecurityGroups
  • ec2:DescribeSubnets
  • ec2:ModifyNetworkInterfaceAttribute
  • ec2:RevokeSecurityGroupEgress

Tasks to complete Option 3

• Task 1: Launch an EC2 instance – optional
• Task 2: Create an RDS database – optional
• Task 3: Manually connect your EC2 instance to your RDS database by creating security groups and assigning them to the instances

Task 1: Launch an EC2 instance – optional

⚠️ Note

Launching an instance is not the focus of this tutorial. If you already have an Amazon EC2 instance and would like to use it in this tutorial, you can skip this task.
Task objective

The objective of this task is to launch an EC2 instance so that you can complete Task 3 where you configure the connection between your EC2 instance and your Amazon RDS database.

Steps to launch an EC2 instance

Use the following steps to launch an EC2 instance for this tutorial.

To view an animation of these steps, see View an animation: Launch an EC2 instance.

EC2 instance configuration

The steps in this task configure the EC2 instance as follows:

- Instance name: tutorial-instance
- AMI: Amazon Linux 2
- Instance type: t2.micro
- Auto-assign public IP: Enabled
- Security group with the following three rules:
  - Allow SSH from your IP address
  - Allow HTTPS traffic from anywhere
  - Allow HTTP traffic from anywhere

⚠️ Important

In a production environment, you should configure your instance to meet your specific needs.

To launch an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the EC2 Dashboard, choose Launch instance.
3. Under Name and tags, for Name, enter a name to identify your instance. For this tutorial, name the instance tutorial-instance-manual-1. While the instance name is not mandatory, the name will help you easily identify it.
4. Under **Application and OS Images**, choose an AMI that meets your web server needs. This tutorial uses **Amazon Linux**.

5. Under **Instance type**, for **Instance type**, select an instance type that meets your web server needs. This tutorial uses **t2.micro**.

   ![Note]
   
   You can use Amazon EC2 under the **Free tier** provided your AWS account is less than 12 months old and you choose a **t2.micro** instance type (or **t3.micro** in Regions where **t2.micro** is not available).

6. Under **Key pair (login)**, for **Key pair name**, choose your key pair.

7. Under **Network settings**, do the following:

   a. For **Network** and **Subnet**, if you haven’t made changes to your default VPC or subnets, you can keep the default settings.

   If you have made changes to your default VPC or subnets, check the following:

   i. The instance must be in the same VPC as the RDS database. By default you have only one VPC.

   ii. The VPC that you’re launching your instance into must have an internet gateway attached to it so that you can access your web server from the internet. Your default VPC is automatically set up with an internet gateway.

   iii. To ensure that your instance receives a public IP address, for **Auto-assign public IP**, check that **Enable** is selected. If **Disable** is selected, choose **Edit** (to the right of **Network Settings**), and then, for **Auto-assign public IP**, choose **Enable**.

   b. To connect to your instance by using SSH, you need a security group rule that authorizes SSH (Linux) or RDP (Windows) traffic from your computer’s public IPv4 address. By default, when you launch an instance, a new security group is created with a rule that allows inbound SSH traffic from anywhere.

   To make sure that only your IP address can connect to your instance, under **Firewall (security groups)**, from the drop-down list next to the **Allow SSH traffic from** check box, choose **My IP**.

   c. To allow traffic from the internet to your instance, select the following check boxes:
8. In the **Summary** panel, review your instance configuration and then choose **Launch instance**.

9. Choose **View all instances** to close the confirmation page and return to the console. Your instance will first be in a pending state, and will then go into the **running** state.

   If the instance fails to launch or the state immediately goes to **terminated** instead of **running**, see [Troubleshoot Amazon EC2 instance launch issues](#).

For more information about launching an instance, see [Launch an instance using the new launch instance wizard](#).

**View an animation: Launch an EC2 instance**

You are now ready for [Task 2: Create an RDS database – optional](#).
Task 2: Create an RDS database – *optional*

**Note**
Creating an RDS database is not the focus of this part of the tutorial. If you already have an RDS database and would like to use it for this tutorial, you can skip this task.

**Task objective**

The objective of this task is to create an RDS database. You'll use this instance in Task 3 when you connect it to your EC2 instance.

**Steps to create an RDS database**

Use the following steps to create an RDS database for Option 3 of this tutorial.

To view an animation of these steps, see View an animation: Create a DB instance.

**RDS database configuration**

The steps in this task configure the RDS database as follows:

- Engine type: MySQL
- Template: Free tier
- DB instance identifier: `tutorial-database-manual`
- DB instance class: `db.t3.micro`

**Important**

In a production environment, you should configure your instance to meet your specific needs.

**To create a MySQL DB instance**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. From the Region selector (at top right), choose the AWS Region in which you created the EC2 instance. The EC2 instance and the DB instance must be in the same Region.
3. On the dashboard, choose **Create database**.

4. Under **Choose a database creation method**, choose **Easy create**. When you choose this option, the automatic connection feature to automatically configure the connection is not available.

5. Under **Engine options**, for **Engine type**, choose **MySQL**.

6. For **DB instance size**, choose **Free tier**.

7. For **DB instance identifier** enter a name for the RDS database. For this tutorial, enter **tutorial-database-manual**.

8. For **Master username**, leave the default name, which is **admin**.

9. For **Master password**, enter a password that you can remember for this tutorial, and then, for **Confirm password**, enter the password again.

10. Choose **Create database**.

    On the **Databases** screen, the **Status** of the new DB instance is **Creating** until the DB instance is ready to use. When the status changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.
View an animation: Create a DB instance

You are now ready for Task 3: Manually connect your EC2 instance to your RDS database by creating security groups and assigning them to the instances.

Task 3: Manually connect your EC2 instance to your RDS database by creating security groups and assigning them to the instances

Task objective

The objective of this task is to reproduce the connection configuration of the automatic connection feature by performing the following manually: You create two new security groups, and then add a security group each to the EC2 instance and the RDS database.
Steps to create new security groups and add them to the instances

Use the following steps to connect an EC2 instance to your RDS database by creating two new security groups. You then add a security group each to the EC2 instance and the RDS database.

To create two new security groups and assign one each to the EC2 instance and RDS database

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. First create the security group to add to the EC2 instance, as follows:
   a. In the navigation pane, choose Security Groups.
   b. Choose Create security group.
   c. For Security group name, enter a descriptive name for the security group. For this tutorial, enter ec2-rds-manual-configuration.
   d. For Description, enter a brief description. For this tutorial, enter EC2 instance security group to allow EC2 instance to securely connect to RDS database.
   e. Choose Create security group. You'll come back to this security group to add an outbound rule after you've created the RDS database security group.
3. Now, create the security group to add to the RDS database, as follows:
   a. In the navigation pane, choose Security Groups.
   b. Choose Create security group.
   c. For Security group name, enter a descriptive name for the security group. For this tutorial, enter rds-ec2-manual-configuration.
   d. For Description, enter a brief description. For this tutorial, enter RDS database security group to allow EC2 instance to securely connect to RDS database.
   e. Under Inbound rules, choose Add rule, and do the following:
      i. For Type, choose MYSQL/Aurora.
      ii. For Source, choose the EC2 instance security group ec2-rds-manual-configuration that you created in Step 2 of this procedure.
   f. Choose Create security group.
4. Edit the EC2 instance security group to add an outbound rule, as follows:
a. In the navigation pane, choose **Security Groups**.

b. Select the EC2 instance security group (you named it `ec2-rds-manual-configuration`), and choose the **Outbound rules** tab.

c. Choose **Edit outbound rules**.

d. Choose **Add rule**, and do the following:

   i. For **Type**, choose **MYSQL/Aurora**.

   ii. For **Source**, choose the RDS database security group `rds-ec2-manual-configuration` that you created in Step 3 of this procedure.

   iii. Choose **Save rules**.

5. Add the EC2 instance security group to the EC2 instance as follows:

   a. In the navigation pane, choose **Instances**.

   b. Select your EC2 instance, and choose **Actions**, **Security**, **Change security groups**.

   c. Under **Associated security groups**, choose the **Select security groups** field, choose `ec2-rds-manual-configuration` that you created earlier, and then choose **Add security group**.

   d. Choose **Save**.

6. Add the RDS database security group to the RDS database as follows:

   a. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

   b. In the navigation pane, choose **Databases** and select your database.

   c. Choose **Modify**.

   d. Under **Connectivity**, for **Security group**, choose `rds-ec2-manual-configuration` that you created earlier, and then choose **Continue**.

   e. Under **Scheduling of modifications**, choose **Apply immediately**.

   f. Choose **Modify DB instance**.

You have now completed the manual steps that mimic the automatic steps that occur when you use the automatic connection feature.

You have completed Option 3 of this tutorial. If you've completed Options 1, 2, and 3, and you no longer need the resources that were created in this tutorial, you should delete them to prevent incurring unnecessary costs. For more information, see [Clean up](#).
Clean up

Now that you have completed the tutorial, it is good practice to clean up (delete) any resources you no longer want to use. Cleaning up AWS resources prevents your account from incurring any further charges.

Topics

- Terminate your EC2 instance
- Delete your RDS database

Terminate your EC2 instance

If you launched an EC2 instance specifically for this tutorial, you can terminate it to stop incurring any charges associated with it.

To terminate an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance that you created for this tutorial, and choose Instance state, Terminate instance.
4. Choose Terminate when prompted for confirmation.

Delete your RDS database

If you created an RDS database specifically for this tutorial, you can delete it to stop incurring any charges associated with it.

To delete an RDS database using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Select the RDS database that you created for this tutorial, and choose Actions, Delete.
4. Enter delete me in the box, and then choose Delete.
Identify your EC2 instances

You might need to determine whether your application is running on an EC2 instance, especially if you have a mixed computing environment. Each instance has a signed instance identity document that you can verify cryptographically. You can find these documents at the following local, non-routable address http://169.254.169.254/latest/dynamic/instance-identity/. For more information, see Instance identity documents for Amazon EC2 instances.

Inspect the system UUID

You can get the system UUID and look in the beginning octet of the UUID for EC2 (in Linux, this might be lowercase ec2). This method is quick, but potentially inaccurate because there's a small chance that a system that is not an EC2 instance could have a UUID that starts with these characters. Furthermore, some versions of SMBIOS use the little-endian format, which doesn't include EC2 at the beginning of the UUID. This might be the case for EC2 instances that use SMBIOS 2.4 for Windows, or for Linux distributions other than Amazon Linux 2 that have their own implementation of SMBIOS.

Linux example: Get the UUID from DMI (HVM AMIs only)

Use the following command to get the UUID using the Desktop Management Interface (DMI):

```
[ec2-user ~]$ sudo dmidecode --string system-uuid
```

In the following example output, the UUID starts with "EC2", which indicates that the system is probably an EC2 instance.

```
EC2E1916-9099-7CAF-FD21-012345ABCDEF
```

In the following example output, the UUID is represented in little-endian format.

```
45E12AEC-DCD1-B213-94ED-012345ABCDEF
```

Alternatively, for instances built on the Nitro system, you can use the following command:

```
[ec2-user ~]$ cat /sys/devices/virtual/dmi/id/board_asset_tag
```

If the output is an instance ID, as the following example output, the system is an EC2 instance:

```
Identify instances
```
**Linux example: Get the UUID from the hypervisor (PV AMIs only)**

Use the following command to get the UUID from the hypervisor:

```
[ec2-user ~]$ cat /sys/hypervisor/uuid
```

In the following example output, the UUID starts with "ec2", which indicates that the system is probably an EC2 instance.

```
ec2e1916-9099-7caf-fd21-012345abcdef
```

**Windows example: Get the UUID using WMI or Windows PowerShell**

Use the Windows Management Instrumentation command line (WMIC) as follows:

```
wmic path win32_computersystemproduct get uuid
```

Alternatively, if you're using Windows PowerShell, use the `Get-WmiObject` cmdlet as follows:

```
PS C:\> Get-WmiObject -query "select uuid from Win32_ComputerSystemProduct" | Select UUID
```

In the following example output, the UUID starts with "EC2", which indicates that the system is probably an EC2 instance.

```
EC2AE145-D1DC-13B2-94ED-012345ABCDEF
```

For instances using SMBIOS 2.4, the UUID might be represented in little-endian format; for example:

```
45E12AEC-DCD1-B213-94ED-012345ABCDEF
```

**Inspect the system virtual machine generation identifier**

A virtual machine generation identifier consists of a unique buffer of 128-bit interpreted as cryptographic random integer identifier. You can retrieve the virtual machine generation identifier to identify your Amazon Elastic Compute Cloud instance. The generation identifier is exposed
within the guest operating system of the instance through an ACPI table entry. The value will change if your machine is cloned, copied, or imported into AWS, such as with VM Import/Export.

**Example: Retrieve the virtual machine generation identifier from Linux**

You can use the following commands to retrieve the virtual machine generation identifier from your instances running Linux.

**Amazon Linux 2**

1. Update your existing software packages, as necessary, using the following command:

   ```
   sudo yum update
   ```

2. If necessary, source the busybox package with the following command:

   ```
   sudo curl https://www.rpmfind.net/linux/epel/next/8/Everything/x86_64/Packages/b/busybox-1.35.0-2.el8.next.x86_64.rpm --output busybox.rpm
   ```

3. If necessary, install the prerequisite packages using the following command:

   ```
   sudo yum install busybox.rpm iasl -y
   ```

4. Run the following `iasl` command to produce output from the ACPI table:

   ```
   sudo iasl -p ./SSDT2 -d /sys/firmware/acpi/tables/SSDT2
   ```

5. Run the following command to review the output of the `iasl` command:

   ```
   cat SSDT2.dsl
   ```

   The output should yield the address space required to retrieve the virtual machine generation identifier:

   ```
   Intel ACPI Component Architecture
   ASL+ Optimizing Compiler/Disassembler version 20190509
   Copyright (c) 2000 - 2019 Intel Corporation

   File appears to be binary: found 32 non-ASCII characters, disassembling
   Binary file appears to be a valid ACPI table, disassembling
   Input file /sys/firmware/acpi/tables/SSDT2, Length 0x7B (123) bytes
   ```
Inspect the system virtual machine generation identifier
6. (Optional) Elevate your terminal permissions for the remaining steps with the following command:

```
sudo -s
```

7. Use the following command to store the previously gathered address space:

```
VMGN_ADDR=0xFED01000
```

8. Use the following command to iterate through the address space and build the virtual machine generation identifier:

```
for offset in 0x0 0x4 0x8 0xc; do busybox devmem \$\((\$VMGN_ADDR + \$offset)) \| sed 's/0x//' \| sed -z '$ s/\n$///' >> vmgenid; done
```

9. Retrieve the virtual machine generation identifier from the output file with the following command:

```
cat vmgenid ; echo
```

Your output should be similar to the following:

```
EC2F335D979132C4165896753E72BD1C
```

Ubuntu

1. Update your existing software packages, as necessary, using the following command:

```
sudo apt update
```

2. If necessary, install the prerequisite packages using the following command:

```
sudo apt install busybox iasl -y
```

3. Run the following `iasl` command to produce output from the ACPI table:
sudo iasl -p ./SSDT2 -d /sys/firmware/acpi/tables/SSDT2

4. Run the following command to review the output of the iasl command:

```bash
cat SSDT2.dsl
```

The output should yield the address space required to retrieve the virtual machine generation identifier:

```
Intel ACPI Component Architecture
ASL+ Optimizing Compiler/Disassembler version 20190509
Copyright (c) 2000 - 2019 Intel Corporation

File appears to be binary: found 32 non-ASCII characters, disassembling
Binary file appears to be a valid ACPI table, disassembling
Input file /sys/firmware/acpi/tables/SSDT2, Length 0x7B (123) bytes
ACPI: SSDT 0x0000000000000000 00007B (v01 AMAZON AMZNSSDT 00000001 AMZN

 * 
 * Disassembly of /sys/firmware/acpi/tables/SSDT2, Tue Mar 29 16:15:14 2022
 * 
 * Original Table Header:
 *   Signature    "SSDT"
 *   Length       0x0000007B (123)
 *   Revision     0x01
 *   Checksum     0xB8
 *   OEM ID       "AMAZON"
```
5. (Optional) Elevate your terminal permissions for the remaining steps with the following command:

```bash
sudo -s
```

6. Use the following commands to store the previously gathered address space:

```bash
VMGN_ADDR=0xFED01000
```

7. Use the following command to iterate through the address space and build the virtual machine generation identifier:

```bash
for offset in 0x0 0x4 0x8 0xc; do busybox devmem $((VMGN_ADDR + $offset)) | sed 's/0x//' | sed -z '$ s/\n//' >> vmgenid; done
```

8. Retrieve the virtual machine generation identifier from the output file with the following command:

```bash
cat vmgenid ; echo
```
Example: Retrieve the virtual machine generation identifier from Windows

You can create a sample application to retrieve the virtual machine generation identifier from your instances running Windows. For more information, see [Obtaining the virtual machine generation identifier](#) in the Microsoft documentation.

Manage system settings for your Amazon EC2 instance

After you've launched your instance, you can log in as an administrator to make changes. This section is focused on managing system settings for your instance.

Contents

- Precision clock and time synchronization on your EC2 instance
- Processor state control for Amazon EC2 Linux instances
- Optimize CPU options
- AMD SEV-SNP for Amazon EC2 instances
- Add Windows system components using installation media
- Manage system users on your Linux instance
- Set the Windows Administrator password for your instance

Precision clock and time synchronization on your EC2 instance

A consistent and accurate time reference on your Amazon EC2 instance is crucial for many server tasks and processes. Time stamps in system logs play an essential role in identifying when issues occurred and the chronological order of events. When you use the AWS CLI or an AWS SDK to make requests from your instance, these tools sign requests on your behalf. If your instance's date and time settings are inaccurate, it can result in a discrepancy between the date in the signature and the date of the request, leading to AWS rejecting your requests.
To address this important aspect, Amazon offers the Amazon Time Sync Service, which is accessible from all EC2 instances and used by various AWS services. The service uses a fleet of satellite-connected and atomic reference clocks in each AWS Region to deliver accurate and current time readings of the Coordinated Universal Time (UTC) global standard.

For the best performance, we recommend using the local Amazon Time Sync Service on your EC2 instances. For a backup to the local Amazon Time Sync Service on your instances, or to connect resources outside of Amazon EC2 to the Amazon Time Sync Service, you can use the public Amazon Time Sync Service located at time.aws.com. The public Amazon Time Sync Service, like the local Amazon Time Sync Service, automatically smears any leap seconds that are added to UTC. The public Amazon Time Sync Service is supported globally by our fleet of satellite-connected and atomic reference clocks in each AWS Region.

**Leap seconds**

Leap seconds, introduced in 1972, are occasional one-second adjustments to UTC time to factor in irregularities in the earth’s rotation in order to accommodate differences between International Atomic Time (TAI) and solar time (Ut1). To manage leap seconds on behalf of customers, we designed leap second smearing within the Amazon Time Sync Service. For more information, see Look Before You Leap – The Coming Leap Second and AWS.

Leap seconds are going away, and we are in full support of the decision made at the 27th General Conference on Weights and Measures to abandon leap seconds by or before 2035.

To support this transition, we still plan on smearing time during a leap second event when accessing the Amazon Time Sync Service over the local NTP connection or our public NTP pools (time.aws.com). The PTP hardware clock, however, does not provide a smeared time option. In the event of a leap second, the PTP hardware clock will add the leap second following UTC standards. Leap-smereared and leap second time sources are the same in most cases. But because they differ during a leap second event, we do not recommend using both smeared and non-smeared time sources in your time client configuration during a leap second event.

Set the time reference on your EC2 instance to use the local Amazon Time Sync Service

The local Amazon Time Sync Service either uses the Network Time Protocol (NTP), or provides a local Precision Time Protocol (PTP) hardware clock on supported instances. The PTP hardware clock supports either an NTP connection (Linux and Windows instances), or a direct PTP connection (Linux instances only). The NTP and direct PTP connections use the same highly accurate time source, but the direct PTP connection is more accurate than the NTP connection. The NTP connection to the Amazon Time Sync Service supports leap smearing while the PTP connection to the PTP hardware clock does not smear time. For more information, see Leap seconds.

Your instances can access the local Amazon Time Sync Service as follows:

  - Through NTP at the following IP address endpoints:
    - IPv4: 169.254.169.123
    - IPv6: fd00:ec2::123 (Only accessible by instances built on the AWS Nitro System.)
  - (Linux only) Through a direct PTP connection to connect to a local PTP hardware clock:
    - PHC0

Amazon Linux AMIs, Windows AMIs, and most partner AMIs configure your instance to use the NTP IPv4 endpoint by default. This is the recommended setting for most customer workloads. No further configuration is required for instances launched from these AMIs unless you want to use the IPv6 endpoint or connect directly to the PTP hardware clock.
NTP and PTP connections do not require any VPC configuration changes, and your instance does not require access to the internet.

Note

Only Linux instances can use a direct PTP connection to connect to the local PTP hardware clock. Windows instances use NTP to connect to the local PTP hardware clock.

- Connect to the IPv6 endpoint of the Amazon Time Sync Service
- Connect to the PTP hardware clock

Connect to the IPv4 endpoint of the Amazon Time Sync Service

This section describes how to configure your instance to use the local Amazon Time Sync Service through the IPv4 endpoint.

Use the instructions for your instance's operating system.

Linux

AL2023 and the latest versions of Amazon Linux 2 and Amazon Linux AMIs are configured to use the Amazon Time Sync Service IPv4 endpoint by default. No further configuration is required for instances launched from these AMIs and you can skip the following procedure.

If you're using an AMI that doesn't have the Amazon Time Sync Service configured by default, use one of the following procedures to configure the Amazon Time Sync Service on your instance using the chrony client. It requires adding a server entry for the Amazon Time Sync Service to the chrony configuration file.

Use the instructions for your instance's operating system.

Amazon Linux

To connect to the IPv4 endpoint of the Amazon Time Sync Service on Amazon Linux using chrony

1. Connect to your instance and uninstall the NTP service.
2. Install the `chrony` package.

```bash
[ec2-user ~]$ sudo yum install chrony
```

3. Open the `/etc/chrony.conf` file using a text editor (such as `vim` or `nano`). Verify that the file includes the following line:

```
server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
```

If the line is present, then the Amazon Time Sync Service is already configured to use the IPv4 endpoint of the Amazon Time Sync Service and you can go to the next step. If not, add the line after any other `server` or `pool` statements that are already present in the file, and save your changes.

4. Restart the `chrony` daemon (`chronyd`).

```bash
[ec2-user ~]$ sudo service chronyd restart
```

```
Starting chronyd: [ OK ]
```

**Note**

On RHEL and CentOS (up to version 6), the service name is `chrony` instead of `chronyd`.

5. To configure `chronyd` to start at each system boot, use the `chkconfig` command.

```bash
[ec2-user ~]$ sudo chkconfig chronyd on
```

6. Verify that `chrony` is using the `169.254.169.123` IPv4 endpoint to synchronize the time.

```bash
[ec2-user ~]$ chronyc sources -v
```

```
210 Number of sources = 7
.-- Source mode '^^' = server, '=' = peer, '#=' = local clock.
```
In the output that's returned, ^* indicates the preferred time source.

7. Verify the time synchronization metrics that are reported by `chrony`.

```
[ec2-user ~]$ chronyc tracking
```

```
Reference ID      : A9FEA97B (169.254.169.123)
Stratum          : 4
Ref time (UTC)   : Wed Nov 22 13:18:34 2017
System time      : 0.0000000626 seconds slow of NTP time
Last offset      : +0.0002852759 seconds
```
To connect to the IPv4 endpoint of the Amazon Time Sync Service on Ubuntu using chrony

1. Connect to your instance and use `apt` to install the `chrony` package.

   ```
   ubuntu:~$ sudo apt install chrony
   ```

   **Note**  
   If necessary, update your instance first by running `sudo apt update`.

2. Open the `/etc/chrony/chrony.conf` file using a text editor (such as `vim` or `nano`). Add the following line before any other `server` or `pool` statements that are already present in the file, and save your changes:

   ```
   server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
   ```

3. Restart the `chrony` service.

   ```
   ubuntu:~$ sudo /etc/init.d/chrony restart
   ```

   Restarting chrony (via systemctl): chrony.service.

4. Verify that `chrony` is using the 169.254.169.123 IPv4 endpoint to synchronize the time.

   ```
   ubuntu:~$ chronyc sources -v
   ```

   210 Number of sources = 7
In the output that's returned, on the line starting with ^* indicates the preferred time source.

5. Verify the time synchronization metrics that are reported by chrony.

```
ubuntu:~$ chronyc tracking
```

Stratum : 4
Ref time (UTC) : Wed Nov 29 07:41:57 2017
SUSE Linux

Starting with SUSE Linux Enterprise Server 15, chrony is the default implementation of NTP.

**To connect to IPv4 endpoint of the Amazon Time Sync Service on SUSE Linux using chrony**

1. Open the `/etc/chrony.conf` file using a text editor (such as **vim** or **nano**).
2. Verify that the file contains the following line:

   ```
   server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
   ```

   If this line is not present, add it.
3. Comment out any other server or pool lines.
4. Open yaST and enable the chrony service.

Windows

Starting with the August 2018 release, Windows AMIs use the Amazon Time Sync Service by default. No further configuration is required for instances launched from these AMIs and you can skip the following procedures.

If you're using an AMI that doesn't have the Amazon Time Sync Service configured by default, first verify your current NTP configuration. If your instance is already using the IPv4 endpoint of the Amazon Time Sync Service, no further configuration is required. If your instance is not using the Amazon Time Sync Service, then complete the procedure to change the NTP server to use the Amazon Time Sync Service.
To verify the NTP configuration

1. From your instance, open a Command Prompt window.
2. Get the current NTP configuration by typing the following command:
   ```bash
   w32tm /query /configuration
   ```
   This command returns the current configuration settings for the Windows instance and will show if you're connected to the Amazon Time Sync Service.
3. (Optional) Get the status of the current configuration by typing the following command:
   ```bash
   w32tm /query /status
   ```
   This command returns information such as the last time the instance synced with the NTP server and the poll interval.

To change the NTP server to use the Amazon Time Sync Service

1. From the Command Prompt window, run the following command:
   ```bash
   w32tm /config /manualpeerlist:169.254.169.123 /syncfromflags:manual /update
   ```
2. Verify your new settings by using the following command:
   ```bash
   w32tm /query /configuration
   ```
   In the output that's returned, verify that `NtpServer` displays the `169.254.169.123` IPv4 endpoint.

Default network time protocol (NTP) settings for Amazon Windows AMIs

Amazon Machine Images (AMIs) generally adhere to the out-of-the-box defaults except in cases where changes are required to function on EC2 infrastructure. The following settings have been determined to work well in a virtual environment, as well as to keep any clock drift to within one second of accuracy:
• **Update Interval** – Governs how frequently the time service will adjust system time towards accuracy. AWS configures the update interval to occur once every two minutes.

• **NTP Server** – Starting with the August 2018 release, AMIs use the Amazon Time Sync Service by default. This time service is accessible from any AWS Region at the 169.254.169.123 IPv4 endpoint. Additionally, the 0x9 flag indicates that the time service is acting as a client, and to use `SpecialPollInterval` to determine how frequently to check in with the configured time server.

• **Type** – "NTP" means that the service acts as a standalone NTP client instead of acting as part of a domain.

• **Enabled and InputProvider** – The time service is enabled and provides time to the operating system.

• **Special Poll Interval** – Checks against the configured NTP Server every 900 seconds (15 minutes).

**Connect to the IPv6 endpoint of the Amazon Time Sync Service**

This section explains how the steps described in [Connect to the IPv4 endpoint of the Amazon Time Sync Service](#) differ if you are configuring your instance to use the local Amazon Time Sync Service through the IPv6 endpoint. It doesn't explain the entire Amazon Time Sync Service configuration process.

The IPv6 endpoint is only accessible on [instances built on the AWS Nitro System](#).

**Note**

We don’t recommend using both the IPv4 and IPv6 endpoint entries together. The IPv4 and IPv6 NTP packets come from the same local server for your instance. Configuring both IPv4 and IPv6 endpoints is unnecessary and will not improve the accuracy of the time on your instance.

Use the instructions for your instance's operating system.

**Linux**

Depending on the Linux distribution you're using, when you reach the step to edit the `chrony.conf` file, you'll be using the IPv6 endpoint of the Amazon Time Sync Service (`fd00:ec2::123`) rather than the IPv4 endpoint (`169.254.169.123`):

```
server fd00:ec2::123 prefer iburst minpoll 4 maxpoll 4
```

Save the file and verify that `chrony` is using the `fd00:ec2::123` IPv6 endpoint to synchronize time:

```
[ec2-user ~]$ chronyc sources -v
```

In the output, if you see the `fd00:ec2::123` IPv6 endpoint, the configuration is complete.
Windows

When you reach the step to change the NTP server to use the Amazon Time Sync Service, you'll be using the IPv6 endpoint of the Amazon Time Sync Service (fd00:ec2::123) rather than the IPv4 endpoint (169.254.169.123):

```w32tm /config /manualpeerlist:fd00:ec2::123 /syncfromflags:manual /update```

Verify that your new settings are using the fd00:ec2::123 IPv6 endpoint to synchronize time:

```w32tm /query /configuration```

In the output, verify that NtpServer displays the fd00:ec2::123 IPv6 endpoint.

Connect to the PTP hardware clock

The PTP hardware clock is part of the AWS Nitro System, so it is directly accessible on supported bare metal and virtualized EC2 instances without using any customer resources.

The NTP endpoints for the PTP hardware clock are the same as those for the regular Amazon Time Sync Service. If your instance has a PTP hardware clock and you configured the NTP connection (to either the IPv4 or IPv6 endpoint), your instance time is automatically sourced from the PTP hardware clock over NTP.

For Linux instances, you can configure a direct PTP connection, which will give you more accurate time than the NTP connection. Windows instances only support an NTP connection to the PTP hardware clock.

Requirements

The PTP hardware clock is available on an instance when the following requirements are met:

- Supported AWS Regions: US East (N. Virginia) and Asia Pacific (Tokyo)
- Supported instance families:
  - **General purpose:** M7a, M7g, M7gd, M7i
  - **Compute optimized:** C7a, C7gd, C7i
  - **Memory optimized:** R7a, R7g, R7gd, R7i
- (Linux only) ENA driver version 2.10.0 or later installed on a supported operating system. For more information about supported operating systems, see the driver prerequisites on GitHub.
(Linux only) Configure a direct PTP connection to the PTP hardware clock

This section describes how to configure your Linux instance to use the local Amazon Time Sync Service through the PTP hardware clock using a direct PTP connection. It requires adding a server entry for the PTP hardware clock in the `chrony` configuration file.

**To configure a direct PTP connection to the PTP hardware clock (Linux instances only)**

1. Connect to your Linux instance and do the following:
   a. Install the Linux kernel driver for Elastic Network Adapter (ENA) version 2.10.0 or later.
   b. Enable the PTP hardware clock.

   For the installation instructions, see [Linux kernel driver for Elastic Network Adapter (ENA) family](https://github.com) on GitHub.

2. Verify that the `/dev/ptp0` device shows up on your instance.

   ```bash
   [ec2-user ~]$ ls /dev/ptp0
   ```

   The following is the expected output. If `/dev/ptp0` is not in the output, the ENA driver was not correctly installed. Review step 1 in this procedure for installing the driver.

   ```bash
   /dev/ptp0
   ```

3. Edit `/etc/chrony.conf` using a text editor and add the following line anywhere in the file.

   ```
   refclock PHC /dev/ptp0 poll 0 delay 0.000010 prefer
   ```

4. Restart chrony.

   ```bash
   [ec2-user ~]$ sudo systemctl restart chronyd
   ```

5. Verify that chrony is using the PTP hardware clock to synchronize the time on this instance.

   ```bash
   [ec2-user ~]$ chronyc sources
   ```

   **Expected output**

   ```
   MS Name/IP address  Stratum Poll Reach LastRx Last sample
   ```
In the output that's returned, * indicates the preferred time source. PHC0 corresponds to the PTP hardware clock. You might need to wait a few seconds after restarting chrony for the asterisk to appear.

**Set the time reference on your EC2 instance or any internet-connected device to use the public Amazon Time Sync Service**

You can set your instance, or any internet-connected device such as your local computer or an on-prem server, to use the public Amazon Time Sync Service, which is accessible over the internet at time.aws.com. You can use the public Amazon Time Sync Service as a backup for the local Amazon Time Sync Service and to connect resources outside of AWS to the Amazon Time Sync Service.

**Note**

For the best performance, we recommend using the *local* Amazon Time Sync Service on your instances, and only using the *public* Amazon Time Sync Service as a backup.

Use the instructions for the operating system of your instance or device.

**Linux**

**To set your Linux instance or device to use the public Amazon Time Sync Service using chrony or ntpd**

1. Edit `/etc/chrony.conf` (if you use chrony) or `/etc/ntp.conf` (if you use ntpd) using a text editor as follows:

   a. To prevent your instance or device from trying to mix smeared and non-smeared servers, remove or comment out lines starting with `server` except any existing connection to the local Amazon Time Sync Service.
Important

If you're setting your EC2 instance to connect to the public Amazon Time Sync Service, do not remove the following line which sets your instance to connect to the local Amazon Time Sync Service. The local Amazon Time Sync Service is a more direct connection and will provide better clock accuracy. The public Amazon Time Sync Service should only be used as a backup.

```
server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
```

b. Add the following line to connect to the public Amazon Time Sync Service.

```
pool time.aws.com iburst
```

2. Restart the daemon using one of the following commands.

- chrony

```
sudo service chronyd force-reload
```

- ntpd

```
sudo service ntp reload
```

macOS

To set your macOS instance or device to use the public Amazon Time Sync Service

1. Open System Preferences.
2. Choose Date & Time, and then choose the Date & Time tab.
3. To make changes, choose the lock icon, and enter your password when prompted.
4. For Set date and time automatically, enter time.aws.com.
**Windows**

**To set your Windows instance or device to use the public Amazon Time Sync Service**

1. Open the **Control Panel**.
2. Choose the **Date and Time** icon.
3. Choose the **Internet Time** tab. This tab is not be available if your PC is part of a domain. In this case, it will synchronize time with the domain controller. You can configure the controller to use the public Amazon Time Sync Service.
4. Choose **Change settings**.
5. Select the check box for **Synchronize with an Internet time server**.
6. Next to **Server**, enter **time.aws.com**.

**To set your Windows Server instance or device to use the public Amazon Time Sync Service**

- Follow [Microsoft's instructions](#) to update your registry.

**Compare timestamps for your Linux instances**

If you're using the Amazon Time Sync Service, you can compare the timestamps on your Amazon EC2 Linux instances with ClockBound to determine the true time of an event. ClockBound measures the clock accuracy of your EC2 instance, and allows you to check if a given timestamp is in the past or future with respect to your instance's current clock. This information is valuable for determining the order and consistency of events and transactions across EC2 instances, independent of each instance's geographic location.

ClockBound is an open source daemon and library. To learn more about ClockBound, including installation instructions, see [ClockBound](#) on [GitHub](#).

ClockBound is only supported for Linux instances.

If you're using the direct PTP connection to the PTP hardware clock, your time daemon, such as chrony, will underestimate the clock error bound. This is because a PTP hardware clock does not pass the correct error bound information to chrony, the way that NTP does. As a result, your clock synchronization daemon assumes the clock is accurate to UTC and thus has an error bound of 0. To measure the full error bound, the Nitro System calculates the error bound of the PTP hardware.
To retrieve the PTP hardware clock error bound

1. First get the correct location of the PTP hardware clock device by using one of the following commands. The path in the command is different depending on the AMI used to launch the instance.

   - For Amazon Linux 2:
     
     ```bash
     cat /sys/class/net/eth0/device/uevent | grep PCI_SLOT_NAME
     ```

   - For Amazon Linux 2023:
     
     ```bash
     cat /sys/class/net/ens5/device/uevent | grep PCI_SLOT_NAME
     ```

   The output is the PCI slot name, which is the location of the PTP hardware clock device. In this example, the location is `0000:00:03.0`.

   ```text
   PCI_SLOT_NAME=0000:00:03.0
   ```

2. To retrieve the PTP hardware clock error bound, run the following command. Include the PCI slot name from the previous step.

   ```bash
   cat /sys/bus/pci/devices/0000:00:03.0/phc_error_bound
   ```

   The output is the clock error bound of the PTP hardware clock, in nanoseconds.

To calculate the correct clock error bound at a specific point in time when using the direct PTP connection to the PTP hardware clock, you must add the clock error bound from chrony or ClockBound at the time that chrony polls the PTP hardware clock. For more information about measuring and monitoring clock accuracy, see Manage Amazon EC2 instance clock accuracy using Amazon Time Sync Service and Amazon CloudWatch – Part 1.
Change the time zone of your instance

Amazon EC2 instances are set to the UTC (Coordinated Universal Time) time zone by default. You can change the time on an instance to the local time zone or to another time zone in your network.

Use the instructions for your instance's operating system.

**Linux**

⚠️ Important

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

**To change the time zone on an AL2023 or Amazon Linux 2 instance**

1. View the system's current time zone setting.

   ```bash
   [ec2-user ~]$ timedatectl
   ```

2. List the available time zones.

   ```bash
   [ec2-user ~]$ timedatectl list-timezones
   ```

3. Set the chosen time zone.

   ```bash
   [ec2-user ~]$ sudo timedatectl set-timezone America/Vancouver
   ```

4. (Optional) Confirm that the current time zone is updated to the new time zone by running the `timedatectl` command again.

   ```bash
   [ec2-user ~]$ timedatectl
   ```

**Windows**

**To change the time zone on a Windows instance**

1. From your instance, open a Command Prompt window.
2. Identify the time zone to use on the instance. To get a list of time zones, use the following command:

```
 tzutil /l
```

This command returns a list of all available time zones in the following format:

```
display name
time zone ID
```

3. Locate the time zone ID to assign to the instance.

4. Assign to another time zone by using the following command:

```
 tzutil /s "Pacific Standard Time"
```

The new time zone should take effect immediately.

**Note**

You can assign the UTC time zone by using the following command:

```
 tzutil /s "UTC"
```

**To prevent your time zone from changing once you set it for Windows Server**

When you change the time zone on a Windows instance, you must ensure that the time zone persists through system restarts. Otherwise, when the instance restarts, it reverts back to using UTC time. You can persist your time zone setting by adding a `RealTimeIsUniversal` registry key. This key is set by default on all current generation instances. To verify whether the `RealTimeIsUniversal` registry key is set, see step 4 in the following procedure. If the key is not set, follow these steps from the beginning.

**To set the RealTimeIsUniversal registry key**

1. From the instance, open a Command Prompt window.
2. Use the following command to add the registry key:
reg add "HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\TimeZoneInformation" /v RealTimeIsUniversal /d 1 /t REG_DWORD /f

3. If you are using a Windows Server 2008 AMI (not Windows Server 2008 R2) that was created before February 22, 2013, we recommend updating to the latest AWS Windows AMI. If you are using an AMI running Windows Server 2008 R2 (not Windows Server 2008), you must verify that the Microsoft hotfix KB2922223 is installed. If this hotfix is not installed, we recommend updating to the latest AWS Windows AMI.

4. (Optional) Verify that the instance saved the key successfully using the following command:

    reg query "HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\TimeZoneInformation" /s

This command returns the subkeys for the TimeZoneInformation registry key. You should see the RealTimelsUniversal key at the bottom of the list, similar to the following:

```
HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\TimeZoneInformation
  Bias                           REG_DWORD     0x1e0
  DaylightBias                   REG_DWORD     0xfffffffc4
  DaylightName                   REG_SZ        @tzres.dll,-211
  DaylightStart                  REG_BINARY    000003000200020000000000000000000
  StandardBias                   REG_DWORD     0x0
  StandardName                   REG_SZ        @tzres.dll,-212
  StandardStart                  REG_BINARY    00000B000100020000000000000000000
  TimeZoneKeyName                 REG_SZ        Pacific Standard Time
  DynamicDaylightTimeDisabled    REG_DWORD     0x0
  ActiveTimeBias                 REG_DWORD     0x1a4
  RealTimeIsUniversal            REG_DWORD     0x1
```

**Processor state control for Amazon EC2 Linux instances**

**C-states** control the sleep levels that a core can enter when it is idle. C-states are numbered starting with C0 (the shallowest state where the core is totally awake and executing instructions) and go to C6 (the deepest idle state where a core is powered off).

**P-states** control the desired performance (in CPU frequency) from a core. P-states are numbered starting from P0 (the highest performance setting where the core is allowed to use Intel Turbo
Boost Technology to increase frequency if possible), and they go from P1 (the P-state that requests the maximum baseline frequency) to P15 (the lowest possible frequency).

### Note

AWS Graviton processors have built-in power saving modes and operate at a fixed frequency. Therefore, they do not provide the ability for the operating system to control C-states and P-states.

### C-states and P-states

The following instance types provide the ability for an operating system to control processor C-states and P-states:

- **General purpose**: m4.10xlarge | m4.16xlarge
- **Compute optimized**: c4.8xlarge
- **Memory optimized**: r4.8xlarge | r4.16xlarge | x1.16xlarge | x1.32xlarge | x1e.8xlarge | x1e.16xlarge | x1e.32xlarge
- **Storage optimized**: d2.8xlarge | i3.8xlarge | i3.16xlarge | i3en.24xlarge | h1.8xlarge | h1.16xlarge
- **Accelerated computing**: f1.16xlarge | g3.16xlarge | p2.16xlarge | p3.16xlarge
- **Bare metal**: All bare metal instances with Intel and AMD processors

### C-states only

The following instance types provide the ability for an operating system to control processor C-states:

- **General purpose**: m5.12xlarge | m5.24xlarge | m5d.12xlarge | m5d.24xlarge | m5n.12xlarge | m5n.24xlarge | m5dn.12xlarge | m5dn.24xlarge | m5zn.6xlarge | m5zn.12xlarge | m6a.24xlarge | m6a.48xlarge | m6i.16xlarge | m6i.32xlarge | m6id.16xlarge | m6id.32xlarge | m6idn.16xlarge | m6in.16xlarge | m6in.32xlarge | m7a.medium | m7a.large | m7a.xlarge | m7a.2xlarge | m7a.4xlarge | m7a.8xlarge | m7a.12xlarge | m7a.16xlarge | m7a.24xlarge | m7a.32xlarge | m7a.48xlarge | m7i.large | m7i.xlarge | m7i.2xlarge | m7i.4xlarge | m7i.8xlarge | m7i.12xlarge | m7i.16xlarge | m7i.24xlarge | m7i.48xlarge
• **Compute optimized**: c5.9xlarge | c5.12xlarge | c5.18xlarge | c5.24xlarge | c5a.24xlarge | c5ad.24xlarge | c5d.9xlarge | c5d.12xlarge | c5d.18xlarge | c5d.24xlarge | c5n.9xlarge | c5n.18xlarge | c6a.24xlarge | c6a.32xlarge | c6i.16xlarge | c6i.32xlarge | c6id.24xlarge | c6id.32xlarge | c7a.medium | c7a.large | c7a.xlarge | c7a.2xlarge | c7a.4xlarge | c7a.8xlarge | c7a.12xlarge | c7a.16xlarge | c7a.24xlarge | c7a.32xlarge | c7a.48xlarge | c7i.large | c7i.xlarge | c7i.2xlarge | c7i.4xlarge | c7i.8xlarge | c7i.12xlarge | c7i.16xlarge | c7i.24xlarge | c7i.48xlarge

• **Memory optimized**: r5.12xlarge | r5.24xlarge | r5b.12xlarge | r5d.12xlarge | r5d.24xlarge | r5n.12xlarge | r5n.24xlarge | r5dn.12xlarge | r5dn.24xlarge | r6a.16xlarge | r6i.16xlarge | r6i.32xlarge | r6id.16xlarge | r6id.32xlarge | r7a.1large | r7a.2large | r7a.4large | r7a.8large | r7a.12large | r7a.16large | r7a.24large | r7a.32large | r7a.48large | r7i.large | r7i.2large | r7i.4large | r7i.8large | r7i.12large | r7i.16large | r7i.24large | r7i.48large | r7iz.large | r7iz.xlarge | r7iz.2large | r7iz.4large | r7iz.8large | r7iz.12large | r7iz.16large | r7iz.32large | u-3tb1.56xlarge | u-6tb1.56xlarge | u-6tb1.112xlarge | u-9tb1.112xlarge | u-12tb1.112xlarge | u-18tb1.112xlarge | u-24tb1.112xlarge | u-7i-12tb.224xlarge | u7in-16tb.224xlarge | u7in-24tb.224xlarge | u7in-32tb.224xlarge | x2idn.32xlarge | x2iedn.16xlarge | x2iezn.12xlarge | z1d.6xlarge | z1d.12xlarge

• **Storage optimized**: d3en.12xlarge | d11.24xlarge | i3en.12xlarge | i3en.24xlarge | i4i.16xlarge | r5b.12xlarge | r5b.24xlarge

• **Accelerated computing**: d11.24xlarge | g5.24xlarge | g5.48xlarge | g6.24xlarge | g6.48xlarge | inf1.24xlarge | p3dn.24xlarge | p4d.24xlarge | p4de.24xlarge | p5.24xlarge | trn1.32xlarge | vt1.24xlarge

You might want to change the C-state or P-state settings to increase processor performance consistency, reduce latency, or tune your instance for a specific workload. The default C-state and P-state settings provide maximum performance, which is optimal for most workloads. However, if your application would benefit from reduced latency at the cost of higher single- or dual-core frequencies, or from consistent performance at lower frequencies as opposed to bursty Turbo Boost frequencies, consider experimenting with the C-state or P-state settings that are available to these instances.
For information about different processor configurations and how to monitor the effects of your configuration for Amazon Linux, see Processor state control for Amazon EC2 Amazon Linux instance in the Amazon Linux 2 User Guide. These procedures were written for, and apply to Amazon Linux; however, they might also work for other Linux distributions with a Linux kernel of 3.9 or newer. For more information about other Linux distributions and processor state control, see your system-specific documentation.

Optimize CPU options

Many Amazon EC2 instances support simultaneous multithreading, which enables multiple threads to run concurrently on a single CPU core. Each thread is represented as a virtual CPU (vCPU) on the instance. An instance has a default number of CPU cores, which varies according to instance type. For example, an m5.xlarge instance type has two CPU cores and two threads per core by default—four vCPUs in total.

Note

Each vCPU is a thread of a CPU core, except for T2 instances, M7a instances, Apple silicon Mac instances, and 64-bit ARM platforms such as instances powered by AWS Graviton processors.

In most cases, there is an Amazon EC2 instance type that has a combination of memory and number of vCPUs to suit your workloads. However, you can specify the following CPU options to optimize your instance for specific workloads or business needs:

- **Number of CPU cores**: You can customize the number of CPU cores for the instance. You might do this to potentially optimize the licensing costs of your software with an instance that has sufficient amounts of RAM for memory-intensive workloads but fewer CPU cores.
- **Threads per core**: You can disable multithreading by specifying a single thread per CPU core. You might do this for certain workloads, such as high performance computing (HPC) workloads.

You can specify these CPU options during instance launch. There is no additional or reduced charge for specifying CPU options. You're charged the same as instances that are launched with default CPU options.

Contents

- Rules for specifying CPU options
Rules for specifying CPU options

To specify the CPU options for your instance, be aware of the following rules:

- You can't specify CPU options for bare metal instances.
- CPU options can only be specified during instance launch and cannot be modified after launch.
- When you launch an instance, you must specify both the number of CPU cores and threads per core in the request. For example requests, see Specify CPU options for your instance.
- The number of vCPUs for the instance is the number of CPU cores multiplied by the threads per core. To specify a custom number of vCPUs, you must specify a valid number of CPU cores and threads per core for the instance type. You cannot exceed the default number of vCPUs for the instance. For more information, see CPU cores and threads per CPU core per instance type.
- To disable multithreading, specify one thread per core.
- When you change the instance type of an existing instance, the CPU options automatically change to the default CPU options for the new instance type.
- The specified CPU options persist after you stop, start, or reboot an instance.

CPU cores and threads per CPU core per instance type

The following tables list the instance types that support specifying CPU options.

Contents

- General purpose instances
- Compute optimized instances
- Memory optimized instances
- Storage optimized instances
- Accelerated computing instances
- High-performance computing instances
