Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and the default user name of the AMI that you used to launch your instance. For RHEL, the default user name is ec2-user or root.

$ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com

For more information about connecting to your instance, see Connect to your Linux instance from Linux or macOS using SSH (p. 816).

2. If you use an HTTP or HTTPS proxy, you must set the http_proxy or https_proxy environment variables in the current shell session.

If you're not using a proxy, you can skip this step.

- For an HTTP proxy server, run the following commands:

  $ export http_proxy=http://hostname:port
  $ export https_proxy=http://hostname:port

- For an HTTPS proxy server, run the following commands:

  $ export http_proxy=https://hostname:port
  $ export https_proxy=https://hostname:port

3. Install the EC2 Instance Connect package on your instance by running the following commands.

The EC2 Instance Connect configuration files for RHEL are provided in a Red Hat Package Manager (RPM) package, with different RPM packages for RHEL 8 and RHEL 9.

- For RHEL 8:

  [ec2-user ~]$
  mkdir /tmp/ec2-instance-connect
  [ec2-user ~]$
  [ec2-user ~]$
  [ec2-user ~]$

- For RHEL 9:

  [ec2-user ~]$
  mkdir /tmp/ec2-instance-connect
Connect to your Linux instance

```bash
```

You should see the following new script in the /opt/aws/bin/ folder:

```
eic_run_authorized_keys
```

4. (Optional) Verify that EC2 Instance Connect was successfully installed on your instance.

- For RHEL 8:
  ```bash
  [ec2-user ~]$ sudo less /lib/systemd/system/ssh.service.d/ec2-instance-connect.conf
  ```
- For RHEL 9:
  ```bash
  [ec2-user ~]$ sudo less /etc/ssh/sshd_config.d/60-ec2-instance-connect.conf
  ```

EC2 Instance Connect was successfully installed if the AuthorizedKeysCommand and AuthorizedKeysCommandUser lines contain the following values:

```
AuthorizedKeysCommand /opt/aws/bin/eic_run_authorized_keys %u %f
AuthorizedKeysCommandUser ec2-instance-connect
```

- AuthorizedKeysCommand sets the eic_run_authorized_keys script to look up the keys from the instance metadata
- AuthorizedKeysCommandUser sets the system user as ec2-instance-connect

**Note**
If you previously configured AuthorizedKeysCommand and AuthorizedKeysCommandUser, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

Ubuntu

**To install EC2 Instance Connect on an instance launched with Ubuntu 16.04 or later**

1. Connect to your instance using SSH.

Replace the example values in the following command with your values. Use the SSH key pair that was assigned to your instance when you launched it and use the default user name of the AMI that you used to launch your instance. For an Ubuntu AMI, the user name is `ubuntu`.

```
$ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see [Connect to your Linux instance from Linux or macOS using SSH](p. 816).
2. (Optional) Ensure your instance has the latest Ubuntu AMI.

Run the following commands to update all the packages on your instance.

```
ubuntu:~$ sudo apt-get update
```

```
ubuntu:~$ sudo apt-get upgrade
```

3. Install the EC2 Instance Connect package on your instance.

```
ubuntu:~$ sudo apt-get install ec2-instance-connect
```

You should see three new scripts in the `/usr/share/ec2-instance-connect/` folder:

```
eic_curl_authorized_keys
eic_parse_authorized_keys
eic_run_authorized_keys
```

4. (Optional) Verify that Instance Connect was successfully installed on your instance.

```
ubuntu:~$ sudo less /lib/systemd/system/ssh.service.d/ec2-instance-connect.conf
```

EC2 Instance Connect was successfully installed if the `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser` lines contain the following values:

```
AuthorizedKeysCommand /usr/share/ec2-instance-connect/eic_run_authorized_keys %u %f
AuthorizedKeysCommandUser ec2-instance-connect
```

- `AuthorizedKeysCommand` sets the `eic_run_authorized_keys` script to look up the keys from the instance metadata
- `AuthorizedKeysCommandUser` sets the system user as `ec2-instance-connect`

**Note**

If you previously configured `AuthorizedKeysCommand` and `AuthorizedKeysCommandUser`, the EC2 Instance Connect installation will not change the values and you will not be able to use EC2 Instance Connect.

For more information about the EC2 Instance Connect package, see [aws/aws-ec2-instance-connect-config](https://github.com/aws/aws-ec2-instance-connect-config) on the GitHub website.

**Connect using EC2 Instance Connect**

The following instructions explain how to connect to your Linux instance using EC2 Instance Connect.

**Decide which connection option to use.** The connection option to use depends on whether your instance has a public IPv4 address:

- **Amazon EC2 console** – To connect using the Amazon EC2 console, the instance must have a public IPv4 address.
- **SSH client** – If the instance does not have a public IP address, you can connect to the instance over a private network using an SSH client. For example, you can connect from within the same VPC or through a VPN connection, transit gateway, or AWS Direct Connect.
EC2 Instance Connect does not support connecting using an IPv6 address.

**Tip**

EC2 Instance Connect is one of the options to connect to your Linux instance. For other options, see Connect to your Linux instance (p. 811). To connect to a Windows instance, see Connect to your Windows instance.

**Connection options for EC2 Instance Connect**

- Connect using the Amazon EC2 console (p. 843)
- Connect using your own key and SSH client (p. 843)
- Use EC2 Instance Connect to connect to your Linux instance with the AWS CLI (p. 844)
- Troubleshoot (p. 846)

**Connect using the Amazon EC2 console**

You can connect to an instance using the Amazon EC2 console by selecting the instance from the console and choosing to connect using EC2 Instance Connect. Instance Connect handles the permissions and provides a successful connection.

To connect using the Amazon EC2 console, the instance must have a public IPv4 address. Before connecting, be sure to review all the prerequisites (p. 831).

**To connect to your instance using the browser-based client from the Amazon EC2 console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Connect.
4. Choose EC2 Instance Connect.
5. Verify the user name and choose Connect to open a terminal window.

**Connect using your own key and SSH client**

You can use your own SSH key and connect to your instance from the SSH client of your choice while using the EC2 Instance Connect API. This enables you to benefit from the Instance Connect capability to push a public key to the instance. This connection method works for instances with public and private IP addresses.

**Requirements**

- Requirements for key pairs
  - Supported types: RSA (OpenSSH and SSH2) and ED25519
  - Supported lengths: 2048 and 4096
  - For more information, see Create a key pair using a third-party tool and import the public key to Amazon EC2 (p. 2012).
- When connecting to an instance that only has private IP addresses, the local computer from which you are initiating the SSH session must have connectivity to the EC2 Instance Connect service endpoint (to push your SSH public key to the instance) as well as network connectivity to the instance's private IP address to establish the SSH session. The EC2 Instance Connect service endpoint is reachable over the internet or over an AWS Direct Connect public virtual interface. To connect to the instance's private IP address, you can leverage services such as AWS Direct Connect, AWS Site-to-Site VPN, or VPC peering.

Before connecting, be sure to review all the prerequisites (p. 831).
To connect to your instance using your own key and any SSH client

1. **(Optional) Generate new SSH private and public keys**

   You can generate new SSH private and public keys, `my_key` and `my_key.pub`, using the following command:

   ```bash
   $ ssh-keygen -t rsa -f my_key
   ```

2. **Push your SSH public key to the instance**

   Use the `send-ssh-public-key` command to push your SSH public key to the instance. If you launched your instance using Amazon Linux 2023 or Amazon Linux 2, the default user name for the AMI is `ec2-user`. If you launched your instance using Ubuntu, the default user name for the AMI is `ubuntu`.

   The following example pushes the public key to the specified instance in the specified Availability Zone, to authenticate `ec2-user`.

   ```bash
   $ aws ec2-instance-connect send-ssh-public-key \
   --region us-west-2 \
   --availability-zone us-west-2b \
   --instance-id i-001234a4bf70dec41EXAMPLE \
   --instance-os-user ec2-user \
   --ssh-public-key file://my_key.pub
   ```

3. **Connect to the instance using your private key**

   Use the `ssh` command to connect to the instance using the private key before the public key is removed from the instance metadata (you have 60 seconds before it is removed). Specify the private key that corresponds to the public key, the default user name for the AMI that you used to launch your instance, and the instance's public DNS name (if connecting over a private network, specify the private DNS name or IP address). Add the `IdentitiesOnly=yes` option to ensure that only the files in the ssh config and the specified key are used for the connection.

   ```bash
   $ ssh -o "IdentitiesOnly=yes" -i my_key ec2-
   user@ec2-198-51-100-1.compute-1.amazonaws.com
   ```

**Use EC2 Instance Connect to connect to your Linux instance with the AWS CLI**

If you know your instance ID, you can use Amazon EC2 Instance Connect to connect to your instance using an SSH client. If you don't specify a connection type, EC2 Instance Connect automatically tries to connect to your instance's public IPv4 address. If your instance doesn't have a public IPv4 address, EC2 Instance Connect then tries to connect to your instance's private IPv4 address through an EC2 Instance Connect Endpoint (p. 847). If your instance doesn't have a private IPv4 address or your VPC doesn't have an EC2 Instance Connect Endpoint, then EC2 Instance Connect tries to connect to your instance's IPv6 address.

Before you connect with this method, ensure that you have configured the AWS CLI, including the credentials that it uses, and that you're using the latest version of the AWS CLI. For more information, see Installing or updating the latest version of the AWS CLI and Configuring the AWS CLI in the AWS Command Line Interface User Guide.
Connection types

auto (default)

The CLI tries to connect using the instance's IP addresses in the following order and with the corresponding connection type:

- Public IPv4: direct
- Private IPv4: eice
- IPv6: direct

direct

The CLI tries to connect using the instance's IP addresses in the following order (it does not connect over an EC2 Instance Connect Endpoint):

- Public IPv4
- IPv6
- Private IPv4
eice

The CLI always uses the instance's private IPv4 address.

Note

In the future, we might change the behavior of the auto connection type. To ensure that your desired connection type is used, we recommend that you explicitly set the --connection-type to either direct or eice.

When you connect to an instance using EC2 Instance Connect, the EC2 Instance Connect API pushes an SSH public key to the instance metadata (p. 1004) where it remains for 60 seconds. An IAM policy attached to your user authorizes your user to push the public key to the instance metadata. For more information about EC2 Instance Connect, see Connect to your Linux instance with EC2 Instance Connect (p. 831).

To connect to an instance using the instance ID

If you only know the instance ID, and want to let EC2 Instance Connect determine the connection type to use when connecting to your instance, use the ec2-instance-connect CLI and specify the ssh command and the instance ID.

```
aws ec2-instance-connect ssh --instance-id i-1234567890example
```

To connect to an instance using the instance ID and an EC2 Instance Connect Endpoint

If you want to connect to your instance over an EC2 Instance Connect Endpoint (p. 847), use the preceding command and also specify the --connection-type parameter with the eice value.

```
aws ec2-instance-connect ssh --instance-id i-1234567890example --connection-type eice
```

To connect to an instance using the instance ID and your own private key file

If you want to connect to your instance over an EC2 Instance Connect Endpoint using your own private key, specify the instance ID and the path to the private key file. Do not include file:// in the path; the following example will fail: file:///path/to/key.

```
aws ec2-instance-connect ssh --instance-id i-1234567890example --private-key-file /path/to/key.pem
```
Troubleshoot

If you receive an error while attempting to connect to your instance, see the following:

- Troubleshoot connecting to your instance (p. 2532)
- How do I troubleshoot issues connecting to my EC2 instance using EC2 Instance Connect?

Uninstall EC2 Instance Connect

To disable EC2 Instance Connect, connect to your instance and uninstall the `ec2-instance-connect` package that is installed on the OS. If the `sshd` configuration matches what it was set to when you installed EC2 Instance Connect, uninstalling `ec2-instance-connect` also removes the `sshd` configuration. If you modified the `sshd` configuration after installing EC2 Instance Connect, you must update it manually.

Amazon Linux

You can uninstall EC2 Instance Connect on Amazon Linux 2023 and Amazon Linux 2 2.0.20190618 or later, where EC2 Instance Connect is preconfigured.

To uninstall EC2 Instance Connect on an instance launched with Amazon Linux 2

1. Connect to your instance using SSH. Specify the SSH key pair you used for your instance when you launched it and the default user name for the Amazon Linux 2023 or Amazon Linux 2 AMI, which is `ec2-user`.

   For example, the following `ssh` command connects to the instance with the public DNS name `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, using the key pair `my_ec2_private_key.pem`.

   $ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com

2. Uninstall the `ec2-instance-connect` package using the `yum` command.

   [ec2-user ~]$ sudo yum remove ec2-instance-connect

Ubuntu

To uninstall EC2 Instance Connect on an instance launched with an Ubuntu AMI

1. Connect to your instance using SSH. Specify the SSH key pair you used for your instance when you launched it and the default user name for the Ubuntu AMI, which is `ubuntu`.

   For example, the following `ssh` command connects to the instance with the public DNS name `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, using the key pair `my_ec2_private_key.pem`.

   $ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-west-2.compute.amazonaws.com

2. Uninstall the `ec2-instance-connect` package using the `apt-get` command.

   ubuntu:~$ sudo apt-get remove ec2-instance-connect
Connect to your Linux instance with AWS Systems Manager Session Manager

Session Manager is a fully managed AWS Systems Manager capability that lets you manage your Amazon EC2 instances through an interactive one-click browser-based shell or through the AWS CLI. You can use Session Manager to start a session with an instance in your account. After the session is started, you can run bash commands as you would through any other connection type. For more information about Session Manager, see AWS Systems Manager Session Manager in the AWS Systems Manager User Guide.

Before attempting to connect to an instance using Session Manager, ensure that the necessary setup steps have been completed. For more information and instructions, see Setting up Session Manager.

To connect to a Linux instance using Session Manager with the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Connect.
4. For Connection method, choose Session Manager.
5. Choose Connect.

Troubleshooting

If you receive an error that you're not authorized to perform one or more Systems Manager actions (ssm:command-name), then you must update your policies to allow you to start sessions from the Amazon EC2 console. For more information, see Quickstart default IAM policies for Session Manager in the AWS Systems Manager User Guide.

Connect to your instances without requiring a public IPv4 address using EC2 Instance Connect Endpoint

EC2 Instance Connect Endpoint allows you to connect to an instance via SSH or RDP without requiring the instance to have a public IPv4 address.

How it works

First, you create an EC2 Instance Connect Endpoint in a subnet in your virtual private cloud (VPC). Then, when you want to connect to an instance, you specify the ID of the instance. You can optionally provide the EC2 Instance Connect Endpoint. The endpoint acts as a private tunnel to the instance.

Once you create an EC2 Instance Connect Endpoint in a subnet, you can use the endpoint to connect to any instance in any subnet in your VPC provided your VPC is configured to allow subnets to communicate.

Note

If you use an EC2 Instance Connect Endpoint in one subnet to connect to an instance in another subnet that is in a different Availability Zone, there is an additional charge for data transfer across Availability Zones.

The following diagram shows a user from the internet connecting to their instances, which are located in private subnets in a VPC. The diagram illustrates the following key components:

- The EC2 Instance Connect Endpoint Service is an AWS service that allows the user to use the EC2 Instance Connect Endpoint to connect from the internet to their instances that are in private subnets.
• The **EC2 Instance Connect Endpoint** in Private subnet A acts as a private tunnel so that the user can connect to their instances that are in the private subnets.

Access to create and connect to EC2 Instance Connect Endpoints is controlled by [IAM permissions](#). You can [configure additional security group rules](#) on your instances to restrict inbound traffic. For example, you can use inbound rules on your instances to only allow traffic on management ports from the EC2 Instance Connect Endpoint.

• **Private subnet A** has an EC2 Instance Connect Endpoint, but **Private subnet B** does not. Based on your VPC configuration, if Private subnet A and Private subnet B are allowed to communicate, then you can use the EC2 Instance Connect Endpoint in Private subnet A to connect to an instance in Private subnet B.
Benefits

EC2 Instance Connect Endpoint provides the following benefits:
You can connect to your instances without requiring the instances to have a public IPv4 address. Starting on February 1, 2024, AWS will charge for all public IPv4 addresses, including public IPv4 addresses associated with running instances and Elastic IP addresses. For more information, see the Public IPv4 Address tab on the Amazon VPC pricing page.

You can connect to your instances from the internet without requiring your VPC to have an internet gateway.

You can control access to the creation and use of the EC2 Instance Connect Endpoints to connect to instances with IAM policies and permissions (p. 852).

All attempts to connect to instances, both successful and unsuccessful, are logged to CloudTrail (p. 865).

Contents

- Prerequisites (p. 850)
- Grant IAM permissions to use EC2 Instance Connect Endpoint (p. 852)
- Security groups for EC2 Instance Connect Endpoint (p. 855)
- Create an EC2 Instance Connect Endpoint (p. 857)
- Connect using EC2 Instance Connect Endpoint to a Linux instance (p. 861)
- Log connections established over EC2 Instance Connect Endpoint (p. 865)
- Remove EC2 Instance Connect Endpoint (p. 867)
- Service-linked role for EC2 Instance Connect Endpoint (p. 868)
- Quotas (p. 871)

Prerequisites

The following are the prerequisites for using EC2 Instance Connect Endpoint to connect to an instance:

- AWS Regions (p. 850)
- AMIs (p. 850)
- IPv4 address (p. 851)
- Security groups (p. 833)
- Grant permissions (p. 833)

AWS Regions

Supported in all AWS Regions except Israel (Tel Aviv).

AMIs

The supported AMIs are dependent on how you connect to your instance using EC2 Instance Connect Endpoint.

Console

If you use the EC2 console to connect to your instance using EC2 Instance Connect Endpoint, the instance must have EC2 Instance Connect installed.

EC2 Instance Connect comes preinstalled on the following AMIs:

- Amazon Linux 2023
- Amazon Linux 2 2.0.20190618 or later
Connect to instances without requiring a public IPv4 address

- Ubuntu 20.04 or later

EC2 Instance Connect is not preinstalled on the following AMIs, but you can install it on instances that are launched using the following AMIs:

- Amazon Linux 2 prior to version 2.0.20190618
- CentOS Stream 8 and 9 – Supported only for instance types that run on Intel/AMD (x86_64)
- macOS Sonoma, Ventura, and Monterey
- Red Hat Enterprise Linux (RHEL) 8 and 9 – Supported only for instance types that run on Intel/AMD (x86_64)
- Ubuntu 16.04 or 18.04

For the installation instructions, see Install EC2 Instance Connect on your EC2 instances (p. 835).

SSH

If you use SSH to connect to your instance using EC2 Instance Connect Endpoint, the supported AMIs are dependent on whether you use your own key pair or you want EC2 Instance Connect to handle the ephemeral key.

If you use your own key pair

You can use any Linux AMI.

If you want EC2 Instance Connect to handle the ephemeral key

The instance must have EC2 Instance Connect installed.

EC2 Instance Connect comes preinstalled on the following AMIs:

- Amazon Linux 2023
- Amazon Linux 2 2.0.20190618 or later
- Ubuntu 20.04 or later

EC2 Instance Connect is not preinstalled on the following AMIs, but you can install it on instances that are launched using the following AMIs:

- Amazon Linux 2 prior to version 2.0.20190618
- CentOS Stream 8 and 9 – Supported only for instance types that run on Intel/AMD (x86_64)
- macOS Sonoma, Ventura, and Monterey
- Red Hat Enterprise Linux (RHEL) 8 and 9 – Supported only for instance types that run on Intel/AMD (x86_64)
- Ubuntu 16.04 or 18.04

For the installation instructions, see Install EC2 Instance Connect on your EC2 instances (p. 835).

RDP

If you use RDP to connect to your instance using EC2 Instance Connect Endpoint, you must use a Windows AMI.

IPv4 address

Your instance must have an IPv4 address (either private or public). EC2 Instance Connect Endpoint does not support connecting using an IPv6 address.
Security groups

The EC2 Instance Connect Endpoint and the instance that you want to connect to are each assigned security groups. For the recommended way to configure the security group rules, see Security groups for EC2 Instance Connect Endpoint (p. 855).

Grant permissions

You must grant the required permissions to every IAM user who will use EC2 Instance Connect Endpoint to connect to an instance. For more information, see Grant IAM permissions to use EC2 Instance Connect Endpoint (p. 852).

Grant IAM permissions to use EC2 Instance Connect Endpoint

To create or use an EC2 Instance Connect Endpoint, you must create an IAM policy that grants your users permissions for the following:

- Create, describe, and delete EC2 Instance Connect Endpoints
- Use the ec2-instance-connect:OpenTunnel action to use EC2 Instance Connect Endpoint to connect to instances

For information about creating IAM policies, see Creating IAM policies in the IAM User Guide.

Example IAM policies for EC2 Instance Connect Endpoint

- Allow users to create, describe, and delete EC2 Instance Connect Endpoints (p. 852)
- Allow users to use EC2 Instance Connect Endpoint to connect to instances (p. 853)
- Allow users to connect only from a specified source IP address range (p. 855)

Allow users to create, describe, and delete EC2 Instance Connect Endpoints

To create an EC2 Instance Connect Endpoint, users require permissions for the following actions:

- ec2:CreateInstanceConnectEndpoint
- ec2:CreateNetworkInterface
- ec2:CreateTags
- iam:CreateServiceLinkedRole

To describe and delete EC2 Instance Connect Endpoints, users require permissions for the following actions:

- ec2:DescribeInstanceConnectEndpoints
- ec2:DeleteInstanceConnectEndpoint

You can create a policy that grants permission to create, describe, and delete EC2 Instance Connect Endpoints in all subnets. Alternatively, you can restrict actions for specified subnets only by specifying the subnet ARNs as the allowed Resource or by using the ec2:SubnetID condition key. You can also use the aws:ResourceTag condition key to explicitly allow or deny endpoint creation with certain tags. For more information, see Policies and permissions in IAM in the IAM User Guide.

Example IAM policy

In the following example IAM policy, the Resource section grants permission to create and delete endpoints in all subnets, specified by the asterisk (*). The ec2:Describe* API actions do not support resource-level permissions. Therefore, the * wildcard is necessary in the Resource element.
Allow users to use EC2 Instance Connect Endpoint to connect to instances

The `ec2-instance-connect:OpenTunnel` action grants permission to establish a TCP connection to an instance to connect over the EC2 Instance Connect Endpoint. You can specify the EC2 Instance Connect Endpoint to use. Alternatively, a Resource with an asterisk (*) allows users to use any available EC2 Instance Connect Endpoint. You can also restrict access to instances based on the presence or absence of resource tags as condition keys.

**Conditions**

- **ec2-instance-connect:remotePort** – Specifies the port on the instance that can be used to establish a TCP connection. When this condition key is used, attempting to connect to an instance on any other port other than the port specified in the policy results in a failure.

- **ec2-instance-connect:privateIpAddress** – Specifies the destination private IP address associated with the instance that you want to establish a TCP connection with. You can specify a single IP address, such as `10.0.0.1/32`, or a range of IPs through CIDRs, such as `10.0.1.0/28`. When this condition key is used, attempting to connect to an instance with a different private IP address or outside the CIDR range results in a failure.

- **ec2-instance-connect:maxTunnelDuration** – Specifies the maximum duration for an established TCP connection. The unit is seconds and the duration ranges from a minimum of 1 second to a maximum of 3,600 seconds (1 hour). If the condition is not specified, the default duration is set to 3,600 seconds (1 hour). Attempting to connect to an instance for longer than the specified duration in the IAM policy or for longer than the default maximum results in a failure. The connection is disconnected after the specified duration.

If `maxTunnelDuration` is specified in the IAM policy and the value specified is less than 3,600 seconds (the default), then you must specify `--max-tunnel-duration` in the command when
A user can also be granted access to establish connections to instances based on the presence of resource tags on the EC2 Instance Connect Endpoint. For more information, see Policies and permissions in IAM in the IAM User Guide.

The ec2-instance-connect:SendSSHPublicKey action grants permission to push the public key to an instance. The ec2:osuser condition specifies the name of the OS (operating system) user that can push the public key to an instance. Use the default user name for the AMI (p. 812) that you used to launch the instance. For more information, see Grant IAM permissions for EC2 Instance Connect (p. 833).

Example IAM policy

The following example IAM policy allows an IAM principal to connect to an instance using only the specified EC2 Instance Connect Endpoint, identified by the specified endpoint ID eice-123456789abcdef. The connection is successfully established only if all the conditions are satisfied, for example, if the SSH connection is established on port 22 of the instance, if the private IP address of the instance lies within the range of 10.0.1.0/31 (between 10.0.1.0 and 10.0.1.1), and the maxTunnelDuration is less than or equal to 3600 seconds. The connection is disconnected after 3600 seconds (1 hour).

The ec2:Describe* API actions do not support resource-level permissions. Therefore, the * wildcard is necessary in the Resource element.

}
]

Allow users to connect only from a specified source IP address range

The following example IAM policy allows an IAM principal to connect to an instance on condition they are connecting from an IP address within the IP address range specified in the policy. If the IAM principal calls OpenTunnel from an IP address not within 192.0.2.0/24 (the example IP address range in this policy), the response will be Access Denied. For more information, see aws:SourceIp in the IAM User Guide.

Security groups for EC2 Instance Connect Endpoint

The EC2 Instance Connect Endpoint and the instance that you want to connect to are each assigned security groups. We recommend that you configure the security group rules [p. 2024] in the way described in this topic.

Topics

855
Connect to instances without requiring a public IPv4 address

- **EC2 Instance Connect Endpoint security group rule** (p. 856)
- **Instance security group rule** (p. 856)
- **Example** (p. 856)

### EC2 Instance Connect Endpoint security group rule

When you create the EC2 Instance Connect Endpoint, if you don't specify a security group, the default security group for the VPC is assigned. The default outbound rule allows all outbound traffic to all destinations. To limit connectivity to only the instances in the VPC, we recommend that the outbound rule only allows traffic to the specified destination.

**Recommended outbound rule**

- Allow outbound traffic to the specified destination (a security group or the VPC CIDR, depending on your security needs).

### Instance security group rule

The instance needs at least one inbound rule to allow traffic from the EC2 Instance Connect Endpoint.

**Recommended inbound rules**

Specify one or more of the following rules, depending on your security needs and whether client IP preservation is enabled:

- Allow inbound traffic from the EC2 Instance Connect Endpoint security group.
- Allow inbound traffic from the client IP address.
- Allow inbound traffic from the VPC CIDR so that any instances in the VPC can send traffic to the destination instance.

The inbound rule that you specify is dependent on whether the EC2 Instance Connect Endpoint is configured to enable client IP preservation. Not all instance types support client IP preservation. For more information, see [Limitations](p. 861).

The following table lists the security group rules for the instance that can be configured depending on the value set for `preserveClientIp`.

<table>
<thead>
<tr>
<th>Client IP preservation</th>
<th>Supported security group rules for the instance</th>
</tr>
</thead>
</table>
| `preserveClientIp=false` | • Allow inbound traffic from the EC2 Instance Connect Endpoint security group.  
                                • Allow inbound traffic from the VPC CIDR. |
| `preserveClientIp=true`  | • Allow inbound traffic from the EC2 Instance Connect Endpoint security group.  
                                • Allow inbound traffic from the client IP address. |

**Example**

In the following image, the EC2 Instance Connect Endpoint is assigned the security group **EIC Endpoint Security Group**. The **EIC Endpoint Security Group** has one outbound rule that allows TCP traffic to
Connect to instances without requiring a public IPv4 address. This configuration means that the EC2 Instance Connect Endpoint can only send traffic to instances that are assigned the Development Security Group. In the image, the instance is assigned the Development Security Group, which means that, in this example, the EC2 Instance Connect Endpoint can send TCP traffic to the instance.

Create an EC2 Instance Connect Endpoint

You can create an EC2 Instance Connect Endpoint in a subnet in your VPC. You can then use the EC2 Instance Connect Endpoint to connect to instances in your VPC without requiring the instances to have a public IPv4 address.

EC2 Instance Connect Endpoint supports client IP preservation. You can configure the EC2 Instance Connect Endpoint to use your client's IP address as the source (preserveClientIp parameter is true) when connecting to an instance.

When you create an EC2 Instance Connect Endpoint, a service-linked role is automatically created for the Amazon EC2 service in AWS Identity and Access Management (IAM). Amazon EC2 uses the service-linked role to provision network interfaces in your account, which are required when creating EC2 Instance Connect Endpoints. For more information, see Service-linked role for EC2 Instance Connect Endpoint (p. 868).

Note
You can't modify an EC2 Instance Connect Endpoint after you've created it. If you want different endpoint settings, you'll need to delete the EC2 Instance Connect Endpoint and create a new one with the desired settings.

Prerequisites

You must have the required IAM permissions to create an EC2 Instance Connect Endpoint. For more information, see Allow users to create, describe, and delete EC2 Instance Connect Endpoints (p. 852).

Create an EC2 Instance Connect Endpoint

Use one of the following methods to create an EC2 Instance Connect Endpoint.

Console

To create an EC2 Instance Connect Endpoint

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the left navigation pane, choose Endpoints.
3. Choose Create endpoint, and then complete the settings in the dialog box, as follows:
Connect to instances without requiring a public IPv4 address
Connect to instances without requiring a public IPv4 address

a. (Optional) For Name tag, enter a name for the endpoint.
b. For Service category, choose EC2 Instance Connect Endpoint.
c. For VPC, select the VPC in which to create the endpoint.
d. Expand Additional settings, and for Preserve Client IP do one of the following:
   - If you want your client's IP address to be used as the source when you connect to an instance, select the check box.
     
     **Note:** When Preserve Client IP is turned on, your instance's security group must allow traffic from your client IP address. For more information, see Instance security group rule (p. 856).
   - If you want the elastic network interface IP address to be used as the source when you connect to an instance, clear the check box. When Preserve Client IP is turned off, you can connect to any IP address that's routable from the VPC.

e. (Optional) For Security groups, select the security group to associate with the endpoint. If you don't select a security group, the default security group for your VPC will be associated with the endpoint. For more information, see Security groups for EC2 Instance Connect Endpoint (p. 855).
f. For Subnet, select the subnet in which to create the endpoint.
g. (Optional) To add a tag, choose Add new tag and enter the tag key and the tag value.
h. Choose Create endpoint.

The initial status is Pending. Before you can connect to an instance using this endpoint, wait until the status is Available. This can take a few minutes. To monitor the endpoint status, see Describe an EC2 Instance Connect Endpoint (p. 860).

AWS CLI

To create an EC2 Instance Connect Endpoint

Use the `create-instance-connect-endpoint` AWS CLI command and specify the subnet in which to create your EC2 Instance Connect Endpoint. Make sure you're using the latest version of the AWS CLI.

```
aws ec2 create-instance-connect-endpoint --region us-east-1 --subnet-id subnet-0123456789example
```

Example output

```
{
  "VpcId": "vpc-0123abcd",
  "InstanceConnectEndpointArn": "arn:aws:ec2:us-east-1:111111111111:instance-connect-endpoint/eice-0123456789example",
  "AvailabilityZone": "us-east-1a",
  "NetworkInterfaceIds": [
    "eni-0123abcd"
  ],
  "preserveClientIp": true,
  "Tags": [],
  "FipsDnsName": "eice-0123456789example.0123abcd.fips.ec2-instance-connect-endpoint.us-east-1.amazonaws.com",
  "StateMessage": ",",
  "State": "create-complete",
  "DnsName": "eice-0123456789example.0123abcd.ec2-instance-connect-endpoint.us-east-1.amazonaws.com",
  "SubnetId": "subnet-0123abcd",
  "OwnerId": "111111111111",
  "SecurityGroupIds": []
}
```
The initial value for the State field is create-in-progress. Before you can connect to an instance using this endpoint, wait until the state is create-complete. This can take a few minutes. To monitor the endpoint state, see Describe an EC2 Instance Connect Endpoint (p. 860).

**Describe an EC2 Instance Connect Endpoint**

Use one of the following methods to describe an EC2 Instance Connect Endpoint.

**Console**

**To view an EC2 Instance Connect Endpoint**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the left navigation pane, choose **Endpoints**.
3. Find the endpoint in the table and select it to view its details. To use the endpoint to connect to an instance, the **Status** field must display **Available**.

**AWS CLI**

**To describe an EC2 Instance Connect Endpoint**

Use the **describe-instance-connect-endpoints** AWS CLI command and specify the EC2 Instance Connect Endpoint ID.

```bash
aws ec2 describe-instance-connect-endpoints --region us-east-1 --instance-connect-endpoint-ids eice-0123456789example
```

Example output - To use the endpoint for connecting to an instance, the State field must show create-complete.

```
{
  "InstanceConnectEndpoints": [
    {
      "OwnerId": "111111111111",
      "InstanceConnectEndpointId": "eice-0123456789example",
      "InstanceConnectEndpointArn": "arn:aws:ec2:us-east-1:111111111111:instance-connect-endpoint/eice-0123456789example",
      "State": "create-complete",
      "StateMessage": "",
      "DnsName": "eice-0123456789example.b67b86ba.ec2-instance-connect-endpoint.us-east-1.amazonaws.com",
      "NetworkInterfaceIds": [
        "eni-0123456789example"
      ],
      "VpcId": "vpc-0123abcd",
      "AvailabilityZone": "us-east-1d",
      "CreatedAt": "2023-02-07T12:05:37+00:00",
      "SubnetId": "subnet-0123abcd",
      "Tags": []
    }
  ]
}
```
Connect using EC2 Instance Connect Endpoint to a Linux instance

EC2 Instance Connect Endpoint allows you to connect to an instance without requiring the instance to have a public IPv4 address. You can connect to any instances that support TCP.

To connect to an instance, specify the instance ID. You can optionally provide the EC2 Instance Connect Endpoint.

For information about how to connect to a Windows instance, see Connect using EC2 Instance Connect Endpoint to a Windows instance in the Amazon EC2 User Guide for Windows Instances.

Topics
- Limitations (p. 861)
- Prerequisites (p. 861)
- Connect to your Linux instance using the Amazon EC2 console (p. 862)
- Connect to your Linux instance using SSH (p. 864)
- Troubleshoot (p. 865)

Limitations
- Only ports 22 and 3389 are supported.
- EC2 Instance Connect Endpoint doesn't support connections to an instance using IPv6 addresses.
- Each EC2 Instance Connect Endpoint can support up to 20 concurrent connections.
- EC2 Instance Connect Endpoint is intended specifically for management traffic use cases and not for high volume data transfers. High volume data transfers are throttled.
- Maximum duration for an established TCP connection: 1 hour (3,600 seconds). You can specify the maximum allowed duration in an IAM policy, which can be 3,600 seconds or less. For more information, see Allow users to use EC2 Instance Connect Endpoint to connect to instances (p. 853).
- When client IP preservation is enabled, the instance to connect to must be in the same VPC as the EC2 Instance Connect Endpoint.
- Client IP preservation is not supported when traffic is routed through an AWS Transit Gateway.
- The following instance types do not support client IP preservation: C1, CG1, CG2, G1, G2, H1, M1, M2, M3, and T1. If you are using these instance types, set the preserveClientIp parameter to false, otherwise attempting to connect to these instance types using EC2 Instance Connect Endpoint will fail. For more information about the preserveClientIp parameter, see step 3.d in the Create an EC2 Instance Connect Endpoint (p. 857) console procedure.

Prerequisites
- You must have the required IAM permission to connect to an EC2 Instance Connect Endpoint. For more information, see Allow users to use EC2 Instance Connect Endpoint to connect to instances (p. 853).
- The EC2 Instance Connect Endpoint must be in the Available (console) or create-complete (AWS CLI) state. To monitor the endpoint state, see Describe an EC2 Instance Connect Endpoint (p. 860).
- Ensure that the security group of the instance that you want to connect to is configured correctly for inbound traffic. For more information, see Instance security group rule (p. 856).
- If you're using the AWS CLI, make sure that you have configured the AWS CLI, including the credentials that it uses, and that you're using the latest version of the AWS CLI. For more information, see Installing or updating the latest version of the AWS CLI and Configuring the AWS CLI in the AWS Command Line Interface User Guide.
Connect to your Linux instance using the Amazon EC2 console

You can connect to an instance using the Amazon EC2 console by selecting the instance from the console and choosing to connect using EC2 Instance Connect, which handles the permissions and provides a successful connection.

To connect to your instance using the browser-based client from the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, choose Connect, and then do the following:
Connect to instance

Connect to your instance i-00ce5b4dc72ef77ca (test-eic) using any of the following:

**EC2 Instance Connect**

- **Instance ID**
  - i-00ce5b4dc72ef77ca (test-eic)

- **Connection Type**
  - Connect using EC2 Instance Connect
    - Connect using the EC2 Instance Connect browser-based client, with a public IPv4 address.

- **Private IP address**
  - 172.31.0.63

- **User name**
  - ec2-user

- **Max tunnel duration (seconds)**
  - The maximum allowed duration of the SSH connection. Must comply with the maximum tunnel duration, which is 3600 seconds (1 hour).
  - 3600

**EC2 Instance Connect Endpoint**

Only endpoints that have completed the creation process can be selected.

- eice-073b6240d11a242c9
a. Choose the **EC2 Instance Connect** tab.
b. For **Connection type**, choose **Connect using EC2 Instance Connect Endpoint**.
c. For **User name**, verify the user name.
d. For **Max tunnel duration (seconds)**, enter the maximum allowed duration for the SSH connection.

The duration must comply with the maxTunnelDuration condition specified in the IAM policy. If you don’t have access to the IAM policy, ask your administrator to verify it. If maxTunnelDuration is not specified in the IAM policy, enter the default, which is **3600** seconds (1 hour).
e. For **EC2 Instance Connect Endpoint**, choose the EC2 Instance Connect Endpoint in the instance’s VPC.
f. Choose **Connect** to open a terminal window.

**Connect to your Linux instance using SSH**

You can use SSH to connect to your Linux instance, and use the open-tunnel command to establish a private tunnel. You can use open-tunnel in single connection or multi-connection mode.

For information about using the AWS CLI to connect to your instance using SSH, see [Use EC2 Instance Connect to connect to your Linux instance with the AWS CLI](p. 844).

The following examples use **OpenSSH**. You can use any other SSH client that supports a proxy mode.

**Single connection**

**To allow only a single connection to an instance using SSH and the open-tunnel command**

Use `ssh` and the `open-tunnel` AWS CLI command as follows. The `-o` proxy command encloses the open-tunnel command that creates the private tunnel to the instance.

```bash
ssh -i my-key-pair.pem ec2-user@i-0123456789example -o ProxyCommand='aws ec2-instance-connect open-tunnel --instance-id i-0123456789example'
```

For:

- `-i` – Specify the key pair that was used to launch the instance.
- `ec2-user@i-0123456789example` – Specify the username of the AMI that was used to launch the instance, and the instance ID.
- `--instance-id` – Specify the ID of the instance to connect to. Alternatively, specify `%h`, which extracts the instance ID from the user.

**Multi-connection**

To allow multiple connections to an instance, first run the `open-tunnel` AWS CLI command to start listening for new TCP connections, and then use `ssh` to create a new TCP connection and a private tunnel to your instance.

**To allow multiple connections to your instance using SSH and the open-tunnel command**

1. Run the following command to start listening for new TCP connections on the specified port on your local machine.

```
aws ec2-instance-connect open-tunnel
```
Amazon Elastic Compute Cloud
User Guide for Linux Instances
Connect to instances without
requiring a public IPv4 address

```
--instance-id i-0123456789example \
--local-port 8888
```

**Expected output**

```
Listening for connections on port 8888.
```

2. In a new terminal window, run the following ssh command to create a new TCP connection and a private tunnel to your instance.

```
ssh -i my-key-pair.pem ec2-user@localhost -p 8888
```

**Expected output – In the first terminal window, you'll see the following:**

```
[1] Accepted new tcp connection, opening websocket tunnel.
```

**You might also see the following:**

```
```

**Troubleshoot**

Use the following information to help diagnose and fix issues that you might encounter when using EC2 Instance Connect Endpoint to connect an instance.

**Can't connect to your instance**

The following are common reasons why you might not be able to connect to your instance.

- Security groups – Check the security groups assigned to the EC2 Instance Connect Endpoint and your instance. For more information about the required security group rules, see Security groups for EC2 Instance Connect Endpoint (p. 855).
- Instance state – Verify that your instance is in the running state.
- Key pair – If the command you're using to connect requires a private key, verify that your instance has a public key and that you have the corresponding private key.
- IAM permissions – Verify that you have the required IAM permissions. For more information, see Grant IAM permissions to use EC2 Instance Connect Endpoint (p. 852).

For more troubleshooting tips, see Troubleshoot connecting to your instance (p. 2532).

**ErrorCode: AccessDeniedException**

If you receive an AccessDeniedException error, and the maxTunnelDuration condition is specified in the IAM policy, be sure to specify the --max-tunnel-duration parameter when connecting to an instance. For more information about this parameter, see open-tunnel in the AWS CLI Command Reference.

**Log connections established over EC2 Instance Connect Endpoint**

You can log resource operations and audit connections established over the EC2 Instance Connect Endpoint with AWS CloudTrail logs.
Log EC2 Instance Connect Endpoint API calls with AWS CloudTrail

EC2 Instance Connect Endpoint resource operations are logged to CloudTrail as management events. When the following API calls are made, the activity is recorded as a CloudTrail event in Event history:

- CreateInstanceConnectEndpoint
- DescribeInstanceConnectEndpoints
- DeleteInstanceConnectEndpoint

You can view, search, and download recent events in your AWS account. For more information, see Viewing events with CloudTrail Event history in the AWS CloudTrail User Guide.

Use AWS CloudTrail to audit users who connect to an instance using EC2 Instance Connect Endpoint

Connection attempts to instances via EC2 Instance Connect Endpoint are logged in CloudTrail in Event history. When a connection to an instance is initiated through an EC2 Instance Connect Endpoint, the connection is logged as a CloudTrail management event with the eventName of OpenTunnel.

You can create Amazon EventBridge rules that route the CloudTrail event to a target. For more information, see the Amazon EventBridge User Guide.

The following is an example of an OpenTunnel management event that was logged in CloudTrail.

```
{
    "eventVersion": "1.08",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "ABCDEFGONOMOOCB6XYTQEXAMPLE",
        "arn": "arn:aws:iam::123456789012:user/IAM-friendly-name",
        "accountId": "123456789012",
        "accessKeyId": "ABCDEFGUKZHNAW4OSN2AEXAMPLE",
        "userName": "IAM-friendly-name"
    },
    "eventTime": "2023-04-11T23:50:40Z",
    "eventSource": "ec2-instance-connect.amazonaws.com",
    "eventName": "OpenTunnel",
    "awsRegion": "us-east-1",
    "sourceIPAddress": "1.2.3.4",
    "userAgent": "aws-cli/1.15.61 Python/2.7.10 Darwin/16.7.0 botocore/1.10.60",
    "requestParameters": {
        "instanceConnectEndpointId": "eici-0123456789EXAMPLE",
        "maxTunnelDuration": "3600",
        "remotePort": "22",
        "privateIpAddress": "10.0.1.1"
    },
    "responseElements": null,
    "requestID": "98deb2c6-3b3a-437c-a680-03c4207b6650",

    "readOnly": false,
    "resources": [{
        "accountId": "123456789012",
        "type": "AWS:EC2:InstanceConnectEndpoint",
        "ARN": "arn:aws:ec2:us-east-1:123456789012:instance-connect-endpoint/eici-0123456789EXAMPLE"
    }]
}
```
Remove EC2 Instance Connect Endpoint

To remove EC2 Instance Connect Endpoint from your VPC, delete the endpoint that was created in a subnet.

When you delete an EC2 Instance Connect Endpoint, it first enters the Deleting (console) or delete-in-progress (AWS CLI) state, and then the delete-complete (AWS CLI) state. In the console, a deleted endpoint no longer appears. If the delete action fails, the state is delete-failed, and the Status message (console) or StateMessage (AWS CLI) provides the failure reason.

Use one of the following methods to delete an EC2 Instance Connect Endpoint.

**Console**

**To delete an EC2 Instance Connect Endpoint**

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the left navigation pane, choose Endpoints.
3. Select the endpoint.
4. Choose Actions, Delete VPC endpoints.
5. When prompted for confirmation, enter delete.
6. Choose Delete.

**AWS CLI**

**To delete an EC2 Instance Connect Endpoint**

Use the delete-instance-connect-endpoints AWS CLI command and specify the ID of the EC2 Instance Connect Endpoint to delete.

```
aws ec2 delete-instance-connect-endpoint --instance-connect-endpoint-id eice-03f5e49b83924bbc7
```

**Example output**

```
{
    "InstanceConnectEndpoint": {
        "OwnerId": "111111111111",
        "InstanceConnectEndpointId": "eice-0123456789example",
        "InstanceConnectEndpointArn": "arn:aws:ec2:us-east-1:111111111111:instance-connect-endpoint/eice-0123456789example",
        "State": "delete-in-progress",
        "StateMessage": ",",
        "NetworkInterfaceIds": [],
        "VpcId": "vpc-0123abcd",
        "AvailabilityZone": "us-east-1d",
        "CreatedAt": "2023-02-07T12:05:37+00:00",
        "SubnetId": "subnet-0123abcd"
    }
}
```
Service-linked role for EC2 Instance Connect Endpoint

Amazon EC2 uses AWS Identity and Access Management (IAM) service-linked roles. A service-linked role is a unique type of IAM role that is linked directly to Amazon EC2. Service-linked roles are predefined by Amazon EC2 and include all the permissions that Amazon EC2 requires to call other AWS services on your behalf. For more information, see Using service-linked roles in the IAM User Guide.

When you create an EC2 Instance Connect Endpoint, the service-linked role named AWSServiceRoleForEC2InstanceConnect and the managed policy named EC2InstanceConnectEndpoint are automatically created in your AWS account, and the managed policy is automatically attached to the service-linked role.

Amazon EC2 uses AWSServiceRoleForEC2InstanceConnect to manage network interfaces in your account that are required when creating EC2 Instance Connect Endpoints.

Permissions granted by AWSServiceRoleForEC2InstanceConnect

Amazon EC2 uses AWSServiceRoleForEC2InstanceConnect to complete the following actions:

- ec2:CreateNetworkInterface – Create network interfaces
- ec2:DeleteNetworkInterface – Delete network interfaces
- ec2:DescribeNetworkInterfaces – Describe network interfaces
- ec2:DescribeAvailabilityZones – Describe Availability Zones
- ec2:ModifyNetworkInterfaceAttribute – Disable source and destination checks

Use service-linked roles

EC2 Instance Connect Endpoint uses the service-linked role named AWSServiceRoleForEC2InstanceConnect to provision network interfaces in your account that are required to use the service.

If you create an EC2 Instance Connect Endpoint, the EC2InstanceConnectEndpoint managed policy is automatically created in your AWS account and attached to the AWSServiceRoleForEC2InstanceConnect service-linked role.

Service Linked Roles for EC2 Instance Connect Endpoint

The AWSServiceRoleForEC2InstanceConnect service-linked role trusts the following services to assume the role:

- ec2-instance-connect.amazonaws.com

The role permissions policy, named EC2InstanceConnectEndpoint, allows EC2 Instance Connect Endpoint to complete the following actions on the specified resources:

- Action: ec2:CreateNetworkInterface – On all subnets and all network interfaces with the non-null tag key InstanceConnectEndpointId to create network interfaces for EC2 Instance Connect Endpoint
- Action: ec2:CreateTags – On all network interfaces created for an EC2 Instance Connect Endpoint at creation time with the tag key **InstanceConnectEndpointId**

- Action: ec2:DeleteNetworkInterface – On network interfaces created for an EC2 Instance Connect Endpoint with tag key **InstanceConnectEndpointId**

- Action: ec2:DescribeNetworkInterfaces – On network interfaces for an Instance Connect Endpoint

- Action: ec2:DescribeAvailabilityZones – For internal mapping of customer’s Availability Zone

- Action: ec2:ModifyNetworkInterfaceAttribute – On all network interfaces to disable source and destination checks

### Trust policy

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "ec2-instance-connect.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

### Permissions policies

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["ec2:DescribeNetworkInterfaces", "ec2:DescribeAvailabilityZones"],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": ["ec2:CreateNetworkInterface"],
      "Resource": "arn:aws:ec2:::*:subnet/*"
    },
    {
      "Effect": "Allow",
      "Action": ["ec2:CreateNetworkInterface"],
      "Resource": "arn:aws:ec2:::*:network-interface/*",
      "Condition": {
        "ForAllValues:StringEquals": {
          "aws:TagKeys": [
```
Creating a service-linked role for EC2 Instance Connect Endpoint

When you create an EC2 Instance Connect Endpoint, the service-linked role `AWSServiceRoleForEC2InstanceConnect` is automatically created for you.

**Important**
Ensure that the AWS account used to create the EC2 Instance Connect Endpoint has an IAM policy attached to it that permits the `iam:CreateServiceLinkedRole` action.
Editing a service-linked role for EC2 Instance Connect Endpoint

EC2 Instance Connect Endpoint doesn't allow you to edit the `AWSServiceRoleForEC2InstanceConnect` service-linked role.

Deleting a service-linked role for EC2 Instance Connect Endpoint

If you no longer need to use EC2 Instance Connect Endpoint, we recommend that you delete the `AWSServiceRoleForEC2InstanceConnect` service-linked role.

**Note**

You can delete the service-linked role only after you delete all EC2 Instance Connect Endpoint resources.

Use the AWS CLI to delete the service-linked role. For more information, see [Deleting a service-linked role](https://docs.aws.amazon.com/IAM/latest/UserGuide/idelman.html) in the IAM User Guide.

Follow these steps to delete the service-linked role using the AWS CLI:

1. Delete all EC2 Instance Connect Endpoints using the `delete-instance-connect-endpoint` command, this will also remove the associated resources.
2. Delete the service linked role using the `delete-service-linked-role` command. Deleting the service-linked role will also delete the associated managed policy.

EC2 Instance Connect Endpoint supports using the `AWSServiceRoleForEC2InstanceConnect` service-linked role in every AWS Region where the service is available.

**AWS managed policies for EC2 Instance Connect Endpoint**

**AWS managed policy: EC2InstanceConnectEndpoint**

This policy is attached to a service-linked role that allows EC2 Instance Connect Endpoint to perform actions on your behalf. For more information, see [EC2InstanceConnectEndpoint](https://docs.aws.amazon.com/elasticbeanstalk/latest/dg/using-ec2-instanceconnect.html) (p. 868).

To view the permissions for this policy, see [Ec2InstanceConnectEndpoint](https://docs.aws.amazon.com/elasticbeanstalk/latest/dg/using-ec2-instanceconnect.html) in the AWS Management Console.

**EC2 Instance Connect Endpoint updates to AWS managed policies**

View details about updates to AWS managed policies for EC2 Instance Connect Endpoint since this service began tracking these changes.

<table>

Connect your EC2 instance to an AWS resource

After you launch an instance, you can connect it to one or more AWS resources.

This section describes how to automatically connect an Amazon EC2 instance to an Amazon RDS database.

**Automatically connect an EC2 instance to an RDS database**

You can use the automatic connection functionality in the Amazon EC2 console to quickly connect one or more EC2 instances to an RDS database to allow traffic between them.

For more information, see How the connection is automatically configured (p. 874). For a detailed walkthrough, which includes other ways to connect an EC2 instance and an RDS database, see Tutorial: Connect an Amazon EC2 instance to an Amazon RDS database (p. 875).

**Topics**

- Costs (p. 872)
- Prerequisites (p. 872)
- Automatically connect an instance and a database (p. 872)
- How the connection is automatically configured (p. 874)

**Costs**

While there is no charge to automatically connect your EC2 instance to an RDS database, you are charged for the underlying services. Data transfer fees will apply if your EC2 instance and RDS database are in different Availability Zones. For information about data transfer fees, see Data Transfer on the Amazon EC2 On-Demand Pricing page.

**Prerequisites**

Before you can automatically connect an EC2 instance to an RDS database, check the following:

- The EC2 instances must be in the Running state. You can't connect an EC2 instance if it's in another state.
- The EC2 instances and the RDS database must be in the same virtual private cloud (VPC). The automatic connection feature is not supported if an EC2 instance and RDS database are in different VPCs.

**Automatically connect an instance and a database**

You can automatically connect an EC2 instance to an RDS database immediately after you've launched your instance, or later.
Automatically connect immediately after launch

Use the following steps to automatically connect an EC2 instance to an RDS database immediately after you've launched the EC2 instance.

To view an animation of these steps, see View an animation: Automatically connect a newly-launched EC2 instance to an RDS database (p. 873).

To automatically connect a newly-launched EC2 instance to an RDS database using the EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the console dashboard, choose Launch instances, and then follow the steps to launch an instance (p. 722).
3. On the instance launch confirmation page, choose Connect an RDS database.
4. In the Connect RDS Database dialog box, do the following:
   a. For Database role, choose either Cluster or Instance.
   b. For RDS database, select a database to connect to.

   Note
   The EC2 instances and the RDS database must be in the same VPC in order to connect to each other.
   c. Choose Connect.

View an animation: Automatically connect a newly-launched EC2 instance to an RDS database

Automatically connect an existing instance

Use the following steps to automatically connect an existing EC2 instance to an RDS database.
To view an animation of these steps, see View an animation: Automatically connect an existing EC2 instance to an RDS database (p. 874).

To automatically connect an existing EC2 instance to an RDS database using the EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select one or more EC2 instances to connect to an RDS database, and then choose Actions, Networking, Connect RDS database.

   If Connect RDS database is not available, check that the EC2 instances are in the Running state and that they are in the same VPC.
4. In the Connect RDS Database dialog box, do the following:
   a. For Database role, choose either Cluster or Instance.
   b. For RDS database, select a database to connect to.

   Note
   The EC2 instances and the RDS database must be in the same VPC in order to connect to each other.
   c. Choose Connect.

View an animation: Automatically connect an existing EC2 instance to an RDS database

For information about how to use the Amazon RDS console to automatically connect an EC2 instance to an RDS database, see Configure automatic network connectivity with an EC2 instance in the Amazon RDS User Guide.

How the connection is automatically configured

When you use the EC2 console to automatically configure the connection between an EC2 instance and an RDS database to allow traffic between them, the connection is configured by security groups (p. 2023).

The security groups are automatically created and added to the EC2 instance and RDS database, as follows:
Amazon EC2 creates a security group called \texttt{ec2-rds-x} and adds it to the EC2 instance. It has one outbound rule that allows traffic to the database by specifying \texttt{rds-ec2-x} (the database security group) as its destination.

Amazon RDS creates a security group called \texttt{rds-ec2-x} and adds it to the database. It has one inbound rule that allows traffic from the EC2 instance by specifying \texttt{ec2-rds-x} (the EC2 instance security group) as its source.

The security groups reference each other as the destination and source, and only allow traffic on the database port. You can reuse these security groups so that any database with the \texttt{rds-ec2-x} security group can talk to any EC2 instance with the \texttt{ec2-rds-x} security group.

The security group names follow a pattern. For the security groups created by Amazon EC2, the pattern is \texttt{ec2-rds-x}, and for the security groups created by Amazon RDS, the pattern is \texttt{rds-ec2-x}. \texttt{x} is a number, which increases by 1 each time a new security group is automatically created.

**Tutorial: Connect an Amazon EC2 instance to an Amazon RDS database**

**Tutorial objective**

The objective of this tutorial is to learn how to configure a secure connection between an Amazon EC2 instance and an Amazon RDS database by using the AWS Management Console.

There are different options for configuring the connection. In this tutorial, we explore the following three options:

- **Option 1: Automatically connect your EC2 instance to your RDS database using the EC2 console (p. 878)**
  
  Use the automatic connection feature in the EC2 console to automatically configure the connection between your EC2 instance and your RDS database to allow traffic between the EC2 instance and the RDS database.

- **Option 2: Automatically connect your EC2 instance to your RDS database using the RDS console (p. 885)**
  
  Use the automatic connection feature in the RDS console to automatically configure the connection between your EC2 instance and your RDS database to allow traffic between the EC2 instance and the RDS database.

- **Option 3: Manually connect your EC2 instance to your RDS database by mimicking the automatic connection feature (p. 892)**
  
  Configure the connection between your EC2 instance to your RDS database by manually configuring and assigning the security groups to reproduce the configuration that is automatically created by the automatic connection feature in Option 1 and Option 2.

**Context**

As context for why you'd want to configure a connection between your EC2 instance and an RDS database, let's consider the following scenario: Your website presents a form to your users to fill in. You need to capture the form data in a database. You can host your website on an EC2 instance that's been configured as a web server, and you can capture the form data in an RDS database. The EC2 instance and the RDS database need to be connected to each other so that the form data can go from the EC2 instance to the RDS database. This tutorial explains how to configure that connection. Note that this is just one example of a use case for connecting an EC2 instance and an RDS database.
Architecture

The following diagram shows the resources that are created and the architectural configuration that results from completing all the steps in this tutorial.

The diagram illustrates the following resources that you'll create:

- You'll create an EC2 instance and an RDS database in the same AWS Region, VPC, and Availability Zone.
- You'll create the EC2 instance in a public subnet.
- You'll create the RDS database in a private subnet.

When you use the RDS console to create the RDS database and automatically connect the EC2 instance, the VPC, DB subnet group, and public access settings for the database are automatically selected. The RDS database is automatically created in a private subnet within the same VPC as the EC2 instance.

- Internet users can connect to the EC2 instance by using SSH or HTTP/HTTPS via an Internet gateway.
- Internet users cannot connect directly to the RDS database; only the EC2 instance is connected to the RDS database.

When you use the automatic connection feature to allow traffic between the EC2 instance and the RDS database, the following security groups are automatically created and added:

- Security group `ec2-rds-x` is created and added to the EC2 instance. It has one outbound rule that references the `rds-ec2-x` security group as its destination. This allows traffic from the EC2 instance to reach the RDS database with the `rds-ec2-x` security group.

- Security group `rds-ec2-x` is created and added to the RDS database. It has one inbound rule that references the `ec2-rds-x` security group as its source. This allows traffic from the EC2 instance with the `ec2-rds-x` security group to reach the RDS database.

By using separate security groups (one for the EC2 instance, and one for the RDS database), you have better control over the security of the instance and the database. If you were to use the same security group on both the instance and the database, and then modified the security group to suit, say, only the database, the modification would affect both the instance and the database. In other words, if you were to use one security group, you could unintentionally modify the security of a resource (either the instance or the database) because you'd forgotten that the security group was attached to it.
The security groups that are automatically created also respect least privilege as they only allow the mutual connection for this workload on the database port by creating a workload-specific security group pair.

**Considerations**

Consider the following when you complete the tasks in this tutorial:

- **Two consoles** – You will use the following two consoles for this tutorial:
  - Amazon EC2 console – You will use the EC2 console to launch instances, to automatically connect an EC2 instance to an RDS database, and for the manual option to configure the connection by creating the security groups.
  - Amazon RDS console – You will use the RDS console to create an RDS database and to automatically connect an EC2 instance to an RDS database.

- **One VPC** – To use the automatic connection feature, your EC2 instance and your RDS database must be in the same VPC.

  If you were to manually configure the connection between your EC2 instance and your RDS database, you could launch your EC2 instance in one VPC and your RDS database in another VPC; however, you’d need to set up additional routing and VPC configuration. This scenario is not covered in this tutorial.

- **One AWS Region** – The EC2 instance and RDS database must be located in the same Region.

- **Two security groups** – The connectivity between the EC2 instance and the RDS database is configured by two security groups—a security group for your EC2 instance, and a security group for your RDS database.

  When you use the automatic connection feature in the EC2 console or RDS console to configure the connectivity (Option 1 and Option 2 of this tutorial), the security groups are automatically created and assigned to the EC2 instance and RDS database.

  If you do not use the automatic connection feature, you’ll need to manually create and assign the security groups. You do this in Option 3 of this tutorial.

**Time to complete the tutorial**

30 minutes

You can complete the entire tutorial in one sitting, or you can complete it one task at a time.

**Costs**

By completing this tutorial, you might incur costs for the AWS resources that you create.

You can use Amazon EC2 under the free tier provided your AWS account is less than 12 months old and you configure your resources according to the free tier requirements.

If your EC2 instance and your RDS database are in different Availability Zones, you will incur data transfer fees. To avoid incurring these fees, the EC2 instance and the RDS database must be in the same Availability Zone. For information about data transfer fees, see Data Transfer on the Amazon EC2 On-Demand Pricing page.

To prevent incurring costs after you’ve completed the tutorial, make sure to delete the resources if they are no longer needed. For the steps to delete the resources, see Clean up (p. 899).
Option 1: Automatically connect your EC2 instance to your RDS database using the EC2 console

Objective

The objective of Option 1 is to explore the automatic connection feature in the EC2 console that automatically configures the connection between your EC2 instance and RDS database to allow traffic from the EC2 instance to the RDS database. In Option 3, you'll learn how to manually configure the connection.

Before you begin

You'll need the following to complete this tutorial:

- An RDS database that is in the same VPC as the EC2 instance. You can either use an existing RDS database or follow the steps in Task 1 to create a new RDS database.
- An EC2 instance that is in the same VPC as the RDS database. You can either use an existing EC2 instance or follow the steps in Task 2 to create a new EC2 instance.
- Permissions to call the following operations:
  - `ec2:AssociateRouteTable`
  - `ec2:AuthorizeSecurityGroupEgress`
  - `ec2:CreateRouteTable`
  - `ec2:CreateSecurityGroup`
  - `ec2:CreateSubnet`
  - `ec2:DescribeInstances`
  - `ec2:DescribeNetworkInterfaces`
  - `ec2:DescribeRouteTables`
  - `ec2:DescribeSecurityGroups`
  - `ec2:DescribeSubnets`
  - `ec2:ModifyNetworkInterfaceAttribute`
  - `ec2:RevokeSecurityGroupEgress`

Tasks to complete Option 1

- **Task 1: Create an RDS database – optional** (p. 878)
- **Task 2: Launch an EC2 instance – optional** (p. 880)
- **Task 3: Automatically connect your EC2 instance to your RDS database** (p. 882)
- **Task 4: Verify the connection configuration** (p. 884)

Task 1: Create an RDS database – optional

**Note**

Creating a Amazon RDS database is not the focus of this tutorial. If you already have an RDS database and would like to use it in this tutorial, you can skip this task.

**Task objective**

The objective of this task is to create an RDS database so that you can complete Task 3 where you configure the connection between your EC2 instance and your RDS database. If you have an RDS database that you can use, you can skip this task.

**Important**

If you use an existing RDS database, make sure that it is in the same VPC as your EC2 instance so that you can use the automatic connection feature.
Steps to create an RDS database

Use the following steps to create an RDS database.

To view an animation of these steps, see View an animation: Create an RDS database (p. 880).

RDS database configuration

The steps in this task configure the RDS database as follows:

- Engine type: MySQL
- Template: Free tier
- DB instance identifier: tutorial-database-1
- DB instance class: db.t3.micro

Important

In a production environment, you should configure your database to meet your specific needs.

To create a MySQL RDS database

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the Region selector (at top right), choose an AWS Region. The database and the EC2 instance must be in the same Region in order to use the automatic connection feature in the EC2 console.
3. On the dashboard, choose Create database.
4. Under Choose a database creation method, check that Standard create is selected. If you choose Easy create, the VPC selector is not available. You must ensure that your database is in the same VPC as your EC2 instance in order to use the automatic connection feature in the EC2 console.
5. Under Engine options, for Engine type, choose MySQL.
6. Under Templates, choose a sample template to meet your needs. For this tutorial, choose Free tier to create a database at no cost. However, note that the free tier is only available if your account is less than 12 months old. Other restrictions apply. You can read more by choosing the Info link in the Free tier box.
7. Under Settings, do the following:
   a. For DB instance identifier, enter a name for the database. For this tutorial, enter tutorial-database-1.
   b. For Master username, leave the default name, which is admin.
   c. For Master password, enter a password that you can remember for this tutorial, and then, for Confirm password, enter the password again.
8. Under Instance configuration, for DB instance class, leave the default, which is db.t3.micro. If your account is less than 12 months, you can use this database class for free. Other restrictions apply. For more information, see AWS Free Tier.
9. Under Connectivity, for Compute resource, choose Don't connect to an EC2 compute resource because you'll connect the EC2 instance and the RDS database later in Task 3.
   (Later, in Option 2 of this tutorial, you'll try out the automatic connection feature in the RDS console by choosing Connect to an EC2 compute resource.)
10. For Virtual private cloud (VPC), choose a VPC. The VPC must have a DB subnet group. To use the automatic connection feature, your EC2 instance and RDS database must be in the same VPC.
11. Keep all the default values for the other fields on this page.
12. Choose Create database.

On the Databases screen, the Status of the new database is Creating until the database is ready to use. When the status changes to Available, you can connect to the database. Depending on the
View an animation: Create an RDS database

You're now ready for Task 2: Launch an EC2 instance – optional (p. 880).

Task 2: Launch an EC2 instance – optional

Note
Launching an instance is not the focus of this tutorial. If you already have an Amazon EC2 instance and would like to use it in this tutorial, you can skip this task.

Task objective
The objective of this task is to launch an EC2 instance so that you can complete Task 3 where you configure the connection between your EC2 instance and your Amazon RDS database. If you have an EC2 instance that you can use, you can skip this task.

Important
If you use an existing EC2 instance, make sure that it is in the same VPC as your RDS database so that you can use the automatic connection feature.

Steps to launch an EC2 instance
Use the following steps to launch an EC2 instance for this tutorial.
To view an animation of these steps, see View an animation: Launch an EC2 instance (p. 882).

EC2 instance configuration

The steps in this task configure the EC2 instance as follows:

- Instance name: **tutorial-instance-1**
- AMI: Amazon Linux 2
- Instance type: t2.micro
- Auto-assign public IP: Enabled
- Security group with the following three rules:
  - Allow SSH from your IP address
  - Allow HTTPS traffic from anywhere
  - Allow HTTP traffic from anywhere

**Important**

In a production environment, you should configure your instance to meet your specific needs.

To launch an EC2 instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the Region selector (at top right), choose an AWS Region. The instance and the RDS database must be in the same Region in order to use the automatic connection feature in the EC2 console.
3. On the EC2 Dashboard, choose Launch instance.
4. Under Name and tags, for Name, enter a name to identify your instance. For this tutorial, name the instance **tutorial-instance-1**. While the instance name is not mandatory, when you select your instance in the EC2 console, the name will help you easily identify it.
5. Under Application and OS Images, choose an AMI that meets your web server needs. This tutorial uses Amazon Linux 2.
6. Under Instance type, for Instance type, select an instance type that meets your web server needs. This tutorial uses t2.micro.

  **Note**
  
  You can use Amazon EC2 under the Free tier provided your AWS account is less than 12 months old and you choose a t2.micro instance type (or t3.micro in Regions where t2.micro is not available).

7. Under Key pair (login), for Key pair name, choose your key pair.
8. Under Network settings, do the following:

   a. For Network and Subnet, if you haven’t made changes to your default VPC or subnets, you can keep the default settings.

   If you have made changes to your default VPC or subnets, check the following:

   i. The instance must be in the same VPC as the RDS database to use the automatic connection feature. By default you have only one VPC.

   ii. The VPC that you’re launching your instance into must have an internet gateway attached to it so that you can access your web server from the internet. Your default VPC is automatically set up with an internet gateway.

   iii. To ensure that your instance receives a public IP address, for Auto-assign public IP, check that Enable is selected. If Disable is selected, choose Edit (to the right of Network Settings), and then, for Auto-assign public IP, choose Enable.
b. To connect to your instance by using SSH, you need a security group rule that authorizes SSH (Linux) or RDP (Windows) traffic from your computer's public IPv4 address. By default, when you launch an instance, a new security group is created with a rule that allows inbound SSH traffic from anywhere.

To make sure that only your IP address can connect to your instance, under Firewall (security groups), from the drop-down list next to the Allow SSH traffic from check box, choose My IP.

c. To allow traffic from the internet to your instance, select the following check boxes:

- Allow HTTPS traffic from the internet
- Allow HTTP traffic from the internet

9. In the Summary panel, review your instance configuration and then choose Launch instance.

10. Keep the confirmation page open. You'll need it for the next task when you automatically connect your instance to your database.

If the instance fails to launch or the state immediately goes to terminated instead of running, see Troubleshoot instance launch issues (p. 2528).

For more information about launching an instance, see Launch an instance using the new launch instance wizard (p. 720).

View an animation: Launch an EC2 instance

You're now ready for Task 3: Automatically connect your EC2 instance to your RDS database (p. 882).

Task 3: Automatically connect your EC2 instance to your RDS database

Task objective

The objective of this task is to use the automatic connection feature in the EC2 console to automatically configure the connection between your EC2 instance and your RDS database.
Steps to connect your EC2 instance and RDS database

Use the following steps to connect your EC2 instance and RDS database using the automatic feature in the EC2 console.

To view an animation of these steps, see View an animation: Automatically connect a newly-launched EC2 instance to an RDS database (p. 883).

To automatically connect an EC2 instance to an RDS database using the EC2 console

1. On the instance launch confirmation page (it should be open from the previous task), choose Connect an RDS database.

   If you closed the confirmation page, follow these steps:
   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. In the navigation pane, choose Instances.
   c. Select the EC2 instance that you just created, and then choose Actions, Networking, Connect RDS database.

      If Connect RDS database is not available, check that the EC2 instance is in the Running state.

2. For Database role, choose Instance. Instance in this case refers to the database instance.

3. For RDS database, choose the RDS database that you created in Task 1.

   Note
   The EC2 instance and the RDS database must be in the same VPC in order to connect to each other.

4. Choose Connect.

View an animation: Automatically connect a newly-launched EC2 instance to an RDS database

You're now ready for Task 4: Verify the connection configuration (p. 884).
Task 4: Verify the connection configuration

Task objective

The objective of this task is to verify that the two security groups were created and assigned to the instance and database.

When you use the automatic connection feature in the EC2 console to configure the connectivity, the security groups are automatically created and assigned to the instance and database, as follows:

- Security group `rds-ec2-x` is created and added to the RDS database. It has one inbound rule that references the `ec2-rds-x` security group as its source. This allows traffic from the EC2 instance with the `ec2-rds-x` security group to reach the RDS database.
- Security group `ec2-rds-x` is created and added to the EC2 instance. It has one outbound rule that references the `rds-ec2-x` security group as its destination. This allows traffic from the EC2 instance to reach the RDS database with the `rds-ec2-x` security group.

Steps to verify the connection configuration

Use the following steps to verify the connection configuration.

To view an animation of these steps, see View an animation: Verify the connection configuration (p. 885).

To verify the connection configuration using the console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation page, choose Databases.
3. Choose the RDS database that you created for this tutorial.
4. On the Connectivity & security tab, under Security, VPC security groups, verify that a security group called `rds-ec2-x` is displayed.
5. Choose the `rds-ec2-x` security group. The Security Groups screen in the EC2 console opens.
6. Choose the `rds-ec2-x` security group to open it.
7. Choose the Inbound rules tab.
8. Verify that the following security group rule exists, as follows:
   - Type: MYSQL/Aurora
   - Port range: 3306
   - Source: `sg-0987654321example / ec2-rds-x` – This is the security group that is assigned to the EC2 instance that you verified in the preceding steps.
   - Description: Rule to allow connections from EC2 instances with `sg-1234567890example` attached
10. In the navigation pane, choose Instances.
11. Choose the EC2 instance that you selected to connect to the RDS database in the previous task, and choose the Security tab.
12. Under Security details, Security groups, verify that a security group called `ec2-rds-x` is in the list. `x` is a number.
13. Choose the `ec2-rds-x` security group to open it.
14. Choose the Outbound rules tab.
15. Verify that the following security group rule exists, as follows:
   - Type: MYSQL/Aurora
• Port range: **3306**
• Destination: *sg-1234567890example / rds-ec2-x*
• Description: **Rule to allow connections to database-tutorial from any instances this security group is attached to**

By verifying that these security groups and security group rules exist and that they are assigned to the RDS database and EC2 instance as described in this procedure, you can verify that the connection was automatically configured by using the automatic connection feature.

**View an animation: Verify the connection configuration**

---

You have completed Option 1 of this tutorial. You can now either complete Option 2, which teaches you how to use the RDS console to automatically connect an EC2 instance to an RDS database, or you can complete Option 3, which teaches you how to manually configure the security groups that were automatically created in Option 1.

**Option 2: Automatically connect your EC2 instance to your RDS database using the RDS console**

**Objective**

The objective of Option 2 is to explore the automatic connect feature in the RDS console that automatically configures the connection between your EC2 instance and RDS database to allow traffic from the EC2 instance to the RDS database. In Option 3, you’ll learn how to manually configure the connection.

**Before you begin**

You’ll need the following to complete this tutorial:
- An EC2 instance that is in the same VPC as the RDS database. You can either use an existing EC2 instance or follow the steps in Task 1 to create a new instance.

- Permissions to call the following operations:
  - ec2:AssociateRouteTable
  - ec2:AuthorizeSecurityGroupEgress
  - ec2:CreateRouteTable
  - ec2:CreateSecurityGroup
  - ec2:CreateSubnet
  - ec2:DescribeInstances
  - ec2:DescribeNetworkInterfaces
  - ec2:DescribeRouteTables
  - ec2:DescribeSecurityGroups
  - ec2:DescribeSubnets
  - ec2:ModifyNetworkInterfaceAttribute
  - ec2:RevokeSecurityGroupEgress

Tasks to complete Option 2

- Task 1: Launch an EC2 instance – optional (p. 886)
- Task 2: Create an RDS database and automatically connect it to your EC2 instance (p. 888)
- Task 3: Verify the connection configuration (p. 890)

Task 1: Launch an EC2 instance – optional

**Note**
Launching an instance is not the focus of this tutorial. If you already have an Amazon EC2 instance and would like to use it in this tutorial, you can skip this task.

**Task objective**

The objective of this task is to launch an EC2 instance so that you can complete Task 2 where you configure the connection between your EC2 instance and your Amazon RDS database. If you have an EC2 instance that you can use, you can skip this task.

**Steps to launch an EC2 instance**

Use the following steps to launch an EC2 instance for this tutorial.

To view an animation of these steps, see View an animation: Launch an EC2 instance (p. 888).

**EC2 instance configuration**

The steps in this task configure the EC2 instance as follows:

- Instance name: **tutorial-instance-2**
- AMI: Amazon Linux 2
- Instance type: t2.micro
- Auto-assign public IP: Enabled
- Security group with the following three rules:
  - Allow SSH from your IP address
  - Allow HTTPS traffic from anywhere
• Allow HTTP traffic from anywhere

Important
In a production environment, you should configure your instance to meet your specific needs.

To launch an EC2 instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the EC2 Dashboard, choose Launch instance.
3. Under Name and tags, for Name, enter a name to identify your instance. For this tutorial, name the instance tutorial-instance-2. While the instance name is not mandatory, when you select your instance in the RDS console, the name will help you easily identify it.
4. Under Application and OS Images, choose an AMI that meets your web server needs. This tutorial uses Amazon Linux.
5. Under Instance type, for Instance type, select an instance type that meets your web server needs. This tutorial uses t2.micro.
   Note
   You can use Amazon EC2 under the Free tier provided your AWS account is less than 12 months old and you choose a t2.micro instance type (or t3.micro in Regions where t2.micro is not available).
6. Under Key pair (login), for Key pair name, choose your key pair.
7. Under Network settings, do the following:
   a. For Network and Subnet, if you haven’t made changes to your default VPC or subnets, you can keep the default settings.
      If you have made changes to your default VPC or subnets, check the following:
      i. The instance must be in the same VPC as the RDS database to use the automatic connection configuration. By default you have only one VPC.
      ii. The VPC that you’re launching your instance into must have an internet gateway attached to it so that you can access your web server from the internet. Your default VPC is automatically set up with an internet gateway.
      iii. To ensure that your instance receives a public IP address, for Auto-assign public IP, check that Enable is selected. If Disable is selected, choose Edit (to the right of Network Settings), and then, for Auto-assign public IP, choose Enable.
   b. To connect to your instance by using SSH, you need a security group rule that authorizes SSH (Linux) or RDP (Windows) traffic from your computer’s public IPv4 address. By default, when you launch an instance, a new security group is created with a rule that allows inbound SSH traffic from anywhere.
      To make sure that only your IP address can connect to your instance, under Firewall (security groups), from the drop-down list next to the Allow SSH traffic from check box, choose My IP.
   c. To allow traffic from the internet to your instance, select the following check boxes:
      • Allow HTTPS traffic from the internet
      • Allow HTTP traffic from the internet
8. In the Summary panel, review your instance configuration and then choose Launch instance.
9. Choose View all instances to close the confirmation page and return to the console. Your instance will first be in a pending state, and will then go into the running state.

If the instance fails to launch or the state immediately goes to terminated instead of running, see Troubleshoot instance launch issues (p. 2528).
For more information about launching an instance, see Launch an instance using the new launch instance wizard (p. 720).

View an animation: Launch an EC2 instance

You're now ready for Task 2: Create an RDS database and automatically connect it to your EC2 instance (p. 888).

Task 2: Create an RDS database and automatically connect it to your EC2 instance

Task objective

The objective of this task is to create an RDS database and use the automatic connection feature in the RDS console to automatically configure the connection between your EC2 instance and your RDS database.

Steps to create an RDS database

Use the following steps to create an RDS database and connect it to your EC2 instance using the automatic feature in the RDS console.

To view an animation of these steps, see View an animation: Create an RDS database and automatically connect it to an EC2 instance (p. 890).

DB instance configuration

The steps in this task configure the DB instance as follows:

- Engine type: MySQL
- Template: Free tier
- DB instance identifier: tutorial-database
To create an RDS database and automatically connect it to an EC2 instance

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the Region selector (at top right), choose the AWS Region in which you created the EC2 instance. The EC2 instance and the RDS database must be in the same Region.
3. On the dashboard, choose Create database.
4. Under Choose a database creation method, check that Standard create is selected. If you choose Easy create, the automatic connection feature is not available.
5. Under Engine options, for Engine type, choose MySQL.
6. Under Templates, choose a sample template to meet your needs. For this tutorial, choose Free tier to create an RDS database at no cost. However, note that the free tier is only available if your account is less than 12 months old. Other restrictions apply. You can read more by choosing the Info link in the Free tier box.
7. Under Settings, do the following:
   a. For DB instance identifier, enter a name for the database. For this tutorial, enter tutorial-database.
   b. For Master username, leave the default name, which is admin.
   c. For Master password, enter a password that you can remember for this tutorial, and then, for Confirm password, enter the password again.
8. Under Instance configuration, for DB instance class, leave the default, which is db.t3.micro. If your account is less than 12 months, you can use this instance for free. Other restrictions apply. For more information, see AWS Free Tier.
9. Under Connectivity, for Compute resource, choose Connect to an EC2 compute resource. This is the automatic connection feature in the RDS console.
10. For EC2 instance, choose the EC2 instance that you want to connect to. For the purposes of this tutorial, you can either choose the instance that you created in the previous task, which you named tutorial-instance, or choose another existing instance. If you don't see your instance in the list, choose the refresh icon to the right of Connectivity.

When you use the automatic connection feature, a security group is added to this EC2 instance, and another security group is added to the RDS database. The security groups are automatically configured to allow traffic between the EC2 instance and the RDS database. In the next task, you'll verify that the security groups were created and assigned to the EC2 instance and RDS database.
11. Choose Create database.

On the Databases screen, the Status of the new database is Creating until the database is ready to use. When the status changes to Available, you can connect to the database. Depending on the database class and the amount of storage, it can take up to 20 minutes before the new database is available.

To learn more, see Configure automatic network connectivity with an EC2 instance in the Amazon RDS User Guide.
Task 3: Verify the connection configuration

Task objective

The objective of this task is to verify that the two security groups were created and assigned to the instance and the database.

When you use the automatic connection feature in the RDS console to configure the connectivity, the security groups are automatically created and assigned to the instance and database, as follows:

- Security group rds-ec2-x is created and added to the RDS database. It has one inbound rule that references the ec2-rds-x security group as its source. This allows traffic from the EC2 instance with the ec2-rds-x security group to reach the RDS database.
- Security group ec2-rds-x is created and added to the EC2 instance. It has one outbound rule that references the rds-ec2-x security group as its destination. This allows traffic from the EC2 instance to reach the RDS database with the rds-ec2-x security group.
Steps to verify the connection configuration

Use the following steps to verify the connection configuration.

To view an animation of these steps, see View an animation: Verify the connection configuration (p. 892).

To verify the connection configuration using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Choose the EC2 instance that you selected to connect to the RDS database in the previous task, and choose the Security tab.
4. Under Security details, Security groups, verify that a security group called ec2-rds-x is in the list. x is a number.
5. Choose the ec2-rds-x security group to open it.
6. Choose the Outbound rules tab.
7. Verify that the following security group rule exists, as follows:
   - Type: MYSQL/Aurora
   - Port range: 3306
   - Destination: sg-1234567890example / rds-ec2-x
   - Description: Rule to allow connections to database-tutorial from any instances this security group is attached to
8. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
9. In the navigation pane, choose Databases.
10. Choose the RDS database that you created for this tutorial.
11. On the Connectivity & security tab, under Security, VPC security groups, verify that a security group called rds-ec2-x is displayed.
13. Choose the rds-ec2-x security group open it.
15. Verify that the following security group rule exists, as follows:
   - Type: MYSQL/Aurora
   - Port range: 3306
   - Source: sg-0987654321example / ec2-rds-x – This is the security group that is assigned to the EC2 instance that you verified in the preceding steps.
   - Description: Rule to allow connections from EC2 instances with sg-1234567890example attached

By verifying that these security groups and security group rules exist and that they are assigned to the EC2 instance and RDS database as described in this procedure, you can verify that the connection was automatically configured by using the automatic connection feature.
You have completed Option 2 of this tutorial. You can now either complete Option 3, which teaches you how to manually configure the security groups that were automatically created in Option 2.

**Option 3: Manually connect your EC2 instance to your RDS database by mimicking the automatic connection feature**

**Objective**

The objective of Option 3 is to learn how to manually configure the connection between an EC2 instance and an RDS database by manually reproducing the configuration of the automatic connection feature.

**Before you begin**

You'll need the following to complete this tutorial:

- An EC2 instance that is in the same VPC as the RDS database. You can either use an existing EC2 instance or follow the steps in Task 1 to create a new instance.
- An RDS database that is in the same VPC as the EC2 instance. You can either use an existing RDS database or follow the steps in Task 2 to create a new database.
- Permissions to call the following operations. If you have completed Option 1 of this tutorial, you already have these permissions.
  - `ec2:AssociateRouteTable`
  - `ec2:AuthorizeSecurityGroupEgress`
  - `ec2:CreateRouteTable`
  - `ec2:CreateSecurityGroup`
  - `ec2:CreateSubnet`
Tasks to complete Option 3

- Task 1: Launch an EC2 instance – optional (p. 893)
- Task 2: Create an RDS database – optional (p. 895)
- Task 3: Manually connect your EC2 instance to your RDS database by creating security groups and assigning them to the instances (p. 897)

Task 1: Launch an EC2 instance – optional

Note
Launching an instance is not the focus of this tutorial. If you already have an Amazon EC2 instance and would like to use it in this tutorial, you can skip this task.

Task objective

The objective of this task is to launch an EC2 instance so that you can complete Task 3 where you configure the connection between your EC2 instance and your Amazon RDS database.

Steps to launch an EC2 instance

Use the following steps to launch an EC2 instance for this tutorial.

To view an animation of these steps, see View an animation: Launch an EC2 instance (p. 895).

EC2 instance configuration

The steps in this task configure the EC2 instance as follows:

- Instance name: tutorial-instance
- AMI: Amazon Linux 2
- Instance type: t2.micro
- Auto-assign public IP: Enabled
- Security group with the following three rules:
  - Allow SSH from your IP address
  - Allow HTTPS traffic from anywhere
  - Allow HTTP traffic from anywhere

Important
In a production environment, you should configure your instance to meet your specific needs.

To launch an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the EC2 Dashboard, choose Launch instance.

3. Under Name and tags, for Name, enter a name to identify your instance. For this tutorial, name the instance tutorial-instance-manual-1. While the instance name is not mandatory, the name will help you easily identify it.

4. Under Application and OS Images, choose an AMI that meets your web server needs. This tutorial uses Amazon Linux.

5. Under Instance type, for Instance type, select an instance type that meets your web server needs. This tutorial uses t2.micro.

   **Note**
   You can use Amazon EC2 under the Free tier provided your AWS account is less than 12 months old and you choose a t2.micro instance type (or t3.micro in Regions where t2.micro is not available).

6. Under Key pair (login), for Key pair name, choose your key pair.

7. Under Network settings, do the following:
   a. For Network and Subnet, if you haven’t made changes to your default VPC or subnets, you can keep the default settings.

   If you have made changes to your default VPC or subnets, check the following:
   i. The instance must be in the same VPC as the RDS database. By default you have only one VPC.
   ii. The VPC that you’re launching your instance into must have an internet gateway attached to it so that you can access your web server from the internet. Your default VPC is automatically set up with an internet gateway.
   iii. To ensure that your instance receives a public IP address, for Auto-assign public IP, check that Enable is selected. If Disable is selected, choose Edit (to the right of Network Settings), and then, for Auto-assign public IP, choose Enable.

   b. To connect to your instance by using SSH, you need a security group rule that authorizes SSH (Linux) or RDP (Windows) traffic from your computer’s public IPv4 address. By default, when you launch an instance, a new security group is created with a rule that allows inbound SSH traffic from anywhere.

   To make sure that only your IP address can connect to your instance, under Firewall (security groups), from the drop-down list next to the Allow SSH traffic from check box, choose My IP.

   c. To allow traffic from the internet to your instance, select the following check boxes:
      - Allow HTTPs traffic from the internet
      - Allow HTTP traffic from the internet

8. In the Summary panel, review your instance configuration and then choose Launch instance.

9. Choose View all instances to close the confirmation page and return to the console. Your instance will first be in a pending state, and will then go into the running state.

   If the instance fails to launch or the state immediately goes to terminated instead of running, see Troubleshoot instance launch issues (p. 2528).

For more information about launching an instance, see Launch an instance using the new launch instance wizard (p. 720).
You are now ready for Task 2: Create an RDS database – optional (p. 895).

Task 2: Create an RDS database – optional

Note
Creating an RDS database is not the focus of this part of the tutorial. If you already have an RDS database and would like to use it for this tutorial, you can skip this task.

Task objective
The objective of this task is to create an RDS database. You’ll use this instance in Task 3 when you connect it to your EC2 instance.

Steps to create an RDS database
Use the following steps to create an RDS database for Option 3 of this tutorial.

To view an animation of these steps, see View an animation: Create a DB instance (p. 897).

RDS database configuration
The steps in this task configure the RDS database as follows:

- Engine type: MySQL
- Template: Free tier
- DB instance identifier: tutorial-database-manual
- DB instance class: db.t3.micro

Important
In a production environment, you should configure your instance to meet your specific needs.
To create a MySQL DB instance

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. From the Region selector (at top right), choose the AWS Region in which you created the EC2 instance. The EC2 instance and the DB instance must be in the same Region.
3. On the dashboard, choose Create database.
4. Under Choose a database creation method, choose Easy create. When you choose this option, the automatic connection feature to automatically configure the connection is not available.
5. Under Engine options, for Engine type, choose MySQL.
6. For DB instance size, choose Free tier.
7. For DB instance identifier enter a name for the RDS database. For this tutorial, enter tutorial-database-manual.
8. For Master username, leave the default name, which is admin.
9. For Master password, enter a password that you can remember for this tutorial, and then, for Confirm password, enter the password again.
10. Choose Create database.

On the Databases screen, the Status of the new DB instance is Creating until the DB instance is ready to use. When the status changes to Available, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.
You are now ready for **Task 3: Manually connect your EC2 instance to your RDS database by creating security groups and assigning them to the instances** (p. 897).

**Task 3: Manually connect your EC2 instance to your RDS database by creating security groups and assigning them to the instances**

**Task objective**

The objective of this task is to reproduce the connection configuration of the automatic connection feature by performing the following manually: You create two new security groups, and then add a security group each to the EC2 instance and the RDS database.

**Steps to create new security groups and add them to the instances**

Use the following steps to connect an EC2 instance to your RDS database by creating two new security groups. You then add a security group each to the EC2 instance and the RDS database.

**To create two new security groups and assign one each to the EC2 instance and RDS database**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. First create the security group to add to the EC2 instance, as follows:
   a. In the navigation pane, choose **Security Groups**.
   b. Choose **Create security group**.
c. For **Security group name**, enter a descriptive name for the security group. For this tutorial, enter `ec2-rds-manual-configuration`.

d. For **Description**, enter a brief description. For this tutorial, enter **EC2 instance security group to allow EC2 instance to securely connect to RDS database**.

e. Choose **Create security group**. You'll come back to this security group to add an outbound rule after you've created the RDS database security group.

3. Now, create the security group to add to the RDS database, as follows:

   a. In the navigation pane, choose **Security Groups**.
      
      b. Choose **Create security group**.
      
      c. For **Security group name**, enter a descriptive name for the security group. For this tutorial, enter `rds-ec2-manual-configuration`.
      
      d. For **Description**, enter a brief description. For this tutorial, enter **RDS database security group to allow EC2 instance to securely connect to RDS database**.
      
      e. Under **Inbound rules**, choose **Add rule**, and do the following:
         
         i. For **Type**, choose **MYSQL/Aurora**.
         
         ii. For **Source**, choose the EC2 instance security group `ec2-rds-manual-configuration` that you created in Step 2 of this procedure.
         
     f. Choose **Create security group**.

4. Edit the EC2 instance security group to add an outbound rule, as follows:

   a. In the navigation pane, choose **Security Groups**.
      
      b. Select the EC2 instance security group (you named it `ec2-rds-manual-configuration`), and choose the **Outbound rules** tab.
      
      c. Choose **Edit outbound rules**.
      
      d. Choose **Add rule**, and do the following:
         
         i. For **Type**, choose **MYSQL/Aurora**.
         
         ii. For **Source**, choose the RDS database security group `rds-ec2-manual-configuration` that you created in Step 3 of this procedure.
         
         iii. Choose **Save rules**.

5. Add the EC2 instance security group to the EC2 instance as follows:

   a. In the navigation pane, choose **Instances**.
      
      b. Select your EC2 instance, and choose **Actions**, **Security**, **Change security groups**.
      
      c. Under **Associated security groups**, choose the **Select security groups** field, choose `ec2-rds-manual-configuration` that you created earlier, and then choose **Add security group**.
      
      d. Choose **Save**.

6. Add the RDS database security group to the RDS database as follows:

   a. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
      
   b. In the navigation pane, choose **Databases** and select your database.
      
   c. Choose **Modify**.
      
   d. Under **Connectivity**, for **Security group**, choose `rds-ec2-manual-configuration` that you created earlier, and then choose **Continue**.
      
   e. Under **Scheduling of modifications**, choose **Apply immediately**.
      
   f. Choose **Modify DB instance**.

You have now completed the manual steps that mimic the automatic steps that occur when you use the automatic connection feature.
You have completed Option 3 of this tutorial. If you've completed Options 1, 2, and 3, and you no longer need the resources that were created in this tutorial, you should delete them to prevent incurring unnecessary costs. For more information, see Clean up (p. 899).

**Clean up**

Now that you have completed the tutorial, it is good practice to clean up (delete) any resources you no longer want to use. Cleaning up AWS resources prevents your account from incurring any further charges.

**Topics**
- Terminate your EC2 instance (p. 899)
- Delete your RDS database (p. 899)

**Terminate your EC2 instance**

If you launched an EC2 instance specifically for this tutorial, you can terminate it to stop incurring any charges associated with it.

**To terminate an instance using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance that you created for this tutorial, and choose Instance state, Terminate instance.
4. Choose Terminate when prompted for confirmation.

**Delete your RDS database**

If you created an RDS database specifically for this tutorial, you can delete it to stop incurring any charges associated with it.

**To delete an RDS database using the console**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Select the RDS database that you created for this tutorial, and choose Actions, Delete.
4. Enter delete me in the box, and then choose Delete.

**Configure your Amazon Linux instance**

After you have successfully launched and logged into your Amazon Linux instance, you can make changes to it. There are many different ways you can configure an instance to meet the needs of a specific application. The following are some common tasks to help get you started.

**Contents**
- Common configuration scenarios (p. 900)
- Manage software on your Amazon Linux instance (p. 900)
- Manage users on your Linux instance (p. 907)
- Processor state control for your EC2 instance (p. 909)
Common configuration scenarios

The base distribution of Amazon Linux contains the software packages and utilities that are required for basic server operations. However, many more software packages are available in various software repositories, and even more packages are available for you to build from source code. For more information on installing and building software from these locations, see Manage software on your Amazon Linux instance.

Amazon Linux instances come pre-configured with an ec2-user, but you may want to add other users that do not have super-user privileges. For more information on adding and removing users, see Manage users on your Linux instance.

The default time configuration for Amazon Linux instances uses Amazon Time Sync Service to set the system time on an instance. The default time zone is UTC. For more information on setting the time zone for an instance or using your own time server, see Set the time for your Linux instance.

If you have your own network with a domain name registered to it, you can change the hostname of an instance to identify itself as part of that domain. You can also change the system prompt to show a more meaningful name without changing the hostname settings. For more information, see Change the hostname of your Amazon Linux instance. You can configure an instance to use a dynamic DNS service provider. For more information, see Set up dynamic DNS on your Amazon Linux instance.

When you launch an instance in Amazon EC2, you have the option of passing user data to the instance that can be used to perform common configuration tasks and even run scripts after the instance starts. You can pass two types of user data to Amazon EC2: cloud-init directives and shell scripts. For more information, see Run commands on your Linux instance at launch.

Manage software on your Amazon Linux instance

The base distribution of Amazon Linux contains the software packages and utilities that are required for basic server operations.

This information applies to Amazon Linux 2 and Amazon Linux. For information about Amazon Linux 2023, see Managing packages and operating system updates in the Amazon Linux 2023 User Guide.

Note
Standard support for the Amazon Linux AMI ended on December 31, 2020. The Amazon Linux AMI is now in a maintenance support phase which ends December 31, 2023. For more information, see the blog post Update on Amazon Linux AMI end-of-life.

Contents

• Update instance software on your Amazon Linux instance (p. 901)
Manage software

- Add repositories on an Amazon Linux instance (p. 903)
- Find and install software packages on an Amazon Linux instance (p. 904)
- Prepare to compile software on an Amazon Linux instance (p. 906)

It is important to keep software up to date. Many packages in a Linux distribution are updated frequently to fix bugs, add features, and protect against security exploits. For more information, see Update instance software on your Amazon Linux instance (p. 901).

By default, Amazon Linux instances launch with the following repositories enabled:

- Amazon Linux 2: amzn2-core and amzn2extra-docker
- Amazon Linux AMI: amzn-main and amzn-updates

While there are many packages available in these repositories that are updated by Amazon Web Services, there might be a package that you want to install that is contained in another repository. For more information, see Add repositories on an Amazon Linux instance (p. 903). For help finding and installing packages in enabled repositories, see Find and install software packages on an Amazon Linux instance (p. 904).

Not all software is available in software packages stored in repositories; some software must be compiled on an instance from its source code. For more information, see Prepare to compile software on an Amazon Linux instance (p. 906).

Amazon Linux instances manage their software using the yum package manager. The yum package manager can install, remove, and update software, as well as manage all of the dependencies for each package. Debian-based Linux distributions, like Ubuntu, use the apt-get command and dpkg package manager, so the yum examples in the following sections do not work for those distributions.

**Update instance software on your Amazon Linux instance**

It is important to keep software up to date. Packages in a Linux distribution are updated frequently to fix bugs, add features, and protect against security exploits. When you first launch and connect to an Amazon Linux instance, you might see a message asking you to update software packages for security purposes. This section shows how to update an entire system, or just a single package.

This information applies to Amazon Linux 2 and Amazon Linux. For information about Amazon Linux 2023, see Managing packages and operating system updates in the Amazon Linux 2023 User Guide.

*Note*
Standard support for the Amazon Linux AMI ended on December 31, 2020. The Amazon Linux AMI is now in a maintenance support phase which ends December 31, 2023. For more information, see the blog post Update on Amazon Linux AMI end-of-life.

For information about changes and updates to Amazon Linux 2, see Amazon Linux 2 release notes.

For information about changes and updates to Amazon Linux 2023, see Amazon Linux 2023 release notes.

*Important*
This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

*Important*
If you launched an EC2 instance that uses an Amazon Linux 2 AMI into an IPv6-only subnet, you must connect to the instance and run sudo amazon-linux-https disable. This lets your AL2 instance connect to the yum repository in S3 over IPv6 using the http patch service.
To update all packages on an Amazon Linux instance

1. (Optional) Start a screen session in your shell window. Sometimes you might experience a network interruption that can disconnect the SSH connection to your instance. If this happens during a long software update, it can leave the instance in a recoverable, although confused state. A screen session allows you to continue running the update even if your connection is interrupted, and you can reconnect to the session later without problems.

   a. Execute the `screen` command to begin the session.

   ```bash
   [ec2-user ~]$ screen
   ```

   b. If your session is disconnected, log back into your instance and list the available screens.

   ```bash
   [ec2-user ~]$ screen -ls
   There is a screen on:
   17793 pts-0.ip-12-34-56-78 (Detached)
   1 Socket in /var/run/screen/S-ec2-user.
   ```

   c. Reconnect to the screen using the `screen -r` command and the process ID from the previous command.

   ```bash
   [ec2-user ~]$ screen -r 17793
   ```

   d. When you are finished using screen, use the `exit` command to close the session.

   ```bash
   [ec2-user ~]$ exit
   [screen is terminating]
   ```

2. Run the `yum update` command. Optionally, you can add the `--security` flag to apply only security updates.

   ```bash
   [ec2-user ~]$ sudo yum update
   ```

3. Review the packages listed, enter `y`, and press Enter to accept the updates. Updating all of the packages on a system can take several minutes. The `yum` output shows the status of the update while it is running.

4. (Optional) Reboot your instance to ensure that you are using the latest packages and libraries from your update; kernel updates are not loaded until a reboot occurs. Updates to any glibc libraries should also be followed by a reboot. For updates to packages that control services, it might be sufficient to restart the services to pick up the updates, but a system reboot ensures that all previous package and library updates are complete.

To update a single package on an Amazon Linux instance

Use this procedure to update a single package (and its dependencies) and not the entire system.

1. Run the `yum update` command with the name of the package to update.

   ```bash
   [ec2-user ~]$ sudo yum update openssl
   ```

2. Review the package information listed, enter `y`, and press Enter to accept the update or updates. Sometimes there will be more than one package listed if there are package dependencies that must be resolved. The `yum` output shows the status of the update while it is running.

3. (Optional) Reboot your instance to ensure that you are using the latest packages and libraries from your update; kernel updates are not loaded until a reboot occurs. Updates to any glibc libraries should also be followed by a reboot. For updates to packages that control services, it might be
sufficient to restart the services to pick up the updates, but a system reboot ensures that all previous package and library updates are complete.

Add repositories on an Amazon Linux instance

This information applies to Amazon Linux 2 and Amazon Linux. For information about Amazon Linux 2023, see Using Deterministic upgrades through versioned repository in the Amazon Linux 2023 User Guide.

**Note**
Standard support for the Amazon Linux AMI ended on December 31, 2020. The Amazon Linux AMI is now in a maintenance support phase which ends December 31, 2023. For more information, see the blog post Update on Amazon Linux AMI end-of-life.

By default, Amazon Linux instances launch with the following repositories enabled:

- Amazon Linux 2: amzn2-core and amzn2extra-docker
- Amazon Linux AMI: amzn-main and amzn-updates

While there are many packages available in these repositories that are updated by Amazon Web Services, there might be a package that you want to install that is contained in another repository.

**Important**
This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

To install a package from a different repository with **yum**, you need to add the repository information to the /etc/yum.conf file or to its own `repository.repo` file in the /etc/yum.repos.d directory. You can do this manually, but most yum repositories provide their own `repository.repo` file at their repository URL.

To determine what yum repositories are already installed

- List the installed yum repositories with the following command:

  ```bash
  [ec2-user ~]$ yum repolist all
  ```

  The resulting output lists the installed repositories and reports the status of each. Enabled repositories display the number of packages they contain.

To add a yum repository to /etc/yum.repos.d

1. Find the location of the `.repo` file. This will vary depending on the repository you are adding. In this example, the `.repo` file is at https://www.example.com/repository.repo.
2. Add the repository with the `yum-config-manager` command.

  ```bash
  [ec2-user ~]$ sudo yum-config-manager --add-repo https://www.example.com/repository.repo
  ```

  Loaded plugins: priorities, update-motd, upgrade-helper
  adding repo from: https://www.example.com/repository.repo
  grabbing file https://www.example.com/repository.repo to /etc/yum.repos.d/repository.repo
  repository.repo                                      | 4.0 kB     00:00
  repo saved to /etc/yum.repos.d/repository.repo
After you install a repository, you must enable it as described in the next procedure.

**To enable a yum repository in */etc/yum.repos.d*  

- Use the `yum-config-manager` command with the `--enable` flag. The following command enables the Extra Packages for Enterprise Linux (EPEL) repository from the Fedora project. By default, this repository is present in */etc/yum.repos.d* on Amazon Linux AMI instances, but it is not enabled.

```bash
[sudo-user ~]$ sudo yum-config-manager --enable epel
```

**Note**  
To enable the EPEL repository on Amazon Linux 2, use the following command:

```bash
```

For information on enabling the EPEL repository on other distributions, such as Red Hat and CentOS, see the EPEL documentation at [https://fedoraproject.org/wiki/EPEL](https://fedoraproject.org/wiki/EPEL).

### Find and install software packages on an Amazon Linux instance

You can use a package management tool to find and install software packages. In Amazon Linux 2 and Amazon Linux, the default software package management tool is YUM. In Amazon Linux 2023, the default software package management tool is DNF. For more information about Amazon Linux 2023, see the [Package management tool](#) in the [Amazon Linux 2023 User Guide](#).

**Note**  
Standard support for the Amazon Linux AMI ended on December 31, 2020. The Amazon Linux AMI is now in a maintenance support phase which ends December 31, 2023. For more information, see the blog post [Update on Amazon Linux AMI end-of-life](#).

### Find software packages on an Amazon Linux instance

You can use the `yum search` command to search the descriptions of packages that are available in your configured repositories. This is especially helpful if you don't know the exact name of the package you want to install. Simply append the keyword search to the command; for multiple word searches, wrap the search query with quotation marks.

**Important**  
This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

```bash
[ec2-user ~]$ yum search "find"
```

The following is example output for Amazon Linux 2.

```
Loaded plugins: extras_suggestions, langpacks, priorities, update-motd
N/S matched: find
findutils.x86_64 : The GNU versions of find utilities (find and xargs)
gedit-plugin-findinfiles.x86_64 : gedit findinfiles plugin
ocaml-findlib-devel.x86_64 : Development files for ocaml-findlib
perl-File-Find-Rule.noarch : Perl module implementing an alternative interface to find
robotfindskitten.x86_64 : A game/zen simulation. You are robot. Your job is to find kitten.
mlocate.x86_64 : An utility for finding files by name
```
ocaml-findlib.x86_64 : Objective CAML package manager and build helper
perl-Devel-Cycle.noarch : Find memory cycles in objects
perl-Devel-EnforceEncapsulation.noarch : Find access violations to blessed objects
perl-File-Find-Rule-Perl.noarch : Common rules for searching for Perl things
perl-File-HomeDir.noarch : Find your home and other directories on any platform
perl-IPC-Cmd.noarch : Finding and running system commands made easy
perl-Perl-MinimumVersion.noarch : Find a minimum required version of perl for Perl code
texlive-xesearch.noarch : A string finder for XeTeX
valgrind.x86_64 : Tool for finding memory management bugs in programs
valgrind.i686 : Tool for finding memory management bugs in programs

The following is example output for Amazon Linux.

Loaded plugins: priorities, security, update-motd, upgrade-helper
N/S Matched: find
findutils.x86_64 : The GNU versions of find utilities (find and xargs)
perl-File-Find-Rule.noarch : Perl module implementing an alternative interface to
File::Find
perl-Module-Find.noarch : Find and use installed modules in a (sub)category
libpuzzle.i686 : Library to quickly find visually similar images (gif, png, jpg)
libpuzzle.x86_64 : Library to quickly find visually similar images (gif, png, jpg)
mlocate.x86_64 : An utility for finding files by name

Multiple word search queries in quotation marks only return results that match the exact query. If you
don't see the expected package, simplify your search to one keyword and then scan the results. You can
also try keyword synonyms to broaden your search.

For more information about packages for Amazon Linux 2 and Amazon Linux, see the following:

- Extras library (Amazon Linux 2) (p. 257)
- Package repository (p. 255)

Install software packages on an Amazon Linux instance

In Amazon Linux 2 and Amazon Linux, the yum package management tool searches all of your enabled
repositories for different software packages and handles any dependencies in the software installation
process. For information about installing software packages in Amazon Linux 2023, see Managing
packages and operating system updates in the Amazon Linux 2023 User Guide.

To install a package from a repository

Use the yum install package command, replacing package with the name of the software to install. For
example, to install the links text-based web browser, enter the following command.

[ec2-user ~]$ sudo yum install links

To install RPM package files that you have downloaded

You can also use yum install to install RPM package files that you have downloaded from the internet.
To do this, append the path name of an RPM file to the installation command instead of a repository
package name.

[ec2-user ~]$ sudo yum install my-package.rpm

To list installed packages

To view a list of installed packages on your instance, use the following command.
Prepare to compile software on an Amazon Linux instance

Open-source software is available on the internet that has not been pre-compiled and made available for download from a package repository. You might eventually discover a software package that you need to compile yourself, from its source code. For your system to be able to compile software in Amazon Linux 2 and Amazon Linux, you need to install several development tools, such as `make`, `gcc`, and `autoconf`.

**Note**
Standard support for the Amazon Linux AMI ended on December 31, 2020. The Amazon Linux AMI is now in a maintenance support phase which ends December 31, 2023. For more information, see the blog post [Update on Amazon Linux AMI end-of-life](https://aws.amazon.com/).  

**Important**
This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

Because software compilation is not a task that every Amazon EC2 instance requires, these tools are not installed by default, but they are available in a package group called "Development Tools" that is easily added to an instance with the `yum groupinstall` command.

```
[ec2-user ~]$ sudo yum groupinstall "Development Tools"
```

Software source code packages are often available for download (from websites such as [https://github.com/](https://github.com/) and [http://sourceforge.net/](http://sourceforge.net/)) as a compressed archive file, called a tarball. These tarballs will usually have the `.tar.gz` file extension. You can decompress these archives with the `tar` command.

```
[ec2-user ~]$ tar -xzf software.tar.gz
```

After you have decompressed and unarchived the source code package, you should look for a README or INSTALL file in the source code directory that can provide you with further instructions for compiling and installing the source code.

### To retrieve source code for Amazon Linux packages

Amazon Web Services provides the source code for maintained packages. You can download the source code for any installed packages with the `yumdownloader --source` command.

- Run the `yumdownloader --source package` command to download the source code for `package`. For example, to download the source code for the htop package, enter the following command.

```
[ec2-user ~]$ yumdownloader --source htop
```

The location of the source RPM is in the directory from which you ran the command.
Manage users on your Linux instance

Each Linux instance launches with a default Linux system user. You can add users to your instance and delete users.

For the default user, the **default user name** is determined by the AMI that was specified when you launched the instance.

**Note**

By default, password authentication and root login are disabled, and sudo is enabled. To log in to your instance, you must use a key pair. For more information about logging in, see [Connect to your Linux instance](#). You can allow password authentication and root login for your instance. For more information, see the documentation for your operating system.

**Note**

Linux system users should not be confused with IAM users. For more information, see [IAM users](#) in the [*IAM User Guide*](#).

**Contents**

- Default user names (p. 907)
- Considerations (p. 907)
- Create a user (p. 908)
- Remove a user (p. 909)

### Default user names

The default user name for your EC2 instance is determined by the AMI that was specified when you launched the instance.

The default user names are:

- For Amazon Linux 2023, Amazon Linux 2, or the Amazon Linux AMI, the user name is `ec2-user`.
- For a CentOS AMI, the user name is `centos` or `ec2-user`.
- For a Debian AMI, the user name is `admin`.
- For a Fedora AMI, the user name is `fedora` or `ec2-user`.
- For a RHEL AMI, the user name is `ec2-user` or `root`.
- For a SUSE AMI, the user name is `ec2-user` or `root`.
- For an Ubuntu AMI, the user name is `ubuntu`.
- For an Oracle AMI, the user name is `ec2-user`.
- For a Bitnami AMI, the user name is `bitnami`.
- Otherwise, check with the AMI provider.

### Considerations

Using the default user is adequate for many applications. However, you may choose to add users so that individuals can have their own files and workspaces. Furthermore, creating users for new users is much more secure than granting multiple (possibly inexperienced) users access to the default user, because the default user can cause a lot of damage to a system when used improperly. For more information, see *Tips for Securing Your EC2 Instance*.
To enable users SSH access to your EC2 instance using a Linux system user, you must share the SSH key with the user. Alternatively, you can use EC2 Instance Connect to provide access to users without the need to share and manage SSH keys. For more information, see Connect to your Linux instance with EC2 Instance Connect (p. 831).

Create a user

First create the user, and then add the SSH public key that allows the user to connect to and log into the instance.

To create a user

1. **Create a new key pair** (p. 2009). You must provide the .pem file to the user for whom you are creating the user. They must use this file to connect to the instance.
2. Retrieve the public key from the key pair that you created in the previous step.

   ```bash
   $ ssh-keygen -y -f /path_to_key_pair/key-pair-name.pem
   ``

   The command returns the public key, as shown in the following example.

   ```plaintext
   ssh-rsa
   AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eYhCeS3pcjqP3maAhDFcvBS706Vhz2ItxC1h
   +PnDSUaw+wNQn/mZphTk/a/gUBjEzoOWbkm4yxyb/w896xbiFveSFJuoP/
   d6RJhJ0l0i8Xr1sLHttnc0k17FbtxJXNLVvVjyDUiBMTjYtvB+QhYXUM0zce5Pjz5/i8SeJtjnV3iAOG/
   cQk+0FzZqaeJAAHcco+CY/SWzUBkzHFJ16HcXv3dWpKvYQ53xqc0+FmUZofz221CBt5IMucXXPkX4xwI
   +z7wB5RBqOQzdBv7yeb70z1PnWOyNqFU0XA246RA8QFY1CNWyI3f0Sp6KLxEEXAMPLE
   ```

3. Connect to the instance.
4. Use the `adduser` command to create the user and add it to the system (with an entry in the `/etc/passwd` file). The command also creates a group and a home directory for the user. In this example, the user is named `newuser`.

   - Amazon Linux and Amazon Linux 2
     With Amazon Linux and Amazon Linux 2, the user is created with password authentication disabled by default.

     ```bash
     [ec2-user ~]$ sudo adduser newuser
     ```
   - Ubuntu
     Include the `--disabled-password` parameter to create the user with password authentication disabled.

     ```bash
     [ubuntu ~]$ sudo adduser newuser --disabled-password
     ```
5. Switch to the new user so that the directory and file that you create will have the proper ownership.

     ```bash
     [ec2-user ~]$ sudo su - newuser
     ```

     The prompt changes from `ec2-user` to `newuser` to indicate that you have switched the shell session to the new user.
6. Add the SSH public key to the user. First create a directory in the user's home directory for the SSH key file, then create the key file, and finally paste the public key into the key file, as described in the following sub-steps.
a. Create a .ssh directory in the newuser home directory and change its file permissions to 700 (only the owner can read, write, or open the directory).

[newuser ~]$ mkdir .ssh
[newuser ~]$ chmod 700 .ssh

**Important**
Without these exact file permissions, the user will not be able to log in.

b. Create a file named authorized_keys in the .ssh directory and change its file permissions to 600 (only the owner can read or write to the file).

[newuser ~]$ touch .ssh/authorized_keys
[newuser ~]$ chmod 600 .ssh/authorized_keys

**Important**
Without these exact file permissions, the user will not be able to log in.

c. Open the authorized_keys file using your favorite text editor (such as vim or nano).

[newuser ~]$ nano .ssh/authorized_keys

Paste the public key that you retrieved in Step 2 into the file and save the changes.

**Important**
Ensure that you paste the public key in one continuous line. The public key must not be split over multiple lines.

The user should now be able to log into the newuser user on your instance, using the private key that corresponds to the public key that you added to the authorized_keys file. For more information about the different methods of connecting to a Linux instance, see Connect to your Linux instance (p. 811).

Remove a user

If a user is no longer needed, you can remove that user so that it can no longer be used.

Use the userdel command to remove the user from the system. When you specify the -r parameter, the user's home directory and mail spool are deleted. To keep the user's home directory and mail spool, omit the -r parameter.

[ec2-user ~]$ sudo userdel -r olduser

Processor state control for your EC2 instance

C-states control the sleep levels that a core can enter when it is idle. C-states are numbered starting with C0 (the shallowest state where the core is totally awake and executing instructions) and go to C6 (the deepest idle state where a core is powered off).

P-states control the desired performance (in CPU frequency) from a core. P-states are numbered starting from P0 (the highest performance setting where the core is allowed to use Intel Turbo Boost Technology
to increase frequency if possible), and they go from P1 (the P-state that requests the maximum baseline frequency) to P15 (the lowest possible frequency).

C-states and P-states

The following instance types provide the ability for an operating system to control processor C-states and P-states:

- General purpose: m4.10xlarge | m4.16xlarge | m5.16xlarge | m5d.16xlarge | m5n.16xlarge | m5zn.16xlarge | m6i.16xlarge | m6d.16xlarge | m7i.16xlarge | m7i.2xlarge | m7i.4xlarge | m7i.8xlarge | m7i.12xlarge | m7i.16xlarge | m7i.24xlarge | m7i.48xlarge
- Compute optimized: c4.8xlarge | c5.meta | c5an.meta | c5dn.meta | c5n.meta | c6i.meta | c6id.meta | c7i.meta-24x1 | c7i.meta-48x1
- Memory optimized: r4.8xlarge | r4.16xlarge | r5.meta | r5b.meta | r5d.meta | r6i.meta | r7i.meta-24x1 | r7i.meta-48x1 | r7iz.meta-16x1 | r7iz.meta-32x1 | u-6tb1.meta | u-9tb1.meta | u-12tb1.meta | u-18tb1.meta | u-24tb1.meta
  - x1.16xlarge | x1.32xlarge | x1e.8xlarge | x1e.16xlarge | x1e.32xlarge
- Storage optimized: d2.8xlarge | d3.meta | d3en.meta | i3.8xlarge | i3.16xlarge | i3.meta | i3en.meta | h1.8xlarge | h1.16xlarge
- Accelerated computing: f1.16xlarge | g3.16xlarge | g4dn.meta | p2.16xlarge | p3.16xlarge

C-states only

The following instance types provide the ability for an operating system to control processor C-states:

- General purpose: m5.12xlarge | m5.24xlarge | m5d.12xlarge | m5d.24xlarge | m5n.12xlarge | m5n.24xlarge | m5dn.12xlarge | m5dn.24xlarge | m6a.12xlarge | m6a.24xlarge | m6ad.meta | m6i.16xlarge | m6i.32xlarge | m7i.1large | m7i.xlarge | m7i.2xlarge | m7i.4xlarge | m7i.8xlarge | m7i.12xlarge | m7i.16xlarge | m7i.24xlarge | m7i.48xlarge
- Compute optimized: c5.9xlarge | c5.12xlarge | c5.18xlarge | c5.24xlarge | c5a.24xlarge | c5d.24xlarge | c5d.9xlarge | c5d.12xlarge | c5d.18xlarge | c5d.24xlarge | c5n.9xlarge | c5n.18xlarge | c5n.24xlarge | c6a.24xlarge | c6a.32xlarge | c6a.48xlarge | c6i.16xlarge | c6i.32xlarge | c7i.large | c7i.xlarge | c7i.2xlarge | c7i.4xlarge | c7i.8xlarge | c7i.12xlarge | c7i.16xlarge | c7i.24xlarge | c7i.48xlarge
- Memory optimized: r5.12xlarge | r5.24xlarge | r5d.12xlarge | r5d.24xlarge | r5n.12xlarge | r5n.24xlarge | r5dn.12xlarge | r5dn.24xlarge | r6a.24xlarge | r6a.48xlarge | r6i.16xlarge | r6i.32xlarge | r6id.32xlarge | r7i.1large | r7i.xlarge | r7i.2xlarge | r7i.4xlarge | r7i.8xlarge | r7i.12xlarge | r7i.16xlarge | r7i.24xlarge | r7i.48xlarge | r7iz.xlarge | r7iz.2xlarge | r7iz.4xlarge | r7iz.8xlarge | r7iz.12xlarge | r7iz.16xlarge | r7iz.32xlarge | u-6tb1.56xlarge | u-6tb1.112xlarge | u-9tb1.112xlarge | u-12tb1.112xlarge | u-18tb1.112xlarge | u-24tb1.112xlarge | z1d.6xlarge | z1d.12xlarge
- Storage optimized: d3en.12xlarge | d1l.24xlarge | i3en.12xlarge | i3en.24xlarge | i4i.meta | r5b.12xlarge | r5b.24xlarge | r5b.48xlarge | i4i.16xlarge
- Accelerated computing: d1l.24xlarge | g5.24xlarge | g5.48xlarge | inf1.24xlarge | p3dn.24xlarge | p4d.24xlarge | p4de.24xlarge | vt1.24xlarge

AWS Graviton processors have built-in power saving modes and operate at a fixed frequency. Therefore, they do not provide the ability for the operating system to control C-states and P-states.

You might want to change the C-state or P-state settings to increase processor performance consistency, reduce latency, or tune your instance for a specific workload. The default C-state and P-state settings provide maximum performance, which is optimal for most workloads. However, if your application would benefit from reduced latency at the cost of higher single- or dual-core frequencies, or from consistent performance at lower frequencies as opposed to bursty Turbo Boost frequencies, consider experimenting with the C-state or P-state settings that are available to these instances.
The following sections describe the different processor state configurations and how to monitor the effects of your configuration. These procedures were written for, and apply to Amazon Linux; however, they may also work for other Linux distributions with a Linux kernel version of 3.9 or newer. For more information about other Linux distributions and processor state control, see your system-specific documentation.

**Note**
The examples on this page use the following:

- The `turbostat` utility to display processor frequency and C-state information. The `turbostat` utility is available on Amazon Linux by default.
- The `stress` command to simulate a workload. To install `stress`, first enable the EPEL repository by running `sudo amazon-linux-extras install epel`, and then run `sudo yum install -y stress`.

If the output does not display the C-state information, include the `--debug` option in the command (`sudo turbostat --debug stress <options>`).

**Contents**

- Highest performance with maximum Turbo Boost frequency (p. 911)
- High performance and low latency by limiting deeper C-states (p. 912)
- Baseline performance with the lowest variability (p. 914)

### Highest performance with maximum Turbo Boost frequency

This is the default processor state control configuration for the Amazon Linux AMI, and it is recommended for most workloads. This configuration provides the highest performance with lower variability. Allowing inactive cores to enter deeper sleep states provides the thermal headroom required for single or dual core processes to reach their maximum Turbo Boost potential.

The following example shows a `c4.8xlarge` instance with two cores actively performing work reaching their maximum processor Turbo Boost frequency.

```
[ec2-user ~]$ sudo turbostat stress -c 2 -t 10
stress: info: [30680] dispatching hogs: 2 cpu, 0 io, 0 vm, 0 hdd
stress: info: [30680] successful run completed in 10s
pk cor CPU %c0 GHz TSC SMI %c1 %c3 %c6 %c7 %pc2 %pc3 %pc6 %pc7
          pkg_W RAM_W PKG_% RAM_%
5.54 3.44 2.90 0 9.18 0.00 85.28 0.00 0.00 0.00 0.00 0.00
94.04 32.70 54.18 0.00
0 0 0 0.12 3.26 2.90 0 3.61 0.00 96.27 0.00 0.00 0.00 0.00 0.00
48.12 18.88 26.02 0.00
0 0 18 0.12 3.26 2.90 0 3.61
0 1 1 0.12 3.26 2.90 0 4.11 0.00 95.77 0.00
0 1 19 0.13 3.27 2.90 0 4.11
0 2 2 0.13 3.28 2.90 0 4.45 0.00 95.42 0.00
0 2 20 0.11 3.27 2.90 0 4.47
0 3 3 0.05 3.42 2.90 0 99.91 0.00 0.05 0.00
0 3 21 97.84 3.45 2.90 0 2.11
... 1 1 10 0.06 3.33 2.90 0 99.88 0.01 0.06 0.00
1 1 28 97.61 3.44 2.90 0 2.32
... 10.002556 sec
```

In this example, vCPUs 21 and 28 are running at their maximum Turbo Boost frequency because the other cores have entered the C6 sleep state to save power and provide both power and thermal headroom for the working cores. vCPUs 3 and 10 (each sharing a processor core with vCPUs 21 and 28) are in the C1 state, waiting for instruction.
In the following example, all 18 cores are actively performing work, so there is no headroom for maximum Turbo Boost, but they are all running at the "all core Turbo Boost" speed of 3.2 GHz.

```
[ec2-user ~]$ sudo turbostat stress -c 36 -t 10
stress: info: [30685] dispatching hogs: 36 cpu, 0 io, 0 vm, 0 hdd
stress: info: [30685] successful run completed in 10s

**High performance and low latency by limiting deeper C-states**

C-states control the sleep levels that a core may enter when it is inactive. You may want to control C-states to tune your system for latency versus performance. Putting cores to sleep takes time, and although a sleeping core allows more headroom for another core to boost to a higher frequency, it takes time for that sleeping core to wake back up and perform work. For example, if a core that is assigned to handle network packet interrupts is asleep, there may be a delay in servicing that interrupt. You can configure the system to not use deeper C-states, which reduces the processor reaction latency, but that in turn also reduces the headroom available to other cores for Turbo Boost.

A common scenario for disabling deeper sleep states is a Redis database application, which stores the database in system memory for the fastest possible query response time.

**To limit deeper sleep states on Amazon Linux 2**

1. Open the `/etc/default/grub` file with your editor of choice.

   ```
   [ec2-user ~]$ sudo vim /etc/default/grub
   ```

2. Edit the `GRUB_CMDLINE_LINUX_DEFAULT` line and add the `intel_idle.max_cstate=1` and `processor.max_cstate=1` options to set C1 as the deepest C-state for idle cores.

   ```
   GRUB_CMDLINE_LINUX_DEFAULT="console=tty0 console=ttyS0,115200n8 net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 intel_idle.max_cstate=1 processor.max_cstate=1"
   GRUB_TIMEOUT=0
   ```

   The `intel_idle.max_cstate=1` option configures the C-state limit for Intel-based instances, and the `processor.max_cstate=1` option configures the C-state limit for AMD-based instances. It is safe to add both options to your configuration. This allows a single configuration to set the desired behavior on both Intel and AMD.

3. Save the file and exit your editor.
4. Run the following command to rebuild the boot configuration.

```bash
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

5. Reboot your instance to enable the new kernel option.

```bash
[ec2-user ~]$ sudo reboot
```

### To limit deeper sleep states on Amazon Linux AMI

1. Open the `/boot/grub/grub.conf` file with your editor of choice.

```bash
[ec2-user ~]$ sudo vim /boot/grub/grub.conf
```

2. Edit the `kernel` line of the first entry and add the `intel_idle.max_cstate=1` and `processor.max_cstate=1` options to set C1 as the deepest C-state for idle cores.

```confs
# created by imagebuilder
default=0
timeout=1
hiddenmenu
title Amazon Linux 2014.09 (3.14.26-24.46.amzn1.x86_64)
root (hd0,0)
kernel /boot/vmlinux-3.14.26-24.46.amzn1.x86_64 root=LABEL=/ console=ttyS0
  intel_idle.max_cstate=1  processor.max_cstate=1
initrd /boot/initramfs-3.14.26-24.46.amzn1.x86_64.img
```

The `intel_idle.max_cstate=1` option configures the C-state limit for Intel-based instances, and the `processor.max_cstate=1` option configures the C-state limit for AMD-based instances. It is safe to add both options to your configuration. This allows a single configuration to set the desired behavior on both Intel and AMD.

3. Save the file and exit your editor.

4. Reboot your instance to enable the new kernel option.

```bash
[ec2-user ~]$ sudo reboot
```

The following example shows a `c4.8xlarge` instance with two cores actively performing work at the "all core Turbo Boost" core frequency.

```bash
[ec2-user ~]$ sudo turbostat stress -c 2 -t 10
stress: info: [5322] dispatching hogs: 2 cpu, 0 io, 0 vm, 0 hdd
stress: info: [5322] successful run completed in 10s
PK COR CPU    %C0  GHz  TSC  SMI    %C1    %C3    %C6    %C7   %PC2   %PC3   %PC6   %PC7
PKG_W RAM_W PKG_% RAM_%
5.56 3.20 2.90   0  94.44   0.00   0.00   0.00   0.00   0.00   0.00   0.00   0.00
131.90 31.11 199.47  0.00
0   0  0.03 2.08 2.90  99.97 0.00 0.00 0.00 0.00 0.00 0.00 0.00 0.00
67.23 17.11 99.76  0.00
0  0  0.01 1.93 2.90  99.99 0.00 0.00 0.00 0.00 0.00 0.00 0.00 0.00
0  1  0.02 1.96 2.90  99.98 0.00 0.00 0.00 0.00 0.00 0.00 0.00 0.00
... 1  1  10  0.02 1.97 2.90  99.98 0.00 0.00 0.00
1  1  28  99.67  3.20 2.90  0.33
1  2  11  0.04 2.63 2.90  99.96 0.00 0.00 0.00
```
In this example, the cores for vCPUs 19 and 28 are running at 3.2 GHz, and the other cores are in the C1 C-state, awaiting instruction. Although the working cores are not reaching their maximum Turbo Boost frequency, the inactive cores will be much faster to respond to new requests than they would be in the deeper C6 C-state.

**Baseline performance with the lowest variability**

You can reduce the variability of processor frequency with P-states. P-states control the desired performance (in CPU frequency) from a core. Most workloads perform better in P0, which requests Turbo Boost. But you may want to tune your system for consistent performance rather than bursty performance that can happen when Turbo Boost frequencies are enabled.

Intel Advanced Vector Extensions (AVX or AVX2) workloads can perform well at lower frequencies, and AVX instructions can use more power. Running the processor at a lower frequency, by disabling Turbo Boost, can reduce the amount of power used and keep the speed more consistent. For more information about optimizing your instance configuration and workload for AVX, see the Intel website.

CPU idle drivers control P-state. Newer CPU generations require updated CPU idle drivers that correspond to the kernel level as follows:

- Linux kernel versions 5.6 and higher (for example, m6i) – Supports Intel Icelake.
- Linux kernel versions 5.10 and higher (for example, m6a) – Supports AMD Milan.

To detect if a running system’s kernel recognizes the CPU, run the following command.

```bash
if [ -d /sys/devices/system/cpu/cpu0/cpuidle ]; then echo "C-state control enabled"; else echo "Kernel cpuidle driver does not recognize this CPU generation"; fi
```

If the output of this command indicates a lack of support, we recommend that you upgrade the kernel.

This section describes how to limit deeper sleep states and disable Turbo Boost (by requesting the P1 P-state) to provide low-latency and the lowest processor speed variability for these types of workloads.

**To limit deeper sleep states and disable Turbo Boost on Amazon Linux 2**

1. Open the `/etc/default/grub` file with your editor of choice.

   `[ec2-user ~]$ sudo vim /etc/default/grub

2. Edit the `GRUB_CMDLINE_LINUX_DEFAULT` line and add the `intel_idle.max_cstate=1` and `processor.max_cstate=1` options to set C1 as the deepest C-state for idle cores.

   ```bash
   GRUB_CMDLINE_LINUX_DEFAULT="console=tty0 console=ttyS0,115200n8 net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 intel_idle.max_cstate=1 processor.max_cstate=1"
   GRUB_TIMEOUT=0
   ```

   The `intel_idle.max_cstate=1` option configures the C-state limit for Intel-based instances, and the `processor.max_cstate=1` option configures the C-state limit for AMD-based instances. It is safe to add both options to your configuration. This allows a single configuration to set the desired behavior on both Intel and AMD.

3. Save the file and exit your editor.
4. Run the following command to rebuild the boot configuration.

[ec2-user ~]$ grub2-mkconfig -o /boot/grub2/grub.cfg

5. Reboot your instance to enable the new kernel option.

[ec2-user ~]$ sudo reboot

6. When you need the low processor speed variability that the P1 P-state provides, run the following command to disable Turbo Boost.

[ec2-user ~]$ sudo sh -c "echo 1 > /sys/devices/system/cpu/intel_pstate/no_turbo"

7. When your workload is finished, you can re-enable Turbo Boost with the following command.

[ec2-user ~]$ sudo sh -c "echo 0 > /sys/devices/system/cpu/intel_pstate/no_turbo"

To limit deeper sleep states and disable Turbo Boost on Amazon Linux AMI

1. Open the /boot/grub/grub.conf file with your editor of choice.

[ec2-user ~]$ sudo vim /boot/grub/grub.conf

2. Edit the kernel line of the first entry and add the intel_idle.max_cstate=1 and processor.max_cstate=1 options to set C1 as the deepest C-state for idle cores.

# created by imagebuilder
default=0
timeout=1
hiddenmenu
title Amazon Linux 2014.09 (3.14.26-24.46.amzn1.x86_64)
root (hd0,0)
kernel /boot/vmlinuz-3.14.26-24.46.amzn1.x86_64 root=LABEL=/ console=ttyS0 intel_idle.max_cstate=1 processor.max_cstate=1
initrd /boot/initramfs-3.14.26-24.46.amzn1.x86_64.img

The intel_idle.max_cstate=1 option configures the C-state limit for Intel-based instances, and the processor.max_cstate=1 option configures the C-state limit for AMD-based instances. It is safe to add both options to your configuration. This allows a single configuration to set the desired behavior on both Intel and AMD.

3. Save the file and exit your editor.

4. Reboot your instance to enable the new kernel option.

[ec2-user ~]$ sudo reboot

5. When you need the low processor speed variability that the P1 P-state provides, run the following command to disable Turbo Boost.

[ec2-user ~]$ sudo sh -c "echo 1 > /sys/devices/system/cpu/intel_pstate/no_turbo"

6. When your workload is finished, you can re-enable Turbo Boost with the following command.

[ec2-user ~]$ sudo sh -c "echo 0 > /sys/devices/system/cpu/intel_pstate/no_turbo"
The following example shows a `c4.8xlarge` instance with two vCPUs actively performing work at the baseline core frequency, with no Turbo Boost.

```
[ec2-user ~]$ sudo turbostat stress -c 2 -t 10
```

```
stress: info: [5389] dispatching hogs: 2 cpu, 0 io, 0 vm, 0 hdd

  0  3  3 0.05 2.90 2.90  0 99.95   0.00   0.00   0.00
  0  3 21 99.95 2.90 2.90  0 0.05
...  1  1 28 99.92 2.90 2.90  0 0.08
  1  2 11 0.06 2.90 2.90  0 99.94   0.00   0.00   0.00
  1  2 29 0.05 2.90 2.90  0 99.95
```

The cores for vCPUs 21 and 28 are actively performing work at the baseline processor speed of 2.9 GHz, and all inactive cores are also running at the baseline speed in the C1 C-state, ready to accept instructions.

## I/O scheduler

The I/O scheduler is a part of the Linux operating system that sorts and merges I/O requests and determines the order in which they are processed.

I/O schedulers are particularly beneficial for devices such as magnetic hard drives, where seek time can be expensive and where it is optimal to merge co-located requests. I/O schedulers have less of an effect with solid state devices and virtualized environments. This is because for solid state devices, sequential and random access don't differ, and for virtualized environments, the host provides its own layer of scheduling.

This topic discusses the Amazon Linux I/O scheduler. For more information about the I/O scheduler used by other Linux distributions, refer to their respective documentation.

### Topics

- Supported schedulers (p. 916)
- Default scheduler (p. 917)
- Change the scheduler (p. 917)

### Supported schedulers

Amazon Linux supports the following I/O schedulers:

- **deadline** — The *Deadline* I/O scheduler sorts I/O requests and handles them in the most efficient order. It guarantees a start time for each I/O request. It also gives I/O requests that have been pending for too long a higher priority.

- **cfq** — The *Completely Fair Queueing* (CFQ) I/O scheduler attempts to fairly allocate I/O resources between processes. It sorts and inserts I/O requests into per-process queues.
Default scheduler

No Operation (noop) is the default I/O scheduler for Amazon Linux. This scheduler is used for the following reasons:

- Many instance types use virtualized devices where the underlying host performs scheduling for the instance.
- Solid state devices are used in many instance types where the benefits of an I/O scheduler have less effect.
- It is the least invasive I/O scheduler, and it can be customized if needed.

Change the scheduler

Changing the I/O scheduler can increase or decrease performance based on whether the scheduler results in more or fewer I/O requests being completed in a given time. This is largely dependent on your workload, the generation of the instance type that's being used, and the type of device being accessed. If you change the I/O scheduler being used, we recommend that you use a tool, such as `iotop`, to measure I/O performance and to determine whether the change is beneficial for your use case.

You can view the I/O scheduler for a device using the following command, which uses `nvme0n1` as an example. Replace `nvme0n1` in the following command with the device listed in `/sys/block` on your instance.

```
$ cat /sys/block/nvme0n1/queue/scheduler
```

To set the I/O scheduler for the device, use the following command.

```
$ echo cfq|deadline|noop > /sys/block/nvme0n1/queue/scheduler
```

For example, to set the I/O scheduler for an `xvda` device from `noop` to `cfq`, use the following command.

```
$ echo cfq > /sys/block/xvda/queue/scheduler
```

Set the time for your Linux instance

A consistent and accurate time reference on your Linux instance is crucial for many server tasks and processes. Time stamps in system logs play an essential role in identifying when issues occurred and the chronological order of events. When you use the AWS CLI or an AWS SDK to make requests from your instance, these tools sign requests on your behalf. If your instance's date and time settings are inaccurate, it can result in a discrepancy between the date in the signature and the date of the request, leading to AWS rejecting your requests.

To address this important aspect, Amazon offers the Amazon Time Sync Service, which is accessible from all EC2 instances and used by various AWS services. The service uses a fleet of satellite-connected and atomic reference clocks in each AWS Region to deliver accurate and current time readings of the Coordinated Universal Time (UTC) global standard.

The Amazon Time Sync Service either uses the Network Time Protocol (NTP), or provides a local Precision Time Protocol (PTP) hardware clock on supported instances (p. 923). The PTP hardware clock supports either NTP or a direct PTP connection. The NTP and direct PTP connections use the same highly
accurate time source, but the direct PTP connection is more accurate than the NTP connection. The NTP connection to the Amazon Time Sync Service supports leap smearing while the PTP connection to the PTP hardware clock does not smear time. For more information, see Leap seconds (p. 927).

For a backup to the local Amazon Time Sync Service on your instance, and to connect resources outside of Amazon EC2 to the Amazon Time Sync Service, you can use the public Amazon Time Sync Service located at time.aws.com. The public Amazon Time Sync Service, like the local Amazon Time Sync Service, automatically smears any leap seconds that are added to UTC. The public Amazon Time Sync Service is supported globally by our fleet of satellite-connected and atomic reference clocks in each AWS Region.

For Windows instances, see Set the time for your Windows instance.

Topics
- Set your instance to use the local Amazon Time Sync Service (p. 918)
- Set your instance or any internet-connected device to use the public Amazon Time Sync Service (p. 924)
- Compare timestamps (p. 925)
- Change the time zone on your instance (p. 926)
- Leap seconds (p. 927)
- Related resources (p. 927)

Set your instance to use the local Amazon Time Sync Service

Your instances can access the local Amazon Time Sync Service as follows:

- Through NTP at the following IP address endpoints:
  - IPv4: 169.254.169.123
  - IPv6: fd00:ec2::123 (Only accessible by instances built on the Nitro System (p. 295).)
- Through a direct PTP connection to connect to a local PTP hardware clock:
  - PHC0

NTP and PTP connections do not require any VPC configuration changes, and your instance does not require access to the internet.

The PTP hardware clock is part of the Nitro System (p. 295), so it is directly accessible on supported bare metal and virtualized EC2 instances (p. 923) without using any customer resources.

The NTP endpoints to the PTP hardware clock are the same as the regular Amazon Time Sync Service connection over IPv4 or IPv6. If your software is configured to the NTP endpoint and is running on an instance with a PTP hardware clock, it will be connected to the PTP hardware clock automatically over NTP.

Amazon Linux 2023 and the latest versions of Amazon Linux 2 and Amazon Linux AMIs are configured to use the Amazon Time Sync Service IPv4 endpoint by default. No further configuration is required for instances launched from these AMIs unless you want to use the IPv6 endpoint or connect directly to the PTP hardware clock. For the IPv6 configuration instructions, see Connect to the IPv6 endpoint of the Amazon Time Sync Service (p. 922). For the PTP hardware clock configuration instructions, see Connect to the PTP hardware clock (p. 923).

If you're using an AMI that doesn't have the Amazon Time Sync Service configured by default, use one of the following procedures to configure the Amazon Time Sync Service on your instance using the chrony client.
• **Connect to the IPv4 endpoint of the Amazon Time Sync Service** (p. 919)
  • **Connect to the IPv6 endpoint of the Amazon Time Sync Service** (p. 922)
  • **Connect to the PTP hardware clock** (p. 923)

**Connect to the IPv4 endpoint of the Amazon Time Sync Service**

This section describes how to configure your instance to use the local Amazon Time Sync Service through the IPv4 endpoint. It requires adding a server entry for the Amazon Time Sync Service to the `chrony` configuration file. On the latest versions of these AMIs, `chrony` is already installed and configured to use the Amazon Time Sync Service IPv4 endpoint.

Use the instructions for your instance's operating system.

**Amazon Linux**

**Note**

On Amazon Linux 2023 and the latest versions of Amazon Linux 2 and Amazon Linux AMI, `chrony` is already installed and configured to use the Amazon Time Sync Service IPv4 endpoint. If you’re using one of these latest AMIs, you can skip this procedure.

**To connect to the IPv4 endpoint of the Amazon Time Sync Service on Amazon Linux using `chrony`**

1. Connect to your instance and uninstall the NTP service.

   ```bash
   [ec2-user ~]$ sudo yum erase 'ntp*'
   ```

2. Install the `chrony` package.

   ```bash
   [ec2-user ~]$ sudo yum install chrony
   ```

3. Open the `/etc/chrony.conf` file using a text editor (such as `vim` or `nano`). Verify that the file includes the following line:

   ```
   server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
   ```

   If the line is present, then the Amazon Time Sync Service is already configured to use the IPv4 endpoint of the Amazon Time Sync Service and you can go to the next step. If not, add the line after any other server or pool statements that are already present in the file, and save your changes.

4. Restart the `chrony` daemon (`chronyd`).

   ```bash
   [ec2-user ~]$ sudo service chronyd restart
   ```

   Starting chronyd: [ OK ]

   **Note**

   On RHEL and CentOS (up to version 6), the service name is `chrony` instead of `chronyd`.

5. To configure `chrony` to start at each system boot, use the `chkconfig` command.

   ```bash
   [ec2-user ~]$ sudo chkconfig chronyd on
   ```

6. Verify that `chrony` is using the 169.254.169.123 IPv4 endpoint to synchronize the time.
Set the time

```bash
[ec2-user ~]$ chronyc sources -v
```

210 Number of sources = 7

```plaintext
|-- Source mode  '^' = server, '=' = peer, '#' = local clock.
  /  | Source state  '*' = current synced, '+' = combined, '-' = not
|  |   combined,
|  |   '/?' = unreachable, 'x' = time may be in error, '~' = time too
|  |   variable.
|  |   \- xxxx [ yyyy ] +/-zzzz
|    | Reachability register (octal) \- | xxxx = adjusted
|    | Log2(Polling interval) \- | yyyy = measured
|    | \ | zzzz = estimated
| MS Name/IP address | Stratum | Poll | Reach | LastRx | Last sample |
|===============================================================================|
|    | ^* 169.254.169.123               | 3   | 6    | 17    | 43    | -30us[ -226us] +/-287us |
|    | ^- ec2-12-34-231-12.eu-west>     | 2   | 6    | 17    | 43   | -388us[ -388us] +/-11ms |
|    | ^- tshirt.heanet.ie              | 1   | 6    | 17    | 44   | +178us[  +25us] +/-1959us |
|    | ^? tbag.heanet.ie                | 0   | 6    | 0     | -    | +0ns[   +0ns] +/-0ns   |
|    | ^? bray.walcz.net                | 0   | 6    | 0     | -    | +0ns[   +0ns] +/-0ns   |
|    | ^? 2a05:d018:c43:e312:ce77:>     | 0   | 6    | 0     | -    | +0ns[   +0ns] +/-0ns   |
|    | ^? 2a05:d018:dab:2701:b70:b>     | 0   | 6    | 0     | -    | +0ns[   +0ns] +/-0ns   |
```

In the output that's returned, ^* indicates the preferred time source.

7. Verify the time synchronization metrics that are reported by chrony.

```bash
[ec2-user ~]$ chronyc tracking
```

To connect to the IPv4 endpoint of the Amazon Time Sync Service on Ubuntu using `chrony`

1. Connect to your instance and use `apt` to install the `chrony` package.

```bash
ubuntu:~$ sudo apt install chrony
```

**Note**
If necessary, update your instance first by running `sudo apt update`.

2. Open the `/etc/chrony/chrony.conf` file using a text editor (such as `vim` or `nano`). Add the following line before any other server or pool statements that are already present in the file, and save your changes:

```bash
server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
```

3. Restart the `chrony` service.

```bash
ubuntu:~$ sudo /etc/init.d/chrony restart
```

Restarting chrony (via systemctl): chrony.service.

4. Verify that `chrony` is using the 169.254.169.123 IPv4 endpoint to synchronize the time.

```bash
ubuntu:~$ chronyc sources -v
```

```
Number of sources = 7

**SUSE Linux**

Starting with SUSE Linux Enterprise Server 15, `chrony` is the default implementation of NTP.

**To connect to IPv4 endpoint of the Amazon Time Sync Service on SUSE Linux using chrony**

1. Open the `/etc/chrony.conf` file using a text editor (such as `vim` or `nano`).
2. Verify that the file contains the following line:

   ```
   server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4
   ```

   If this line is not present, add it.
3. Comment out any other server or pool lines.
4. Open yaST and enable the chrony service.

**Connect to the IPv6 endpoint of the Amazon Time Sync Service**

This section explains how the steps described in [Connect to the IPv4 endpoint of the Amazon Time Sync Service (p. 919)](#) differ if you are configuring your instance to use the local Amazon Time Sync Service through the IPv6 endpoint. It doesn't explain the entire Amazon Time Sync Service configuration process.

The IPv6 endpoint is only accessible on instances built on the [Nitro System (p. 295)](#).

**Note**

We don't recommend using both the IPv4 and IPv6 endpoint entries together in your `chrony.conf` file. The IPv4 and IPv6 NTP packets come from the same local server for your instance. Configuring both IPv4 and IPv6 endpoints is unnecessary and will not improve the accuracy of the time on your instance.

Depending on the Linux distribution you are using, when you reach the step to edit the `chrony.conf` file, you'll be using the IPv6 endpoint of the Amazon Time Sync Service (`fd00:ec2::123`) rather than the IPv4 endpoint (`169.254.169.123`).
Amazon Elastic Compute Cloud
User Guide for Linux Instances

Set the time

```bash
server fd00:ec2::123 prefer iburst minpoll 4 maxpoll 4
```

Save the file and verify that `chrony` is using the fd00:ec2::123 IPv6 endpoint to synchronize time:

```
[ec2-user ~] $ chronyc sources -v
```

In the output, if you see the fd00:ec2::123 IPv6 endpoint, the configuration is complete.

**Connect to the PTP hardware clock**

This section describes how to configure your instance to use the local Amazon Time Sync Service through the PTP hardware clock using a direct PTP connection. It requires adding a server entry for the PTP hardware clock to the `chrony` configuration file.

If your instance has a PTP hardware clock and you configured the NTP connection (to either the IPv4 or the IPv6 endpoint), your instance time is automatically sourced from the PTP hardware clock. The steps below configure the direct PTP connection, which will give you more accurate time than the NTP connection.

**Requirements**

The PTP hardware clock is available on an instance when the following requirements are met:

- Supported AWS Region: Asia Pacific (Tokyo)
- Supported instance family: R7g
- ENA driver version 2.10.0 or later installed on a supported operating system. For more information about supported operating systems, see the driver prerequisites on GitHub.

**To connect to the PTP hardware clock**

1. Connect to your instance and install the Linux kernel driver for Elastic Network Adapter (ENA) version 2.10.0 or later. For the installation instructions, see Linux kernel driver for Elastic Network Adapter (ENA) family on GitHub.

2. Verify that the `/dev/ptp0` device shows up on your instance.

```
[ec2-user ~] $ ls /dev/ptp0
```

The following is the expected output. If `/dev/ptp0` is not in the output, the ENA driver was not correctly installed. Review step 1 in this procedure for installing the driver.

```
/dev/ptp0
```

3. Edit `/etc/chrony.conf` using a text editor and add the following line anywhere in the file.

```
refclock PHC /dev/ptp0 poll 0 delay 0.000010 prefer
```

4. Restart chrony using the following command.

```
[ec2-user ~] $ sudo systemctl restart chronyd
```

5. Verify that chrony is using the PTP hardware clock to synchronize the time on this instance.

```
[ec2-user ~] $ chronyc sources
```
Set the time

<table>
<thead>
<tr>
<th>MS Name/IP address</th>
<th>Stratum</th>
<th>Poll</th>
<th>Reach</th>
<th>Last Rx</th>
<th>Last sample</th>
</tr>
</thead>
<tbody>
<tr>
<td>#* PHC0</td>
<td>0</td>
<td>0</td>
<td>377</td>
<td>1</td>
<td>+2ns (+1ns) +/- 5031ns</td>
</tr>
</tbody>
</table>

In the output that's returned, * indicates the preferred time source. PHC0 corresponds to the PTP hardware clock. You might need to wait a few seconds after restarting chrony for the asterisk to appear.

Set your instance or any internet-connected device to use the public Amazon Time Sync Service

You can set your instance, or any internet-connected device such as your local computer or an on-prem server, to use the public Amazon Time Sync Service, which is accessible over the internet at time.aws.com. You can use the public Amazon Time Sync Service as a backup for the local Amazon Time Sync Service and to connect resources outside of AWS to the Amazon Time Sync Service.

Depending on the operating system of your instance or device, use one of the following procedures to set your instance or device to use the public Amazon Time Sync Service.

Linux

To set your Linux instance or device to use the public Amazon Time Sync Service using chrony or ntpd

1. Edit /etc/chrony.conf (if you use chrony) or /etc/ntp.conf (if you use ntpd) using a text editor as follows:

   a. To prevent your instance or device from trying to mix smeared and non-smeared servers, remove or comment out lines starting with server except any existing connection to the local Amazon Time Sync Service.

   Important
   If you're setting your EC2 instance to connect to the public Amazon Time Sync Service, do not remove the following line which sets your instance to connect to the local Amazon Time Sync Service. The local Amazon Time Sync Service is a more direct connection and will provide better clock accuracy. The public Amazon Time Sync Service should only be used as a backup.

   server 169.254.169.123 prefer iburst minpoll 4 maxpoll 4

   b. Add the following line to connect to the public Amazon Time Sync Service.

   pool time.aws.com iburst

2. Restart the daemon using one of the following commands.

   - chrony
     
     sudo service chronyd force-reload
   
   - ntpd
     
     sudo service ntp reload
macOS

To set your macOS instance or device to use the public Amazon Time Sync Service

1. Open **System Preferences**.
2. Choose **Date & Time**, and then choose the **Date & Time** tab.
3. To make changes, choose the lock icon, and enter your password when prompted.
4. For **Set date and time automatically**, enter **time.aws.com**.

Windows

To set your Windows instance or device to use the public Amazon Time Sync Service

1. Open the **Control Panel**.
2. Choose the **Date and Time** icon.
3. Choose the **Internet Time** tab. This tab is not available if your PC is part of a domain. In this case, it will synchronize time with the domain controller. You can configure the controller to use the public Amazon Time Sync Service.
4. Choose **Change settings**.
5. Select the check box for **Synchronize with an Internet time server**.
6. Next to **Server**, enter **time.aws.com**.

To set your Windows Server instance or device to use the public Amazon Time Sync Service

- Follow [Microsoft's instructions](https://docs.microsoft.com) to update your registry.

**Compare timestamps**

If you're using the Amazon Time Sync Service, you can compare the timestamps on your Amazon EC2 instances with ClockBound to determine the true time of an event. ClockBound measures the clock accuracy of your EC2 instance, and allows you to check if a given timestamp is in the past or future with respect to your instance's current clock. This information is valuable for determining the order and consistency of events and transactions across EC2 instances, independent of each instance's geographic location.

ClockBound is an open source daemon and library. To learn more about ClockBound, including installation instructions, see [ClockBound](https://github.com/clockbound) on GitHub.

If you're using the direct PTP connection to the PTP hardware clock, your time daemon, such as chrony, will underestimate the clock error bound. This is because a PTP hardware clock does not pass the correct error bound information to chrony, the way that NTP does. As a result, your clock synchronization daemon assumes the clock is accurate to UTC and thus has an error bound of 0. To measure the full error bound, the Nitro System calculates the error bound of the PTP hardware clock, and makes it available to your EC2 instance over the ENA driver `sysfs` filesystem. You can read this directly as a value, in nanoseconds, using the following command:

```
    cat /sys/devices/pci0000:00/0000:00:05.0/phc_error_bound
```

The output is the clock error bound of the PTP hardware clock, in nanoseconds.

To calculate the correct clock error bound at a specific point in time when using the direct PTP connection to the PTP hardware clock, you must add the clock error bound from chrony or ClockBound...
at the time that chrony polls the PTP hardware clock. For more information about measuring and
monitoring clock accuracy, see Manage Amazon EC2 instance clock accuracy using Amazon Time Sync
Service and Amazon CloudWatch – Part 1.

Change the time zone on your instance

Amazon Linux instances are set to the UTC (Coordinated Universal Time) time zone by default. You can
change the time on an instance to the local time zone or to another time zone in your network.

Important
This information applies to Amazon Linux. For information about other distributions, see their
specific documentation.

To change the time zone on an Amazon Linux 2023 or Amazon Linux 2 instance

1. View the system's current time zone setting.

```
[ec2-user ~]$ timedatectl
```

2. List the available time zones.

```
[ec2-user ~]$ timedatectl list-timezones
```

3. Set the chosen time zone.

```
[ec2-user ~]$ sudo timedatectl set-timezone America/Vancouver
```

4. (Optional) Confirm that the current time zone is updated to the new time zone by running the
timedatectl command again.

```
[ec2-user ~]$ timedatectl
```

To change the time zone on an Amazon Linux instance

1. Identify the time zone to use on the instance. The /usr/share/zoneinfo directory contains a
hierarchy of time zone data files. Browse the directory structure at that location to find a file for
your time zone.

```
[ec2-user ~]$ ls /usr/share/zoneinfo
Africa  Chile  GB  Indian  Mideast  posixrules  US
America  CST6CDT  GB-Eire  Iran  MST  PRC  UTC
Antarctica  Cuba  GMT  iso3166.tab  MST7MDT  PST8PDT  WET
Arctic  EET  GMT0  Israel  Navajo  right  W-SU
...
```

Some of the entries at this location are directories (such as America), and these directories contain
time zone files for specific cities. Find your city (or a city in your time zone) to use for the instance.

2. Update the /etc/sysconfig/clock file with the new time zone. In this example, we use the time
zone data file for Los Angeles, /usr/share/zoneinfo/America/Los_Angeles.

   a. Open the /etc/sysconfig/clock file with a text editor (such as vim or nano). You need to
      use sudo with your editor command because /etc/sysconfig/clock is owned by root.

```
[ec2-user ~]$ sudo nano /etc/sysconfig/clock
```

926
b. Locate the ZONE entry, and change it to the time zone file (omitting the /usr/share/zoneinfo section of the path). For example, to change to the Los Angeles time zone, change the ZONE entry to the following:

```bash
ZONE="America/Los_Angeles"
```

**Note**
Do not change the UTC=true entry to another value. This entry is for the hardware clock, and does not need to be adjusted when you're setting a different time zone on your instance.

c. Save the file and exit the text editor.

3. Create a symbolic link between /etc/localtime and the time zone file so that the instance finds the time zone file when it references local time information.

```
[ec2-user ~]$ sudo ln -sf /usr/share/zoneinfo/America/Los_Angeles /etc/localtime
```

4. Reboot the system to pick up the new time zone information in all services and applications.

```
[ec2-user ~]$ sudo reboot
```

5. (Optional) Confirm that the current time zone is updated to the new time zone by using the `date` command. The current time zone appears in the output. In the following example, the current time zone is PDT, which refers to the Los Angeles time zone.

```
[ec2-user ~]$ date
Sun Aug 16 05:45:16 PDT 2020
```

**Leap seconds**

Leap seconds, introduced in 1972, are occasional one-second adjustments to UTC time to factor in irregularities in the earth's rotation in order to accommodate differences between International Atomic Time (TAI) and solar time (UT1). To manage leap seconds on behalf of customers, we designed leap second smearing within the Amazon Time Sync Service. For more information, see [Look Before You Leap - The Coming Leap Second and AWS](https://aws.amazon.comgetTimeSyncService/look-before-you-leap/). Leap seconds are going away, and we are in full support of the decision made at the [27th General Conference on Weights and Measures to abandon leap seconds by or before 2035](https://www.imo.org/en/OurWork/ConferencesAndMeetings/27thGeneralConferenceOnWeightsAndMeasuresaggio/). To support this transition, we still plan on smearing time during a leap second event when accessing the Amazon Time Sync Service over the local NTP connection or our public NTP pools (time.aws.com). The PTP hardware clock, however, does not provide a smeared time option. In the event of a leap second, the PTP hardware clock will add the leap second following UTC standards. Leap-smeared and leap second time sources are the same in most cases. But because they differ during a leap second event, we do not recommend using both smeared and non-smeared time sources in your time client configuration during a leap second event.

Optimize CPU options

Many Amazon EC2 instances support simultaneous multithreading, which enables multiple threads to run concurrently on a single CPU core. Each thread is represented as a virtual CPU (vCPU) on the instance. An instance has a default number of CPU cores, which varies according to instance type. For example, an m5.xlarge instance type has two CPU cores and two threads per core by default—four vCPUs in total.

Note
Each vCPU is a thread of a CPU core, except for T2 instances, M7a instances, Apple Silicon Mac instances, and 64-bit ARM platforms such as instances powered by AWS Graviton processors.

In most cases, there is an Amazon EC2 instance type that has a combination of memory and number of vCPUs to suit your workloads. However, you can specify the following CPU options to optimize your instance for specific workloads or business needs:

- **Number of CPU cores**: You can customize the number of CPU cores for the instance. You might do this to potentially optimize the licensing costs of your software with an instance that has sufficient amounts of RAM for memory-intensive workloads but fewer CPU cores.
- **Threads per core**: You can disable multithreading by specifying a single thread per CPU core. You might do this for certain workloads, such as high performance computing (HPC) workloads.

You can specify these CPU options during instance launch. There is no additional or reduced charge for specifying CPU options. You’re charged the same as instances that are launched with default CPU options.

Contents

- Rules for specifying CPU options (p. 928)
- CPU cores and threads per CPU core per instance type (p. 928)
- Specify CPU options for your instance (p. 983)
- View the CPU options for your instance (p. 987)

Rules for specifying CPU options

To specify the CPU options for your instance, be aware of the following rules:

- You can’t specify CPU options for bare metal instances.
- CPU options can only be specified during instance launch and cannot be modified after launch.
- When you launch an instance, you must specify both the number of CPU cores and threads per core in the request. For example requests, see Specify CPU options for your instance (p. 983).
- The number of vCPUs for the instance is the number of CPU cores multiplied by the threads per core. To specify a custom number of vCPUs, you must specify a valid number of CPU cores and threads per core for the instance type. You cannot exceed the default number of vCPUs for the instance. For more information, see CPU cores and threads per CPU core per instance type (p. 928).
- To disable multithreading, specify one thread per core.
- When you change the instance type (p. 479) of an existing instance, the CPU options automatically change to the default CPU options for the new instance type.
- The specified CPU options persist after you stop, start, or reboot an instance.

CPU cores and threads per CPU core per instance type

The following tables list the instance types that support specifying CPU options.
## Contents

- General purpose instances (p. 929)
- Compute optimized instances (p. 943)
- Memory optimized instances (p. 955)
- Storage optimized instances (p. 974)
- Accelerated computing instances (p. 979)

Specify CPU options for your instance

You can specify CPU options during instance launch.

The following examples describe how to specify the CPU options when using the launch instance wizard in the EC2 console and the `run-instances` AWS CLI command, and the create launch template page in the EC2 console and the `create-launch-template` AWS CLI command. For EC2 Fleet or Spot Fleet, you must specify the CPU options in a launch template.

The following examples are for an `r4.4xlarge` instance type, which has the following default values (p. 955):

- Default CPU cores: 8
- Default threads per core: 2
- Default vCPUs: 16 (8 * 2)
- Valid number of CPU cores: 1, 2, 3, 4, 5, 6, 7, 8
- Valid number of threads per core: 1, 2

**Disable multithreading**

To disable multithreading, specify 1 thread per core.

New console

**To disable multithreading during instance launch**

1. Follow the [Quickly launch an instance (p. 722)](#) procedure and configure your instance as needed.
2. Expand **Advanced details**, and select the **Specify CPU options** check box.
3. For **Core count**, choose the number of required CPU cores. In this example, to specify the default CPU core count for an \textit{r4.4xlarge} instance, choose 8.
4. To disable multithreading, for **Threads per core**, choose 1.
5. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see Launch an instance using the new launch instance wizard (p. 720).

**Old console**

**To disable multithreading during instance launch**

1. Follow the Launch an instance using the old launch instance wizard (p. 730) procedure.
2. On the **Configure Instance Details** page, for **CPU options**, choose **Specify CPU options**.
3. For **Core count**, choose the number of required CPU cores. In this example, to specify the default CPU core count for an \textit{r4.4xlarge} instance, choose 8.
4. To disable multithreading, for **Threads per core**, choose 1.
5. Continue as prompted by the wizard. When you’ve finished reviewing your options on the **Review Instance Launch** page, choose **Launch**. For more information, see Launch an instance using the old launch instance wizard (p. 730).

**AWS CLI**

**To disable multithreading during instance launch**

Use the \texttt{run-instances} AWS CLI command and specify a value of 1 for \texttt{ThreadsPerCore} for the --cpu-options parameter. For \texttt{CoreCount}, specify the number of CPU cores. In this example, to specify the default CPU core count for an \textit{r4.4xlarge} instance, specify a value of 8.

```bash
aws ec2 run-instances \\
  --image-id \textit{ami-1a2b3c4d} \\
  --instance-type \textit{r4.4xlarge} \\
  --cpu-options "CoreCount=8,ThreadsPerCore=1" \\
  --key-name \textit{MyKeyPair}
```

**Specify a custom number of vCPUs at launch**

You can customize the number of CPU cores and threads per core for the instance.

The following example launches an \textit{r4.4xlarge} instance with six vCPUs.

**New console**

**To specify a custom number of vCPUs during instance launch**

1. Follow the Quickly launch an instance (p. 722) procedure and configure your instance as needed.
2. Expand **Advanced details**, and select the **Specify CPU options** check box.
3. To get 6 vCPUs, specify 3 CPU cores and 2 threads per core, as follows:
   - For **Core count**, choose 3.
   - For **Threads per core**, choose 2.
4. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**. For more information, see Launch an instance using the new launch instance wizard (p. 720).
Old console

**To specify a custom number of vCPUs during instance launch**

3. To get 6 vCPUs, specify 3 CPU cores and 2 threads per core, as follows:
   - For **Core count**, choose 3.
   - For **Threads per core**, choose 2.

AWS CLI

**To specify a custom number of vCPUs during instance launch**

Use the `run-instances` AWS CLI command and specify the number of CPU cores and number of threads in the `--cpu-options` parameter. You can specify 3 CPU cores and 2 threads per core to get 6 vCPUs.

```
aws ec2 run-instances \
 --image-id ami-1a2b3c4d \
 --instance-type r4.4xlarge \
 --cpu-options "CoreCount=3,ThreadsPerCore=2" \
 --key-name MyKeyPair
```

Alternatively, specify 6 CPU cores and 1 thread per core (disable multithreading) to get 6 vCPUs:

```
aws ec2 run-instances \
 --image-id ami-1a2b3c4d \
 --instance-type r4.4xlarge \
 --cpu-options "CoreCount=6,ThreadsPerCore=1" \
 --key-name MyKeyPair
```

**Specify a custom number of vCPUs in a launch template**

You can customize the number of CPU cores and threads per core for the instance in a launch template.

The following example creates a launch template that specifies the configuration for an `r4.4xlarge` instance with 6 vCPUs.

Console

**To specify a custom number of vCPUs in a launch template**

2. Expand **Advanced details**, and select the **Specify CPU options** check box.
3. To get 6 vCPUs, specify 3 CPU cores and 2 threads per core, as follows:
   - For **Core count**, choose 3.
   - For **Threads per core**, choose 2.
4. In the **Summary** panel, review your instance configuration, and then choose **Create launch template**. For more information, see [Launch an instance from a launch template (p. 736)](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/launch-templates.html).
AWS CLI

To specify a custom number of vCPUs in a launch template

Use the create-launch-template AWS CLI command and specify the number of CPU cores and number of threads in the CpuOptions parameter. You can specify 3 CPU cores and 2 threads per core to get 6 vCPUs.

```
aws ec2 create-launch-template \
  --launch-template-name TemplateForCPUOptions \
  --version-description CPUOptionsVersion1 \
  --launch-template-data file://template-data.json
```

The following is an example JSON file that contains the launch template data, which includes the CPU options, for the instance configuration for this example.

```
{

  }],
  "ImageId": "ami-8c1be5f6",
  "InstanceType": "r4.4xlarge",
  "TagSpecifications": [{
    "ResourceType": "instance",
    "Tags": [{
      "Key": "Name",
      "Value": "webserver"
    }]
  }],
  "CpuOptions": {
    "CoreCount": 3,
    "ThreadsPerCore": 2
  }
}
```

Alternatively, specify 6 CPU cores and 1 thread per core (disable multithreading) to get 6 vCPUs:

```
{
  "NetworkInterfaces": [{
    "AssociatePublicIpAddress": true,
    "DeviceIndex": 0,
    "Ipv6AddressCount": 1,
    "SubnetId": "subnet-7b16de0c"
  }],
  "ImageId": "ami-8c1be5f6",
  "InstanceType": "r4.4xlarge",
  "TagSpecifications": [{
    "ResourceType": "instance",
    "Tags": [{
      "Key": "Name",
      "Value": "webserver"
    }]
  }],
  "CpuOptions": {
    "CoreCount": 6,
    "ThreadsPerCore": 1
  }
}
```
View the CPU options for your instance

You can view the CPU options for an existing instance in the Amazon EC2 console or by describing the instance using the AWS CLI.

Console

To view the CPU options for an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose Instances and select the instance.
3. On the Details tab, under Host and placement group, find Number of vCPUs.

AWS CLI

To view the CPU options for an instance (AWS CLI)

Use the describe-instances command.

```bash
aws ec2 describe-instances --instance-ids i-123456789abcde123
```

```
... "Instances": [
  { "Monitoring": {
    "State": "disabled"
  }, "PublicDnsName": "ec2-198-51-100-5.eu-central-1.compute.amazonaws.com", "State": {
    "Code": 16,
    "Name": "running"
  }, "EbsOptimized": false, "LaunchTime": "2018-05-08T13:40:33.000Z", "PublicIpAddress": "198.51.100.5", "PrivateIpAddress": "172.31.2.206", "ProductCodes": [], "VpcId": "vpc-1a2b3c4d", "CpuOptions": {
    "CoreCount": 34,
    "ThreadsPerCore": 1
  }, "StateTransitionReason": "",
  ...
}...]
```

In the output that's returned, the CoreCount field indicates the number of cores for the instance. The ThreadsPerCore field indicates the number of threads per core.

Alternatively, connect to your instance and use a tool such as lscpu to view the CPU information for your instance.

You can use AWS Config to record, assess, audit, and evaluate configuration changes for instances, including terminated instances. For more information, see Getting Started with AWS Config in the AWS Config Developer Guide.
CPU features

Amazon EC2 instances support the following CPU features. Support varies by instance type. Refer to the documentation for each CPU feature for more information about the supported instance types.

Topics

- AMD SEV-SNP (p. 988)

AMD SEV-SNP

AMD Secure Encrypted Virtualization-Secure Nested Paging (AMD SEV-SNP) is a CPU feature that provides the following properties:

- **Attestation** – AMD SEV-SNP enables you to retrieve a signed attestation report that contains a cryptographic measure that can be used to validate the instance's state and identity, and that it is running on genuine AMD hardware. For more information, see Attestation with AMD SEV-SNP (p. 991).
- **Memory encryption** – Starting with AMD EPYC (Milan), AWS Graviton2, and Intel Xeon Scalable (Ice Lake) processors, instance memory is always encrypted. Instances that are enabled for AMD SEV-SNP use an instance-specific key for their memory encryption.

Pricing

When you launch an Amazon EC2 instance with AMD SEV-SNP turned on, you are charged an additional hourly usage fee that is equivalent to 10 percent of the On-Demand hourly rate of the selected instance type.

This AMD SEV-SNP usage fee is a separate charge to your Amazon EC2 instance usage. Reserved Instances, Savings Plans, and operating system usage don't impact this fee.

If you configure a Spot Instance to launch with AMD SEV-SNP (p. 988) turned on, you are charged an additional hourly usage fee that is equivalent to 10 percent of the On-Demand hourly rate of the selected instance type. If the allocation strategy uses price as an input, Spot Fleet does not include this additional fee; only the Spot price is used.

Requirements

To use AMD SEV-SNP, you must do the following:

- Use one of the following supported instance types:
  - **General purpose**: m6a.large | m6a.xlarge | m6a.2xlarge | m6a.4xlarge | m6a.8xlarge
  - **Compute optimized**: c6a.large | c6a.xlarge | c6a.2xlarge | c6a.4xlarge | c6a.8xlarge | c6a.12xlarge | c6a.16xlarge
  - **Memory optimized**: r6a.large | r6a.xlarge | r6a.2xlarge | r6a.4xlarge
- Launch your instance in a supported AWS Region. Currently, only US East (Ohio) and Europe (Ireland) are supported.
- Use an AMI with uefi or uefi-preferred boot mode and an operating system that supports AMD SEV-SNP. For more information about AMD SEV-SNP support on your operating system, refer to the respective operating system's documentation. For AWS, AMD SEV-SNP is supported on Amazon Linux 2023, RHEL 9.3, and Ubuntu 23.04 and later.

Considerations

Keep the following in mind when working with AMD SEV-SNP.
• AMD SEV-SNP can only be turned on when you launch an instance. When AMD SEV-SNP is turned on during launch, it will remain turned on throughout the instance's lifecycle.

• You can change the instance type (p. 479) for an instance that has AMD SEV-SNP turned on only to another instance type that supports AMD SEV-SNP.

• Hibernation and Nitro Enclaves are not supported when AMD SEV-SNP is turned on.

• Dedicated Hosts are not supported.

• If the underlying host for your instance is scheduled for maintenance, you will receive a scheduled event notification 14 days before the event. You must manually stop or restart your instance to move it to a new host.

Concepts and terminology

Before you begin using AMD SEV-SNP, ensure that you are familiar with the following concepts and terminology.

AMD SEV-SNP attestation report

The AMD SEV-SNP attestation report is a document that an instance can request from the CPU. The AMD SEV-SNP attestation report can be used to validate the state and identity of an instance, and to verify that it is running in a sanctioned AMD environment. The report includes a launch measurement, which is a cryptographic hash of the initial boot state of an instance, including its initial instance memory contents and initial state of the vCPUs. The AMD SEV-SNP attestation report is signed with a VLEK signature that chains back to an AMD root of trust.

VLEK

The Versioned Loaded Endorsement Key (VLEK) is a versioned signing key that is certified by AMD and used by the AMD CPU to sign the AMD SEV-SNP attestation reports. VLEK signatures can be validated using certificates provided by AMD.

OVMF binary

The Open Virtual Machine Firmware (OVMF) is the early-boot code that is used to provide a UEFI environment for the instance. The early-boot code is run before the code in the AMI is booted. The OVMF also finds and runs the boot loader provided in the AMI. For more information, see the OVMF repository.

Working with AMD SEV-SNP

Topics

• Find supported instance types (p. 989)
• Turn on AMD SEV-SNP at launch (p. 990)
• Check AMD SEV-SNP status (p. 990)

Find supported instance types

You can use the AWS CLI to find instance types that support AMD SEV-SNP.

AWS CLI

To find the instance types that support AMD SEV-SNP using the AWS CLI, use the following describe-instance-types command.

$ aws ec2 describe-instance-types \
  --filters Name=processor-info.supported-features,Values=amd-sev-snp \

CPU features

Example output.

```
[  
  "r6a.2xlarge",
  "m6a.large",
  "m6a.2xlarge",
  "r6a.xlarge",
  "c6a.16xlarge",
  "c6a.8xlarge",
  "m6a.4xlarge",
  "c6a.12xlarge",
  "r6a.4xlarge",
  "c6a.xlarge",
  "c6a.xlarge",
  "c6a.4xlarge",
  "c6a.2xlarge",
  "m6a.xlarge",
  "c6a.large",
  "r6a.large",
  "m6a.8xlarge"
]
```

**Turn on AMD SEV-SNP at launch**

You can use the AWS CLI to launch an instance with AMD SEV-SNP turned on.

**AWS CLI**

To launch an instance with AMD SEV-SNP turned on using the AWS CLI, use the `run-instances` command and include the `--cpu-options AmdSevSnp=enabled` option. For `--image-id`, specify an AMI with the `uefi` or `uefi-preferred` boot mode and an operating system that supports AMD SEV-SNP. For `--instance-type`, specify a supported instance type.

```
$ aws ec2 run-instances \
--image-id supported_ami_id \
--instance-type supported_instance_type \
--key-name key_pair_name \
--subnet-id subnet_id \
--cpu-options AmdSevSnp=enabled
```

**Check AMD SEV-SNP status**

You can use one of the following methods to find instance types that support AMD SEV-SNP.

**AWS CLI**

To check whether AMD SEV-SNP is turned on for an instance using the AWS CLI, use the `describe-instances` command. For `--instance-ids`, specify the ID of the instance to check.

```
$ aws ec2 describe-instances --instance-ids instance_id
```

In the command output, the value for `AmdSevSnp` in `CpuOptions` indicates whether AMD SEV-SNP is turned on or off.

**AWS CloudTrail**

In the AWS CloudTrail event for the instance launch request, a value of "cpuOptions": {"AmdSevSnp": enabled} indicates that AMD SEV-SNP is turned on for the instance.
Attestation with AMD SEV-SNP

Attestation is a process that allows your instance to prove its state and identity. When you turn on AMD SEV-SNP for your instance, you can request an AMD SEV-SNP attestation report from the underlying processor. The AMD SEV-SNP attestation report contains a cryptographic hash, called the launch measurement, of the initial guest memory contents and initial vCPU state. The attestation report is signed with a VLEK signature that chains back to an AMD root of trust. You can use the launch measurement included in the attestation report to validate that the instance is running in a genuine AMD environment and to validate the initial boot code that was used to launch the instance.

To perform attestation with AMD SEV-SNP, complete the following steps.

Step 1: Get the attestation report

In this step, you install the required tools, and then request the AMD SEV-SNP attestation report from the processor and the VLEK signing key for the processor.

1. You must use the `sev-guest` utility to request the attestation report from the CPU. To install the `sev-guest` utility from the `sev-guest` repository, run the following commands.

   ```bash
   $ git clone https://github.com/AMDESE/sev-guest.git
   $ cd sev-guest
   $ make sev-guest-get-report
   $ make sev-guest-parse-report
   ```

2. Use the `sev-guest` utility to request the attestation report and the VLEK certificate that was used to sign the attestation report.

   ```bash
   $ sudo ./sev-guest-get-report guest_report.bin -x
   ```

   The command creates two files:
   - `guest_report.bin` – The signed attestation report.
   - `a8074bc2-a25a-483e-aae6-39c045a0b8a1` – The VLEK certificate, in Distinguished Encoding Rules (DER) format, that was used to sign the attestation report.

Step 2: Validate the attestation report’s signature

The attestation report is signed with a certificate, called the Versioned Loaded Endorsement Key (VLEK), which is issued by AMD for AWS. In this step, you will validate that the VLEK certificate is issued by AMD, and that the attestation report is signed by that VLEK certificate.

1. You must use the `sev-tool` utility to validate that the attestation report is signed by the VLEK certificate. The utility requires that the attestation report and the VLEK certificate be in a folder named `/certs`. Run the following command to create the `/certs` directory.

   ```bash
   $ sudo mkdir certs
   ```

2. Convert the DER-encoded VLEK certificate (`a8074bc2-a25a-483e-aae6-39c045a0b8a1`) into the PEM format, which is required by the `sev-guest` utility.

   ```bash
   $ sudo openssl x509 -inform der -in a8074bc2-a25a-483e-aae6-39c045a0b8a1 -out certs/vcek.pem
   ```

   The VLEK certificate is written to a new file, named `vcek.pem`, in the `/certs` directory.

3. Download the VLEK root of trust certificates from the official AMD website to the `/certs` directory.
4. Use `openssl` to validate that the VLEK certificate is signed by the AMD root of trust certificates.

```bash
$ sudo openssl verify --CAfile certs/cert_chain.pem certs/vcek.pem
```

Expected output.

```
certs/vcek.pem: OK
```

5. Copy the attestation report to the `/certs` directory.

```bash
$ sudo cp guest_report.bin certs/
```

6. You must use the `sev-tool` utility to validate the attestation report signature. Run the following commands to install the `sev-tool` utility.

```bash
$ cd ..
$ git clone https://github.com/AMDESE/sev-tool.git
$ cd sev-tool
$ autoreconf -vif && ./configure && make
```

7. Use the `sev-tool` utility to validate that the attestation report is signed by the VLEK certificate.

```bash
$ sudo ./src/sevtool --ofolder ../sev-guest/certs --validate_guest_report
```

Expected output.

```
Guest report validated successfully!
```

---

**Change the hostname of your Amazon Linux instance**

When you launch an instance into a private VPC, Amazon EC2 assigns a guest OS hostname. The type of hostname that Amazon EC2 assigns depends on your subnet settings. For more information about EC2 hostnames, see Amazon EC2 instance hostname types (p. 1374).

A typical Amazon EC2 private DNS name for an EC2 instance configured to use IP-based naming with an IPv4 address looks something like this: `ip-12-34-56-78.us-west-2.compute.internal`, where the name consists of the internal domain, the service (in this case, `compute`), the region, and a form of the private IPv4 address. Part of this hostname is displayed at the shell prompt when you log into your instance (for example, `ip-12-34-56-78`). Each time you stop and restart your Amazon EC2 instance (unless you are using an Elastic IP address), the public IPv4 address changes, and so does your public DNS name, system hostname, and shell prompt.

**Important**

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

**Change the system hostname**

If you have a public DNS name registered for the IP address of your instance (such as `webserver.mydomain.com`), you can set the system hostname so your instance identifies itself as a part of that domain. This also changes the shell prompt so that it displays the first portion of this name
instead of the hostname supplied by AWS (for example, ip-12-34-56-78). If you do not have a public DNS name registered, you can still change the hostname, but the process is a little different.

In order for your hostname update to persist, you must verify that the preserve_hostname cloud-init setting is set to true. You can run the following command to edit or add this setting:

```
sudo vi /etc/cloud/cloud.cfg
```

If the preserve_hostname setting is not listed, add the following line of text to the end of the file:

```
preserve_hostname: true
```

To change the system hostname to a public DNS name

Follow this procedure if you already have a public DNS name registered.

1. • For Amazon Linux 2: Use the hostnamectl command to set your hostname to reflect the fully qualified domain name (such as webserver.mydomain.com).

   ```
   [ec2-user ~]$ sudo hostnamectl set-hostname webserver.mydomain.com
   ```

   • For Amazon Linux AMI: On your instance, open the /etc/sysconfig/network configuration file in your favorite text editor and change the HOSTNAME entry to reflect the fully qualified domain name (such as webserver.mydomain.com).

   ```
   HOSTNAME=webserver.mydomain.com
   ```

2. Reboot the instance to pick up the new hostname.

   ```
   [ec2-user ~]$ sudo reboot
   ```

Alternatively, you can reboot using the Amazon EC2 console (on the Instances page, select the instance and choose Instance state, Reboot instance).

3. Log into your instance and verify that the hostname has been updated. Your prompt should show the new hostname (up to the first ".") and the hostname command should show the fully-qualified domain name.

   ```
   [ec2-user@webserver ~]$ hostname
   webserver.mydomain.com
   ```

To change the system hostname without a public DNS name

1. • For Amazon Linux 2: Use the hostnamectl command to set your hostname to reflect the desired system hostname (such as webserver).

   ```
   [ec2-user ~]$ sudo hostnamectl set-hostname webserver
   ```

   • For Amazon Linux AMI: On your instance, open the /etc/sysconfig/network configuration file in your favorite text editor and change the HOSTNAME entry to reflect the desired system hostname (such as webserver).

   ```
   HOSTNAME=webserver
   ```

2. Open the /etc/hosts file in your favorite text editor and change the entry beginning with 127.0.0.1 to match the example below, substituting your own hostname.
Amazon Elastic Compute Cloud  
User Guide for Linux Instances  
Change the hostname

| 127.0.0.1 webserver.localdomain webserver localhost4 localhost4.localdomain4 |

3. Reboot the instance to pick up the new hostname.

```
[ec2-user ~]$ sudo reboot
```

Alternatively, you can reboot using the Amazon EC2 console (on the Instances page, select the instance and choose Instance state, Reboot instance).

4. Log into your instance and verify that the hostname has been updated. Your prompt should show the new hostname (up to the first ".") and the hostname command should show the fully-qualified domain name.

```
[ec2-user@webserver ~]$ hostname
webserver.localdomain
```

You can also implement more programmatic solutions, such as specifying user data to configure your instance. If your instance is part of an Auto Scaling group, you can use lifecycle hooks to define user data. For more information, see Run commands on your Linux instance at launch and Lifecycle hook for instance launch in the AWS CloudFormation User Guide.

**Change the shell prompt without affecting the hostname**

If you do not want to modify the hostname for your instance, but you would like to have a more useful system name (such as `webserver`) displayed than the private name supplied by AWS (for example, `ip-12-34-56-78`), you can edit the shell prompt configuration files to display your system nickname instead of the hostname.

**To change the shell prompt to a host nickname**

1. Create a file in `/etc/profile.d` that sets the environment variable called NICKNAME to the value you want in the shell prompt. For example, to set the system nickname to `webserver`, run the following command.

```
[ec2-user ~]$ sudo sh -c 'echo "export NICKNAME=webserver" > /etc/profile.d/prompt.sh'
```

2. Open the `/etc/bashrc` (Red Hat) or `/etc/bash.bashrc` (Debian/Ubuntu) file in your favorite text editor (such as `vim` or `nano`). You need to use `sudo` with the editor command because `/etc/bashrc` and `/etc/bash.bashrc` are owned by root.

3. Edit the file and change the shell prompt variable (PS1) to display your nickname instead of the hostname. Find the following line that sets the shell prompt in `/etc/bashrc` or `/etc/bash.bashrc` (several surrounding lines are shown below for context; look for the line that starts with `"$PS1"`):

```
# Turn on checkwinsize
shopt -s checkwinsize
[ "$PS1" = "\(\[ -n \"\H\" \] && \H)\" ] && PS1="[\u@\h \W]\$ "
# You might want to have e.g. tty in prompt (e.g. more virtual machines)
# and console windows
```

Change the \h (the symbol for hostname) in that line to the value of the NICKNAME variable.

```
# Turn on checkwinsize
shopt -s checkwinsize
```

994
4. (Optional) To set the title on shell windows to the new nickname, complete the following steps.
   a. Create a file named `/etc/sysconfig/bash-prompt-xterm`.
      ```
      [ec2-user ~]$ sudo touch /etc/sysconfig/bash-prompt-xterm
      ```
   b. Make the file executable using the following command.
      ```
      [ec2-user ~]$ sudo chmod +x /etc/sysconfig/bash-prompt-xterm
      ```
   c. Open the `/etc/sysconfig/bash-prompt-xterm` file in your favorite text editor (such as `vim` or `nano`). You need to use `sudo` with the editor command because `/etc/sysconfig/bash-prompt-xterm` is owned by `root`.
   d. Add the following line to the file.
      ```
      echo -ne "\033[0;${USER}@${NICKNAME}:${PWD/#$HOME/-}\007"
      ```

5. Log out and then log back in to pick up the new nickname value.

### Change the hostname on other Linux distributions

The procedures on this page are intended for use with Amazon Linux only. For more information about other Linux distributions, see their specific documentation and the following articles:

- How do I assign a static hostname to a private Amazon EC2 instance running RHEL 7 or Centos 7?

### Set up dynamic DNS on your Amazon Linux instance

When you launch an EC2 instance, it is assigned a public IP address and a public Domain Name System (DNS) name that you can use to reach it from the internet. Because there are so many hosts in the Amazon Web Services domain, these public names must be quite long for each name to remain unique. A typical Amazon EC2 public DNS name looks something like this: `ec2-12-34-56-78.us-west-2.compute.amazonaws.com`, where the name consists of the Amazon Web Services domain, the service (in this case, compute), the AWS Region, and a form of the public IP address.

Dynamic DNS services provide custom DNS host names within their domain area that can be easy to remember and that can also be more relevant to your host's use case. Some of these services are also free of charge. You can use a dynamic DNS provider with Amazon EC2 and configure the instance to update the IP address associated with a public DNS name each time the instance starts. There are many different providers to choose from, and the specific details of choosing a provider and registering a name with them are outside the scope of this guide.

**Important**

This information applies to Amazon Linux. For information about other distributions, see their specific documentation.

#### To use dynamic DNS with Amazon EC2

1. Sign up with a dynamic DNS service provider and register a public DNS name with their service. This procedure uses the free service from `noip.com/free` as an example.
2. Configure the dynamic DNS update client. After you have a dynamic DNS service provider and a public DNS name registered with their service, point the DNS name to the IP address for your
instance. Many providers (including noip.com) allow you to do this manually from your account page on their website, but many also support software update clients. If an update client is running on your EC2 instance, your dynamic DNS record is updated each time the IP address changes, as happens after a shutdown and restart. In this example, you install the noip2 client, which works with the service provided by noip.com.

a. Enable the Extra Packages for Enterprise Linux (EPEL) repository to gain access to the noip2 client.

   Note
   Amazon Linux instances have the GPG keys and repository information for the EPEL repository installed by default; however, Red Hat and CentOS instances must first install the epel-release package before you can enable the EPEL repository. For more information and to download the latest version of this package, see https://fedoraproject.org/wiki/EPEL.

b. Install the noip package.

   [ec2-user ~]$ sudo yum install -y noip

c. Create the configuration file. Enter the login and password information when prompted and answer the subsequent questions to configure the client.

   [ec2-user ~]$ sudo noip2 -C

3. Enable the noip service.

   • For Amazon Linux 2

   [ec2-user ~]$ sudo systemctl enable noip.service

   • For Amazon Linux AMI

   [ec2-user ~]$ sudo chkconfig noip on

4. Start the noip service.

   • For Amazon Linux 2

   [ec2-user ~]$ sudo systemctl start noip.service

   • For Amazon Linux AMI

   [ec2-user ~]$ sudo service noip start

This command starts the client, which reads the configuration file (/etc/no-ip2.conf) that you created earlier and updates the IP address for the public DNS name that you chose.
Verify that the update client has set the correct IP address for your dynamic DNS name. Allow a few minutes for the DNS records to update, and then try to connect to your instance using SSH with the public DNS name that you configured in this procedure.

Run commands on your Linux instance at launch

When you launch an instance in Amazon EC2, you have the option of passing user data to the instance that can be used to perform common automated configuration tasks and even run scripts after the instance starts. You can pass two types of user data to Amazon EC2: shell scripts and cloud-init directives. You can also pass this data into the launch instance wizard as plain text, as a file (this is useful for launching instances using the command line tools), or as base64-encoded text (for API calls).

If you're interested in more complex automation scenarios, you might consider AWS CloudFormation or AWS OpsWorks. For more information, see the following:

- Deploying applications on Amazon EC2 with AWS CloudFormation in the AWS CloudFormation User Guide.
- AWS OpsWorks User Guide.

For information about running commands on your Windows instance at launch, see Run commands on your Windows instance at launch and Manage Windows instance configuration in the Amazon EC2 User Guide for Windows Instances.

In the following examples, the commands from the Install a LAMP Web Server on Amazon Linux 2 (p. 36) are converted to a shell script and a set of cloud-init directives that run when the instance launches. In each example, the following tasks are performed by the user data:

- The distribution software packages are updated.
- The necessary web server, php, and mariadb packages are installed.
- The httpd service is started and turned on via systemctl.
- The ec2-user is added to the apache group.
- The appropriate ownership and file permissions are set for the web directory and the files contained within it.
- A simple web page is created to test the web server and PHP engine.

Contents

- Prerequisites (p. 997)
- User data and shell scripts (p. 998)
- User data and the console (p. 998)
- User data and cloud-init directives (p. 1000)
- User data and the AWS CLI (p. 1001)
- Combine shell scripts and cloud-init directives (p. 1003)

Prerequisites

The examples in this topic assume the following:

- Your instance has a public DNS name that is reachable from the internet. For more information, see Auto-assign Public IP in the Network settings (p. 724) section and Create a security group (p. 9).
• The security group associated with your instance is configured to allow SSH (port 22) traffic so that you can connect to the instance to view the output log files. For more information, see Create a security group (p. 9).

• Your instance is launched with an Amazon Linux 2 AMI. These instructions are intended for use with Amazon Linux 2, and the commands and directives may not work for other Linux distributions. For more information about other distributions, such as their support for cloud-init, see their specific documentation.

User data and shell scripts

If you are familiar with shell scripting, this is the easiest and most complete way to send instructions to an instance at launch. Adding these tasks at boot time adds to the amount of time it takes to boot the instance. You should allow a few minutes of extra time for the tasks to complete before you test that the user script has finished successfully.

Important
By default, user data scripts and cloud-init directives run only during the boot cycle when you first launch an instance. You can update your configuration to ensure that your user data scripts and cloud-init directives run every time you restart your instance. For more information, see How can I utilize user data to automatically run a script with every restart of my Amazon EC2 Linux instance? in the AWS Knowledge Center.

User data shell scripts must start with the #! characters and the path to the interpreter you want to read the script (commonly /bin/bash). For a great introduction on shell scripting, see the BASH Programming HOW-TO at the Linux Documentation Project (tldp.org).

Scripts entered as user data are run as the root user, so do not use the sudo command in the script. Remember that any files you create will be owned by the root user; if you need a non-root user to have file access, you should modify the permissions accordingly in the script. Also, because the script is not run interactively, you cannot include commands that require user feedback (such as yum update without the -y flag).

If you use an AWS API, including the AWS CLI, in a user data script, you must use an instance profile when launching the instance. An instance profile provides the appropriate AWS credentials required by the user data script to issue the API call. For more information, see Using instance profiles in the IAM User Guide. The permissions you assign to the IAM role depend on which services you are calling with the API. For more information, see IAM roles for Amazon EC2.

The permissions you assign to the IAM role depend on which services you are calling with the API.

The cloud-init output log file captures console output so it is easy to debug your scripts following a launch if the instance does not behave the way you intended. To view the log file, connect to the instance (p. 811) and open /var/log/cloud-init-output.log.

When a user data script is processed, it is copied to and run from /var/lib/cloud/instances/instance-id/. The script is not deleted after it is run. Be sure to delete the user data scripts from /var/lib/cloud/instances/instance-id/ before you create an AMI from the instance. Otherwise, the script will exist in this directory on any instance launched from the AMI.

User data and the console

You can specify instance user data when you launch the instance. If the root volume of the instance is an EBS volume, you can also stop the instance and update its user data.

Specify instance user data at launch

Follow the procedure for launching an instance (p. 722). The User data field is located in the Advanced details (p. 727) section of the launch instance wizard. Enter your shell script in the User data field, and then complete the instance launch procedure.
In the example script below, the script creates and configures our web server.

```bash
#!/bin/bash
yum update -y
amazon-linux-extras install -y lamp-mariadb10.2-php7.2 php7.2
yum install -y httpd mariadb-server
systemctl start httpd
systemctl enable httpd
usermod -a -G apache ec2-user
chown -R ec2-user:apache /var/www
chmod 2775 /var/www
find /var/www -type d -exec chmod 2775 {} \
find /var/www -type f -exec chmod 0664 {} \

```

Allow enough time for the instance to launch and run the commands in your script, and then check to see that your script has completed the tasks that you intended.

For our example, in a web browser, enter the URL of the PHP test file the script created. This URL is the public DNS address of your instance followed by a forward slash and the file name.

```
http://my.public.dns.amazonaws.com/phpinfo.php
```

You should see the PHP information page. If you are unable to see the PHP information page, check that the security group you are using contains a rule to allow HTTP (port 80) traffic. For more information, see Add rules to a security group (p. 2032).

(Optional) If your script did not accomplish the tasks you were expecting it to, or if you just want to verify that your script completed without errors, connect to the instance (p. 811), examine the cloud-init output log file (/var/log/cloud-init-output.log), and look for error messages in the output.

For additional debugging information, you can create a Mime multipart archive that includes a cloud-init data section with the following directive:

```
output : { all : '| tee -a /var/log/cloud-init-output.log' }
```

This directive sends command output from your script to /var/log/cloud-init-output.log. For more information about cloud-init data formats and creating Mime multi part archive, see cloud-init Formats.

**View and update the instance user data**

To update the instance user data, you must first stop the instance. If the instance is running, you can view the user data but you cannot modify it.

**Warning**
When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

**To modify instance user data**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Instance state, Stop instance. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.
4. When prompted for confirmation, choose Stop. It can take a few minutes for the instance to stop.
5. With the instance still selected, choose Actions, Instance settings, Edit user data.
6. Modify the user data as needed, and then choose Save.
7. Start the instance. The new user data is visible on your instance after you start it; however, user data scripts are not run.

User data and cloud-init directives

The cloud-init package configures specific aspects of a new Amazon Linux instance when it is launched; most notably, it configures the `.ssh/authorized_keys` file for the ec2-user so you can log in with your own private key. For more information about the configuration tasks that the cloud-init package performs for Amazon Linux instances, see cloud-init (p. 259).

The cloud-init user directives can be passed to an instance at launch the same way that a script is passed, although the syntax is different. For more information about cloud-init, see http://cloudinit.readthedocs.org/en/latest/index.html.

**Important**
By default, user data scripts and cloud-init directives run only during the boot cycle when you first launch an instance. You can update your configuration to ensure that your user data scripts and cloud-init directives run every time you restart your instance. For more information, see How can I utilize user data to automatically run a script with every restart of my Amazon EC2 Linux instance? in the AWS Knowledge Center.

Adding these tasks at boot time adds to the amount of time it takes to boot an instance. You should allow a few minutes of extra time for the tasks to complete before you test that your user data directives have completed.

To pass cloud-init directives to an instance with user data

1. Follow the procedure for launching an instance (p. 722). The User data field is located in the Advanced details (p. 727) section of the launch instance wizard. Enter your cloud-init directive text in the User data field, and then complete the instance launch procedure.

   In the example below, the directives create and configure a web server on Amazon Linux 2. The `#cloud-config` line at the top is required in order to identify the commands as cloud-init directives.

   ```
   #cloud-config
   repo_update: true
   repo_upgrade: all

   packages:
   - httpd
   - mariadb-server

   runcmd:
   - [ sh, -c, "amazon-linux-extras install -y lamp-mariadb10.2-php7.2 php7.2" ]
   - systemctl start httpd
   - sudo systemctl enable httpd
   - [ sh, -c, "usermod -a -G apache ec2-user" ]
   - [ sh, -c, "chown -R ec2-user:apache /var/www" ]
   - chmod 2775 /var/www
   - [ find, /var/www, -type, d, -exec, chmod, 2775, {}, \; ]
   - [ find, /var/www, -type, f, -exec, chmod, 0664, {}, \; ]
   ```

2. Allow enough time for the instance to launch and run the directives in your user data, and then check to see that your directives have completed.
For this example, in a web browser, enter the URL of the PHP test file the directives created. This URL is the public DNS address of your instance followed by a forward slash and the file name.

```
http://my.public.dns.amazonaws.com/phpinfo.php
```

You should see the PHP information page. If you are unable to see the PHP information page, check that the security group you are using contains a rule to allow HTTP (port 80) traffic. For more information, see Add rules to a security group (p. 2032).

3. (Optional) If your directives did not accomplish the tasks you were expecting them to, or if you just want to verify that your directives completed without errors, connect to the instance (p. 811), examine the output log file (/var/log/cloud-init-output.log), and look for error messages in the output. For additional debugging information, you can add the following line to your directives:

```
output : { all : '| tee -a /var/log/cloud-init-output.log' }
```

This directive sends runcmd output to /var/log/cloud-init-output.log.

### User data and the AWS CLI

You can use the AWS CLI to specify, modify, and view the user data for your instance. For information about viewing user data from your instance using instance metadata, see Retrieve instance user data from your instance (p. 1030).

On Windows, you can use the AWS Tools for Windows PowerShell instead of using the AWS CLI. For more information, see User data and the Tools for Windows PowerShell in the Amazon EC2 User Guide for Windows Instances.

**Example: Specify user data at launch**

To specify user data when you launch your instance, use the run-instances command with the --user-data parameter. With run-instances, the AWS CLI performs base64 encoding of the user data for you.

The following example shows how to specify a script as a string on the command line:

```
aws ec2 run-instances --image-id ami-abcd1234 --count 1 --instance-type m3.medium --key-name my-key-pair --subnet-id subnet-abcd1234 --security-group-ids sg-abcd1234 --user-data echo user data
```

The following example shows how to specify a script using a text file. Be sure to use the file:// prefix to specify the file.

```
aws ec2 run-instances --image-id ami-abcd1234 --count 1 --instance-type m3.medium --key-name my-key-pair --subnet-id subnet-abcd1234 --security-group-ids sg-abcd1234 --user-data file://my_script.txt
```

The following is an example text file with a shell script.

```
#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on
```

**Example: Modify the user data of a stopped instance**
You can modify the user data of a stopped instance using the `modify-instance-attribute` command. With `modify-instance-attribute`, the AWS CLI does not perform base64 encoding of the user data for you.

- On a **Linux** computer, use the base64 command to encode the user data.

```bash
base64 my_script.txt >my_script_base64.txt
```

- On a **Windows** computer, use the certutil command to encode the user data. Before you can use this file with the AWS CLI, you must remove the first (BEGIN CERTIFICATE) and last (END CERTIFICATE) lines.

```bash
certutil -encode my_script.txt my_script_base64.txt
notepad my_script_base64.txt
```

Use the `--attribute` and `--value` parameters to use the encoded text file to specify the user data. Be sure to use the `file://` prefix to specify the file.

```bash
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --attribute userData --value file://my_script_base64.txt
```

**Example: Clear the user data of a stopped instance**

To delete the existing user data, use the `modify-instance-attribute` command as follows:

```bash
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --user-data Value=
```

**Example: View user data**

To retrieve the user data for an instance, use the `describe-instance-attribute` command. With `describe-instance-attribute`, the AWS CLI does not perform base64 decoding of the user data for you.

```bash
aws ec2 describe-instance-attribute --instance-id i-1234567890abcdef0 --attribute userData
```

The following is example output with the user data base64 encoded.

```
{
    "UserData": {
        "Value": "IyEvYmluL2Jhc2gKeXVtIHVwZGF0ZSAteQpzZXJ2aWNlIGh0dHBkIHN0YXJ0CmNoa2NvbmZpZyBodHRwZCBvbg==",
        "InstanceId": "i-1234567890abcdef0"
    }
}
```

- On a **Linux** computer, use the `--query` option to get the encoded user data and the base64 command to decode it.

```bash
aws ec2 describe-instance-attribute --instance-id i-1234567890abcdef0 --attribute userData --output text --query "UserData.Value" | base64 --decode
```

- On a **Windows** computer, use the `--query` option to get the coded user data and the certutil command to decode it. Note that the encoded output is stored in a file and the decoded output is stored in another file.

```bash
aws ec2 describe-instance-attribute --instance-id i-1234567890abcdef0 --attribute userData --output text --query "UserData.Value" >my_output.txt
```
Run commands at launch

```
certutil -decode my_output.txt my_output_decoded.txt
type my_output_decoded.txt
```

The following is example output.

```
#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on
```

Combine shell scripts and cloud-init directives

By default, you can include only one content type in user data at a time. However, you can use the text/cloud-config and text/x-shellscript content-types in a mime-multi part file to include both a shell script and cloud-init directives in your user data.

The following shows the mime-multi part format.

```
Content-Type: multipart/mixed; boundary="//"
MIME-Version: 1.0

--//
Content-Type: text/cloud-config; charset="us-ascii"
MIME-Version: 1.0
Content-Transfer-Encoding: 7bit
Content-Disposition: attachment; filename="cloud-config.txt"
#cloud-config
could-init directives

--//
Content-Type: text/x-shellscript; charset="us-ascii"
MIME-Version: 1.0
Content-Transfer-Encoding: 7bit
Content-Disposition: attachment; filename="userdata.txt"

#!/bin/bash
shell script commands
--//--
```

For example, the following user data includes cloud-init directives and a bash shell script. The cloud-init directives creates a file (/test-cloudinit/cloud-init.txt), and writes Created by cloud-init to that file. The bash shell script creates a file (/test-userscript/userscript.txt) and writes Created by bash shell script to that file.

```
Content-Type: multipart/mixed; boundary="//"
MIME-Version: 1.0

--//--
Content-Type: text/cloud-config; charset="us-ascii"
MIME-Version: 1.0
Content-Transfer-Encoding: 7bit
Content-Disposition: attachment; filename="cloud-config.txt"
#cloud-config
runcmd:
  - [ mkdir, /test-cloudinit ]
write_files:
  - path: /test-cloudinit/cloud-init.txt
```
Instance metadata and user data

Instance metadata is data about your instance that you can use to configure or manage the running instance. Instance metadata is divided into categories (p. 1032), for example, host name, events, and security groups.

You can also use instance metadata to access user data that you specified when launching your instance. For example, you can specify parameters for configuring your instance, or include a simple script. You can build generic AMIs and use user data to modify the configuration files supplied at launch time. For example, if you run web servers for various small businesses, they can all use the same generic AMI and retrieve their content from the Amazon S3 bucket that you specify in the user data at launch. To add a new customer at any time, create a bucket for the customer, add their content, and launch your AMI with the unique bucket name provided to your code in the user data. If you launch more than one instance at the same time, the user data is available to all instances in that reservation. Each instance that is part of the same reservation has a unique ami-launch-index number, allowing you to write code that controls what to do. For example, the first host might elect itself as the original node in a cluster. For a detailed AMI launch example, see Example: AMI launch index value (p. 1041).

EC2 instances can also include dynamic data, such as an instance identity document that is generated when the instance is launched. For more information, see Dynamic data categories (p. 1041).

Important
Although you can only access instance metadata and user data from within the instance itself, the data is not protected by authentication or cryptographic methods. Anyone who has direct access to the instance, and potentially any software running on the instance, can view its metadata. Therefore, you should not store sensitive data, such as passwords or long-lived encryption keys, as user data.

Note
The examples in this topic use the IPv4 address of the Instance Metadata Service (IMDS): 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the IMDS is compatible with IMDSv2 commands. The IPv6 address is only accessible on Instances built on the Nitro System (p. 295).

Contents
- Use IMDSv2 (p. 1005)
- Configure the instance metadata options (p. 1010)
- Retrieve instance metadata (p. 1021)
- Work with instance user data (p. 1030)
- Retrieve dynamic data (p. 1031)
- Instance metadata categories (p. 1032)
- Example: AMI launch index value (p. 1041)
Use IMDSv2

You can access instance metadata from a running instance using one of the following methods:

- Instance Metadata Service Version 1 (IMDSv1) – a request/response method
- Instance Metadata Service Version 2 (IMDSv2) – a session-oriented method

By default, you can use either IMDSv1 or IMDSv2, or both.

You can configure the Instance Metadata Service (IMDS) on each instance so that local code or users must use IMDSv2. When you specify that IMDSv2 must be used, IMDSv1 no longer works. For information about how to configure your instance to use IMDSv2, see Configure the instance metadata options (p. 1010).

The PUT or GET headers are unique to IMDSv2. If these headers are present in the request, then the request is intended for IMDSv2. If no headers are present, it is assumed the request is intended for IMDSv1.

For an extensive review of IMDSv2, see Add defense in depth against open firewalls, reverse proxies, and SSRF vulnerabilities with enhancements to the EC2 Instance Metadata Service.

To retrieve instance metadata, see Retrieve instance metadata (p. 1021).

Topics

- How Instance Metadata Service Version 2 works (p. 1005)
- Transition to using Instance Metadata Service Version 2 (p. 1007)
- Use a supported AWS SDK (p. 1010)

How Instance Metadata Service Version 2 works

IMDSv2 uses session-oriented requests. With session-oriented requests, you create a session token that defines the session duration, which can be a minimum of one second and a maximum of six hours. During the specified duration, you can use the same session token for subsequent requests. After the specified duration expires, you must create a new session token to use for future requests.

Note

The examples in this section use the IPv4 address of the Instance Metadata Service (IMDS): 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the IMDS is compatible with IMDSv2 commands. The IPv6 address is only accessible on Instances built on the Nitro System (p. 295).

The following example uses a Linux shell script and IMDSv2 to retrieve the top-level instance metadata items. The example:

- Creates a session token lasting six hours (21,600 seconds) using the PUT request
- Stores the session token header in a variable named TOKEN
- Requests the top-level metadata items using the token

You can run two separate commands, or combine them.

Separate commands
First, generate a token using the following command.

```
```

Then, use the token to generate top-level metadata items using the following command.

```
```

**Combined commands**

You can store the token and combine the commands. The following example combines the above two commands and stores the session token header in a variable named TOKEN.

```
```

After you've created a token, you can reuse it until it expires. In the following example command, which gets the ID of the AMI used to launch the instance, the token that is stored in $TOKEN in the previous example is reused.

```
```

When you use IMDSv2 to request instance metadata, the request must include the following:

1. Use a PUT request to initiate a session to the instance metadata service. The PUT request returns a token that must be included in subsequent GET requests to the instance metadata service. The token is required to access metadata using IMDSv2.
2. Include the token in all GET requests to the IMDS. When token usage is set to required, requests without a valid token or with an expired token receive a 401 - Unauthorized HTTP error code.
   - The token is an instance-specific key. The token is not valid on other EC2 instances and will be rejected if you attempt to use it outside of the instance on which it was generated.
   - The PUT request must include a header that specifies the time to live (TTL) for the token, in seconds, up to a maximum of six hours (21,600 seconds). The token represents a logical session. The TTL specifies the length of time that the token is valid and, therefore, the duration of the session.
   - After a token expires, to continue accessing instance metadata, you must create a new session using another PUT.
   - You can choose to reuse a token or create a new token with every request. For a small number of requests, it might be easier to generate and immediately use a token each time you need to access the IMDS. But for efficiency, you can specify a longer duration for the token and reuse it rather than having to write a PUT request every time you need to request instance metadata. There is no practical limit on the number of concurrent tokens, each representing its own session. IMDSv2 is, however, still constrained by normal IMDS connection and throttling limits. For more information, see [Query throttling](p. 1028).

HTTP GET and HEAD methods are allowed in IMDSv2 instance metadata requests. PUT requests are rejected if they contain an X-Forwarded-For header.
By default, the response to PUT requests has a response hop limit (time to live) of 1 at the IP protocol level. If you need a bigger hop limit, you can adjust it by using the modify-instance-metadata-options AWS CLI command. For example, you might need a bigger hop limit for backward compatibility with container services running on the instance. For more information, see Modify instance metadata options for existing instances (p. 1016).

Transition to using Instance Metadata Service Version 2

When migrating to IMDSv2, we recommend that you use the following tools and transition path.

Topics

- Tools for helping with the transition to IMDSv2 (p. 1007)
- Recommended path to requiring IMDSv2 (p. 1008)

Tools for helping with the transition to IMDSv2

If your software uses IMDSv1, use the following tools to help reconfigure your software to use IMDSv2.

AWS software

The latest versions of the AWS CLI and AWS SDKs support IMDSv2. To use IMDSv2, make sure that your EC2 instances have the latest versions of the CLI and SDKs. For information about updating the CLI, see Installing, updating, and uninstalling the AWS CLI in the AWS Command Line Interface User Guide.

All Amazon Linux 2 software packages support IMDSv2.

For the minimum AWS SDK versions that support IMDSv2, see Use a supported AWS SDK (p. 1010).

IMDS Packet Analyzer

The IMDS Packet Analyzer is an open-sourced tool that identifies and logs IMDSv1 calls from your instance’s boot phase. This can assist in identifying the software making IMDSv1 calls on EC2 instances, allowing you to pinpoint exactly what you need to update to get your instances ready to use IMDSv2 only. You can run IMDS Packet Analyzer from a command line or install it as a service. For more information, see IMDS Packet Analyzer on GitHub.

CloudWatch

IMDSv2 uses token-backed sessions, while IMDSv1 does not. The MetadataNoToken CloudWatch metric tracks the number of calls to the Instance Metadata Service (IMDS) that are using IMDSv1. By tracking this metric to zero, you can determine if and when all of your software has been upgraded to use IMDSv2. For more information, see Instance metrics (p. 1300).

Updates to EC2 APIs and CLIs

For new instances, you can use the RunInstances API to launch new instances that require the use of IMDSv2. For more information, see Configure instance metadata options for new instances (p. 1011).

For existing instances, you can use the ModifyInstanceMetadataOptions API to require the use of IMDSv2. For more information, see Modify instance metadata options for existing instances (p. 1016).

To require the use of IMDSv2 on all new instances launched by Auto Scaling groups, your Auto Scaling groups can use either a launch template or a launch configuration. When you create a launch template or create a launch configuration, you must configure the MetadataOptions parameters to require the use of IMDSv2. The Auto Scaling group launches new instances using the new launch template or launch configuration, but existing instances are not affected. For existing instances in
an Auto Scaling group, you can use the ModifyInstanceMetadataOptions API to require the use of IMDSv2 on the existing instances, or terminate the instances and the Auto Scaling group will launch new replacement instances with the instance metadata options settings that are defined in the new launch template or launch configuration.

Use an AMI that configures IMDSv2 by default

When you launch an instance, you can automatically configure it to use IMDSv2 by default (the HttpTokens parameter is set to required) by launching it with an AMI that is configured with the ImdsSupport parameter set to v2.0. You can set the ImdsSupport parameter to v2.0 when you register the AMI using the register-image CLI command, or you can modify an existing AMI by using the modify-image-attribute CLI command. For more information, see Configure the AMI (p. 1012).

IAM policies and SCPs

You can use an IAM policy or AWS Organizations service control policy (SCP) to control users as follows:

- Can't launch an instance using the RunInstances API unless the instance is configured to use IMDSv2.
- Can't modify a running instance using the ModifyInstanceMetadataOptions API to re-enable IMDSv1.

The IAM policy or SCP must contain the following IAM condition keys:

- ec2:MetadataHttpEndpoint
- ec2:MetadataHttpPutResponseHopLimit
- ec2:MetadataHttpTokens

If a parameter in the API or CLI call does not match the state specified in the policy that contains the condition key, the API or CLI call fails with an UnauthorizedOperation response.

Furthermore, you can choose an additional layer of protection to enforce the change from IMDSv1 to IMDSv2. At the access management layer with respect to the APIs called via EC2 Role credentials, you can use a new condition key in either IAM policies or AWS Organizations service control policies (SCPs). Specifically, by using the condition key ec2:RoleDelivery with a value of 2.0 in your IAM policies, API calls made with EC2 Role credentials obtained from IMDSv1 will receive an UnauthorizedOperation response. The same thing can be achieved more broadly with that condition required by an SCP. This ensures that credentials delivered via IMDSv1 cannot actually be used to call APIs because any API calls not matching the specified condition will receive an UnauthorizedOperation error.

For example IAM policies, see Work with instance metadata (p. 1981). For more information on SCPs, see Service Control Policies in the AWS Organizations User Guide.

Recommended path to requiring IMDSv2

Using the above tools, we recommend that you follow this path for transitioning to IMDSv2.

**Step 1: At the start**

Update the SDKs, CLIs, and your software that use Role credentials on their EC2 instances to versions compatible with IMDSv2. For information about updating the CLI, see Upgrading to the latest version of the AWS CLI in the AWS Command Line Interface User Guide.

Then, change your software that directly accesses instance metadata (in other words, that does not use an SDK) using the IMDSv2 requests. You can use the IMDS Packet Analyzer to identify the software that you need to change to use IMDSv2 requests.
Step 2: Track your transition progress

Track your transition progress by using the CloudWatch metric MetadataNoToken. This metric shows the number of IMDSv1 calls to the IMDS on your instances. For more information, see Instance metrics (p. 1300).

Step 3: When there is zero IMDSv1 usage

When the CloudWatch metric MetadataNoToken records zero IMDSv1 usage, your instances are ready to be fully transitioned to using IMDSv2. At this stage, you can do the following:

- **New instances**
  
  When launching a new instance, you can do the following:
  
  - Amazon EC2 console: In the launch instance wizard, set Metadata accessible to Enabled and Metadata version to V2 only (token required). For more information, see Configure the instance at launch (p. 1011).
  
  - AWS CLI: Use the run-instances CLI command to specify that only IMDSv2 is to be used.

- **Existing instances**
  
  For existing instances, you can do the following:
  
  - Amazon EC2 console: On the Instances page, select your instance, choose Actions, Instance settings, Modify instance metadata options, and for IMDSv2, choose Required. For more information, see Require the use of IMDSv2 (p. 1017).
  
  - AWS CLI: Use the modify-instance-metadata-options CLI command to specify that only IMDSv2 is to be used.

  You can modify the instance metadata options on running instances, and you don't need to restart the instances after modifying the instance metadata options.

Step 4: Check if your instances are transitioned to IMDSv2

You can check if any instances are not yet configured to require the use of IMDSv2, in other words, IMDSv2 is still configured as optional. If any instances are still configured as optional, you can modify the instance metadata options to make IMDSv2 required by repeating the preceding Step 3 (p. 1009).

To filter your instances:

- Amazon EC2 console: On the Instances page, filter your instances by using the IMDSv2 = optional filter. For more information about filtering, see Filter resources using the console (p. 2499). You can also view whether IMDSv2 is required or optional for each instance: In the Preferences window, toggle on IMDSv2 to add the IMDSv2 column to the Instances table.

- AWS CLI: Use the describe-instances CLI command and filter by metadata-options.http-tokens = optional, as follows:

  ```bash
  aws ec2 describe-instances --filters "Name=metadata-options.http-tokens,Values=optional" --query "Reservations[*].Instances[*].[InstanceId]" --output text
  ```

Step 5: When all of your instances are transitioned to IMDSv2

The ec2:MetadataHttpTokens, ec2:MetadataHttpPutResponseHopLimit, and ec2:MetadataHttpEndpoint IAM condition keys can be used to control the use of the RunInstances and the ModifyInstanceMetadataOptions APIs and corresponding CLIs. If a policy is created, and a
parameter in the API call does not match the state specified in the policy using the condition key, the API or CLI call fails with an UnauthorizedOperation response. For example IAM policies, see Work with instance metadata (p. 1981).

Use a supported AWS SDK

To use IMDSv2, your EC2 instances must use an AWS SDK version that supports using IMDSv2. The latest versions of all the AWS SDKs support using IMDSv2.

Important

We recommend that you to stay up to date with SDK releases to keep up with the latest features, security updates, and underlying dependencies. Continued use of an unsupported SDK version is not recommended and is done at your discretion. For more information, see the AWS SDKs and Tools maintenance policy in the AWS SDKs and Tools Reference Guide.

The following are the minimum versions that support using IMDSv2:

- **AWS CLI** – 1.16.289
- **AWS Tools for Windows PowerShell** – 4.0.1.0
- **AWS SDK for .NET** – 3.3.634.1
- **AWS SDK for C++** – 1.7.229

- **AWS SDK for Python (Boto3)** – 1.12.6
- **AWS SDK for Ruby** – 3.79.0

Configure the instance metadata options

Instance metadata (p. 1004) is data about an instance that you can use to configure or manage the instance. You can configure instance metadata options for new or existing instances as follows:

- Require the use of IMDSv2 when requesting instance metadata
- Specify the PUT response hop limit
- Turn off access to instance metadata

You can also use IAM condition keys in an IAM policy or SCP as follows:

- Allow an instance to launch only if it's configured to require the use of IMDSv2
- Restrict the number of allowed hops
- Turn off access to instance metadata

Note

You should proceed cautiously and conduct careful testing before making any changes. Take note of the following:
If you enforce the use of IMDSv2, applications or agents that use IMDSv1 for instance metadata access will break.

If you turn off all access to instance metadata, applications or agents that rely on instance metadata access to function will break.

For IMDSv2, you must use /latest/api/token when retrieving the token.

Tasks

- Configure instance metadata options for new instances (p. 1011)
- Modify instance metadata options for existing instances (p. 1016)

Configure instance metadata options for new instances

You can configure the following instance metadata options.

Options

- Require the use of IMDSv2 (p. 1011)
- Configure IPv4 and IPv6 endpoints (p. 1014)
- Turn off access to instance metadata (p. 1015)

Require the use of IMDSv2

Use one of the following methods to require the use of IMDSv2 on your instances.

To require IMDSv2

- Configure the instance at launch (p. 1011)
- Configure the AMI (p. 1012)
- Use an IAM policy (p. 1014)

Configure the instance at launch

When you launch an instance (p. 722), you can configure the instance to require the use of IMDSv2 by configuring the following fields:

- Amazon EC2 console: Set Metadata version to V2 only (token required).
- AWS CLI: Set HttpTokens to required.

When you specify that IMDSv2 is required, you must also enable the Instance Metadata Service (IMDS) endpoint by setting Metadata accessible to Enabled (console) or HttpEndpoint to enabled (AWS CLI).

New console

To require the use of IMDSv2 on a new instance

- When launching a new instance in the Amazon EC2 console, expand Advanced details, and do the following:
  - For Metadata accessible, choose Enabled.
  - For Metadata version, choose V2 only (token required).

  For more information, see Advanced details (p. 727).
Old console

**To require the use of IMDSv2 on a new instance**

- When launching a new instance in the Amazon EC2 console, select the following options on the Configure Instance Details page:
  - Under Advanced Details, for Metadata accessible, select Enabled.
  - For Metadata version, select V2 (token required).

For more information, see [Step 3: Configure Instance Details (p. 732)](#).

AWS CLI

**To require the use of IMDSv2 on a new instance**

The following `run-instances` example launches a c6i.large instance with `--metadata-options` set to `HttpTokens=required`. When you specify a value for `HttpTokens`, you must also set `HttpEndpoint` to enabled. Because the secure token header is set to required for metadata retrieval requests, this requires the instance to use IMDSv2 when requesting instance metadata.

```
aws ec2 run-instances \
  --image-id ami-0abcdef1234567890 \
  --instance-type c6i.large \
  ... \
  --metadata-options "HttpEndpoint=enabled,HttpTokens=required"
```

PowerShell

**To require the use of IMDSv2 on a new instance**

The following `New-EC2Instance` Cmdlet example launches a c6i.large instance with `MetadataOptions_HttpEndpoint` set to enabled and the `MetadataOptions_HttpTokens` parameter to required. When you specify a value for `HttpTokens`, you must also set `HttpEndpoint` to enabled. Because the secure token header is set to required for metadata retrieval requests, this requires the instance to use IMDSv2 when requesting instance metadata.

```
New-EC2Instance `
  -ImageId ami-0abcdef1234567890 ` 
  -InstanceType c6i.large ` 
  -MetadataOptions_HttpEndpoint enabled ` 
  -MetadataOptions_HttpTokens required
```

AWS CloudFormation

**To specify the metadata options for an instance using AWS CloudFormation, see the AWS::EC2::LaunchTemplate MetadataOptions property in the AWS CloudFormation User Guide.**

**Configure the AMI**

When you register a new AMI or modify an existing AMI, you can set the `imds-support` parameter to v2.0. Instances launched from this AMI will have Metadata version set to V2 only (token required) (console) or `HttpTokens` set to required (AWS CLI). With these settings, the instance requires that IMDSv2 is used when requesting instance metadata.

Note that when you set `imds-support` to v2.0, instances launched from this AMI will also have Metadata response hop limit (console) or `http-put-response-hop-limit` (AWS CLI) set to 2.
**Important**
Do not use this parameter unless your AMI software supports IMDSv2. After you set the value to v2.0, you can’t undo it. The only way to "reset" your AMI is to create a new AMI from the underlying snapshot.

**To configure a new AMI for IMDSv2**

Use one of the following methods to configure a new AMI IMDSv2.

**AWS CLI**

The following `register-image` example registers an AMI using the specified snapshot of an EBS root volume as device /dev/xvda. Specify v2.0 for the `imds-support` parameter so that instances launched from this AMI will require that IMDSv2 is used when requesting instance metadata.

```bash
aws ec2 register-image \
   --name my-image \
   --root-device-name /dev/xvda \
   --block-device-mappings DeviceName=/dev/xvda,Ebs={SnapshotId=snap-0123456789example} \
   --architecture x86_64 \
   --imds-support v2.0
```

**PowerShell**

The following `Register-EC2Image` Cmdlet example registers an AMI using the specified snapshot of an EBS root volume as device /dev/xvda. Specify v2.0 for the `ImdsSupport` parameter so that instances launched from this AMI will require that IMDSv2 is used when requesting instance metadata.

```powershell
Import-Module AWS.Tools.EC2  # Required for Amazon.EC2.Model object creation.
Register-EC2Image ` `-Name 'my-image' ` `-RootDeviceName '/dev/xvda' ` `-BlockDeviceMapping @( `   New-Object Amazon.EC2.Model.BlockDeviceMapping `   `   -PropertyName DeviceName `   `   `   `   -Value '/dev/xvda' `   `   `   -Property EBS `   `   `   `   -Value (New-Object Amazon.EC2.Model.EbsBlockDevice -PropertyName SnapshotId `   `   `   `   `   -Value 'snap-0123456789example' `   `   `   `   `   -PropertyName VolumeType `   `   `   `   `   -Value 'gp3' `   `   `   `   }} ` `-Architecture x86_64 ` `-ImdsSupport v2.0
```

**To configure an existing AMI for IMDSv2**

Use one of the following methods to configure an existing AMI for IMDSv2.

**AWS CLI**

The following `modify-image-attribute` example modifies an existing AMI for IMDSv2 only. Specify v2.0 for the `imds-support` parameter so that instances launched from this AMI will require that IMDSv2 is used when requesting instance metadata.

```bash
aws ec2 modify-image-attribute \
```

1013
**Amazon Elastic Compute Cloud**

**User Guide for Linux Instances**

**Instance metadata and user data**

---

```
--image-id ami-0123456789example 
--imds-support v2.0
```

**PowerShell**

The following `Edit-EC2ImageAttribute` Cmdlet example modifies an existing AMI for IMDSv2 only. Specify v2.0 for the `imds-support` parameter so that instances launched from this AMI will require that IMDSv2 is used when requesting instance metadata.

```
Edit-EC2ImageAttribute `'
   -ImageId ami-0abcdef1234567890 `'
   -ImdsSupport 'v2.0'
```

**Use an IAM policy**

You can create an IAM policy that prevents users from launching new instances unless they require IMDSv2 on the new instance.

**To enforce the use of IMDSv2 on all new instances by using an IAM policy**

To ensure that users can only launch instances that require the use of IMDSv2 when requesting instance metadata, you can specify that the condition to require IMDSv2 must be met before an instance can be launched. For the example IAM policy, see [Work with instance metadata](p. 1981).

**Configure IPv4 and IPv6 endpoints**

By default, the IPv6 endpoint is disabled. This is true even if you are launching an instance into an IPv6-only subnet. You can choose to enable the IPv6 endpoint at instance launch when using the AWS CLI. This option is not available in the Amazon EC2 console.

The IPv6 endpoint for the IMDS is only accessible on [Instances built on the Nitro System](p. 295).

**To configure IPv4 and IPv6 endpoints**

User one of the following methods to launch an instance with the IPv6 endpoint enabled for IMDS.

**AWS CLI**

The following `run-instances` example launches a `c6i.large` instance with the IPv6 endpoint enabled for the IMDS. To enable the IPv6 endpoint, for the `--metadata-options` parameter, specify `HttpProtocolIpv6=enabled`. When you specify a value for `HttpProtocolIpv6`, you must also set `HttpEndpoint` to enabled.

```
aws ec2 run-instances `\n   --image-id ami-0abcdef1234567890 `\n   --instance-type c6i.large `\n   ... `\n   --metadata-options "HttpEndpoint=enabled,HttpProtocolIpv6=enabled"
```

**PowerShell**

The following `New-EC2Instance` Cmdlet example launches a `c6i.large` instance with the IPv6 endpoint enabled for the IMDS. To enable the IPv6 endpoint, specify `MetadataOptions_HttpProtocolIpv6` as enabled. When you specify a value for `MetadataOptions_HttpProtocolIpv6`, you must also set `MetadataOptions_HttpEndpoint` to enabled.

```
```
New-EC2Instance -ImageId ami-0abcdef1234567890 -InstanceType c6i.large -MetadataOptions_HttpEndpoint enabled -MetadataOptions_HttpProtocolIpv6 enabled

**Turn off access to instance metadata**

You can turn off access to the instance metadata by disabling the IMDS when you launch an instance. You can turn on access later by re-enabling the IMDS. For more information, see [Turn on access to instance metadata](p. 1019).

**Important**

You can choose to disable the IMDS at launch or after launch. If you disable the IMDS at launch, the following might not work:

- You might not have SSH access to your instance. The `public-keys/0/openssh-key`, which is your instance's public SSH key, will not be accessible because the key is normally provided and accessed from EC2 instance metadata.
- EC2 user data will not be available and will not run at instance start. EC2 user data is hosted on the IMDS. If you disable the IMDS, you effectively turn off access to user data.

To access this functionality, you can re-enable the IMDS after launch.

**New console**

**To turn off access to instance metadata at launch**

- Launch the instance ([p. 722]) in the Amazon EC2 console with the following specified under **Advanced details**:
  - For **Metadata accessible**, choose **Disabled**.

For more information, see [Advanced details](p. 727).

**Old console**

**To turn off access to instance metadata at launch**

- Launch the instance in the Amazon EC2 console with the following option selected on the **Configure Instance Details** page:
  - Under **Advanced Details**, for **Metadata accessible**, select **Disabled**.

For more information, see [Step 3: Configure Instance Details](p. 732).

**AWS CLI**

**To turn off access to instance metadata at launch at launch**

Launch the instance with **--metadata-options** set to **HttpEndpoint=disabled**.

```
aws ec2 run-instances \
  --image-id ami-0abcdef1234567890 \
  --instance-type c6i.large \
  ... \
  --metadata-options "HttpEndpoint=disabled"
```
PowerShell

**To turn off access to instance metadata at launch at launch**

The following `New-EC2Instance` Cmdlet example launches an instance with MetadataOptions_HttpEndpoint set to disabled.

```
New-EC2Instance -ImageId ami-0abcdef1234567890 -InstanceType c6i.large -MetadataOptions_HttpEndpoint disabled
```

AWS CloudFormation

To specify the metadata options for an instance using AWS CloudFormation, see the AWS::EC2::LaunchTemplate MetadataOptions property in the AWS CloudFormation User Guide.

Modify instance metadata options for existing instances

You can modify the instance metadata options for existing instances.

You can also create an IAM policy that prevents users from modifying the instance metadata options on existing instances. To control which users can modify the instance metadata options, specify a policy that prevents all users other than users with a specified role to use the ModifyInstanceMetadataOptions API. For the example IAM policy, see Work with instance metadata (p. 1981).

Query instance metadata options for existing instances

You can query the instance metadata options for your existing instances by using one of the following methods.

Console

**To query the instance metadata options for an existing instance using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select your instance.
4. Choose Actions, Instance settings, Modify instance metadata options.
5. Review the current instance metadata options in the Modify instance metadata options dialog box.

AWS CLI

**To query the instance metadata options for an existing instance using the AWS CLI**

Use the `describe-instances` CLI command.

```
aws ec2 describe-instances
   --instance-id i-1234567890abcdef0
   --query 'Reservations[].Instances[].MetadataOptions'
```

PowerShell

**To query the instance metadata options for an existing instance using the Tools for PowerShell**

Use the `Get-EC2Instance` Cmdlet.
Instance metadata and user data

(\(\text{Get-EC2Instance} \:\:\text{InstanceId} \text{\(i-1234567898abcdef0\))}.\text{Instances}.\text{MetadataOptions}\)

**Require the use of IMDSv2**

Use one of the following methods to modify the instance metadata options on an existing instance to require that IMDSv2 is used when requesting instance metadata. When IMDSv2 is required, IMDSv1 cannot be used.

**Console**

**To require the use of IMDSv2 on an existing instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select your instance.
4. Choose **Actions, Instance settings, Modify instance metadata options**.
5. In the **Modify instance metadata options** dialog box, do the following:
   a. For **Instance metadata service**, select **Enable**.
   b. For **IMDSv2**, choose **Required**.
   c. Choose **Save**.

**AWS CLI**

**To require the use of IMDSv2 on an existing instance**

Use the **modify-instance-metadata-options** CLI command and set the **http-tokens** parameter to **required**. When you specify a value for **http-tokens**, you must also set **http-endpoint** to enabled.

```
aws ec2 modify-instance-metadata-options \\
   --instance-id i-1234567898abcdef0 \\
   --http-tokens required \\
   --http-endpoint enabled
```

**PowerShell**

**To require the use of IMDSv2 on an existing instance**

Use the **Edit-EC2InstanceMetadataOption** Cmdlet and set the **HttpTokens** parameter to **required**. When you specify a value for **HttpTokens**, you must also set **HttpEndpoint** to enabled.

```
(\(\text{Edit-EC2InstanceMetadataOption} \:\:\text{InstanceId} \text{\(i-1234567898abcdef0\))} \\
   -HttpTokens required \\
   -HttpEndpoint enabled).\text{InstanceMetadataOptions}\)
```

**Restore the use of IMDSv1**

When IMDSv2 is required, IMDSv1 will not work when requesting instance metadata. When IMDSv2 is optional, then both IMDSv2 and IMDSv1 will work. Therefore, to restore IMDSv1, make IMDSv2 optional by using one of the following methods.
Console

**To restore the use of IMDSv1 on an instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select your instance.
4. Choose **Actions, Instance settings, Modify instance metadata options**.
5. In the **Modify instance metadata options** dialog box, do the following:
   a. For **Instance metadata service**, make sure that **Enable** is selected.
   b. For **IMDSv2**, choose **Optional**.
   c. Choose **Save**.

AWS CLI

**To restore the use of IMDSv1 on an instance**

You can use the `modify-instance-metadata-options` CLI command with `http-tokens` set to `optional` to restore the use of IMDSv1 when requesting instance metadata.

```
aws ec2 modify-instance-metadata-options \
   --instance-id i-1234567898abcdef0 \
   --http-tokens optional \
   --http-endpoint enabled
```

PowerShell

**To restore the use of IMDSv1 on an instance**

You can use the `Edit-EC2InstanceMetadataOption` Cmdlet with `HttpTokens` set to `optional` to restore the use of IMDSv1 when requesting instance metadata.

```
(\n   Edit-EC2InstanceMetadataOption `\n   -InstanceId i-1234567898abcdef0 `\n   -HttpTokens optional `\n   -HttpEndpoint enabled).InstanceMetadataOptions
```

**Change the PUT response hop limit**

For existing instances, you can change the settings of the PUT response hop limit.

Currently only the AWS CLI and AWS SDKs support changing the PUT response hop limit.

AWS CLI

**To change the PUT response hop limit**

Use the `modify-instance-metadata-options` CLI command and set the `http-put-response-hop-limit` parameter to the required number of hops. In the following example, the hop limit is set to 3. Note that when specifying a value for `http-put-response-hop-limit`, you must also set `http-endpoint` to enabled.

```
aws ec2 modify-instance-metadata-options \
   --instance-id i-1234567898abcdef0 \
   --http-put-response-hop-limit 3 \
   --http-endpoint enabled
```
PowerShell

To change the PUT response hop limit

Use the `Edit-EC2InstanceMetadataOption` Cmdlet and set the `HttpPutResponseHopLimit` parameter to the required number of hops. In the following example, the hop limit is set to 3. Note that when specifying a value for `HttpPutResponseHopLimit`, you must also set `HttpEndpoint` to enabled.

```powershell
(Edit-EC2InstanceMetadataOption -InstanceId i-1234567898abcdef0 -HttpPutResponseHopLimit 3 -HttpEndpoint enabled).InstanceMetadataOptions
```

Enable the IPv6 endpoint for your instance

By default, the IPv6 endpoint is disabled. This is true even if you have launched an instance into an IPv6-only subnet. The IPv6 endpoint for the IMDS is only accessible on Instances built on the Nitro System (p. 295).

Currently only the AWS CLI and AWS SDKs support enabling the IPv6 endpoint for your instance.

AWS CLI

To enable the IPv6 endpoint for your instance

Use the `modify-instance-metadata-options` CLI command and set the `http-protocol-ipv6` parameter to enabled. Note that when specifying a value for `http-protocol-ipv6`, you must also set `http-endpoint` to enabled.

```bash
aws ec2 modify-instance-metadata-options --instance-id i-1234567898abcdef0 --http-protocol-ipv6 enabled --http-endpoint enabled
```

PowerShell

To enable the IPv6 endpoint for your instance

Use the `Edit-EC2InstanceMetadataOption` Cmdlet and set the `HttpProtocolIpv6` parameter to enabled. Note that when specifying a value for `HttpProtocolIpv6`, you must also set `HttpEndpoint` to enabled.

```powershell
(Edit-EC2InstanceMetadataOption -InstanceId i-1234567898abcdef0 -HttpProtocolIpv6 enabled -HttpEndpoint enabled).InstanceMetadataOptions
```

Turn on access to instance metadata

You can turn on access to instance metadata by enabling the HTTP endpoint of the IMDS on your instance, regardless of which version of the IMDS you are using. You can reverse this change at any time by disabling the HTTP endpoint.
Use one of the following methods to turn on access to instance metadata on an instance.

**Console**

**To turn on access to instance metadata**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select your instance.
4. Choose **Actions, Instance settings, Modify instance metadata options**.
5. In the **Modify instance metadata options** dialog box, do the following:
   a. For **Instance metadata service**, select **Enable**.
   b. Choose **Save**.

**AWS CLI**

**To turn on access to instance metadata**

Use the `modify-instance-metadata-options` CLI command and set the `http-endpoint` parameter to enabled.

```
aws ec2 modify-instance-metadata-options \
  --instance-id i-1234567898abcdef0 \
  --http-endpoint enabled
```

**PowerShell**

**To turn on access to instance metadata**

Use the `Edit-EC2InstanceMetadataOption` Cmdlet and set the `HttpEndpoint` parameter to enabled.

```
(Edit-EC2InstanceMetadataOption `\n  -InstanceId i-1234567898abcdef0 `\n  -HttpEndpoint enabled).InstanceMetadataOptions
```

**Turn off access to instance metadata**

You can turn off access to instance metadata by disabling the HTTP endpoint of the IMDS on your instance, regardless of which version of the IMDS you are using. You can reverse this change at any time by enabling the HTTP endpoint.

Use one of the following methods to turn off access to instance metadata on an instance.

**Console**

**To turn off access to instance metadata**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select your instance.
4. Choose **Actions, Instance settings, Modify instance metadata options**.
5. In the **Modify instance metadata options** dialog box, do the following:
   a. For **Instance metadata service**, clear **Enable**.
   b. Choose **Save**.

**AWS CLI**

**To turn off access to instance metadata**

Use the `modify-instance-metadata-options` CLI command and set the `http-endpoint` parameter to disabled.

```
aws ec2 modify-instance-metadata-options \
   --instance-id i-1234567898abcdef0 \
   --http-endpoint disabled
```

**PowerShell**

**To turn off access to instance metadata**

Use the `Edit-EC2InstanceMetadataOption` Cmdlet and set the `HttpEndpoint` parameter to disabled.

```
(Edit-EC2InstanceMetadataOption \
    -InstanceId i-1234567898abcdef0 \
    -HttpEndpoint disabled).InstanceMetadataOptions
```

**Retrieve instance metadata**

Because your instance metadata is available from your running instance, you do not need to use the Amazon EC2 console or the AWS CLI. This can be helpful when you're writing scripts to run from your instance. For example, you can access the local IP address of your instance from instance metadata to manage a connection to an external application.

Instance metadata is divided into categories. For a description of each instance metadata category, see [Instance metadata categories](#) (p. 1032).

To view all categories of instance metadata from within a running instance, use the following IPv4 or IPv6 URIs.

**IPv4**

```
```

**IPv6**

```
http://[fd00:ec2::254]/latest/meta-data/
```

The IP addresses are link-local addresses and are valid only from the instance. For more information, see [Link-local addresses](#) (p. 1374) in this user guide and [Link-local address](#) on Wikipedia.

**Note**

The examples in this section use the IPv4 address of the IMDS: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable
and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the IMDS is compatible with IMDSv2 commands. The IPv6 address is only accessible on Instances built on the Nitro System (p. 295).

The command format is different, depending on whether you use IMDSv1 or IMDSv2. By default, you can use both versions of the IMDS. To require the use of IMDSv2, see Use IMDSv2 (p. 1005).

You can use a tool such as cURL, as shown in the following example.

IMDSv2

```
```

IMDSv1

```
```

For the command to retrieve instance metadata from a Windows instance, see Retrieve instance metadata in the Amazon EC2 User Guide for Windows Instances.

**Costs**

You are not billed for HTTP requests used to retrieve instance metadata and user data.

**Considerations**

To avoid problems with instance metadata retrieval, consider the following:

- **In a container environment, we recommend setting the hop limit to 2.**

  The AWS SDKs use IMDSv2 calls by default. If the IMDSv2 call receives no response, the SDK retries the call and, if still unsuccessful, uses IMDSv1. This can result in a delay, especially in a container environment. In a container environment, if the hop limit is 1, the IMDSv2 response does not return because going to the container is considered an additional network hop. To avoid the process of falling back to IMDSv1 and the resultant delay, in a container environment we recommend that you set the hop limit to 2. For more information, see Configure the instance metadata options (p. 1010).

- **For IMDSv2, you must use /latest/api/token when retrieving the token.**

  Issuing PUT requests to any version-specific path, for example /2021-03-23/api/token, will result in the metadata service returning 403 Forbidden errors. This behavior is intended.

- **If IMDSv2 is required, IMDSv1 does not work.**

  You can check if IMDSv2 is required for an instance, as follows: Select the instance to view its details, and check the value for IMDSv2. The value is either Required (only IMDSv2 can be used) or Optional (IMDSv2 and IMDSv1 can be used).

**Responses and error messages**

All instance metadata is returned as text (HTTP content type text/plain).

A request for a specific metadata resource returns the appropriate value, or a 404 - Not Found HTTP error code if the resource is not available.
A request for a general metadata resource (the URI ends with a `/`) returns a list of available resources, or a 404 - Not Found HTTP error code if there is no such resource. The list items are on separate lines, terminated by line feeds (ASCII 10).

For requests made using Instance Metadata Service Version 2, the following HTTP error codes can be returned:

- **400 - Missing or Invalid Parameters** – The PUT request is not valid.
- **401 - Unauthorized** – The GET request uses an invalid token. The recommended action is to generate a new token.
- **403 - Forbidden** – The request is not allowed or the IMDS is turned off.

### Examples of retrieving instance metadata

The following examples provide commands that you can use on a Linux instance. For the commands to retrieve instance metadata from a Windows instance, see Retrieve instance metadata in the Amazon EC2 User Guide for Windows Instances.

**Examples**

- Get the available versions of the instance metadata (p. 1023)
- Get the top-level metadata items (p. 1024)
- Get the list of available public keys (p. 1026)
- Show the formats in which public key 0 is available (p. 1026)
- Get public key 0 (in the OpenSSH key format) (p. 1027)
- Get the subnet ID for an instance (p. 1027)
- Get the instance tags for an instance (p. 1028)

### Get the available versions of the instance metadata

This example gets the available versions of the instance metadata. Each version refers to an instance metadata build when new instance metadata categories were released. The instance metadata build versions do not correlate with the Amazon EC2 API versions. The earlier versions are available to you in case you have scripts that rely on the structure and information present in a previous version.

**Note**

To avoid having to update your code every time Amazon EC2 releases a new instance metadata build, we recommend that you use `latest` in the path, and not the version number. For example, use `latest` as follows:

```
```

**IMDSv2**

```
```

2007-01-19
2007-03-01
2007-08-29
2007-10-10
2007-12-15
2008-02-01
2008-09-01
2009-04-04
2011-01-01
2011-05-01
2012-01-12
IMDSv1

```
[ec2-user ~]$ curl http://169.254.169.254/1.0

```

Get the list of available public keys

This example gets the list of available public keys.

IMDSv2

```
0=my-public-key
```

IMDSv1

```
0=my-public-key
```

Show the formats in which public key 0 is available

This example shows the formats in which public key 0 is available.

IMDSv2

```
```

IMDSv1

```
```
Get public key 0 (in the OpenSSH key format)

This example gets public key 0 (in the OpenSSH key format).

IMDSv2

```
```

Get the subnet ID for an instance

This example gets the subnet ID for an instance.

IMDSv2

```
```

1027
IMDSv1

Get the instance tags for an instance

In the following examples, the sample instance has tags on instance metadata enabled (p. 2520) and the instance tags Name=MyInstance and Environment=Dev.

This example gets all the instance tag keys for an instance.

IMDSv2

The following example gets the value of the Name key that was obtained in the preceding example. The IMDSv2 request uses the stored token that was created in the preceding example command, assuming it has not expired.

Query throttling

We throttle queries to the IMDS on a per-instance basis, and we place limits on the number of simultaneous connections from an instance to the IMDS.

If you're using the IMDS to retrieve AWS security credentials, avoid querying for credentials during every transaction or concurrently from a high number of threads or processes, as this might lead to throttling. Instead, we recommend that you cache the credentials until they start approaching their expiry time. For
more information about IAM role and security credentials associated with the role, see Retrieve security credentials from instance metadata (p. 1996).

If you are throttled while accessing the IMDS, retry your query with an exponential backoff strategy.

**Limit IMDS access**

You can consider using local firewall rules to disable access from some or all processes to the IMDS.

**Note**

For Instances built on the Nitro System (p. 295), IMDS can be reached from your own network when a network appliance within your VPC, such as a virtual router, forwards packets to the IMDS address, and the default source/destination check on the instance is disabled. To prevent a source from outside your VPC reaching IMDS, we recommend that you modify the configuration of the network appliance to drop packets with the destination IPv4 address of IMDS 169.254.169.254 and, if you enabled the IPv6 endpoint, the IPv6 address of IMDS fd00:ec2::254.

**Using iptables to limit access**

The following example uses Linux iptables and its owner module to prevent the Apache webserver (based on its default installation user ID of apache) from accessing 169.254.169.254. It uses a deny rule to reject all instance metadata requests (whether IMDSv1 or IMDSv2) from any process running as that user.

```
$ sudo iptables --append OUTPUT --proto tcp --destination 169.254.169.254 --match owner --uid-owner apache --jump REJECT
```

Or, you can consider only allowing access to particular users or groups, by using allow rules. Allow rules might be easier to manage from a security perspective, because they require you to make a decision about what software needs access to instance metadata. If you use allow rules, it’s less likely you will accidentally allow software to access the metadata service (that you did not intend to have access) if you later change the software or configuration on an instance. You can also combine group usage with allow rules, so that you can add and remove users from a permitted group without needing to change the firewall rule.

The following example prevents access to the IMDS by all processes, except for processes running in the user account trustworthy-user.

```
$ sudo iptables --append OUTPUT --proto tcp --destination 169.254.169.254 --match owner ! --uid-owner trustworthy-user --jump REJECT
```

**Note**

- To use local firewall rules, you need to adapt the preceding example commands to suit your needs.
- By default, iptables rules are not persistent across system reboots. They can be made to be persistent by using OS features, not described here.
- The iptables owner module only matches group membership if the group is the primary group of a given local user. Other groups are not matched.

**Using PF or IPFW to limit access**

If you are using FreeBSD or OpenBSD, you can also consider using PF or IPFW. The following examples limit access to the IMDS to just the root user.

**PF**
Work with instance user data

You can use instance user data to customize your instances. When you launch an instance, you can store parameters or scripts as user data. Any scripts in user data are run when you launch the instance. You can view user data as an instance attribute. You can also view user data from your instance through the Instance Metadata Service (IMDS).

Considerations

- User data is treated as opaque data: what you give is what you get back. It is up to the instance to interpret it.
- User data must be base64-encoded. The Amazon EC2 console can perform the base64-encoding for you or accept base64-encoded input.
- User data is limited to 16 KB, in raw form, before it is base64-encoded. The size of a string of length $n$ after base64-encoding is $\text{ceil}(n/3)*4$.
- User data must be base64-decoded when you retrieve it. If you retrieve the data using instance metadata or the console, it's decoded for you automatically.
- If you stop an instance, modify its user data, and start the instance, the updated user data is not run when you start the instance.
- User data is an instance attribute. If you create an AMI from an instance, the instance user data is not included in the AMI.

Specify instance user data at launch

You can specify user data when you launch an instance. For console directions, see Specify instance user data at launch (p. 998). For an example that uses the AWS CLI, see the section called "User data and the AWS CLI" (p. 1001).

Modify instance user data

You can modify user data for instances with an EBS root volume. The instance must be in the stopped state. For console directions, see View and update the instance user data (p. 999). For an example that uses the AWS CLI, see modify-instance-attribute.

Retrieve instance user data from your instance

Note

The examples in this section use the IPv4 address of the IMDS: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable

$ block out inet proto tcp from any to 169.254.169.254

$ pass out inet proto tcp from any to 169.254.169.254 user root

IPFW

$ allow tcp from any to 169.254.169.254 uid root

$ deny tcp from any to 169.254.169.254

Note

The order of the PF and IPFW commands matter. PF defaults to last matching rule and IPFW defaults to first matching rule.
and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the IMDS is compatible with IMDSv2 commands. The IPv6 address is only accessible on Instances built on the Nitro System (p. 295).

To retrieve user data from an instance, use the following URI.

```
http://169.254.169.254/latest/user-data
```

A request for user data returns the data as it is (content type application/octet-stream).

This example returns user data that was provided as comma-separated text.

**IMDSv2**

```
1234,john,reboot,true | 4512,richard, | 173,,,
```

**IMDSv1**

```
1234,john,reboot,true | 4512,richard, | 173,,,
```

This example returns user data that was provided as a script.

**IMDSv2**

```
#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on
```

**IMDSv1**

```
#!/bin/bash
yum update -y
service httpd start
chkconfig httpd on
```

**Retrieve instance user data from your computer**

You can retrieve user data for an instance from your own computer. For console directions, see View and update the instance user data (p. 999). For an example that uses the AWS CLI, see User data and the AWS CLI (p. 1001).

**Retrieve dynamic data**

To retrieve dynamic data from within a running instance, use the following URI.
Note
The examples in this section use the IPv4 address of the IMDS: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the IMDS is compatible with IMDSv2 commands. The IPv6 address is only accessible on \textit{Instances built on the Nitro System} (p. 295).

This example shows how to retrieve the high-level instance identity categories.

\textbf{IMDSv2}

```
&& curl -H "X-aws-ec2-metadata-token: $TOKEN" -v http://169.254.169.254/latest/dynamic/instance-identity/\n  rsa2048\n  pkcs7\n  document\n  signature\n  dsa2048
```

\textbf{IMDSv1}

```
[ec2-user ~]$ curl http://169.254.169.254/latest/dynamic/instance-identity/\n  rsa2048\n  pkcs7\n  document\n  signature\n  dsa2048
```

For more information about dynamic data and examples of how to retrieve it, see \textit{Instance identity documents} (p. 1044).

**Instance metadata categories**

Instance metadata is divided into categories. To retrieve instance metadata, you specify the category in the request, and the metadata is returned in the response.

When new categories are released, a new instance metadata build is created with a new version number. In the following table, the \textbf{Version when category was released} column specifies the build version when an instance metadata category was released. To avoid having to update your code every time Amazon EC2 releases a new instance metadata build, use \textit{latest} instead of the version number in your metadata requests. For more information, see \textit{Get the available versions of the instance metadata} (p. 1023).

When Amazon EC2 releases a new instance metadata category, the instance metadata for the new category might not be available for existing instances. With instances built on the \textit{Nitro system} (p. 295), you can retrieve instance metadata only for the categories that were available at launch. For instances with the Xen hypervisor, you can \textit{stop and then start} (p. 768) the instance to update the categories that are available for the instance.

The following table lists the categories of instance metadata. Some of the category names include placeholders for data that is unique to your instance. For example, \textit{mac} represents the MAC address for the network interface. You must replace the placeholders with actual values when you retrieve the instance metadata.
<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>
<th>Version when category was released</th>
</tr>
</thead>
<tbody>
<tr>
<td>ami-id</td>
<td>The AMI ID used to launch the instance.</td>
<td>1.0</td>
</tr>
<tr>
<td>ami-launch-index</td>
<td>If you started more than one instance at the same time, this value indicates the order in which the instance was launched. The value of the first instance launched is 0.</td>
<td>1.0</td>
</tr>
<tr>
<td>ami-manifest-path</td>
<td>The path to the AMI manifest file in Amazon S3. If you used an Amazon EBS-backed AMI to launch the instance, the returned result is unknown.</td>
<td>1.0</td>
</tr>
<tr>
<td>ancestor-ami-ids</td>
<td>The AMI IDs of any instances that were rebundled to create this AMI. This value will only exist if the AMI manifest file contained an ancestor-amis key.</td>
<td>2007-10-10</td>
</tr>
<tr>
<td>autoscaling/target-</td>
<td>Value showing the target Auto Scaling lifecycle state that an Auto Scaling instance is transitioning to. Present when the instance transitions to one of the target lifecycle states after March 10, 2022. Possible values: Detached</td>

</tbody>
</table>

### Example: AMI launch index value

This example demonstrates how you can use both user data and instance metadata to configure your instances.
Note
The examples in this section use the IPv4 address of the IMDS: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00::ec2:254. The IPv6 address of the IMDS is compatible with IMDSv2 commands. The IPv6 address is only accessible on Instances built on the Nitro System (p. 295).

Alice wants to launch four instances of her favorite database AMI, with the first acting as the original instance and the remaining three acting as replicas. When she launches them, she wants to add user data about the replication strategy for each replica. She is aware that this data will be available to all four instances, so she needs to structure the user data in a way that allows each instance to recognize which parts are applicable to it. She can do this using the ami-launch-index instance metadata value, which will be unique for each instance. If she starts more than one instance at the same time, the ami-launch-index indicates the order in which the instances were launched. The value of the first instance launched is 0.

Here is the user data that Alice has constructed.

```
replicate-every=1min | replicate-every=5min | replicate-every=10min
```

The `replicate-every=1min` data defines the first replica's configuration, `replicate-every=5min` defines the second replica's configuration, and so on. Alice decides to provide this data as an ASCII string with a pipe symbol (|) delimiting the data for the separate instances.

Alice launches four instances using the `run-instances` command, specifying the user data.

```
aws ec2 run-instances \
  --image-id ami-0abcdef1234567890 \
  --count 4 \
  --instance-type t2.micro \
  --user-data "replicate-every=1min | replicate-every=5min | replicate-every=10min"
```

After they're launched, all instances have a copy of the user data and the common metadata shown here:

- AMI ID: ami-0abcdef1234567890
- Reservation ID: r-1234567890abcdef0
- Public keys: none
- Security group name: default
- Instance type: t2.micro

However, each instance has certain unique metadata.

### Instance 1

<table>
<thead>
<tr>
<th>Metadata</th>
<th>Value</th>

<tr>
<td>local-ipv4</td>
<td>10.251.50.38</td>
</tr>
</tbody>
</table>

Alice can use the ami-launch-index value to determine which portion of the user data is applicable to a particular instance.

1. She connects to one of the instances, and retrieves the ami-launch-index for that instance to ensure it is one of the replicas:
Instance metadata and user data

IMDSv2

For the following steps, the IMDSv2 requests use the stored token from the preceding IMDSv2 command, assuming the token has not expired.

IMDSv1

2.

2. She saves the ami-launch-index as a variable.

IMDSv2

IMDSv1

3. She saves the user data as a variable.

IMDSv2

IMDSv1

4. Finally, Alice uses the `cut` command to extract the portion of the user data that is applicable to that instance.

IMDSv2

[ec2-user ~]$ echo $user_data | cut -d"\n" -f"$ami_launch_index" \
replicate-every=5min

IMDSv1

[ec2-user ~]$ echo $user_data | cut -d"\n" -f"$ami_launch_index" \
replicate-every=5min

Instance identity documents

Each instance that you launch has an instance identity document that provides information about the instance itself. You can use the instance identity document to validate the attributes of the instance.
The instance identity document is generated when the instance is stopped and started, restarted, or launched. The instance identity document is exposed (in plaintext JSON format) through the Instance Metadata Service (IMDS). The IPv4 address 169.254.169.254 is a link-local address and is valid only from the instance. For more information, see Link-local address on Wikipedia. The IPv6 address fd00:ec2::254 is a unique local address and is valid only from the instance. For more information, see Unique local address on Wikipedia.

Note
The examples in this section use the IPv4 address of the IMDS: 169.254.169.254. If you are retrieving instance metadata for EC2 instances over the IPv6 address, ensure that you enable and use the IPv6 address instead: fd00:ec2::254. The IPv6 address of the IMDS is compatible with IMDSv2 commands. The IPv6 address is only accessible on Instances built on the Nitro System (p. 295).

You can retrieve the instance identity document from a running instance at any time. The instance identity document includes the following information:

<table>
<thead>
<tr>
<th>Data</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>accountId</td>
<td>The ID of the AWS account that launched the instance.</td>
</tr>
<tr>
<td>architecture</td>
<td>The architecture of the AMI used to launch the instance (i386</td>
</tr>
<tr>
<td>availabilityZone</td>
<td>The Availability Zone in which the instance is running.</td>
</tr>
<tr>
<td>billingProducts</td>
<td>The billing products of the instance.</td>
</tr>
<tr>
<td>devpayProductCodes</td>
<td>Deprecated.</td>
</tr>
<tr>
<td>imageId</td>
<td>The ID of the AMI used to launch the instance.</td>
</tr>
<tr>
<td>instanceId</td>
<td>The ID of the instance.</td>
</tr>
<tr>
<td>instanceType</td>
<td>The instance type of the instance.</td>
</tr>
<tr>
<td>kernelId</td>
<td>The ID of the kernel associated with the instance, if applicable.</td>
</tr>
<tr>
<td>marketplaceProductCodes</td>
<td>AWS Marketplace product code of the AMI used to launch the instance.</td>
</tr>
<tr>
<td>pendingTime</td>
<td>The date and time that the instance was launched.</td>
</tr>
<tr>
<td>privateIp</td>
<td>The private IPv4 address of the instance.</td>
</tr>
<tr>
<td>ramdiskId</td>
<td>The ID of the RAM disk associated with the instance, if applicable.</td>
</tr>
<tr>
<td>region</td>
<td>The Region in which the instance is running.</td>
</tr>
<tr>
<td>version</td>
<td>The version of the instance identity document format.</td>
</tr>
</tbody>
</table>

Retrieve the plaintext instance identity document

To retrieve the plaintext instance identity document

Connect to the instance and run one of the following commands depending on the version of the IMDS used by the instance.
IMDSv2

IMDSv1

The following is example output.

```
{
    "devpayProductCodes" : null,
    "marketplaceProductCodes" : [ "1abc2defghijklm3nopqrs4tu" ],
    "availabilityZone" : "us-west-2b",
    "privateIp" : "10.158.112.84",
    "version" : "2017-09-30",
    "instanceId" : "i-1234567890abcdef0",
    "billingProducts" : null,
    "instanceType" : "t2.micro",
    "accountId" : "123456789012",
    "imageId" : "ami-5fb8c835",
    "pendingTime" : "2016-11-19T16:32:11Z",
    "architecture" : "x86_64",
    "kernelId" : null,
    "ramdiskId" : null,
    "region" : "us-west-2"
}
```

Verify the instance identity document

If you intend to use the contents of the instance identity document for an important purpose, you should verify its contents and authenticity before using it.

The plaintext instance identity document is accompanied by three hashed and encrypted signatures. You can use these signatures to verify the origin and authenticity of the instance identity document and the information that it includes. The following signatures are provided:

- Base64-encoded signature—This is a base64-encoded SHA256 hash of the instance identity document that is encrypted using an RSA key pair.
- PKCS7 signature—This is a SHA1 hash of the instance identity document that is encrypted using a DSA key pair.
- RSA-2048 signature—This is a SHA256 hash of the instance identity document that is encrypted using an RSA-2048 key pair.

Each signature is available at a different endpoint in the instance metadata. You can use any one of these signatures depending on your hashing and encryption requirements. To verify the signatures, you must use the corresponding AWS public certificate.

The following topics provide detailed steps for validating the instance identity document using each signature.

- Use the PKCS7 signature to verify the instance identity document (p. 1047)
- Use the base64-encoded signature to verify the instance identity document (p. 1048)
Use the RSA-2048 signature to verify the instance identity document (p. 1049)

Use the PKCS7 signature to verify the instance identity document

This topic explains how to verify the instance identity document using the PKCS7 signature and the AWS DSA public certificate.

To verify the instance identity document using the PKCS7 signature and the AWS DSA public certificate

1. Connect to the instance.
2. Retrieve the PKCS7 signature from the instance metadata and add it to a new file named `pkcs7` along with the required header and footer. Use one of the following commands depending on the IMDS version used by the instance.

**IMDSv2**

```bash
$ echo "-----BEGIN PKCS7-----" >> pkcs7
&& echo "" >> pkcs7
&& echo "-----END PKCS7-----" >> pkcs7
```

**IMDSv1**

```bash
$ echo "-----BEGIN PKCS7-----" >> pkcs7
&& echo "" >> pkcs7
&& echo "-----END PKCS7-----" >> pkcs7
```

3. Find the DSA public certificate for your Region in *AWS public certificates* (p. 1049) and add the contents to a new file named certificate.

4. Use the OpenSSL smime command to verify the signature. Include the -verify option to indicate that the signature needs to be verified, and the -noverify option to indicate that the certificate does not need to be verified.

```bash
$ openssl smime -verify -in pkcs7 -inform PEM -certfile certificate -noverify | tee document
```

If the signature is valid, the Verification successful message appears.

The command also writes the contents of the instance identity document to a new file named `document`. You can compare the contents of the of the instance identity document from the instance metadata with the contents of this file using the following commands.

```bash
$ openssl dgst -sha256 < document
```

If the signature cannot be verified, contact AWS Support.
Use the base64-encoded signature to verify the instance identity document

This topic explains how to verify the instance identity document using the base64-encoded signature and the AWS RSA public certificate.

To validate the instance identity document using the base64-encoded signature and the AWS RSA public certificate

1. Connect to the instance.
2. Retrieve the base64-encoded signature from the instance metadata, convert it to binary, and add it to a file named `signature`. Use one of the following commands depending on the IMDS version used by the instance.

IMDSv2

```bash
```

IMDSv1

```bash
```

3. Retrieve the plaintext instance identity document from the instance metadata and add it to a file named `document`. Use one of the following commands depending on the IMDS version used by the instance.

IMDSv2

```bash
```

IMDSv1

```bash
```

4. Find the RSA public certificate for your Region in AWS public certificates (p. 1049) and add the contents to a new file named `certificate`.

5. Extract the public key from the AWS RSA public certificate and save it to a file named `key`.

```bash
$ openssl x509 -pubkey -noout -in certificate >> key
```

6. Use OpenSSL `dgst` command to verify the instance identity document.

```bash
$ openssl dgst -sha256 -verify key -signature signature document
```

If the signature is valid, the Verification successful message appears.

The command also writes the contents of the instance identity document to a new file named `document`. You can compare the contents of the of the instance identity document from the instance metadata with the contents of this file using the following commands.
Use the RSA-2048 signature to verify the instance identity document

This topic explains how to verify the instance identity document using the RSA-2048 signature and the AWS RSA-2048 public certificate.

To verify the instance identity document using the RSA-2048 signature and the AWS RSA-2048 public certificate

1. Connect to the instance.
2. Retrieve the RSA-2048 signature from the instance metadata and add it to a file named `rsa2048` along the required header and footer. Use one of the following commands depending on the IMDS version used by the instance.

**IMDSv2**

```bash
$ echo "-----BEGIN PKCS7-----" >> rsa2048
&& echo "" >> rsa2048
&& echo "-----END PKCS7-----" >> rsa2048
```

**IMDSv1**

```bash
$ echo "-----BEGIN PKCS7-----" >> rsa2048
&& echo "" >> rsa2048
&& echo "-----END PKCS7-----" >> rsa2048
```

3. Find the **RSA-2048** public certificate for your Region in [AWS public certificates (p. 1049)](#) and add the contents to a new file named `certificate`.
4. Use the **OpenSSL smime** command to verify the signature. Include the `-verify` option to indicate that the signature needs to be verified, and the `-noverify` option to indicate that the certificate does not need to be verified.

```bash
$ openssl smime -verify -in rsa2048 -inform PEM -certfile certificate -noverify | tee document
```

If the signature is valid, the **Verification successful** message appears. If the signature cannot be verified, contact AWS Support.

AWS public certificates

The following AWS public certificates can be used to verify the contents of an instance's instance identity document as described in the following topics:
Ensure that you use the correct certificate for your Region and for the verification procedure that you're using. If you're verifying the PKCS7 signature, use the DSA certificate. If you're verifying the base64-encoded signature, use the RSA certificate. If you're verifying the RSA-2048 signature, use the RSA-2048 certificate.

Expand each Region below to view the Region-specific certificates.

Instance identity roles

Each instance that you launch has an instance identity role that represents its identity. An instance identity role is a type of IAM role. AWS services and features that are integrated to use the instance identity role can use it to identify the instance to the service.

The instance identity role credentials are accessible from the Instance Metadata Service (IMDS) at /identity-credentials/ec2/security-credentials/ec2-instance. The credentials consist of an AWS temporary access key pair and a session token. They are used to sign AWS Sigv4 requests to the AWS services that use the instance identity role. The credentials are present in the instance metadata regardless of whether a service or feature that makes use of instance identity roles is enabled on the instance.

Instance identity roles are automatically created when an instance is launched, have no role-trust policy document, and are not subject to any identity or resource policy.

Supported services

The following AWS services use the instance identity role:

- **Amazon EC2** – **EC2 Instance Connect** (p. 831) uses the instance identity role to update the host keys for a Linux instance.
- **Amazon GuardDuty** – **EKS Runtime Monitoring** uses the instance identity role to allow the runtime agent to send security telemetry to the GuardDuty VPC endpoint.
- **AWS Security Token Service (AWS STS)** – Instance identity role credentials can be used with the AWS STS `GetCallerIdentity` action.
- **AWS Systems Manager** – When using Default Host Management Configuration, AWS Systems Manager uses the identity provided by the instance identity role to register EC2 instances. After identifying your instance, Systems Manager can pass your AWSSystemsManagerDefaultEC2InstanceManagementRole IAM role to your instance.

Instance identity roles can't be used with other AWS services or features because they do not have an integration with instance identity roles.

Instance identity role ARN

The instance identity role ARN takes the following format:

```
arn:aws-partition:iam::account-number:assumed-role/aws:ec2-instance-instance-id
```
For example:

```
arn:aws:iam::0123456789012:assumed-role/aws:ec2-instance/i-0123456789example
```

For more information about ARNs, see Amazon Resource Names (ARNs) in the IAM User Guide.

## Amazon Elastic Inference

**Note**

Starting April 15, 2023, AWS will not onboard new customers to Amazon Elastic Inference (EI), and will help current customers migrate their workloads to options that offer better price and performance. After April 15, 2023, new customers will not be able to launch instances with Amazon EI accelerators in Amazon SageMaker, Amazon ECS, or Amazon EC2. However, customers who have used Amazon EI at least once during the past 30-day period are considered current customers and will be able to continue using the service.

Amazon Elastic Inference (EI) is a resource you can attach to your Amazon EC2 CPU instances for your deep learning (DL) inference workloads.

For more information about Amazon EI, see the Amazon Elastic Inference Developer Guide.

### Identify EC2 Linux instances

You might need to determine whether your application is running on an EC2 instance.

For information about identifying Windows instances, see Identify EC2 Windows instances in the Amazon EC2 User Guide for Windows Instances.

### Inspect the instance identity document

For a definitive and cryptographically verified method of identifying an EC2 instance, check the instance identity document, including its signature. These documents are available on every EC2 instance at the local, non-routable address http://169.254.169.254/latest/dynamic/instance-identity/.

For more information, see Instance identity documents (p. 1044).

### Inspect the system UUID

You can get the system UUID and look for the presence of the characters "ec2" or "EC2" in the beginning octet of the UUID. This method to determine whether a system is an EC2 instance is quick but potentially inaccurate because there is a small chance that a system that is not an EC2 instance could have a UUID that starts with these characters. Furthermore, for EC2 instances that are not using Amazon Linux 2, the distribution's implementation of SMBIOS might represent the UUID in little-endian format, therefore the "EC2" characters do not appear at the beginning of the UUID.

**Example : Get the UUID from DMI (HVM AMIs only)**

Use the following command to get the UUID using the Desktop Management Interface (DMI):

```
[ec2-user ~]$ sudo dmidecode --string system-uuid
```

In the following example output, the UUID starts with "EC2", which indicates that the system is probably an EC2 instance.
Inspect the system virtual machine generation identifier

A virtual machine generation identifier consists of a unique buffer of 128-bit interpreted as cryptographic random integer identifier. You can retrieve the virtual machine generation identifier to identify your Amazon Elastic Compute Cloud instance. The generation identifier is exposed within the guest operating system of the instance through an ACPI table entry. The value will change if your machine is cloned, copied, or imported into AWS, such as with VM Import/Export.

Example: Get the UUID from the hypervisor (PV AMIs only)

Use the following command to get the UUID from the hypervisor:

```
[ec2-user ~]$ cat /sys/hypervisor/uuid
```

In the following example output, the UUID starts with "ec2", which indicates that the system is probably an EC2 instance.

```
e2ce1916-9099-7caf-fd21-012345abcdef
```

Example: Retrieve the virtual machine generation identifier from Linux

You can use the following commands to retrieve the virtual machine generation identifier from your instances running Linux.

Amazon Linux 2

1. Update your existing software packages, as necessary, using the following command:

   ```
sudo yum update
   ```

2. If necessary, source the busybox package with the following command:

   ```
sudo curl https://www.rpmfind.net/linux/epel/next/8/Everything/x86_64/Packages/b/busybox-1.35.0-2.el8.next.x86_64.rpm --output busybox.rpm
   ```

3. If necessary, install the prerequisite packages using the following command:

   ```
sudo yum install busybox.rpm iasl -y
   ```
4. Run the following `iasl` command to produce output from the ACPI table:

```bash
sudo iasl -p ./SSDT2 -d /sys/firmware/acpi/tables/SSDT2
```

5. Run the following command to review the output of the `iasl` command:

```bash
cat SSDT2.dsl
```

The output should yield the address space required to retrieve the virtual machine generation identifier:

```
```

```

```

Your output should be similar to the following:

```
EC2F335D979132C4165896753E72BD1C
```
EC2 Fleet and Spot Fleet

EC2 Fleet and Spot Fleet are designed to be a useful way to launch a fleet—or group—of instances with AWS. Each instance in a fleet is based on a launch template (p. 736).

Fleets provide the following features and benefits. These benefits make it possible for you to maximize cost savings and optimize availability and performance when running applications on multiple EC2 instances.

**Multiple instance types and purchase options**
In a single API call, a fleet can launch multiple instance types and purchase options (Spot and On-Demand Instances), allowing you to optimize costs through Spot Instance usage. You can also take advantage of Reserved Instance and Savings Plan discounts by using them in conjunction with On-Demand Instances in the fleet.

**Distributing instances across Availability Zones**
A fleet automatically attempts to distribute instances evenly across multiple Availability Zones for high availability. This provides resiliency in case an Availability Zone becomes unavailable. As an added benefit, you can access a deeper Amazon EC2 capacity pool when compared to fleets in a single Availability Zone.

**Automated replacement of Spot Instances**
If your fleet includes Spot Instances, it can automatically request replacement Spot capacity if your Spot Instances are interrupted or become impaired due to a change in instance health. Through Capacity Rebalancing, a fleet can also monitor and proactively replace your Spot Instances that are at an elevated risk of interruption.

As a general best practice, we recommend launching fleets of Spot and On-Demand Instances with Amazon EC2 Auto Scaling because it provides additional features you can use to manage your fleet. The list of additional features includes automatic health check replacements for both Spot and On-Demand Instances, application-based health checks, and an integration with Elastic Load Balancing to ensure an even distribution of application traffic to your healthy instances. You can also use Auto Scaling groups when you use AWS services such as Amazon ECS, Amazon EKS (self-managed node groups), and Amazon VPC Lattice. For more information, see the Amazon EC2 Auto Scaling User Guide.

EC2 Fleet is a good option if you require more flexibility for managing aspects of the instance lifecycle or the scaling mechanisms. You can also use Spot Fleet, but we don't recommend that you do because it's a legacy API with no planned investment. However, if you are already using Spot Fleet, you can continue using it. Spot Fleet and EC2 Fleet offer the same core functionality.

**Topics**
- EC2 Fleet (p. 1089)
- Spot Fleet (p. 1152)
- Monitor fleet events using Amazon EventBridge (p. 1206)
- Tutorials for EC2 Fleet and Spot Fleet (p. 1222)
- Example configurations for EC2 Fleet and Spot Fleet (p. 1235)
- Fleet quotas (p. 1262)
Demand Instance, Reserved Instance, and Savings Plan purchasing options together. Using EC2 Fleet, you can:

- Define separate Spot and On-Demand capacity targets and the maximum amount you’re willing to pay per hour
- Specify the instance types that work best for your applications
- Specify how Amazon EC2 should distribute your fleet capacity within each purchasing option

You can also set a maximum amount per hour that you’re willing to pay for your fleet, and EC2 Fleet launches instances until it reaches the maximum amount. When the maximum amount you’re willing to pay is reached, the fleet stops launching instances even if it hasn’t met the target capacity.

The EC2 Fleet attempts to launch the number of instances that are required to meet the target capacity specified in your request. If you specified a total maximum price per hour, it fulfills the capacity until it reaches the maximum amount that you’re willing to pay. The fleet can also attempt to maintain its target Spot capacity if your Spot Instances are interrupted. For more information, see How Spot Instances work (p. 554).

You can specify an unlimited number of instance types per EC2 Fleet. Those instance types can be provisioned using both Spot and On-Demand purchasing options. You can also specify multiple Availability Zones, specify different maximum Spot prices for each instance, and choose additional Spot options for each fleet. Amazon EC2 uses the specified options to provision capacity when the fleet launches.

While the fleet is running, if Amazon EC2 reclaims a Spot Instance because of a price increase or instance failure, EC2 Fleet can try to replace the instances with any of the instance types that you specify. This makes it easier to regain capacity during a spike in Spot pricing. You can develop a flexible and elastic resourcing strategy for each fleet. For example, within specific fleets, your primary capacity can be On-Demand supplemented with less-expensive Spot capacity if available.

If you have Reserved Instances and you specify On-Demand Instances in your fleet, EC2 Fleet uses your Reserved Instances. For example, if your fleet specifies an On-Demand Instance as c4.large, and you have Reserved Instances for c4.large, you receive the Reserved Instance pricing. The same applies if you use a Savings Plan.

There is no additional charge for using EC2 Fleet. You pay only for the EC2 instances that the fleet launches for you.

Contents
- EC2 Fleet limitations (p. 1091)
- Burstable performance instances (p. 1091)
- EC2 Fleet request types (p. 1091)
- EC2 Fleet configuration strategies (p. 1109)
EC2 Fleet limitations

The following limitations apply to EC2 Fleet:

- EC2 Fleet is available only through the Amazon EC2 API, AWS CLI, AWS SDKs, and AWS CloudFormation.
- An EC2 Fleet request can’t span AWS Regions. You need to create a separate EC2 Fleet for each Region.
- An EC2 Fleet request can’t span different subnets from the same Availability Zone.

Burstable performance instances

If you launch your Spot Instances using a burstable performance instance type (p. 330), and if you plan to use your burstable performance Spot Instances immediately and for a short duration, with no idle time for accruing CPU credits, we recommend that you launch them in Standard mode (p. 345) to avoid paying higher costs. If you launch burstable performance Spot Instances in Unlimited mode (p. 338) and burst CPU immediately, you’ll spend surplus credits for bursting. If you use the instance for a short duration, the instance doesn’t have time to accrue CPU credits to pay down the surplus credits, and you are charged for the surplus credits when you terminate the instance.

Unlimited mode is suitable for burstable performance Spot Instances only if the instance runs long enough to accrue CPU credits for bursting. Otherwise, paying for surplus credits makes burstable performance Spot Instances more expensive than using other instances. For more information, see When to use unlimited mode versus fixed CPU (p. 340).

Launch credits are meant to provide a productive initial launch experience for T2 instances by providing sufficient compute resources to configure the instance. Repeated launches of T2 instances to access new launch credits is not permitted. If you require sustained CPU, you can earn credits (by idling over some period), use Unlimited mode (p. 338) for T2 Spot Instances, or use an instance type with dedicated CPU.

EC2 Fleet request types

There are three types of EC2 Fleet requests:

- instant
  
  If you configure the request type as instant, EC2 Fleet places a synchronous one-time request for your desired capacity. In the API response, it returns the instances that launched, along with errors for those instances that could not be launched. For more information, see Use an EC2 Fleet of type 'instant' (p. 1092).

- request
  
  If you configure the request type as request, EC2 Fleet places an asynchronous one-time request for your desired capacity. Thereafter, if capacity is diminished because of Spot interruptions, the fleet does not attempt to replenish Spot Instances, nor does it submit requests in alternative Spot capacity pools if capacity is unavailable.

- maintain
  
  (Default) If you configure the request type as maintain, EC2 Fleet places an asynchronous request for your desired capacity, and maintains capacity by automatically replenishing any interrupted Spot Instances.
Use an EC2 Fleet of type 'instant'

The EC2 Fleet of type instant is a synchronous one-time request that makes only one attempt to launch your desired capacity. The API response lists the instances that launched, along with errors for those instances that could not be launched. There are several benefits to using an EC2 Fleet of type instant, which are described in this article. Example configurations are provided at the end of the article.

For workloads that need a launch-only API to launch EC2 instances, you can use the RunInstances API. However, with RunInstances, you can only launch On-Demand Instances or Spot Instances, but not both in the same request. Furthermore, when you use RunInstances to launch Spot Instances, your Spot Instance request is limited to one instance type and one Availability Zone. This targets a single Spot capacity pool (a set of unused instances with the same instance type and Availability Zone). If the Spot capacity pool does not have sufficient Spot Instance capacity for your request, the RunInstances call fails.

Instead of using RunInstances to launch Spot Instances, we recommend that you rather use the CreateFleet API with the type parameter set to instant for the following benefits:

- **Launch On-Demand Instances and Spot Instances in one request.** An EC2 Fleet can launch On-Demand Instances, Spot Instances, or both. The request for Spot Instances is fulfilled if there is available capacity and the maximum price per hour for your request exceeds the Spot price.

- **Increase the availability of Spot Instances.** By using an EC2 Fleet of type instant, you can launch Spot Instances following Spot best practices with the resulting benefits:
  - **Spot best practice: Be flexible about instance types and Availability Zones.**
    Benefit: By specifying several instance types and Availability Zones, you increase the number of Spot capacity pools. This gives the Spot service a better chance of finding and allocating your desired Spot compute capacity. A good rule of thumb is to be flexible across at least 10 instance types for each workload, and make sure that all Availability Zones are configured for use in your VPC.
  - **Spot best practice: Use the capacity-optimized allocation strategy.**
    Benefit: The capacity-optimized allocation strategy automatically provisions instances from the most-available Spot capacity pools. Because your Spot Instance capacity is sourced from pools with optimal capacity, this decreases the possibility that your Spot Instances will be interrupted when Amazon EC2 needs the capacity back.

- **Get access to a wider set of capabilities.** For workloads that need a launch-only API, and where you prefer to manage the lifecycle of your instance rather than let EC2 Fleet manage it for you, use the EC2 Fleet of type instant instead of the RunInstances API. EC2 Fleet provides a wider set of capabilities than RunInstances, as demonstrated in the following examples. For all other workloads, you should use Amazon EC2 Auto Scaling because it supplies a more comprehensive feature set for a wide variety of workloads, like ELB-backed applications, containerized workloads, and queue processing jobs.

You can use EC2 Fleet of type instant to launch instances into Capacity Blocks. For more information, see Tutorial: Launch instances into Capacity Blocks (p. 1231).

AWS services like Amazon EC2 Auto Scaling and Amazon EMR use EC2 Fleet of type instant to launch EC2 instances.

**Prerequisites for EC2 Fleet of type instant**

For the prerequisites for creating an EC2 Fleet, see EC2 Fleet prerequisites (p. 1135).

**How instant EC2 Fleet works**

When working with an EC2 Fleet of type instant, the sequence of events is as follows:
1. Configure the CreateFleet request type as instant. For more information, see Create an EC2 Fleet (p. 1140). Note that after you make the API call, you can't modify it.

2. When you make the API call, EC2 Fleet places a synchronous one-time request for your desired capacity.

3. The API response lists the instances that launched, along with errors for those instances that could not be launched.

4. You can describe your EC2 Fleet, list the instances associated with your EC2 Fleet, and view the history of your EC2 Fleet.

5. After your instances have launched, you can delete the fleet request. When deleting the fleet request, you can also choose to terminate the associated instances, or leave them running.

6. You can terminate the instances at any time.

Examples

The following examples show how to use EC2 Fleet of type instant for different use cases. For more information about using the EC2 CreateFleet API parameters, see CreateFleet in the Amazon EC2 API Reference.

Examples

- Example 1: Launch Spot Instances with the capacity-optimized allocation strategy (p. 1093)
- Example 2: Launch a single Spot Instance with the capacity-optimized allocation strategy (p. 1095)
- Example 3: Launch Spot Instances using instance weighting (p. 1096)
- Example 4: Launch Spot Instances within single Availability zone (p. 1097)
- Example 5: Launch Spot Instances of single instance type within single Availability zone (p. 1099)
- Example 6: Launch Spot Instances only if minimum target capacity can be launched (p. 1100)
- Example 7: Launch Spot Instances only if minimum target capacity can be launched of same Instance Type in a single Availability Zone (p. 1101)
- Example 8: Launch instances with multiple Launch Templates (p. 1103)
- Example 9: Launch Spot Instance with a base of On-Demand Instances (p. 1104)
- Example 10: Launch Spot Instances using capacity-optimized allocation strategy with a base of On-Demand Instances using Capacity Reservations and the prioritized allocation strategy (p. 1105)
- Example 11: Launch Spot Instances using capacity-optimized-prioritized allocation strategy (p. 1108)

Example 1: Launch Spot Instances with the capacity-optimized allocation strategy

The following example specifies the parameters required in an EC2 Fleet of type instant: a launch template, target capacity, default purchasing option, and launch template overrides.

- The launch template is identified by its launch template name and version number.
- The 12 launch template overrides specify 4 different instance types and 3 different subnets, each in a separate Availability Zone. Each instance type and subnet combination defines a Spot capacity pool, resulting in 12 Spot capacity pools.
- The target capacity for the fleet is 20 instances.
- The default purchasing option is spot, which results in the fleet attempting to launch 20 Spot Instances into the Spot capacity pool with optimal capacity for the number of instances that are launching.

    "TotalTargetCapacity": 20,
    "DefaultTargetCapacityType": "spot"
  },
  "Type": "instant"
Example 2: Launch a single Spot Instance with the capacity-optimized allocation strategy

You can optimally launch one Spot Instance at a time by making multiple EC2 Fleet API calls of type `instant`, by setting the `TotalTargetCapacity` to 1.

The following example specifies the parameters required in an EC2 Fleet of type `instant`: a launch template, target capacity, default purchasing option, and launch template overrides. The launch template is identified by its launch template name and version number. The 12 launch template overrides have 4 different instance types and 3 different subnets, each in a separate Availability Zone. The target capacity for the fleet is 1 instance, and the default purchasing option is spot, which results in the fleet attempting to launch a Spot Instance from one of the 12 Spot capacity pools based on the capacity-optimized allocation strategy, to launch a Spot Instance from the most-available capacity pool.

```json
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized"
    },
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "ec2-fleet-lt1",
                "Version": "$Latest"
            },
            "Overrides": [
                {
                    "InstanceType": "c5.large",
                    "SubnetId": "subnet-fae8c380"
                },
                {
                    "InstanceType": "c5.large",
                    "SubnetId": "subnet-e7188bab"
                },
                {
                    "InstanceType": "c5.large",
                    "SubnetId": "subnet-49e41922"
                },
                {
                    "InstanceType": "c5d.large",
                    "SubnetId": "subnet-fae8c380"
                },
                {
                    "InstanceType": "c5d.large",
                    "SubnetId": "subnet-e7188bab"
                },
                {
                    "InstanceType": "c5d.large",
                    "SubnetId": "subnet-49e41922"
                },
                {
                    "InstanceType": "m5.large",
                    "SubnetId": "subnet-fae8c380"
                },
                {
                    "InstanceType": "m5.large",
                    "SubnetId": "subnet-e7188bab"
                },
                {
                    "InstanceType": "m5.large",
                    "SubnetId": "subnet-49e41922"
                }
            ]
        }
    ]
}
```
Example 3: Launch Spot Instances using instance weighting

The following examples use instance weighting, which means that the price is per unit hour instead of per instance hour. Each launch configuration lists a different instance type and a different weight based on how many units of the workload can run on the instance assuming a unit of the workload requires a 15 GB of memory and 4 vCPUs. For example an m5.xlarge (4 vCPUs and 16 GB of memory) can run one unit and is weighted 1, m5.2xlarge (8 vCPUs and 32 GB of memory) can run 2 units and is weighted 2, and so on. The total target capacity is set to 40 units. The default purchasing option is spot, and the allocation strategy is capacity-optimized, which results in either 40 m5.xlarge (40 divided by 1), 20 m5.2xlarge (40 divided by 2), 10 m5.4xlarge (40 divided by 4), 5 m5.8xlarge (40 divided by 8), or a mix of the instance types with weights adding up to the desired capacity based on the capacity-optimized allocation strategy.

For more information, see EC2 Fleet instance weighting (p. 1132).
Example 4: Launch Spot Instances within single Availability zone

You can configure a fleet to launch all instances in a single Availability Zone by setting the Spot options SingleAvailabilityZone to true.

The 12 launch template overrides have different instance types and subnets (each in a separate Availability Zone) but the same weighted capacity. The total target capacity is 20 instances, the default purchasing option is spot, and the Spot allocation strategy is capacity-optimized. The EC2 Fleet launches 20 Spot Instances all in a single AZ, from the Spot capacity pool(s) with optimal capacity using the launch specifications.
{ "SpotOptions": { "AllocationStrategy": "capacity-optimized", "SingleAvailabilityZone": true }, "LaunchTemplateConfigs": [ { "LaunchTemplateName": "ec2-fleet-lt1", "Version": "$Latest" }, "Overrides": [ { "InstanceType": "c5.4xlarge", "SubnetId": "subnet-fae8c380" }, { "InstanceType": "c5d.4xlarge", "SubnetId": "subnet-e7188bab" }, { "InstanceType": "c5d.4xlarge", "SubnetId": "subnet-49e41922" }, { "InstanceType": "c5.4xlarge", "SubnetId": "subnet-fae8c380" }, { "InstanceType": "c5d.4xlarge", "SubnetId": "subnet-e7188bab" }, { "InstanceType": "c5d.4xlarge", "SubnetId": "subnet-49e41922" }, { "InstanceType": "m5.4xlarge", "SubnetId": "subnet-fae8c380" }, { "InstanceType": "m5.4xlarge", "SubnetId": "subnet-e7188bab" }, { "InstanceType": "m5d.4xlarge", "SubnetId": "subnet-49e41922" }, { "InstanceType": "m5d.4xlarge", "SubnetId": "subnet-fae8c380" }, { "InstanceType": "m5d.4xlarge", "SubnetId": "subnet-e7188bab" }, { "InstanceType": "m5d.4xlarge", "SubnetId": "subnet-49e41922" } ] }, "TargetCapacitySpecification": { "TotalTargetCapacity": 20,}
Example 5: Launch Spot Instances of single instance type within single Availability zone

You can configure a fleet to launch all instances of the same instance type and in a single Availability Zone by setting the SpotOptions SingleInstanceType to true and SingleAvailabilityZone to true.

The 12 launch template overrides have different instance types and subnets (each in a separate Availability Zone) but the same weighted capacity. The total target capacity is 20 instances, the default purchasing option is spot, the Spot allocation strategy is capacity-optimized. The EC2 Fleet launches 20 Spot Instances of the same instance type all in a single AZ from the Spot Instance pool with optimal capacity using the launch specifications.

```json
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized",
        "SingleInstanceType": true,
        "SingleAvailabilityZone": true
    },
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "ec2-fleet-lt1",
                "Version": "$Latest"
            },
            "Overrides": [
                {
                    "InstanceType": "c5.4xlarge",
                    "SubnetId": "subnet-fae8c380"
                },
                {
                    "InstanceType": "c5.4xlarge",
                    "SubnetId": "subnet-e7188bab"
                },
                {
                    "InstanceType": "c5.4xlarge",
                    "SubnetId": "subnet-49e41922"
                },
                {
                    "InstanceType": "c5d.4xlarge",
                    "SubnetId": "subnet-fae8c380"
                },
                {
                    "InstanceType": "c5d.4xlarge",
                    "SubnetId": "subnet-e7188bab"
                },
                {
                    "InstanceType": "c5d.4xlarge",
                    "SubnetId": "subnet-49e41922"
                },
                {
                    "InstanceType": "m5.4xlarge",
                    "SubnetId": "subnet-fae8c380"
                },
                {
                    "InstanceType": "m5.4xlarge",
                    "SubnetId": "subnet-e7188bab"
                },
                {
                    "InstanceType": "m5.4xlarge",
                    "SubnetId": "subnet-49e41922"
                }
            ]
        }
    ]
}
```
Example 6: Launch Spot Instances only if minimum target capacity can be launched

You can configure a fleet to launch instances only if the minimum target capacity can be launched by setting the Spot options MinTargetCapacity to the minimum target capacity you want to launch together.

The 12 launch template overrides have different instance types and subnets (each in a separate Availability Zone) but the same weighted capacity. The total target capacity and the minimum target capacity are both set to 20 instances, the default purchasing option is spot, the Spot allocation strategy is capacity-optimized. The EC2 Fleet launches 20 Spot Instances from the Spot capacity pool with optimal capacity using the launch template overrides, only if it can launch all 20 instances at the same time.
Example 7: Launch Spot Instances only if minimum target capacity can be launched of same Instance Type in a single Availability Zone

You can configure a fleet to launch instances only if the minimum target capacity can be launched with a single instance type in a single Availability Zone by setting the Spot options MinTargetCapacity to the minimum target capacity you want to launch together along with SingleInstanceType and SingleAvailabilityZone options.

The 12 launch specifications which override the launch template, have different instance types and subnets (each in a separate Availability Zone) but the same weighted capacity. The total target capacity and the minimum target capacity are both set to 20 instances, the default purchasing option is spot, the Spot allocation strategy is capacity-optimized, the SingleInstanceType is true and SingleAvailabilityZone is true. The EC2 Fleet launches 20 Spot Instances of the same Instance type all in a single AZ from the Spot capacity pool with optimal capacity using the launch specifications, only if it can launch all 20 instances at the same time.

```json
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized",
```
"SingleInstanceType": true,
"SingleAvailabilityZone": true,
"MinTargetCapacity": 20,
"LaunchTemplateConfigs": [
  {
    "LaunchTemplateSpecification": {
      "LaunchTemplateName": "ec2-fleet-lt1",
      "Version": "$Latest"
    },
    "Overrides": [
      {
        "InstanceType": "c5.4xlarge",
        "SubnetId": "subnet-fae8c380"
      },
      {
        "InstanceType": "c5.4xlarge",
        "SubnetId": "subnet-e7188bab"
      },
      {
        "InstanceType": "c5.4xlarge",
        "SubnetId": "subnet-49e41922"
      },

Example 8: Launch instances with multiple Launch Templates

You can configure a fleet to launch instances with different launch specifications for different instance
types or a group of instance types, by specifying multiple launch templates. In this example we want
have different EBS volume sizes for different instance types and we have that configured in the launch
templates ec2-fleet-lt-4xl, ec2-fleet-lt-9xl and ec2-fleet-lt-18xl.

In this example, we are using 3 different launch templates for the 3 instance types based on their size.
The launch specification overrides on all the launch templates use instance weights based on the vCPUs
on the instance type. The total target capacity is 144 units, the default purchasing option is spot, and
the Spot allocation strategy is capacity-optimized. The EC2 Fleet can either launch 9 c5n.4xlarge (144
divided by 16) using the launch template ec2-fleet-4xl or 4 c5n.9xlarge (144 divided by 36) using the
launch template ec2-fleet-9xl, or 2 c5n.18xlarge (144 divided by 72) using the launch template ec2-
fleet-18xl, or a mix of the instance types with weights adding up to the desired capacity based on the
capacity-optimized allocation strategy.

```json
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized"
    },
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "ec2-fleet-lt-18xl",
                "Version": "$Latest"
            },
            "Overrides": [
                {
                    "InstanceType": "c5n.18xlarge",
                    "SubnetId": "subnet-fae8c380",
                    "WeightedCapacity": 72
                },
                {
                    "InstanceType": "c5n.18xlarge",
                    "SubnetId": "subnet-e7188bab",
                    "WeightedCapacity": 72
                },
                {
                    "InstanceType": "c5n.18xlarge",
                    "SubnetId": "subnet-49e41922",
                    "WeightedCapacity": 72
                }
            ]
        },
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "ec2-fleet-lt-9xl",
                "Version": "$Latest"
            },
            "Overrides": [
                {
                    "InstanceType": "c5n.9xlarge",
                    "SubnetId": "subnet-fae8c380",
                    "WeightedCapacity": 36
                },
                {
                    "InstanceType": "c5n.9xlarge",
                    "SubnetId": "subnet-e7188bab",
                    "WeightedCapacity": 36
                }
            ]
        }
    ]
}
```
Example 9: Launch Spot Instance with a base of On-Demand Instances

The following example specifies the total target capacity of 20 instances for the fleet, and a target capacity of 5 On-Demand Instances. The default purchasing option is spot. The fleet launches 5 On-Demand Instance as specified, but needs to launch 15 more instances to fulfill the total target capacity. The purchasing option for the difference is calculated as TotalTargetCapacity – OnDemandTargetCapacity = DefaultTargetCapacityType, which results in the fleet launching 15 Spot Instances form one of the 12 Spot capacity pools based on the capacity-optimized allocation strategy.

```json
{  "SpotOptions": {   "AllocationStrategy": "capacity-optimized"  },  "LaunchTemplateConfigs": [   {     "LaunchTemplateSpecification": {       "LaunchTemplateName": "ec2-fleet-lt1",       "Version": "$Latest"     },     "Overrides": [       {         "InstanceType": "c5.large",         "SubnetId": "subnet-fae8c380"       },       {         "InstanceType": "c5n.4xlarge",         "SubnetId": "subnet-e7188bab",         "WeightedCapacity": 16       }     ]   }  ],  "TargetCapacitySpecification": {   "TotalTargetCapacity": 144,   "DefaultTargetCapacityType": "spot"  },  "Type": "instant"}
```
Example 10: Launch Spot Instances using capacity-optimized allocation strategy with a base of On-Demand Instances using Capacity Reservations and the prioritized allocation strategy

You can configure a fleet to use On-Demand Capacity Reservations first when launching a base of On-Demand Instances with the default target capacity type as spot by setting the usage strategy for Capacity Reservations to use-capacity-reservations-first. And if multiple instance pools have unused Capacity Reservations, the chosen On-Demand allocation strategy is applied. In this example, the On-Demand allocation strategy is prioritized.

In this example, there are 6 available unused Capacity Reservations. This is less than the fleet's target On-Demand capacity of 10 On-Demand Instances.
The account has the following 6 unused Capacity Reservations in 2 pools. The number of Capacity
Reservations in each pool is indicated by AvailableInstanceCount.

```
{
    "CapacityReservationId": "cr-111",
    "InstanceType": "m5.large",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 3,
    "InstanceMatchCriteria": "open",
    "State": "active"
}
{
    "CapacityReservationId": "cr-222",
    "InstanceType": "c5.large",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 3,
    "InstanceMatchCriteria": "open",
    "State": "active"
}
```

The following fleet configuration shows only the pertinent configurations for this example. The On-Demand allocation strategy is prioritized, and the usage strategy for Capacity Reservations is use-capacity-reservations-first. The Spot allocation strategy is capacity-optimized. The total target capacity is 20, the On-Demand target capacity is 10, and the default target capacity type is spot.

```
{
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized"
    },
    "OnDemandOptions": {
        "OnDemandOptions": {
            "CapacityReservationOptions": {
                "UsageStrategy": "use-capacity-reservations-first"
            },
            "AllocationStrategy": "prioritized"
        },
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "ec2-fleet-lt1",
                    "Version": "$Latest"
                },
                "Overrides": [
                    {
                        "InstanceType": "c5.large",
                        "SubnetId": "subnet-49e41922",
                        "Priority": 3.0
                    },
                    {
                        "InstanceType": "c5.large",
                        "SubnetId": "subnet-e7188bab",
                        "Priority": 2.0
                    },
                    {
                        "InstanceType": "c5.large",
                        "SubnetId": "subnet-49e41922",
                        "Priority": 3.0
                    },
                    {
                        "InstanceType": "c5.large",
                        "SubnetId": "subnet-fae8c380",
                        "Priority": 1.0
                    }
                ]
            }
        ]
    }
}```
After you create the instant fleet using the preceding configuration, the following 20 instances are launched to meet the target capacity:

- 7 c5.large On-Demand Instances in us-east-1a – c5.large in us-east-1a is prioritized first, and there are 3 available unused c5.large Capacity Reservations. The Capacity Reservations are used first to launch 3 On-Demand Instances plus 4 additional On-Demand Instances are launched according to the On-Demand allocation strategy, which is prioritized in this example.

- 3 m5.large On-Demand Instances in us-east-1a – m5.large in us-east-1a is prioritized second, and there are 3 available unused c3.large Capacity Reservations.
- 10 Spot Instances from one of the 12 Spot capacity pools that has the optimal capacity according to the capacity-optimized allocation strategy.

After the fleet is launched, you can run `describe-capacity-reservations` to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the c5.large and m5.large Capacity Reservations were used.

```json
{
  "CapacityReservationId": "cr-111",
  "InstanceType": "m5.large",
  "AvailableInstanceCount": 0
}
{
  "CapacityReservationId": "cr-222",
  "InstanceType": "c5.large",
  "AvailableInstanceCount": 0
}
```

**Example 11: Launch Spot Instances using capacity-optimized-prioritized allocation strategy**

The following example specifies the parameters required in an EC2 Fleet of type instant: a launch template, target capacity, default purchasing option, and launch template overrides. The launch template is identified by its launch template name and version number. The 12 launch specifications which override the launch template have 4 different instance types with a priority assigned, and 3 different subnets, each in a separate Availability Zone. The target capacity for the fleet is 20 instances, and the default purchasing option is spot, which results in the fleet attempting to launch 20 Spot Instances from one of the 12 Spot capacity pools based on the capacity-optimized-prioritized allocation strategy, which implements priorities on a best-effort basis, but optimizes for capacity first.

```json
{
  "SpotOptions": {  
    "AllocationStrategy": "capacity-optimized-prioritized"
  },
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateName": "ec2-fleet-lt1",
        "Version": "$Latest"
      },
      "Overrides": [  
        {  
          "InstanceType": "c5.large",
          "SubnetId": "subnet-fae8c380",
          "Priority": 1.0
        },
        {  
          "InstanceType": "c5.large",
          "SubnetId": "subnet-e7188bab",
          "Priority": 1.0
        },
        {  
          "InstanceType": "c5.large",
          "SubnetId": "subnet-49e41922",
          "Priority": 1.0
        },
        {  
          "InstanceType": "c5d.large",
          "SubnetId": "subnet-fae8c380",
          "Priority": 2.0
        }
      ]
    }
  ]
}
```
EC2 Fleet configuration strategies

An EC2 Fleet is a group of On-Demand Instances and Spot Instances. EC2 Fleet can also be a group of Capacity Blocks instances.

**On-Demand Instances and Spot Instances**

The EC2 Fleet attempts to launch the number of instances that are required to meet the target capacity that you specify in the fleet request. The fleet can comprise only On-Demand Instances, only Spot Instances, or a combination of both On-Demand Instances and Spot Instances. The request for Spot Instances is fulfilled if there is available capacity and the maximum price per hour for your request exceeds the Spot price. The fleet also attempts to maintain its target capacity if your Spot Instances are interrupted.
You can also set a maximum amount per hour that you’re willing to pay for your fleet, and EC2 Fleet launches instances until it reaches the maximum amount. When the maximum amount you’re willing to pay is reached, the fleet stops launching instances even if it hasn’t met the target capacity.

A *Spot capacity pool* is a set of unused EC2 instances with the same instance type and Availability Zone. When you create an EC2 Fleet, you can include multiple launch specifications, which vary by instance type, Availability Zone, subnet, and maximum price. The fleet selects the Spot capacity pools that are used to fulfill the request, based on the launch specifications included in your request, and the configuration of the request. The Spot Instances come from the selected pools.

An EC2 Fleet enables you to provision large amounts of EC2 capacity that makes sense for your application based on number of cores or instances, or amount of memory. For example, you can specify an EC2 Fleet to launch a target capacity of 200 instances, of which 130 are On-Demand Instances and the rest are Spot Instances.

**Capacity Blocks instances**

Capacity Blocks for ML allow you to reserve GPU instances on a future date to support you short duration machine learning (ML) workloads. Instances that run in a Capacity Block are automatically placed close together inside *Amazon EC2 UltraClusters*. For more information about Capacity Blocks, see [Capacity Blocks for ML](#).

Use the appropriate configuration strategies to create an EC2 Fleet that meets your needs.

- [Plan an EC2 Fleet](#) (p. 1110)
- [Allocation strategies for Spot Instances](#) (p. 1111)
- [Attribute-based instance type selection for EC2 Fleet](#) (p. 1114)
- [Configure EC2 Fleet for On-Demand backup](#) (p. 1127)
- [Capacity Rebalancing](#) (p. 1128)
- [Maximum price overrides](#) (p. 1131)
- [Control spending](#) (p. 1132)
- [EC2 Fleet instance weighting](#) (p. 1132)

**Plan an EC2 Fleet**

When planning your EC2 Fleet, we recommend that you do the following:

- Determine whether you want to create an EC2 Fleet that submits a synchronous or asynchronous one-time request for the desired target capacity, or one that maintains a target capacity over time. For more information, see [EC2 Fleet request types](#) (p. 1091).
- Determine the instance types that meet your application requirements.
- If you plan to include Spot Instances in your EC2 Fleet, review [Spot Best Practices](#) before you create the fleet. Use these best practices when you plan your fleet so that you can provision the instances at the lowest possible price.
- Determine the target capacity for your EC2 Fleet. You can set target capacity in instances or in custom units. For more information, see [EC2 Fleet instance weighting](#) (p. 1132).
- Determine what portion of the EC2 Fleet target capacity must be On-Demand capacity and Spot capacity. You can specify 0 for On-Demand capacity or Spot capacity, or both.
- Determine your price per unit, if you are using instance weighting. To calculate the price per unit, divide the price per instance hour by the number of units (or weight) that this instance represents. If you are not using instance weighting, the default price per unit is the price per instance hour.
EC2 Fleet configuration strategies

- Determine the maximum amount per hour that you're willing to pay for your fleet. For more information, see Control spending (p. 1132).
- Review the possible options for your EC2 Fleet. For information about the fleet parameters, see create-fleet in the AWS CLI Command Reference. For EC2 Fleet configuration examples, see EC2 Fleet example configurations (p. 1235).

Allocation strategies for Spot Instances

Your launch configuration determines all the possible Spot capacity pools (instance types and Availability Zones) from which EC2 Fleet can launch Spot Instances. However, when launching instances, EC2 Fleet uses the allocation strategy that you specify to pick the specific pools from all your possible pools.

Note
If you configure your Spot Instance to launch with AMD SEV-SNP (p. 988) turned on, you are charged an additional hourly usage fee that is equivalent to 10% of the On-Demand hourly rate of the selected instance type. If the allocation strategy uses price as an input, EC2 Fleet does not include this additional fee; only the Spot price is used.

Allocation strategies

You can specify one of the following allocation strategies for Spot Instances:

price-capacity-optimized (recommended)

EC2 Fleet identifies the pools with the highest capacity availability for the number of instances that are launching. This means that we will request Spot Instances from the pools that we believe have the lowest chance of interruption in the near term. EC2 Fleet then requests Spot Instances from the lowest priced of these pools.

The price-capacity-optimized allocation strategy is the best choice for most Spot workloads, such as stateless containerized applications, microservices, web applications, data and analytics jobs, and batch processing.

capacity-optimized

EC2 Fleet identifies the pools with the highest capacity availability for the number of instances that are launching. This means that we will request Spot Instances from the pools that we believe have the lowest chance of interruption in the near term. You can optionally set a priority for each instance type in your fleet using capacity-optimized-prioritized. EC2 Fleet optimizes for capacity first, but honors instance type priorities on a best-effort basis.

With Spot Instances, pricing changes slowly over time based on long-term trends in supply and demand, but capacity fluctuates in real time. The capacity-optimized strategy automatically launches Spot Instances into the most available pools by looking at real-time capacity data and predicting which are the most available. This works well for workloads that may have a higher cost of interruption associated with restarting work, such as long Continuous Integration (CI), image and media rendering, Deep Learning, and High Performance Compute (HPC) workloads that may have a higher cost of interruption associated with restarting work. By offering the possibility of fewer interruptions, the capacity-optimized strategy can lower the overall cost of your workload.

Alternatively, you can use the capacity-optimized-prioritized allocation strategy with a priority parameter to order instance types from highest to lowest priority. You can set the same priority for different instance types. EC2 Fleet will optimize for capacity first, but will honor instance type priorities on a best-effort basis (for example, if honoring the priorities will not significantly affect EC2 Fleet's ability to provision optimal capacity). This is a good option for workloads where the possibility of disruption must be minimized and the preference for certain instance types matters. Using priorities is supported only if your fleet uses a launch template. Note that when you
set the priority for capacity-optimized-prioritized, the same priority is also applied to your On-Demand Instances if the On-Demand AllocationStrategy is set to prioritized.

diversified

The Spot Instances are distributed across all Spot capacity pools.

lowest-price

The Spot Instances come from the lowest priced pool that has available capacity. This is the default strategy. However, we recommend that you override the default by specifying the price-capacity-optimized allocation strategy.

If the lowest priced pool doesn't have available capacity, the Spot Instances come from the next lowest priced pool that has available capacity.

If a pool runs out of capacity before fulfilling your desired capacity, EC2 Fleet will continue to fulfill your request by drawing from the next lowest priced pool. To ensure that your desired capacity is met, you might receive Spot Instances from several pools.

Because this strategy only considers instance price and not capacity availability, it might lead to high interruption rates.

InstancePoolsToUseCount

The number of Spot pools across which to allocate your target Spot capacity. Valid only when the allocation strategy is set to lowest-price. EC2 Fleet selects the lowest priced Spot pools and evenly allocates your target Spot capacity across the number of Spot pools that you specify.

Note that EC2 Fleet attempts to draw Spot Instances from the number of pools that you specify on a best effort basis. If a pool runs out of Spot capacity before fulfilling your target capacity, EC2 Fleet will continue to fulfill your request by drawing from the next lowest priced pool. To ensure that your target capacity is met, you might receive Spot Instances from more than the number of pools that you specified. Similarly, if most of the pools have no Spot capacity, you might receive your full target capacity from fewer than the number of pools that you specified.

Choose the appropriate allocation strategy

You can optimize your fleet for your use case by choosing the appropriate Spot allocation strategy. For On-Demand Instance target capacity, EC2 Fleet always selects the least expensive instance type based on the public On-Demand price, while following the allocation strategy—either price-capacity-optimized, capacity-optimized, diversified, or lowest-price—for Spot Instances.

Balance lowest price and capacity availability

To balance the trade-offs between the lowest priced Spot capacity pools and the Spot capacity pools with the highest capacity availability, we recommend that you use the price-capacity-optimized allocation strategy. This strategy makes decisions about which pools to request Spot Instances from based on both the price of the pools and the capacity availability of Spot Instances in those pools. This means that we will request Spot Instances from the pools that we believe have the lowest chance of interruption in the near term, while still taking price into consideration.

If your fleet runs resilient and stateless workloads, including containerized applications, microservices, web applications, data and analytics jobs, and batch processing, then use the price-capacity-optimized allocation strategy for optimal cost savings and capacity availability.

If your fleet runs workloads that might have a higher cost of interruption associated with restarting work, then you should implement checkpointing so that applications can restart from that point if they're interrupted. By using checkpointing, you make the price-capacity-optimized allocation strategy a good fit for these workloads because it allocates capacity from the lowest priced pools that also offer a low Spot Instance interruption rate.
For an example configuration that uses the price-capacity-optimized allocation strategy, see
Example 11: Launch Spot Instances in a price-capacity-optimized fleet (p. 1248).

When workloads have a high cost of interruption

You can optionally use the capacity-optimized strategy if you run workloads that either use similarly
priced instance types, or where the cost of interruption is so significant that any cost saving is inadequate
in comparison to a marginal increase in interruptions. This strategy allocates capacity from the most
available Spot capacity pools that offer the possibility of fewer interruptions, which can lower the overall
cost of your workload. For an example configuration that uses the capacity-optimized allocation
strategy, see Example 9: Launch Spot Instances in a capacity-optimized fleet (p. 1246).

When the possibility of interruptions must be minimized but the preference for certain instance types
matters, you can express your pool priorities by using the capacity-optimized-prioritized allocation strategy and then setting the order of instance types to use from highest to lowest priority.
For an example configuration, see Example 10: Launch Spot Instances in a capacity-optimized fleet with
priorities (p. 1247).

Note that using priorities is supported only if your fleet uses a launch template. Also note that when you
set priorities for capacity-optimized-prioritized, the same priorities are also applied to your On-
Demand Instances if the On-Demand AllocationStrategy is set to prioritized.

When your workload is time flexible and capacity availability is not a factor

If your fleet is small or runs for a short time, you can use price-capacity-optimized to maximize
cost savings while still considering capacity availability.

If your workload is time flexible and capacity availability is not a factor, you can optionally use the
lowest-price allocation strategy to maximize cost savings. Note, however, that because the lowest-
price allocation strategy only considers instance price and not capacity availability, it might lead to high
Spot Instance interruption rates.

When your fleet is large or runs for a long time

If your fleet is large or runs for a long time, you can improve the availability of your fleet by distributing
the Spot Instances across multiple pools using the diversified strategy. For example, if your EC2 Fleet
specifies 10 pools and a target capacity of 100 instances, the fleet launches 10 Spot Instances in each
pool. If the Spot price for one pool exceeds your maximum price for this pool, only 10% of your fleet is
affected. Using this strategy also makes your fleet less sensitive to increases in the Spot price in any one
pool over time. With the diversified strategy, the EC2 Fleet does not launch Spot Instances into any
pools with a Spot price that is equal to or higher than the On-Demand price.

To create an inexpensive and diversified fleet, use the lowest-price strategy in combination with
InstancePoolsToUseCount. For example, if your target capacity is 10 Spot Instances, and you specify
2 Spot capacity pools (for InstancePoolsToUseCount), EC2 Fleet will draw on the two lowest priced
pools to fulfill your Spot capacity.

You can use a low or high number of Spot capacity pools across which to allocate your Spot Instances.
For example, if you run batch processing, we recommend specifying a low number of Spot capacity
pools (for example, InstancePoolsToUseCount=2) to ensure that your queue always has compute
capacity while maximizing savings. If you run a web service, we recommend specifying a high number of
Spot capacity pools (for example, InstancePoolsToUseCount=10) to minimize the impact if a Spot
capacity pool becomes temporarily unavailable.

Note that EC2 Fleet attempts to draw Spot Instances from the number of pools that you specify on
a best effort basis. If a pool runs out of Spot capacity before fulfilling your target capacity, EC2 Fleet
will continue to fulfill your request by drawing from the next lowest priced pool. To ensure that your
target capacity is met, you might receive Spot Instances from more than the number of pools that you
specified. Similarly, if most of the pools have no Spot capacity, you might receive your full target capacity
from fewer than the number of pools that you specified.
Maintain target capacity

After Spot Instances are terminated due to a change in the Spot price or available capacity of a Spot capacity pool, an EC2 Fleet of type maintain launches replacement Spot Instances. The allocation strategy determines the pools from which the replacement instances are launched, as follows:

- If the allocation strategy is price-capacity-optimized, the fleet launches replacement instances in the pools that have the most Spot Instance capacity availability while also taking price into consideration and identifying lowest priced pools with high capacity availability.
- If the allocation strategy is capacity-optimized, the fleet launches replacement instances in the pools that have the most Spot Instance capacity availability.
- If the allocation strategy is diversified, the fleet distributes the replacement Spot Instances across the remaining pools.
- If the allocation strategy is lowest-price, the fleet launches replacement instances in the pool where the Spot price is currently the lowest.
- If the allocation strategy is lowest-price in combination with InstancePoolsToUseCount, the fleet selects the Spot capacity pools with the lowest price and launches Spot Instances across the number of Spot capacity pools that you specify.

Attribute-based instance type selection for EC2 Fleet

When you create an EC2 Fleet, you must specify one or more instance types for configuring the On-Demand Instances and Spot Instances in the fleet. As an alternative to manually specifying the instance types, you can specify the attributes that an instance must have, and Amazon EC2 will identify all the instance types with those attributes. This is known as attribute-based instance type selection. For example, you can specify the minimum and maximum number of vCPUs required for your instances, and EC2 Fleet will launch the instances using any available instance types that meet those vCPU requirements.

Attribute-based instance type selection is ideal for workloads and frameworks that can be flexible about what instance types they use, such as when running containers or web fleets, processing big data, and implementing continuous integration and deployment (CI/CD) tooling.

Benefits

Attribute-based instance type selection has the following benefits:

- With so many instance types available, finding the right instance types for your workload can be time consuming. When you specify instance attributes, the instance types will automatically have the required attributes for your workload.
- To manually specify multiple instance types for an EC2 Fleet, you must create a separate launch template override for each instance type. But with attribute-based instance type selection, to provide multiple instance types, you need only specify the instance attributes in the launch template or in a launch template override.
- When you specify instance attributes rather than instance types, your fleet can use newer generation instance types as they're released, "future proofing" the fleet's configuration.
- When you specify instance attributes rather than instance types, EC2 Fleet can select from a wide range of instance types for launching Spot Instances, which adheres to the Spot best practice of instance type flexibility (p. 552).

Topics

- How attribute-based instance type selection works (p. 1115)
- Considerations (p. 1116)
- Create an EC2 Fleet with attribute-based instance type selection (p. 1117)
How attribute-based instance type selection works

To use attribute-based instance type selection in your fleet configuration, you replace the list of instance types with a list of instance attributes that your instances require. EC2 Fleet will launch instances on any available instance types that have the specified instance attributes.

Topics

- Types of instance attributes (p. 1115)
- Where to configure attribute-based instance type selection (p. 1115)
- How EC2 Fleet uses attribute-based instance type selection when provisioning a fleet (p. 1115)
- Price protection (p. 1116)

Types of instance attributes

There are several instance attributes that you can specify to express your compute requirements. For a description of each attribute and the default values, see InstanceRequirements in the Amazon EC2 API Reference.

Where to configure attribute-based instance type selection

Depending on whether you use the console or the AWS CLI, you can specify the instance attributes for attribute-based instance type selection as follows:

In the console, you can specify the instance attributes in the following fleet configuration component:

- In a launch template, and then reference the launch template in the fleet request

In the AWS CLI, you can specify the instance attributes in one or all of the following fleet configuration components:

- In a launch template, and then reference the launch template in the fleet request
- In a launch template override
  
  If you want a mix of instances that use different AMIs, you can specify instance attributes in multiple launch template overrides. For example, different instance types can use x86 and Arm-based processors.
- In a launch specification

How EC2 Fleet uses attribute-based instance type selection when provisioning a fleet

EC2 Fleet provisions a fleet in the following way:

- EC2 Fleet identifies the instance types that have the specified attributes.
- EC2 Fleet uses price protection to determine which instance types to exclude.
- EC2 Fleet determines the capacity pools from which it will consider launching the instances based on the AWS Regions or Availability Zones that have matching instance types.
- EC2 Fleet applies the specified allocation strategy to determine from which capacity pools to launch the instances.

Note that attribute-based instance type selection does not pick the capacity pools from which to provision the fleet; that's the job of the allocation strategies. There might be a large number of
instance types with the specified attributes, and some of them might be expensive. The default allocation strategy of lowest-price for Spot and On-Demand guarantees that EC2 Fleet will launch instances from the least expensive capacity pools.

If you specify an allocation strategy, EC2 Fleet will launch instances according to the specified allocation strategy.

- For Spot Instances, attribute-based instance type selection supports the price-capacity-optimized, capacity-optimized, and lowest-price allocation strategies.
- For On-Demand Instances, attribute-based instance type selection supports the lowest-price allocation strategy.
- If there is no capacity for the instance types with the specified instance attributes, no instances can be launched, and the fleet returns an error.

Price protection

Price protection is a feature that prevents your EC2 Fleet from using instance types that you would consider too expensive even if they happen to fit the attributes that you specified. When you create a fleet with attribute-based instance type selection, price protection is enabled by default, with separate thresholds for On-Demand Instances and Spot Instances. When Amazon EC2 selects instance types with your attributes, it excludes instance types priced above your threshold. The thresholds represent the maximum you'll pay, expressed as a percentage above the least expensive current generation M, C, or R instance type with your specified attributes.

If you don't specify a threshold, the following thresholds are used by default:

- For On-Demand Instances, the price protection threshold is set at 20 percent.
- For Spot Instances, the price protection threshold is set at 100 percent.

To specify the price protection threshold

While creating the EC2 Fleet, configure the fleet for attribute-based instance type selection, and then do the following:

- To specify the On-Demand Instance price protection threshold, in the JSON configuration file, in the InstanceRequirements structure, for OnDemandMaxPricePercentageOverLowestPrice, enter the price protection threshold as a percentage.
- To specify the Spot Instance price protection threshold, in the JSON configuration file, in the InstanceRequirements structure, for SpotMaxPricePercentageOverLowestPrice, enter the price protection threshold as a percentage.

For more information about creating the fleet, see Create an EC2 Fleet with attribute-based instance type selection (p. 1117).

Note

When creating the EC2 Fleet, if you set TargetCapacityUnitType to vcpu or memory-mib, the price protection threshold is applied based on the per-vCPU or per-memory price instead of the per-instance price.

Considerations

- You can specify either instance types or instance attributes in an EC2 Fleet, but not both at the same time.

When using the CLI, the launch template overrides will override the launch template. For example, if the launch template contains an instance type and the launch template override contains instance
attributes, the instances that are identified by the instance attributes will override the instance type in
the launch template.

- When using the CLI, when you specify instance attributes as overrides, you can't also specify weights or
  priorities.
- You can specify a maximum of four InstanceRequirements structures in a request configuration.

Create an EC2 Fleet with attribute-based instance type selection

You can configure a fleet to use attribute-based instance type selection by using the AWS CLI.

To create an EC2 Fleet with attribute-based instance type selection (AWS CLI)

Use the create-fleet (AWS CLI) command to create an EC2 Fleet. Specify the fleet configuration in a JSON
file.

```bash
aws ec2 create-fleet \
  --region us-east-1 \
  --cli-input-json file://file_name.json
```

Example file_name.json file

The following example contains the parameters that configure an EC2 Fleet to use attribute-based
instance type selection, and is followed by a text explanation.

```json
{
  "SpotOptions": {
    "AllocationStrategy": "price-capacity-optimized"
  },
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateName": "my-launch-template",
        "Version": "1"
      },
      "Overrides": [
        {
          "InstanceRequirements": {
            "VCpuCount": {
              "Min": 2
            },
            "MemoryMiB": {
              "Min": 4
            }
          }
        }
      ]
    }
  ],
  "TargetCapacitySpecification": {
    "TotalTargetCapacity": 20,
    "DefaultTargetCapacityType": "spot"
  },
  "Type": "instant"
}
```

The attributes for attribute-based instance type selection are specified in the InstanceRequirements
structure. In this example, two attributes are specified:

- V Cp uCount – A minimum of 2 vCPUs is specified. Because no maximum is specified, there is no
  maximum limit.
- MemoryMiB – A minimum of 4 MiB of memory is specified. Because no maximum is specified, there is
  no maximum limit.
Any instance types that have 2 or more vCPUs and 4 MiB or more of memory will be identified. However, price protection and the allocation strategy might exclude some instance types when EC2 Fleet provisions the fleet (p. 1115).

For a list and descriptions of all the possible attributes that you can specify, see InstanceRequirements in the Amazon EC2 API Reference.

Note
When InstanceRequirements is included in the fleet configuration, InstanceType and WeightedCapacity must be excluded; they cannot determine the fleet configuration at the same time as instance attributes.

The JSON also contains the following fleet configuration:

- "AllocationStrategy": "price-capacity-optimized" – The allocation strategy for the Spot Instances in the fleet.
- "LaunchTemplateName": "my-launch-template", "Version": "1" – The launch template contains some instance configuration information, but if any instance types are specified, they will be overridden by the attributes that are specified in InstanceRequirements.
- "TotalTargetCapacity": 20 – The target capacity is 20 instances.
- "DefaultTargetCapacityType": "spot" – The default capacity is Spot Instances.
- "Type": "instant" – The request type for the fleet is instant.

Examples of configurations that are valid and not valid

If you use the AWS CLI to create an EC2 Fleet, you must make sure that your fleet configuration is valid. The following examples show configurations that are valid and not valid.

Configurations are considered not valid when they contain the following:

- A single Overrides structure with both InstanceRequirements and InstanceType
- Two Overrides structures, one with InstanceRequirements and the other with InstanceType
- Two InstanceRequirements structures with overlapping attribute values within the same LaunchTemplateSpecification

Example configurations

- Valid configuration: Single launch template with overrides (p. 1118)
- Valid configuration: Single launch template with multiple InstanceRequirements (p. 1119)
- Valid configuration: Two launch templates, each with overrides (p. 1120)
- Valid configuration: Only InstanceRequirements specified, no overlapping attribute values (p. 1121)
- Configuration not valid: Overrides contain InstanceRequirements and InstanceType (p. 1122)
- Configuration not valid: Two Overrides contain InstanceRequirements and InstanceType (p. 1122)
- Configuration not valid: Overlapping attribute values (p. 1123)

Valid configuration: Single launch template with overrides

The following configuration is valid. It contains one launch template and one Overrides structure containing one InstanceRequirements structure. A text explanation of the example configuration follows.

```
{
    "LaunchTemplateConfigs": [
    {
        "LaunchTemplateSpecification": {
```
InstanceRequirements

To use attribute-based instance selection, you must include the InstanceRequirements structure in your fleet configuration, and specify the desired attributes for the instances in the fleet.

In the preceding example, the following instance attributes are specified:

- **VCpuCount** – The instance types must have a minimum of 2 and a maximum of 8 vCPUs.
- **MemoryMiB** – The instance types must have a maximum of 10240 MiB of memory. A minimum of 0 indicates no minimum limit.
- **MemoryGiBPerVCpu** – The instance types must have a maximum of 10,000 GiB of memory per vCPU. The Min parameter is optional. By omitting it, you indicate no minimum limit.

**TargetCapacityUnitType**

The TargetCapacityUnitType parameter specifies the unit for the target capacity. In the example, the target capacity is 5000 and the target capacity unit type is vcpu, which together specify a desired target capacity of 5,000 vCPUs. EC2 Fleet will launch enough instances so that the total number of vCPUs in the fleet is 5,000 vCPUs.

Valid configuration: Single launch template with multiple InstanceRequirements

The following configuration is valid. It contains one launch template and one Overrides structure containing two InstanceRequirements structures. The attributes specified in InstanceRequirements are valid because the values do not overlap—the first InstanceRequirements structure specifies a VCPUCount of 0-2 vCPUs, while the second InstanceRequirements structure specifies 4-8 vCPUs.
Valid configuration: Two launch templates, each with overrides

The following configuration is valid. It contains two launch templates, each with one `Overrides` structure containing one `InstanceRequirements` structure. This configuration is useful for arm and x86 architecture support in the same fleet.
Valid configuration: Only InstanceRequirements specified, no overlapping attribute values

The following configuration is valid. It contains two LaunchTemplateSpecification structures, each with a launch template and an Overrides structure containing an InstanceRequirements structure. The attributes specified in InstanceRequirements are valid because the values do not overlap—the first InstanceRequirements structure specifies a VcpuCount of 0-2 vCPUs, while the second InstanceRequirements structure specifies 4-8 vCPUs.
Configuration not valid: Overrides contain InstanceRequirements and InstanceType

The following configuration is not valid. The Overrides structure contains both InstanceRequirements and InstanceType. For the Overrides, you can specify either InstanceRequirements or InstanceType, but not both.

```
{  
  "LaunchTemplateConfigs": [  
    {  
      "LaunchTemplateSpecification": {  
        "LaunchTemplateName": "MyLaunchTemplate",  
        "Version": "1"  
      },  
      "Overrides": [  
        {  
          "InstanceRequirements": {  
            "VCpuCount": {  
              "Min": 0,  
              "Max": 2  
            },  
            "MemoryMiB": {  
              "Min": 0  
            }  
          }  
        },  
        {  
          "InstanceType": "m5.large"  
        }  
      ]  
    },  
    {  
      "LaunchTemplateSpecification": {  
        "LaunchTemplateName": "MyLaunchTemplate",  
        "Version": "1"  
      },  
      "TargetCapacitySpecification": {  
        "TotalTargetCapacity": 1,  
        "DefaultTargetCapacityType": "spot"  
      }  
    }  
  ]
}
```

Configuration not valid: Two Overrides contain InstanceRequirements and InstanceType

The following configuration is not valid. The Overrides structures contain both InstanceRequirements and InstanceType. You can specify either InstanceRequirements or InstanceType, but not both, even if they're in different Overrides structures.
Configuration not valid: Overlapping attribute values

The following configuration is not valid. The two InstanceRequirements structures each contain
"VCpuCount": {"Min": 0, "Max": 2}. The values for these attributes overlap, which will result in
duplicate capacity pools.

```json
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "MyLaunchTemplate",
                "Version": "1"
            },
            "Overrides": [
                {
                    "InstanceRequirements": {
                        "VCpuCount": {
                            "Min": 0,
                            "Max": 2
                        },
                        "MemoryMiB": {
                            "Min": 0
                        }
                    }
                }
            ],
            "TargetCapacitySpecification": {
                "TotalTargetCapacity": 1,
                "DefaultTargetCapacityType": "spot"
            }
        },
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "MyOtherLaunchTemplate",
                "Version": "1"
            },
            "Overrides": [
                {
                    "InstanceType": "m5.large"
                }
            ]
        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 1,
        "DefaultTargetCapacityType": "spot"
    }
}
```
Preview instance types with specified attributes

You can use the `get-instance-types-from-instance-requirements` AWS CLI command to preview the instance types that match the attributes that you specify. This is especially useful for working out what attributes to specify in your request configuration without launching any instances. Note that the command does not consider available capacity.

To preview a list of instance types by specifying attributes using the AWS CLI

1. (Optional) To generate all of the possible attributes that can be specified, use the `get-instance-types-from-instance-requirements` command and the `--generate-cli-skeleton` parameter. You can optionally direct the output to a file to save it by using `input > attributes.json`.

```bash/aws ec2 get-instance-types-from-instance-requirements \
--region us-east-1 \ 
--generate-cli-skeleton input > attributes.json
```

Expected output

```json
{
  "DryRun": true,
  "ArchitectureTypes": [
    "i386"
  ],
  "VirtualizationTypes": [
    "hvm"
  ],
  "InstanceRequirements": {
    "VcpuCount": {
      "Min": 0,
      "Max": 0
    },
    "MemoryMiB": {
      "Min": 0,
      "Max": 0
    },
    "CpuManufacturers": [
      "intel"
    ],
    "MemoryGiBPerVCpu": {
```
Create a JSON configuration file using the output from the previous step, and configure it as follows:

**Note**
You must provide values for ArchitectureTypes, VirtualizationTypes, VCPUCount, and MemoryMiB. You can omit the other attributes; when omitted, the default values are used.
For a description of each attribute and their default values, see get-instance-types-from-instance-requirements in the Amazon EC2 Command Line Reference.

a. For ArchitectureTypes, specify one or more types of processor architecture.
b. For VirtualizationTypes, specify one or more types of virtualization.
c. For VcpuCount, specify the minimum and maximum number of vCPUs. To specify no minimum limit, for Min, specify 0. To specify no maximum limit, omit the Max parameter.
d. For MemoryMiB, specify the minimum and maximum amount of memory in MiB. To specify no minimum limit, for Min, specify 0. To specify no maximum limit, omit the Max parameter.
e. You can optionally specify one or more of the other attributes to further constrain the list of instance types that are returned.

3. To preview the instance types that have the attributes that you specified in the JSON file, use the get-instance-types-from-instance-requirements command, and specify the name and path to your JSON file by using the --cli-input-json parameter. You can optionally format the output to appear in a table format.

```bash
aws ec2 get-instance-types-from-instance-requirements \
--cli-input-json file://attributes.json \
--output table
```

Example attributes.json file

In this example, the required attributes are included in the JSON file. They are ArchitectureTypes, VirtualizationTypes, VcpuCount, and MemoryMiB. In addition, the optional InstanceGenerations attribute is also included. Note that for MemoryMiB, the Max value can be omitted to indicate that there is no limit.

```
{
    "ArchitectureTypes": ["x86_64"],
    "VirtualizationTypes": ["hvm"],
    "InstanceRequirements": {
        "VcpuCount": {
            "Min": 4,
            "Max": 6
        },
        "MemoryMiB": {
            "Min": 2048
        },
        "InstanceGenerations": [
            "current"
        ]
    }
}
```

Example output

```
+----------------------------------------+
| GetInstanceTypesFromInstanceRequirements |
|-----------------------------------------|---|
| InstanceTypes                          |
|-----------------------------------------|---|
| +----------------------------------------|
| InstanceType                           |
| +----------------------------------------|
```

1126
After identifying instance types that meet your needs, make note of the instance attributes that you used so that you can use them when configuring your fleet request.

Configure EC2 Fleet for On-Demand backup

If you have urgent, unpredictable scaling needs, such as a news website that must scale during a major news event or game launch, we recommend that you specify alternative instance types for your On-Demand Instances, in the event that your preferred option does not have sufficient available capacity. For example, you might prefer c5.2xlarge On-Demand Instances, but if there is insufficient available capacity, you’d be willing to use some c4.2xlarge instances during peak load. In this case, EC2 Fleet attempts to fulfill all of your target capacity using c5.2xlarge instances, but if there is insufficient capacity, it automatically launches c4.2xlarge instances to fulfill the target capacity.

Topics
- Prioritize instance types for On-Demand capacity (p. 1127)
- Use Capacity Reservations for On-Demand Instances (p. 1128)

Prioritize instance types for On-Demand capacity

When EC2 Fleet attempts to fulfill your On-Demand capacity, it defaults to launching the lowest priced instance type first. If AllocationStrategy is set to prioritized, EC2 Fleet uses priority to determine which instance type to use first in fulfilling On-Demand capacity. The priority is assigned to the launch template override, and the highest priority is launched first.

Example: Prioritize instance types

In this example, you configure three launch template overrides, each with a different instance type.

The On-Demand price for the instance types range in price. The following are the instance types used in this example, listed in order of price, starting with the least expensive instance type:

- m4.large – least expensive
- m5.large
- m5a.large

If you do not use priority to determine the order, the fleet fulfills the On-Demand capacity by starting with the least expensive instance type.

However, say you have unused m5.large Reserved Instances that you want to use first. You can set the launch template override priority so that the instance types are used in the order of priority, as follows:

- m5.large – priority 1
- m4.large – priority 2
- m5a.large – priority 3
Use Capacity Reservations for On-Demand Instances

With On-Demand Capacity Reservations, you can reserve compute capacity for your On-Demand Instances in a specified Availability Zone for any duration. You can configure an EC2 Fleet to use the Capacity Reservations first when launching On-Demand Instances.

Capacity Reservations are configured as either open or targeted. EC2 Fleet can launch On-Demand Instances into either open or targeted Capacity Reservations, as follows:

- If a Capacity Reservation is open, On-Demand Instances that have matching attributes automatically run in the reserved capacity.
- If a Capacity Reservation is targeted, On-Demand Instances must specifically target it to run in the reserved capacity. This is useful for using up specific Capacity Reservations or for controlling when to use specific Capacity Reservations.

If you use targeted Capacity Reservations in your EC2 Fleet, there must be enough Capacity Reservations to fulfil the target On-Demand capacity, otherwise the launch fails. To avoid a launch fail, rather add the targeted Capacity Reservations to a resource group, and then target the resource group. The resource group doesn't need to have enough Capacity Reservations; if it runs out of Capacity Reservations before the target On-Demand capacity is fulfilled, the fleet can launch the remaining target capacity into regular On-Demand capacity.

To use Capacity Reservations with EC2 Fleet

1. Configure the fleet as type instant. You can't use Capacity Reservations for fleets of other types.
2. Configure the usage strategy for Capacity Reservations as use-capacity-reservations-first.
3. In the launch template, for Capacity reservation, choose either Open or Target by group. If you choose Target by group, specify the Capacity Reservations resource group ID.

When the fleet attempts to fulfil the On-Demand capacity, if it finds that multiple instance pools have unused matching Capacity Reservations, it determines the pools in which to launch the On-Demand Instances based on the On-Demand allocation strategy (lowest-price or prioritized).

For examples of how to configure a fleet to use Capacity Reservations to fulfil On-Demand capacity, see EC2 Fleet example configurations (p. 1235), specifically Examples 5 through 7.

For information about configuring Capacity Reservations, see On-Demand Capacity Reservations (p. 659) and the On-Demand Capacity Reservation FAQs.

Capacity Rebalancing

You can configure EC2 Fleet to launch a replacement Spot Instance when Amazon EC2 emits a rebalance recommendation to notify you that a Spot Instance is at an elevated risk of interruption. Capacity Rebalancing helps you maintain workload availability by proactively augmenting your fleet with a new Spot Instance before a running instance is interrupted by Amazon EC2. For more information, see EC2 instance rebalance recommendations (p. 584).

To configure EC2 Fleet to launch a replacement Spot Instance, use the create-fleet (AWS CLI) command and the relevant parameters in the MaintenanceStrategies structure. For more information, see the example launch configuration (p. 1245).

Limitations

- Capacity Rebalancing is available only for fleets of type maintain.
When the fleet is running, you can't modify the Capacity Rebalancing setting. To change the Capacity Rebalancing setting, you must delete the fleet and create a new fleet.

**Configuration options**

The ReplacementStrategy for EC2 Fleet supports the following two values:

- **launch-before-terminate**
  
  Amazon EC2 terminates the Spot Instances that receive a rebalance notification after new replacement Spot Instances are launched. When you specify `launch-before-terminate`, you must also specify a value for `termination-delay`. After the new replacement instances are launched, Amazon EC2 waits for the duration of the `termination-delay`, and then terminates the old instances. For `termination-delay`, the minimum is 120 seconds (2 minutes), and the maximum is 7200 seconds (2 hours).

  We recommend that you use `launch-before-terminate` only if you can predict how long your instance shutdown procedures will take to complete. This will ensure that the old instances are terminated only after the shutdown procedures are completed. Note that Amazon EC2 can interrupt the old instances with a two-minute warning before the `termination-delay`.

  We strongly recommend against using the lowest-price allocation strategy in combination with `launch-before-terminate` to avoid having replacement Spot Instances that are also at an elevated risk of interruption.

- **launch**
  
  Amazon EC2 launches replacement Spot Instances when a rebalance notification is emitted for existing Spot Instances. Amazon EC2 does not terminate the instances that receive a rebalance notification. You can terminate the old instances, or you can leave them running. You are charged for all instances while they are running.

**Considerations**

If you configure an EC2 Fleet for Capacity Rebalancing, consider the following:

- **Provide as many Spot capacity pools in the request as possible**

  Configure your EC2 Fleet to use multiple instance types and Availability Zones. This provides the flexibility to launch Spot Instances in various Spot capacity pools. For more information, see [Be flexible about instance types and Availability Zones](p. 552).

- **Avoid an elevated risk of interruption of replacement Spot Instances**

  Your replacement Spot Instances may be at an elevated risk of interruption if you use the lowest-price allocation strategy. This is because Amazon EC2 will always launch instances in the lowest priced pool that has available capacity at that moment, even if your replacement Spot Instances are likely to be interrupted soon after being launched. To avoid an elevated risk of interruption, we strongly recommend against using the lowest-price allocation strategy, and instead recommend the capacity-optimized or capacity-optimized-prioritized allocation strategy. These strategies ensure that replacement Spot Instances are launched in the most optimal Spot capacity pools, and are therefore less likely to be interrupted in the near future. For more information, see [Use the price and capacity optimized allocation strategy](p. 552).

- **Amazon EC2 will only launch a new instance if availability is the same or better**

  One of the goals of Capacity Rebalancing is to improve a Spot Instance's availability. If an existing Spot Instance receives a rebalance recommendation, Amazon EC2 will only launch a new instance
if the new instance provides the same or better availability than the existing instance. If the risk of interruption of a new instance will be worse than the existing instance, then Amazon EC2 will not launch a new instance. Amazon EC2 will, however, continue to assess the Spot capacity pools, and will launch a new instance if availability improves.

There is a chance that your existing instance will be interrupted without Amazon EC2 proactively launching a new instance. When this happens, Amazon EC2 will attempt to launch a new instance regardless of whether the new instance has a high risk of interruption.

**Capacity Rebalancing does not increase your Spot Instance interruption rate**

When you enable Capacity Rebalancing, it does not increase your Spot Instance interruption rate (p. 587) (the number of Spot Instances that are reclaimed when Amazon EC2 needs the capacity back). However, if Capacity Rebalancing detects an instance is at risk of interruption, Amazon EC2 will immediately attempt to launch a new instance. The result is that more instances might be replaced than if you’d waited for Amazon EC2 to launch a new instance after the at-risk instance was interrupted.

While you might replace more instances with Capacity Rebalancing enabled, you benefit from being proactive rather than reactive by having more time to take action before your instances are interrupted. With a Spot Instance interruption notice (p. 593), you typically only have up to two minutes to gracefully shut down your instance. With Capacity Rebalancing launching a new instance in advance, you give existing processes a better chance of completing on your at-risk instance, you can start your instance shutdown procedures, and prevent new work from being scheduled on your at-risk instance. You can also start preparing the newly-launched instance to take over the application. With Capacity Rebalancing's proactive replacement, you benefit from graceful continuity.

As a theoretical example to demonstrate the risks and benefits of using Capacity Rebalancing, consider the following scenario:

- 2:00 PM – A rebalance recommendation is received for instance-A, and Amazon EC2 immediately starts attempting to launch a replacement instance-B, giving you time to start your shutdown procedures.*
- 2:30 PM – A rebalance recommendation is received for instance-B, replaced with instance-C, giving you time to start your shutdown procedures.*
- 2:32 PM – If Capacity Rebalancing wasn’t enabled, and if a Spot Instance interruption notice would’ve been received at 2:32 PM for instance-A, you would only have had up to two minutes to take action, but Instance-A would have been running up till this time.

* If launch-before-terminate is specified, Amazon EC2 will terminate the at-risk instance after the replacement instance comes online.

**Amazon EC2 can launch new replacement Spot Instances until fulfilled capacity is double target capacity**

When an EC2 Fleet is configured for Capacity Rebalancing, the fleet attempts to launch a new replacement Spot Instance for every Spot Instance that receives a rebalance recommendation. After a Spot Instance receives a rebalance recommendation, it is no longer counted as part of the fulfilled capacity. Depending on the replacement strategy, Amazon EC2 either terminates the instance after a preconfigured termination delay, or leaves it running. This gives you the opportunity to perform rebalancing actions (p. 584) on the instance.

If your fleet reaches double its target capacity, it stops launching new replacement instances even if the replacement instances themselves receive a rebalance recommendation.

For example, you create an EC2 Fleet with a target capacity of 100 Spot Instances. All of the Spot Instances receive a rebalance recommendation, which causes Amazon EC2 to launch 100 replacement Spot Instances. This raises the number of fulfilled Spot Instances to 200, which is double the target capacity. Some of the replacement instances receive a rebalance recommendation,
but no more replacement instances are launched because the fleet cannot exceed double its target capacity.

Note that you are charged for all of the instances while they are running.

**We recommend that you configure EC2 Fleet to terminate Spot Instances that receive a rebalance recommendation**

If you configure your EC2 Fleet for Capacity Rebalancing, we recommend that you choose `launch-before-terminate` with an appropriate termination delay only if you can predict how long your instance shutdown procedures will take to complete. This will ensure that the old instances are terminated only after the shutdown procedures are completed.

If you choose to terminate the instances that are recommended for rebalance yourself, we recommend that you monitor the rebalance recommendation signal that is received by the Spot Instances in the fleet. By monitoring the signal, you can quickly perform rebalancing actions on the affected instances before Amazon EC2 interrupts them, and then you can manually terminate them. If you do not terminate the instances, you continue paying for them while they are running. Amazon EC2 does not automatically terminate the instances that receive a rebalance recommendation.

You can set up notifications using Amazon EventBridge or instance metadata. For more information, see [Monitor rebalance recommendation signals](p. 585).

**EC2 Fleet does not count instances that receive a rebalance recommendation when calculating fulfilled capacity during scale in or out**

If your EC2 Fleet is configured for Capacity Rebalancing, and you change the target capacity to either scale in or scale out, the fleet does not count the instances that are marked for rebalance as part of the fulfilled capacity, as follows:

- **Scale in** – If you decrease your desired target capacity, Amazon EC2 terminates instances that are not marked for rebalance until the desired capacity is reached. The instances that are marked for rebalance are not counted towards the fulfilled capacity.

  For example, you create an EC2 Fleet with a target capacity of 100 Spot Instances. 10 instances receive a rebalance recommendation, so Amazon EC2 launches 10 new replacement instances, resulting in a fulfilled capacity of 110 instances. You then reduce the target capacity to 50 (scale in), but the fulfilled capacity is actually 60 instances because the 10 instances that are marked for rebalance are not terminated by Amazon EC2. You need to manually terminate these instances, or you can leave them running.

- **Scale out** – If you increase your desired target capacity, Amazon EC2 launches new instances until the desired capacity is reached. The instances that are marked for rebalance are not counted towards the fulfilled capacity.

  For example, you create an EC2 Fleet with a target capacity of 100 Spot Instances. 10 instances receive a rebalance recommendation, so the fleet launches 10 new replacement instances, resulting in a fulfilled capacity of 110 instances. You then increase the target capacity to 200 (scale out), but the fulfilled capacity is actually 210 instances because the 10 instances that are marked for rebalance are not counted by the fleet as part of the target capacity. You need to manually terminate these instances, or you can leave them running.

**Maximum price overrides**

Each EC2 Fleet can either include a global maximum price, or use the default (the On-Demand price). The fleet uses this as the default maximum price for each of its launch specifications.

You can optionally specify a maximum price in one or more launch specifications. This price is specific to the launch specification. If a launch specification includes a specific price, the EC2 Fleet uses this...
maximum price, overriding the global maximum price. Any other launch specifications that do not include a specific maximum price still use the global maximum price.

Control spending

EC2 Fleet stops launching instances when it has met one of the following parameters: the TotalTargetCapacity or the MaxTotalPrice (the maximum amount you're willing to pay). To control the amount you pay per hour for your fleet, you can specify the MaxTotalPrice. When the maximum total price is reached, EC2 Fleet stops launching instances even if it hasn't met the target capacity.

The following examples show two different scenarios. In the first, EC2 Fleet stops launching instances when it has met the target capacity. In the second, EC2 Fleet stops launching instances when it has reached the maximum amount you're willing to pay (MaxTotalPrice).

Example: Stop launching instances when target capacity is reached

Given a request for m4.large On-Demand Instances, where:

- On-Demand Price: $0.10 per hour
- OnDemandTargetCapacity: 10
- MaxTotalPrice: $1.50

EC2 Fleet launches 10 On-Demand Instances because the total of $1.00 (10 instances x $0.10) does not exceed the MaxTotalPrice of $1.50 for On-Demand Instances.

Example: Stop launching instances when maximum total price is reached

Given a request for m4.large On-Demand Instances, where:

- On-Demand Price: $0.10 per hour
- OnDemandTargetCapacity: 10
- MaxTotalPrice: $0.80

If EC2 Fleet launches the On-Demand target capacity (10 On-Demand Instances), the total cost per hour would be $1.00. This is more than the amount ($0.80) specified for MaxTotalPrice for On-Demand Instances. To prevent spending more than you're willing to pay, EC2 Fleet launches only 8 On-Demand Instances (below the On-Demand target capacity) because launching more would exceed the MaxTotalPrice for On-Demand Instances.

EC2 Fleet instance weighting

When you create an EC2 Fleet, you can define the capacity units that each instance type would contribute to your application's performance. You can then adjust your maximum price for each launch specification by using instance weighting.

By default, the price that you specify is per instance hour. When you use the instance weighting feature, the price that you specify is per unit hour. You can calculate your price per unit hour by dividing your price for an instance type by the number of units that it represents. EC2 Fleet calculates the number of instances to launch by dividing the target capacity by the instance weight. If the result isn't an integer, the fleet rounds it up to the next integer, so that the size of your fleet is not below its target capacity. The fleet can select any pool that you specify in your launch specification, even if the capacity of the instances launched exceeds the requested target capacity.

The following table includes examples of calculations to determine the price per unit for an EC2 Fleet with a target capacity of 10.
Use EC2 Fleet instance weighting as follows to provision the target capacity that you want in the pools with the lowest price per unit at the time of fulfillment:

1. Set the target capacity for your EC2 Fleet either in instances (the default) or in the units of your choice, such as virtual CPUs, memory, storage, or throughput.
2. Set the price per unit.
3. For each launch specification, specify the weight, which is the number of units that the instance type represents toward the target capacity.

### Instance weighting example

Consider an EC2 Fleet request with the following configuration:

- A target capacity of 24
- A launch specification with an instance type `r3.xlarge` and a weight of 6
- A launch specification with an instance type `c3.xlarge` and a weight of 5

The weights represent the number of units that instance type represents toward the target capacity. If the first launch specification provides the lowest price per unit (price for `r3.xlarge` per instance hour divided by 6), the EC2 Fleet would launch four of these instances (24 divided by 6).

If the second launch specification provides the lowest price per unit (price for `c3.xlarge` per instance hour divided by 5), the EC2 Fleet would launch five of these instances (24 divided by 5, result rounded up).

### Instance weighting and allocation strategy

Consider an EC2 Fleet request with the following configuration:

- A target capacity of 30 Spot Instances
- A launch specification with an instance type `c3.xlarge` and a weight of 8
- A launch specification with an instance type `m3.xlarge` and a weight of 8
- A launch specification with an instance type `r3.xlarge` and a weight of 8

The EC2 Fleet would launch four instances (30 divided by 8, result rounded up). With the lowest-price strategy, all four instances come from the pool that provides the lowest price per unit. With the diversified strategy, the fleet launches one instance in each of the three pools, and the fourth instance in whichever of the three pools provides the lowest price per unit.
Work with EC2 Fleets

To start using an EC2 Fleet, you create a request that includes the total target capacity, On-Demand capacity, Spot capacity, one or more launch specifications for the instances, and the maximum price that you are willing to pay. The fleet request must include a launch template that defines the information that the fleet needs to launch an instance, such as an AMI, instance type, subnet or Availability Zone, and one or more security groups. You can specify launch specification overrides for the instance type, subnet, Availability Zone, and maximum price you're willing to pay, and you can assign weighted capacity to each launch specification override.

The EC2 Fleet launches On-Demand Instances when there is available capacity, and launches Spot Instances when your maximum price exceeds the Spot price and capacity is available.

If your fleet includes Spot Instances, Amazon EC2 can attempt to maintain your fleet target capacity as Spot prices change.

An EC2 Fleet request of type maintain or request remains active until it expires or you delete it. When you delete a fleet of type maintain or request, you can specify whether deletion terminates the instances in that fleet. Otherwise, the On-Demand Instances run until you terminate them, and the Spot Instances run until they are interrupted or you terminate them.

Contents

EC2 Fleet request states

An EC2 Fleet request can be in one of the following states:

submitted

The EC2 Fleet request is being evaluated and Amazon EC2 is preparing to launch the target number of instances. The request can include On-Demand Instances, Spot Instances, or both. If a request would exceed your fleet limits, it is deleted immediately.

active

The EC2 Fleet request has been validated and Amazon EC2 is attempting to maintain the target number of running instances. The request remains in this state until it is modified or deleted.

modifying

The EC2 Fleet request is being modified. The request remains in this state until the modification is fully processed or the request is deleted. Only a maintain fleet type can be modified. This state does not apply to other request types.

deleted_running

The EC2 Fleet request is deleted and does not launch additional instances. Its existing instances continue to run until they are interrupted or terminated manually. The request remains in this state
until all instances are interrupted or terminated. Only an EC2 Fleet of type maintain or request can have running instances after the EC2 Fleet request is deleted. A deleted instant fleet with running instances is not supported. This state does not apply to instant fleets.

deleted_terminating

The EC2 Fleet request is deleted and its instances are terminating. The request remains in this state until all instances are terminated.

deleted

The EC2 Fleet is deleted and has no running instances. The request is deleted two days after its instances are terminated.

**EC2 Fleet prerequisites**

To create an EC2 Fleet, the following prerequisites must be in place:

- [Launch template](p. 1135)
- [Service-linked role for EC2 Fleet](p. 1135)
- [Grant access to customer managed keys for use with encrypted AMIs and EBS snapshots](p. 1136)
- [Permissions for EC2 Fleet users](p. 1136)

**Launch template**

A launch template includes information about the instances to launch, such as the instance type, Availability Zone, and the maximum price that you are willing to pay. For more information, see [Launch an instance from a launch template](p. 736).

**Service-linked role for EC2 Fleet**

The `AWSServiceRoleForEC2Fleet` role grants the EC2 Fleet permission to request, launch, terminate, and tag instances on your behalf. Amazon EC2 uses this service-linked role to complete the following actions:

- `ec2:RunInstances` – Launch instances.
- `ec2:RequestSpotInstances` – Request Spot Instances.
- `ec2:TerminateInstances` – Terminate instances.
- `ec2:DescribeImages` – Describe Amazon Machine Images (AMIs) for the Spot Instances.
- `ec2:DescribeInstanceStatus` – Describe the status of the Spot Instances.
- `ec2:DescribeSubnets` – Describe the subnets for Spot Instances.
- `ec2:CreateTags` – Add tags to the EC2 Fleet, instances, and volumes.

Ensure that this role exists before you use the AWS CLI or an API to create an EC2 Fleet.

**Note**

An instant EC2 Fleet does not require this role.

To create the role, use the IAM console as follows.

**To create the AWSServiceRoleForEC2Fleet role for EC2 Fleet**

2. In the navigation pane, choose Roles, and then choose Create role.
3. For Select type of trusted entity, choose AWS service.
4. For **Choose the service that will use this role**, choose **EC2 - Fleet**, and then choose **Next: Permissions, Next: Tags, and Next: Review**.

5. On the **Review** page, choose **Create role**.

If you no longer need to use EC2 Fleet, we recommend that you delete the **AWSServiceRoleForEC2Fleet** role. After this role is deleted from your account, you can create the role again if you create another fleet.

For more information, see [Using service-linked roles](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_sldr-index.html) in the *IAM User Guide*.

**Grant access to customer managed keys for use with encrypted AMIs and EBS snapshots**

If you specify an [encrypted AMI](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/EC2UG-EncryptedAMIs.html) (p. 239) or an [encrypted Amazon EBS snapshot](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/ENCRYPTED-VOLUMES-ATTACH-MNT-OPEN.txt.html) (p. 2316) in your EC2 Fleet and you use an AWS KMS key for encryption, you must grant the **AWSServiceRoleForEC2Fleet** role permission to use the customer managed key so that Amazon EC2 can launch instances on your behalf. To do this, you must add a grant to the customer managed key, as shown in the following procedure.

When providing permissions, grants are an alternative to key policies. For more information, see [Using grants](https://docs.aws.amazon.com/AWSEKS/latest/DeveloperGuide/using-service-linked-roles.html) and [Using key policies in AWS KMS](https://docs.aws.amazon.com/AWSEKS/latest/DeveloperGuide/key-policies.html) in the *AWS Key Management Service Developer Guide*.

**To grant the AWSServiceRoleForEC2Fleet role permissions to use the customer managed key**

- Use the `create-grant` command to add a grant to the customer managed key and to specify the principal (the **AWSServiceRoleForEC2Fleet** service-linked role) that is given permission to perform the operations that the grant permits. The customer managed key is specified by the key-id parameter and the ARN of the customer managed key. The principal is specified by the grantee-principal parameter and the ARN of the **AWSServiceRoleForEC2Fleet** service-linked role.

  ```bash
  aws kms create-grant \
  --region us-east-1 \
  --key-id arn:aws:kms:us-east-1:444455556666:key/1234abcd-12ab-34cd-56ef-1234567890ab \
  --grantee-principal arn:aws:iam::111122223333:role/AWSServiceRoleForEC2Fleet \
  --operations "Decrypt" "Encrypt" "GenerateDataKey" "GenerateDataKeyWithoutPlaintext" "CreateGrant" "DescribeKey" "ReEncryptFrom" "ReEncryptTo"
  ```

**Permissions for EC2 Fleet users**

If your users will create or manage an EC2 Fleet, be sure to grant them the required permissions.

**To create a policy for EC2 Fleet**

2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Create policy** page, choose the **JSON** tab, replace the text with the following, and choose **Review policy**.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Action": [
   ```
The `ec2:*` grants a user permission to call all Amazon EC2 API actions. To limit the user to specific Amazon EC2 API actions, specify those actions instead.

The user must have permission to call the `iam:ListRoles` action to enumerate existing IAM roles, the `iam:PassRole` action to specify the EC2 Fleet role, and the `iam:ListInstanceProfiles` action to enumerate existing instance profiles.

(Optional) To enable a user to create roles or instance profiles using the IAM console, you must also add the following actions to the policy:

- `iam:AddRoleToInstanceProfile`
- `iam:AttachRolePolicy`
- `iam:CreateInstanceProfile`
- `iam:CreateRole`
- `iam:GetRole`
- `iam:ListPolicies`

5. On the **Review policy** page, enter a policy name and description, and choose Create policy.

6. To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:
  
  Create a permission set. Follow the instructions in [Create a permission set](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users.html) in the **AWS IAM Identity Center User Guide**.

- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider (federation)](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users.html) in the **IAM User Guide**.

- IAM users:

  - Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users.html) in the **IAM User Guide**.

  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user (console)](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users.html) in the **IAM User Guide**.

**EC2 Fleet health checks**

EC2 Fleet checks the health status of the instances in the fleet every two minutes. The health status of an instance is either healthy or unhealthy.

EC2 Fleet determines the health status of an instance by using the status checks provided by Amazon EC2. An instance is determined as unhealthy when the status of either the instance status check or the
system status check is impaired for three consecutive health status checks. For more information, see Status checks for your instances (p. 1267).

You can configure your fleet to replace unhealthy Spot Instances. After setting ReplaceUnhealthyInstances to true, a Spot Instance is replaced when it is reported as unhealthy. The fleet can go below its target capacity for up to a few minutes while an unhealthy Spot Instance is being replaced.

Requirements

- Health check replacement is supported only for EC2 Fleets that maintain a target capacity (fleets of type maintain), and not for fleets of type request or instant.
- Health check replacement is supported only for Spot Instances. This feature is not supported for On-Demand Instances.
- You can configure your EC2 Fleet to replace unhealthy instances only when you create it.
- Users can use health check replacement only if they have permission to call the ec2:DescribeInstanceStatus action.

To configure an EC2 Fleet to replace unhealthy Spot Instances

1. Follow the steps for creating an EC2 Fleet. For more information, see Create an EC2 Fleet (p. 1140).
2. To configure the fleet to replace unhealthy Spot Instances, in the JSON file, for ReplaceUnhealthyInstances, enter true.

Generate an EC2 Fleet JSON configuration file

To view the full list of EC2 Fleet configuration parameters, you can generate a JSON file. For a description of each parameter, see create-fleet in the AWS CLI Command Reference.

To generate a JSON file with all possible EC2 Fleet parameters using the command line

- Use the create-fleet (AWS CLI) command and the --generate-cli-skeleton parameter to generate an EC2 Fleet JSON file, and direct the output to a file to save it.

```bash
aws ec2 create-fleet \ 
   --generate-cli-skeleton input > ec2createfleet.json
```

Example output

```json
{
   "DryRun": true,
   "ClientToken": "",

]
Create an EC2 Fleet

To create an EC2 Fleet, you need only specify the following parameters:
• **LaunchTemplateId** or **LaunchTemplateName** – Specifies the launch template to use (which contains the parameters for the instances to launch, such as the instance type, Availability Zone, and the maximum price you're willing to pay)

• **TotalTargetCapacity** – Specifies the total target capacity for the fleet

• **DefaultTargetCapacityType** – Specifies whether the default purchasing option is On-Demand or Spot

You can specify multiple launch specifications that override the launch template. The launch specifications can vary by instance type, Availability Zone, subnet, and maximum price, and can include a different weighted capacity. Alternatively, you can specify the attributes that an instance must have, and Amazon EC2 will identify all the instance types with those attributes. For more information, see [Attribute-based instance type selection for EC2 Fleet](p. 1114).

If you do not specify a parameter, the fleet uses the default value for the parameter.

Specify the fleet parameters in a JSON file. For more information, see [Generate an EC2 Fleet JSON configuration file](p. 1138).

There is currently no console support for creating an EC2 Fleet.

**To create an EC2 Fleet (AWS CLI)**

• Use the `create-fleet` (AWS CLI) command to create an EC2 Fleet and specify the JSON file that contains the fleet configuration parameters.

```bash
aws ec2 create-fleet --cli-input-json file://file_name.json
```

For example configuration files, see [EC2 Fleet example configurations](p. 1235).

The following is example output for a fleet of type `request` or `maintain`.

```json
{
  "FleetId": "fleet-12a34b55-67cd-8ef9-ba9b-9208dEXAMPLE"
}
```

The following is example output for a fleet of type `instant` that launched the target capacity.

```json
{
  "FleetId": "fleet-12a34b55-67cd-8ef9-ba9b-9208dEXAMPLE",
  "Errors": [],
  "Instances": [
    {
      "LaunchTemplateAndOverrides": {
        "LaunchTemplateSpecification": {
          "LaunchTemplateId": "lt-01234a567b8910abcEXAMPLE",
          "Version": "1"
        },
        "Overrides": {
          "InstanceType": "c5.large",
          "AvailabilityZone": "us-east-1a"
        }
      },
      "Lifecycle": "on-demand",
      "InstanceIds": [
        "i-1234567890abcdef0",
        "i-9876543210abcdef9"
      ],
      "InstanceType": "c5.large",
    }
  ]
}
```
The following is example output for a fleet of type instant that launched part of the target capacity with errors for instances that were not launched.

```
{
  "FleetId": "fleet-12a34b55-67cd-8ef9-ba9b-9208dEXAMPLE",
  "Errors": [
    {
      "LaunchTemplateAndOverrides": {
        "LaunchTemplateSpecification": {
          "LaunchTemplateId": "lt-01234a567b8910abcEXAMPLE",
          "Version": "1"
        },
        "Overrides": {
          "InstanceType": "c4.xlarge",
          "AvailabilityZone": "us-east-1a"
        },
        "Lifecycle": "on-demand",
        "ErrorCode": "InsufficientInstanceCapacity",
        "ErrorMessage": ""
      }
    },
    "Instances": [
      {
        "LaunchTemplateAndOverrides": {
          "LaunchTemplateSpecification": {
            "LaunchTemplateId": "lt-01234a567b8910abcEXAMPLE",
            "Version": "1"
          },
          "Overrides": {
            "InstanceType": "c5.large",
            "AvailabilityZone": "us-east-1a"
          },
          "Lifecycle": "on-demand",
          "InstanceIds": [
            "i-1234567890abcdef0",
            "i-9876543210abcdef9"
          ]
        }
      }
    ]
  }
```

The following is example output for a fleet of type instant that launched no instances.

```
{
  "FleetId": "fleet-12a34b55-67cd-8ef9-ba9b-9208dEXAMPLE",
  "Errors": [
    {
      "LaunchTemplateAndOverrides": {
        "LaunchTemplateSpecification": {
          "LaunchTemplateId": "lt-01234a567b8910abcEXAMPLE",
          "Version": "1"
        },
        "Overrides": {
          "InstanceType": "c4.large",
          "AvailabilityZone": "us-east-1a"
        },
        "Lifecycle": "on-demand",
        "InstanceIds": [
          "i-567901234abcdef0",
          "i-5432109876abcdef9"
        ]
      }
    }
  ],
  "Instances": [

      }
    }
  ]
```

1142
Tag an EC2 Fleet

To help categorize and manage your EC2 Fleet requests, you can tag them with custom metadata. You can assign a tag to an EC2 Fleet request when you create it, or afterward.

When you tag a fleet request, the instances and volumes that are launched by the fleet are not automatically tagged. You need to explicitly tag the instances and volumes launched by the fleet. You can choose to assign tags to only the fleet request, or to only the instances launched by the fleet, or to only the volumes attached to the instances launched by the fleet, or to all three.

**Note**
For instant fleet types, you can tag volumes that are attached to On-Demand Instances and Spot Instances. For request or maintain fleet types, you can only tag volumes that are attached to On-Demand Instances.

For more information about how tags work, see [Tag your Amazon EC2 resources](p. 2507).

**Prerequisite**
Grant the user the permission to tag resources. For more information, see [Example: Tag resources](p. 1977).

**To grant a user the permission to tag resources**
Create a IAM policy that includes the following:
The `ec2:CreateTags` action. This grants the user permission to create tags.
- The `ec2:CreateFleet` action. This grants the user permission to create an EC2 Fleet request.
- For Resource, we recommend that you specify "*". This allows users to tag all resource types.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "TagEC2FleetRequest",
      "Effect": "Allow",
      "Action": [
        "ec2:CreateTags",
        "ec2:CreateFleet"
      ],
      "Resource": "*"
    }
  ]
}
```

**Important**

We currently do not support resource-level permissions for the `create-fleet` resource. If you specify `create-fleet` as a resource, you will get an unauthorized exception when you try to tag the fleet. The following example illustrates how not to set the policy.

```
{
  "Effect": "Allow",
  "Action": [
    "ec2:CreateTags",
    "ec2:CreateFleet"
  ],
}
```

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

  Create a permission set. Follow the instructions in [Create a permission set](https://docs.aws.amazon.com/IAM/latest/UserGuide/id-users-users-control.html) in the AWS IAM Identity Center User Guide.

- Users managed in IAM through an identity provider:

- IAM users:
  - Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles-create.html) in the IAM User Guide.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user (console)](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users-consoleadd permissions.html) in the IAM User Guide.

**To tag a new EC2 Fleet request**

To tag an EC2 Fleet request when you create it, specify the key-value pair in the [JSON file](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/ec2-fleet-manage.html#ec2-fleet-manage-tag) used to create the fleet. The value for `ResourceType` must be `fleet`. If you specify another value, the fleet request fails.

**To tag instances and volumes launched by an EC2 Fleet**

To tag instances and volumes when they are launched by the fleet, specify the tags in the [launch template](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/elastic-fleets-launch-template-creating.html) that is referenced in the EC2 Fleet request.
**Note**
You can’t tag volumes attached to Spot Instances that are launched by a request or maintain fleet type.

**To tag an existing EC2 Fleet request, instance, and volume (AWS CLI)**

Use the `create-tags` command to tag existing resources.

```
aws ec2 create-tags \\
--resources fleet-12a34b55-67cd-8ef9-ba9b-9208deEXAMPLE i-1234567890abcdef0 vol-1234567890EXAMPLE \\
--tags Key=purpose,Value=test
```

**Describe your EC2 Fleet**

You can describe your EC2 Fleet configuration, the instances in your EC2 Fleet, and the event history of your EC2 Fleet.

**To describe your EC2 Fleets (AWS CLI)**

Use the `describe-fleets` command to describe your EC2 Fleets.

```
aws ec2 describe-fleets
```

**Important**
If a fleet is of type `instant`, you must specify the fleet ID, otherwise it does not appear in the response. Include `--fleet-ids` as follows:

```
aws ec2 describe-fleets --fleet-ids fleet-8a22eee4-f489-ab02-06b8-832a7EXAMPLE
```

**Example output**

```
{
  "Fleets": [ {
    "ActivityStatus": "fulfilled",
    "CreateTime": "2022-02-09T03:35:52+00:00",
    "FleetId": "fleet-364457cd-3a7a-4ed9-83d0-7b63e51bb1b7",
    "FleetState": "active",
    "ExcessCapacityTerminationPolicy": "termination",
    "FulfilledCapacity": 2.0,
    "FulfilledOnDemandCapacity": 0.0,
    "LaunchTemplateConfigs": [ {
      "LaunchTemplateSpecification": {
        "LaunchTemplateName": "my-launch-template",
        "Version": "$Latest"
      }
    } ],
    "TargetCapacitySpecification": { "TotalTargetCapacity": 2, "OnDemandTargetCapacity": 0, "SpotTargetCapacity": 2, "SpotTargetCapacity": "Spot" },
    "TerminateInstancesWithExpiration": false,
    "Type": "maintain",
    "ReplaceUnhealthyInstances": false,
    "ReplaceSuspendedInstances": false
  }
]```
Use the `describe-fleet-instances` command to describe the instances for the specified EC2 Fleet. The returned list of running instances is refreshed periodically and might be out of date.

```bash
aws ec2 describe-fleet-instances --fleet-id fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE
```

Example output

```
{
  "ActiveInstances": [
    {
      "InstanceId": "i-09cd95999cb3765e",
      "InstanceHealth": "healthy",
      "InstanceType": "m4.large",
      "SpotInstanceRequestId": "sir-86k84j6p"
    },
    {
      "InstanceId": "i-09cf95167ca219f17",
      "InstanceHealth": "healthy",
      "InstanceType": "m4.large",
      "SpotInstanceRequestId": "sir-dvxi7fsm"
    }
  ],
  "FleetId": "fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE"
}
```

Use the `describe-fleet-history` command to describe the history for the specified EC2 Fleet for the specified time.

```bash
aws ec2 describe-fleet-history --fleet-id fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE --start-time 2018-04-10T00:00:00Z
```

Example output

```
{
  "HistoryRecords": [
    {
      "EventInformation": {
        "EventSubType": "submitted"
      },
      "EventType": "fleetRequestChange",
      "Timestamp": "2020-09-01T18:26:05.000Z"
    },
    {
      "EventInformation": {
        "EventSubType": "active"
      },
      "EventType": "fleetRequestChange",
      "Timestamp": "2020-09-01T18:26:15.000Z"
    },
    {
```

1146
Modify an EC2 Fleet

You can modify an EC2 Fleet that is in the submitted or active state. When you modify a fleet, it enters the modifying state.

You can only modify an EC2 Fleet that is of type maintain. You cannot modify an EC2 Fleet of type request or instant.

You can modify the following parameters of an EC2 Fleet:

- target-capacity-specification – Increase or decrease the target capacity for TotalTargetCapacity, OnDemandTargetCapacity, and SpotTargetCapacity.
- excess-capacity-termination-policy – Whether running instances should be terminated if the total target capacity of the EC2 Fleet is decreased below the current size of the fleet. Valid values are no-termination and termination.

When you increase the target capacity, the EC2 Fleet launches the additional instances according to the instance purchasing option specified for DefaultTargetCapacityType, which are either On-Demand Instances or Spot Instances.

If the DefaultTargetCapacityType is spot, the EC2 Fleet launches the additional Spot Instances according to its allocation strategy. If the allocation strategy is lowest-price, the fleet launches the instances from the lowest priced Spot capacity pool in the request. If the allocation strategy is diversified, the fleet distributes the instances across the pools in the request.

When you decrease the target capacity, the EC2 Fleet deletes any open requests that exceed the new target capacity. You can request that the fleet terminate instances until the size of the fleet reaches the new target capacity. If the allocation strategy is lowest-price, the fleet terminates the instances with the highest price per unit. If the allocation strategy is diversified, the fleet terminates instances
across the pools. Alternatively, you can request that EC2 Fleet keep the fleet at its current size, but not replace any Spot Instances that are interrupted or any instances that you terminate manually.

When an EC2 Fleet terminates a Spot Instance because the target capacity was decreased, the instance receives a Spot Instance interruption notice.

To modify an EC2 Fleet (AWS CLI)

Use the `modify-fleet` command to update the target capacity of the specified EC2 Fleet.

```
aws ec2 modify-fleet \
  --fleet-id fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
  --target-capacity-specification TotalTargetCapacity=20
```

If you are decreasing the target capacity but want to keep the fleet at its current size, you can modify the previous command as follows.

```
aws ec2 modify-fleet \
  --fleet-id fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
  --target-capacity-specification TotalTargetCapacity=10 \
  --excess-capacity-termination-policy no-termination
```

Delete an EC2 Fleet

If you no longer require an EC2 Fleet, you can delete it. After you delete a fleet, all Spot requests associated with the fleet are canceled, so that no new Spot Instances are launched.

When you delete an EC2 Fleet, you must also specify if you want to terminate all of its instances. These include both On-Demand Instances and Spot Instances.

If you specify that the instances must be terminated when the fleet is deleted, the fleet enters the `deleted_terminating` state. Otherwise, it enters the `deleted_running` state, and the instances continue to run until they are interrupted or you terminate them manually.

Restrictions

- You can delete up to 25 instant fleets in a single request. If you exceed this number, no instant fleets are deleted and an error is returned. There is no restriction on the number of fleets of type maintain or request that can be deleted in a single request.
- Up to 1000 instances can be terminated in a single request to delete instant fleets.

To delete an EC2 Fleet and terminate its instances (AWS CLI)

Use the `delete-fleets` command and the `--terminate-instances` parameter to delete the specified EC2 Fleet and terminate its associated instances.

```
aws ec2 delete-fleets \
  --fleet-ids fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
  --terminate-instances
```

Example output

```
{
  "UnsuccessfulFleetDeletions": [],
  "SuccessfulFleetDeletions": [
    {
      "FleetId": "fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE",
      "State": "deleted_terminating",
      "UnsuccessfulTerminations": []
    }
  ]
}```
To delete an EC2 Fleet without terminating its instances (AWS CLI)

You can modify the previous command using the `--no-terminate-instances` parameter to delete the specified EC2 Fleet without terminating its associated instances.

```
aws ec2 delete-fleets \
--fleet-ids fleet-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
--no-terminate-instances
```

Example output

```
{
  "UnsuccessfulFleetDeletions": [],
  "SuccessfulFleetDeletions": [
    {
      "CurrentFleetState": "deleted_running",
      "PreviousFleetState": "active",
      "FleetId": "fleet-4b8aaae8-dfb5-436d-a4c6-3dafa4c6b7dcEXAMPLE"
    }
  ]
}
```

Troubleshoot when a fleet fails to delete

If an EC2 Fleet fails to delete, UnsuccessfulFleetDeletions in the output returns the ID of the EC2 Fleet, an error code, and an error message.

The error codes are:

- ExceededInstantFleetNumForDeletion
- fleetIdDoesNotExist
- fleetIdMalformed
- fleetNotInDeletableState
- NoTerminateInstancesNotSupported
- UnauthorizedOperation
- unexpectedError

Troubleshooting ExceededInstantFleetNumForDeletion

If you try to delete more than 25 instant fleets in a single request, the ExceededInstantFleetNumForDeletion error is returned. The following is example output for this error.

```
{
  "UnsuccessfulFleetDeletions": [
    {
      ...
Troubleshoot NoTerminateInstancesNotSupported

If you specify that the instances in an instant fleet must not be terminated when you delete the fleet, the NoTerminateInstancesNotSupported error is returned. --no-terminate-instances is not supported for instant fleets. The following is example output for this error:

```
{
  "UnsuccessfulFleetDeletions": [
    {
      "FleetId": "fleet-5d130460-0c26-bfd9-2c32-0100a098f625",
      "Error": {
        "Message": "Can't delete more than 25 instant fleets in a single request.",
        "Code": "ExceededInstantFleetNumForDeletion"
      }
    },
    {
      "FleetId": "fleet-9a941b23-0286-5bf4-2430-03a029a07e31",
      "Error": {
        "Message": "Can't delete more than 25 instant fleets in a single request.",
        "Code": "ExceededInstantFleetNumForDeletion"
      }
    }
  ],
  "SuccessfulFleetDeletions": []
}
```

Troubleshoot UnauthorizedOperation

If you do not have permission to terminate instances, you get the UnauthorizedOperation error when deleting a fleet that must terminate its instances. The following is the error response.

```
<Response><Errors><Error><Code>UnauthorizedOperation</Code><Message>You are not authorized to perform this operation. Encoded authorization failure message: VvuncIxj7Z_CPGNYXWgquFV-YjByeAU66Q9752NTq-T3-qnDLws6JLfdKn5MM1q5s6cGqjjPtEdpnsGhzzyHasFH0aRY3paDVravowW25azn6KNkUQ71Fwh3yujt2dtnCdduIFre7FYAjl1ERmkf0Dht7N6G5K1weBHTurzDK6A560Y2nOv5SuMmmBYl9UNqazJ95Ne5N6xKMzqaKtyRbk02Rzu5V2vn9VMa6fmaMVHbY9JhLvypLcMujtJ76H9ytg2zRPV11U5v2s-UgZ7Hnp2y6yhUsudh10Ng6Byu8_y_Hte1S4vCf4c0qawqzMNe6rcmCQvhtCxtXsbkgyaEbcwmm2m01-EMheKFZe3LrDtyQpYcEik_mhFX1wtQOcnNcmnxj2Az3vb3VMYypDT5xj0v1PXOD2uqWHS23YKXYWwzqLHeRF2o41UHB6W17mXsS87k7XAfDPxjPT9vzHtQiloz5iVStjSFWg7ed__1rsnxWmpSu8gI48ZLRfpoQzFqRmKO_QI8BNs6NWzC4yox-9gDcheuR0GpkrpIC9YPMLK5</Message></Error><Errors><ErrorID>89b1215c-7814-40ae-a8db-41761f43f2b0</ErrorID></Errors></Response>
```

To resolve the error, you must add the ec2:TerminateInstances action to the IAM policy, as shown in the following example.
Spot Fleet

A Spot Fleet is a set of Spot Instances and optionally On-Demand Instances that is launched based on criteria that you specify. The Spot Fleet selects the Spot capacity pools that meet your needs and launches Spot Instances to meet the target capacity for the fleet. By default, Spot Fleets are set to maintain target capacity by launching replacement instances after Spot Instances in the fleet are terminated. You can submit a Spot Fleet as a one-time request, which does not persist after the instances have been terminated. You can include On-Demand Instance requests in a Spot Fleet request.

Note

If you want to use a console to create a fleet that includes Spot Instances, we recommend using an Auto Scaling group rather than Spot Fleet. For more information, see Auto Scaling groups with multiple instance types and purchase options in the Amazon EC2 Auto Scaling User Guide. If you want to use the AWS CLI to create a fleet that includes Spot Instances, we recommend using either an Auto Scaling group or EC2 Fleet rather than Spot Fleet. The RequestSpotFleet API, on which Spot Fleet is based, is a legacy API with no planned investment. For more information about the recommended APIs to use, see Which is the best Spot request method to use? (p. 553).

Topics

- Spot Fleet request types (p. 1152)
- Spot Fleet configuration strategies (p. 1153)
- Work with Spot Fleets (p. 1177)
- CloudWatch metrics for Spot Fleet (p. 1198)
- Automatic scaling for Spot Fleet (p. 1200)

Spot Fleet request types

There are two types of Spot Fleet requests:

request

If you configure the request type as request, Spot Fleet places an asynchronous one-time request for your desired capacity. Thereafter, if capacity is diminished because of Spot interruptions, the fleet does not attempt to replenish Spot Instances, nor does it submit requests in alternative Spot capacity pools if capacity is unavailable.

maintain

If you configure the request type as maintain, Spot Fleet places an asynchronous request for your desired capacity, and maintains capacity by automatically replenishing any interrupted Spot Instances.

To specify the type of request in the Amazon EC2 console, do the following when creating a Spot Fleet request:

- To create a Spot Fleet of type request, clear the Maintain target capacity check box.
- To create a Spot Fleet of type maintain, select the Maintain target capacity check box.

For more information, see Create a Spot Fleet request using defined parameters (console) (p. 1186).

Both types of requests benefit from an allocation strategy. For more information, see Allocation strategies for Spot Instances (p. 1154).
Spot Fleet configuration strategies

A Spot Fleet is a collection, or fleet, of Spot Instances, and optionally On-Demand Instances.

The Spot Fleet attempts to launch the number of Spot Instances and On-Demand Instances to meet the target capacity that you specified in the Spot Fleet request. The request for Spot Instances is fulfilled if there is available capacity and the maximum price you specified in the request exceeds the current Spot price. The Spot Fleet also attempts to maintain its target capacity fleet if your Spot Instances are interrupted.

You can also set a maximum amount per hour that you're willing to pay for your fleet, and Spot Fleet launches instances until it reaches the maximum amount. When the maximum amount you're willing to pay is reached, the fleet stops launching instances even if it hasn't met the target capacity.

A Spot capacity pool is a set of unused EC2 instances with the same instance type (for example, m5.large), operating system, Availability Zone, and network platform. When you make a Spot Fleet request, you can include multiple launch specifications, that vary by instance type, AMI, Availability Zone, or subnet. The Spot Fleet selects the Spot capacity pools that are used to fulfill the request, based on the launch specifications included in your Spot Fleet request, and the configuration of the Spot Fleet request. The Spot Instances come from the selected pools.

Contents

- Plan a Spot Fleet request (p. 1153)
- Allocation strategies for Spot Instances (p. 1154)
- Attribute-based instance type selection for Spot Fleet (p. 1157)
- On-Demand in Spot Fleet (p. 1171)
- Capacity Rebalancing (p. 1172)
- Spot price overrides (p. 1175)
- Control spending (p. 1175)
- Spot Fleet instance weighting (p. 1176)

Plan a Spot Fleet request

Before you create a Spot Fleet request, review Spot Best Practices. Use these best practices when you plan your Spot Fleet request so that you can provision the type of instances you want at the lowest possible price. We also recommend that you do the following:

- Determine whether you want to create a Spot Fleet that submits a one-time request for the desired target capacity, or one that maintains a target capacity over time.
- Determine the instance types that meet your application requirements.
- Determine the target capacity for your Spot Fleet request. You can set the target capacity in instances or in custom units. For more information, see Spot Fleet instance weighting (p. 1176).
- Determine what portion of the Spot Fleet target capacity must be On-Demand capacity. You can specify 0 for On-Demand capacity.
- Determine your price per unit, if you are using instance weighting. To calculate the price per unit, divide the price per instance hour by the number of units (or weight) that this instance represents. If you are not using instance weighting, the default price per unit is the price per instance hour.
- Review the possible options for your Spot Fleet request. For more information, see the request-spot-fleet command in the AWS CLI Command Reference. For additional examples, see Spot Fleet example configurations (p. 1249).
Allocation strategies for Spot Instances

Your launch configuration determines all the possible Spot capacity pools (instance types and Availability Zones) from which Spot Fleet can launch Spot Instances. However, when launching instances, Spot Fleet uses the allocation strategy that you specify to pick the specific pools from all your possible pools.

**Note**

If you configure your Spot Instance to launch with AMD SEV-SNP (p. 988) turned on, you are charged an additional hourly usage fee that is equivalent to 10% of the On-Demand hourly rate of the selected instance type. If the allocation strategy uses price as an input, Spot Fleet does not include this additional fee; only the Spot price is used.

Allocation strategies

You can specify one of the following allocation strategies for your Spot Instances:

- **priceCapacityOptimized (recommended)**
  
  Spot Fleet identifies the pools with the highest capacity availability for the number of instances that are launching. This means that we will request Spot Instances from the pools that we believe have the lowest chance of interruption in the near term. Spot Fleet then requests Spot Instances from the lowest priced of these pools.

  The `priceCapacityOptimized` allocation strategy is the best choice for most Spot workloads, such as stateless containerized applications, microservices, web applications, data and analytics jobs, and batch processing.

- **capacityOptimized**

  Spot Fleet identifies the pools with the highest capacity availability for the number of instances that are launching. This means that we will request Spot Instances from the pools that we believe have the lowest chance of interruption in the near term. You can optionally set a priority for each instance type in your fleet using `capacityOptimizedPrioritized`. Spot Fleet optimizes for capacity first, but honors instance type priorities on a best-effort basis.

  With Spot Instances, pricing changes slowly over time based on long-term trends in supply and demand, but capacity fluctuates in real time. The `capacityOptimized` strategy automatically launches Spot Instances into the most available pools by looking at real-time capacity data and predicting which are the most available. This works well for workloads that may have a higher cost of interruption associated with restarting work, such as long Continuous Integration (CI), image and media rendering, Deep Learning, and High Performance Compute (HPC) workloads that may have a higher cost of interruption associated with restarting work. By offering the possibility of fewer interruptions, the `capacityOptimized` strategy can lower the overall cost of your workload.

  Alternatively, you can use the `capacityOptimizedPrioritized` allocation strategy with a priority parameter to order instance types from highest to lowest priority. You can set the same priority for different instance types. Spot Fleet will optimize for capacity first, but will honor instance type priorities on a best-effort basis (for example, if honoring the priorities will not significantly affect Spot Fleet's ability to provision optimal capacity). This is a good option for workloads where the possibility of disruption must be minimized and the preference for certain instance types matters. Using priorities is supported only if your fleet uses a launch template. Note that when you set the priority for `capacityOptimizedPrioritized`, the same priority is also applied to your On-Demand Instances if the On-Demand AllocationStrategy is set to prioritized.

- **diversified**

  The Spot Instances are distributed across all pools.
lowestPrice

The Spot Instances come from the lowest priced pool that has available capacity. This is the default strategy. However, we recommend that you override the default by specifying the `priceCapacityOptimized` allocation strategy.

If the lowest priced pool doesn't have available capacity, the Spot Instances come from the next lowest priced pool that has available capacity.

If a pool runs out of capacity before fulfilling your desired capacity, Spot Fleet will continue to fulfill your request by drawing from the next lowest priced pool. To ensure that your desired capacity is met, you might receive Spot Instances from several pools.

Because this strategy only considers instance price and not capacity availability, it might lead to high interruption rates.

InstancePoolsToUseCount

The number of Spot pools across which to allocate your target Spot capacity. Valid only when the allocation strategy is set to `lowestPrice`. Spot Fleet selects the lowest priced Spot pools and evenly allocates your target Spot capacity across the number of Spot pools that you specify.

Note that Spot Fleet attempts to draw Spot Instances from the number of pools that you specify on a best effort basis. If a pool runs out of capacity before fulfilling your target capacity, Spot Fleet will continue to fulfill your request by drawing from the next lowest priced pool. To ensure that your target capacity is met, you might receive Spot Instances from more than the number of pools that you specified. Similarly, if most of the pools have no Spot capacity, you might receive your full target capacity from fewer than the number of pools that you specified.

Choose an appropriate allocation strategy

You can optimize your fleet for your use case by choosing the appropriate Spot allocation strategy. For On-Demand Instance target capacity, Spot Fleet always selects the least expensive instance type based on the public On-Demand price, while following the allocation strategy—either `priceCapacityOptimized`, `capacityOptimized`, `diversified`, or `lowestPrice`—for Spot Instances.

Balance lowest price and capacity availability

To balance the trade-offs between the lowest priced Spot capacity pools and the Spot capacity pools with the highest capacity availability, we recommend that you use the `priceCapacityOptimized` allocation strategy. This strategy makes decisions about which pools to request Spot Instances from based on both the price of the pools and the capacity availability of Spot Instances in those pools. This means that we will request Spot Instances from the pools that we believe have the lowest chance of interruption in the near term, while still taking price into consideration.

If your fleet runs resilient and stateless workloads, including containerized applications, microservices, web applications, data and analytics jobs, and batch processing, then use the `priceCapacityOptimized` allocation strategy for optimal cost savings and capacity availability.

If your fleet runs workloads that might have a higher cost of interruption associated with restarting work, then you should implement checkpointing so that applications can restart from that point if they're interrupted. By using checkpointing, you make the `priceCapacityOptimized` allocation strategy a good fit for these workloads because it allocates capacity from the lowest priced pools that also offer a low Spot Instance interruption rate.

For an example configuration that uses the `priceCapacityOptimized` allocation strategy, see Example 10: Launch Spot Instances in a capacity-optimized fleet with priorities (p. 1247).
When workloads have a high cost of interruption

You can optionally use the capacityOptimized strategy if you run workloads that either use similarly priced instance types, or where the cost of interruption is so significant that any cost saving is inadequate in comparison to a marginal increase in interruptions. This strategy allocates capacity from the most available Spot capacity pools that offer the possibility of fewer interruptions, which can lower the overall cost of your workload. For an example configuration that uses the capacityOptimized allocation strategy, see Example 8: Configure Capacity Rebalancing to launch replacement Spot Instances (p. 1245).

When the possibility of interruptions must be minimized but the preference for certain instance types matters, you can express your pool priorities by using the capacityOptimizedPrioritized allocation strategy and then setting the order of instance types to use from highest to lowest priority. For an example configuration, see Example 9: Launch Spot Instances in a capacity-optimized fleet (p. 1246).

Note that using priorities is supported only if your fleet uses a launch template. Also note that when you set priorities for capacityOptimizedPrioritized, the same priorities are also applied to your On-Demand Instances if the On-Demand AllocationStrategy is set to prioritized.

When your workload is time flexible and capacity availability is not a factor

If your fleet is small or runs for a short time, you can use priceCapacityOptimized to maximize cost savings while still considering capacity availability.

If your workload is time flexible and capacity availability is not a factor, you can optionally use the lowestPrice allocation strategy to maximize cost savings. Note, however, that because the lowestPrice allocation strategy only considers instance price and not capacity availability, it might lead to high Spot Instance interruption rates.

When your fleet is large or runs for a long time

If your fleet is large or runs for a long time, you can improve the availability of your fleet by distributing the Spot Instances across multiple pools using the diversified strategy. For example, if your Spot Fleet specifies 10 pools and a target capacity of 100 instances, the fleet launches 10 Spot Instances in each pool. If the Spot price for one pool exceeds your maximum price for this pool, only 10% of your fleet is affected. Using this strategy also makes your fleet less sensitive to increases in the Spot price in any one pool over time. With the diversified strategy, the Spot Fleet does not launch Spot Instances into any pools with a Spot price that is equal to or higher than the On-Demand price.

To create an inexpensive and diversified fleet, use the lowestPrice strategy in combination with InstancePoolsToUseCount. For example, if your target capacity is 10 Spot Instances, and you specify 2 Spot capacity pools (for InstancePoolsToUseCount), Spot Fleet will draw on the two lowest priced pools to fulfill your Spot capacity.

You can use a low or high number of Spot capacity pools across which to allocate your Spot Instances. For example, if you run batch processing, we recommend specifying a low number of Spot capacity pools (for example, InstancePoolsToUseCount=2) to ensure that your queue always has compute capacity while maximizing savings. If you run a web service, we recommend specifying a high number of Spot capacity pools (for example, InstancePoolsToUseCount=10) to minimize the impact if a Spot capacity pool becomes temporarily unavailable.

Note that Spot Fleet attempts to draw Spot Instances from the number of pools that you specify on a best effort basis. If a pool runs out of Spot capacity before fulfilling your target capacity, Spot Fleet will continue to fulfill your request by drawing from the next lowest priced pool. To ensure that your target capacity is met, you might receive Spot Instances from more than the number of pools that you specified. Similarly, if most of the pools have no Spot capacity, you might receive your full target capacity from fewer than the number of pools that you specified.
Maintain target capacity

After Spot Instances are terminated due to a change in the Spot price or available capacity of a Spot capacity pool, a Spot Fleet of type maintain launches replacement Spot Instances. The allocation strategy determines the pools from which the replacement instances are launched, as follows:

- If the allocation strategy is priceCapacityOptimized, the fleet launches replacement instances in the pools that have the most Spot Instance capacity availability while also taking price into consideration and identifying lowest priced pools with high capacity availability.
- If the allocation strategy is capacityOptimized, the fleet launches replacement instances in the pools that have the most Spot Instance capacity availability.
- If the allocation strategy is diversified, the fleet distributes the replacement Spot Instances across the remaining pools.
- If the allocation strategy is lowestPrice, the fleet launches replacement instances in the pool where the Spot price is currently the lowest.
- If the allocation strategy is lowestPrice in combination with InstancePoolsToUseCount, the fleet selects the Spot capacity pools with the lowest price and launches Spot Instances across the number of Spot capacity pools that you specify.

Attribute-based instance type selection for Spot Fleet

When you create a Spot Fleet, you must specify one or more instance types for configuring the On-Demand Instances and Spot Instances in the fleet. As an alternative to manually specifying the instance types, you can specify the attributes that an instance must have, and Amazon EC2 will identify all the instance types with those attributes. This is known as attribute-based instance type selection. For example, you can specify the minimum and maximum number of vCPUs required for your instances, and Spot Fleet will launch the instances using any available instance types that meet those vCPU requirements.

Attribute-based instance type selection is ideal for workloads and frameworks that can be flexible about what instance types they use, such as when running containers or web fleets, processing big data, and implementing continuous integration and deployment (CI/CD) tooling.

Benefits

Attribute-based instance type selection has the following benefits:

- With so many instance types available, finding the right instance types for your workload can be time consuming. When you specify instance attributes, the instance types will automatically have the required attributes for your workload.
- To manually specify multiple instance types for a Spot Fleet, you must create a separate launch template override for each instance type. But with attribute-based instance type selection, to provide multiple instance types, you need only specify the instance attributes in the launch template or in a launch template override.
- When you specify instance attributes rather than instance types, your fleet can use newer generation instance types as they're released, “future proofing” the fleet's configuration.
- When you specify instance attributes rather than instance types, Spot Fleet can select from a wide range of instance types for launching Spot Instances, which adheres to the Spot best practice of instance type flexibility (p. 552).

Topics

- How attribute-based instance type selection works (p. 1158)
- Considerations (p. 1160)
- Create a Spot Fleet with attribute-based instance type selection (p. 1160)
How attribute-based instance type selection works

To use attribute-based instance type selection in your fleet configuration, you replace the list of instance types with a list of instance attributes that your instances require. Spot Fleet will launch instances on any available instance types that have the specified instance attributes.

Topics

- Types of instance attributes (p. 1158)
- Where to configure attribute-based instance type selection (p. 1158)
- How Spot Fleet uses attribute-based instance type selection when provisioning a fleet (p. 1158)
- Price protection (p. 1159)

Types of instance attributes

There are several instance attributes that you can specify to express your compute requirements. For a description of each attribute and the default values, see InstanceRequirements in the Amazon EC2 API Reference.

Where to configure attribute-based instance type selection

Depending on whether you use the console or the AWS CLI, you can specify the instance attributes for attribute-based instance type selection as follows:

In the console, you can specify the instance attributes in one or both of the following fleet configuration components:

- In a launch template, and then reference the launch template in the fleet request
- In the fleet request

In the AWS CLI, you can specify the instance attributes in one or all of the following fleet configuration components:

- In a launch template, and reference the launch template in the fleet request
- In a launch template override
  
  If you want a mix of instances that use different AMIs, you can specify instance attributes in multiple launch template overrides. For example, different instance types can use x86 and Arm-based processors.
- In a launch specification

How Spot Fleet uses attribute-based instance type selection when provisioning a fleet

Spot Fleet provisions a fleet in the following way:

- Spot Fleet identifies the instance types that have the specified attributes.
- Spot Fleet uses price protection to determine which instance types to exclude.
- Spot Fleet determines the capacity pools from which it will consider launching the instances based on the AWS Regions or Availability Zones that have matching instance types.
- Spot Fleet applies the specified allocation strategy to determine from which capacity pools to launch the instances.
Note that attribute-based instance type selection does not pick the capacity pools from which to provision the fleet; that’s the job of the allocation strategies. There might be a large number of instance types with the specified attributes, and some of them might be expensive. The default allocation strategy of lowestPrice for Spot and On-Demand guarantees that Spot Fleet will launch instances from the least expensive capacity pools.

If you specify an allocation strategy, Spot Fleet will launch instances according to the specified allocation strategy.

- For Spot Instances, attribute-based instance type selection supports the capacityOptimizedPrioritized, capacityOptimized and lowestPrice allocation strategies.
- For On-Demand Instances, attribute-based instance type selection supports the lowestPrice allocation strategy.
- If there is no capacity for the instance types with the specified instance attributes, no instances can be launched, and the fleet returns an error.

**Price protection**

Price protection is a feature that prevents your Spot Fleet from using instance types that you would consider too expensive even if they happen to fit the attributes that you specified. When you create a fleet with attribute-based instance type selection, price protection is enabled by default, with separate thresholds for On-Demand Instances and Spot Instances. When Amazon EC2 selects instance types with your attributes, it excludes instance types priced above your threshold. The thresholds represent the maximum you’ll pay, expressed as a percentage above the least expensive current generation M, C, or R instance type with your specified attributes.

If you don’t specify a threshold, the following thresholds are used by default:

- For On-Demand Instances, the price protection threshold is set at 20 percent.
- For Spot Instances, the price protection threshold is set at 100 percent.

**To specify the price protection threshold**

While creating the Spot Fleet, configure the fleet for attribute-based instance type selection, and then do the following:

- **Console**

  To specify the On-Demand Instance price protection threshold, under Additional instance attribute, choose On-demand price protection, and then choose Add attribute. For On-Demand price protection percentage, enter the price protection threshold as a percentage.

  To specify the Spot Instance price protection threshold, under Additional instance attribute, choose Spot price protection, and then choose Add attribute. For Spot price protection percentage, enter the price protection threshold as a percentage.

- **AWS CLI**

  To specify the On-Demand Instance price protection threshold, in the JSON configuration file, in the InstanceRequirements structure, for OnDemandMaxPricePercentageOverLowestPrice, enter the price protection threshold as a percentage.

  To specify the Spot Instance price protection threshold, in the JSON configuration file, in the InstanceRequirements structure, for SpotMaxPricePercentageOverLowestPrice, enter the price protection threshold as a percentage.
For more information about creating the fleet, see Create a Spot Fleet with attribute-based instance type selection (p. 1160).

Note
When creating the Spot Fleet, if you set Total target capacity type to vCPUs or Memory (MiB) (console) or TargetCapacityUnitType to vcpu or memory-mib (AWS CLI), the price protection threshold is applied based on the per-vCPU or per-memory price instead of the per-instance price.

Considerations

- You can specify either instance types or instance attributes in a Spot Fleet, but not both at the same time.

  When using the CLI, the launch template overrides will override the launch template. For example, if the launch template contains an instance type and the launch template override contains instance attributes, the instances that are identified by the instance attributes will override the instance type in the launch template.

- When using the CLI, when you specify instance attributes as overrides, you can’t also specify weights or priorities.

- You can specify a maximum of four InstanceRequirements structures in a request configuration.

Create a Spot Fleet with attribute-based instance type selection

You can configure a fleet to use attribute-based instance type selection by using the Amazon EC2 console or the AWS CLI.

Topics

- Create a Spot Fleet using the console (p. 1160)
- Create a Spot Fleet using the AWS CLI (p. 1161)

Create a Spot Fleet using the console

To configure a Spot Fleet for attribute-based instance type selection (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests, and then choose Request Spot Instances.
3. Follow the steps to create a Spot Fleet. For more information, see Create a Spot Fleet request using defined parameters (console) (p. 1186).

   While creating the Spot Fleet, configure the fleet for attribute-based instance type selection as follows:

   a. For Instance type requirements, choose Specify instance attributes that match your compute requirements.

   b. For vCPUs, enter the desired minimum and maximum number of vCPUs. To specify no limit, select No minimum, No maximum, or both.

   c. For Memory (GiB), enter the desired minimum and maximum amount of memory. To specify no limit, select No minimum, No maximum, or both.

   d. (Optional) For Additional instance attributes, you can optionally specify one or more attributes to express your compute requirements in more detail. Each additional attribute adds further constraints to your request.

   e. (Optional) Expand Preview matching instance types to view the instance types that have your specified attributes.
Create a Spot Fleet using the AWS CLI

To configure a Spot Fleet for attribute-based instance type selection (AWS CLI)

Use the request-spot-fleet (AWS CLI) command to create a Spot Fleet. Specify the fleet configuration in a JSON file.

```bash
aws ec2 request-spot-fleet
--region us-east-1
--spot-fleet-request-config file://file_name.json
```

Example `file_name.json` file

The following example contains the parameters that configure a Spot Fleet to use attribute-based instance type selection, and is followed by a text explanation.

```json
{
    "AllocationStrategy": "priceCapacityOptimized",
    "TargetCapacity": 20,
    "Type": "request",
    "LaunchTemplateConfigs": [{
        "LaunchTemplateSpecification": {
            "LaunchTemplateName": "my-launch-template",
            "Version": "1"
        },
        "Overrides": [{
            "InstanceRequirements": {
                "VCpuCount": {
                    "Min": 2
                },
                "MemoryMiB": {
                    "Min": 4
                }
            }
        }]
    }]
}
```

The attributes for attribute-based instance type selection are specified in the `InstanceRequirements` structure. In this example, two attributes are specified:

- **VCpuCount** – A minimum of 2 vCPUs is specified. Because no maximum is specified, there is no maximum limit.
- **MemoryMiB** – A minimum of 4 MiB of memory is specified. Because no maximum is specified, there is no maximum limit.

Any instance types that have 2 or more vCPUs and 4 MiB or more of memory will be identified. However, price protection and the allocation strategy might exclude some instance types when Spot Fleet provisions the fleet (p. 1158).

For a list and descriptions of all the possible attributes that you can specify, see `InstanceRequirements` in the [Amazon EC2 API Reference](https://docs.aws.amazon.com/AWSEC2/latest/APIReference/).

**Note**

When `InstanceRequirements` is included in the fleet configuration, `InstanceType` and `WeightedCapacity` must be excluded; they cannot determine the fleet configuration at the same time as instance attributes.

The JSON also contains the following fleet configuration:
• "AllocationStrategy": "priceCapacityOptimized" – The allocation strategy for the Spot Instances in the fleet.
• "LaunchTemplateName": "my-launch-template", "Version": "1" – The launch template contains some instance configuration information, but if any instance types are specified, they will be overridden by the attributes that are specified in InstanceRequirements.
• "TargetCapacity": 20 – The target capacity is 20 instances.
• "Type": "request" – The request type for the fleet is request.

Examples of configurations that are valid and not valid

If you use the AWS CLI to create a Spot Fleet, you must make sure that your fleet configuration is valid. The following examples show configurations that are valid and not valid.

Configurations are considered not valid when they contain the following:

• A single Overrides structure with both InstanceRequirements and InstanceType
• Two Overrides structures, one with InstanceRequirements and the other with InstanceType
• Two InstanceRequirements structures with overlapping attribute values within the same LaunchTemplateSpecification

Example configurations

• Valid configuration: Single launch template with overrides (p. 1162)
• Valid configuration: Single launch template with multiple InstanceRequirements (p. 1163)
• Valid configuration: Two launch templates, each with overrides (p. 1164)
• Valid configuration: Only InstanceRequirements specified, no overlapping attribute values (p. 1165)
• Configuration not valid: Overrides contain InstanceRequirements and InstanceType (p. 1166)
• Configuration not valid: Two Overrides contain InstanceRequirements and InstanceType (p. 1166)
• Configuration not valid: Overlapping attribute values (p. 1167)

Valid configuration: Single launch template with overrides

The following configuration is valid. It contains one launch template and one Overrides structure containing one InstanceRequirements structure. A text explanation of the example configuration follows.

```json
{
   "SpotFleetRequestConfig": {
      "AllocationStrategy": "lowestPrice",
      "ExcessCapacityTerminationPolicy": "default",
      "IamFleetRole": "arn:aws:iam::000000000000:role/aws-ec2-spot-fleet-tagging-role",
      "LaunchTemplateConfigs": [
         {
            "LaunchTemplateName": "My-launch-template",
            "Version": "1"
         }
      ],
      "Overrides": [
         {
            "InstanceRequirements": {
               "VCpuCount": {
                  "Min": 2,
                  "Max": 8
               },
               "MemoryMib": {
                  "Min": 0,
```
InstanceRequirements

To use attribute-based instance selection, you must include the InstanceRequirements structure in your fleet configuration, and specify the desired attributes for the instances in the fleet.

In the preceding example, the following instance attributes are specified:

- **VCpuCount** – The instance types must have a minimum of 2 and a maximum of 8 vCPUs.
- **MemoryMiB** – The instance types must have a maximum of 10240 MiB of memory. A minimum of 0 indicates no minimum limit.
- **MemoryGiBPerVCpu** – The instance types must have a maximum of 10,000 GiB of memory per vCPU. The Min parameter is optional. By omitting it, you indicate no minimum limit.

TargetCapacityUnitType

The TargetCapacityUnitType parameter specifies the unit for the target capacity. In the example, the target capacity is 5000 and the target capacity unit type is vcpu, which together specify a desired target capacity of 5,000 vCPUs. Spot Fleet will launch enough instances so that the total number of vCPUs in the fleet is 5,000 vCPUs.

Valid configuration: Single launch template with multiple InstanceRequirements

The following configuration is valid. It contains one launch template and one Overrides structure containing two InstanceRequirements structures. The attributes specified in InstanceRequirements are valid because the values do not overlap—the first InstanceRequirements structure specifies a VcpuCount of 0-2 vCPUs, while the second InstanceRequirements structure specifies 4-8 vCPUs.
Valid configuration: Two launch templates, each with overrides

The following configuration is valid. It contains two launch templates, each with one Overrides structure containing one InstanceRequirements structure. This configuration is useful for arm and x86 architecture support in the same fleet.

```json
{
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "lowestPrice",
        "ExcessCapacityTerminationPolicy": "default",
        "IamFleetRole": "arn:aws:iam::000000000000:role/aws-ec2-spot-fleet-tagging-role",
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "armLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                    {
                        "InstanceRequirements": {
                            "VCpuCount": {
                                "Min": 0,
                                "Max": 2
                            },
                            "MemoryMiB": {
                                "Min": 0
                            }
                        }
                    },
                    {
                        "LaunchTemplateSpecification": {
                            "LaunchTemplateName": "x86LaunchTemplate",
                            "Version": "1"
                        },
                        "Overrides": [
                            {
                                "InstanceRequirements": {
                                    "VCpuCount": {
                                        "Min": 0,
                                        "Max": 2
                                    },
                                    "MemoryMiB": {
                                        "Min": 0
                                    }
                                }
                            }
                        ]
                    }
                ]
            }
        ]
    }
}
```
Valid configuration: Only InstanceRequirements specified, no overlapping attribute values

The following configuration is valid. It contains two LaunchTemplateSpecification structures, each with a launch template and an Overrides structure containing an InstanceRequirements structure. The attributes specified in InstanceRequirements are valid because the values do not overlap—the first InstanceRequirements structure specifies a VcpuCount of 0-2 vCPUs, while the second InstanceRequirements structure specifies 4-8 vCPUs.

```json
{
  "SpotFleetRequestConfig": {
    "AllocationStrategy": "lowestPrice",
    "ExcessCapacityTerminationPolicy": "default",
    "IamFleetRole": "arn:aws:iam::000000000000:role/aws-ec2-spot-fleet-tagging-role",
    "LaunchTemplateConfigs": [
      {
        "LaunchTemplateSpecification": {
          "LaunchTemplateName": "MyLaunchTemplate",
          "Version": "1"
        },
        "Overrides": [
          {
            "InstanceRequirements": {
              "VcpuCount": {
                "Min": 0,
                "Max": 2
              },
              "MemoryMiB": {
                "Min": 0
              }
            }
          }
        ]
      },
      {
        "LaunchTemplateSpecification": {
          "LaunchTemplateName": "MyOtherLaunchTemplate",
          "Version": "1"
        },
        "Overrides": [
          {
            "InstanceRequirements": {
              "VcpuCount": {
                "Min": 4,
                "Max": 8
              },
              "MemoryMiB": {
                "Min": 0
              }
            }
          }
        ]
      }
    ]
  }
}
```
Configuration not valid: Overrides contain InstanceRequirements and InstanceType

The following configuration is not valid. The Overrides structure contains both InstanceRequirements and InstanceType. For the Overrides, you can specify either InstanceRequirements or InstanceType, but not both.

```json
{
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "lowestPrice",
        "ExcessCapacityTerminationPolicy": "default",
        "IamFleetRole": "arn:aws:iam::000000000000:role/aws-ec2-spot-fleet-tagging-role",
        "LaunchTemplateConfigs": [
            {
                "LaunchTemplateSpecification": {
                    "LaunchTemplateName": "MyLaunchTemplate",
                    "Version": "1"
                },
                "Overrides": [
                    {
                        "InstanceRequirements": {
                            "VCpuCount": {
                                "Min": 0,
                                "Max": 2
                            },
                            "MemoryMiB": {
                                "Min": 0
                            }
                        }
                    },
                    {
                        "InstanceType": "m5.large"
                    }
                ]
            },
            {
                "TargetCapacity": 1,
                "OnDemandTargetCapacity": 0,
                "Type": "maintain"
            }
        ]
    }  
}
```

Configuration not valid: Two Overrides contain InstanceRequirements and InstanceType

The following configuration is not valid. The Overrides structures contain both InstanceRequirements and InstanceType. You can specify either InstanceRequirements or InstanceType, but not both, even if they're in different Overrides structures.

```json
{
```

1166
Configuration not valid: Overlapping attribute values

The following configuration is not valid. The two InstanceRequirements structures each contain
"VCpuCount": {"Min": 0, "Max": 2}. The values for these attributes overlap, which will result in
duplicate capacity pools.
Preview instance types with specified attributes

You can use the `get-instance-types-from-instance-requirements` AWS CLI command to preview the instance types that match the attributes that you specify. This is especially useful for working out what attributes to specify in your request configuration without launching any instances. Note that the command does not consider available capacity.

To preview a list of instance types by specifying attributes using the AWS CLI

1. (Optional) To generate all of the possible attributes that can be specified, use the `get-instance-types-from-instance-requirements` command and the `--generate-cli-skeleton` parameter. You can optionally direct the output to a file to save it by using `input > attributes.json`.

```bash
aws ec2 get-instance-types-from-instance-requirements \
  --region us-east-1 \
  --generate-cli-skeleton input > attributes.json
```

Expected output

```json
{
  "DryRun": true,
  "ArchitectureTypes": [
    "i386"
  ],
  "VirtualizationTypes": [
    "hvm"
  ],
  "InstanceRequirements": {
    "VCpuCount": {
      "Min": 0,
      "Max": 0
    },
    "MemoryMiB": {
      "Min": 0,
      "Max": 0
    }
  }
}
```
2. Create a JSON configuration file using the output from the previous step, and configure it as follows:
Note
You must provide values for ArchitectureTypes, VirtualizationTypes, VCPUCount, and MemoryMiB. You can omit the other attributes; when omitted, the default values are used.
For a description of each attribute and their default values, see get-instance-types-from-instance-requirements in the Amazon EC2 Command Line Reference.

a. For ArchitectureTypes, specify one or more types of processor architecture.
b. For VirtualizationTypes, specify one or more types of virtualization.
c. For VCPUCount, specify the minimum and maximum number of vCPUs. To specify no minimum limit, for Min, specify 0. To specify no maximum limit, omit the Max parameter.
d. For MemoryMiB, specify the minimum and maximum amount of memory in MiB. To specify no minimum limit, for Min, specify 0. To specify no maximum limit, omit the Max parameter.
e. You can optionally specify one or more of the other attributes to further constrain the list of instance types that are returned.

3. To preview the instance types that have the attributes that you specified in the JSON file, use the get-instance-types-from-instance-requirements command, and specify the name and path to your JSON file by using the --cli-input-json parameter. You can optionally format the output to appear in a table format.

```
aws ec2 get-instance-types-from-instance-requirements \
   --cli-input-json file://attributes.json \
   --output table
```

Example attributes.json file
In this example, the required attributes are included in the JSON file. They are ArchitectureTypes, VirtualizationTypes, VCPUCount, and MemoryMiB. In addition, the optional InstanceGenerations attribute is also included. Note that for MemoryMiB, the Max value can be omitted to indicate that there is no limit.

```
{
   "ArchitectureTypes": [ "x86_64" ],
   "VirtualizationTypes": [ "hvm" ],
   "InstanceRequirements": {
      "VCPUCount": { 
         "Min": 4,
         "Max": 6
      },
      "MemoryMiB": { 
         "Min": 2048
      },
      "InstanceGenerations": [ 
         "current"
      ]
   }
}
```

Example output
```
------------------------------------------
|GetInstanceTypesFromInstanceRequirements|
------------------------------------------
aws ec2 get-instance-types-from-instance-requirements \
   --cli-input-json file://attributes.json \
   --output table
```

1170
4. After identifying instance types that meet your needs, make note of the instance attributes that you used so that you can use them when configuring your fleet request.

### On-Demand in Spot Fleet

To ensure that you always have instance capacity, you can include a request for On-Demand capacity in your Spot Fleet request. In your Spot Fleet request, you specify your desired target capacity and how much of that capacity must be On-Demand. The balance comprises Spot capacity, which is launched if there is available Amazon EC2 capacity and availability. For example, if in your Spot Fleet request you specify the target capacity as 10 and the On-Demand capacity as 8, Amazon EC2 launches 8 capacity units as On-Demand, and 2 capacity units (10-8=2) as Spot.

#### Prioritize instance types for On-Demand capacity

When Spot Fleet attempts to fulfill your On-Demand capacity, it defaults to launching the lowest priced instance type first. If `OnDemandAllocationStrategy` is set to `prioritized`, Spot Fleet uses priority to determine which instance type to use first in fulfilling On-Demand capacity.

The priority is assigned to the launch template override, and the highest priority is launched first.

**Example: Prioritize instance types**

In this example, you configure three launch template overrides, each with a different instance type.

The On-Demand price for the instance types range in price. The following are the instance types used in this example, listed in order of priority, starting with the cheapest instance type:

- `m4.large` – cheapest
- `m5.large`
- `m5a.large`

If you do not use priority to determine the order, the fleet fulfills the On-Demand capacity by starting with the cheapest instance type.

However, say you have unused `m5.large` Reserved Instances that you want to use first. You can set the launch template override priority so that the instance types are used in the order of priority, as follows:

- `m5.large` – priority 1
- `m4.large` – priority 2
- `m5a.large` – priority 3
Capacity Rebalancing

You can configure Spot Fleet to launch a replacement Spot Instance when Amazon EC2 emits a rebalance recommendation to notify you that a Spot Instance is at an elevated risk of interruption. Capacity Rebalancing helps you maintain workload availability by proactively augmenting your fleet with a new Spot Instance before a running instance is interrupted by Amazon EC2. For more information, see EC2 instance rebalance recommendations (p. 584).

To configure Spot Fleet to launch a replacement Spot Instance, you can use the Amazon EC2 console or the AWS CLI.

- Amazon EC2 console: You must select the Capacity rebalance check box when you create the Spot Fleet. For more information, see step 6.d. in Create a Spot Fleet request using defined parameters (console) (p. 1186).
- AWS CLI: Use the request-spot-fleet command and the relevant parameters in the SpotMaintenanceStrategies structure. For more information, see the example launch configuration (p. 1258).

Limitations

- Capacity Rebalancing is available only for fleets of type maintain.
- When the fleet is running, you can't modify the Capacity Rebalancing setting. To change the Capacity Rebalancing setting, you must delete the fleet and create a new fleet.

Configuration options

The ReplacementStrategy for Spot Fleet supports the following two values:

launch-before-terminate

Amazon EC2 terminates the Spot Instances that receive a rebalance notification after new replacement Spot Instances are launched. When you specify launch-before-terminate, you must also specify a value for termination-delay. After the new replacement instances are launched, Amazon EC2 waits for the duration of the termination-delay, and then terminates the old instances. For termination-delay, the minimum is 120 seconds (2 minutes), and the maximum is 7200 seconds (2 hours).

We recommend that you use launch-before-terminate only if you can predict how long your instance shutdown procedures will take to complete. This will ensure that the old instances are terminated only after the shutdown procedures are completed. Note that Amazon EC2 can interrupt the old instances with a two-minute warning before the termination-delay.

We strongly recommend against using the lowestPrice allocation strategy in combination with launch-before-terminate to avoid having replacement Spot Instances that are also at an elevated risk of interruption.

launch

Amazon EC2 launches replacement Spot Instances when a rebalance notification is emitted for existing Spot Instances. Amazon EC2 does not terminate the instances that receive a rebalance notification. You can terminate the old instances, or you can leave them running. You are charged for all instances while they are running.

Considerations

If you configure a Spot Fleet for Capacity Rebalancing, consider the following:
Provide as many Spot capacity pools in the request as possible

Configure your Spot Fleet to use multiple instance types and Availability Zones. This provides the flexibility to launch Spot Instances in various Spot capacity pools. For more information, see Be flexible about instance types and Availability Zones (p. 552).

Avoid an elevated risk of interruption of replacement Spot Instances

Your replacement Spot Instances may be at an elevated risk of interruption if you use the lowestPrice allocation strategy. This is because Amazon EC2 will always launch instances in the lowest priced pool that has available capacity at that moment, even if your replacement Spot Instances are likely to be interrupted soon after being launched. To avoid an elevated risk of interruption, we strongly recommend against using the lowestPrice allocation strategy, and instead recommend the capacityOptimized or capacityOptimizedPrioritized allocation strategy. These strategies ensure that replacement Spot Instances are launched in the most optimal Spot capacity pools, and are therefore less likely to be interrupted in the near future. For more information, see Use the price and capacity optimized allocation strategy (p. 552).

Amazon EC2 will only launch a new instance if availability is the same or better

One of the goals of Capacity Rebalancing is to improve a Spot Instance's availability. If an existing Spot Instance receives a rebalance recommendation, Amazon EC2 will only launch a new instance if the new instance provides the same or better availability than the existing instance. If the risk of interruption of a new instance will be worse than the existing instance, then Amazon EC2 will not launch a new instance. Amazon EC2 will, however, continue to assess the Spot capacity pools, and will launch a new instance if availability improves.

There is a chance that your existing instance will be interrupted without Amazon EC2 proactively launching a new instance. When this happens, Amazon EC2 will attempt to launch a new instance regardless of whether the new instance has a high risk of interruption.

Capacity Rebalancing does not increase your Spot Instance interruption rate

When you enable Capacity Rebalancing, it does not increase your Spot Instance interruption rate (p. 587) (the number of Spot Instances that are reclaimed when Amazon EC2 needs the capacity back). However, if Capacity Rebalancing detects an instance is at risk of interruption, Amazon EC2 will immediately attempt to launch a new instance. The result is that more instances might be replaced than if you'd waited for Amazon EC2 to launch a new instance after the at-risk instance was interrupted.

While you might replace more instances with Capacity Rebalancing enabled, you benefit from being proactive rather than reactive by having more time to take action before your instances are interrupted. With a Spot Instance interruption notice (p. 593), you typically only have up to two minutes to gracefully shut down your instance. With Capacity Rebalancing launching a new instance in advance, you give existing processes a better chance of completing on your at-risk instance, you can start your instance shutdown procedures, and prevent new work from being scheduled on your at-risk instance. You can also start preparing the newly-launched instance to take over the application. With Capacity Rebalancing’s proactive replacement, you benefit from graceful continuity.

As a theoretical example to demonstrate the risks and benefits of using Capacity Rebalancing, consider the following scenario:

- 2:00 PM – A rebalance recommendation is received for instance-A, and Amazon EC2 immediately starts attempting to launch a replacement instance-B, giving you time to start your shutdown procedures.*
- 2:30 PM – A rebalance recommendation is received for instance-B, replaced with instance-C, giving you time to start your shutdown procedures.*
- 2:32 PM – If Capacity Rebalancing wasn't enabled, and if a Spot Instance interruption notice would've been received at 2:32 PM for instance-A, you would only have had up to two minutes to take action, but instance-A would have been running up till this time.
If launch-before-terminate is specified, Amazon EC2 will terminate the at-risk instance after
the replacement instance comes online.

Amazon EC2 can launch new replacement Spot Instances until fulfilled capacity is double target
capacity

When a Spot Fleet is configured for Capacity Rebalancing, Amazon EC2 attempts to launch a new
replacement Spot Instance for every Spot Instance that receives a rebalance recommendation. After
a Spot Instance receives a rebalance recommendation, it is no longer counted as part of the fulfilled
capacity. Depending on the replacement strategy, Amazon EC2 either terminates the instance after
a preconfigured termination delay, or leaves it running. This gives you the opportunity to perform
rebalancing actions (p. 584) on the instance.

If your fleet reaches double its target capacity, it stops launching new replacement instances even if
the replacement instances themselves receive a rebalance recommendation.

For example, you create a Spot Fleet with a target capacity of 100 Spot Instances. All of the
Spot Instances receive a rebalance recommendation, which causes Amazon EC2 to launch 100
replacement Spot Instances. This raises the number of fulfilled Spot Instances to 200, which is
double the target capacity. Some of the replacement instances receive a rebalance recommendation,
but no more replacement instances are launched because the fleet cannot exceed double its target
capacity.

Note that you are charged for all of the instances while they are running.

We recommend that you configure Spot Fleet to terminate Spot Instances that receive a rebalance
recommendation

If you configure your Spot Fleet for Capacity Rebalancing, we recommend that you choose launch-
before-terminate with an appropriate termination delay only if you can predict how long your
instance shutdown procedures will take to complete. This will ensure that the old instances are
terminated only after the shutdown procedures are completed.

If you choose to terminate the instances that are recommended for rebalance yourself, we
recommend that you monitor the rebalance recommendation signal that is received by the Spot
Instances in the fleet. By monitoring the signal, you can quickly perform rebalancing actions (p. 584)
on the affected instances before Amazon EC2 interrupts them, and then you can manually
terminate them. If you do not terminate the instances, you continue paying for them while they
are running. Amazon EC2 does not automatically terminate the instances that receive a rebalance
recommendation.

You can set up notifications using Amazon EventBridge or instance metadata. For more information,
see Monitor rebalance recommendation signals (p. 585).

Spot Fleet does not count instances that receive a rebalance recommendation when calculating
fulfilled capacity during scale in or out

If your Spot Fleet is configured for Capacity Rebalancing, and you change the target capacity to
either scale in or scale out, the fleet does not count the instances that are marked for rebalance as
part of the fulfilled capacity, as follows:

• Scale in – If you decrease your desired target capacity, Amazon EC2 terminates instances that are
  not marked for rebalance until the desired capacity is reached. The instances that are marked for
  rebalance are not counted towards the fulfilled capacity.

For example, you create a Spot Fleet with a target capacity of 100 Spot Instances. 10 instances
receive a rebalance recommendation, so Amazon EC2 launches 10 new replacement instances,
resulting in a fulfilled capacity of 110 instances. You then reduce the target capacity to 50 (scale
in), but the fulfilled capacity is actually 60 instances because the 10 instances that are marked for
rebalance are not terminated by Amazon EC2. You need to manually terminate these instances, or
you can leave them running.
• Scale out – If you increase your desired target capacity, Amazon EC2 launches new instances until the desired capacity is reached. The instances that are marked for rebalance are not counted towards the fulfilled capacity.

For example, you create a Spot Fleet with a target capacity of 100 Spot Instances. 10 instances receive a rebalance recommendation, so Amazon EC2 launches 10 new replacement instances, resulting in a fulfilled capacity of 110 instances. You then increase the target capacity to 200 (scale out), but the fulfilled capacity is actually 210 instances because the 10 instances that are marked for rebalance are not counted by the fleet as part of the target capacity. You need to manually terminate these instances, or you can leave them running.

Spot price overrides

Each Spot Fleet request can include a global maximum price, or use the default (the On-Demand price). Spot Fleet uses this as the default maximum price for each of its launch specifications.

You can optionally specify a maximum price in one or more launch specifications. This price is specific to the launch specification. If a launch specification includes a specific price, the Spot Fleet uses this maximum price, overriding the global maximum price. Any other launch specifications that do not include a specific maximum price still use the global maximum price.

Control spending

Spot Fleet stops launching instances when it has either reached the target capacity or the maximum amount you're willing to pay. To control the amount you pay per hour for your fleet, you can specify the SpotMaxTotalPrice for Spot Instances and the OnDemandMaxTotalPrice for On-Demand Instances. When the maximum total price is reached, Spot Fleet stops launching instances even if it hasn't met the target capacity.

The following examples show two different scenarios. In the first, Spot Fleet stops launching instances when it has met the target capacity. In the second, Spot Fleet stops launching instances when it has reached the maximum amount you're willing to pay.

Example: Stop launching instances when target capacity is reached

Given a request for m4.large On-Demand Instances, where:

• On-Demand Price: $0.10 per hour
• OnDemandTargetCapacity: 10
• OnDemandMaxTotalPrice: $1.50

Spot Fleet launches 10 On-Demand Instances because the total of $1.00 (10 instances x $0.10) does not exceed the OnDemandMaxTotalPrice of $1.50.

Example: Stop launching instances when maximum total price is reached

Given a request for m4.large On-Demand Instances, where:

• On-Demand Price: $0.10 per hour
• OnDemandTargetCapacity: 10
• OnDemandMaxTotalPrice: $0.80

If Spot Fleet launches the On-Demand target capacity (10 On-Demand Instances), the total cost per hour would be $1.00. This is more than the amount ($0.80) specified for OnDemandMaxTotalPrice.
To prevent spending more than you're willing to pay, Spot Fleet launches only 8 On-Demand Instances (below the On-Demand target capacity) because launching more would exceed the OnDemandMaxTotalPrice.

**Spot Fleet instance weighting**

When you request a fleet of Spot Instances, you can define the capacity units that each instance type would contribute to your application's performance, and adjust your maximum price for each Spot capacity pool accordingly using *instance weighting*.

By default, the price that you specify is *per instance hour*. When you use the instance weighting feature, the price that you specify is *per unit hour*. You can calculate your price per unit hour by dividing your price for an instance type by the number of units that it represents. Spot Fleet calculates the number of Spot Instances to launch by dividing the target capacity by the instance weight. If the result isn’t an integer, the Spot Fleet rounds it up to the next integer, so that the size of your fleet is not below its target capacity. Spot Fleet can select any pool that you specify in your launch specification, even if the capacity of the instances launched exceeds the requested target capacity.

The following tables provide examples of calculations to determine the price per unit for a Spot Fleet request with a target capacity of 10.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Instance weight</th>
<th>Price per instance hour</th>
<th>Price per unit hour</th>
<th>Number of instances launched</th>
</tr>
</thead>
<tbody>
<tr>
<td>r3.xlarge</td>
<td>2</td>
<td>$0.05</td>
<td>.025</td>
<td>5 (10 divided by 2)</td>
</tr>
<tr>
<td>r3.8xlarge</td>
<td>8</td>
<td>$0.10</td>
<td>.0125</td>
<td>2 (10 divided by 8, result rounded up)</td>
</tr>
</tbody>
</table>

Use Spot Fleet instance weighting as follows to provision the target capacity that you want in the pools with the lowest price per unit at the time of fulfillment:

1. Set the target capacity for your Spot Fleet either in instances (the default) or in the units of your choice, such as virtual CPUs, memory, storage, or throughput.
2. Set the price per unit.
3. For each launch configuration, specify the weight, which is the number of units that the instance type represents toward the target capacity.

**Instance weighting example**

Consider a Spot Fleet request with the following configuration:

- A target capacity of 24
- A launch specification with an instance type r3.2xlarge and a weight of 6
- A launch specification with an instance type c3.xlarge and a weight of 5
Work with Spot Fleets

To start using a Spot Fleet, you create a Spot Fleet request that includes the target capacity, an optional On-Demand portion, one or more launch specifications for the instances, and the maximum price that you are willing to pay. The fleet request must include a launch specification that defines the information that the fleet needs to launch an instance, such as an AMI, instance type, subnet or Availability Zone, and one or more security groups.

If your fleet includes Spot Instances, Amazon EC2 can attempt to maintain your fleet target capacity as Spot prices change.

It is not possible to modify the target capacity of a one-time request after it's been submitted. To change the target capacity, cancel the request and submit a new one.

A Spot Fleet request remains active until it expires or you cancel it. When you cancel a fleet request, you can specify whether canceling the request terminates the Spot Instances in that fleet.

Contents

- Spot Fleet request states (p. 1177)
- Spot Fleet health checks (p. 1178)
- Spot Fleet permissions (p. 1179)
- Create a Spot Fleet request (p. 1185)
- Tag a Spot Fleet (p. 1189)
- Describe your Spot Fleet (p. 1195)
- Modify a Spot Fleet request (p. 1196)
- Cancel a Spot Fleet request (p. 1197)

Spot Fleet request states

A Spot Fleet request can be in one of the following states:
• submitted – The Spot Fleet request is being evaluated and Amazon EC2 is preparing to launch the target number of instances. If a request would exceed your Spot Fleet limits, it is canceled immediately.

• active – The Spot Fleet has been validated and Amazon EC2 is attempting to maintain the target number of running Spot Instances. The request remains in this state until it is modified or canceled.

• modifying – The Spot Fleet request is being modified. The request remains in this state until the modification is fully processed or the Spot Fleet is canceled. A one-time request cannot be modified, and this state does not apply to such Spot requests.

• cancelled_running – The Spot Fleet is canceled and does not launch additional Spot Instances. Its existing Spot Instances continue to run until they are interrupted or terminated. The request remains in this state until all instances are interrupted or terminated.

• cancelled_terminating – The Spot Fleet is canceled and its Spot Instances are terminating. The request remains in this state until all instances are terminated.

• cancelled – The Spot Fleet is canceled and has no running Spot Instances. The Spot Fleet request is deleted two days after its instances were terminated.

Spot Fleet health checks

Spot Fleet checks the health status of the Spot Instances in the fleet every two minutes. The health status of an instance is either healthy or unhealthy.

Spot Fleet determines the health status of an instance by using the status checks provided by Amazon EC2. An instance is determined as unhealthy when the status of either the instance status check or the system status check is impaired for three consecutive health checks. For more information, see Status checks for your instances (p. 1267).

You can configure your fleet to replace unhealthy Spot Instances. After enabling health check replacement, a Spot Instance is replaced when it is reported as unhealthy. The fleet could go below its target capacity for up to a few minutes while an unhealthy Spot Instance is being replaced.

Requirements

• Health check replacement is supported only for Spot Fleets that maintain a target capacity (fleets of type maintain), not for one-time Spot Fleets (fleets of type request).

• Health check replacement is supported only for Spot Instances. This feature is not supported for On-Demand Instances.

• You can configure your Spot Fleet to replace unhealthy instances only when you create it.

• Users can use health check replacement only if they have permission to call the ec2:DescribeInstanceStatus action.

Console

To configure a Spot Fleet to replace unhealthy Spot Instances using the console

1. Follow the steps for creating a Spot Fleet. For more information, see Create a Spot Fleet request using defined parameters (console) (p. 1186).

2. To configure the fleet to replace unhealthy Spot Instances, for Health check, choose Replace unhealthy instances. To enable this option, you must first choose Maintain target capacity.
To configure a Spot Fleet to replace unhealthy Spot Instances using the AWS CLI

1. Follow the steps for creating a Spot Fleet. For more information, see Create a Spot Fleet using the AWS CLI (p. 1188).
2. To configure the fleet to replace unhealthy Spot Instances, for ReplaceUnhealthyInstances, enter true.

Spot Fleet permissions

If your users will create or manage a Spot Fleet, you need to grant them the required permissions.

If you use the Amazon EC2 console to create a Spot Fleet, it creates two service-linked roles named AWSServiceRoleForEC2SpotFleet and AWSServiceRoleForEC2Spot, and a role named aws-ec2-spot-fleet-tagging-role that grant the Spot Fleet the permissions to request, launch, terminate, and tag resources on your behalf. If you use the AWS CLI or an API, you must ensure that these roles exist.

Use the following instructions to grant the required permissions and create the roles.

Permissions and roles

- Grant permission to users for Spot Fleet (p. 1179)
- Service-linked role for Spot Fleet (p. 1181)
- Service-linked role for Spot Instances (p. 1183)
- IAM role for tagging a Spot Fleet (p. 1183)

Grant permission to users for Spot Fleet

If your users will create or manage a Spot Fleet, be sure to grant them the required permissions.

To create a policy for Spot Fleet

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Policies, Create policy.
3. On the Create policy page, choose JSON, and replace the text with the following.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:RunInstances",
                "ec2:CreateTags",
                "ec2:RequestSpotFleet",
                "ec2:ModifySpotFleetRequest",
                "ec2:CancelSpotFleetRequests",
                "ec2:DescribeSpotFleetRequests",
                "ec2:DescribeSpotFleetInstances",
                "ec2:DescribeSpotFleetRequestHistory"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
```
The preceding example policy grants a user the permissions required for most Spot Fleet use cases. To limit the user to specific API actions, specify only those API actions instead.

**Required EC2 and IAM APIs**

The following APIs must be included in the policy:

- `ec2:RunInstances` – Required to launch instances in a Spot Fleet
- `ec2:CreateTags` – Required to tag the Spot Fleet request, instances, or volumes
- `iam:PassRole` – Required to specify the Spot Fleet role
- `iam:CreateServiceLinkedRole` – Required to create the service-linked role
- `iam:ListRoles` – Required to enumerate existing IAM roles
- `iam:ListInstanceProfiles` – Required to enumerate existing instance profiles

**Important**

If you specify a role for the IAM instance profile in the launch specification or launch template, you must grant the user the permission to pass the role to the service. To do this, in the IAM policy include "arn:aws:iam::*:role/IamInstanceProfile-role" as a resource for the `iam:PassRole` action. For more information, see [Granting a user permissions to pass a role to an AWS service](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_manage_permissions.html) in the IAM User Guide.

**Spot Fleet APIs**

Add the following Spot Fleet API actions to your policy, as needed:

- `ec2:RequestSpotFleet`
- `ec2:ModifySpotFleetRequest`
- `ec2:CancelSpotFleetRequests`
- `ec2:DescribeSpotFleetRequests`
- `ec2:DescribeSpotFleetInstances`
- `ec2:DescribeSpotFleetRequestHistory`

**Optional IAM APIs**

(Optional) To enable a user to create roles or instance profiles using the IAM console, you must add the following actions to the policy:

- `iam:AddRoleToInstanceProfile`
- `iam:AttachRolePolicy`
- `iam:CreateInstanceProfile`
- `iam:CreateRole`
Work with Spot Fleets

- `iam:GetRole`
- `iam:ListPolicies`

4. Choose **Review policy**.

5. On the **Review policy** page, enter a policy name and description, and choose **Create policy**.

6. To provide access, add permissions to your users, groups, or roles:

   - Users and groups in AWS IAM Identity Center:
     
     Create a permission set. Follow the instructions in **Create a permission set** in the *AWS IAM Identity Center User Guide*.

   - Users managed in IAM through an identity provider:
     
     Create a role for identity federation. Follow the instructions in **Creating a role for a third-party identity provider (federation)** in the *IAM User Guide*.

   - IAM users:
     
     - Create a role that your user can assume. Follow the instructions in **Creating a role for an IAM user** in the *IAM User Guide*.
     
     - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in **Adding permissions to a user (console)** in the *IAM User Guide*.

### Service-linked role for Spot Fleet

Amazon EC2 uses service-linked roles for the permissions that it requires to call other AWS services on your behalf. A service-linked role is a unique type of IAM role that is linked directly to an AWS service. Service-linked roles provide a secure way to delegate permissions to AWS services because only the linked service can assume a service-linked role. For more information, see **Using Service-Linked Roles** in the *IAM User Guide*.

Amazon EC2 uses the service-linked role named **AWSServiceRoleForEC2SpotFleet** to launch and manage instances on your behalf.

**Important**

If you specify an **encrypted AMI (p. 239)** or an **encrypted Amazon EBS snapshot (p. 2316)** in your Spot Fleet, you must grant the **AWSServiceRoleForEC2SpotFleet** role permission to use the CMK so that Amazon EC2 can launch instances on your behalf. For more information, see **Grant access to CMKs for use with encrypted AMIs and EBS snapshots (p. 1182)**.

**Permissions granted by AWSServiceRoleForEC2SpotFleet**

Amazon EC2 uses **AWSServiceRoleForEC2SpotFleet** to complete the following actions:

- `ec2:RequestSpotInstances` - Request Spot Instances
- `ec2:RunInstances` - Launch instances
- `ec2:TerminateInstances` - Terminate instances
- `ec2:DescribeImages` - Describe Amazon Machine Images (AMIs) for the instances
- `ec2:DescribeInstanceStatus` - Describe the status of the instances
- `ec2:DescribeSubnets` - Describe the subnets for the instances
- `ec2:CreateTags` - Add tags to the Spot Fleet request, instances, and volumes
- `elasticloadbalancing:RegisterInstancesWithLoadBalancer` - Add the specified instances to the specified load balancer
- `elasticloadbalancing:RegisterTargets` - Register the specified targets with the specified target group

1181
Create the service-linked role

Under most circumstances, you don't need to manually create a service-linked role. Amazon EC2 creates the AWSServiceRoleForEC2SpotFleet service-linked role the first time you create a Spot Fleet using the console.

If you had an active Spot Fleet request before October 2017, when Amazon EC2 began supporting this service-linked role, Amazon EC2 created the AWSServiceRoleForEC2SpotFleet role in your AWS account. For more information, see A new role appeared in my AWS account in the IAM User Guide.

If you use the AWS CLI or an API to create a Spot Fleet, you must first ensure that this role exists.

To create AWSServiceRoleForEC2SpotFleet using the console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles.
3. Choose Create role.
4. For Select type of trusted entity, choose AWS service.
5. Under Choose a use case, Or select a service to view its use cases, choose EC2.
6. Under Select your use case, choose EC2 - Spot Fleet.
7. Choose Next: Permissions.
8. On the next page, choose Next: Tags.

To create AWSServiceRoleForEC2SpotFleet using the AWS CLI

Use the create-service-linked-role command as follows.

```
aws iam create-service-linked-role --aws-service-name spotfleet.amazonaws.com
```

If you no longer need to use Spot Fleet, we recommend that you delete the AWSServiceRoleForEC2SpotFleet role. After this role is deleted from your account, Amazon EC2 will create the role again if you request a Spot Fleet using the console. For more information, see Deleting a Service-Linked Role in the IAM User Guide.

Grant access to CMKs for use with encrypted AMIs and EBS snapshots

If you specify an encrypted AMI (p. 239) or an encrypted Amazon EBS snapshot (p. 2316) in your Spot Fleet request and you use a customer managed customer master key (CMK) for encryption, you must grant the AWSServiceRoleForEC2SpotFleet role permission to use the CMK so that Amazon EC2 can launch instances on your behalf. To do this, you must add a grant to the CMK, as shown in the following procedure.

When providing permissions, grants are an alternative to key policies. For more information, see Using Grants and Using Key Policies in AWS KMS in the AWS Key Management Service Developer Guide.

To grant the AWSServiceRoleForEC2SpotFleet role permissions to use the CMK

- Use the create-grant command to add a grant to the CMK and to specify the principal (the AWSServiceRoleForEC2SpotFleet service-linked role) that is given permission to perform the operations that the grant permits. The CMK is specified by the key-id parameter and the ARN of the CMK. The principal is specified by the grantee-principal parameter and the ARN of the AWSServiceRoleForEC2SpotFleet service-linked role.
aws kms create-grant \
  --region us-east-1 \
  --key-id arn:aws:kms:us-east-1:444455556666:key/1234abcd-12ab-34cd-56ef-1234567890ab \
  --grantee-principal arn:aws:iam::111122223333:role/AWSServiceRoleForEC2SpotFleet \
  --operations "Decrypt" "Encrypt" "GenerateDataKey" \
  "GenerateDataKeyWithoutPlaintext" "CreateGrant" "DescribeKey" "ReEncryptFrom"  \
  "ReEncryptTo"

Service-linked role for Spot Instances

Amazon EC2 uses the service-linked role named AWSServiceRoleForEC2Spot to launch and manage Spot Instances on your behalf. For more information, see Service-linked role for Spot Instance requests (p. 560).

IAM role for tagging a Spot Fleet

The aws-ec2-spot-fleet-tagging-role IAM role grants the Spot Fleet permission to tag the Spot Fleet request, instances, and volumes. For more information, see Tag a Spot Fleet (p. 1189).

Important

If you choose to tag instances in the fleet and you also choose to maintain target capacity (the Spot Fleet request is of type maintain), the differences in the permissions that are set for the user and the IamFleetRole might lead to inconsistent tagging behavior of instances in the fleet. If the IamFleetRole does not include the CreateTags permission, some of the instances launched by the fleet might not be tagged. While we are working to fix this inconsistency, to ensure that all instances launched by the fleet are tagged, we recommend that you use the aws-ec2-spot-fleet-tagging-role role for the IamFleetRole. Alternatively, to use an existing role, attach the AmazonEC2SpotFleetTaggingRole AWS Managed Policy to the existing role. Otherwise, you need to manually add the CreateTags permission to your existing policy.

To create the IAM role for tagging a Spot Fleet

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles.
3. Choose Create role.
4. On the Select trusted entity page, under Trusted entity type, choose AWS service.
5. Under Use case, from Use cases for other AWS services, choose EC2, and then choose EC2 - Spot Fleet Tagging.
6. Choose Next.
7. On the Add permissions page, choose Next.
8. On the Name, review, and create page, for Role name, enter a name for the role (for example, aws-ec2-spot-fleet-tagging-role).
9. Review the information on the page, and then choose Create role.

Cross-service confused deputy prevention

The confused deputy problem is a security issue where an entity that doesn't have permission to perform an action can coerce a more-privileged entity to perform the action. We recommend that you use the aws:SourceArn and aws:SourceAccount global condition context keys in the aws-ec2-spot-fleet-tagging-role trust policy to limit the permissions that Spot Fleet gives another service to the resource.
To add the aws:SourceArn and aws:SourceAccount condition keys to the aws-ec2-spot-fleet-tagging-role trust policy

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles.
3. Find the aws-ec2-spot-fleet-tagging-role that you created previously and choose the link (not the check box).
4. Under Summary, choose the Trust relationships tab, and then choose Edit trust policy.
5. In the JSON statement, add a Condition element containing your aws:SourceAccount and aws:SourceArn global condition context keys to prevent the confused deputy problem, as follows:

```
"Condition": {
  "ArnLike": {
    "aws:SourceArn": "arn:aws:ec2:us-east-1:account_id:spot-fleet-request/sfr-***"
  },
  "StringEquals": {
    "aws:SourceAccount": "account_id"
  }
}
```

**Note**

If the aws:SourceArn value contains the account ID and you use both global condition context keys, the aws:SourceAccount value and the account in the aws:SourceArn value must use the same account ID when used in the same policy statement.

The final trust policy will be as follows:

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Sid": "ConfusedDeputyPreventionExamplePolicy",
    "Effect": "Allow",
    "Principal": {
      "Service": "spotfleet.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws:ec2:us-east-1:account_id:spot-fleet-request/sfr-***"
      },
      "StringEquals": {
        "aws:SourceAccount": "account_id"
      }
    }
  }
}
```

6. Choose Update policy.

The following table provides potential values for aws:SourceArn to limit the scope of the your aws-ec2-spot-fleet-tagging-role in varying degrees of specificity.

<table>
<thead>
<tr>
<th>API operation</th>
<th>Called service</th>
<th>Scope</th>
<th>aws:SourceArn</th>
</tr>
</thead>
<tbody>
<tr>
<td>RequestSpotFleet</td>
<td>AWS STS (AssumeRole)</td>
<td>Limit the AssumeRole capability on aws-ec2-spot-fleet-tagging-role to</td>
<td>arn:aws:ec2:<em>:123456789012:spot-fleet-request/sfr-</em>**</td>
</tr>
</tbody>
</table>
Create a Spot Fleet request

Using the AWS Management Console, quickly create a Spot Fleet request by choosing only your application or task need and minimum compute specs. Amazon EC2 configures a fleet that best meets your needs and follows Spot best practice. For more information, see Quickly create a Spot Fleet request (console) (p. 1185). Otherwise, you can modify any of the default settings. For more information, see Create a Spot Fleet request using defined parameters (console) (p. 1186) and Create a Spot Fleet using the AWS CLI (p. 1188).

Options for creating a Spot Fleet

- Quickly create a Spot Fleet request (console) (p. 1185)
- Create a Spot Fleet request using defined parameters (console) (p. 1186)
- Create a Spot Fleet using the AWS CLI (p. 1188)

Quickly create a Spot Fleet request (console)

Follow these steps to quickly create a Spot Fleet request.

To create a Spot Fleet request using the recommended settings (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. If you are new to Spot, you see a welcome page; choose Get started. Otherwise, choose Request Spot Instances.
4. Under **Launch parameters**, choose **Manually configure launch parameters**.
5. For **AMI**, choose an AMI.
6. Under **Target capacity**, for **Total target capacity**, specify the number of units to request. For the type of unit, you can choose **Instances**, **vCPUs**, or **Memory (MiB)**.
7. For **Your fleet request at a glance**, review your fleet configuration, and choose **Launch**.

**Create a Spot Fleet request using defined parameters (console)**

You can create a Spot Fleet by using parameters that you define.

**To create a Spot Fleet request using defined parameters (console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Spot Requests**.
3. If you are new to Spot, you see a welcome page; choose **Get started**. Otherwise, choose **Request Spot Instances**.
4. For **Launch parameters**, do the following:
   a. To define the launch parameters in the Spot console, choose **Manually configure launch parameters**.
   b. For **AMI**, choose one of the basic AMIs provided by AWS, or choose **Search for AMI** to use an AMI from our user community, the AWS Marketplace, or one of your own.
   c. (Optional) For **Key pair name**, choose an existing key pair or create a new one.
      [Existing key pair] Choose the key pair.
      [New key pair] Choose **Create new key pair** to go the **Key Pairs** page. When you are done, return to the **Spot Requests** page and refresh the list.
   d. (Optional) Expand **Additional launch parameters**, and do the following:
      i. (Optional) To enable Amazon EBS optimization, for **EBS-optimized**, select **Launch EBS-optimized instances**.
      ii. (Optional) To add temporary block-level storage for your instances, for **Instance store**, choose **Attach at launch**.
      iii. (Optional) To add storage, choose **Add new volume**, and specify additional instance store volumes or Amazon EBS volumes, depending on the instance type.
      iv. (Optional) By default, basic monitoring is enabled for your instances. To enable detailed monitoring, for **Monitoring**, select **Enable CloudWatch detailed monitoring**.
      v. (Optional) To run a Dedicated Spot Instance, for **Tenancy**, choose **Dedicated - run a dedicated instance**.
      vi. (Optional) For **Security groups**, choose one or more security groups or create a new one.
         [Existing security group] Choose one or more security groups.
         [New security group] Choose **Create new security group** to go the **Security Groups** page. When you are done, return to the **Spot Requests** and refresh the list.
      vii. (Optional) To make your instances reachable from the internet, for **Auto-assign IPv4 Public IP**, choose **Enable**.
      viii. (Optional) To launch your Spot Instances with an IAM role, for **IAM instance profile**, choose the role.
      ix. (Optional) To run a start-up script, copy it to **User data**.
      x. (Optional) To add a tag, choose **Create tag** and enter the key and value for the tag, and choose **Create**. Repeat for each tag.
For each tag, to tag the instances and the Spot Fleet request with the same tag, ensure that both **Instances** and **Fleet** are selected. To tag only the instances launched by the fleet, clear **Fleet**. To tag only the Spot Fleet request, clear **Instances**.

5. For **Additional request details**, do the following:
   a. Review the additional request details. To make changes, clear **Apply defaults**.
   b. (Optional) For **IAM fleet role**, you can use the default role or choose a different role. To use the default role after changing the role, choose **Use default role**.
   c. (Optional) For **Maximum price**, you can use the default maximum price (the On-Demand price) or specify the maximum price you are willing to pay. If your maximum price is lower than the Spot price for the instance types that you selected, your Spot Instances are not launched.
   d. (Optional) To create a request that is valid only during a specific time period, edit **Request valid from** and **Request valid until**.
   e. (Optional) By default, we terminate your Spot Instances when the Spot Fleet request expires. To keep them running after your request expires, clear **Terminate the instances when the request expires**.
   f. (Optional) To register your Spot Instances with a load balancer, choose **Receive traffic from one or more load balancers** and choose one or more Classic Load Balancers or target groups.

6. For **Minimum compute unit**, choose the minimum hardware specifications (vCPUs, memory, and storage) that you need for your application or task, either as **specs** or as an **instance type**.
   - For **as specs**, specify the required number of vCPUs and amount of memory.
   - For **as an instance type**, accept the default instance type, or choose **Change instance type** to choose a different instance type.

7. For **Target capacity**, do the following:
   a. For **Total target capacity**, specify the number of units to request. For the type of unit, you can choose **Instances**, **vCPUs**, or **Memory (MiB)**. To specify a target capacity of 0 so that you can add capacity later, choose **Maintain target capacity**.
   b. (Optional) For **Include On-Demand base capacity**, specify the number of On-Demand units to request. The number must be less than the **Total target capacity**. Amazon EC2 calculates the difference, and allocate the difference to Spot units to request.
      
      **Important**
      To specify optional On-Demand capacity, you must first choose a launch template.
   c. (Optional) By default, the Spot service terminates Spot Instances when they are interrupted. To maintain the target capacity, select **Maintain target capacity**. You can then specify that the Spot service terminates, stops, or hibernates Spot Instances when they are interrupted. To do so, choose the corresponding option from **Interruption behavior**.
   d. (Optional) To allow Spot Fleet to launch a replacement Spot Instance when an instance rebalance notification is emitted for an existing Spot Instance in the fleet, select **Capacity rebalance**, and then choose an instance replacement strategy. If you choose **Launch before terminate**, specify the delay (in seconds) before Spot Fleet terminates the old instances. For more information, see Capacity Rebalancing (p. 1172).
   e. (Optional) To control the amount you pay per hour for all the Spot Instances in your fleet, select **Set maximum cost for Spot Instances** and then enter the maximum total amount you're willing to pay per hour. When the maximum total amount is reached, Spot Fleet stops launching Spot Instances even if it hasn't met the target capacity. For more information, see Control spending (p. 1175).

8. For **Network**, do the following:
   a. For **Network**, choose an existing VPC or create a new one.

[Existing VPC] Choose the VPC.
Work with Spot Fleets

[New VPC] Choose Create new VPC to go to the Amazon VPC console. When you are done, return to the wizard and refresh the list.

b. (Optional) For Availability Zone, let AWS choose the Availability Zones for your Spot Instances, or specify one or more Availability Zones.

If you have more than one subnet in an Availability Zone, choose the appropriate subnet from Subnet. To add subnets, choose Create new subnet to go to the Amazon VPC console. When you are done, return to the wizard and refresh the list.

9. For Instance type requirements, you can either specify instance attributes and let Amazon EC2 identify the optimal instance types with these attributes, or you can specify a list of instances. For more information, see Attribute-based instance type selection for Spot Fleet (p. 1157).

   a. If you choose Specify instance attributes that match your compute requirements, specify your instance attributes as follows:
      
      i. For vCPUs, enter the desired minimum and maximum number of vCPUs. To specify no limit, select No minimum, No maximum, or both.
      
      ii. For Memory (GiB), enter the desired minimum and maximum amount of memory. To specify no limit, select No minimum, No maximum, or both.
      
      iii. (Optional) For Additional instance attributes, you can optionally specify one or more attributes to express your compute requirements in more detail. Each additional attribute adds a further constraint to your request. You can omit the additional attributes; when omitted, the default values are used. For a description of each attribute and their default values, see get-spot-placement-scores in the Amazon EC2 Command Line Reference.
      
      iv. (Optional) To view the instance types with your specified attributes, expand Preview matching instance types. To exclude instance types from being used in your request, select the instances and then choose Exclude selected instance types.

   b. If you choose Manually select instance types, Spot Fleet provides a default list of instance types. To select more instance types, choose Add instance types, select the instance types to use in your request, and choose Select. To delete instance types, select the instance types and choose Delete.

10. For Allocation strategy, choose the strategy that meets your needs. For more information, see Allocation strategies for Spot Instances (p. 1154).

11. For Your fleet request at a glance, review your fleet configuration, and make any adjustments if necessary.

12. (Optional) To download a copy of the launch configuration for use with the AWS CLI, choose JSON config.

13. Choose Launch.

The Spot Fleet request type is fleet. When the request is fulfilled, requests of type instance are added, where the state is active and the status is fulfilled.

Create a Spot Fleet using the AWS CLI

To create a Spot Fleet request using the AWS CLI

• Use the request-spot-fleet command to create a Spot Fleet request.

```bash
aws ec2 request-spot-fleet --spot-fleet-request-config file://config.json
```

For example configuration files, see Spot Fleet example configurations (p. 1249).

The following is example output:
Tag a Spot Fleet

To help categorize and manage your Spot Fleet requests, you can tag them with custom metadata. You can assign a tag to a Spot Fleet request when you create it, or afterward. You can assign tags using the Amazon EC2 console or a command line tool.

When you tag a Spot Fleet request, the instances and volumes that are launched by the Spot Fleet are not automatically tagged. You need to explicitly tag the instances and volumes launched by the Spot Fleet. You can choose to assign tags to only the Spot Fleet request, or to only the instances launched by the fleet, or to only the volumes attached to the instances launched by the fleet, or to all three.

**Note**

Volume tags are only supported for volumes that are attached to On-Demand Instances. You can't tag volumes that are attached to Spot Instances.

For more information about how tags work, see [Tag your Amazon EC2 resources](p. 2507).

Contents

- Prerequisite (p. 1189)
- Tag a new Spot Fleet (p. 1190)
- Tag a new Spot Fleet and the instances and volumes that it launches (p. 1191)
- Tag an existing Spot Fleet (p. 1193)
- View Spot Fleet request tags (p. 1194)

Prerequisite

Grant the user the permission to tag resources. For more information, see [Example: Tag resources](p. 1977).

To grant a user the permission to tag resources

Create an IAM policy that includes the following:

- The `ec2:CreateTags` action. This grants the user permission to create tags.
- The `ec2:RequestSpotFleet` action. This grants the user permission to create a Spot Fleet request.
- For `Resource`, you must specify `"*"`. This allows users to tag all resource types.
**Important**
We currently do not support resource-level permissions for the `spot-fleet-request` resource. If you specify `spot-fleet-request` as a resource, you will get an unauthorized exception when you try to tag the fleet. The following example illustrates how *not* to set the policy.

```json
{
   "Effect": "Allow",
   "Action": [
   "ec2:CreateTags",
   "ec2:RequestSpotFleet"
   ],
}
```

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:
  
  Create a permission set. Follow the instructions in [Create a permission set](https://docs.aws.amazon.com/IAM/latest/UserGuide/id-principal-permissions.html) in the *AWS IAM Identity Center User Guide*.

- Users managed in IAM through an identity provider:
  
  Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider (federation)](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_providers_federation.html) in the *IAM User Guide*.

- IAM users:
  
  - Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles.html) in the *IAM User Guide*.
  
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user (console)](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users.html) in the *IAM User Guide*.

**Tag a new Spot Fleet**

**To tag a new Spot Fleet request using the console**

2. To add a tag, expand **Additional configurations**, choose **Add new tag**, and enter the key and value for the tag. Repeat for each tag.
   
   For each tag, you can tag the Spot Fleet request and the instances with the same tag. To tag both, ensure that both **Instance tags** and **Fleet tags** are selected. To tag only the Spot Fleet request, clear **Instance tags**. To tag only the instances launched by the fleet, clear **Fleet tags**.
3. Complete the required fields to create a Spot Fleet request, and then choose **Launch**. For more information, see [Create a Spot Fleet request using defined parameters (console)](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/spot-fleet-requests.html).

**To tag a new Spot Fleet request using the AWS CLI**

To tag a Spot Fleet request when you create it, configure the Spot Fleet request configuration as follows:

- Specify the tags for the Spot Fleet request in `SpotFleetRequestConfig`.
- For `ResourceType`, specify `spot-fleet-request`. If you specify another value, the fleet request will fail.
For Tags, specify the key-value pair. You can specify more than one key-value pair.

In the following example, the Spot Fleet request is tagged with two tags: Key=Environment and Value=Production, and Key=Cost-Center and Value=123.

```
{
  "SpotFleetRequestConfig": {
    "AllocationStrategy": "lowestPrice",
    "ExcessCapacityTerminationPolicy": "default",
    "IamFleetRole": "arn:aws:iam::111122223333:role/aws-ec2-spot-fleet-tagging-role",
    "LaunchSpecifications": [
      {
        "ImageId": "ami-0123456789EXAMPLE",
        "InstanceType": "c4.large"
      }
    ],
    "SpotPrice": "5",
    "TargetCapacity": 2,
    "TerminateInstancesWithExpiration": true,
    "Type": "maintain",
    "ReplaceUnhealthyInstances": true,
    "InstanceInterruptionBehavior": "terminate",
    "InstancePoolsToUseCount": 1,
    "TagSpecifications": [
      {
        "ResourceType": "spot-fleet-request",
        "Tags": [
          {
            "Key": "Environment",
            "Value": "Production"
          },
          {
            "Key": "Cost-Center",
            "Value": "123"
          }
        ]
      }
    ]
  }
}
```

Tag a new Spot Fleet and the instances and volumes that it launches

To tag a new Spot Fleet request and the instances and volumes that it launches using the AWS CLI

To tag a Spot Fleet request when you create it, and to tag the instances and volumes when they are launched by the fleet, configure the Spot Fleet request configuration as follows:

**Spot Fleet request tags:**

- Specify the tags for the Spot Fleet request in SpotFleetRequestConfig.
- For ResourceType, specify spot-fleet-request. If you specify another value, the fleet request will fail.
- For Tags, specify the key-value pair. You can specify more than one key-value pair.

**Instance tags:**

- Specify the tags for the instances in LaunchSpecifications.
- For ResourceType, specify instance. If you specify another value, the fleet request will fail.
For Tags, specify the key-value pair. You can specify more than one key-value pair.

Alternatively, you can specify the tags for the instance in the launch template (p. 743) that is referenced in the Spot Fleet request.

Volume tags:

- Specify the tags for the volumes in the launch template (p. 743) that is referenced in the Spot Fleet request. Volume tagging in LaunchSpecifications is not supported.

In the following example, the Spot Fleet request is tagged with two tags: Key=Environment and Value=Production, and Key=Cost-Center and Value=123. The instances that are launched by the fleet are tagged with one tag (which is the same as one of the tags for the Spot Fleet request): Key=Cost-Center and Value=123.

```json
{
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "lowestPrice",
        "ExcessCapacityTerminationPolicy": "default",
        "IamFleetRole": "arn:aws:iam::111122223333:role/aws-ec2-spot-fleet-tagging-role",
        "LaunchSpecifications": [
            {
                "ImageId": "ami-0123456789EXAMPLE",
                "InstanceType": "c4.large",
                "TagSpecifications": [
                    {
                        "ResourceType": "instance",
                        "Tags": [
                            {
                                "Key": "Cost-Center",
                                "Value": "123"
                            }
                        ]
                    }
                ],
                "SpotPrice": "$5",
                "TargetCapacity": 2,
                "TerminateInstancesWithExpiration": true,
                "Type": "maintain",
                "ReplaceUnhealthyInstances": true,
                "InstanceInterruptionBehavior": "terminate",
                "InstancePoolsToUseCount": 1,
                "TagSpecifications": [
                    {
                        "ResourceType": "spot-fleet-request",
                        "Tags": [
                            {
                                "Key": "Environment",
                                "Value": "Production"
                            },
                            {
                                "Key": "Cost-Center",
                                "Value": "123"
                            }
                        ]
                    }
                ]
            }
        ],
        "TargetCapacity": 2,
        "TerminateInstancesWithExpiration": true,
        "Type": "maintain",
        "ReplaceUnhealthyInstances": true,
        "InstanceInterruptionBehavior": "terminate",
        "InstancePoolsToUseCount": 1,
        "TagSpecifications": [
            {
                "ResourceType": "spot-fleet-request",
                "Tags": [
                    {
                        "Key": "Environment",
                        "Value": "Production"
                    },
                    {
                        "Key": "Cost-Center",
                        "Value": "123"
                    }
                ]
            }
        ]
    }
}
```
To tag instances launched by a Spot Fleet using the AWS CLI

To tag instances when they are launched by the fleet, you can either specify the tags in the launch template (p. 743) that is referenced in the Spot Fleet request, or you can specify the tags in the Spot Fleet request configuration as follows:

- Specify the tags for the instances in LaunchSpecifications.
- For ResourceType, specify instance. If you specify another value, the fleet request will fail.
- For Tags, specify the key-value pair. You can specify more than one key-value pair.

In the following example, the instances that are launched by the fleet are tagged with one tag: Key=Cost-Center and Value=123.

```
{
   "SpotFleetRequestConfig": {
      "AllocationStrategy": "lowestPrice",
      "ExcessCapacityTerminationPolicy": "default",
      "IamFleetRole": "arn:aws:iam::111122223333:role/aws-ec2-spot-fleet-tagging-role",
      "LaunchSpecifications": [
         {
            "ImageId": "ami-0123456789EXAMPLE",
            "InstanceType": "c4.large",
            "TagSpecifications": [
               {
                  "ResourceType": "instance",
                  "Tags": [
                     {
                        "Key": "Cost-Center",
                        "Value": "123"
                     }
                  ]
               }
            ],
            "SpotPrice": "5",
            "TargetCapacity": 2,
            "TerminateInstancesWithExpiration": true,
            "Type": "maintain",
            "ReplaceUnhealthyInstances": true,
            "InstanceInterruptionBehavior": "terminate",
            "InstancePoolsToUseCount": 1
         }
      ],
      "SpotPrice": "5",
      "TargetCapacity": 2,
      "TerminateInstancesWithExpiration": true,
      "Type": "maintain",
      "ReplaceUnhealthyInstances": true,
      "InstanceInterruptionBehavior": "terminate",
      "InstancePoolsToUseCount": 1
   }
}
```

To tag volumes attached to On-Demand Instances launched by a Spot Fleet using the AWS CLI

To tag volumes when they are created by the fleet, you must specify the tags in the launch template (p. 743) that is referenced in the Spot Fleet request.

**Note**

Volume tags are only supported for volumes that are attached to On-Demand Instances. You can't tag volumes that are attached to Spot Instances.

Volume tagging in LaunchSpecifications is not supported.

**Tag an existing Spot Fleet**

**To tag an existing Spot Fleet request using the console**

After you have created a Spot Fleet request, you can add tags to the fleet request using the console.
To work with Spot Fleets:

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Select your Spot Fleet request.
4. Choose the Tags tab and choose Create Tag.

To tag an existing Spot Fleet request using the AWS CLI:

You can use the create-tags command to tag existing resources. In the following example, the existing Spot Fleet request is tagged with Key=purpose and Value=test.

```bash
aws ec2 create-tags --resources sfr-11112222-3333-4444-5555-66666EXAMPLE --tags Key=purpose,Value=test
```

View Spot Fleet request tags

To view Spot Fleet request tags using the console:

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Select your Spot Fleet request and choose the Tags tab.

To describe Spot Fleet request tags:

Use the describe-tags command to view the tags for the specified resource. In the following example, you describe the tags for the specified Spot Fleet request.

```bash
aws ec2 describe-tags --filters "Name=resource-id,Values=sfr-11112222-3333-4444-5555-66666EXAMPLE"
```

```json
{
  "Tags": [
    {
      "Key": "Environment",
      "ResourceId": "sfr-11112222-3333-4444-5555-66666EXAMPLE",
      "ResourceType": "spot-fleet-request",
      "Value": "Production"
    },
    {
      "Key": "Another key",
      "ResourceId": "sfr-11112222-3333-4444-5555-66666EXAMPLE",
      "ResourceType": "spot-fleet-request",
      "Value": "Another value"
    }
  ]
}
```

You can also view the tags of a Spot Fleet request by describing the Spot Fleet request.

Use the describe-spot-fleet-requests command to view the configuration of the specified Spot Fleet request, which includes any tags that were specified for the fleet request.

```bash
aws ec2 describe-spot-fleet-requests --spot-fleet-request-ids sfr-11112222-3333-4444-5555-66666EXAMPLE
```
Describe your Spot Fleet

The Spot Fleet launches Spot Instances when your maximum price exceeds the Spot price and capacity is available. The Spot Instances run until they are interrupted or you terminate them.

To describe your Spot Fleet (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Select your Spot Fleet request. To see the configuration details, choose Description.
4. To list the Spot Instances for the Spot Fleet, choose Instances.
5. To view the history for the Spot Fleet, choose History.

To describe your Spot Fleet (AWS CLI)

Use the `describe-spot-fleet-requests` command to describe your Spot Fleet requests.

```
aws ec2 describe-spot-fleet-requests
```
Use the `describe-spot-fleet-instances` command to describe the Spot Instances for the specified Spot Fleet.

```
aws ec2 describe-spot-fleet-instances \
    --spot-fleet-request-id sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE
```

Use the `describe-spot-fleet-request-history` command to describe the history for the specified Spot Fleet request.

```
aws ec2 describe-spot-fleet-request-history \
    --spot-fleet-request-id sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
    --start-time 2015-05-18T00:00:00Z
```

### Modify a Spot Fleet request

You can modify an active Spot Fleet request to complete the following tasks:

- Increase the target capacity and On-Demand portion
- Decrease the target capacity and On-Demand portion

**Note**

You can't modify a one-time Spot Fleet request. You can only modify a Spot Fleet request if you selected **Maintain target capacity** when you created the Spot Fleet request.

When you increase the target capacity, the Spot Fleet launches additional Spot Instances. When you increase the On-Demand portion, the Spot Fleet launches additional On-Demand Instances.

When you increase the target capacity, the Spot Fleet launches the additional Spot Instances according to the allocation strategy for its Spot Fleet request. If the allocation strategy is `lowestPrice`, the Spot Fleet launches the instances from the lowest priced Spot capacity pool in the Spot Fleet request. If the allocation strategy is `diversified`, the Spot Fleet distributes the instances across the pools in the Spot Fleet request.

When you decrease the target capacity, the Spot Fleet cancels any open requests that exceed the new target capacity. You can request that the Spot Fleet terminate Spot Instances until the size of the fleet reaches the new target capacity. If the allocation strategy is `lowestPrice`, the Spot Fleet terminates the instances with the highest price per unit. If the allocation strategy is `diversified`, the Spot Fleet terminates instances across the pools. Alternatively, you can request that the Spot Fleet keep the fleet at its current size, but not replace any Spot Instances that are interrupted or that you terminate manually.

When a Spot Fleet terminates an instance because the target capacity was decreased, the instance receives a Spot Instance interruption notice.

**To modify a Spot Fleet request (console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request.
4. Choose **Actions, Modify target capacity**.
5. In **Modify target capacity**, do the following:
   a. Enter the new target capacity and On-Demand portion.
   b. (Optional) If you are decreasing the target capacity but want to keep the fleet at its current size, clear **Terminate instances**.
c. Choose Submit.

To modify a Spot Fleet request using the AWS CLI

Use the modify-spot-fleet-request command to update the target capacity of the specified Spot Fleet request.

```
aws ec2 modify-spot-fleet-request \
  --spot-fleet-request-id sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
  --target-capacity 20
```

You can modify the previous command as follows to decrease the target capacity of the specified Spot Fleet without terminating any Spot Instances as a result.

```
aws ec2 modify-spot-fleet-request \
  --spot-fleet-request-id sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
  --target-capacity 10 \
  --excess-capacity-termination-policy NoTermination
```

Cancel a Spot Fleet request

If you no longer require a Spot Fleet, you can cancel the Spot Fleet request. After you cancel a fleet request, all Spot requests associated with the fleet are also canceled, so that no new Spot Instances are launched.

When you cancel a Spot Fleet request, you must also specify if you want to terminate all of its instances. These include both On-Demand Instances and Spot Instances.

If you specify that the instances must be terminated when the fleet request is canceled, the fleet request enters the cancelled_terminating state. Otherwise, the fleet request enters the cancelled_running state and the instances continue to run until they are interrupted or you terminate them manually.

To cancel a Spot Fleet request (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Select your Spot Fleet request.
4. Choose Actions, Cancel request.
5. In the Cancel Spot request dialog box, do the following:
   a. To terminate the associated instances at the same time as canceling the Spot Fleet request, leave the Terminate instances check box selected. To cancel the Spot Fleet request without terminating the associated instances, clear the Terminate instances check box.
   b. Choose Confirm.

To cancel a Spot Fleet request and terminate its instances using the AWS CLI

Use the cancel-spot-fleet-requests command to cancel the specified Spot Fleet request and terminate its On-Demand Instances and Spot Instances.

```
aws ec2 cancel-spot-fleet-requests \
  --spot-fleet-request-ids sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
  --terminate-instances
```
Example output

```json
{
  "SuccessfulFleetRequests": [
    {
      "SpotFleetRequestId": "sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE",
      "CurrentSpotFleetRequestState": "cancelled_terminating",
      "PreviousSpotFleetRequestState": "active"
    }
  ],
  "UnsuccessfulFleetRequests": []
}
```

To cancel a Spot Fleet request without terminating its instances using the AWS CLI

You can modify the previous command using the `--no-terminate-instances` parameter to cancel the specified Spot Fleet request without terminating its On-Demand Instances and Spot Instances.

```bash
aws ec2 cancel-spot-fleet-requests \
  --spot-fleet-request-ids sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE \
  --no-terminate-instances
```

Example output

```json
{
  "SuccessfulFleetRequests": [
    {
      "SpotFleetRequestId": "sfr-73fbd2ce-aa30-494c-8788-1cee4EXAMPLE",
      "CurrentSpotFleetRequestState": "cancelled_running",
      "PreviousSpotFleetRequestState": "active"
    }
  ],
  "UnsuccessfulFleetRequests": []
}
```

CloudWatch metrics for Spot Fleet

Amazon EC2 provides Amazon CloudWatch metrics that you can use to monitor your Spot Fleet.

**Important**

To ensure accuracy, we recommend that you enable detailed monitoring when using these metrics. For more information, see [Enable or turn off detailed monitoring for your instances](p. 1298).

For more information about CloudWatch metrics provided by Amazon EC2, see [Monitor your instances using CloudWatch](p. 1298).

Spot Fleet metrics

The AWS/EC2Spot namespace includes the following metrics, plus the CloudWatch metrics for the Spot Instances in your fleet. For more information, see [Instance metrics](p. 1300).

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AvailableInstancePoolsCount</td>
<td>The Spot capacity pools specified in the Spot Fleet request. Units: Count</td>
</tr>
</tbody>
</table>
## CloudWatch metrics for Spot Fleet

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BidsSubmittedForCapacity</td>
<td>The capacity for which Amazon EC2 has submitted Spot Fleet requests.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>EligibleInstancePoolCount</td>
<td>The Spot capacity pools specified in the Spot Fleet request where Amazon EC2 can fulfill requests. Amazon EC2 does not fulfill requests in pools where the maximum price you're willing to pay for Spot Instances is less than the Spot price or the Spot price is greater than the price for On-Demand Instances.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>FulfilledCapacity</td>
<td>The capacity that Amazon EC2 has fulfilled.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>MaxPercentCapacityAllocation</td>
<td>The maximum value of PercentCapacityAllocation across all Spot Fleet pools specified in the Spot Fleet request.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
<tr>
<td>PendingCapacity</td>
<td>The difference between TargetCapacity and FulfilledCapacity.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>PercentCapacityAllocation</td>
<td>The capacity allocated for the Spot capacity pool for the specified dimensions. To get the maximum value recorded across all Spot capacity pools, use MaxPercentCapacityAllocation.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
<tr>
<td>TargetCapacity</td>
<td>The target capacity of the Spot Fleet request.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>TerminatingCapacity</td>
<td>The capacity that is being terminated because the provisioned capacity is greater than the target capacity.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
</tbody>
</table>

If the unit of measure for a metric is Count, the most useful statistic is Average.

### Spot Fleet dimensions

To filter the data for your Spot Fleet, use the following dimensions.

<table>
<thead>
<tr>
<th>Dimensions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AvailabilityZone</td>
<td>Filter the data by Availability Zone.</td>
</tr>
<tr>
<td>FleetRequestId</td>
<td>Filter the data by Spot Fleet request.</td>
</tr>
<tr>
<td>InstanceType</td>
<td>Filter the data by instance type.</td>
</tr>
</tbody>
</table>
View the CloudWatch metrics for your Spot Fleet

You can view the CloudWatch metrics for your Spot Fleet using the Amazon CloudWatch console. These metrics are displayed as monitoring graphs. These graphs show data points if the Spot Fleet is active.

Metrics are grouped first by namespace, and then by the various combinations of dimensions within each namespace. For example, you can view all Spot Fleet metrics or Spot Fleet metrics groups by Spot Fleet request ID, instance type, or Availability Zone.

To view Spot Fleet metrics

2. In the navigation pane, choose Metrics.
3. Choose the EC2 Spot namespace.
   
   **Note**
   If the EC2 Spot namespace is not displayed, there are two reasons for this. Either you've not yet used Spot Fleet—only the AWS services that you're using send metrics to Amazon CloudWatch. Or, if you've not used Spot Fleet for the past two weeks, the namespace does not appear.
4. (Optional) To filter the metrics by dimension, select one of the following:
   - Fleet Request Metrics – Group by Spot Fleet request
   - By Availability Zone – Group by Spot Fleet request and Availability Zone
   - By Instance Type – Group by Spot Fleet request and instance type
   - By Availability Zone/Instance Type – Group by Spot Fleet request, Availability Zone, and instance type
5. To view the data for a metric, select the check box next to the metric.

![CloudWatch Metrics](image)

Automatic scaling for Spot Fleet

*Automatic scaling* is the ability to increase or decrease the target capacity of your Spot Fleet automatically based on demand. A Spot Fleet can either launch instances (scale out) or terminate instances (scale in), within the range that you choose, in response to one or more scaling policies.

Spot Fleet supports the following types of automatic scaling:

- **Target tracking scaling** (p. 1202) – Increase or decrease the current capacity of the fleet based on a target value for a specific metric. This is similar to the way that your thermostat maintains the temperature of your home—you select temperature and the thermostat does the rest.
• **Step scaling (p. 1203)** – Increase or decrease the current capacity of the fleet based on a set of scaling adjustments, known as step adjustments, that vary based on the size of the alarm breach.

• **Scheduled scaling (p. 1205)** – Increase or decrease the current capacity of the fleet based on the date and time.

If you are using instance weighting (p. 1176), keep in mind that Spot Fleet can exceed the target capacity as needed. Fulfilled capacity can be a floating-point number but target capacity must be an integer, so Spot Fleet rounds up to the next integer. You must take these behaviors into account when you look at the outcome of a scaling policy when an alarm is triggered. For example, suppose that the target capacity is 30, the fulfilled capacity is 30.1, and the scaling policy subtracts 1. When the alarm is triggered, the automatic scaling process subtracts 1 from 30.1 to get 29.1 and then rounds it up to 30, so no scaling action is taken. As another example, suppose that you selected instance weights of 2, 4, and 8, and a target capacity of 10, but no weight 2 instances were available so Spot Fleet provisioned instances of weights 4 and 8 for a fulfilled capacity of 12. If the scaling policy decreases target capacity by 20% and an alarm is triggered, the automatic scaling process subtracts 12*0.2 from 12 to get 9.6 and then rounds it up to 10, so no scaling action is taken.

The scaling policies that you create for Spot Fleet support a cooldown period. This is the number of seconds after a scaling activity completes where previous trigger-related scaling activities can influence future scaling events. For scale-out policies, while the cooldown period is in effect, the capacity that has been added by the previous scale-out event that initiated the cooldown is calculated as part of the desired capacity for the next scale out. The intention is to continuously (but not excessively) scale out. For scale in policies, the cooldown period is used to block subsequent scale in requests until it has expired. The intention is to scale in conservatively to protect your application's availability. However, if another alarm triggers a scale-out policy during the cooldown period after a scale-in, automatic scaling scales out your scalable target immediately.

We recommend that you scale based on instance metrics with a 1-minute frequency because that ensures a faster response to utilization changes. Scaling on metrics with a 5-minute frequency can result in slower response time and scaling on stale metric data. To send metric data for your instances to CloudWatch in 1-minute periods, you must specifically enable detailed monitoring. For more information, see Enable or turn off detailed monitoring for your instances (p. 1298) and Create a Spot Fleet request using defined parameters (console) (p. 1186).

For more information about configuring scaling for Spot Fleet, see the following resources:

- **application-autoscaling** section of the AWS CLI Command Reference
- Application Auto Scaling API Reference
- Application Auto Scaling User Guide

## IAM permissions required for Spot Fleet automatic scaling

Automatic scaling for Spot Fleet is made possible by a combination of the Amazon EC2, Amazon CloudWatch, and Application Auto Scaling APIs. Spot Fleet requests are created with Amazon EC2, alarms are created with CloudWatch, and scaling policies are created with Application Auto Scaling.

In addition to the IAM permissions for Spot Fleet (p. 1179) and Amazon EC2, the user that accesses fleet scaling settings must have the appropriate permissions for the services that support dynamic scaling. Users must have permissions to use the actions shown in the following example policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [  
```
You can also create your own IAM policies that allow more fine-grained permissions for calls to the Application Auto Scaling API. For more information, see Authentication and Access Control in the Application Auto Scaling User Guide.

The Application Auto Scaling service also needs permission to describe your Spot Fleet and CloudWatch alarms, and permissions to modify your Spot Fleet target capacity on your behalf. If you enable automatic scaling for your Spot Fleet, it creates a service-linked role named AWSServiceRoleForApplicationAutoScaling_EC2SpotFleetRequest. This service-linked role grants Application Auto Scaling permission to describe the alarms for your policies, to monitor the current capacity of the fleet, and to modify the capacity of the fleet. The original managed Spot Fleet role for Application Auto Scaling was aws-ec2-spot-fleet-autoscale-role, but it is no longer required. The service-linked role is the default role for Application Auto Scaling. For more information, see Service-Linked Roles in the Application Auto Scaling User Guide.

Scale Spot Fleet using a target tracking policy

With target tracking scaling policies, you select a metric and set a target value. Spot Fleet creates and manages the CloudWatch alarms that trigger the scaling policy and calculates the scaling adjustment based on the metric and the target value. The scaling policy adds or removes capacity as required to keep the metric at, or close to, the specified target value. In addition to keeping the metric close to the target value, a target tracking scaling policy also adjusts to the fluctuations in the metric due to a fluctuating load pattern and minimizes rapid fluctuations in the capacity of the fleet.

You can create multiple target tracking scaling policies for a Spot Fleet, provided that each of them uses a different metric. The fleet scales based on the policy that provides the largest fleet capacity. This enables you to cover multiple scenarios and ensure that there is always enough capacity to process your application workloads.

To ensure application availability, the fleet scales out proportionally to the metric as fast as it can, but scales in more gradually.

When a Spot Fleet terminates an instance because the target capacity was decreased, the instance receives a Spot Instance interruption notice.

Do not edit or delete the CloudWatch alarms that Spot Fleet manages for a target tracking scaling policy. Spot Fleet deletes the alarms automatically when you delete the target tracking scaling policy.

Limitation
The Spot Fleet request must have a request type of maintain. Automatic scaling is not supported for requests of type request.

**To configure a target tracking policy (console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Spot Requests.
3. Select your Spot Fleet request and choose Auto Scaling.
4. If automatic scaling is not configured, choose Configure.
5. Use **Scale capacity between** to set the minimum and maximum capacity for your fleet. Automatic scaling does not scale your fleet below the minimum capacity or above the maximum capacity.
6. For **Policy name**, enter a name for the policy.
7. Choose a **Target metric**.
8. Enter a **Target value** for the metric.
9. (Optional) Set **Cooldown period** to modify the default cooldown period.
10. (Optional) Select **Disable scale-in** to omit creating a scale-in policy based on the current configuration. You can create a scale-in policy using a different configuration.
11. Choose **Save**.

**To configure a target tracking policy using the AWS CLI**

1. Register the Spot Fleet request as a scalable target using the `register-scalable-target` command.
2. Create a scaling policy using the `put-scaling-policy` command.

**Scale Spot Fleet using step scaling policies**

With step scaling policies, you specify CloudWatch alarms to trigger the scaling process. For example, if you want to scale out when CPU utilization reaches a certain level, create an alarm using the CPUUtilization metric provided by Amazon EC2.

When you create a step scaling policy, you must specify one of the following scaling adjustment types:

- **Add** – Increase the target capacity of the fleet by a specified number of capacity units or a specified percentage of the current capacity.
- **Remove** – Decrease the target capacity of the fleet by a specified number of capacity units or a specified percentage of the current capacity.
- **Set to** – Set the target capacity of the fleet to the specified number of capacity units.

When an alarm is triggered, the automatic scaling process calculates the new target capacity using the fulfilled capacity and the scaling policy, and then updates the target capacity accordingly. For example, suppose that the target capacity and fulfilled capacity are 10 and the scaling policy adds 1. When the alarm is triggered, the automatic scaling process adds 1 to 10 to get 11, so Spot Fleet launches 1 instance.

When a Spot Fleet terminates an instance because the target capacity was decreased, the instance receives a Spot Instance interruption notice.

**Limitation**

The Spot Fleet request must have a request type of maintain. Automatic scaling is not supported for requests of type request, or Spot blocks.
Prerequisites

- Consider which CloudWatch metrics are important to your application. You can create CloudWatch alarms based on metrics provided by AWS or your own custom metrics.
- For the AWS metrics that you will use in your scaling policies, enable CloudWatch metrics collection if the service that provides the metrics does not enable it by default.

To create a CloudWatch alarm

2. In the navigation pane, choose Alarms.
3. Choose Create alarm.
4. On the Specify metric and conditions page, choose Select metric.
5. Choose EC2 Spot, Fleet Request Metrics, select a metric (for example, TargetCapacity), and then choose Select metric.

The Specify metric and conditions page appears, showing a graph and other information about the metric you selected.
6. For Period, choose the evaluation period for the alarm, for example, 1 minute. When evaluating the alarm, each period is aggregated into one data point.

   Note
   A shorter period creates a more sensitive alarm.

7. For Conditions, define the alarm by defining the threshold condition. For example, you can define a threshold to trigger the alarm whenever the value of the metric is greater than or equal to 80 percent.
8. Under Additional configuration, for Datapoints to alarm, specify how many datapoints (evaluation periods) must be in the ALARM state to trigger the alarm, for example, 1 evaluation period or 2 out of 3 evaluation periods. This creates an alarm that goes to ALARM state if that many consecutive periods are breaching. For more information, see Evaluating an Alarm in the Amazon CloudWatch User Guide.
9. For Missing data treatment, choose one of the options (or leave the default of Treat missing data as missing). For more information, see Configuring How CloudWatch Alarms Treat Missing Data in the Amazon CloudWatch User Guide.
10. Choose Next.
11. (Optional) To receive notification of a scaling event, for Notification, you can choose or create the Amazon SNS topic you want to use to receive notifications. Otherwise, you can delete the notification now and add one later as needed.
12. Choose Next.
13. Under Add a description, enter a name and description for the alarm and choose Next.
14. Choose Create alarm.

To configure a step scaling policy for your Spot Fleet (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Spot Requests.
3. Select your Spot Fleet request and choose Auto Scaling.
4. If automatic scaling is not configured, choose Configure.
5. Use Scale capacity between to set the minimum and maximum capacity for your fleet. Automatic scaling does not scale your fleet below the minimum capacity or above the maximum capacity.
6. Initially, Scaling policies contains policies named ScaleUp and ScaleDown. You can complete these policies, or choose Remove policy to delete them. You can also choose Add policy.
7. To define a policy, do the following:
   a. For **Policy name**, enter a name for the policy.
   b. For **Policy trigger**, select an existing alarm or choose **Create new alarm** to open the Amazon CloudWatch console and create an alarm.
   c. For **Modify capacity**, select a scaling adjustment type, select a number, and select a unit.
   d. (Optional) To perform step scaling, choose **Define steps**. By default, an add policy has a lower bound of -infinity and an upper bound of the alarm threshold. By default, a remove policy has a lower bound of the alarm threshold and an upper bound of +infinity. To add another step, choose **Add step**.
   e. (Optional) To modify the default value for the cooldown period, select a number from **Cooldown period**.

8. Choose **Save**.

**To configure step scaling policies for your Spot Fleet using the AWS CLI**

1. Register the Spot Fleet request as a scalable target using the `register-scalable-target` command.
2. Create a scaling policy using the `put-scaling-policy` command.
3. Create an alarm that triggers the scaling policy using the `put-metric-alarm` command.

**Scale Spot Fleet using scheduled scaling**

Scaling based on a schedule enables you to scale your application in response to predictable changes in demand. To use scheduled scaling, you create **scheduled actions**, which tell Spot Fleet to perform scaling activities at specific times. When you create a scheduled action, you specify an existing Spot Fleet, when the scaling activity should occur, minimum capacity, and maximum capacity. You can create scheduled actions that scale one time only or that scale on a recurring schedule.

You can only create a scheduled action for Spot Fleets that already exist. You can't create a scheduled action at the same time that you create a Spot Fleet.

**Limitation**

The Spot Fleet request must have a request type of **maintain**. Automatic scaling is not supported for requests of type **request**, or Spot blocks.

**To create a one-time scheduled action**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request and choose the **Scheduled Scaling** tab near the bottom of the screen.
4. Choose **Create Scheduled Action**.
5. For **Name**, specify a name for the scheduled action.
6. Enter a value for **Minimum capacity**, **Maximum capacity**, or both.
7. For **Recurrence**, choose **Once**.
8. (Optional) Choose a date and time for **Start time**, **End time**, or both.
9. Choose **Submit**.

**To scale on a recurring schedule**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request and choose the **Scheduled Scaling** tab near the bottom of the screen.
4. For **Recurrence**, choose one of the predefined schedules (for example, **Every day**), or choose **Custom** and enter a cron expression. For more information about the cron expressions supported by scheduled scaling, see [Cron Expressions](#) in the *Amazon CloudWatch Events User Guide*.
5. (Optional) Choose a date and time for **Start time**, **End time**, or both.
6. Choose **Submit**.

**To edit a scheduled action**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request and choose the **Scheduled Scaling** tab near the bottom of the screen.
4. Select the scheduled action and choose **Actions**, **Edit**.
5. Make the needed changes and choose **Submit**.

**To delete a scheduled action**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Spot Requests**.
3. Select your Spot Fleet request and choose the **Scheduled Scaling** tab near the bottom of the screen.
4. Select the scheduled action and choose **Actions**, **Delete**.
5. When prompted for confirmation, choose **Delete**.

**To manage scheduled scaling using the AWS CLI**

Use the following commands:

- `put-scheduled-action`
- `describe-scheduled-actions`
- `delete-scheduled-action`

---

## Monitor fleet events using Amazon EventBridge

When the state of an EC2 Fleet or Spot Fleet changes, the fleet emits a notification. The notification is made available as an event that is sent to Amazon EventBridge (formerly known as Amazon CloudWatch Events). Events are emitted on a best effort basis.

With Amazon EventBridge, you can create rules that trigger programmatic actions in response to an event. For example, you can create two EventBridge rules, one that's triggered when a fleet state changes, and one that's triggered when an instance in the fleet is terminated. You can configure the first rule so that, if the fleet state changes, the rule invokes an SNS topic to send an email notification to you. You can configure the second rule so that, if an instance is terminated, the rule invokes a Lambda function to launch a new instance.

**Topics**

- [EC2 Fleet event types](#)
- [Spot Fleet event types](#)
EC2 Fleet event types

Note
Only fleets of type maintain and request emit events. Fleets of type instant do not emit events because they submit synchronous one-time requests, and the state of the fleet is known immediately in the response.

There are five EC2 Fleet event types. For each event type, there are several sub-types.

The events are sent to EventBridge in JSON format. The following fields in the event form the event pattern that is defined in the rule, and which trigger an action:

"source": "aws.ec2fleet"

Identifies that the event is from EC2 Fleet.
"detail-type": "EC2 Fleet State Change"

Identifies the event type.
"detail": { "sub-type": "submitted" }

Identifies the event sub-type.

Event types
- EC2 Fleet State Change (p. 1207)
- EC2 Fleet Spot Instance Request Change (p. 1208)
- EC2 Fleet Instance Change (p. 1209)
- EC2 Fleet Information (p. 1210)
- EC2 Fleet Error (p. 1210)

EC2 Fleet State Change

EC2 Fleet sends an EC2 Fleet State Change event to Amazon EventBridge when an EC2 Fleet changes state.

The following is example data for this event.

```
{
  "version": "0",
  "id": "715ed6b3-b8fc-27fe-fad6-528c7b8bf8a2",
  "detail-type": "EC2 Fleet State Change",
  "source": "aws.ec2fleet",
  "account": "123456789012",
  "time": "2020-11-09T09:00:20Z",
  "region": "us-east-1",
  "resources": ["arn:aws:ec2:us-east-1:123456789012:fleet/fleet-598fb973-87b7-422d-be4d-6b8009bfff0a"],
  "detail": {
    "sub-type": "active"
  }
}```
The possible values for sub-type are:

**active**

The EC2 Fleet request has been validated and Amazon EC2 is attempting to maintain the target number of running instances.

**deleted**

The EC2 Fleet request is deleted and has no running instances. The EC2 Fleet will be deleted two days after its instances are terminated.

**deleted_running**

The EC2 Fleet request is deleted and does not launch additional instances. Its existing instances continue to run until they are interrupted or terminated. The request remains in this state until all instances are interrupted or terminated.

**deleted_terminating**

The EC2 Fleet request is deleted and its instances are terminating. The request remains in this state until all instances are terminated.

**expired**

The EC2 Fleet request has expired. If the request was created with TerminateInstancesWithExpiration set, a subsequent terminated event indicates that the instances are terminated.

**modify_in_progress**

The EC2 Fleet request is being modified. The request remains in this state until the modification is fully processed.

**modify_succeeded**

The EC2 Fleet request was modified.

**submitted**

The EC2 Fleet request is being evaluated and Amazon EC2 is preparing to launch the target number of instances.

**progress**

The EC2 Fleet request is in the process of being fulfilled.

---

**EC2 Fleet Spot Instance Request Change**

EC2 Fleet sends an EC2 Fleet Spot Instance Request Change event to Amazon EventBridge when a Spot Instance request in the fleet changes state.

The following is example data for this event.

```json
{
    "version": "0",
    "id": "19331f74-bf4b-a3dd-0f1b-ddb1422032b9",
    "detail-type": "EC2 Fleet Spot Instance Request Change",
    "source": "aws.ec2fleet",
    "account": "123456789012",
    "time": "2020-11-09T09:00:05Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:fleet/fleet-83fd4e48-552a-40ef-9532-82a3acca5f10"
    ]
}
```
The possible values for sub-type are:

- **active**
  The Spot Instance request is fulfilled and has an associated Spot Instance.

- **cancelled**
  You cancelled the Spot Instance request, or the Spot Instance request expired.

- **disabled**
  You stopped the Spot Instance.

- **submitted**
  The Spot Instance request is submitted.

### EC2 Fleet Instance Change

EC2 Fleet sends an **EC2 Fleet Instance Change** event to Amazon EventBridge when an instance in the fleet changes state.

The following is example data for this event.

```json
{
    "version": "0",
    "id": "542ce428-c8f1-0608-c015-e8ed522c5bc",
    "detail-type": "EC2 Fleet Instance Change",
    "source": "aws.ec2fleet",
    "account": "123456789012",
    "time": "2020-11-09T09:00:23Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:fleet/fleet-598fb973-87b7-422d-be4d-6b0809bffe0a"
    ],
    "detail": {
        "instance-id": "i-0c594155dd5ff1829",
        "description": "{"instanceType":"c5.large","image":"ami-6057e21a","productDescription":"Linux/UNIX","availabilityZone":"us-east-1"}",
        "sub-type": "launched"
    }
}
```

The possible values for sub-type are:

- **launched**
  A new instance was launched.

- **terminated**
  The instance was terminated.
EC2 Fleet event types

**termination_notified**

An instance termination notification was sent when a Spot Instance was terminated by Amazon EC2 during scale-down, when the target capacity of the fleet was modified down, for example, from a target capacity of 4 to a target capacity of 3.

**EC2 Fleet Information**

EC2 Fleet sends an EC2 Fleet Information event to Amazon EventBridge when there is an error during fulfillment. The information event does not block the fleet from attempting to fulfill its target capacity.

The following is example data for this event.

```json
{
  "version": "0",
  "id": "76529817-d605-4571-7224-d36cc1b2c0c4",
  "detail-type": "EC2 Fleet Information",
  "source": "aws.ec2fleet",
  "account": "123456789012",
  "time": "2020-11-09T08:17:07Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2:us-east-1:123456789012:fleet/fleet-8becf5fe-
    bb9e-415d-8f54-3fa5a8628b91"
  ],
  "detail": {
    "description": "c4.xlarge, ami-0947d2ba12ee1ff75, Linux/UNIX, us-east-1a,
    Spot price in either SpotFleetRequestConfigData or SpotFleetLaunchSpecification or
    LaunchTemplate or LaunchTemplateOverrides is less than Spot market price $0.0619",
    "sub-type": "launchSpecUnusable"
  }
}
```

The possible values for sub-type are:

- **fleetProgressHalted**
  
  The price in every launch specification is not valid because it is below the Spot price (all the launch specifications have produced launchSpecUnusable events). A launch specification might become valid if the Spot price changes.

- **launchSpecTemporarilyBlacklisted**
  
  The configuration is not valid and several attempts to launch instances have failed. For more information, see the description of the event.

- **launchSpecUnusable**
  
  The price in a launch specification is not valid because it is below the Spot price.

- **registerWithLoadBalancersFailed**
  
  An attempt to register instances with load balancers failed. For more information, see the description of the event.

**EC2 Fleet Error**

EC2 Fleet sends an EC2 Fleet Error event to Amazon EventBridge when there is an error during fulfillment. The error event blocks the fleet from attempting to fulfill its target capacity.
The following is example data for this event.

```
{
  "version": "0",
  "id": "69849a22-6d0f-d4ce-602b-b47c1c98240e",
  "detail-type": "EC2 Fleet Error",
  "source": "aws.ec2fleet",
  "account": "123456789012",
  "time": "2020-10-07T01:44:24Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2:us-east-1:123456789012:fleet/fleet-9bb19bc6-60d3-4fd2-ae47-d33e68eafa08"
  ],
  "detail": {
    "description": "m3.large, ami-00068cd7555f543d5, Linux/UNIX: IPv6 is not supported for the instance type 'm3.large'.",
    "sub-type": "spotFleetRequestConfigurationInvalid"
  }
}
```

The possible values for `sub-type` are:

- `iamFleetRoleInvalid`
  The EC2 Fleet does not have the required permissions to either launch or terminate an instance.

- `allLaunchSpecsTemporarilyBlacklisted`
  None of the configurations are valid, and several attempts to launch instances have failed. For more information, see the description of the event.

- `spotInstanceCountLimitExceeded`
  You've reached the limit on the number of Spot Instances that you can launch.

- `spotFleetRequestConfigurationInvalid`
  The configuration is not valid. For more information, see the description of the event.

---

## Spot Fleet event types

There are five Spot Fleet event types. For each event type, there are several sub-types.

The events are sent to EventBridge in JSON format. The following fields in the event form the event pattern that is defined in the rule, and which trigger an action:

- "source": "aws.ec2spotfleet"
  Identifies that the event is from Spot Fleet.

- "detail-type": "EC2 Spot Fleet State Change"
  Identifies the event type.

- "detail": { "sub-type": "submitted" }
  Identifies the event sub-type.

### Event types

- [EC2 Spot Fleet State Change (p. 1212)](#)
- [EC2 Spot Fleet Spot Instance Request Change (p. 1213)](#)
- [EC2 Spot Fleet Instance Change (p. 1213)](#)
EC2 Spot Fleet State Change

Spot Fleet sends an EC2 Spot Fleet State Change event to Amazon EventBridge when a Spot Fleet changes state.

The following is example data for this event.

```json
{
    "version": "0",
    "id": "d1af1091-6cc3-2e24-203a-3b870e455d5b",
    "detail-type": "EC2 Spot Fleet State Change",
    "source": "aws.ec2spotfleet",
    "account": "123456789012",
    "time": "2020-11-09T08:57:06Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:spot-fleet-request/sfr-4b6d274d-0cea-4b2c-b3be-9dc627ad1f55"
    ],
    "detail": {
        "sub-type": "submitted"
    }
}
```

The possible values for sub-type are:

- **active**
  - The Spot Fleet request has been validated and Amazon EC2 is attempting to maintain the target number of running instances.

- **cancelled**
  - The Spot Fleet request is canceled and has no running instances. The Spot Fleet will be deleted two days after its instances are terminated.

- **cancelled_running**
  - The Spot Fleet request is canceled and does not launch additional instances. Its existing instances continue to run until they are interrupted or terminated. The request remains in this state until all instances are interrupted or terminated.

- **cancelled_terminating**
  - The Spot Fleet request is canceled and its instances are terminating. The request remains in this state until all instances are terminated.

- **expired**
  - The Spot Fleet request has expired. If the request was created with TerminateInstancesWithExpiration set, a subsequent terminated event indicates that the instances are terminated.

- **modify_in_progress**
  - The Spot Fleet request is being modified. The request remains in this state until the modification is fully processed.

- **modify_succeeded**
  - The Spot Fleet request was modified.
Spot Fleet event types

submitted

The Spot Fleet request is being evaluated and Amazon EC2 is preparing to launch the target number of instances.

progress

The Spot Fleet request is in the process of being fulfilled.

EC2 Spot Fleet Spot Instance Request Change

Spot Fleet sends an EC2 Spot Fleet Spot Instance Request Change event to Amazon EventBridge when a Spot Instance request in the fleet changes state.

The following is example data for this event.

```
{
    "version": "0",
    "id": "cd141ef0-14af-d670-a71d-fe46e9971bd2",
    "detail-type": "EC2 Spot Fleet Spot Instance Request Change",
    "source": "aws.ec2spotfleet",
    "account": "123456789012",
    "time": "2020-11-09T08:53:21Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:spot-fleet-request/sfr-a98d2133-941a-47dc-8b03-0f94c6852ad1"
    ],
    "detail": {
        "spot-instance-request-id": "sir-a2w9gc5h",
        "description": "SpotInstanceRequestId sir-a2w9gc5h, PreviousState: cancelled_running",
        "sub-type": "cancelled"
    }
}
```

The possible values for sub-type are:

active

The Spot Instance request is fulfilled and has an associated Spot Instance.

cancelled

You cancelled the Spot Instance request, or the Spot Instance request expired.

disabled

You stopped the Spot Instance.

submitted

The Spot Instance request is submitted.

EC2 Spot Fleet Instance Change

Spot Fleet sends an EC2 Spot Fleet Instance Change event to Amazon EventBridge when an instance in the fleet changes state.

The following is example data for this event.

```
{

}
```
The possible values for sub-type are:

**launched**

A new instance was launched.

**terminated**

The instance was terminated.

**termination_notified**

An instance termination notification was sent when a Spot Instance was terminated by Amazon EC2 during scale-down, when the target capacity of the fleet was modified down, for example, from a target capacity of 4 to a target capacity of 3.

### EC2 Spot Fleet Information

Spot Fleet sends an EC2 Spot Fleet Information event to Amazon EventBridge when there is an error during fulfillment. The information event does not block the fleet from attempting to fulfil its target capacity.

The following is example data for this event.

```json
{
    "version": "0",
    "id": "73a60f70-3409-a66c-635c-7f66c5f5b669",
    "detail-type": "EC2 Spot Fleet Information",
    "source": "aws.ec2spotfleet",
    "account": "123456789012",
    "time": "2020-11-08T20:56:12Z",
    "region": "us-east-1",
    "resource": [
        "arn:aws:ec2:us-east-1:123456789012:spot-fleet-request/sfr-2531ea06-af18-4647-8757-7d69c94971b1"
    ],
    "detail": {
        "instance-id": "i-08b90df1e09c30c9b",
        "description": "r3.8xlarge, ami-032930428bf1abbff, Linux/UNIX, us-east-1a, Spot bid price is less than Spot market price $0.5291",
        "sub-type": "launchSpecUnusable"
    }
}
```

The possible values for sub-type are:
fleetProgressHalted

The price in every launch specification is not valid because it is below the Spot price (all the launch specifications have produced launchSpecUnusable events). A launch specification might become valid if the Spot price changes.

launchSpecTemporarilyBlacklisted

The configuration is not valid and several attempts to launch instances have failed. For more information, see the description of the event.

launchSpecUnusable

The price in a launch specification is not valid because it is below the Spot price.

registerWithLoadBalancersFailed

An attempt to register instances with load balancers failed. For more information, see the description of the event.

EC2 Spot Fleet Error

Spot Fleet sends an EC2 Spot Fleet Error event to Amazon EventBridge when there is an error during fulfillment. The error event blocks the fleet from attempting to fulfil its target capacity.

The following is example data for this event.

```
{
  "version": "0",
  "id": "10adc4e7-675c-643e-125c-5bfa1b1ba5d2",
  "detail-type": "EC2 Spot Fleet Error",
  "source": "aws.ec2spotfleet",
  "account": "123456789012",
  "time": "2020-11-09T06:56:07Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2:us-east-1:123456789012:spot-fleet-request/sfr-38725d30-25f1-4f30-83ce-2907c56dba17"
  ],
  "detail": {
    "description": "r4.2xlarge, ami-032930428bf1abbff, Linux/UNIX: The associatePublicIPAddress parameter can only be specified for the network interface with DeviceIndex 0. ",
    "sub-type": "spotFleetRequestConfigurationInvalid"
  }
}
```

The possible values for sub-type are:

iamFleetRoleInvalid

The Spot Fleet does not have the required permissions to either launch or terminate an instance.

allLaunchSpecsTemporarilyBlacklisted

None of the configurations are valid, and several attempts to launch instances have failed. For more information, see the description of the event.

spotInstanceCountLimitExceeded

You've reached the limit on the number of Spot Instances that you can launch.

spotFleetRequestConfigurationInvalid

The configuration is not valid. For more information, see the description of the event.
Create Amazon EventBridge rules

When a notification of a state change is emitted for an EC2 Fleet or Spot Fleet, the event for the notification is sent to Amazon EventBridge. If EventBridge detects an event pattern that matches a pattern defined in a rule, EventBridge invokes a target (or targets) specified in the rule.

You can write an EventBridge rule and automate what actions to take when the event pattern matches the rule.

Topics
- Create Amazon EventBridge rules to monitor EC2 Fleet events (p. 1216)
- Create Amazon EventBridge rules to monitor Spot Fleet events (p. 1219)

Create Amazon EventBridge rules to monitor EC2 Fleet events

When a notification of a state change is emitted for an EC2 Fleet, the event for the notification is sent to Amazon EventBridge in the form of a JSON file. You can write an EventBridge rule to automate what actions to take when an event pattern matches the rule. If EventBridge detects an event pattern that matches a pattern defined in a rule, EventBridge invokes the target (or targets) specified in the rule.

The following fields form the event pattern that is defined in the rule:

"source": "aws.ec2fleet"

Identifies that the event is from EC2 Fleet.

"detail-type": "EC2 Fleet State Change"

Identifies the event type.

"detail": { "sub-type": "submitted" }

Identifies the event sub-type.

For the list of EC2 Fleet events and example event data, see the section called "EC2 Fleet event types" (p. 1207).

Examples
- Create an EventBridge rule to send a notification (p. 1216)
- Create an EventBridge rule to trigger a Lambda function (p. 1218)

Create an EventBridge rule to send a notification

The following example creates an EventBridge rule to send an email, text message, or mobile push notification every time that Amazon EC2 emits an EC2 Fleet state change notification. The signal in this example is emitted as an EC2 Fleet State Change event, which triggers the action defined by the rule.

Before creating the EventBridge rule, you must create the Amazon SNS topic for the email, text message, or mobile push notification.

To create an EventBridge rule to send a notification when an EC2 Fleet state changes

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. Choose Create rule.
3. For **Define rule detail**, do the following:
   a. Enter a **Name** for the rule, and, optionally, a description.
      A rule can't have the same name as another rule in the same Region and on the same event bus.
   b. For **Event bus**, choose **default**. When an AWS service in your account generates an event, it always goes to your account's default event bus.
   c. For **Rule type**, choose **Rule with an event pattern**.
   d. Choose **Next**.

4. For **Build event pattern**, do the following:
   a. For **Event source**, choose **AWS events or EventBridge partner events**.
   b. For **Event pattern**, for this example you'll specify the following event pattern to match the EC2 Fleet Instance Change event.

   ```
   {  
     "source": ["aws.ec2fleet"],  
     "detail-type": ["EC2 Fleet Instance Change"]  
   }
   ```

   To add the event pattern, you can either use a template by choosing **Event pattern form**, or specify your own pattern by choosing **Custom pattern (JSON editor)**, as follows:
   i. To use a template to create the event pattern, do the following:
      A. Choose **Event pattern form**.
      B. For **Event source**, choose **AWS services**.
      C. For **AWS Service**, choose **EC2 Fleet**.
      D. For **Event type**, choose **EC2 Fleet Instance Change**.
      E. To customize the template, choose **Edit pattern** and make your changes to match the example event pattern.
   ii. (Alternative) To specify a custom event pattern, do the following:
      A. Choose **Custom pattern (JSON editor)**.
      B. In the **Event pattern** box, add the event pattern for this example.

   c. Choose **Next**.

5. For **Select target(s)**, do the following:
   a. For **Target types**, choose **AWS service**.
   b. For **Select a target**, choose **SNS topic** to send an email, text message, or mobile push notification when the event occurs.
   c. For **Topic**, choose an existing topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see *Using Amazon SNS for application-to-person (A2P) messaging* in the *Amazon Simple Notification Service Developer Guide*.
   d. (Optional) Under **Additional settings**, you can optionally configure additional settings. For more information, see *Creating Amazon EventBridge rules that react to events* (step 16) in the *Amazon EventBridge User Guide*.

   e. Choose **Next**.

6. (Optional) For **Tags**, you can optionally assign one or more tags to your rule, and then choose **Next**.

7. For **Review and create**, do the following:
   a. Review the details of the rule and modify them as necessary.
   b. Choose **Create rule**.
Create an EventBridge rule to trigger a Lambda function

The following example creates an EventBridge rule to trigger a Lambda function every time that Amazon EC2 emits an EC2 Fleet instance change notification for when an instance is launched. The signal in this example is emitted as an EC2 Fleet Instance Change event, sub-type launched, which triggers the action defined by the rule.

Before creating the EventBridge rule, you must create the Lambda function.

To create the Lambda function to use in the EventBridge rule

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. Choose Create function.
3. Enter a name for your function, configure the code, and then choose Create function.

For more information about using Lambda, see Create a Lambda function with the console in the AWS Lambda Developer Guide.

To create an EventBridge rule to trigger a Lambda function when an instance in an EC2 Fleet changes state

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. Choose Create rule.
3. For Define rule detail, do the following:
   a. Enter a Name for the rule, and, optionally, a description.
   b. For Event bus, choose default. When an AWS service in your account generates an event, it always goes to your account's default event bus.
   c. For Rule type, choose Rule with an event pattern.
   d. Choose Next.
4. For Build event pattern, do the following:
   a. For Event source, choose AWS events or EventBridge partner events.
   b. For Event pattern, for this example you'll specify the following event pattern to match the EC2 Fleet Instance Change event and launched sub-type.

```json
{
    "source": ["aws.ec2fleet"],
    "detail-type": ["EC2 Fleet Instance Change"],
    "detail": {
        "sub-type": ["launched"]
    }
}
```

To add the event pattern, you can either use a template by choosing Event pattern form, or specify your own pattern by choosing Custom pattern (JSON editor), as follows:

i. To use a template to create the event pattern, do the following:
   A. Choose Event pattern form.
   B. For Event source, choose AWS services.
Create Amazon EventBridge rules to monitor Spot Fleet events

When a notification of a state change is emitted for a Spot Fleet, the event for the notification is sent to Amazon EventBridge in the form of a JSON file. You can write an EventBridge rule to automate what actions to take when an event pattern matches the rule. If EventBridge detects an event pattern that matches a pattern defined in a rule, EventBridge invokes the target (or targets) specified in the rule.

The following fields form the event pattern that is defined in the rule:

"source": "aws.ec2spotfleet"

Identifies that the event is from Spot Fleet.

"detail-type": "EC2 Spot Fleet State Change"

Identifies the event type.

"detail": {
"sub-type": "submitted"
}

Identifies the event sub-type.

For the list of Spot Fleet events and example event data, see the section called “Spot Fleet event types” (p. 1211).

Examples
Create an EventBridge rule to send a notification

The following example creates an EventBridge rule to send an email, text message, or mobile push notification every time that Amazon EC2 emits a Spot Fleet state change notification. The signal in this example is emitted as an EC2 Spot Fleet State Change event, which triggers the action defined by the rule. Before creating the EventBridge rule, you must create the Amazon SNS topic for the email, text message, or mobile push notification.

To create an EventBridge rule to send a notification when a Spot Fleet state changes

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. Choose Create rule.
3. For Define rule detail, do the following:
   a. Enter a Name for the rule, and, optionally, a description. A rule can't have the same name as another rule in the same Region and on the same event bus.
   b. For Event bus, choose default. When an AWS service in your account generates an event, it always goes to your account's default event bus.
   c. For Rule type, choose Rule with an event pattern.
   d. Choose Next.
4. For Build event pattern, do the following:
   a. For Event source, choose AWS events or EventBridge partner events.
   b. For Event pattern, for this example you'll specify the following event pattern to match the EC2 Spot Fleet Instance Change event.

   ```json
   {
     "source": ["aws.ec2spotfleet"],
     "detail-type": ["EC2 Spot Fleet Instance Change"]
   }
   ```

   To add the event pattern, you can either use a template by choosing Event pattern form, or specify your own pattern by choosing Custom pattern (JSON editor), as follows:
   i. To use a template to create the event pattern, do the following:
      A. Choose Event pattern form.
      B. For Event source, choose AWS services.
      C. For AWS Service, choose EC2 Spot Fleet.
      D. For Event type, choose EC2 Spot Fleet Instance Change.
      E. To customize the template, choose Edit pattern and make your changes to match the example event pattern.
   ii. (Alternative) To specify a custom event pattern, do the following:
      A. Choose Custom pattern (JSON editor).
      B. In the Event pattern box, add the event pattern for this example.
   c. Choose Next.
5. For Select target(s), do the following:
   a. For Target types, choose AWS service.
b. For **Select a target**, choose **SNS topic** to send an email, text message, or mobile push notification when the event occurs.

c. For **Topic**, choose an existing topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the Amazon Simple Notification Service Developer Guide.

d. (Optional) Under **Additional settings**, you can optionally configure additional settings. For more information, see Creating Amazon EventBridge rules that react to events (step 16) in the Amazon EventBridge User Guide.

e. Choose **Next**.

6. (Optional) For **Tags**, you can optionally assign one or more tags to your rule, and then choose **Next**.

7. For **Review and create**, do the following:

   a. Review the details of the rule and modify them as necessary.
   
   b. Choose **Create rule**.

For more information, see Amazon EventBridge rules and Amazon EventBridge event patterns in the Amazon EventBridge User Guide

### Create an EventBridge rule to trigger a Lambda function

The following example creates an EventBridge rule to trigger a Lambda function every time that Amazon EC2 emits a Spot Fleet instance change notification for when an instance is launched. The signal in this example is emitted as an EC2 Spot Fleet Instance Change event, sub-type launched, which triggers the action defined by the rule.

Before creating the EventBridge rule, you must create the Lambda function.

**To create the Lambda function to use in the EventBridge rule**

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. Choose **Create function**.
3. Enter a name for your function, configure the code, and then choose **Create function**.

   For more information about using Lambda, see Create a Lambda function with the console in the AWS Lambda Developer Guide.

**To create an EventBridge rule to trigger a Lambda function when an instance in a Spot Fleet changes state**

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. Choose **Create rule**.
3. For **Define rule detail**, do the following:

   a. Enter a **Name** for the rule, and, optionally, a description.

      A rule can't have the same name as another rule in the same Region and on the same event bus.

   b. For **Event bus**, choose **default**. When an AWS service in your account generates an event, it always goes to your account's default event bus.

   c. For **Rule type**, choose **Rule with an event pattern**.

   d. Choose **Next**.

4. For **Build event pattern**, do the following:

   a. For **Event source**, choose **AWS events or EventBridge partner events**.
b. For **Event pattern**, for this example you’ll specify the following event pattern to match the EC2 Spot Fleet Instance Change event and launched sub-type.

```json
{
  "source": ["aws.ec2spotfleet"],
  "detail-type": ["EC2 Spot Fleet Instance Change"],
  "detail": {
    "sub-type": ["launched"]
  }
}
```

To add the event pattern, you can either use a template by choosing **Event pattern form**, or specify your own pattern by choosing **Custom pattern (JSON editor)**, as follows:

i. To use a template to create the event pattern, do the following:
   A. Choose **Event pattern form**.
   B. For **Event source**, choose **AWS services**.
   C. For **AWS Service**, choose **EC2 Spot Fleet**.
   D. For **Event type**, choose **EC2 Spot Fleet Instance Change**.
   E. Choose **Edit pattern**, and add "detail": {"sub-type": ["launched"]} to match the example event pattern. For proper JSON format, insert a comma (,) after the preceding square bracket (]).

ii. (Alternative) To specify a custom event pattern, do the following:
   A. Choose **Custom pattern (JSON editor)**.
   B. In the **Event pattern** box, add the event pattern for this example.
   c. Choose **Next**.

5. For **Select target(s)**, do the following:
   a. For **Target types**, choose **AWS service**.
   b. For **Select a target**, choose **SNS topic** to send an email, text message, or mobile push notification when the event occurs.
   c. For **Topic**, choose **Lambda function**, and for **Function**, choose the function that you created to respond when the event occurs.
   d. (Optional) Under **Additional settings**, you can optionally configure additional settings. For more information, see **Creating Amazon EventBridge rules that react to events** (step 16) in the **Amazon EventBridge User Guide**.
   e. Choose **Next**.

6. (Optional) For **Tags**, you can optionally assign one or more tags to your rule, and then choose **Next**.

7. For **Review and create**, do the following:
   a. Review the details of the rule and modify them as necessary.
   b. Choose **Create rule**.

For a tutorial on how to create a Lambda function and an EventBridge rule that runs the Lambda function, see **Tutorial: Log the State of an Amazon EC2 Instance Using EventBridge** in the **AWS Lambda Developer Guide**.

Tutorials for EC2 Fleet and Spot Fleet

The following tutorials take you through the common processes for creating EC2 Fleets and Spot Fleets.
Tutorial: Use EC2 Fleet with instance weighting

This tutorial uses a fictitious company called Example Corp to illustrate the process of requesting an EC2 Fleet using instance weighting.

Objective

Example Corp, a pharmaceutical company, wants to use the computational power of Amazon EC2 for screening chemical compounds that might be used to fight cancer.

Planning

Example Corp first reviews Spot Best Practices. Next, Example Corp determines the requirements for their EC2 Fleet.

Instance types

Example Corp has a compute- and memory-intensive application that performs best with at least 60 GB of memory and eight virtual CPUs (vCPUs). They want to maximize these resources for the application at the lowest possible price. Example Corp decides that any of the following EC2 instance types would meet their needs:

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Memory (GiB)</th>
<th>vCPUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>r3.2xlarge</td>
<td>61</td>
<td>8</td>
</tr>
<tr>
<td>r3.4xlarge</td>
<td>122</td>
<td>16</td>
</tr>
<tr>
<td>r3.8xlarge</td>
<td>244</td>
<td>32</td>
</tr>
</tbody>
</table>

Target capacity in units

With instance weighting, target capacity can equal a number of instances (the default) or a combination of factors such as cores (vCPUs), memory (GiBs), and storage (GBs). By considering the base for their application (60 GB of RAM and eight vCPUs) as one unit, Example Corp decides that 20 times this amount would meet their needs. So the company sets the target capacity of their EC2 Fleet request to 20.

Instance weights

After determining the target capacity, Example Corp calculates instance weights. To calculate the instance weight for each instance type, they determine the units of each instance type that are required to reach the target capacity as follows:

- r3.2xlarge (61.0 GB, 8 vCPUs) = 1 unit of 20
• r3.4xlarge (122.0 GB, 16 vCPUs) = 2 units of 20
• r3.8xlarge (244.0 GB, 32 vCPUs) = 4 units of 20

Therefore, Example Corp assigns instance weights of 1, 2, and 4 to the respective launch configurations in their EC2 Fleet request.

**Price per unit hour**

Example Corp uses the On-Demand price per instance hour as a starting point for their price. They could also use recent Spot prices, or a combination of the two. To calculate the price per unit hour, they divide their starting price per instance hour by the weight. For example:

<table>
<thead>
<tr>
<th>Instance type</th>
<th>On-Demand price</th>
<th>Instance weight</th>
<th>Price per unit hour</th>
</tr>
</thead>
<tbody>
<tr>
<td>r3.2xLarge</td>
<td>$0.7</td>
<td>1</td>
<td>$0.7</td>
</tr>
<tr>
<td>r3.4xLarge</td>
<td>$1.4</td>
<td>2</td>
<td>$0.7</td>
</tr>
<tr>
<td>r3.8xLarge</td>
<td>$2.8</td>
<td>4</td>
<td>$0.7</td>
</tr>
</tbody>
</table>

Example Corp could use a global price per unit hour of $0.7 and be competitive for all three instance types. They could also use a global price per unit hour of $0.7 and a specific price per unit hour of $0.9 in the r3.8xlarge launch specification.

**Verify permissions**

Before creating an EC2 Fleet, Example Corp verifies that it has an IAM role with the required permissions. For more information, see [EC2 Fleet prerequisites](p. 1135).

**Create a launch template**

Next, Example Corp creates a launch template. The launch template ID is used in the following step. For more information, see [Create a launch template](p. 743).

**Create the EC2 Fleet**

Example Corp creates a file, config.json, with the following configuration for its EC2 Fleet. In the following example, replace the resource identifiers with your own resource identifiers.

```json
{
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateId": "lt-07b3bc7625cdab851",
        "Version": "1"
      },
      "Overrides": [
        {
          "InstanceType": "r3.2xlarge",
          "SubnetId": "subnet-482e4972",
          "WeightedCapacity": 1
        },
        {
          "InstanceType": "r3.4xlarge",
          "SubnetId": "subnet-482e4972",
          "WeightedCapacity": 2
        }
      ]
    }
  ]
}
```
Example Corp creates the EC2 Fleet using the following `create-fleet` command.

```bash
aws ec2 create-fleet \
   --cli-input-json file://config.json
```

For more information, see Create an EC2 Fleet (p. 1140).

**Fulfillment**

The allocation strategy determines which Spot capacity pools your Spot Instances come from.

With the lowest-price strategy (which is the default strategy), the Spot Instances come from the pool with the lowest price per unit at the time of fulfillment. To provide 20 units of capacity, the EC2 Fleet launches either 20 `r3.2xlarge` instances (20 divided by 1), 10 `r3.4xlarge` instances (20 divided by 2), or 5 `r3.8xlarge` instances (20 divided by 4).

If Example Corp used the diversified strategy, the Spot Instances would come from all three pools. The EC2 Fleet would launch 6 `r3.2xlarge` instances (which provide 6 units), 3 `r3.4xlarge` instances (which provide 6 units), and 2 `r3.8xlarge` instances (which provide 8 units), for a total of 20 units.

**Tutorial: Use EC2 Fleet with On-Demand as the primary capacity**

This tutorial uses a fictitious company called ABC Online to illustrate the process of requesting an EC2 Fleet with On-Demand as the primary capacity, and Spot capacity if available.

**Objective**

ABC Online, a restaurant delivery company, wants to be able to provision Amazon EC2 capacity across EC2 instance types and purchasing options to achieve their desired scale, performance, and cost.

**Plan**

ABC Online requires a fixed capacity to operate during peak periods, but would like to benefit from increased capacity at a lower price. ABC Online determines the following requirements for their EC2 Fleet:

- On-Demand Instance capacity – ABC Online requires 15 On-Demand Instances to ensure that they can accommodate traffic at peak periods.
• Spot instance capacity – ABC Online would like to improve performance, but at a lower price, by provisioning 5 Spot Instances.

Verify permissions

Before creating an EC2 Fleet, ABC Online verifies that it has an IAM role with the required permissions. For more information, see EC2 Fleet prerequisites (p. 1135).

Create a launch template

Next, ABC Online creates a launch template. The launch template ID is used in the following step. For more information, see Create a launch template (p. 743).

Create the EC2 Fleet

ABC Online creates a file, config.json, with the following configuration for its EC2 Fleet. In the following example, replace the resource identifiers with your own resource identifiers.

```json
{
   "LaunchTemplateConfigs": [
      {
         "LaunchTemplateSpecification": {
            "LaunchTemplateId": "lt-07b3bc7625cdab851",
            "Version": "2"
         }
      }
   ],
   "TargetCapacitySpecification": {
      "TotalTargetCapacity": 20,
      "OnDemandTargetCapacity": 15,
      "DefaultTargetCapacityType": "spot"
   }
}
```

ABC Online creates the EC2 Fleet using the following create-fleet command.

```bash
aws ec2 create-fleet \
   --cli-input-json file://config.json
```

For more information, see Create an EC2 Fleet (p. 1140).

Fulfillment

The allocation strategy determines that the On-Demand capacity is always fulfilled, while the balance of the target capacity is fulfilled as Spot if there is capacity and availability.

Tutorial: Launch On-Demand Instances using targeted Capacity Reservations

This tutorial walks you through all the steps that you must perform so that your EC2 Fleet launches On-Demand Instances into targeted Capacity Reservations.

You will learn how to configure a fleet to use targeted On-Demand Capacity Reservations first when launching On-Demand Instances. You will also learn how to configure the fleet so that, when the total
On-Demand target capacity exceeds the number of available unused Capacity Reservations, the fleet uses the specified allocation strategy for selecting the instance pools in which to launch the remaining target capacity.

**EC2 Fleet configuration**

In this tutorial, the fleet configuration is as follows:

- **Target capacity**: 10 On-Demand Instances
- **Total unused targeted Capacity Reservations**: 6 (less than the fleet's On-Demand target capacity of 10 On-Demand Instances)
- **Number of Capacity Reservation pools**: 2 (us-east-1a and us-east-1b)
- **Number of Capacity Reservations per pool**: 3
- **On-Demand allocation strategy**: lowest-price (When the number of unused Capacity Reservations is less than the On-Demand target capacity, the fleet determines the pools in which to launch the remaining On-Demand capacity based on the On-Demand allocation strategy.)

Note that you can also use the prioritized allocation strategy instead of the lowest-price allocation strategy.

To launch On-Demand Instances into targeted Capacity Reservations, you must perform a number of steps, as follows:

- **Step 1**: Create Capacity Reservations (p. 1227)
- **Step 2**: Create a Capacity Reservation resource group (p. 1228)
- **Step 3**: Add the Capacity Reservations to the Capacity Reservation resource group (p. 1228)
- **(Optional) Step 4**: View the Capacity Reservations in the resource group (p. 1228)
- **Step 5**: Create a launch template that specifies that the Capacity Reservation targets a specific resource group (p. 1229)
- **(Optional) Step 6**: Describe the launch template (p. 1229)
- **Step 7**: Create an EC2 Fleet (p. 1230)
- **(Optional) Step 8**: View the number of remaining unused Capacity Reservations (p. 1231)

**Step 1: Create Capacity Reservations**

Use the `create-capacity-reservation` command to create the Capacity Reservations, three for us-east-1a and another three for us-east-1b. Except for the Availability Zone, the other attributes of the Capacity Reservations are identical.

3 Capacity Reservations in us-east-1a

```bash
aws ec2 create-capacity-reservation \
    --availability-zone us-east-1a\n    --instance-type c5.xlarge\n    --instance-platform Linux/UNIX \n    --instance-count 3 \n    --instance-match-criteria targeted
```

Example of resulting Capacity Reservation ID

| cr-1234567890abcdef1 | 1227 |
3 Capacity Reservations in us-east-1b

aws ec2 create-capacity-reservation \
   --availability-zone us-east-1b\n   --instance-type c5.xlarge\n   --instance-platform Linux/UNIX \n   --instance-count 3 \n   --instance-match-criteria targeted

Example of resulting Capacity Reservation ID

cr-54321abcdef567890

Step 2: Create a Capacity Reservation resource group

Use the resource-groups service and the create-group command to create a Capacity Reservation resource group. In this example, the resource group is named my-cr-group. For information about why you must create a resource group, see Use Capacity Reservations for On-Demand Instances (p. 1128).

aws resource-groups create-group \
   --name my-cr-group \
   --configuration '{"Type":"AWS::EC2::CapacityReservationPool"}' '{"Type":"AWS::ResourceGroups::Generic", "Parameters": [{"Name": "allowed-resource-types", "Values": ["AWS::EC2::CapacityReservation"]}]}'

Step 3: Add the Capacity Reservations to the Capacity Reservation resource group

Use the resource-groups service and the group-resources command to add the Capacity Reservations that you created in Step 1 to the Capacity Reservations resource group. Note that you must reference the On-Demand Capacity Reservations by their ARNs.

aws resource-groups group-resources \
   --group my-cr-group \
   --resource-arns \
   arn:aws:ec2:us-east-1:123456789012:capacity-reservation/cr-1234567890abcdef1 \
   arn:aws:ec2:us-east-1:123456789012:capacity-reservation/cr-54321abcdef567890

Example output

{
   "Failed": [],
   "Succeeded": [
      "arn:aws:ec2:us-east-1:123456789012:capacity-reservation/cr-54321abcdef567890"
   ]
}

(Optional) Step 4: View the Capacity Reservations in the resource group

Use the resource-groups service and the list-group-resources command to optionally describe the resource group to view its Capacity Reservations.
aws resource-groups list-group-resources --group my-cr-group

Example output

```
{
    "ResourceIdentifiers": [
        {
            "ResourceType": "AWS::EC2::CapacityReservation",
        },
        {
            "ResourceType": "AWS::EC2::CapacityReservation",
        }
    ]
}
```

Step 5: Create a launch template that specifies that the Capacity Reservation targets a specific resource group

Use the `create-launch-template` command to create a launch template in which to specify the Capacity Reservations to use. In this example, the fleet will use targeted Capacity Reservations, which have been added to a resource group. Therefore, the launch template data specifies that the Capacity Reservation targets a specific resource group. In this example, the launch template is named `my-launch-template`.

```
aws ec2 create-launch-template
   --launch-template-name my-launch-template
   --launch-template-data
      '"ImageId": "ami-0123456789example",
      "CapacityReservationSpecification":
         {
            "CapacityReservationTarget":
               { "CapacityReservationResourceGroupArn": "arn:aws:resource-groups:us-east-1:123456789012:group/my-cr-group" }
        }
    ',
```

(Optional) Step 6: Describe the launch template

Use the `describe-launch-template` command to optionally describe the launch template to view its configuration.

```
aws ec2 describe-launch-template-versions --launch-template-name my-launch-template
```

Example output

```
{
    "LaunchTemplateVersions": [
        {
            "LaunchTemplateId": "lt-01234567890example",
            "LaunchTemplateName": "my-launch-template",
            "VersionNumber": 1,
            "CreateTime": "2021-01-19T20:50:19.000Z",
            "CreatedBy": "arn:aws:iam::123456789012:user/Admin",
            "DefaultVersion": true,
```
"LaunchTemplateData": { 
  "ImageId": "ami-0947d2ba12ee1ff75",
  "CapacityReservationSpecification": {
    "CapacityReservationTarget": {
      "CapacityReservationResourceGroupArn": "arn:aws:resource-groups:us-east-1:123456789012:group/my-cr-group"
    }
  }
}
]
}
]

**Step 7: Create an EC2 Fleet**

Create an EC2 Fleet that specifies the configuration information for the instances that it will launch. The following EC2 Fleet configuration shows only the pertinent configurations for this example. The launch template `my-launch-template` is the launch template you created in Step 5. There are two instance pools, each with the same instance type (`c5.xlarge`), but with different Availability Zones (`us-east-1a` and `us-east-1b`). The price of the instance pools is the same because pricing is defined for the Region, not per Availability Zone. The total target capacity is 10, and the default target capacity type is on-demand. The On-Demand allocation strategy is lowest-price. The usage strategy for Capacity Reservations is use-capacity-reservations-first.

**Note**
The fleet type must be instant. Other fleet types do not support use-capacity-reservations-first.

```json
{
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateName": "my-launch-template",
        "Version": "1"
      },
      "Overrides": [
        {
          "InstanceType": "c5.xlarge",
          "AvailabilityZone": "us-east-1a"
        },
        {
          "InstanceType": "c5.xlarge",
          "AvailabilityZone": "us-east-1b"
        }
      ]
    }
  ],
  "TargetCapacitySpecification": {
    "TotalTargetCapacity": 10,
    "DefaultTargetCapacityType": "on-demand"
  },
  "OnDemandOptions": {
    "AllocationStrategy": "lowest-price",
    "CapacityReservationOptions": {
      "UsageStrategy": "use-capacity-reservations-first"
    }
  },
  "Type": "instant"
}
```

After you create the instant fleet using the preceding configuration, the following 10 instances are launched to meet the target capacity:
• The Capacity Reservations are used first to launch 6 On-Demand Instances as follows:
  • 3 On-Demand Instances are launched into the 3 c5.xlarge targeted Capacity Reservations in us-east-1a
  • 3 On-Demand Instances are launched into the 3 c5.xlarge targeted Capacity Reservations in us-east-1b
• To meet the target capacity, 4 additional On-Demand Instances are launched into regular On-Demand capacity according to the On-Demand allocation strategy, which is lowest-price in this example. However, because the pools are the same price (because price is per Region and not per Availability Zone), the fleet launches the remaining 4 On-Demand Instances into either of the pools.

(Optional) Step 8: View the number of remaining unused Capacity Reservations

After the fleet is launched, you can optionally run describe-capacity-reservations to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the Capacity Reservations in all of the pools were used.

```json
{ "CapacityReservationId": "cr-111",
  "InstanceType": "c5.xlarge",
  "AvailableInstanceCount": 0
}
{ "CapacityReservationId": "cr-222",
  "InstanceType": "c5.xlarge",
  "AvailableInstanceCount": 0
}
```

Tutorial: Launch instances into Capacity Blocks

This tutorial walks you through the steps that you must perform so that your EC2 Fleet launches instances into Capacity Blocks.

You can use EC2 Fleet of type instant to launch instances into Capacity Blocks. For more information, see Use an EC2 Fleet of type 'instant' (p. 1092).

In most cases, the target capacity of the EC2 Fleet request should be less than or equal to the available capacity of the Capacity Block reservation that you are targeting. Target capacity requests that exceed the limits of the Capacity Block reservation will not be fulfilled. If the target capacity request exceeds the limits of your Capacity Block reservation, you will receive an Insufficient Capacity Exception for the capacity that exceeds the limits of your Capacity Block reservation.

**Note**
For Capacity Blocks, EC2 Fleet will not fallback to launching On-Demand Instances for the remainder of the desired target capacity.

If EC2 Fleet is unable to fulfill the requested target capacity in an available Capacity Block reservation, EC2 Fleet will fulfill as much capacity as it can and return the instances that it was able to launch. You can repeat the call to EC2 Fleet again until all the instances are provisioned.

After configuring the EC2 Fleet request, you must wait until the start date of your Capacity Block reservation. If you make requests to EC2 Fleet to launch into a Capacity Block that hasn't started yet, you will receive an Insufficient Capacity Error.

After your Capacity Block reservation becomes active, you can make EC2 Fleet API calls and provision the instances into your Capacity Block based on the parameters you selected. Instances running in the
Capacity Block continue to run until you stop or terminate them through a separate Amazon EC2 API call or until Amazon EC2 terminates the instances when the Capacity Block reservation ends.

**Considerations**

- Multiple Capacity Blocks in the same CreateFleet request aren't supported.
- Using OnDemandTargetCapacity or SpotTargetCapacity while also setting capacity-block as the DefaultTargetCapacity isn't supported.
- If DefaultTargetCapacityType is set to capacity-block, you can't provide OnDemandOptions::CapacityReservationOptions. An exception will occur.

**Create a launch template**

The launch template ID is used in the following step. For more information, see Create a launch template (p. 743).

To configure the launch template, for InstanceMarketOptionsRequest, set MarketType to capacity-block. Specify the Capacity Block reservation ID that you are targeting by setting the CapacityReservationID parameter.

**Create the EC2 Fleet**

Create a file, config.json, with the following configuration for its EC2 Fleet. In the following example, replace the resource identifiers with your own resource identifiers.

```json
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "CBR-launch-template",
                "Version": "1"
            },
            "Overrides": [
                {
                    "InstanceType": "p5.48xlarge",
                    "AvailabilityZone": "us-east-1a"
                }
            ],
            "TargetCapacitySpecification": {
                "TotalTargetCapacity": 10,
                "DefaultTargetCapacityType": "capacity-block"
            },
            "Type": "instant"
        }
    ],
    "Type": "instant"
}
```

Use the following create-fleet command.

```
aws ec2 create-fleet \
    --cli-input-json file://config.json
```

For more information, see Create an EC2 Fleet (p. 1140).

**Tutorial: Use Spot Fleet with instance weighting**

This tutorial uses a fictitious company called Example Corp to illustrate the process of requesting a Spot Fleet using instance weighting.
Objective

Example Corp, a pharmaceutical company, wants to leverage the computational power of Amazon EC2 for screening chemical compounds that might be used to fight cancer.

Planning

Example Corp first reviews Spot Best Practices. Next, Example Corp determines the following requirements for their Spot Fleet.

Instance types

Example Corp has a compute- and memory-intensive application that performs best with at least 60 GB of memory and eight virtual CPUs (vCPUs). They want to maximize these resources for the application at the lowest possible price. Example Corp decides that any of the following EC2 instance types would meet their needs:

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Memory (GiB)</th>
<th>vCPUs</th>
</tr>
</thead>
<tbody>
<tr>
<td>r3.2xlarge</td>
<td>61</td>
<td>8</td>
</tr>
<tr>
<td>r3.4xlarge</td>
<td>122</td>
<td>16</td>
</tr>
<tr>
<td>r3.8xlarge</td>
<td>244</td>
<td>32</td>
</tr>
</tbody>
</table>

Target capacity in units

With instance weighting, target capacity can equal a number of instances (the default) or a combination of factors such as cores (vCPUs), memory (GiBs), and storage (GBs). By considering the base for their application (60 GB of RAM and eight vCPUs) as 1 unit, Example Corp decides that 20 times this amount would meet their needs. So the company sets the target capacity of their Spot Fleet request to 20.

Instance weights

After determining the target capacity, Example Corp calculates instance weights. To calculate the instance weight for each instance type, they determine the units of each instance type that are required to reach the target capacity as follows:

- r3.2xlarge (61.0 GB, 8 vCPUs) = 1 unit of 20
- r3.4xlarge (122.0 GB, 16 vCPUs) = 2 units of 20
- r3.8xlarge (244.0 GB, 32 vCPUs) = 4 units of 20

Therefore, Example Corp assigns instance weights of 1, 2, and 4 to the respective launch configurations in their Spot Fleet request.

Price per unit hour

Example Corp uses the On-Demand price per instance hour as a starting point for their price. They could also use recent Spot prices, or a combination of the two. To calculate the price per unit hour, they divide their starting price per instance hour by the weight. For example:

<table>
<thead>
<tr>
<th>Instance type</th>
<th>On-Demand price</th>
<th>Instance weight</th>
<th>Price per unit hour</th>
</tr>
</thead>
<tbody>
<tr>
<td>r3.2xLarge</td>
<td>$0.7</td>
<td>1</td>
<td>$0.7</td>
</tr>
<tr>
<td>r3.4xLarge</td>
<td>$1.4</td>
<td>2</td>
<td>$0.7</td>
</tr>
<tr>
<td>Instance type</td>
<td>On-Demand price</td>
<td>Instance weight</td>
<td>Price per unit hour</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------</td>
<td>-----------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>r3.8xLarge</td>
<td>$2.8</td>
<td>4</td>
<td>$0.7</td>
</tr>
</tbody>
</table>

Example Corp could use a global price per unit hour of $0.7 and be competitive for all three instance types. They could also use a global price per unit hour of $0.7 and a specific price per unit hour of $0.9 in the r3.8xlarge launch specification.

### Verify permissions

Before creating a Spot Fleet request, Example Corp verifies that it has an IAM role with the required permissions. For more information, see [Spot Fleet permissions (p. 1179)](#).

### Create the request

Example Corp creates a file, config.json, with the following configuration for its Spot Fleet request:

```json
{
    "SpotPrice": "0.70",
    "TargetCapacity": 20,
    "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
    "LaunchSpecifications": [
        {
            "ImageId": "ami-1a2b3c4d",
            "InstanceType": "r3.2xlarge",
            "SubnetId": "subnet-482e4972",
            "WeightedCapacity": 1
        },
        {
            "ImageId": "ami-1a2b3c4d",
            "InstanceType": "r3.4xlarge",
            "SubnetId": "subnet-482e4972",
            "WeightedCapacity": 2
        },
        {
            "ImageId": "ami-1a2b3c4d",
            "InstanceType": "r3.8xlarge",
            "SubnetId": "subnet-482e4972",
            "SpotPrice": "0.90",
            "WeightedCapacity": 4
        }
    ]
}
```

Example Corp creates the Spot Fleet request using the `request-spot-fleet` command.

```bash
aws ec2 request-spot-fleet --spot-fleet-request-config file://config.json
```

For more information, see [Spot Fleet request types (p. 1152)](#).

### Fulfillment

The allocation strategy determines which Spot capacity pools your Spot Instances come from.

With the `lowestPrice` strategy (which is the default strategy), the Spot Instances come from the pool with the lowest price per unit at the time of fulfillment. To provide 20 units of capacity, the Spot Fleet launches either 20 r3.2xlarge instances (20 divided by 1), 10 r3.4xlarge instances (20 divided by 2), or 5 r3.8xlarge instances (20 divided by 4).
If Example Corp used the diversified strategy, the Spot Instances would come from all three pools. The Spot Fleet would launch 6 r3.2xlarge instances (which provide 6 units), 3 r3.4xlarge instances (which provide 6 units), and 2 r3.8xlarge instances (which provide 8 units), for a total of 20 units.

Example configurations for EC2 Fleet and Spot Fleet

The following examples show launch configurations that you can use to create EC2 Fleets and Spot Fleets.

Topics

- EC2 Fleet example configurations (p. 1235)
- Spot Fleet example configurations (p. 1249)

EC2 Fleet example configurations

The following examples show launch configurations that you can use with the `create-fleet` command to create an EC2 Fleet. For more information about the parameters, see `create-fleet` in the AWS CLI Command Reference.

Examples

- Example 1: Launch Spot Instances as the default purchasing option (p. 1235)
- Example 2: Launch On-Demand Instances as the default purchasing option (p. 1236)
- Example 3: Launch On-Demand Instances as the primary capacity (p. 1236)
- Example 4: Launch Spot Instances using the lowest-price allocation strategy (p. 1237)
- Example 5: Launch On-Demand Instances using multiple Capacity Reservations (p. 1237)
- Example 6: Launch On-Demand Instances using Capacity Reservations when the total target capacity exceeds the number of unused Capacity Reservations (p. 1240)
- Example 7: Launch On-Demand Instances using targeted Capacity Reservations (p. 1242)
- Example 8: Configure Capacity Rebalancing to launch replacement Spot Instances (p. 1245)
- Example 9: Launch Spot Instances in a capacity-optimized fleet (p. 1246)
- Example 10: Launch Spot Instances in a capacity-optimized fleet with priorities (p. 1247)
- Example 11: Launch Spot Instances in a price-capacity-optimized fleet (p. 1248)
- Example 12: Configure attribute-based instance type selection (p. 1249)

Example 1: Launch Spot Instances as the default purchasing option

The following example specifies the minimum parameters required in an EC2 Fleet: a launch template, target capacity, and default purchasing option. The launch template is identified by its launch template ID and version number. The target capacity for the fleet is 2 instances, and the default purchasing option is spot, which results in the fleet launching 2 Spot Instances.

```json
{
   "LaunchTemplateConfigs": [
      {
         "LaunchTemplateName": {
            "LaunchTemplateName": "lt-0e8c754449b27161c",
            "Version": "1"
         }
      }
   ]
}
```
Example 2: Launch On-Demand Instances as the default purchasing option

The following example specifies the minimum parameters required in an EC2 Fleet: a launch template, target capacity, and default purchasing option. The launch template is identified by its launch template ID and version number. The target capacity for the fleet is 2 instances, and the default purchasing option is on-demand, which results in the fleet launching 2 On-Demand Instances.

```json
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "lt-0e8c754449b27161c",
                "Version": "1"
            }
        },
        {
            "TargetCapacitySpecification": {
                "TotalTargetCapacity": 2,
                "DefaultTargetCapacityType": "on-demand"
            }
        }
    ]
}
```

Example 3: Launch On-Demand Instances as the primary capacity

The following example specifies the total target capacity of 2 instances for the fleet, and a target capacity of 1 On-Demand Instance. The default purchasing option is spot. The fleet launches 1 On-Demand Instance as specified, but needs to launch one more instance to fulfill the total target capacity. The purchasing option for the difference is calculated as TotalTargetCapacity – OnDemandTargetCapacity = DefaultTargetCapacityType, which results in the fleet launching 1 Spot Instance.

```json
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "lt-0e8c754449b27161c",
                "Version": "1"
            }
        },
        {
            "TargetCapacitySpecification": {
                "TotalTargetCapacity": 2,
                "OnDemandTargetCapacity": 1,
                "DefaultTargetCapacityType": "spot"
            }
        }
    ]
}
```
Example 4: Launch Spot Instances using the lowest-price allocation strategy

If the allocation strategy for Spot Instances is not specified, the default allocation strategy, which is lowest-price, is used. The following example uses the lowest-price allocation strategy. The three launch specifications, which override the launch template, have different instance types but the same weighted capacity and subnet. The total target capacity is 2 instances and the default purchasing option is spot. The EC2 Fleet launches 2 Spot Instances using the instance type of the launch specification with the lowest price.

```
{
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateId": "lt-0e8c754449b27161c",
        "Version": "1"
      }
    },
    {
      "Overrides": [
        {
          "InstanceType": "c4.large",
          "WeightedCapacity": 1,
          "SubnetId": "subnet-a4f6c5d3"
        },
        {
          "InstanceType": "c3.large",
          "WeightedCapacity": 1,
          "SubnetId": "subnet-a4f6c5d3"
        },
        {
          "InstanceType": "c5.large",
          "WeightedCapacity": 1,
          "SubnetId": "subnet-a4f6c5d3"
        }
      ]
    }
  ],
  "TargetCapacitySpecification": {
    "TotalTargetCapacity": 2,
    "DefaultTargetCapacityType": "spot"
  }
}
```

Example 5: Launch On-Demand Instances using multiple Capacity Reservations

You can configure a fleet to use On-Demand Capacity Reservations first when launching On-Demand Instances by setting the usage strategy for Capacity Reservations to use-capacity-reservations-first. This example demonstrates how the fleet selects the Capacity Reservations to use when there are more Capacity Reservations than are needed to fulfil the target capacity.

In this example, the fleet configuration is as follows:

- Target capacity: 12 On-Demand Instances
- Total unused Capacity Reservations: 15 (more than the fleet's target capacity of 12 On-Demand Instances)
- Number of Capacity Reservation pools: 3 (m5.large, m4.xlarge, and m4.2xlarge)
• Number of Capacity Reservations per pool: 5
• On-Demand allocation strategy: lowest-price (When there are multiple unused Capacity Reservations in multiple instance pools, the fleet determines the pools in which to launch the On-Demand Instances based on the On-Demand allocation strategy.)

Note that you can also use the prioritized allocation strategy instead of the lowest-price allocation strategy.

Capacity Reservations

The account has the following 15 unused Capacity Reservations in 3 different pools. The number of Capacity Reservations in each pool is indicated by AvailableInstanceCount.

```json
{
    "CapacityReservationId": "cr-111",
    "InstanceType": "m5.large",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 5,
    "InstanceMatchCriteria": "open",
    "State": "active"
}
{
    "CapacityReservationId": "cr-222",
    "InstanceType": "m4.xlarge",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 5,
    "InstanceMatchCriteria": "open",
    "State": "active"
}
{
    "CapacityReservationId": "cr-333",
    "InstanceType": "m4.2xlarge",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 5,
    "InstanceMatchCriteria": "open",
    "State": "active"
}
```

Fleet configuration

The following fleet configuration shows only the pertinent configurations for this example. The total target capacity is 12, and the default target capacity type is on-demand. The On-Demand allocation strategy is lowest-price. The usage strategy for Capacity Reservations is use-capacity-reservations-first.

In this example, the On-Demand Instance price is:

• m5.large – $0.096 per hour
• m4.xlarge – $0.20 per hour
• m4.2xlarge – $0.40 per hour

Note

The fleet type must be of type instant. Other fleet types do not support use-capacity-reservations-first.
After you create the instant fleet using the preceding configuration, the following 12 instances are launched to meet the target capacity:

- 5 `m5.large` On-Demand Instances in `us-east-1a` – `m5.large` in `us-east-1a` is the lowest price, and there are 5 available unused `m5.large` Capacity Reservations
- 5 `m4.xlarge` On-Demand Instances in `us-east-1a` – `m4.xlarge` in `us-east-1a` is the next lowest price, and there are 5 available unused `m4.xlarge` Capacity Reservations
- 2 `m4.2xlarge` On-Demand Instances in `us-east-1a` – `m4.2xlarge` in `us-east-1a` is the third lowest price, and there are 5 available unused `m4.2xlarge` Capacity Reservations of which only 2 are needed to meet the target capacity

After the fleet is launched, you can run `describe-capacity-reservations` to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the `m5.large` and `m4.xlarge` Capacity Reservations were used, with 3 `m4.2xlarge` Capacity Reservations remaining unused.
Example 6: Launch On-Demand Instances using Capacity Reservations when the total target capacity exceeds the number of unused Capacity Reservations

You can configure a fleet to use On-Demand Capacity Reservations first when launching On-Demand Instances by setting the usage strategy for Capacity Reservations to use-capacity-reservations-first. This example demonstrates how the fleet selects the instance pools in which to launch On-Demand Instances when the total target capacity exceeds the number of available unused Capacity Reservations.

In this example, the fleet configuration is as follows:

- Target capacity: 16 On-Demand Instances
- Total unused Capacity Reservations: 15 (less than the fleet's target capacity of 16 On-Demand Instances)
- Number of Capacity Reservation pools: 3 (m5.large, m4.xlarge, and m4.2xlarge)
- Number of Capacity Reservations per pool: 5
- On-Demand allocation strategy: lowest-price (When the number of unused Capacity Reservations is less than the On-Demand target capacity, the fleet determines the pools in which to launch the remaining On-Demand capacity based on the On-Demand allocation strategy.)

Note that you can also use the prioritized allocation strategy instead of the lowest-price allocation strategy.

Capacity Reservations

The account has the following 15 unused Capacity Reservations in 3 different pools. The number of Capacity Reservations in each pool is indicated by AvailableInstanceCount.

```json
[
  {
    "CapacityReservationId": "cr-111",
    "InstanceType": "m5.large",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 5,
    "InstanceMatchCriteria": "open",
    "State": "active"
  }
]
[
  {
    "CapacityReservationId": "cr-222",
    "InstanceType": "m4.xlarge",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 0
  }
]
[
  {
    "CapacityReservationId": "cr-333",
    "InstanceType": "m4.2xlarge",
    "InstancePlatform": "Linux/UNIX",
    "AvailabilityZone": "us-east-1a",
    "AvailableInstanceCount": 3
  }
]```
Fleet configuration

The following fleet configuration shows only the pertinent configurations for this example. The total target capacity is 16, and the default target capacity type is on-demand. The On-Demand allocation strategy is lowest-price. The usage strategy for Capacity Reservations is use-capacity-reservations-first.

In this example, the On-Demand Instance price is:

- m5.large – $0.096 per hour
- m4.xlarge – $0.20 per hour
- m4.2xlarge – $0.40 per hour

Note
The fleet type must be instant. Other fleet types do not support use-capacity-reservations-first.

```json
{
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateId": "lt-0e8c754449b27161c",
                "Version": "1"
            }
        },
        {
            "InstanceType": "m5.large",
            "AvailabilityZone": "us-east-1a",
            "WeightedCapacity": 1
        },
        {
            "InstanceType": "m4.xlarge",
            "AvailabilityZone": "us-east-1a",
            "WeightedCapacity": 1
        },
        {
            "InstanceType": "m4.2xlarge",
            "AvailabilityZone": "us-east-1a",
            "WeightedCapacity": 1
        }
    ]
}
```
After you create the instant fleet using the preceding configuration, the following 16 instances are launched to meet the target capacity:

- 6 m5.large On-Demand Instances in us-east-1a – m5.large in us-east-1a is the lowest price, and there are 5 available unused m5.large Capacity Reservations. The Capacity Reservations are used first to launch 5 On-Demand Instances. After the remaining m4.xlarge and m4.2xlarge Capacity Reservations are used, to meet the target capacity an additional On-Demand Instance is launched according to the On-Demand allocation strategy, which is lowest-price in this example.
- 5 m4.xlarge On-Demand Instances in us-east-1a – m4.xlarge in us-east-1a is the next lowest price, and there are 5 available unused m4.xlarge Capacity Reservations
- 5 m4.2xlarge On-Demand Instances in us-east-1a – m4.2xlarge in us-east-1a is the third lowest price, and there are 5 available unused m4.2xlarge Capacity Reservations

After the fleet is launched, you can run describe-capacity-reservations to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the Capacity Reservations in all of the pools were used.

Example 7: Launch On-Demand Instances using targeted Capacity Reservations

You can configure a fleet to use targeted On-Demand Capacity Reservations first when launching On-Demand Instances by setting the usage strategy for Capacity Reservations to use-capacity-reservations-first. This example demonstrates how to launch On-Demand Instances into targeted Capacity Reservations, where the attributes of the Capacity Reservations are the same except for their Availability Zones (us-east-1a and us-east-1b). It also demonstrates how the fleet selects the instance pools in which to launch On-Demand Instances when the total target capacity exceeds the number of available unused Capacity Reservations.
In this example, the fleet configuration is as follows:

- Target capacity: 10 On-Demand Instances
- Total unused targeted Capacity Reservations: 6 (less than the fleet's On-Demand target capacity of 10 On-Demand Instances)
- Number of Capacity Reservation pools: 2 (us-east-1a and us-east-1b)
- Number of Capacity Reservations per pool: 3
- On-Demand allocation strategy: lowest-price (When the number of unused Capacity Reservations is less than the On-Demand target capacity, the fleet determines the pools in which to launch the remaining On-Demand capacity based on the On-Demand allocation strategy.)

Note that you can also use the prioritized allocation strategy instead of the lowest-price allocation strategy.

For a walkthrough of the procedures that you must perform to accomplish this example, see Tutorial: Launch On-Demand Instances using targeted Capacity Reservations (p. 1226).

Capacity Reservations

The account has the following 6 unused Capacity Reservations in 2 different pools. In this example, the pools differ by their Availability Zones. The number of Capacity Reservations in each pool is indicated by AvailableInstanceCount.

```json
{
   "CapacityReservationId": "cr-111",
   "InstanceType": "c5.xlarge",
   "InstancePlatform": "Linux/UNIX",
   "AvailabilityZone": "us-east-1a",
   "AvailableInstanceCount": 3,
   "InstanceMatchCriteria": "open",
   "State": "active"
}

{
   "CapacityReservationId": "cr-222",
   "InstanceType": "c5.xlarge",
   "InstancePlatform": "Linux/UNIX",
   "AvailabilityZone": "us-east-1b",
   "AvailableInstanceCount": 3,
   "InstanceMatchCriteria": "open",
   "State": "active"
}
```

Fleet configuration

The following fleet configuration shows only the pertinent configurations for this example. The total target capacity is 10, and the default target capacity type is on-demand. The On-Demand allocation strategy is lowest-price. The usage strategy for Capacity Reservations is use-capacity-reservations-first.

In this example, the On-Demand Instance price for c5.xlarge in us-east-1 is $0.17 per hour.

**Note**

The fleet type must be instant. Other fleet types do not support use-capacity-reservations-first.

```json
{
}```
After you create the `instant` fleet using the preceding configuration, the following 10 instances are launched to meet the target capacity:

- The Capacity Reservations are used first to launch 6 On-Demand Instances as follows:
  - 3 On-Demand Instances are launched into the 3 `c5.xlarge` targeted Capacity Reservations in `us-east-1a`
  - 3 On-Demand Instances are launched into the 3 `c5.xlarge` targeted Capacity Reservations in `us-east-1b`
- To meet the target capacity, 4 additional On-Demand Instances are launched into regular On-Demand capacity according to the On-Demand allocation strategy, which is `lowest-price` in this example. However, because the pools are the same price (because price is per Region and not per Availability Zone), the fleet launches the remaining 4 On-Demand Instances into either of the pools.

After the fleet is launched, you can run `describe-capacity-reservations` to see how many unused Capacity Reservations are remaining. In this example, you should see the following response, which shows that all of the Capacity Reservations in all of the pools were used.

```json
{
  "CapacityReservationId": "cr-111",
  "InstanceType": "c5.xlarge",
  "AvailableInstanceCount": 0
}
{
  "CapacityReservationId": "cr-222",
  "InstanceType": "c5.xlarge",
  "AvailableInstanceCount": 0
}
```
Example 8: Configure Capacity Rebalancing to launch replacement Spot Instances

The following example configures the EC2 Fleet to launch a replacement Spot Instance when Amazon EC2 emits a rebalance recommendation for a Spot Instance in the fleet. To configure the automatic replacement of Spot Instances, for ReplacementStrategy, specify launch-before-terminate. To configure the time delay from when the new replacement Spot Instances are launched to when the old Spot Instances are automatically deleted, for termination-delay, specify a value in seconds. For more information, see Configuration options (p. 1129).

Note
We recommend using launch-before-terminate only if you can predict how long your instance shutdown procedures will take to complete so that the old instances are only terminated after these procedures are completed. You are charged for all instances while they are running.

The effectiveness of the Capacity Rebalancing strategy depends on the number of Spot capacity pools specified in the EC2 Fleet request. We recommend that you configure the fleet with a diversified set of instance types and Availability Zones, and for AllocationStrategy, specify capacity-optimized. For more information about what you should consider when configuring an EC2 Fleet for Capacity Rebalancing, see Capacity Rebalancing (p. 1128).

```json
{
    "ExcessCapacityTerminationPolicy": "termination",
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "LaunchTemplate",
                "Version": "1"
            },
            "Overrides": [
                {
                    "InstanceType": "c3.large",
                    "WeightedCapacity": 1,
                    "Placement": {
                        "AvailabilityZone": "us-east-1a"
                    }
                },
                {
                    "InstanceType": "c4.large",
                    "WeightedCapacity": 1,
                    "Placement": {
                        "AvailabilityZone": "us-east-1a"
                    }
                },
                {
                    "InstanceType": "c5.large",
                    "WeightedCapacity": 1,
                    "Placement": {
                        "AvailabilityZone": "us-east-1a"
                    }
                }
            ]
        }
    ],
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 5,
        "DefaultTargetCapacityType": "spot"
    },
    "SpotOptions": {
        "AllocationStrategy": "capacity-optimized",
        "MaintenanceStrategies": {
```

1245
Example 9: Launch Spot Instances in a capacity-optimized fleet

The following example demonstrates how to configure an EC2 Fleet with a Spot allocation strategy that optimizes for capacity. To optimize for capacity, you must set AllocationStrategy to capacity-optimized.

In the following example, the three launch specifications specify three Spot capacity pools. The target capacity is 50 Spot Instances. The EC2 Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with optimal capacity for the number of instances that are launching.

```json

"SpotOptions": {
    "AllocationStrategy": "capacity-optimized",
},
"LaunchTemplateConfigs": [
    {
        "LaunchTemplateSpecification": {
            "LaunchTemplateName": "my-launch-template",
            "Version": "1"
        },
        "Overrides": [
            {
                "InstanceType": "r4.2xlarge",
                "Placement": {
                    "AvailabilityZone": "us-west-2a"
                },
            },
            {
                "InstanceType": "m4.2xlarge",
                "Placement": {
                    "AvailabilityZone": "us-west-2b"
                },
            },
            {
                "InstanceType": "c5.2xlarge",
                "Placement": {
                    "AvailabilityZone": "us-west-2b"
                }
            }
        ]
    },
    "TargetCapacitySpecification": {
        "TotalTargetCapacity": 50,
        "DefaultTargetCapacityType": "spot"
    }
}
```
Example 10: Launch Spot Instances in a capacity-optimized fleet with priorities

The following example demonstrates how to configure an EC2 Fleet with a Spot allocation strategy that optimizes for capacity while using priority on a best-effort basis.

When using the capacity-optimized-prioritized allocation strategy, you can use the Priority parameter to specify the priorities of the Spot capacity pools, where the lower the number the higher priority. You can also set the same priority for several Spot capacity pools if you favor them equally. If you do not set a priority for a pool, the pool will be considered last in terms of priority.

To prioritize Spot capacity pools, you must set AllocationStrategy to capacity-optimized-prioritized. EC2 Fleet will optimize for capacity first, but will honor the priorities on a best-effort basis (for example, if honoring the priorities will not significantly affect EC2 Fleet's ability to provision optimal capacity). This is a good option for workloads where the possibility of disruption must be minimized and the preference for certain instance types matters.

In the following example, the three launch specifications specify three Spot capacity pools. Each pool is prioritized, where the lower the number the higher priority. The target capacity is 50 Spot Instances. The EC2 Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with the highest priority on a best-effort basis, but optimizes for capacity first.

```json
{
   "SpotOptions": {
      "AllocationStrategy": "capacity-optimized-prioritized"
   },
   "LaunchTemplateConfigs": [
      {
         "LaunchTemplateSpecification": {
            "LaunchTemplateName": "my-launch-template",
            "Version": "1"
         },
         "Overrides": [
            {
               "InstanceType": "r4.2xlarge",
               "Priority": 1,
               "Placement": {
                  "AvailabilityZone": "us-west-2a"
               }
            },
            {
               "InstanceType": "m4.2xlarge",
               "Priority": 2,
               "Placement": {
                  "AvailabilityZone": "us-west-2b"
               }
            },
            {
               "InstanceType": "c5.2xlarge",
               "Priority": 3,
               "Placement": {
                  "AvailabilityZone": "us-west-2b"
               }
            }
         ]
      }
   ],
   "TargetCapacitySpecification": {
      "TotalTargetCapacity": 50,
      "DefaultTargetCapacityType": "spot"
   }
}
```
Example 11: Launch Spot Instances in a price-capacity-optimized fleet

The following example demonstrates how to configure an EC2 Fleet with a Spot allocation strategy that optimizes for both capacity and lowest price. To optimize for capacity while taking price into consideration, you must set the Spot AllocationStrategy to price-capacity-optimized.

In the following example, the three launch specifications specify three Spot capacity pools. The target capacity is 50 Spot Instances. The EC2 Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with optimal capacity for the number of instances that are launching while also choosing the pool that is the lowest priced.

```json
{
  "SpotOptions": {
    "AllocationStrategy": "price-capacity-optimized",
    "MinTargetCapacity": 2,
    "SingleInstanceType": true
  },
  "OnDemandOptions": {
    "AllocationStrategy": "lowest-price"
  },
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateName": "my-launch-template",
        "Version": "1"
      },
      "Overrides": [
        {
          "InstanceType": "r4.2xlarge",
          "Placement": {
            "AvailabilityZone": "us-west-2a"
          }
        },
        {
          "InstanceType": "m4.2xlarge",
          "Placement": {
            "AvailabilityZone": "us-west-2b"
          }
        },
        {
          "InstanceType": "c5.2xlarge",
          "Placement": {
            "AvailabilityZone": "us-west-2b"
          }
        }
      ]
    }
  ],
  "TargetCapacitySpecification": {
    "TotalTargetCapacity": 50,
    "OnDemandTargetCapacity": 0,
    "SpotTargetCapacity": 50,
    "DefaultTargetCapacityType": "spot"
  },
  "Type": "instant"
}
```
Example 12: Configure attribute-based instance type selection

The following example demonstrates how to configure an EC2 Fleet to use attribute-based instance type selection for identifying instance types. To specify the required instance attributes, you specify the attributes in the InstanceRequirements structure.

In the following example, two instance attributes are specified:

- **VCpuCount** – A minimum of 2 vCPUs is specified. Because no maximum is specified, there is no maximum limit.
- **MemoryMiB** – A minimum of 4 MiB of memory is specified. Because no maximum is specified, there is no maximum limit.

Any instance types that have 2 or more vCPUs and 4 MiB or more of memory will be identified. However, price protection and the allocation strategy might exclude some instance types when EC2 Fleet provisions the fleet (p. 1115).

For a list and descriptions of all the possible attributes that you can specify, see InstanceRequirements in the Amazon EC2 API Reference.

```
{
  "SpotOptions": {
    "AllocationStrategy": "price-capacity-optimized"
  },
  "LaunchTemplateConfigs": [{
    "LaunchTemplateSpecification": {
      "LaunchTemplateName": "my-launch-template",
      "Version": "1"
    },
    "Overrides": [{
      "InstanceRequirements": {
        "VCpuCount": {
          "Min": 2
        },
        "MemoryMiB": {
          "Min": 4
        }
      }
    }]
  }],
  "TargetCapacitySpecification": {
    "TotalTargetCapacity": 20,
    "DefaultTargetCapacityType": "spot",
    "Type": "instant"
}
```

Spot Fleet example configurations

The following examples show launch configurations that you can use with the request-spot-fleet command to create a Spot Fleet request. For more information, see Create a Spot Fleet request (p. 1185).

**Note**

For Spot Fleet, you can't specify a network interface ID in a launch template or launch specification. Make sure you omit the NetworkInterfaceID parameter in your launch template or launch specification.

**Examples**
Example 1: Launch Spot Instances using the lowest-priced Availability Zone or subnet in the Region (p. 1250)

The following example specifies a single launch specification without an Availability Zone or subnet. The Spot Fleet launches the instances in the lowest-priced Availability Zone that has a default subnet. The price you pay does not exceed the On-Demand price.

```
{
  "TargetCapacity": 20,
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [
    {
      "ImageId": "ami-1a2b3c4d",
      "KeyName": "my-key-pair",
      "SecurityGroups": [
        {
          "GroupId": "sg-1a2b3c4d"
        }
      ],
      "InstanceType": "m3.medium",
      "IamInstanceProfile": {
        "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
      }
    }
  ]
}
```

Example 2: Launch Spot Instances using the lowest-priced Availability Zone or subnet in a specified list

The following examples specify two launch specifications with different Availability Zones or subnets, but the same instance type and AMI.

Availability Zones

The Spot Fleet launches the instances in the default subnet of the lowest-priced Availability Zone that you specified.

```
{
```

```
1250```
"TargetCapacity": 20,
"IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
"LaunchSpecifications": [
  {
    "ImageId": "ami-1a2b3c4d",
    "KeyName": "my-key-pair",
    "SecurityGroups": [
      {
        "GroupId": "sg-1a2b3c4d"
      }
    ],
    "InstanceType": "m3.medium",
    "Placement": {
      "AvailabilityZone": "us-west-2a, us-west-2b"
    },
    "IamInstanceProfile": {
      "Arn": "arn:aws:iam::123456789012:instance-profile/my-iam-role"
    }
  }
]
}

Subnets

You can specify default subnets or nondefault subnets, and the nondefault subnets can be from a
default VPC or a nondefault VPC. The Spot service launches the instances in whichever subnet is in the
lowest-priced Availability Zone.

You can't specify different subnets from the same Availability Zone in a Spot Fleet request.

If the instances are launched in a default VPC, they receive a public IPv4 address by default. If the
instances are launched in a nondefault VPC, they do not receive a public IPv4 address by default. Use
a network interface in the launch specification to assign a public IPv4 address to instances launched in
a nondefault VPC. When you specify a network interface, you must include the subnet ID and security
group ID using the network interface.
Example 3: Launch Spot Instances using the lowest-priced instance type in a specified list

The following examples specify two launch configurations with different instance types, but the same AMI and Availability Zone or subnet. The Spot Fleet launches the instances using the specified instance type with the lowest price.

**Availability Zone**

```json
{
   "TargetCapacity": 20,
   "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
   "LaunchSpecifications": [
      {
         "ImageId": "ami-1a2b3c4d",
         "SecurityGroups": [
            {
               "GroupId": "sg-1a2b3c4d"
            }
         ],
         "InstanceType": "c5.4xlarge",
         "Placement": {
            "AvailabilityZone": "us-west-2b"
         }
      },
      {
         "ImageId": "ami-1a2b3c4d",
         "SecurityGroups": [
            {
               "GroupId": "sg-1a2b3c4d"
            }
         ],
         "InstanceType": "r3.8xlarge",
         "Placement": {
            "AvailabilityZone": "us-west-2b"
         }
      }
   ]
}
```

**Subnet**

```json
{
   "TargetCapacity": 20,
   "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
   "LaunchSpecifications": [
      {
         "NetworkInterfaces": [
            {
               "DeviceIndex": 0,
               "SubnetId": "subnet-1a2b3c4d",
               "Groups": [ "sg-1a2b3c4d" ],
               "AssociatePublicIpAddress": true
            }
         ],
         "IamInstanceProfile": {
            "Arn": "arn:aws:iam::880185128111:instance-profile/my-iam-role"
         }
      }
   ]
}
```
Example 4. Override the price for the request

We recommended that you use the default maximum price, which is the On-Demand price. If you prefer, you can specify a maximum price for the fleet request and maximum prices for individual launch specifications.

The following examples specify a maximum price for the fleet request and maximum prices for two of the three launch specifications. The maximum price for the fleet request is used for any launch specification that does not specify a maximum price. The Spot Fleet launches the instances using the instance type with the lowest price.

Availability Zone

```json
{
  "SpotPrice": "1.00",
  "TargetCapacity": 30,
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [
    {
      "ImageId": "ami-1a2b3c4d",
      "InstanceType": "c3.2xlarge",
      "Placement": {
        "AvailabilityZone": "us-west-2b"
      },
      "SpotPrice": "0.10"
    },
    {
      "ImageId": "ami-1a2b3c4d",
      "InstanceType": "c3.4xlarge",
      "Placement": {
        "AvailabilityZone": "us-west-2b"
      },
      "SpotPrice": "0.20"
    },
    {
      "ImageId": "ami-1a2b3c4d",
      "InstanceType": "c3.8xlarge",
      "Placement": {
        "AvailabilityZone": "us-west-2b"
      }
    }
  ]
}
```
Example 5: Launch a Spot Fleet using the diversified allocation strategy

The following example uses the diversified allocation strategy. The launch specifications have different instance types but the same AMI and Availability Zone or subnet. The Spot Fleet distributes the 30 instances across the three launch specifications, such that there are 10 instances of each type. For more information, see Allocation strategies for Spot Instances (p. 1154).

Availability Zone

```json
{
  "SpotPrice": "0.70",
  "TargetCapacity": 30,
  "AllocationStrategy": "diversified",
  "IamFleetRole": "arn:aws:iam::123456789012:role/aws-ec2-spot-fleet-tagging-role",
  "LaunchSpecifications": [
    {
      "ImageId": "ami-1a2b3c4d",
      "InstanceId": "c4.2xlarge",
      "AvailabilityZone": "us-west-2b"
    },
    {
      "ImageId": "ami-1a2b3c4d",
      "InstanceId": "m3.2xlarge",
      "AvailabilityZone": "us-west-2b"
    }
  ]
}
```
A best practice to increase the chance that a spot request can be fulfilled by EC2 capacity in the event of an outage in one of the Availability Zones is to diversify across zones. For this scenario, include each Availability Zone available to you in the launch specification. And, instead of using the same subnet each time, use three unique subnets (each mapping to a different zone).
Example 6: Launch a Spot Fleet using instance weighting

The following examples use instance weighting, which means that the price is per unit hour instead of per instance hour. Each launch configuration lists a different instance type and a different weight. The Spot Fleet selects the instance type with the lowest price per unit hour. The Spot Fleet calculates the number of Spot Instances to launch by dividing the target capacity by the instance weight. If the result isn't an integer, the Spot Fleet rounds it up to the next integer, so that the size of your fleet is not below its target capacity.

If the `r3.2xlarge` request is successful, Spot provisions 4 of these instances. Divide 20 by 6 for a total of 3.33 instances, then round up to 4 instances.

If the `c3.xlarge` request is successful, Spot provisions 7 of these instances. Divide 20 by 3 for a total of 6.66 instances, then round up to 7 instances.

For more information, see Spot Fleet instance weighting (p. 1176).

Availability Zone
Example 7: Launch a Spot Fleet with On-Demand capacity

To ensure that you always have instance capacity, you can include a request for On-Demand capacity in your Spot Fleet request. If there is capacity, the On-Demand request is always fulfilled. The balance of the target capacity is fulfilled as Spot if there is capacity and availability.

The following example specifies the desired target capacity as 10, of which 5 must be On-Demand capacity. Spot capacity is not specified; it is implied in the balance of the target capacity minus the On-Demand capacity. Amazon EC2 launches 5 capacity units as On-Demand, and 5 capacity units (10-5=5) as Spot if there is available Amazon EC2 capacity and availability.

For more information, see On-Demand in Spot Fleet (p. 1171).
Example 8: Configure Capacity Rebalancing to launch replacement Spot Instances

The following example configures the Spot Fleet to launch a replacement Spot Instance when Amazon EC2 emits a rebalance recommendation for a Spot Instance in the fleet. To configure the automatic replacement of Spot Instances, for `ReplacementStrategy`, specify `launch-before-terminate`. To configure the time delay from the launch of the new replacement Spot Instances to the automatic deletion of the old Spot Instances, for `termination-delay`, specify a value in seconds. For more information, see Configuration options (p. 1172).

**Note**

We recommend using `launch-before-terminate` only if you can predict how long your instance shutdown procedures will take to complete. This ensures that the old instances are terminated only after the shutdown procedures are completed. You are charged for all instances while they are running.

The effectiveness of the Capacity Rebalancing strategy depends on the number of Spot capacity pools specified in the Spot Fleet request. We recommend that you configure the fleet with a diversified set of instance types and Availability Zones, and for `AllocationStrategy`, specify `capacityOptimized`. For more information about what you should consider when configuring a Spot Fleet for Capacity Rebalancing, see Capacity Rebalancing (p. 1172).
Example 9: Launch Spot Instances in a capacity-optimized fleet

The following example demonstrates how to configure a Spot Fleet with a Spot allocation strategy that optimizes for capacity. To optimize for capacity, you must set AllocationStrategy to capacityOptimized.

In the following example, the three launch specifications specify three Spot capacity pools. The target capacity is 50 Spot Instances. The Spot Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with optimal capacity for the number of instances that are launching.

```json
{
    "TargetCapacity": "50",
    "SpotFleetRequestConfig": {
        "AllocationStrategy": "capacityOptimized",
    },
    "LaunchTemplateConfigs": [
        {
            "LaunchTemplateSpecification": {
                "LaunchTemplateName": "my-launch-template",
                "Version": "1"
            },
            "Overrides": [
                {
                    "InstanceType": "r4.2xlarge",
                    "AvailabilityZone": "us-west-2a"
                },
                {
                    "InstanceType": "m4.2xlarge",
                    "AvailabilityZone": "us-west-2b"
                },
                {
                    "InstanceType": "c5.2xlarge",
                    "AvailabilityZone": "us-west-2b"
                }
            ]
        }
    ]
}
```
Example 10: Launch Spot Instances in a capacity-optimized fleet with priorities

The following example demonstrates how to configure a Spot Fleet with a Spot allocation strategy that optimizes for capacity while using priority on a best-effort basis.

When using the `capacityOptimizedPrioritized` allocation strategy, you can use the `Priority` parameter to specify the priorities of the Spot capacity pools, where the lower the number the higher priority. You can also set the same priority for several Spot capacity pools if you favor them equally. If you do not set a priority for a pool, the pool will be considered last in terms of priority.

To prioritize Spot capacity pools, you must set `AllocationStrategy` to `capacityOptimizedPrioritized`. Spot Fleet will optimize for capacity first, but will honor the priorities on a best-effort basis (for example, if honoring the priorities will not significantly affect Spot Fleet's ability to provision optimal capacity). This is a good option for workloads where the possibility of disruption must be minimized and the preference for certain instance types matters.

In the following example, the three launch specifications specify three Spot capacity pools. Each pool is prioritized, where the lower the number the higher priority. The target capacity is 50 Spot Instances. The Spot Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with the highest priority on a best-effort basis, but optimizes for capacity first.

```
{
  "TargetCapacity": "50",
  "SpotFleetRequestConfig": {
    "AllocationStrategy": "capacityOptimizedPrioritized"
  },
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateName": "my-launch-template",
        "Version": "1"
      },
      "Overrides": [
        {
          "InstanceType": "r4.2xlarge",
          "Priority": 1,
          "AvailabilityZone": "us-west-2a"
        },
        {
          "InstanceType": "m4.2xlarge",
          "Priority": 2,
          "AvailabilityZone": "us-west-2b"
        },
        {
          "InstanceType": "c5.2xlarge",
          "Priority": 3,
          "AvailabilityZone": "us-west-2b"
        }
      ]
    }
  ]
}
```

Example 11: Launch Spot Instances in a priceCapacityOptimized fleet

The following example demonstrates how to configure a Spot Fleet with a Spot allocation strategy that optimizes for both capacity and lowest price. To optimize for capacity while taking price into consideration, you must set the Spot `AllocationStrategy` to `priceCapacityOptimized`.

```
{
  "TargetCapacity": "50",
  "SpotFleetRequestConfig": {
    "AllocationStrategy": "priceCapacityOptimized"
  },
  "LaunchTemplateConfigs": [
    {
      "LaunchTemplateSpecification": {
        "LaunchTemplateName": "my-launch-template",
        "Version": "1"
      },
      "Overrides": [
        {
          "InstanceType": "r4.2xlarge",
          "Priority": 1,
          "AvailabilityZone": "us-west-2a"
        },
        {
          "InstanceType": "m4.2xlarge",
          "Priority": 2,
          "AvailabilityZone": "us-west-2b"
        },
        {
          "InstanceType": "c5.2xlarge",
          "Priority": 3,
          "AvailabilityZone": "us-west-2b"
        }
      ]
    }
  ]
}
```
In the following example, the three launch specifications specify three Spot capacity pools. The target capacity is 50 Spot Instances. The Spot Fleet attempts to launch 50 Spot Instances into the Spot capacity pool with optimal capacity for the number of instances that are launching while also choosing the pool that is the lowest priced.

```
{
  "SpotFleetRequestConfig": {
    "AllocationStrategy": "priceCapacityOptimized",
    "OnDemandAllocationStrategy": "lowestPrice",
    "ExcessCapacityTerminationPolicy": "default",
    "IamFleetRole": "arn:aws:iam::111111111111:role/aws-ec2-spot-fleet-tagging-role",
    "LaunchTemplateConfigs": [
      {
        "LaunchTemplateSpecification": {
          "LaunchTemplateId": "lt-0123456789example",
          "Version": "1"
        },
        "Overrides": [
          {
            "InstanceType": "r4.2xlarge",
            "AvailabilityZone": "us-west-2a"
          },
          {
            "InstanceType": "m4.2xlarge",
            "AvailabilityZone": "us-west-2b"
          },
          {
            "InstanceType": "c5.2xlarge",
            "AvailabilityZone": "us-west-2b"
          }
        ]
      },
      "TargetCapacity": 50,
      "Type": "request"
    }
  }
```

**Example 12: Configure attribute-based instance type selection**

The following example demonstrates how to configure a Spot Fleet to use attribute-based instance type selection for identifying instance types. To specify the required instance attributes, you specify the attributes in the `InstanceRequirements` structure.

In the following example, two instance attributes are specified:

- **VCpuCount** – A minimum of 2 vCPUs is specified. Because no maximum is specified, there is no maximum limit.
- **MemoryMiB** – A minimum of 4 MiB of memory is specified. Because no maximum is specified, there is no maximum limit.

Any instance types that have 2 or more vCPUs and 4 MiB or more of memory will be identified. However, price protection and the allocation strategy might exclude some instance types when Spot Fleet provisions the fleet (p. 1158).

For a list and descriptions of all the possible attributes that you can specify, see [InstanceRequirements](#) in the Amazon EC2 API Reference.

```
{
  "AllocationStrategy": "priceCapacityOptimized",
```
Fleet quotas

The usual Amazon EC2 quotas (formerly referred to as limits) apply to instances launched by an EC2 Fleet or a Spot Fleet, such as Spot Instance limits (p. 610) and volume limits (p. 2444).

In addition, the following quotas apply:

<table>
<thead>
<tr>
<th>Quota description</th>
<th>Quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>The number of EC2 Fleets and Spot Fleets per Region in the active, deleted_running, and cancelled_running states</td>
<td>1,000¹²³⁴</td>
</tr>
<tr>
<td>The number of Spot capacity pools (unique combination of instance type and subnet)</td>
<td>300¹⁴</td>
</tr>
<tr>
<td>The size of the user data in a launch specification</td>
<td>16 KB²</td>
</tr>
<tr>
<td>The target capacity per EC2 Fleet or Spot Fleet</td>
<td>10,000</td>
</tr>
<tr>
<td>The target capacity across all EC2 Fleets and Spot Fleets in a Region</td>
<td>100,000¹</td>
</tr>
<tr>
<td>An EC2 Fleet request or a Spot Fleet request can't span Regions.</td>
<td></td>
</tr>
<tr>
<td>An EC2 Fleet request or a Spot Fleet request can't span different subnets from the same Availability Zone.</td>
<td></td>
</tr>
</tbody>
</table>

¹ These quotas apply to both your EC2 Fleets and your Spot Fleets.

² These are hard quotas. You cannot request an increase for these quotas.

³ After you delete an EC2 Fleet or cancel a Spot Fleet request, and if you specified that the fleet should not terminate its Spot Instances when you deleted or canceled the request, the fleet request enters the deleted_running (EC2 Fleet) or cancelled_running (Spot Fleet) state and the instances continue
to run until they are interrupted or you terminate them manually. If you terminate the instances, the fleet request enters the deleted_terminating (EC2 Fleet) or cancelled_terminating (Spot Fleet) state and does not count towards this quota. For more information, see Delete an EC2 Fleet (p. 1148) and Cancel a Spot Fleet request (p. 1197).

This quota only applies to fleets of type request or maintain. This quota does not apply to instant fleets.

**Request a quota increase for target capacity**

If you need more than the default quota for target capacity, you can request a quota increase.

**To request a quota increase for target capacity**

1. Open the AWS Support Center Create case form.
2. Choose **Service limit increase**.
3. For **Limit type**, choose **EC2 Fleet**.
4. For **Region**, choose the AWS Region in which to request the quota increase.
5. For **Limit**, choose **Target Fleet Capacity per Fleet (in units)** or **Target Fleet Capacity per Region (in units)**, depending on which quota you want to increase.
6. For **New limit value**, enter the new quota value.
7. To request an increase for another quota, choose **Add another request**, and repeat Steps 4–6.
8. For **Use case description**, enter your reason for requesting a quota increase.
9. Under **Contact options**, specify your preferred contact language and contact method.
10. Choose **Submit**.
Monitor Amazon EC2

Monitoring is an important part of maintaining the reliability, availability, and performance of your Amazon Elastic Compute Cloud (Amazon EC2) instances and your AWS solutions. You should collect monitoring data from all of the parts in your AWS solutions so that you can more easily debug a multi-point failure if one occurs. Before you start monitoring Amazon EC2, however, you should create a monitoring plan that should include:

- What are your goals for monitoring?
- What resources will you monitor?
- How often will you monitor these resources?
- What monitoring tools will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something goes wrong?

After you have defined your monitoring goals and have created your monitoring plan, the next step is to establish a baseline for normal Amazon EC2 performance in your environment. You should measure Amazon EC2 performance at various times and under different load conditions. As you monitor Amazon EC2, you should store a history of monitoring data that you collect. You can compare current Amazon EC2 performance to this historical data to help you to identify normal performance patterns and performance anomalies, and devise methods to address them. For example, you can monitor CPU utilization, disk I/O, and network utilization for your EC2 instances. When performance falls outside your established baseline, you might need to reconfigure or optimize the instance to reduce CPU utilization, improve disk I/O, or reduce network traffic.

To establish a baseline you should, at a minimum, monitor the following items:

<table>
<thead>
<tr>
<th>Item to monitor</th>
<th>Amazon EC2 metric</th>
<th>Monitoring agent/CloudWatch Logs</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU utilization</td>
<td>CPUUtilization (p. 1300)</td>
<td></td>
</tr>
<tr>
<td>Network utilization</td>
<td>NetworkIn (p. 1300)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>NetworkOut (p. 1300)</td>
<td></td>
</tr>
<tr>
<td>Disk performance</td>
<td>DiskReadOps (p. 1300)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>DiskWriteOps (p. 1300)</td>
<td></td>
</tr>
<tr>
<td>Disk Reads/Writes</td>
<td>DiskReadBytes (p. 1300)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>DiskWriteBytes (p. 1300)</td>
<td></td>
</tr>
<tr>
<td>Memory utilization, disk swap utilization, disk space utilization, page file utilization, log collection</td>
<td>[Linux and Windows Server instances] Collect Metrics and Logs from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent</td>
<td>[Migration from previous CloudWatch Logs agent on</td>
</tr>
</tbody>
</table>
Automated and manual monitoring

AWS provides various tools that you can use to monitor Amazon EC2. You can configure some of these tools to do the monitoring for you, while some of the tools require manual intervention.

Monitoring tools

- Automated monitoring tools (p. 1265)
- Manual monitoring tools (p. 1266)

Automated monitoring tools

You can use the following automated monitoring tools to watch Amazon EC2 and report back to you when something is wrong:

- **System status checks** – monitor the AWS systems required to use your instance to ensure that they are working properly. These checks detect problems with your instance that require AWS involvement to repair. When a system status check fails, you can choose to wait for AWS to fix the issue or you can resolve it yourself (for example, by stopping and restarting or terminating and replacing an instance). Examples of problems that cause system status checks to fail include:
  - Loss of network connectivity
  - Loss of system power
  - Software issues on the physical host
  - Hardware issues on the physical host that impact network reachability

For more information, see Status checks for your instances (p. 1267).

- **Instance status checks** – monitor the software and network configuration of your individual instance. These checks detect problems that require your involvement to repair. When an instance status check fails, typically you will need to address the problem yourself (for example, by rebooting the instance or by making modifications in your operating system). Examples of problems that may cause instance status checks to fail include:
  - Failed system status checks
  - Misconfigured networking or startup configuration
  - Exhausted memory
  - Corrupted file system
  - Incompatible kernel

For more information, see Status checks for your instances (p. 1267).

- **Amazon CloudWatch alarms** – watch a single metric over a time period you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. Alarms invoke actions for sustained state changes only. CloudWatch alarms will not invoke actions simply because they are in a particular state; the state
must have changed and been maintained for a specified number of periods. For more information, see Monitor your instances using CloudWatch (p. 1298).

- **Amazon EventBridge** – automate your AWS services and respond automatically to system events. Events from AWS services are delivered to EventBridge in near real time, and you can specify automated actions to take when an event matches a rule you write. For more information, see What is Amazon EventBridge?

- **Amazon CloudWatch Logs** – monitor, store, and access your log files from Amazon EC2 instances, AWS CloudTrail, or other sources. For more information, see the Amazon CloudWatch Logs User Guide.

- **CloudWatch agent** – collect logs and system-level metrics from both hosts and guests on your EC2 instances and on-premises servers. For more information, see Collecting Metrics and Logs from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent in the Amazon CloudWatch User Guide.

- **AWS Management Pack for Microsoft System Center Operations Manager** – links Amazon EC2 instances and the Windows or Linux operating systems running inside them. The AWS Management Pack is an extension to Microsoft System Center Operations Manager. It uses a designated computer in your datacenter (called a watcher node) and the Amazon Web Services APIs to remotely discover and collect information about your AWS resources. For more information, see AWS Management Pack for Microsoft System Center.

### Manual monitoring tools

Another important part of monitoring Amazon EC2 involves manually monitoring those items that the monitoring scripts, status checks, and CloudWatch alarms don't cover. The Amazon EC2 and CloudWatch console dashboards provide an at-a-glance view of the state of your Amazon EC2 environment.

- **Amazon EC2 Dashboard** shows:
  - Service Health and Scheduled Events by Region
  - Instance state
  - Status checks
  - Alarm status
  - Instance metric details (In the navigation pane choose Instances, select an instance, and choose the Monitoring tab)
  - Volume metric details (In the navigation pane choose Volumes, select a volume, and choose the Monitoring tab)

- **Amazon CloudWatch Dashboard** shows:
  - Current alarms and status
  - Graphs of alarms and resources
  - Service health status

In addition, you can use CloudWatch to do the following:

- Graph Amazon EC2 monitoring data to troubleshoot issues and discover trends
- Search and browse all your AWS resource metrics
- Create and edit alarms to be notified of problems
- See at-a-glance overviews of your alarms and AWS resources

### Best practices for monitoring

Use the following best practices for monitoring to help you with your Amazon EC2 monitoring tasks.

- Make monitoring a priority to head off small problems before they become big ones.
Monitor the status of your instances

You can monitor the status of your instances by viewing status checks and scheduled events for your instances.

A status check gives you the information that results from automated checks performed by Amazon EC2. These automated checks detect whether specific issues are affecting your instances. The status check information, together with the data provided by Amazon CloudWatch, gives you detailed operational visibility into each of your instances.

You can also see status of specific events that are scheduled for your instances. The status of events provides information about upcoming activities that are planned for your instances, such as rebooting or retirement. They also provide the scheduled start and end time of each event.

Contents

- Status checks for your instances (p. 1267)
- State change events for your instances (p. 1273)
- Scheduled events for your instances (p. 1275)

Status checks for your instances

With instance status monitoring, you can quickly determine whether Amazon EC2 has detected any problems that might prevent your instances from running applications. Amazon EC2 performs automated checks on every running EC2 instance to identify hardware and software issues. You can view the results of these status checks to identify specific and detectable problems. The event status data augments the information that Amazon EC2 already provides about the state of each instance (such as pending, running, stopping) and the utilization metrics that Amazon CloudWatch monitors (CPU utilization, network traffic, and disk activity).

Status checks are performed every minute, returning a pass or a fail status. If all checks pass, the overall status of the instance is **OK**. If one or more checks fail, the overall status is **impaired**. Status checks are built into Amazon EC2, so they cannot be disabled or deleted.

When a status check fails, the corresponding CloudWatch metric for status checks is incremented. For more information, see Status check metrics (p. 1308). You can use these metrics to create CloudWatch alarms that are triggered based on the result of the status checks. For example, you can create an alarm to warn you if status checks fail on a specific instance. For more information, see Create and edit status check alarms (p. 1271).
You can also create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically recovers the instance if it becomes impaired due to an underlying issue. For more information, see Recover your instance (p. 807).

Contents

- Types of status checks (p. 1268)
- Working with status checks (p. 1269)

Types of status checks

There are three types of status checks.

- System status checks (p. 1268)
- Instance status checks (p. 1268)
- Attached EBS status checks (p. 1269)

System status checks

System status checks monitor the AWS systems on which your instance runs. These checks detect underlying problems with your instance that require AWS involvement to repair. When a system status check fails, you can choose to wait for AWS to fix the issue, or you can resolve it yourself. For instances backed by Amazon EBS, you can stop and start the instance yourself, which in most cases results in the instance being migrated to a new host. For Linux instances backed by instance store, you can terminate and replace the instance. For Windows instances, the root volume must be an Amazon EBS volume; instance store is not supported for the root volume. Note that instance store volumes are ephemeral and all data is lost when the instance is stopped.

The following are examples of problems that can cause system status checks to fail:

- Loss of network connectivity
- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host that impact network reachability

If a system status check fails, we increment the StatusCheckFailed_System (p. 1308) metric.

Bare metal instances

If you perform a restart from the operating system on a bare metal instance, the system status check might temporarily return a fail status. When the instance becomes available, the system status check should return a pass status.

Instance status checks

Instance status checks monitor the software and network configuration of your individual instance. Amazon EC2 checks the health of the instance by sending an address resolution protocol (ARP) request to the network interface (NIC). These checks detect problems that require your involvement to repair. When an instance status check fails, you typically must address the problem yourself (for example, by rebooting the instance or by making instance configuration changes).

The following are examples of problems that can cause instance status checks to fail:

- Failed system status checks
- Incorrect networking or startup configuration
- Exhausted memory
• Corrupted file system
• Incompatible kernel

If an instance status check fails, we increment the `StatusCheckFailed_Instance` metric.

**Bare metal instances**

If you perform a restart from the operating system on a bare metal instance, the instance status check might temporarily return a fail status. When the instance becomes available, the instance status check should return a pass status.

**Attached EBS status checks**

Attached EBS status checks monitor if the Amazon EBS volumes attached to an instance are reachable and able to complete I/O operations. The `StatusCheckFailed_AttachedEBS` metric is a binary value that indicates impairment if one or more of the EBS volumes attached to the instance are unable to complete I/O operations. These status checks detect underlying issues with the compute or Amazon EBS infrastructure. When the attached EBS status check metric fails, you can either wait for AWS to resolve the issue, or you can take actions, such as replacing the affected volumes or stopping and restarting the instance.

The following are examples of issues that can cause attached EBS status checks to fail:

• Hardware or software issues on the storage subsystems underlying the EBS volumes
• Hardware issues on the physical host that impact reachability of the EBS volumes
• Connectivity issues between the instance and EBS volumes

You can use the `StatusCheckFailed_AttachedEBS` metric to help improve the resilience of your workload. You can use this metric to create Amazon CloudWatch alarms that are triggered based on the result of the status check. For example, you could fail over to a secondary instance or Availability Zone when you detect a prolonged impact. Alternatively, you can monitor the I/O performance of each attached volume using EBS CloudWatch metrics to detect and replace the impaired volume. If your workload is not driving I/O to any of the EBS volumes attached to your instance, and the attached EBS status check indicates an impairment, you can stop and start the instance to address issues with the physical host that is impacting the reachability of the EBS volumes.

**Note**

• The attached EBS status check metric is available only for Nitro instances.
• You can monitor the attached EBS status check metric by creating a CloudWatch alarm based on the `StatusCheckFailed_AttachedEBS` metric. You can't view this status check by using the `describe-instance-status` AWS CLI command.

**Working with status checks**

You can work with status checks using the console and command line tools, such as the AWS CLI.

**Topics**

• View status checks (p. 1269)
• Report instance status (p. 1271)
• Create and edit status check alarms (p. 1271)

**View status checks**

To view status checks, use one of the following methods:
Amazon EC2 console

To view status checks (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. On the Instances page, the Status check column lists the operational status of each instance.
4. To view the status of a specific instance, select the instance, and then choose the Status checks tab.

If your instance has a failed status check, you typically must address the problem yourself (for example, by rebooting the instance or by making instance configuration changes). To troubleshoot system or instance status check failures yourself, see Troubleshoot instances with failed status checks (p. 2554).

5. To review the CloudWatch metrics for status checks, select the instance, and then choose the Monitoring tab. Scroll until you see the graphs for the following metrics:
   - Status check failed (any)
   - Status check failed (instance)
   - Status check failed (system)

   For more information, see the section called “Status check metrics” (p. 1308).

Command line

You can view status checks for running instances by using the describe-instance-status (AWS CLI) command.

To view the status of all instances, use the following command.

```
aws ec2 describe-instance-status
```

To get the status of all instances with an instance status of impaired, use the following command.

```
aws ec2 describe-instance-status \
--filters Name=instance-status.status,Values=impaired
```

To get the status of a single instance, use the following command.
Report instance status

You can provide feedback if you are having problems with an instance whose status is not shown as impaired, or if you want to send AWS additional details about the problems you are experiencing with an impaired instance.

We use reported feedback to identify issues impacting multiple customers, but do not respond to individual account issues. Providing feedback does not change the status check results that you currently see for the instance.

To report instance status, use one of the following methods:

Amazon EC2 console

To report instance status (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, choose the Status Checks tab, choose Actions (the second Actions menu in the bottom half of the page), and then choose Report instance status.
4. Complete the Report instance status form, and then choose Submit.

Command line

Use the report-instance-status (AWS CLI) command to send feedback about the status of an impaired instance.

```
aws ec2 report-instance-status \
  --instances i-1234567890abcdef0 \
  --status impaired \
  --reason-codes code
```

Alternatively, use the following commands:

- Send-EC2InstanceStatus (AWS Tools for Windows PowerShell)
- ReportInstanceStatus (Amazon EC2 Query API)

Create and edit status check alarms

You can use the status check metrics (p. 1308) to create CloudWatch alarms to notify you when an instance has a failed status check.

To create a status check alarm, use one of the following methods:
Amazon EC2 console

Use the following procedure to configure an alarm that sends you a notification by email, or stops, terminates, or recovers an instance when it fails a status check.

**To create a status check alarm (console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance, choose the **Status Checks** tab, and choose **Actions, Create status check alarm**.
4. On the **Manage CloudWatch alarms** page, under **Add or edit alarm**, choose **Create an alarm**.
5. For **Alarm notification**, turn the toggle on to configure Amazon Simple Notification Service (Amazon SNS) notifications. Select an existing Amazon SNS topic or enter a name to create a new topic.

   If you add an email address to the list of recipients or created a new topic, Amazon SNS sends a subscription confirmation email message to each new address. Each recipient must confirm the subscription by choosing the link contained in that message. Alert notifications are sent only to confirmed addresses.

6. For **Alarm action**, turn the toggle on to specify an action to take when the alarm is triggered. Select the action.
7. For **Alarm thresholds**, specify the metric and criteria for the alarm.

   You can leave the default settings for **Group samples by (Average)** and **Type of data to sample (Status check failed:either)**, or you can change them to suit your needs.

   For **Consecutive period**, set the number of periods to evaluate and, in **Period**, enter the evaluation period duration before triggering the alarm and sending an email.

8. (Optional) For **Sample metric data**, choose **Add to dashboard**.
9. Choose **Create**.

If you need to make changes to an instance status alarm, you can edit it.

**To edit a status check alarm using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, Monitoring, Manage CloudWatch alarms**.
4. On the **Manage CloudWatch alarms** page, under **Add or edit alarm**, choose **Edit an alarm**.
5. For **Search for alarm**, choose the alarm.
6. When you are finished making changes, choose **Update**.

Command line

In the following example, the alarm publishes a notification to an SNS topic, `arn:aws:sns:us-west-2:111122223333:my-sns-topic`, when the instance fails either the instance check or system status check for at least two consecutive periods. The CloudWatch metric used is `StatusCheckFailed`.

**To create a status check alarm using the AWS CLI**

1. Select an existing SNS topic or create a new one. For more information, see [Using the AWS CLI with Amazon SNS](https://aws.amazon.com) in the [AWS Command Line Interface User Guide](https://aws.amazon.com).
2. Use the following `list-metrics` command to view the available Amazon CloudWatch metrics for Amazon EC2.

```bash
aws cloudwatch list-metrics --namespace AWS/EC2
```

3. Use the following `put-metric-alarm` command to create the alarm.

```bash
aws cloudwatch put-metric-alarm --alarm-name StatusCheckFailed-Alarm-for-i-1234567890abcdef0 --metric-name StatusCheckFailed --namespace AWS/EC2 --statistic Maximum --dimensions Name=InstanceId,Value=i-1234567890abcdef0 --unit Count --period 300 --evaluation-periods 2 --threshold 1 --comparison-operator GreaterThanOrEqualToThreshold --alarm-actions arn:aws:sns:us-west-2:1111222333:my-sns-topic
```

The period is the time frame, in seconds, in which Amazon CloudWatch metrics are collected. This example uses 300, which is 60 seconds multiplied by 5 minutes. The evaluation period is the number of consecutive periods for which the value of the metric must be compared to the threshold. This example uses 2. The alarm actions are the actions to perform when this alarm is triggered. This example configures the alarm to send an email using Amazon SNS.

## State change events for your instances

Amazon EC2 sends an EC2 Instance State-change Notification event to Amazon EventBridge when the state of an instance changes.

The following is example data for this event. In this example, the instance entered the pending state.

```json
{
    "id":"7bf73129-1428-4cd3-a780-95db273d1602",
    "detail-type":"EC2 Instance State-change Notification",
    "source":"aws.ec2",
    "account":"123456789012",
    "time":"2021-11-11T21:29:54Z",
    "region":"us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:123456789012:instance/i-abcd1111"
    ],
    "detail": {
        "instance-id": "i-abcd1111",
        "state": "pending"
    }
}
```

The possible values for state are:

- pending
- running
- stopping
- stopped
- shutting-down
- terminated

When you launch or start an instance, it enters the pending state and then the running state. When you stop an instance, it enters the stopping state and then the stopped state. When you terminate an instance, it enters the shutting-down state and then the terminated state.
Get an email notification when an instance changes state

To receive email notifications when your instance changes state, create an Amazon SNS topic and then create an EventBridge rule for the EC2 Instance State-change Notification event.

To create an SNS topic

2. In the navigation pane, choose Topics.
3. Choose Create topic.
4. For Type, choose Standard.
5. For Name, enter a name for your topic.
6. Choose Create topic.
7. Choose Create subscription.
8. For Protocol, choose Email.
9. For Endpoint, enter the email address that receives the notifications.
10. Choose Create subscription.
11. You'll receive an email message with the following subject line: AWS Notification - Subscription Confirmation. Follow the directions to confirm your subscription.

To create an EventBridge rule

1. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
2. Choose Create rule.
3. For Name, enter a name for your rule.
4. For Rule type, choose Rule with an event pattern.
5. Choose Next.
6. For Event pattern, do the following:
   a. For Event source, choose AWS services.
   b. For AWS service, choose EC2.
   c. For Event type, choose EC2 Instance State-change Notification.
   d. By default, we send notifications for any state change for any instance. If you prefer, you can select specific states or specific instances.
7. Choose Next.
8. Specify a target as follows:
   a. For Target types, choose AWS service.
   b. For Select a target, choose SNS topic.
   c. For Topic, choose the SNS topic that you created in the previous procedure.
9. Choose Next.
10. (Optional) Add tags to your rule.
11. Choose Next.
12. Choose Create rule.
13. To test your rule, initiate a state change. For example, start a stopped instance, stop a running instance, or launch an instance. You'll receive email messages with the following subject line: AWS Notification Message. The body of the email contains the event data.
Scheduled events for your instances

AWS can schedule events for your instances, such as a reboot, stop/start, or retirement. These events do not occur frequently. If one of your instances will be affected by a scheduled event, AWS sends an email to the email address that's associated with your AWS account prior to the scheduled event. The email provides details about the event, including the start and end date. Depending on the event, you might be able to take action to control the timing of the event. AWS also sends an AWS Health event, which you can monitor and manage by using Amazon CloudWatch Events. For more information about monitoring AWS Health events with CloudWatch, see Monitoring AWS Health events with CloudWatch Events.

Scheduled events are managed by AWS; you cannot schedule events for your instances. You can view the events scheduled by AWS, customize scheduled event notifications to include or remove tags from the email notification, and perform actions when an instance is scheduled to reboot, retire, or stop.

To update the contact information for your account so that you can be sure to be notified about scheduled events, go to the Account Settings page.

Note
When an instance is affected by a scheduled event, and it is part of an Auto Scaling group, Amazon EC2 Auto Scaling eventually replaces it as part of its health checks, with no further action necessary on your part. For more information about the health checks performed by Amazon EC2 Auto Scaling, see Health checks for Auto Scaling instances in the Amazon EC2 Auto Scaling User Guide.

Contents
- Types of scheduled events (p. 1275)
- View scheduled events (p. 1275)
- Customize scheduled event notifications (p. 1279)
- Work with instances scheduled to stop or retire (p. 1281)
- Work with instances scheduled for reboot (p. 1282)
- Work with instances scheduled for maintenance (p. 1283)
- Reschedule a scheduled event (p. 1284)
- Define event windows for scheduled events (p. 1286)

Types of scheduled events

Amazon EC2 can create the following types of events for your instances, where the event occurs at a scheduled time:

- **Instance stop**: At the scheduled time, the instance is stopped. When you start it again, it's migrated to a new host. Applies only to instances backed by Amazon EBS.
- **Instance retirement**: At the scheduled time, the instance is stopped if it is backed by Amazon EBS, or terminated if it is backed by instance store.
- **Instance reboot**: At the scheduled time, the instance is rebooted.
- **System reboot**: At the scheduled time, the host for the instance is rebooted.
- **System maintenance**: At the scheduled time, the instance might be temporarily affected by network maintenance or power maintenance.

View scheduled events

In addition to receiving notification of scheduled events in email, you can check for scheduled events by using one of the following methods.
New console

To view scheduled events for your instances using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. The dashboard displays any resources with an associated event under Scheduled events.

3. For more detail, choose Events in the navigation pane. Any resources with an associated event are displayed. You can filter by characteristics such as event type, resource type, and Availability Zone.

Old console

To view scheduled events for your instances using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. You can view scheduled events in the following screens:
   - In the navigation pane, choose Events. Any resources with an associated event are displayed. You can filter by resource type, or by specific event types. You can select the resource to view details.
   - Alternatively, in the navigation pane, choose EC2 Dashboard. Any resources with an associated event are displayed under Scheduled Events.
Scheduled Events

US West (Oregon):
1 instances have scheduled events

- Some events are also shown for affected resources. For example, in the navigation pane, choose Instances and select an instance. If the instance has an associated instance stop or instance retirement event, it is displayed in the lower pane.

AWS CLI

To view scheduled events for your instances using the AWS CLI

Use the `describe-instance-status` command.

```bash
aws ec2 describe-instance-status
  --instance-id i-1234567890abcdef0
  --query "InstanceStatuses[].Events"
```

The following example output shows a reboot event.

```
[  
  {
    "InstanceEventId": "instance-event-0d59937288b749b32",
    "Code": "system-reboot",
    "Description": "The instance is scheduled for a reboot",
    "NotAfter": "2019-03-15T22:00:00.000Z",
    "NotBefore": "2019-03-14T20:00:00.000Z",
    "NotBeforeDeadline": "2019-04-05T11:00:00.000Z"
  }
]
```

The following example output shows an instance retirement event.

```
[  
  {
    "InstanceEventId": "instance-event-0e439355b779n26",
    "Code": "instance-stop",
    "Description": "The instance is running on degraded hardware",
    "NotBefore": "2015-05-23T00:00:00.000Z"
  }
]
```

PowerShell

To view scheduled events for your instances using the AWS Tools for Windows PowerShell

Use the following `Get-EC2InstanceStatus` command.
The following example output shows an instance retirement event.

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
<th>NotBefore</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance-stop</td>
<td>The instance is running on degraded hardware</td>
<td>5/23/2015 12:00:00 AM</td>
</tr>
</tbody>
</table>

### Instance metadata

#### To view scheduled events for your instances using instance metadata

You can retrieve information about active maintenance events for your instances from the instance metadata (p. 1004) by using Instance Metadata Service Version 2 or Instance Metadata Service Version 1.

**IMDSv2**

```
```

**IMDSv1**

```
```

The following is example output with information about a scheduled system reboot event, in JSON format.

```
[
  {
    "NotBefore" : "21 Jan 2019 09:00:43 GMT",
    "Code" : "system-reboot",
    "Description" : "scheduled reboot",
    "EventId" : "instance-event-0d59937288b749b32",
    "NotAfter" : "21 Jan 2019 09:17:23 GMT",
    "State" : "active"
  }
]
```

#### To view event history about completed or canceled events for your instances using instance metadata

You can retrieve information about completed or canceled events for your instances from instance metadata (p. 1004) by using Instance Metadata Service Version 2 or Instance Metadata Service Version 1.

**IMDSv2**

```
```

**IMDSv1**
The following is example output with information about a system reboot event that was canceled, and a system reboot event that was completed, in JSON format.

```
[
  {
    "NotBefore" : "21 Jan 2019 09:00:43 GMT",
    "Code" : "system-reboot",
    "Description" : "[Canceled] scheduled reboot",
    "EventId" : "instance-event-0d59937288b749b32",
    "NotAfter" : "21 Jan 2019 09:17:23 GMT",
    "State" : "canceled"
  },
  {
    "NotBefore" : "29 Jan 2019 09:00:43 GMT",
    "Code" : "system-reboot",
    "Description" : "[Completed] scheduled reboot",
    "EventId" : "instance-event-0d59937288b749b32",
    "NotAfter" : "29 Jan 2019 09:17:23 GMT",
    "State" : "completed"
  }
]
```

AWS Health

You can use the AWS Health Dashboard to learn about events that can affect your instance. The AWS Health Dashboard organizes issues in three groups: open issues, scheduled changes, and other notifications. The scheduled changes group contains items that are ongoing or upcoming.

For more information, see [Getting started with the AWS Health Dashboard](https://docs.aws.amazon.com/health/latest/ug/dashboard-intro.html) in the AWS Health User Guide.

Customize scheduled event notifications

You can customize scheduled event notifications to include tags in the email notification. This makes it easier to identify the affected resource (instances or Dedicated Hosts) and to prioritize actions for the upcoming event.

When you customize event notifications to include tags, you can choose to include:

- All of the tags that are associated with the affected resource
- Only specific tags that are associated with the affected resource

For example, suppose that you assign `application`, `costcenter`, `project`, and `owner` tags to all of your instances. You can choose to include all of the tags in event notifications. Alternatively, if you'd like to see only the `owner` and `project` tags in event notifications, then you can choose to include only those tags.

After you select the tags to include, the event notifications will include the resource ID (instance ID or Dedicated Host ID) and the tag key and value pairs that are associated with the affected resource.

Tasks

- [Include tags in event notifications](https://docs.aws.amazon.com/health/latest/ug/dashboard-intro.html)
- [Remove tags from event notifications](https://docs.aws.amazon.com/health/latest/ug/dashboard-intro.html)
- [View the tags to be included in event notifications](https://docs.aws.amazon.com/health/latest/ug/dashboard-intro.html)
Include tags in event notifications

The tags that you choose to include apply to all resources (instances and Dedicated Hosts) in the selected Region. To customize event notifications in other Regions, first select the required Region and then perform the following steps.

You can include tags in event notifications by using one of the following methods.

New console

To include tags in event notifications

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Actions, Manage event notifications.
4. Turn on Include tags in event notifications.
5. Do one of the following, depending on the tags that you want to include in event notifications:
   - To include all tags associated with the affected instance or Dedicated Host, select Include all tags.
   - To select the tags to include, select Choose the tags to include and then select or enter the tag keys.
6. Choose Save.

AWS CLI

To include all tags in event notifications

Use the register-instance-event-notification-attributes AWS CLI command and set the IncludeAllTagsOfInstance parameter to true.

```bash
aws ec2 register-instance-event-notification-attributes --instance-tag-attribute "IncludeAllTagsOfInstance=true"
```

To include specific tags in event notifications

Use the register-instance-event-notification-attributes AWS CLI command and specify the tags to include by using the InstanceTagKeys parameter.

```bash
aws ec2 register-instance-event-notification-attributes --instance-tag-attribute 'InstanceTagKeys=["tag_key_1", "tag_key_2", "tag_key_3"]'
```

Remove tags from event notifications

You can remove tags from event notifications by using one of the following methods.

New console

To remove tags from event notifications

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Actions, Manage event notifications.
4. To remove all tags from event notifications, turn off Include tags in event notifications.
5. To remove specific tags from event notifications, choose the X for the corresponding tag keys.
6. Choose Save.

**AWS CLI**

**To remove all tags from event notifications**

Use the `deregister-instance-event-notification-attributes` AWS CLI command and set the `IncludeAllTagsOfInstance` parameter to false.

```
aws ec2 deregister-instance-event-notification-attributes --instance-tag-attribute "IncludeAllTagsOfInstance=false"
```

**To remove specific tags from event notifications**

Use the `deregister-instance-event-notification-attributes` AWS CLI command and specify the tags to remove by using the `InstanceTagKeys` parameter.

```
aws ec2 deregister-instance-event-notification-attributes --instance-tag-attribute 'InstanceTagKeys=["tag_key_1", "tag_key_2", "tag_key_3"]'
```

**View the tags to be included in event notifications**

You can view the tags that are to be included in event notifications by using one of the following methods.

**New console**

**To view the tags that are to be included in event notifications**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Actions, Manage event notifications.

**AWS CLI**

**To view the tags that are to be included in event notifications**

Use the `describe-instance-event-notification-attributes` AWS CLI command.

```
aws ec2 describe-instance-event-notification-attributes
```

**Work with instances scheduled to stop or retire**

When AWS detects irreparable failure of the underlying host for your instance, it schedules the instance to stop or terminate, depending on the type of root device for the instance. If the root device is an EBS volume, the instance is scheduled to stop. If the root device is an instance store volume, the instance is scheduled to terminate. For more information, see Instance retirement (p. 797).

**Important**

Any data stored on instance store volumes is lost when an instance is stopped, hibernated, or terminated. This includes instance store volumes that are attached to an instance that has an
EBS volume as the root device. Be sure to save data from your instance store volumes that you might need later before the instance is stopped, hibernated, or terminated.

**Actions for Instances Backed by Amazon EBS**

You can wait for the instance to stop as scheduled. Alternatively, you can stop and start the instance yourself, which migrates it to a new host. For more information about stopping your instance, in addition to information about the changes to your instance configuration when it's stopped, see *Stop and start your instance* (p. 768).

You can automate an immediate stop and start in response to a scheduled instance stop event. For more information, see *Automating Actions for EC2 Instances* in the *AWS Health User Guide*.

**Actions for Instances Backed by Instance Store**

We recommend that you launch a replacement instance from your most recent AMI and migrate all necessary data to the replacement instance before the instance is scheduled to terminate. Then, you can terminate the original instance, or wait for it to terminate as scheduled.

**Work with instances scheduled for reboot**

When AWS must perform tasks such as installing updates or maintaining the underlying host, it can schedule the instance or the underlying host for a reboot. You can *reschedule most reboot events* (p. 1284) so that your instance is rebooted at a specific date and time that suits you.

**View the reboot event type**

You can view whether a reboot event is an instance reboot or a system reboot by using one of the following methods.

**New console**

**To view the type of scheduled reboot event using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose *Events*.
3. Choose *Resource type: instance* from the filter list.
4. For each instance, view the value in the *Event type* column. The value is either *system-reboot* or *instance-reboot*.

**Old console**

**To view the type of scheduled reboot event using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose *Events*.
3. Choose *Instance resources* from the filter list.
4. For each instance, view the value in the *Event Type* column. The value is either *system-reboot* or *instance-reboot*.

**AWS CLI**

**To view the type of scheduled reboot event using the AWS CLI**

Use the *describe-instance-status* command.
For scheduled reboot events, the value for Code is either system-reboot or instance-reboot. The following example output shows a system-reboot event.

```json
[  
    "Events": [  
      {  
        "InstanceEventId": "instance-event-0d5937288b749b32",  
        "Code": "system-reboot",  
        "Description": "The instance is scheduled for a reboot",  
        "NotAfter": "2019-03-14T22:00:00.000Z",  
        "NotBefore": "2019-03-14T20:00:00.000Z",  
        "NotBeforeDeadline": "2019-04-05T11:00:00.000Z"
      }
    ]
]
```

### Actions for instance reboot

You can wait for the instance reboot to occur within its scheduled maintenance window, reschedule (p. 1284) the instance reboot to a date and time that suits you, or reboot (p. 796) the instance yourself at a time that is convenient for you.

After your instance is rebooted, the scheduled event is cleared and the event's description is updated. The pending maintenance to the underlying host is completed, and you can begin using your instance again after it has fully booted.

### Actions for system reboot

It is not possible for you to reboot the system yourself. You can wait for the system reboot to occur during its scheduled maintenance window, or you can reschedule (p. 1284) the system reboot to a date and time that suits you. A system reboot typically completes in a matter of minutes. After the system reboot has occurred, the instance retains its IP address and DNS name, and any data on local instance store volumes is preserved. After the system reboot is complete, the scheduled event for the instance is cleared, and you can verify that the software on your instance is operating as expected.

Alternatively, if it is necessary to maintain the instance at a different time and you can't reschedule the system reboot, then you can stop and start an Amazon EBS-backed instance, which migrates it to a new host. However, the data on the local instance store volumes is not preserved. You can also automate an immediate instance stop and start in response to a scheduled system reboot event. For more information, see Automating Actions for EC2 Instances in the AWS Health User Guide. For an instance store-backed instance, if you can't reschedule the system reboot, then you can launch a replacement instance from your most recent AMI, migrate all necessary data to the replacement instance before the scheduled maintenance window, and then terminate the original instance.

### Work with instances scheduled for maintenance

When AWS must maintain the underlying host for an instance, it schedules the instance for maintenance. There are two types of maintenance events: network maintenance and power maintenance.

During network maintenance, scheduled instances lose network connectivity for a brief period of time. Normal network connectivity to your instance is restored after maintenance is complete.

During power maintenance, scheduled instances are taken offline for a brief period, and then rebooted. When a reboot is performed, all of your instance's configuration settings are retained.
After your instance has rebooted (this normally takes a few minutes), verify that your application is working as expected. At this point, your instance should no longer have a scheduled event associated with it, or if it does, the description of the scheduled event begins with [Completed]. It sometimes takes up to 1 hour for the instance status description to refresh. Completed maintenance events are displayed on the Amazon EC2 console dashboard for up to a week.

**Actions for Instances Backed by Amazon EBS**

You can wait for the maintenance to occur as scheduled. Alternatively, you can stop and start the instance, which migrates it to a new host. For more information about stopping your instance, in addition to information about the changes to your instance configuration when it's stopped, see [Stop and start your instance](p. 768).

You can automate an immediate stop and start in response to a scheduled maintenance event. For more information, see [Automating Actions for EC2 Instances](p. 1285) in the AWS Health User Guide.

**Actions for instances backed by instance store**

You can wait for the maintenance to occur as scheduled. Alternatively, if you want to maintain normal operation during a scheduled maintenance window, you can launch a replacement instance from your most recent AMI, migrate all necessary data to the replacement instance before the scheduled maintenance window, and then terminate the original instance.

**Reschedule a scheduled event**

You can reschedule an event so that it occurs at a specific date and time that suits you. Only events that have a deadline date can be rescheduled. There are other [limitations for rescheduling an event](p. 1285).

You can reschedule an event by using one of the following methods.

**New console**

**To reschedule an event using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Events**.
3. Choose **Resource type: instance** from the filter list.
4. Select one or more instances, and then choose **Actions, Schedule event**.

Only events that have an event deadline date, indicated by a value for **Deadline**, can be rescheduled. If one of the selected events does not have a deadline date, **Actions, Schedule event** is disabled.

5. For **New start time**, enter a new date and time for the event. The new date and time must occur before the **Event deadline**.
6. Choose **Save**.

It might take a minute or 2 for the updated event start time to be reflected in the console.

**Old console**

**To reschedule an event using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Events**.
3. Choose **Instance resources** from the filter list.
4. Select one or more instances, and then choose **Actions, Schedule Event**.
Scheduled events

Only events that have an event deadline date, indicated by a value for **Event Deadline**, can be rescheduled.

5. For **Event start time**, enter a new date and time for the event. The new date and time must occur before the **Event Deadline**.

6. Choose **Schedule Event**.

   It might take a minute or 2 for the updated event start time to be reflected in the console.

AWS CLI

**To reschedule an event using the AWS CLI**

1. Only events that have an event deadline date, indicated by a value for **NotBeforeDeadline**, can be rescheduled. Use the **describe-instance-status** command to view the **NotBeforeDeadline** parameter value.

   
   ```
   aws ec2 describe-instance-status --instance-id i-1234567890abcdef0
   ```

   The following example output shows a system-reboot event that can be rescheduled because **NotBeforeDeadline** contains a value.

   ```
   [   "Events": [     {       "InstanceEventId": "instance-event-0d59937288b749b32",       "Code": "system-reboot",       "Description": "The instance is scheduled for a reboot",       "NotAfter": "2019-03-14T22:00:00.000Z",       "NotBefore": "2019-03-14T20:00:00.000Z",       "NotBeforeDeadline": "2019-04-05T11:00:00.000Z"     }   ]
   ```

   2. To reschedule the event, use the **modify-instance-event-start-time** command. Specify the new event start time by using the **not-before** parameter. The new event start time must fall before the **NotBeforeDeadline**.

   ```
   aws ec2 modify-instance-event-start-time --instance-id i-1234567890abcdef0 --instance-event-id instance-event-0d59937288b749b32 --not-before 2019-03-25T10:00:00.000
   ```

   It might take a minute or 2 before the **describe-instance-status** command returns the updated **not-before** parameter value.

**Limitations**

- Only events with an event deadline date can be rescheduled. The event can be rescheduled up to the event deadline date. The **Deadline** column in the console and the **NotBeforeDeadline** field in the AWS CLI indicate if the event has a deadline date.

- Only events that have not yet started can be rescheduled. The **Start time** column in the console and the **NotBefore** field in the AWS CLI indicate the event start time. Events that are scheduled to start in the next 5 minutes cannot be rescheduled.

- The new event start time must be at least 60 minutes from the current time.
If you reschedule multiple events using the console, the event deadline date is determined by the event with the earliest event deadline date.

Define event windows for scheduled events

You can define custom event windows that recur weekly for scheduled events that reboot, stop, or terminate your Amazon EC2 instances. You can associate one or more instances with an event window. If a scheduled event for those instances is planned, AWS will schedule the events within the associated event window.

You can use event windows to maximize workload availability by specifying event windows that occur during off-peak periods for your workload. You can also align the event windows with your internal maintenance schedules.

You define an event window by specifying a set of time ranges. The minimum time range is 2 hours. The combined time ranges must total at least 4 hours.

You can associate one or more instances with an event window by using either instance IDs or instance tags. You can also associate Dedicated Hosts with an event window by using the host ID.

**Warning**
Event windows are applicable only for scheduled events that stop, reboot, or terminate instances.
Event windows are not applicable for:

- Expedited scheduled events and network maintenance events.
- Unscheduled maintenance such as AutoRecovery and unplanned reboots.

Work with event windows

- Considerations (p. 1286)
- View event windows (p. 1287)
- Create event windows (p. 1288)
- Modify event windows (p. 1292)
- Delete event windows (p. 1296)
- Tag event windows (p. 1297)

Considerations

- All event window times are in UTC.
- The minimum weekly event window duration is 4 hours.
- The time ranges within an event window must each be at least 2 hours.
- Only one target type (instance ID, Dedicated Host ID, or instance tag) can be associated with an event window.
- A target (instance ID, Dedicated Host ID, or instance tag) can only be associated with one event window.
- A maximum of 100 instance IDs, or 50 Dedicated Host IDs, or 50 instance tags can be associated with an event window. The instance tags can be associated with any number of instances.
- A maximum of 200 event windows can be created per AWS Region.
- Multiple instances that are associated with event windows can potentially have scheduled events occur at the same time.
- If AWS has already scheduled an event, modifying an event window won't change the time of the scheduled event. If the event has a deadline date, you can reschedule the event (p. 1284).
Scheduled events

- You can stop and start an instance prior to the scheduled event, which migrates the instance to a new host, and the scheduled event will no longer take place.

View event windows

You can view event windows by using one of the following methods.

Console

To view event windows using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Actions, Manage event windows.
4. Select an event window to view its details.

AWS CLI

To describe all event windows using the AWS CLI

Use the describe-instance-event-windows command.

aws ec2 describe-instance-event-windows \
--region us-east-1

Expected output

```
{
   "InstanceEventWindows": [
   {
      "InstanceEventWindowId": "iew-0abcdef1234567890",
      "Name": "myEventWindowName",
      "CronExpression": "* 21-23 * * 2,3",
      "AssociationTarget": {
         "InstanceIds": [
            "i-1234567890abcdef0",
            "i-0598c7d556eba48d7"
         ],
         "Tags": [],
         "DedicatedHostIds": []
      },
      "State": "active",
      "Tags": []
   }
   ...
   ],
   "NextToken": "9d624e0c-388b-4862-a31e-a85c64fc1d4a"
}
```

To describe a specific event window using the AWS CLI

Use the describe-instance-event-windows command with the --instance-event-window-id parameter to describe a specific event window.

aws ec2 describe-instance-event-windows \
--region us-east-1
To describe event windows that match one or more filters using the AWS CLI

Use the describe-instance-event-windows command with the --filters parameter. In the following example, the instance-id filter is used to describe all of the event windows that are associated with the specified instance.

When a filter is used, it performs a direct match. However, the instance-id filter is different. If there is no direct match to the instance ID, then it falls back to indirect associations with the event window, such as the instance's tags or Dedicated Host ID (if the instance is on a Dedicated Host).

For the list of supported filters, see describe-instance-event-windows in the AWS CLI Reference.

```
aws ec2 describe-instance-event-windows \
   --region us-east-1 \
   --filters Name=instance-id,Values=i-1234567890abcdef0 \
   --max-results 100 \
   --next-token <next-token-value>
```

Expected output

In the following example, the instance is on a Dedicated Host, which is associated with the event window.

```
{
   "InstanceEventWindows": [
      {
         "InstanceEventWindowId": "iew-0dbc0adb66f235982",
         "TimeRanges": [
            {
               "StartWeekDay": "sunday",
               "StartHour": 2,
               "EndWeekDay": "sunday",
               "EndHour": 8
            }
         ],
         "Name": "myEventWindowName",
         "AssociationTarget": {
            "InstanceIds": [],
            "Tags": [],
            "DedicatedHostIds": [
               "h-0140d9a7ecbd102dd"
            ]
         },
         "State": "active",
         "Tags": []
      }
   ]
}
```

Create event windows

You can create one or more event windows. For each event window, you specify one or more blocks of time. For example, you can create an event window with blocks of time that occur every day at 4 AM for 2 hours. Or you can create an event window with blocks of time that occur on Sundays from 2 AM to 4 AM and on Wednesdays from 3 AM to 5 AM.

For the event window constraints, see Considerations (p. 1286) earlier in this topic.
Event windows recur weekly until you delete them.

Use one of the following methods to create an event window.

Console

**To create an event window using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Create instance event window.
4. For **Event window name**, enter a descriptive name for the event window.
5. For **Event window schedule**, choose to specify the blocks of time in the event window by using the cron schedule builder or by specifying time ranges.

   - If you choose **Cron schedule builder**, specify the following:
     1. For **Days (UTC)**, specify the days of the week on which the event window occurs.
     2. For **Start time (UTC)**, specify the time when the event window begins.
     3. For **Duration**, specify the duration of the blocks of time in the event window. The minimum duration per block of time is 2 hours. The minimum duration of the event window must equal or exceed 4 hours in total. All times are in UTC.

   - If you choose **Time ranges**, choose **Add new time range** and specify the start day and time and the end day and time. Repeat for each time range. The minimum duration per time range is 2 hours. The minimum duration for all time ranges combined must equal or exceed 4 hours in total.

6. (Optional) For **Target details**, associate one or more instances with the event window so that if the instances are scheduled for maintenance, the scheduled event will occur during the associated event window. You can associate one or more instances with an event window by using instance IDs or instance tags. You can associate Dedicated Hosts with an event window by using the host ID.

   Note that you can create the event window without associating a target with the window. Later, you can modify the window to associate one or more targets.

7. (Optional) For **Event window tags**, choose **Add tag**, and enter the key and value for the tag. Repeat for each tag.
8. Choose **Create event window**.

AWS CLI

To create an event window using the AWS CLI, you first create the event window, and then you associate one or more targets with the event window.

**Create an event window**

You can define either a set of time ranges or a cron expression when creating the event window, but not both.

**To create an event window with a time range using the AWS CLI**

Use the `create-instance-event-window` command and specify the `--time-range` parameter. You can’t also specify the `--cron-expression` parameter.

```
aws ec2 create-instance-event-window
  --region us-east-1
  --time-range StartWeekDay=monday,StartHour=2,EndWeekDay=wednesday,EndHour=8
```
Scheduled events

**--tag-specifications** "ResourceType=instance-event-window,Tags=[{Key=K1,Value=V1}]"

\ 

**--name** myEventWindowName

**Expected output**

```
{
  "InstanceEventWindow": {
    "InstanceEventWindowId": "iew-0abcdef1234567890",
    "TimeRanges": [ 
      { 
        "StartWeekDay": "monday",
        "StartHour": 2,
        "EndWeekDay": "wednesday",
        "EndHour": 8 
      }
    ],
    "Name": "myEventWindowName",
    "State": "creating",
    "Tags": [ 
      { 
        "Key": "K1",
        "Value": "V1"
      }
    ]
  }
}
```

**To create an event window with a cron expression using the AWS CLI**

Use the `create-instance-event-window` command and specify the `--cron-expression` parameter. You can’t also specify the `--time-range` parameter.

```
aws ec2 create-instance-event-window \
  --region us-east-1 \
  --cron-expression "* 21-23 * * 2,3" \
  --tag-specifications "ResourceType=instance-event-window,Tags=[{Key=K1,Value=V1}]" \
  --name myEventWindowName
```

**Expected output**

```
{
  "InstanceEventWindow": {
    "InstanceEventWindowId": "iew-0abcdef1234567890",
    "Name": "myEventWindowName",
    "CronExpression": "* 21-23 * * 2,3",
    "State": "creating",
    "Tags": [ 
      { 
        "Key": "K1",
        "Value": "V1"
      }
    ]
  }
}
```

**Associate a target with an event window**

You can associate only one type of target (instance IDs, Dedicated Host IDs, or instance tags) with an event window.
To associate instance tags with an event window using the AWS CLI

Use the `associate-instance-event-window` command and specify the `instance-event-window-id` parameter to specify the event window. To associate instance tags, specify the `--association-target` parameter, and for the parameter values, specify one or more tags.

```
aws ec2 associate-instance-event-window
   --region us-east-1
   --instance-event-window-id iew-0abcdef1234567890
   --association-target "InstanceTags=[{Key=k2,Value=v2},{Key=k1,Value=v1}]"
```

Expected output

```
{
   "InstanceEventWindow": {
      "InstanceEventWindowId": "i-0abcdef1234567890",
      "Name": "myEventWindowName",
      "CronExpression": "* 21-23 * * 2,3",
      "AssociationTarget": {
         "InstanceIds": [],
         "Tags": [
            { "Key": "k2", "Value": "v2" },
            { "Key": "k1", "Value": "v1" }
         ],
         "DedicatedHostIds": []
      },
      "State": "creating"
   }
}
```

To associate one or more instances with an event window using the AWS CLI

Use the `associate-instance-event-window` command and specify the `instance-event-window-id` parameter to specify the event window. To associate instances, specify the `--association-target` parameter, and for the parameter values, specify one or more instance IDs.

```
aws ec2 associate-instance-event-window
   --region us-east-1
   --instance-event-window-id iew-0abcdef1234567890
   --association-target "InstanceIds=i-1234567890abcdef0,i-0598c7d356eba48d7"
```

Expected output

```
{
   "InstanceEventWindow": {
      "InstanceEventWindowId": "i-0abcdef1234567890",
      "Name": "myEventWindowName",
      "CronExpression": "* 21-23 * * 2,3",
      "AssociationTarget": {
         "InstanceIds": [
            "i-1234567890abcdef0",
            "i-0598c7d356eba48d7"
         ],
         "Tags": [],
         "DedicatedHostIds": []
      }
   }
}
```
To associate a Dedicated Host with an event window using the AWS CLI

Use the `associate-instance-event-window` command and specify the `instance-event-window-id` parameter to specify the event window. To associate a Dedicated Host, specify the `--association-target` parameter, and for the parameter values, specify one or more Dedicated Host IDs.

```
aws ec2 associate-instance-event-window \
  --region us-east-1 \
  --instance-event-window-id iew-0abcdef1234567890 \
  --association-target "DedicatedHostIds=h-029fa35a02b99801d"
```

Expected output

```
{
  "InstanceEventWindow": {
    "InstanceEventWindowId": "iew-0abcdef1234567890",
    "Name": "myEventWindowName",
    "CronExpression": "* 21-23 * * 2,3",
    "AssociationTarget": {
      "InstanceIds": [],
      "Tags": [],
      "DedicatedHostIds": ["h-029fa35a02b99801d"]
    },
    "State": "creating"
  }
}
```

Modify event windows

You can modify all of the fields of an event window except its ID. For example, when daylight savings begin, you might want to modify the event window schedule. For existing event windows, you might want to add or remove targets.

Use one of the following methods to modify an event window.

**Console**

**To modify an event window using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Events**.
3. Choose **Actions, Manage event windows**.
4. Select the event window to modify, and then choose **Actions, Modify instance event window**.
5. Modify the fields in the event window, and then choose **Modify event window**.

**AWS CLI**

To modify an event window using the AWS CLI, you can modify the time range or cron expression, and associate or disassociate one or more targets with the event window.
Modify the event window time

You can modify either a time range or a cron expression when modifying the event window, but not both.

To modify the time range of an event window using the AWS CLI

Use the `modify-instance-event-window` command and specify the event window to modify. Specify the `--time-range` parameter to modify the time range. You can't also specify the `--cron-expression` parameter.

```
aws ec2 modify-instance-event-window \
  --region us-east-1 \
  --instance-event-window-id iev-0abcdef1234567890 \
  --time-range StartWeekDay=monday,StartHour=2,EndWeekDay=wednesday,EndHour=8
```

Expected output

```json
{
  "InstanceEventWindow": {
    "InstanceEventWindowId": "iew-0abcdef1234567890",
    "TimeRanges": [
      {
        "StartWeekDay": "monday",
        "StartHour": 2,
        "EndWeekDay": "wednesday",
        "EndHour": 8
      }
    ],
    "Name": "myEventWindowName",
    "AssociationTarget": {
      "InstanceIds": [
        "i-0abcdef1234567890",
        "i-0be35f9acbbba01f0"
      ],
      "Tags": [],
      "DedicatedHostIds": []
    },
    "State": "creating",
    "Tags": [
      {
        "Key": "K1",
        "Value": "V1"
      }
    ]
  }
}
```

To modify a set of time ranges for an event window using the AWS CLI

Use the `modify-instance-event-window` command and specify the event window to modify. Specify the `--time-range` parameter to modify the time range. You can't also specify the `--cron-expression` parameter in the same call.

```
aws ec2 modify-instance-event-window \
  --region us-east-1 \
  --instance-event-window-id iev-0abcdef1234567890 \
  --time-range '[{"StartWeekDay": "monday", "StartHour": 2, "EndWeekDay": "wednesday", "EndHour": 8}],
  [{"StartWeekDay": "thursday", "StartHour": 2, "EndWeekDay": "friday", "EndHour": 8}]'
```
Expected output

```json
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "TimeRanges": [
            {
                "StartWeekDay": "monday",
                "StartHour": 2,
                "EndWeekDay": "wednesday",
                "EndHour": 8
            },
            {
                "StartWeekDay": "thursday",
                "StartHour": 2,
                "EndWeekDay": "friday",
                "EndHour": 8
            }
        ],
        "Name": "myEventWindowName",
        "AssociationTarget": {
            "InstanceIds": [
                "i-0abcdef1234567890",
                "i-0be35f9acbb8ba01f0"
            ],
            "Tags": [],
            "DedicatedHostIds": []
        },
        "State": "creating",
        "Tags": [
            {
                "Key": "K1",
                "Value": "V1"
            }
        ]
    }
}
```

To modify the cron expression of an event window using the AWS CLI

Use the `modify-instance-event-window` command and specify the event window to modify. Specify the `--cron-expression` parameter to modify the cron expression. You can't also specify the `--time-range` parameter.

```
aws ec2 modify-instance-event-window \
   --region us-east-1 \
   --instance-event-window-id iew-0abcdef1234567890 \
   --cron-expression \\n   "* 21-23 * * 2,3"
```

Expected output

```json
{
    "InstanceEventWindow": {
        "InstanceEventWindowId": "iew-0abcdef1234567890",
        "Name": "myEventWindowName",
        "CronExpression": \\n        "* 21-23 * * 2,3",
        "AssociationTarget": {
            "InstanceIds": [
                "i-0abcdef1234567890",
                "i-0be35f9acbb8ba01f0"
            ],
            "Tags": []
        }
    }
}```
Modify the targets associated with an event window

You can associate additional targets with an event window. You can also disassociate existing targets from an event window. However, only one type of target (instance IDs, Dedicated Host IDs, or instance tags) can be associated with an event window.

To associate additional targets with an event window

For the instructions on how to associate targets with an event window, see Associate a target with an event window.

To disassociate instance tags from an event window using the AWS CLI

Use the disassociate-instance-event-window command and specify the instance-event-window-id parameter to specify the event window. To disassociate instance tags, specify the --association-target parameter, and for the parameter values, specify one or more tags.

```
aws ec2 disassociate-instance-event-window \
  --region us-east-1 \
  --instance-event-window-id iew-0abcdef1234567890 \
  --association-target "InstanceTags=([{Key=k2,Value=v2},{Key=k1,Value=v1}]"
```

Expected output

```json
{
   "InstanceEventWindow": {
      "InstanceEventWindowId": "i-0abcdef1234567890",
      "Name": "myEventWindowName",
      "CronExpression": "* 21-23 * * 2,3",
      "AssociationTarget": {
         "InstanceIds": []
      },
      "Tags": []
   },
   "State": "creating"
}
```

To disassociate one or more instances from an event window using the AWS CLI

Use the disassociate-instance-event-window command and specify the instance-event-window-id parameter to specify the event window. To disassociate instances, specify the --association-target parameter, and for the parameter values, specify one or more instance IDs.

```
aws ec2 disassociate-instance-event-window \
  --region us-east-1 \
  --instance-event-window-id iew-0abcdef1234567890 \
  --association-target "InstanceIds=i-1234567890abcdef0,i-0598c7d356eba48d7"
```
Amazon Elastic Compute Cloud
User Guide for Linux Instances
Scheduled events

Expected output

```
{
  "InstanceState": {
    "InstanceStateId": "i-0abcdef1234567890",
    "InstanceId": "i-0abcdef1234567890",
    "State": "running"
  },
  "InstanceType": "c3.large",
  "LaunchTime": "2020-01-01T00:00:00Z"
}
```

To disassociate a Dedicated Host from an event window using the AWS CLI

Use the `disassociate-instance-event-window` command and specify the `instance-event-window-id` parameter to specify the event window. To disassociate a Dedicated Host, specify the `--association-target` parameter, and for the parameter values, specify one or more Dedicated Host IDs.

```
aws ec2 disassociate-instance-event-window \
  --region us-east-1 \
  --instance-event-window-id iew-0abcdef1234567890 \
  --association-target DedicatedHostIds=h-029fa35a02b99801d
```

Expected output

```
{
  "InstanceState": {
    "InstanceStateId": "i-0abcdef1234567890",
    "InstanceId": "i-0abcdef1234567890",
    "State": "running"
  },
  "InstanceType": "c3.large",
  "LaunchTime": "2020-01-01T00:00:00Z"
}
```

Delete event windows

You can delete one event window at a time by using one of the following methods.

**Console**

**To delete an event window using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Events**.
3. Choose **Actions, Manage event windows**.
4. Select the event window to delete, and then choose **Actions, Delete instance event window**.
5. When prompted, enter **delete**, and then choose **Delete**.

1296
AWS CLI

**To delete an event window using the AWS CLI**

Use the `delete-instance-event-window` command and specify the event window to delete.

```bash
aws ec2 delete-instance-event-window \
  --region us-east-1 \
  --instance-event-window-id iew-0abcdef1234567890
```

**To force delete an event window using the AWS CLI**

Use the `--force-delete` parameter if the event window is currently associated with targets.

```bash
aws ec2 delete-instance-event-window \
  --region us-east-1 \
  --instance-event-window-id iew-0abcdef1234567890 \
  --force-delete
```

**Expected output**

```json
{
  "InstanceEventWindowState": {
    "InstanceEventWindowId": "iew-0abcdef1234567890",
    "State": "deleting"
  }
}
```

**Tag event windows**

You can tag an event window when you create it, or afterwards.

To tag an event window when you create it, see Create event windows (p. 1288).

Use one of the following methods to tag an event window.

**Console**

**To tag an existing event window using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events.
3. Choose Actions, Manage event windows.
4. Select the event window to tag, and then choose Actions, Manage instance event window tags.
5. Choose Add tag to add a tag. Repeat for each tag.
6. Choose Save.

**AWS CLI**

**To tag an existing event window using the AWS CLI**

Use the `create-tags` command to tag existing resources. In the following example, the existing event window is tagged with Key=purpose and Value=test.

```bash
aws ec2 create-tags \
  --resources iew-0abcdef1234567890 \
  --tags Key=purpose,Value=test
```
Monitor your instances using CloudWatch

You can monitor your instances using Amazon CloudWatch, which collects and processes raw data from Amazon EC2 into readable, near real-time metrics. These statistics are recorded for a period of 15 months, so that you can access historical information and gain a better perspective on how your web application or service is performing.

By default, Amazon EC2 sends metric data to CloudWatch in 5-minute periods. To send metric data for your instance to CloudWatch in 1-minute periods, you can enable detailed monitoring on the instance. For more information, see Enable or turn off detailed monitoring for your instances (p. 1298).

The Amazon EC2 console displays a series of graphs based on the raw data from Amazon CloudWatch. Depending on your needs, you might prefer to get data for your instances from Amazon CloudWatch instead of the graphs in the console.

For Amazon CloudWatch billing and cost information, see CloudWatch billing and cost in the Amazon CloudWatch User Guide.

Contents
- Enable or turn off detailed monitoring for your instances (p. 1298)
- List the available CloudWatch metrics for your instances (p. 1300)
- Get statistics for metrics for your instances (p. 1313)
- Graph metrics for your instances (p. 1321)
- Create a CloudWatch alarm for an instance (p. 1321)
- Create alarms that stop, terminate, reboot, or recover an instance (p. 1322)

Enable or turn off detailed monitoring for your instances

By default, your instance is enabled for basic monitoring. You can optionally enable detailed monitoring.

The following table highlights the differences between basic monitoring and detailed monitoring for instances.

<table>
<thead>
<tr>
<th>Monitoring type</th>
<th>Description</th>
<th>Charges</th>
</tr>
</thead>
<tbody>
<tr>
<td>Basic monitoring</td>
<td>Only status check metrics are available in 1-minute periods.</td>
<td>No charge.</td>
</tr>
<tr>
<td></td>
<td>All other metrics are available in 5-minute periods.</td>
<td></td>
</tr>
<tr>
<td>Detailed monitoring</td>
<td>All metrics, including status check metrics, are available in 1-minute periods. To get this level of data, you must specifically enable it for the instance. For the instances where you've enabled detailed monitoring, you can also get aggregated data across groups of similar instances.</td>
<td>You are charged per metric that is sent to CloudWatch. You are not charged for data storage. For more information, see Paid tier and Example 1 - EC2 Detailed Monitoring on the Amazon CloudWatch pricing page.</td>
</tr>
</tbody>
</table>
Enable detailed monitoring

Topics

- Required IAM permissions (p. 1299)
- Enable detailed monitoring (p. 1299)
- Turn off detailed monitoring (p. 1299)

Required IAM permissions

To enable detailed monitoring for an instance, your user must have permission to use the MonitorInstances API action. To turn off detailed monitoring for an instance, your user must have permission to use the UnmonitorInstances API action.

Enable detailed monitoring

You can enable detailed monitoring on an instance as you launch it or after the instance is running or stopped. Enabling detailed monitoring on an instance does not affect the monitoring of the EBS volumes attached to the instance. For more information, see Amazon CloudWatch metrics for Amazon EBS (p. 2389).

Console

To enable detailed monitoring for an existing instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Actions, Monitoring, Manage detailed monitoring.
4. On the Detailed monitoring detail page, for Detailed monitoring, select the Enable check box.
5. Choose Save.

To enable detailed monitoring when launching an instance

When launching an instance using the AWS Management Console, select the Monitoring check box on the Configure Instance Details page.

AWS CLI

To enable detailed monitoring for an existing instance

Use the following monitor-instances command to enable detailed monitoring for the specified instances.

```
aws ec2 monitor-instances --instance-ids i-1234567890abcdef0
```

To enable detailed monitoring when launching an instance

Use the run-instances command with the --monitoring flag to enable detailed monitoring.

```
aws ec2 run-instances --image-id ami-09092360 --monitoring Enabled=true...
```

Turn off detailed monitoring

You can turn off detailed monitoring on an instance as you launch it or after the instance is running or stopped.
List the available CloudWatch metrics for your instances

Amazon EC2 sends metrics to Amazon CloudWatch. You can use the AWS Management Console, the AWS CLI, or an API to list the metrics that Amazon EC2 sends to CloudWatch. By default, each data point covers the 5 minutes that follow the start time of activity for the instance. If you've enabled detailed monitoring, each data point covers the next minute of activity from the start time. Note that for the Minimum, Maximum, and Average statistics, the minimum granularity for the metrics that EC2 provides is 1 minute.

For information about getting the statistics for these metrics, see Get statistics for metrics for your instances (p. 1313).

Contents

- Instance metrics (p. 1300)
- CPU credit metrics (p. 1304)
- Dedicated Host metrics (p. 1305)
- Amazon EBS metrics for Nitro-based instances (p. 1305)
- Status check metrics (p. 1308)
- Traffic mirroring metrics (p. 1308)
- Auto Scaling group metrics (p. 1309)
- Amazon EC2 metric dimensions (p. 1309)
- Amazon EC2 usage metrics (p. 1309)
- List metrics using the console (p. 1310)
- List metrics using the AWS CLI (p. 1312)

Instance metrics

The AWS/EC2 namespace includes the following instance metrics.

To turn off detailed monitoring

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Actions, Monitoring, Manage detailed monitoring.
4. On the Detailed monitoring detail page, for Detailed monitoring, clear the Enable check box.
5. Choose Save.

AWS CLI

To turn off detailed monitoring

Use the following unmonitor-instances command to turn off detailed monitoring for the specified instances.

```bash
aws ec2 unmonitor-instances --instance-ids i-1234567890abcdef0
```
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUUtilization</td>
<td>The percentage of physical CPU time that Amazon EC2 uses to run the EC2 instance, which includes time spent to run both the user code and the Amazon EC2 code.</td>
</tr>
<tr>
<td></td>
<td>At a very high level, CPUUtilization is the sum of guest CPUUtilization and hypervisor CPUUtilization.</td>
</tr>
<tr>
<td></td>
<td>Tools in your operating system can show a different percentage than CloudWatch due to factors such as legacy device simulation, configuration of non-legacy devices, interrupt-heavy workloads, live migration, and live update.</td>
</tr>
<tr>
<td></td>
<td>Units: Percent</td>
</tr>
<tr>
<td>DiskReadOps</td>
<td>Completed read operations from all instance store volumes available to the instance in a specified period of time.</td>
</tr>
<tr>
<td></td>
<td>To calculate the average I/O operations per second (IOPS) for the period, divide the total operations in the period by the number of seconds in that period.</td>
</tr>
<tr>
<td></td>
<td>If there are no instance store volumes, either the value is 0 or the metric is not reported.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>DiskWriteOps</td>
<td>Completed write operations to all instance store volumes available to the instance in a specified period of time.</td>
</tr>
<tr>
<td></td>
<td>To calculate the average I/O operations per second (IOPS) for the period, divide the total operations in the period by the number of seconds in that period.</td>
</tr>
<tr>
<td></td>
<td>If there are no instance store volumes, either the value is 0 or the metric is not reported.</td>
</tr>
<tr>
<td></td>
<td>Units: Count</td>
</tr>
<tr>
<td>DiskReadBytes</td>
<td>Bytes read from all instance store volumes available to the instance.</td>
</tr>
<tr>
<td></td>
<td>This metric is used to determine the volume of the data the application reads from the hard disk of the instance. This can be used to determine the speed of the application.</td>
</tr>
<tr>
<td></td>
<td>The number reported is the number of bytes received during the period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function DIFF_TIME to find the bytes per second. For example, if you have graphed DiskReadBytes in CloudWatch as m1, the metric math formula m1/(DIFF_TIME(m1)) returns the metric in bytes/second. For more information about DIFF_TIME and other metric math functions, see Use metric math in the Amazon CloudWatch User Guide.</td>
</tr>
</tbody>
</table>

1301
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DiskWriteBytes</td>
<td>Bytes written to all instance store volumes available to the instance. This metric is used to determine the volume of the data the application writes onto the hard disk of the instance. This can be used to determine the speed of the application. The number reported is the number of bytes received during the period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function DIFF_TIME to find the bytes per second. For example, if you have graphed DiskWriteBytes in CloudWatch as m1, the metric math formula m1/(DIFF_TIME(m1)) returns the metric in bytes/second. For more information about DIFF_TIME and other metric math functions, see Use metric math in the Amazon CloudWatch User Guide.</td>
</tr>
<tr>
<td>MetadataNoToken</td>
<td>The number of times the Instance Metadata Service was successfully accessed using a method that does not use a token. This metric is used to determine if there are any processes accessing instance metadata that are using Instance Metadata Service Version 1, which does not use a token. If all requests use token-backed sessions, i.e., Instance Metadata Service Version 2, the value is 0. For more information, see Transition to using Instance Metadata Service Version 2 (p. 1007).</td>
</tr>
<tr>
<td>NetworkIn</td>
<td>The number of bytes received by the instance on all network interfaces. This metric identifies the volume of incoming network traffic to a single instance. The number reported is the number of bytes received during the period. If you are using basic (5-minute) monitoring and the statistic is Sum, you can divide this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring and the statistic is Sum, divide it by 60. You can also use the CloudWatch metric math function DIFF_TIME to find the bytes per second. For example, if you have graphed NetworkIn in CloudWatch as m1, the metric math formula m1/(DIFF_TIME(m1)) returns the metric in bytes/second. For more information about DIFF_TIME and other metric math functions, see Use metric math in the Amazon CloudWatch User Guide.</td>

<tr>
<td>NetworkOut</td>
<td>The number of bytes sent out by the instance on all network interfaces. This metric identifies the volume of outgoing network traffic from a single instance. The number reported is the number of bytes sent during the period. If you are using basic (5-minute) monitoring and the statistic is Sum, you can divide this number by 300 to find Bytes/second. If you have detailed (1-minute) monitoring and the statistic is Sum, divide it by 60. You can also use the CloudWatch metric math function DIFF_TIME to find the bytes per second. For example, if you have graphed NetworkOut in CloudWatch as m1, the metric math formula m1/(DIFF_TIME(m1)) returns the metric in bytes/second. For more information about DIFF_TIME and other metric math functions, see Use metric math in the Amazon CloudWatch User Guide.</td>
</tr>
<tr>
<td>NetworkPacketsIn</td>
<td>The number of packets received by the instance on all network interfaces. This metric identifies the volume of incoming traffic in terms of the number of packets on a single instance. This metric is available for basic monitoring only (5-minute periods). To calculate the number of packets per second (PPS) your instance received for the 5 minutes, divide the Sum statistic value by 300. You can also use the CloudWatch metric math function DIFF_TIME to find the packets per second. For example, if you have graphed NetworkPacketsIn in CloudWatch as m1, the metric math formula m1/(DIFF_TIME(m1)) returns the metric in packets/second. For more information about DIFF_TIME and other metric math functions, see Use metric math in the Amazon CloudWatch User Guide.</td>
</tr>
<tr>
<td>NetworkPacketsOut</td>
<td>The number of packets sent out by the instance on all network interfaces. This metric identifies the volume of outgoing traffic in terms of the number of packets on a single instance. This metric is available for basic monitoring only (5-minute periods). To calculate the number of packets per second (PPS) your instance sent for the 5 minutes, divide the Sum statistic value by 300. You can also use the CloudWatch metric math function DIFF_TIME to find the packets per second. For example, if you have graphed NetworkPacketsOut in CloudWatch as m1, the metric math formula m1/(DIFF_TIME(m1)) returns the metric in packets/second. For more information about DIFF_TIME and other metric math functions, see Use metric math in the Amazon CloudWatch User Guide.</td>
</tr>
</tbody>
</table>
CPU credit metrics

The AWS/EC2 namespace includes the following CPU credit metrics for your burstable performance instances (p. 330).

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUCreditUsage</td>
<td>The number of CPU credits spent by the instance for CPU utilization. One CPU credit equals one vCPU running at 100% utilization for one minute or an equivalent combination of vCPUs, utilization, and time (for example, one vCPU running at 50% utilization for two minutes or two vCPUs running at 25% utilization for two minutes). CPU credit metrics are available at a 5-minute frequency only. If you specify a period greater than five minutes, use the Sum statistic instead of the Average statistic. Units: Credits (vCPU-minutes)</td>
</tr>
<tr>
<td>CPUCreditBalance</td>
<td>The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the CPUCreditBalance also includes the number of launch credits that have been accrued. Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits do not count towards the limit. The credits in the CPUCreditBalance are available for the instance to spend to burst beyond its baseline CPU utilization. When an instance is running, credits in the CPUCreditBalance do not expire. When a T3 or T3a instance stops, the CPUCreditBalance value persists for seven days. Thereafter, all accrued credits are lost. When a T2 instance stops, the CPUCreditBalance value does not persist, and all accrued credits are lost. CPU credit metrics are available at a 5-minute frequency only. Units: Credits (vCPU-minutes)</td>
</tr>
<tr>
<td>CPUSurplusCreditBalance</td>
<td>The number of surplus credits that have been spent by an unlimited instance when its CPUCreditBalance value is zero. The CPUSurplusCreditBalance value is paid down by earned CPU credits. If the number of surplus credits exceeds the maximum number of credits that the instance can earn in a 24-hour period, the spent surplus credits above the maximum incur an additional charge. CPU credit metrics are available at a 5-minute frequency only. Units: Credits (vCPU-minutes)</td>
</tr>
</tbody>
</table>
## List available metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPUSurplusCreditsCharged</td>
<td>The number of spent surplus credits that are not paid down by earned CPU credits, and which thus incur an additional charge.</td>
</tr>
<tr>
<td></td>
<td>Spent surplus credits are charged when any of the following occurs:</td>
</tr>
<tr>
<td></td>
<td>• The spent surplus credits exceed the maximum number of credits that the instance can earn in a 24-hour period. Spent surplus credits above the maximum are charged at the end of the hour.</td>
</tr>
<tr>
<td></td>
<td>• The instance is stopped or terminated.</td>
</tr>
<tr>
<td></td>
<td>• The instance is switched from unlimited to standard.</td>
</tr>
<tr>
<td></td>
<td>CPU credit metrics are available at a 5-minute frequency only.</td>
</tr>
<tr>
<td></td>
<td>Units: Credits (vCPU-minutes)</td>
</tr>
</tbody>
</table>

### Dedicated Host metrics

The AWS/EC2 namespace includes the following metrics for T3 Dedicated Hosts.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DedicatedHostCPUUtilization</td>
<td>The percentage of allocated compute capacity that is currently in use by the instances running on the Dedicated Host.</td>
</tr>
<tr>
<td></td>
<td>Unit: Percent</td>
</tr>
</tbody>
</table>

### Amazon EBS metrics for Nitro-based instances

The AWS/EC2 namespace includes additional Amazon EBS metrics for volumes that are attached to Nitro-based instances that are not bare metal instances.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBSReadOps</td>
<td>Completed read operations from all Amazon EBS volumes attached to the instance in a specified period of time.</td>
</tr>
<tr>
<td></td>
<td>To calculate the average read I/O operations per second (Read IOPS) for the period, divide the total operations in the period by the number of seconds in that period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to calculate the Read IOPS. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function DIFF_TIME to find the operations per second. For example, if you have graphed EBSReadOps in CloudWatch as m1, the metric math formula m1/ (DIFF_TIME(m1)) returns the metric in operations/second. For more information about DIFF_TIME and</td>

<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>other metric math functions, see <a href="#">Use metric math</a> in the <em>Amazon CloudWatch User Guide</em>.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td>EBSWriteOps</td>
<td>Completed write operations to all EBS volumes attached to the instance in a specified period of time.</td>
</tr>
<tr>
<td></td>
<td>To calculate the average write I/O operations per second (Write IOPS) for the period, divide the total operations in the period by the number of seconds in that period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to calculate the Write IOPS. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function <code>DIFF_TIME</code> to find the operations per second. For example, if you have graphed EBSWriteOps in CloudWatch as m1, the metric math formula <code>m1/(DIFF_TIME(m1))</code> returns the metric in operations/second. For more information about <code>DIFF_TIME</code> and other metric math functions, see <a href="#">Use metric math</a> in the <em>Amazon CloudWatch User Guide</em>.</td>
</tr>
<tr>
<td></td>
<td>Unit: Count</td>
</tr>
<tr>
<td>EBSReadBytes</td>
<td>Bytes read from all EBS volumes attached to the instance in a specified period of time.</td>
</tr>
<tr>
<td></td>
<td>The number reported is the number of bytes read during the period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to find Read Bytes/second. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function <code>DIFF_TIME</code> to find the bytes per second. For example, if you have graphed EBSReadBytes in CloudWatch as m1, the metric math formula <code>m1/(DIFF_TIME(m1))</code> returns the metric in bytes/second. For more information about <code>DIFF_TIME</code> and other metric math functions, see <a href="#">Use metric math</a> in the <em>Amazon CloudWatch User Guide</em>.</td>
</tr>
<tr>
<td></td>
<td>Unit: Bytes</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>

</tr>
<tr>
<td></td>
<td>The Sum statistic is not applicable to this metric.</td>
</tr>
<tr>
<td></td>
<td>Unit: Percent</td>
</tr>
</tbody>
</table>

For information about the metrics provided for your EBS volumes, see [Metrics for Amazon EBS volumes](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/metrics-for-amazon-ebsvolumes.html). For information about the metrics provided for your Spot fleets, see [CloudWatch metrics for Spot Fleet](https://docs.aws.amazon.com/AmazonCloudWatch/latest/api/audience-reference.html).
Status check metrics

By default, status check metrics are available at a 1-minute frequency at no charge. For a newly-launched instance, status check metric data is only available after the instance has completed the initialization state (within a few minutes of the instance entering the running state). For more information about EC2 status checks, see Status checks for your instances (p. 1267).

The AWS/EC2 namespace includes the following status check metrics.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>StatusCheckFailed</td>
<td>Reports whether the instance has passed both the instance status check and the system status check in the last minute. This metric can be either 0 (passed) or 1 (failed). By default, this metric is available at a 1-minute frequency at no charge. Units: Count</td>
</tr>
<tr>
<td>StatusCheckFailed_Instance</td>
<td>Reports whether the instance has passed the instance status check in the last minute. This metric can be either 0 (passed) or 1 (failed). By default, this metric is available at a 1-minute frequency at no charge. Units: Count</td>
</tr>
<tr>
<td>StatusCheckFailed_System</td>
<td>Reports whether the instance has passed the system status check in the last minute. This metric can be either 0 (passed) or 1 (failed). By default, this metric is available at a 1-minute frequency at no charge. Units: Count</td>
</tr>
<tr>
<td>StatusCheckFailed_AttachedEBS</td>
<td>Reports whether the instance has passed the attached EBS status check in the last minute. This metric can be either 0 (passed) or 1 (failed). By default, this metric is available at a 1-minute frequency at no charge. Units: Count</td>
</tr>
</tbody>
</table>

Traffic mirroring metrics

The AWS/EC2 namespace includes metrics for mirrored traffic. For more information, see Monitor mirrored traffic using Amazon CloudWatch in the Amazon VPC Traffic Mirroring Guide.
Auto Scaling group metrics

The AWS/AutoScaling namespace includes metrics for Auto Scaling groups. For more information, see Monitor CloudWatch metrics for your Auto Scaling groups and instances in the Amazon EC2 Auto Scaling User Guide.

Amazon EC2 metric dimensions

You can use the following dimensions to refine the metrics listed in the previous tables.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AutoScalingGroupName</td>
<td>This dimension filters the data you request for all instances in a specified capacity group. An Auto Scaling group is a collection of instances you define if you're using Auto Scaling. This dimension is available only for Amazon EC2 metrics when the instances are in such an Auto Scaling group. Available for instances with Detailed or Basic Monitoring enabled.</td>
</tr>
<tr>
<td>ImageId</td>
<td>This dimension filters the data you request for all instances running this Amazon EC2 Amazon Machine Image (AMI). Available for instances with Detailed Monitoring enabled.</td>
</tr>
<tr>
<td>InstanceId</td>
<td>This dimension filters the data you request for the identified instance only. This helps you pinpoint an exact instance from which to monitor data.</td>
</tr>
<tr>
<td>InstanceType</td>
<td>This dimension filters the data you request for all instances running with this specified instance type. This helps you categorize your data by the type of instance running. For example, you might compare data from an m1.small instance and an m1.large instance to determine which has the better business value for your application. Available for instances with Detailed Monitoring enabled.</td>
</tr>
</tbody>
</table>

Amazon EC2 usage metrics

You can use CloudWatch usage metrics to provide visibility into your account's usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

Amazon EC2 usage metrics correspond to AWS service quotas. You can configure alarms that alert you when your usage approaches a service quota. For more information about CloudWatch integration with service quotas, see AWS usage metrics in the Amazon CloudWatch User Guide.

Amazon EC2 publishes the following metrics in the AWS/Usage namespace.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourceCount</td>
<td>The number of the specified resources running in your account. The resources are defined by the dimensions associated with the metric. The most useful statistic for this metric is MAXIMUM, which represents the maximum number of resources used during the 1-minute period.</td>
</tr>
</tbody>
</table>
The following dimensions are used to refine the usage metrics that are published by Amazon EC2.

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service</td>
<td>The name of the AWS service containing the resource. For Amazon EC2 usage metrics, the value for this dimension is EC2.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of entity that is being reported. Currently, the only valid value for Amazon EC2 usage metrics is Resource.</td>
</tr>
<tr>
<td>Resource</td>
<td>The type of resource that is running. Currently, the only valid value for Amazon EC2 usage metrics is vCPU, which returns information on instances that are running.</td>
</tr>
<tr>
<td>Class</td>
<td>The class of resource being tracked. For Amazon EC2 usage metrics with vCPU as the value of the Resource dimension, the valid values are Standard/OnDemand, F/OnDemand, G/OnDemand, Inf/OnDemand, P/OnDemand, and X/OnDemand. The values for this dimension define the first letter of the instance types that are reported by the metric. For example, Standard/OnDemand returns information about all running instances with types that start with A, C, D, H, I, M, R, T, and Z, and G/OnDemand returns information about all running instances with types that start with G.</td>
</tr>
</tbody>
</table>

**List metrics using the console**

Metrics are grouped first by namespace, and then by the various dimension combinations within each namespace. For example, you can view all metrics provided by Amazon EC2, or metrics grouped by instance ID, instance type, image (AMI) ID, or Auto Scaling group.

**To view available metrics by category (console)**

2. In the navigation pane, choose Metrics.
3. Choose the EC2 metric namespace.
4. Select a metric dimension (for example, **Per-Instance Metrics**).
5. To sort the metrics, use the column heading. To graph a metric, select the check box next to the metric. To filter by resource, choose the resource ID and then choose Add to search. To filter by metric, choose the metric name and then choose Add to search.

List metrics using the AWS CLI

Use the list-metrics command to list the CloudWatch metrics for your instances.

To list all the available metrics for Amazon EC2 (AWS CLI)

The following example specifies the AWS/EC2 namespace to view all the metrics for Amazon EC2.

```
aws cloudwatch list-metrics --namespace AWS/EC2
```

The following is example output:

```
{
  "Metrics": [
    {
      "Namespace": "AWS/EC2",
      "Dimensions": [
        {
          "Name": "InstanceId",
          "Value": "i-1234567890abcdef0"
        }
      ],
      "MetricName": "NetworkOut"
    },
    {
      "Namespace": "AWS/EC2",
      "Dimensions": [
        {
          "Name": "InstanceId",
          "Value": "i-1234567890abcdef0"
        }
      ],
      "MetricName": "CPUUtilization"
    }
  ]
}
```
Get statistics for metrics for your instances

You can get statistics for the CloudWatch metrics for your instances.

Contents

- Statistics overview (p. 1313)
- Get statistics for a specific instance (p. 1314)
- Aggregate statistics across instances (p. 1317)
- Aggregate statistics by Auto Scaling group (p. 1319)
- Aggregate statistics by AMI (p. 1320)

Statistics overview

Statistics are metric data aggregations over specified periods of time. CloudWatch provides statistics based on the metric data points provided by your custom data or provided by other services in AWS to CloudWatch. Aggregations are made using the namespace, metric name, dimensions, and the data point unit of measure, within the time period you specify. The following table describes the available statistics.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum</td>
<td>The lowest value observed during the specified period. You can use this value to determine low volumes of activity for your application.</td>
</tr>
<tr>
<td>Statistic</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>Maximum</td>
<td>The highest value observed during the specified period. You can use this value to determine high volumes of activity for your application.</td>
</tr>
<tr>
<td>Sum</td>
<td>All values submitted for the matching metric added together. This statistic can be useful for determining the total volume of a metric.</td>
</tr>
<tr>
<td>Average</td>
<td>The value of Sum / SampleCount during the specified period. By comparing this statistic with the Minimum and Maximum, you can determine the full scope of a metric and how close the average use is to the Minimum and Maximum. This comparison helps you to know when to increase or decrease your resources as needed.</td>
</tr>
<tr>
<td>SampleCount</td>
<td>The count (number) of data points used for the statistical calculation.</td>
</tr>
<tr>
<td>pNN.NN</td>
<td>The value of the specified percentile. You can specify any percentile, using up to two decimal places (for example, p95.45).</td>
</tr>
</tbody>
</table>

Get statistics for a specific instance

The following examples show you how to use the AWS Management Console or the AWS CLI to determine the maximum CPU utilization of a specific EC2 instance.

Requirements

- You must have the ID of the instance. You can get the instance ID using the AWS Management Console or the `describe-instances` command.
- By default, basic monitoring is enabled, but you can enable detailed monitoring. For more information, see Enable or turn off detailed monitoring for your instances (p. 1298).

To display the CPU utilization for a specific instance (console)

2. In the navigation pane, choose Metrics.
3. Choose the EC2 metric namespace.
4. Choose the **Per-Instance Metrics** dimension.
5. In the search field, enter **CPUUtilization** and press Enter. Choose the row for the specific instance, which displays a graph for the **CPUUtilization** metric for the instance. To name the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose custom.

![Graph of CPUUtilization](image)

6. To change the statistic or the period for the metric, choose the **Graphed metrics** tab. Choose the column heading or an individual value, and then choose a different value.

**To get the CPU utilization for a specific instance (AWS CLI)**

Use the following `get-metric-statistics` command to get the **CPUUtilization** metric for the specified instance, using the specified period and time interval:

```bash
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name CPUUtilization --period 3600 --statistics Maximum --dimensions Name=InstanceId,Value=i-1234567890abcdef0 --start-time 2022-10-18T23:18:00 --end-time 2022-10-19T23:18:00
```

The following is example output. Each value represents the maximum CPU utilization percentage for a single EC2 instance.
Aggregate statistics across instances

Aggregate statistics are available for instances that have detailed monitoring enabled. Instances that use basic monitoring are not included in the aggregates. Before you can get statistics aggregated across instances, you must enable detailed monitoring (p. 1299) (at an additional charge), which provides data in 1-minute periods.

Note that Amazon CloudWatch cannot aggregate data across AWS Regions. Metrics are completely separate between Regions.

This example shows you how to use detailed monitoring to get the average CPU usage for your EC2 instances. Because no dimension is specified, CloudWatch returns statistics for all dimensions in the AWS/EC2 namespace.

Important
This technique for retrieving all dimensions across an AWS namespace does not work for custom namespaces that you publish to Amazon CloudWatch. With custom namespaces, you must specify the complete set of dimensions that are associated with any given data point to retrieve statistics that include the data point.

To display average CPU utilization across your instances (console)

2. In the navigation pane, choose Metrics.
3. Choose the EC2 namespace and then choose Across All Instances.
4. Choose the row that contains CPUUtilization, which displays a graph for the metric for all your EC2 instances. To name the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose custom.
5. To change the statistic or the period for the metric, choose the **Graphed metrics** tab. Choose the column heading or an individual value, and then choose a different value.

**To get average CPU utilization across your instances (AWS CLI)**

Use the `get-metric-statistics` command as follows to get the average of the `CPUUtilization` metric across your instances.

```bash
aws cloudwatch get-metric-statistics
   --namespace AWS/EC2
   --metric-name CPUUtilization
   --period 3600  --statistics "Average" "SampleCount"
   --start-time 2022-10-11T23:18:00
   --end-time 2022-10-12T23:18:00
```

The following is example output:

```json
{
   "Datapoints": [
      {
         "SampleCount": 238.0,
         "Timestamp": "2022-10-12T07:18:00Z",
         "Average": 0.038235294117647062,
         "Unit": "Percent"
      },
      {
         "SampleCount": 240.0,
         "Timestamp": "2022-10-12T09:18:00Z",
         "Average": 0.16670833333333332,
         "Unit": "Percent"
      },
      {
         "SampleCount": 240.0,
         "Timestamp": "2022-10-12T11:18:00Z",
         "Average": 0.16670833333333332,
         "Unit": "Percent"
      }
   ]
}
```
Aggregate statistics by Auto Scaling group

You can aggregate statistics for the EC2 instances in an Auto Scaling group. Note that Amazon CloudWatch cannot aggregate data across AWS Regions. Metrics are completely separate between Regions.

This example shows you how to retrieve the total bytes written to disk for one Auto Scaling group. The total is computed for 1-minute periods for a 24-hour interval across all EC2 instances in the specified Auto Scaling group.

To display DiskWriteBytes for the instances in an Auto Scaling group (console)

2. In the navigation pane, choose Metrics.
3. Choose the EC2 namespace and then choose By Auto Scaling Group.
4. Choose the row for the DiskWriteBytes metric and the specific Auto Scaling group, which displays a graph for the metric for the instances in the Auto Scaling group. To name the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose custom.
5. To change the statistic or the period for the metric, choose the Graphed metrics tab. Choose the column heading or an individual value, and then choose a different value.

To display DiskWriteBytes for the instances in an Auto Scaling group (AWS CLI)

Use the get-metric-statistics command as follows.

```
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name DiskWriteBytes --period 360 --statistics "Sum" "SampleCount" --dimensions Name=AutoScalingGroupName,Value=my-asg --start-time 2022-10-16T23:18:00 --end-time 2022-10-18T23:18:00
```

The following is example output:

```json
{
    "Datapoints": [
        {
            "SampleCount": 238.0,
            "Timestamp": "2022-10-11T23:18:00Z",
            "Average": 0.041596638655462197,
            "Unit": "Percent"
        },
        ...
    ],
    "Label": "CPUUtilization"
}
```
Aggregate statistics by AMI

You can aggregate statistics for your instances that have detailed monitoring enabled. Instances that use basic monitoring are not included in the aggregates. Before you can get statistics aggregated across instances, you must enable detailed monitoring (p. 1299) (at an additional charge), which provides data in 1-minute periods.

Note that Amazon CloudWatch cannot aggregate data across AWS Regions. Metrics are completely separate between Regions.

This example shows you how to determine average CPU utilization for all instances that use a specific Amazon Machine Image (AMI). The average is over 60-second time intervals for a one-day period.

To display the average CPU utilization by AMI (console)

2. In the navigation pane, choose Metrics.
3. Choose the EC2 namespace and then choose By Image (AMI) Id.
4. Choose the row for the CPUUtilization metric and the specific AMI, which displays a graph for the metric for the specified AMI. To name the graph, choose the pencil icon. To change the time range, select one of the predefined values or choose custom.
5. To change the statistic or the period for the metric, choose the Graphed metrics tab. Choose the column heading or an individual value, and then choose a different value.

To get the average CPU utilization for an image ID (AWS CLI)

Use the get-metric-statistics command as follows.

```
aws cloudwatch get-metric-statistics --namespace AWS/EC2 --metric-name CPUUtilization --period 3600 --statistics Average --dimensions Name=ImageId,Value=ami-3c47a355 --start-time 2022-10-10T00:00:00 --end-time 2022-10-11T00:00:00
```

The following is example output. Each value represents an average CPU utilization percentage for the EC2 instances running the specified AMI.

```
{
    "Datapoints": [
        { "Timestamp": "2022-10-10T07:00:00Z",
          "Average": 0.04100000000000001,  "Unit": "Percent"
        },
        { "Timestamp": "2022-10-10T14:00:00Z",
          "Average": 0.0795799831932779085,  "Unit": "Percent"
        },
        { "Timestamp": "2022-10-10T06:00:00Z",
          "Average": 0.036000000000000011,  "Unit": "Percent"
        },
        ...  
```
Graph metrics for your instances

After you launch an instance, you can open the Amazon EC2 console and view the monitoring graphs for the instance on the Monitoring tab. Each graph is based on one of the available Amazon EC2 metrics.

The following graphs are available:

- Average CPU Utilization (Percent)
- Average Disk Reads (Bytes)
- Average Disk Writes (Bytes)
- Maximum Network In (Bytes)
- Maximum Network Out (Bytes)
- Summary Disk Read Operations (Count)
- Summary Disk Write Operations (Count)
- Summary Status (Any)
- Summary Status Instance (Count)
- Summary Status System (Count)

For more information about the metrics and the data they provide to the graphs, see List the available CloudWatch metrics for your instances (p. 1300).

Graph metrics using the CloudWatch console

You can also use the CloudWatch console to graph metric data generated by Amazon EC2 and other AWS services. For more information, see Graphing metrics in the Amazon CloudWatch User Guide.

Create a CloudWatch alarm for an instance

You can create a CloudWatch alarm that monitors CloudWatch metrics for one of your instances. CloudWatch will automatically send you a notification when the metric reaches a threshold you specify. You can create a CloudWatch alarm using the Amazon EC2 console, or using the more advanced options provided by the CloudWatch console.

To create an alarm using the CloudWatch console

For examples, see Creating Amazon CloudWatch Alarms in the Amazon CloudWatch User Guide.

To create an alarm using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Actions, Monitor and troubleshoot, Manage CloudWatch alarms.
4. On the Manage CloudWatch alarms detail page, under Add or edit alarm, select Create an alarm.
5. For Alarm notification, choose whether to configure Amazon Simple Notification Service (Amazon SNS) notifications. Enter an existing Amazon SNS topic or enter a name to create a new topic.
6. For Alarm action, choose whether to specify an action to take when the alarm is triggered. Choose an action from the list.
For **Alarm thresholds**, select the metric and criteria for the alarm. For example, to create an alarm that is triggered when CPU utilization reaches 80% for a 5 minute period, do the following:

- Keep the default setting for **Group samples by (Average)** and **Type of data to sample (CPU utilization)**.
- Choose **>=** for **Alarm when** and enter **0.80** for **Percent**.
- Enter **1** for **Consecutive period** and select **5 minutes** for **Period**.

(Optional) For **Sample metric data**, choose **Add to dashboard**.

Choose **Create**.

You can edit your CloudWatch alarm settings from the Amazon EC2 console or the CloudWatch console. If you want to delete your alarm, you can do so from the CloudWatch console. For more information, see **Editing or deleting a CloudWatch alarm** in the *Amazon CloudWatch User Guide*.

**Create alarms that stop, terminate, reboot, or recover an instance**

Using Amazon CloudWatch alarm actions, you can create alarms that automatically stop, terminate, reboot, or recover your instances. You can use the stop or terminate actions to help you save money when you no longer need an instance to be running. You can use the reboot and recover actions to automatically reboot those instances or recover them onto new hardware if a system impairment occurs.

**Note**

For Amazon CloudWatch alarms billing and pricing information, see **CloudWatch billing and cost** in the *Amazon CloudWatch User Guide*.

The AWS/ServiceRoleForCloudWatchEvents service-linked role enables AWS to perform alarm actions on your behalf. The first time you create an alarm in the AWS Management Console, the AWS CLI, or the IAM API, CloudWatch creates the service-linked role for you.

There are a number of scenarios in which you might want to automatically stop or terminate your instance. For example, you might have instances dedicated to batch payroll processing jobs or scientific computing tasks that run for a period of time and then complete their work. Rather than letting those instances sit idle (and accrue charges), you can stop or terminate them, which can help you to save money. The main difference between using the stop and the terminate alarm actions is that you can easily start a stopped instance if you need to run it again later, and you can keep the same instance ID and root volume. However, you cannot start a terminated instance. Instead, you must launch a new instance. When an instance is stopped or terminated, data on instance store volumes is lost.

You can add the stop, terminate, reboot, or recover actions to any alarm that is set on an Amazon EC2 per-instance metric, including basic and detailed monitoring metrics provided by Amazon CloudWatch (in the AWS/EC2 namespace), as well as any custom metrics that include the **InstanceId** dimension, as long as its value refers to a valid running Amazon EC2 instance.

**Console support**

You can create alarms using the Amazon EC2 console or the CloudWatch console. The procedures in this documentation use the Amazon EC2 console. For procedures that use the CloudWatch console, see **Create alarms that stop, terminate, reboot, or recover an instance** in the *Amazon CloudWatch User Guide*.

**Permissions**

You must have the **iam:CreateServiceLinkedRole** to create or modify an alarm that performs EC2 alarm actions. A service role is an **IAM role** that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see **Creating a role to delegate permissions to an AWS service** in the *IAM User Guide*. 

---

1322
Add stop actions to Amazon CloudWatch alarms

You can create an alarm that stops an Amazon EC2 instance when a certain threshold has been met. For example, you may run development or test instances and occasionally forget to shut them off. You can create an alarm that is triggered when the average CPU utilization percentage has been lower than 10 percent for 24 hours, signaling that it is idle and no longer in use. You can adjust the threshold, duration, and period to suit your needs, plus you can add an Amazon Simple Notification Service (Amazon SNS) notification so that you receive an email when the alarm is triggered.

Instances that use an Amazon EBS volume as the root device can be stopped or terminated, whereas instances that use the instance store as the root device can only be terminated. Data on instance store volumes is lost when the instance is terminated or stopped.

To create an alarm to stop an idle instance (Amazon EC2 console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Actions, Monitor and troubleshoot, Manage CloudWatch alarms.

Alternatively, you can choose the plus sign (+) in the Alarm status column.

4. On the Manage CloudWatch alarms page, do the following:
   a. Choose Create an alarm.
   b. To receive an email when the alarm is triggered, for Alarm notification, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the Amazon Simple Notification Service Developer Guide.
   c. Toggle on Alarm action, and choose Stop.
   d. For Group samples by and Type of data to sample, choose a statistic and a metric. In this example, choose Average and CPU utilization.
   e. For Alarm When and Percent, specify the metric threshold. In this example, specify <= and 10 percent.
   f. For Consecutive period and Period, specify the evaluation period for the alarm. In this example, specify 1 consecutive period of 5 Minutes.
   g. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for Alarm name, enter a new name. Alarm names must contain only ASCII characters.

   **Note**
   You can adjust the alarm configuration based on your own requirements before creating the alarm, or you can edit them later. This includes the metric, threshold, duration, action, and notification settings. However, after you create an alarm, you cannot edit its name later.
   h. Choose Create.
Create alarms that stop, terminate, reboot, or recover an instance

Add terminate actions to Amazon CloudWatch alarms

You can create an alarm that terminates an EC2 instance automatically when a certain threshold has been met (as long as termination protection is not enabled for the instance). For example, you might want to terminate an instance when it has completed its work, and you don’t need the instance again. If you might want to use the instance later, you should stop the instance instead of terminating it. Data on instance store volumes is lost when the instance is terminated. For information about enabling and disabling termination protection for an instance, see Enable termination protection (p. 800).

To create an alarm to terminate an idle instance (Amazon EC2 console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Actions, Monitor and troubleshoot, Manage CloudWatch alarms.

Alternatively, you can choose the plus sign (+) in the Alarm status column.
4. On the Manage CloudWatch alarms page, do the following:
   a. Choose Create an alarm.
   b. To receive an email when the alarm is triggered, for Alarm notification, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the Amazon Simple Notification Service Developer Guide.
   c. Toggle on Alarm action, and choose Terminate.
   d. For Group samples by and Type of data to sample, choose a statistic and a metric. In this example, choose Average and CPU utilization.
   e. For Alarm When and Percent, specify the metric threshold. In this example, specify => and 10 percent.
   f. For Consecutive period and Period, specify the evaluation period for the alarm. In this example, specify 24 consecutive periods of 1 Hour.
   g. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for Alarm name, enter a new name. Alarm names must contain only ASCII characters.

       Note
       You can adjust the alarm configuration based on your own requirements before creating the alarm, or you can edit them later. This includes the metric, threshold, duration, action, and notification settings. However, after you create an alarm, you cannot edit its name later.
   h. Choose Create.

Add reboot actions to Amazon CloudWatch alarms

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically reboots the instance. The reboot alarm action is recommended for Instance Health Check failures (as opposed to the recover alarm action, which is suited for System Health Check failures). An instance reboot is equivalent to an operating system reboot. In most cases, it takes only a few minutes to reboot your instance. When you reboot an instance, it remains on the same physical host, so your instance keeps its public DNS name, private IP address, and any data on its instance store volumes.

Rebooting an instance doesn't start a new instance billing period (with a minimum one-minute charge), unlike stopping and restarting your instance. Data on instance store volumes is retained when the instance is rebooted. The instance store volumes must be re-mounted into the filesystem after a reboot. For more information, see Reboot your instance (p. 796).
Important
To avoid a race condition between the reboot and recover actions, avoid setting the same number of evaluation periods for a reboot alarm and a recover alarm. We recommend that you set reboot alarms to three evaluation periods of one minute each. For more information, see Evaluating an alarm in the Amazon CloudWatch User Guide.

To create an alarm to reboot an instance (Amazon EC2 console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Actions, Monitor and troubleshoot, Manage CloudWatch alarms.

Alternatively, you can choose the plus sign (+) in the Alarm status column.

4. On the Manage CloudWatch alarms page, do the following:
   a. Choose Create an alarm.
   b. To receive an email when the alarm is triggered, for Alarm notification, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the Amazon Simple Notification Service Developer Guide.
   c. Toggle on Alarm action, and choose Reboot.
   d. For Group samples by and Type of data to sample, choose a statistic and a metric. In this example, choose Average and Status check failed: instance.
   e. For Consecutive period and Period, specify the evaluation period for the alarm. In this example, enter 3 consecutive periods of 5 Minutes.
   f. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for Alarm name, enter a new name. Alarm names must contain only ASCII characters.
   g. Choose Create.

Add recover actions to Amazon CloudWatch alarms

You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance. If the instance becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair, you can automatically recover the instance. Terminated instances cannot be recovered. A recovered instance is identical to the original instance, including the instance ID, private IP addresses, Elastic IP addresses, and all instance metadata.

CloudWatch prevents you from adding a recovery action to an alarm that is on an instance which does not support recovery actions.

When the StatusCheckFailed_System alarm is triggered, and the recover action is initiated, you are notified by the Amazon SNS topic that you chose when you created the alarm and associated the recover action. During instance recovery, the instance is migrated during an instance reboot, and any data that is in-memory is lost. When the process is complete, information is published to the SNS topic you’ve configured for the alarm. Anyone who is subscribed to this SNS topic receives an email notification that includes the status of the recovery attempt and any further instructions. You notice an instance reboot on the recovered instance.

Note
The recover action can be used only with StatusCheckFailed_System, not with StatusCheckFailed_Instance.

The following problems can cause system status checks to fail:

- Loss of network connectivity
Create alarms that stop, terminate, reboot, or recover an instance

- Loss of system power
- Software issues on the physical host
- Hardware issues on the physical host that impact network reachability

The recover action is supported only on instances that meet certain characteristics. For more information, see Recover your instance.

If your instance has a public IP address, it retains the public IP address after recovery.

**Important**

To avoid a race condition between the reboot and recover actions, avoid setting the same number of evaluation periods for a reboot alarm and a recover alarm. We recommend that you set recover alarms to two evaluation periods of one minute each. For more information, see Evaluating an alarm in the Amazon CloudWatch User Guide.

**To create an alarm to recover an instance (Amazon EC2 console)**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Actions, Monitor and troubleshoot, Manage CloudWatch alarms.

Alternatively, you can choose the plus sign (+) in the Alarm status column.

4. On the Manage CloudWatch alarms page, do the following:
   a. Choose Create an alarm.
   b. To receive an email when the alarm is triggered, for Alarm notification, choose an existing Amazon SNS topic. You first need to create an Amazon SNS topic using the Amazon SNS console. For more information, see Using Amazon SNS for application-to-person (A2P) messaging in the Amazon Simple Notification Service Developer Guide.

   **Note**

   Users must subscribe to the specified SNS topic to receive email notifications when the alarm is triggered. The AWS account root user always receives email notifications when automatic instance recovery actions occur, even if an SNS topic is not specified or the root user is not subscribed to the specified SNS topic.

   c. Toggle on Alarm action, and choose Recover.
   d. For Group samples by and Type of data to sample, choose a statistic and a metric. In this example, choose Average and Status check failed: system.
   e. For Consecutive period and Period, specify the evaluation period for the alarm. In this example, enter 2 consecutive periods of 5 Minutes.
   f. Amazon CloudWatch automatically creates an alarm name for you. To change the name, for Alarm name, enter a new name. Alarm names must contain only ASCII characters.
   g. Choose Create.

**Use the Amazon CloudWatch console to view alarm and action history**

You can view alarm and action history in the Amazon CloudWatch console. Amazon CloudWatch keeps the last two weeks’ worth of alarm and action history.

**To view the history of triggered alarms and actions (CloudWatch console)**

Create alarms that stop, terminate, reboot, or recover an instance

2. In the navigation pane, choose Alarms.
3. Select an alarm.
4. The Details tab shows the most recent state transition along with the time and metric values.
5. Choose the History tab to view the most recent history entries.

Amazon CloudWatch alarm action scenarios

You can use the Amazon EC2 console to create alarm actions that stop or terminate an Amazon EC2 instance when certain conditions are met. In the following screen capture of the console page where you set the alarm actions, we've numbered the settings. We've also numbered the settings in the scenarios that follow, to help you create the appropriate actions.

New console

```
<table>
<thead>
<tr>
<th>Alarm notification</th>
<th>Info</th>
<th>Choose an existing topic or enter a name to create a new topic</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>

Create alarms that stop, terminate, reboot, or recover an instance

### Scenario 1: Stop idle development and test instances
Create an alarm that stops an instance used for software development or testing when it has been idle for at least an hour.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Stop</td>
</tr>
<tr>
<td>2</td>
<td>Maximum</td>
</tr>
<tr>
<td>3</td>
<td>CPU Utilization</td>
</tr>
<tr>
<td>4</td>
<td>&lt;=</td>
</tr>
<tr>
<td>5</td>
<td>10%</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>1 Hour</td>
</tr>
</tbody>
</table>

### Scenario 2: Stop idle instances
Create an alarm that stops an instance and sends an email when the instance has been idle for 24 hours.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Stop and email</td>
</tr>
<tr>
<td>2</td>
<td>Average</td>
</tr>
<tr>
<td>3</td>
<td>CPU Utilization</td>
</tr>
<tr>
<td>4</td>
<td>&lt;=</td>
</tr>
<tr>
<td>5</td>
<td>5%</td>
</tr>
</tbody>
</table>
Create alarms that stop, terminate, reboot, or recover an instance

### Scenario 3: Send email about web servers with unusually high traffic

Create an alarm that sends email when an instance exceeds 10 GB of outbound network traffic per day.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Email</td>
</tr>
<tr>
<td>2</td>
<td>Sum</td>
</tr>
<tr>
<td>3</td>
<td>Network Out</td>
</tr>
<tr>
<td>4</td>
<td>&gt;</td>
</tr>
<tr>
<td>5</td>
<td>10 GB</td>
</tr>
<tr>
<td>6</td>
<td>24</td>
</tr>
<tr>
<td>7</td>
<td>1 Hour</td>
</tr>
</tbody>
</table>

### Scenario 4: Stop web servers with unusually high traffic

Create an alarm that stops an instance and send a text message (SMS) if outbound traffic exceeds 1 GB per hour.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Stop and send SMS</td>
</tr>
<tr>
<td>2</td>
<td>Sum</td>
</tr>
<tr>
<td>3</td>
<td>Network Out</td>
</tr>
<tr>
<td>4</td>
<td>&gt;</td>
</tr>
<tr>
<td>5</td>
<td>1 GB</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>1 Hour</td>
</tr>
</tbody>
</table>

### Scenario 5: Stop an impaired instance

Create an alarm that stops an instance that fails three consecutive status checks (performed at 5-minute intervals).

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Stop</td>
</tr>
</tbody>
</table>
Automate using EventBridge

**Scenario 6: Terminate instances when batch processing jobs are complete**

Create an alarm that terminates an instance that runs batch jobs when it is no longer sending results data.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Terminate</td>
</tr>
<tr>
<td>2</td>
<td>Maximum</td>
</tr>
<tr>
<td>3</td>
<td>Network Out</td>
</tr>
<tr>
<td>4</td>
<td>&lt;=</td>
</tr>
<tr>
<td>5</td>
<td>100,000 bytes</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>5 Minutes</td>
</tr>
</tbody>
</table>

**Automate Amazon EC2 using EventBridge**

You can use Amazon EventBridge to automate your AWS services and respond automatically to system events, such as application availability issues or resource changes. Events from AWS services are delivered to EventBridge in near real time. You can create rules to indicate which events you're interested in, and the actions to take when an event matches a rule. The actions that can be automatically triggered include the following:

- Invoke an AWS Lambda function
- Invoke Amazon EC2 Run Command
- Relay the event to Amazon Kinesis Data Streams
- Activate an AWS Step Functions state machine
- Notify an Amazon SNS topic
- Notify an Amazon SQS queue

The following are examples of how you can use EventBridge with Amazon EC2:

- Activate a Lambda function whenever an instance enters the running state.
- Notify an Amazon SNS topic when an Amazon EBS volume is created or modified.
• Send a command to one or more Amazon EC2 instances using Amazon EC2 Run Command whenever a certain event in another AWS service occurs.

For more information, see the Amazon EventBridge User Guide.

Amazon EC2 event types

Amazon EC2 supports the following event types:

- EC2 AMI State Change (p. 244)
- EC2 Fleet Error (p. 1210)
- EC2 Fleet Information (p. 1210)
- EC2 Fleet Instance Change (p. 1209)
- EC2 Fleet Spot Instance Request Change (p. 1208)
- EC2 Fleet State Change (p. 1207)
- EC2 Instance Rebalance Recommendation (p. 585)
- EC2 Instance State-change Notification (p. 1273)
- EC2 Spot Fleet Error (p. 1215)
- EC2 Spot Fleet Information (p. 1214)
- EC2 Spot Fleet Instance Change (p. 1213)
- EC2 Spot Fleet Spot Instance Request Change (p. 1213)
- EC2 Spot Fleet State Change (p. 1212)
- EC2 Spot Instance Interruption Warning (p. 594)
- EC2 Spot Instance Request Fulfillment (p. 583)
- EC2 ODCR Underutilization Notification (p. 697)

For information about the event types supported by Amazon EBS, see the section called "EBS EventBridge events" (p. 2400).

Monitor memory and disk metrics for Amazon EC2 Linux instances

You can use Amazon CloudWatch to collect metrics and logs from the operating systems for your EC2 instances.

**Important**
The CloudWatch monitoring scripts are deprecated. We strongly recommend that you use the CloudWatch agent to collect metrics and logs. For more information, see Collect Metrics from Amazon EC2 Instances and On-Premises Servers with the CloudWatch Agent in the Amazon CloudWatch User Guide.

If you are still migrating from the deprecated monitoring scripts to the agent, and require information about the monitoring scripts, see Deprecated: Collect metrics using the CloudWatch monitoring scripts (p. 1332).

Collect metrics using the CloudWatch agent

You can use the CloudWatch agent to collect both system metrics and log files from Amazon EC2 instances and on-premises servers. The agent supports both Windows Server and Linux, and enables you to select the metrics to be collected, including sub-resource metrics such as per-CPU core.
Deprecated: Collect metrics using the CloudWatch monitoring scripts

**Important**

The CloudWatch monitoring scripts are deprecated. This page provides information about those monitoring scripts for customers who are still using them, but the monitoring scripts are no longer available.

We strongly recommend that you use the CloudWatch agent to collect metrics and logs. For more information, see [Collect metrics and logs from Amazon EC2 instances and on-premises servers with the CloudWatch agent](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/aws-monitoring-cloudwatch-agent.html) in the *Amazon CloudWatch User Guide*.

The monitoring scripts demonstrate how to produce and consume custom metrics for Amazon CloudWatch. These sample Perl scripts comprise a fully functional example that reports memory, swap, and disk space utilization metrics for a Linux instance.

Standard Amazon CloudWatch usage charges for custom metrics apply to your use of these scripts. For more information, see the [Amazon CloudWatch](https://aws.amazon.com/cloudwatch/pricing/) pricing page.

**Contents**

- [Supported systems](#) (p. 1332)
- [Required permissions](#) (p. 1332)
- [Install required packages](#) (p. 1333)
- [Install monitoring scripts](#) (p. 1334)
- [mon-put-instance-data.pl](#) (p. 1335)
- [mon-get-instance-stats.pl](#) (p. 1338)
- [View your custom metrics in the console](#) (p. 1339)
- [Troubleshoot](#) (p. 1339)

**Supported systems**

The monitoring scripts were tested on instances using the following systems. Using the monitoring scripts on any other operating system is unsupported.

- Amazon Linux 2
- Amazon Linux AMI 2014.09.2 and later
- Red Hat Enterprise Linux 6.9 and 7.4
- SUSE Linux Enterprise Server 12
- Ubuntu Server 14.04 and 16.04

**Required permissions**

Ensure that the scripts have permission to call the following actions by associating an IAM role with your instance:

- `cloudwatch:PutMetricData`
- `cloudwatch:GetMetricStatistics`
- `cloudwatch:ListMetrics`
For more information, see Work with IAM roles (p. 1998).

Install required packages

With some versions of Linux, you must install additional Perl modules before you can use the monitoring scripts.

To install the required packages on Amazon Linux 2 and Amazon Linux AMI

1. Log on to your instance. For more information, see Connect to your Linux instance (p. 811).
2. At a command prompt, install packages as follows:

```
sudo yum install -y perl-Switch perl-DateTime perl-Sys-Syslog perl-LWP-Protocol-https perl-Digest-SHA.x86_64
```

To install the required packages on Ubuntu

1. Log on to your instance. For more information, see Connect to your Linux instance (p. 811).
2. At a command prompt, install packages as follows:

```
sudo apt-get update
sic
dudo apt-get install unzip
sudo apt-get install libwww-perl libdatetime-perl
```

To install the required packages on Red Hat Enterprise Linux 7

1. Log on to your instance. For more information, see Connect to your Linux instance (p. 811).
2. At a command prompt, install packages as follows:

```
sudo yum install perl-Switch perl-DateTime perl-Sys-Syslog perl-LWP-Protocol-https perl-Digest-SHA --enablerepo="rhui-REGION-rhel-server-optional" -y
sudo yum install zip unzip
```

To install the required packages on Red Hat Enterprise Linux 6.9

1. Log on to your instance. For more information, see Connect to your Linux instance (p. 811).
2. At a command prompt, install packages as follows:

```
sudo yum install perl-DateTime perl-CPAN perl-Net-SSLeay perl-IO-Socket-SSL perl-Digest-SHA gcc -y
sudo yum install zip unzip
```

3. Run CPAN as an elevated user:

```
sudo cpan
```

Press ENTER through the prompts until you see the following prompt:

```
cpan[1]>
4. At the CPAN prompt, run each of the below commands: run one command and it installs, and when you return to the CPAN prompt, run the next command. Press ENTER like before when prompted to continue through the process:

```
cpan[1]> install YAML
cpan[2]> install LWP::Protocol::https
cpan[3]> install Sys::Syslog
ncpan[4]> install Switch
```

To install the required packages on SUSE

1. Log on to your instance. For more information, see [Connect to your Linux instance](p. 811).
2. On servers running SUSE Linux Enterprise Server 12, you might need to download the perl-Switch package. You can download and install this package using the following commands:

```
sudo rpm -i perl-Switch-2.17-32.1.noarch.rpm
```
3. Install the required packages as follows:

```
sudo zypper install perl-Switch perl-DateTime
sudo zypper install -y "perl(LWP::Protocol::https)"
```

Install monitoring scripts

The following steps show you how to download, uncompress, and configure the CloudWatch monitoring scripts on an EC2 Linux instance.

To download, install, and configure the monitoring scripts

1. At a command prompt, move to a folder where you want to store the monitoring scripts and run the following command to download them:

```
curl https://aws-cloudwatch.s3.amazonaws.com/downloads/CloudWatchMonitoringScripts-1.2.2.zip -O
```
2. Run the following commands to install the monitoring scripts you downloaded:

```
unzip CloudWatchMonitoringScripts-1.2.2.zip && 
rm CloudWatchMonitoringScripts-1.2.2.zip && 
  cd aws-scripts-mon
```

The package for the monitoring scripts contains the following files:

- **CloudWatchClient.pm** – Shared Perl module that simplifies calling Amazon CloudWatch from other scripts.
- **mon-put-instance-data.pl** – Collects system metrics on an Amazon EC2 instance (memory, swap, disk space utilization) and sends them to Amazon CloudWatch.
- **mon-get-instance-stats.pl** – Queries Amazon CloudWatch and displays the most recent utilization statistics for the EC2 instance on which this script is run.
- **awscreds.template** – File template for AWS credentials that stores your access key ID and secret access key.
mon-put-instance-data.pl

This script collects memory, swap, and disk space utilization data on the current system. It then makes a remote call to Amazon CloudWatch to report the collected data as custom metrics.

Options

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--mem-util</td>
<td>Collects and sends the MemoryUtilization metrics in percentages. This metric counts memory allocated by applications and the operating system as used, and also includes cache and buffer memory as used if you specify the --mem-used-incl-cache-buff option.</td>
</tr>
<tr>
<td>--mem-used</td>
<td>Collects and sends the MemoryUsed metrics, reported in megabytes. This metric counts memory allocated by applications and the operating system as used, and also includes cache and buffer memory as used if you specify the --mem-used-incl-cache-buff option.</td>
</tr>
<tr>
<td>--mem-used-incl-cache-buff</td>
<td>If you include this option, memory currently used for cache and buffers is counted as &quot;used&quot; when the metrics are reported for --mem-util, --mem-used, and --mem-avail.</td>
</tr>
<tr>
<td>--mem-avail</td>
<td>Collects and sends the MemoryAvailable metrics, reported in megabytes. This metric counts memory allocated by applications and the operating system as used, and also includes cache and buffer memory as used if you specify the --mem-used-incl-cache-buff option.</td>
</tr>
<tr>
<td>--swap-util</td>
<td>Collects and sends SwapUtilization metrics, reported in percentages.</td>
</tr>
<tr>
<td>--swap-used</td>
<td>Collects and sends SwapUsed metrics, reported in megabytes.</td>
</tr>
<tr>
<td>--disk-path=PATH</td>
<td>Selects the disk on which to report. PATH can specify a mount point or any file located on a mount point for the filesystem that needs to be reported. For selecting multiple disks, specify a --disk-path=PATH for each one of them.</td>
</tr>
<tr>
<td></td>
<td>To select a disk for the filesystems mounted on / and /home, use the following parameters:</td>
</tr>
<tr>
<td></td>
<td>--disk-path=/ --disk-path=/home</td>
</tr>
<tr>
<td>--disk-space-util</td>
<td>Collects and sends the DiskSpaceUtilization metric for the selected disks. The metric is reported in percentages. Note that the disk utilization metrics calculated by this script differ from the values calculated by the df -k -l command. If you find the values from df -k -l more useful, you can change the calculations in the script.</td>
</tr>
</tbody>
</table>
### Name | Description
--- | ---
--disk-space-used | Collects and sends the DiskSpaceUsed metric for the selected disks. The metric is reported by default in gigabytes. Due to reserved disk space in Linux operating systems, disk space used and disk space available might not accurately add up to the amount of total disk space.

--disk-space-avail | Collects and sends the DiskSpaceAvailable metric for the selected disks. The metric is reported in gigabytes. Due to reserved disk space in the Linux operating systems, disk space used and disk space available might not accurately add up to the amount of total disk space.

--memory-units=UNITS | Specifies units in which to report memory usage. If not specified, memory is reported in megabytes. UNITS may be one of the following: bytes, kilobytes, megabytes, gigabytes.

--disk-space-units=UNITS | Specifies units in which to report disk space usage. If not specified, disk space is reported in gigabytes. UNITS may be one of the following: bytes, kilobytes, megabytes, gigabytes.

--aws-credential-file=PATH | Provides the location of the file containing AWS credentials. This parameter cannot be used with the --aws-access-key-id and --aws-secret-key parameters.

--aws-access-key-id=VALUE | Specifies the AWS access key ID to use to identify the caller. Must be used together with the --aws-secret-key option. Do not use this option with the --aws-credential-file parameter.

--aws-secret-key=VALUE | Specifies the AWS secret access key to use to sign the request to CloudWatch. Must be used together with the --aws-access-key-id option. Do not use this option with --aws-credential-file parameter.

--aws-iam-role=VALUE | Specifies the IAM role used to provide AWS credentials. The value =VALUE is required. If no credentials are specified, the default IAM role associated with the EC2 instance is applied. Only one IAM role can be used. If no IAM roles are found, or if more than one IAM role is found, the script will return an error. Do not use this option with the --aws-credential-file, --aws-access-key-id, or --aws-secret-key parameters.

--aggregated=[=only] | Adds aggregated metrics for instance type, AMI ID, and overall for the Region. The value =only is optional; if specified, the script reports only aggregated metrics.

--auto-scaling=[=only] | Adds aggregated metrics for the Auto Scaling group. The value =only is optional; if specified, the script reports only Auto Scaling metrics. The IAM policy associated with the IAM user or role using the scripts need to have permissions to call the EC2 action DescribeTags.
Collect metrics using the CloudWatch monitoring scripts

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--verify</td>
<td>Performs a test run of the script that collects the metrics, prepares a complete HTTP request, but does not actually call CloudWatch to report the data. This option also checks that credentials are provided. When run in verbose mode, this option outputs the metrics that will be sent to CloudWatch.</td>
</tr>
<tr>
<td>--from-cron</td>
<td>Use this option when calling the script from cron. When this option is used, all diagnostic output is suppressed, but error messages are sent to the local system log of the user.</td>
</tr>
<tr>
<td>--verbose</td>
<td>Displays detailed information about what the script is doing.</td>
</tr>
<tr>
<td>--help</td>
<td>Displays usage information.</td>
</tr>
<tr>
<td>--version</td>
<td>Displays the version number of the script.</td>
</tr>
</tbody>
</table>

Examples

The following examples assume that you provided an IAM role or awscreds.conf file. Otherwise, you must provide credentials using the --aws-access-key-id and --aws-secret-key parameters for these commands.

The following example performs a simple test run without posting data to CloudWatch.

```
./mon-put-instance-data.pl --mem-util --verify --verbose
```

The following example collects all available memory metrics and sends them to CloudWatch, counting cache and buffer memory as used.

```
./mon-put-instance-data.pl --mem-used-incl-cache-buff --mem-util --mem-used --mem-avail
```

The following example collects aggregated metrics for an Auto Scaling group and sends them to Amazon CloudWatch without reporting individual instance metrics.

```
./mon-put-instance-data.pl --mem-util --mem-used --mem-avail --auto-scaling=only
```

The following example collects aggregated metrics for instance type, AMI ID and region, and sends them to Amazon CloudWatch without reporting individual instance metrics.

```
./mon-put-instance-data.pl --mem-util --mem-used --mem-avail --aggregated=only
```

To set a cron schedule for metrics reported to CloudWatch, start editing the crontab using the `crontab -e` command. Add the following command to report memory and disk space utilization to CloudWatch every five minutes:

```
*/5 * * * * ~/aws-scripts-mon/mon-put-instance-data.pl --mem-used-incl-cache-buff --mem-util --disk-space-util --disk-path=/ --from-cron
```

If the script encounters an error, it writes the error message in the system log.
mon-get-instance-stats.pl

This script queries CloudWatch for statistics on memory, swap, and disk space metrics within the time interval provided using the number of most recent hours. This data is provided for the Amazon EC2 instance on which this script is run.

Options

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--recent-hours=N</td>
<td>Specifies the number of recent hours to report on, as represented by N where N is an integer.</td>
</tr>
<tr>
<td>--aws-credential-file=PATH</td>
<td>Provides the location of the file containing AWS credentials.</td>
</tr>
<tr>
<td>--aws-access-key-id=VALUE</td>
<td>Specifies the AWS access key ID to use to identify the caller. Must be used together with the --aws-secret-key option. Do not use this option with the --aws-credential-file option.</td>
</tr>
<tr>
<td>--aws-secret-key=VALUE</td>
<td>Specifies the AWS secret access key to use to sign the request to CloudWatch. Must be used together with the --aws-access-key-id option. Do not use this option with --aws-credential-file option.</td>
</tr>
<tr>
<td>--aws-iam-role=VALUE</td>
<td>Specifies the IAM role used to provide AWS credentials. The value =VALUE is required. If no credentials are specified, the default IAM role associated with the EC2 instance is applied. Only one IAM role can be used. If no IAM roles are found, or if more than one IAM role is found, the script will return an error. Do not use this option with the --aws-credential-file, --aws-access-key-id, or --aws-secret-key parameters.</td>
</tr>
<tr>
<td>--verify</td>
<td>Performs a test run of the script. This option also checks that credentials are provided.</td>
</tr>
<tr>
<td>--verbose</td>
<td>Displays detailed information about what the script is doing.</td>
</tr>
<tr>
<td>--help</td>
<td>Displays usage information.</td>
</tr>
<tr>
<td>--version</td>
<td>Displays the version number of the script.</td>
</tr>
</tbody>
</table>

Example

To get utilization statistics for the last 12 hours, run the following command:

`.mon-get-instance-stats.pl --recent-hours=12`

The following is an example response:

```
Instance metric statistics for the last 12 hours.

CPU Utilization
    Average: 1.06%, Minimum: 0.00%, Maximum: 15.22%

Memory Utilization
    Average: 6.84%, Minimum: 6.82%, Maximum: 6.89%
```
Swap Utilization
- Average: N/A, Minimum: N/A, Maximum: N/A

Disk Space Utilization on /dev/xvda1 mounted as /
- Average: 9.69%, Minimum: 9.69%, Maximum: 9.69%

View your custom metrics in the console

After you successfully run the `mon-put-instance-data.pl` script, you can view your custom metrics in the Amazon CloudWatch console.

**To view custom metrics**
1. Run `mon-put-instance-data.pl` as described previously.
3. Choose **View Metrics**.
4. For **Viewing**, your custom metrics posted by the script are displayed with the prefix System/Linux.

Troubleshoot

The **CloudWatchClient.pm** module caches instance metadata locally. If you create an AMI from an instance where you have run the monitoring scripts, any instances launched from the AMI within the cache TTL (default: six hours, 24 hours for Auto Scaling groups) emit metrics using the instance ID of the original instance. After the cache TTL time period passes, the script retrieves fresh data and the monitoring scripts use the instance ID of the current instance. To immediately correct this, remove the cached data using the following command:

```bash
rm /var/tmp/aws-mon/instance-id
```

Log Amazon EC2 and Amazon EBS API calls with AWS CloudTrail

Amazon EC2 and Amazon EBS are integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Amazon EC2 and Amazon EBS. CloudTrail captures all API calls for Amazon EC2 and Amazon EBS as events, including calls from the console and from code calls to the APIs. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Amazon EC2 and Amazon EBS. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the information collected by CloudTrail, you can determine the request that was made to Amazon EC2 and Amazon EBS, the IP address from which the request was made, who made the request, when it was made, and additional details.

To learn more about CloudTrail, see the [AWS CloudTrail User Guide](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/cloudtrail.html).

Amazon EC2 and Amazon EBS information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Amazon EC2 and Amazon EBS, that activity is recorded in a CloudTrail event along with other AWS service events...
in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing events with CloudTrail Event history](#).

For an ongoing record of events in your AWS account, including events for Amazon EC2 and Amazon EBS, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see:

- [Creating a trail for your AWS account](#)
- [AWS service integrations with CloudTrail logs](#)
- [Configuring Amazon SNS notifications for CloudTrail](#)
- [Receiving CloudTrail log files from multiple Regions](#) and [Receiving CloudTrail log files from multiple accounts](#)

All Amazon EC2 actions, and Amazon EBS management actions, are logged by CloudTrail and are documented in the [Amazon EC2 API Reference](#). For example, calls to the `RunInstances`, `DescribeInstances`, or `CreateImage` actions generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the [CloudTrail userIdentity element](#).

## Understand Amazon EC2 and Amazon EBS log file entries

A trail is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following log file record shows that a user terminated an instance.

```json
{
    "Records": [
        {
            "eventVersion": "1.03",
            "userIdentity": {
                "type": "Root",
                "principalId": "123456789012",
                "arn": "arn:aws:iam::123456789012:root",
                "accountId": "123456789012",
                "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
                "userName": "user"
            },
            "eventTime": "2016-05-20T08:27:45Z",
            "eventSource": "ec2.amazonaws.com",
            "eventName": "TerminateInstances",
            "awsRegion": "us-west-2",
            "eventDetails": {
                "instanceId": "i-12345678901234567",
                "instanceType": "t2.micro",
                "vpcId": "vpc-12345678901234567",
                "subnetId": "subnet-12345678901234567",
                "securityGroupIds": [
                    "sg-12345678901234567",
                    "sg-23456789012345678"
                ]
            }
        }
    ]
}
```
Use AWS CloudTrail to audit users that connect via EC2 Instance Connect

Use AWS CloudTrail to audit users that connect to your instances via EC2 Instance Connect.

To audit SSH activity via EC2 Instance Connect using the AWS CloudTrail console

1. Open the AWS CloudTrail console at https://console.aws.amazon.com/cloudtrail/.
2. Verify that you are in the correct Region.
3. In the navigation pane, choose Event history.
5. (Optional) For Time range, select a time range.
6. Choose the Refresh events icon.
7. The page displays the events that correspond to the SendSSHPublicKey API calls. Expand an event using the arrow to view additional details, such as the user name and AWS access key that was used to make the SSH connection, and the source IP address.
8. To display the full event information in JSON format, choose View event. The requestParameters field contains the destination instance ID, OS user name, and public key that were used to make the SSH connection.

```json
{
    "eventVersion": "1.05",
    "userIdentity": {
        "type": "IAMUser",
        "principalId": "ABCDEFGONOMOOCB6XYTQEXAMPLE",

If you have configured your AWS account to collect CloudTrail events in an S3 bucket, you can download and audit the information programmatically. For more information, see [Getting and viewing your CloudTrail log files](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/GetAndViewCloudTrailLogFiles.html) in the *AWS CloudTrail User Guide*.
Networking in Amazon EC2

Amazon VPC enables you to launch AWS resources, such as Amazon EC2 instances, into a virtual network dedicated to your AWS account, known as a virtual private cloud (VPC). When you launch an instance, you can select a subnet from the VPC. The instance is configured with a primary network interface, which is a logical virtual network card. The instance receives a primary private IP address from the IPv4 address of the subnet, and it is assigned to the primary network interface.

You can control whether the instance receives a public IP address from Amazon's pool of public IP addresses. The public IP address of an instance is associated with your instance only until it is stopped or terminated. If you require a persistent public IP address, you can allocate an Elastic IP address for your AWS account and associate it with an instance or a network interface. An Elastic IP address remains associated with your AWS account until you release it, and you can move it from one instance to another as needed. You can bring your own IP address range to your AWS account, where it appears as an address pool, and then allocate Elastic IP addresses from your address pool.

To increase network performance and reduce latency, you can launch instances in a placement group. You can get significantly higher packet per second (PPS) performance using enhanced networking. You can accelerate high performance computing and machine learning applications using an Elastic Fabric Adapter (EFA), which is a network device that you can attach to a supported instance type.

Features

- Regions and Zones (p. 1343)
- Amazon EC2 instance IP addressing (p. 1358)
- Amazon EC2 instance hostname types (p. 1374)
- Bring your own IP addresses (BYOIP) in Amazon EC2 (p. 1378)
- Elastic IP addresses (p. 1392)
- Elastic network interfaces (p. 1404)
- Amazon EC2 instance network bandwidth (p. 1460)
- Enhanced networking on Linux (p. 1461)
- Elastic Fabric Adapter (p. 1508)
- Amazon EC2 instance topology (p. 1560)
- Placement groups (p. 1572)
- Virtual private clouds (p. 1592)

Regions and Zones

Amazon EC2 is hosted in multiple locations world-wide. These locations are composed of AWS Regions, Availability Zones, Local Zones, AWS Outposts, and Wavelength Zones.

- Each Region is a separate geographic area.
- Availability Zones are multiple, isolated locations within each Region.
• Local Zones provide you the ability to place resources, such as compute and storage, in multiple locations closer to your end users.

• AWS Outposts brings native AWS services, infrastructure, and operating models to virtually any data center, co-location space, or on-premises facility.

• Wavelength Zones allow developers to build applications that deliver ultra-low latencies to 5G devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks.

AWS operates state-of-the-art, highly available data centers. Although rare, failures can occur that affect the availability of instances that are in the same location. If you host all of your instances in a single location that is affected by a failure, none of your instances would be available.

To help you determine which deployment is best for you, see AWS Wavelength FAQs.

Contents

• Regions (p. 1344)
• Availability Zones (p. 1349)
• Local Zones (p. 1353)
• Wavelength Zones (p. 1355)
• AWS Outposts (p. 1357)

Regions

Each Region is designed to be isolated from the other Regions. This achieves the greatest possible fault tolerance and stability.

When you view your resources, you see only the resources that are tied to the Region that you specified. This is because Regions are isolated from each other, and we don't automatically replicate resources across Regions.

When you launch an instance, you must select an AMI that's in the same Region. If the AMI is in another Region, you can copy the AMI to the Region you're using. For more information, see Copy an AMI (p. 209).

Note that there is a charge for data transfer between Regions. For more information, see Amazon EC2 Pricing - Data Transfer.

Contents

• Available Regions (p. 1344)
• Regions and endpoints (p. 1346)
• Describe your Regions (p. 1346)
• Get the Region display name (p. 1347)
• Specify the Region for a resource (p. 1348)

Available Regions

Your account determines the Regions that are available to you.

• An AWS account provides multiple Regions so that you can launch Amazon EC2 instances in locations that meet your requirements. For example, you might want to launch instances in Europe to be closer to your European customers or to meet legal requirements.
• An AWS GovCloud (US-West) account provides access to the AWS GovCloud (US-West) Region and the AWS GovCloud (US-East) Region. For more information, see [AWS GovCloud (US)](https://aws.amazon.com/govcloud/)
• An Amazon AWS (China) account provides access to the Beijing and Ningxia Regions only. For more information, see [Amazon Web Services in China](https://aws.amazon.com/cn/).

The following table lists the Regions provided by an AWS account. You can’t describe or access additional Regions from an AWS account, such as the AWS GovCloud (US) Regions or the China Regions. To use a Region introduced after March 20, 2019, you must enable the Region. For more information, see [Specify which AWS Regions your account can use](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/region-list.html) in the [AWS Account Management Reference Guide](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_manage_regions.html).

For more information, see [AWS Global Infrastructure](#).

The number and mapping of Availability Zones per Region may vary between AWS accounts. To list the Availability Zones that are available to your account, you can use the Amazon EC2 console or the command line interface. For more information, see [Describe your Regions](#).

### Regions and endpoints

When you work with an instance using the command line interface or API actions, you must specify its Regional endpoint. For more information about the Regions and endpoints for Amazon EC2, see [Amazon EC2 endpoints and quotas](#) in the [Amazon Web Services General Reference](#).

For more information about endpoints and protocols in AWS GovCloud (US-West), see [Service Endpoints](#) in the [AWS GovCloud (US) User Guide](#).

### Describe your Regions

You can use the Amazon EC2 console or the command line interface to determine which Regions are available for your account. For more information about these command line interfaces, see [Access Amazon EC2](#).

**To find your Regions using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. From the navigation bar, choose the Regions selector.
3. Your EC2 resources for the selected Region are displayed on the EC2 Dashboard in the Resources section.

**To find your Regions using the AWS CLI**

Use the `describe-regions` command as follows to describe the Regions that are enabled for your account.

```
aws ec2 describe-regions
```

To describe all Regions, including any Regions that are disabled for your account, add the `--all-regions` option as follows.

```
aws ec2 describe-regions --all-regions
```

**Get the Region display name**

You can use AWS Systems Manager Parameter Store to view the display name of a Region. Each Region has public parameters in the following path.

```
/aws/service/global-infrastructure/regions/region-code
```

The public parameters for a Region include the following:

- `/aws/service/global-infrastructure/regions/region-code/domain`
- `/aws/service/global-infrastructure/regions/region-code/geolocationCountry`
- `/aws/service/global-infrastructure/regions/region-code/geolocationRegion`
- `/aws/service/global-infrastructure/regions/region-code/longName`
- `/aws/service/global-infrastructure/regions/region-code/partition`
The `longName` parameter contains the Region display name. The following `get-parameters-by-path` command returns the display name of the `af-south-1` Region. It uses the `--query` option to scope the output to the name of the Region. You must enclose the query string in single quotes on Linux. To run this command using the Windows Command Prompt, either omit the single quotes or change them to double quotes.

**Linux**

```bash
aws ssm get-parameters-by-path \
   --path /aws/service/global-infrastructure/regions/af-south-1 \
   --query 'Parameters[?Name.contains(@,`longName`)].Value' \
   --output text
```

**Windows**

```bash
aws ssm get-parameters-by-path ^
   --path /aws/service/global-infrastructure/regions/af-south-1 ^
   --query "Parameters[?Name.contains(@,`longName`)].Value" ^
   --output text
```

The following is example output.

Africa (Cape Town)

For more information, see Working with public parameters in the AWS Systems Manager User Guide.

**Specify the Region for a resource**

Every time you create an Amazon EC2 resource, you can specify the Region for the resource. You can specify the Region for a resource using the AWS Management Console or the command line.

**Considerations**

Some AWS resources might not be available in all Regions. Ensure that you can create the resources that you need in the desired Regions before you launch an instance.

**To specify the Region for a resource using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, choose the Regions selector and then choose the Region.
### To specify the default Region using the command line

You can set the value of an environment variable to the desired Regional endpoint (for example, https://ec2.us-east-2.amazonaws.com):

- AWS_DEFAULT_REGION (AWS CLI)
- Set-AWSDefaultRegion (AWS Tools for Windows PowerShell)

Alternatively, you can use the --region (AWS CLI) or -Region (AWS Tools for Windows PowerShell) command line option with each individual command. For example, --region us-east-2.

For more information about the endpoints for Amazon EC2, see Service endpoints in the AWS General Reference.

### Availability Zones

Each Region has multiple, isolated locations known as Availability Zones. The code for Availability Zone is its Region code followed by a letter identifier. For example, us-east-1a.

When you launch an instance, you select a Region and a virtual private cloud (VPC), and then you can either select a subnet from one of the Availability Zones or let us choose one for you. If you distribute your instances across multiple Availability Zones and one instance fails, you can design your application so that an instance in another Availability Zone can handle requests. You can also use Elastic IP addresses to mask the failure of an instance in one Availability Zone by rapidly remapping the address to an instance in another Availability Zone.

The following diagram illustrates multiple Availability Zones in an AWS Region. Availability Zone A and Availability Zone B each have one subnet, and each subnet has instances. Availability Zone C has no subnets, therefore you can't launch instances into this Availability Zone.
As Availability Zones grow over time, our ability to expand them can become constrained. If this happens, we might restrict you from launching an instance in a constrained Availability Zone unless you already have an instance in that Availability Zone. Eventually, we might also remove the constrained Availability Zone from the list of Availability Zones for new accounts. Therefore, your account might have a different number of available Availability Zones in a Region than another account.

Contents

- AZ IDs (p. 1351)
- Describe your Availability Zones (p. 1351)
- Launch instances in an Availability Zone (p. 1352)
- Migrate an instance to another Availability Zone (p. 1352)
AZ IDs

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to codes for each AWS account. For example, the Availability Zone `us-east-1a` for your AWS account might not be the same physical location as `us-east-1a` for another AWS account.

To coordinate Availability Zones across accounts, you must use the AZ ID, which is a unique and consistent identifier for an Availability Zone. For example, `use1-az1` is an AZ ID for the `us-east-1` Region and it has the same physical location in every AWS account. You can view the AZ IDs for your account to determine the physical location of your resources relative to the resources in another account. For example, if you share a subnet in the Availability Zone with the AZ ID `use1-az2` with another account, this subnet is available to that account in the Availability Zone whose AZ ID is also `use1-az2`.

The following diagram illustrates two accounts with different mappings of Availability Zone code to AZ ID.

![Diagram showing different mappings of Availability Zone code to AZ ID for two accounts.]

Describe your Availability Zones

You can use the Amazon EC2 console or the command line interface to determine which Availability Zones are available for your account. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

To find your Availability Zones using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, choose the Regions selector and then choose the Region.
3. On the navigation pane, choose EC2 Dashboard.
4. The Availability Zones are listed in the Service health pane.

To find your Availability Zones using the AWS CLI

- Use the describe-availability-zones command as follows to describe the Availability Zones within the specified Region that are enabled for your account.
Launch instances in an Availability Zone

When you launch an instance, select a Region that puts your instances closer to specific customers, or meets the legal or other requirements that you have. By launching your instances in separate Availability Zones, you can protect your applications from the failure of a single location.

When you launch an instance, you can optionally specify an Availability Zone in the Region that you are using. If you do not specify an Availability Zone, we select an Availability Zone for you. When you launch your initial instances, we recommend that you accept the default Availability Zone, because this allows us to select the best Availability Zone for you based on system health and available capacity. If you launch additional instances, specify an Availability Zone only if your new instances must be close to, or separated from, your running instances.

Migrate an instance to another Availability Zone

If necessary, you can migrate an instance from one Availability Zone to another. For example, if you try to modify the instance type of your instance and we can't launch an instance of the new instance type in the current Availability Zone, you can migrate the instance to an Availability Zone with capacity for the new instance type.

The migration process involves:

- Creating an AMI from the original instance
- Launching an instance in the new Availability Zone
- Updating the configuration of the new instance, as shown in the following procedure

To migrate an instance to another Availability Zone

1. Create an AMI from the instance. The procedure depends on your operating system and the type of root device volume for the instance. For more information, see the documentation that corresponds to your operating system and root device volume:
   - Create an Amazon EBS-backed Linux AMI
   - Create an instance store-backed Linux AMI
   - Create a custom Windows AMI

2. If you need to preserve the private IPv4 address of the instance, you must delete the subnet in the current Availability Zone and then create a subnet in the new Availability Zone with the same IPv4 address range as the original subnet. Note that you must terminate all instances in a subnet before you can delete it. Therefore, you should create AMIs from all of the instances in your subnet so that you can move all instances from the current subnet to the new subnet.

3. Launch an instance from the AMI that you just created, specifying the new Availability Zone or subnet. You can use the same instance type as the original instance, or select a new instance type. For more information, see Launch instances in an Availability Zone (p. 1352).

4. If the original instance has an associated Elastic IP address, associate it with the new instance. For more information, see Disassociate an Elastic IP address (p. 1397).
5. If the original instance is a Reserved Instance, change the Availability Zone for your reservation. (If you also changed the instance type, you can also change the instance type for your reservation.) For more information, see Submit modification requests (p. 538).

6. (Optional) Terminate the original instance. For more information, see Terminate an instance (p. 806).

Local Zones

A Local Zone is an extension of an AWS Region in geographic proximity to your users. Local Zones have their own connections to the internet and support AWS Direct Connect, so that resources created in a Local Zone can serve local users with low-latency communications. For more information, see AWS Local Zones.

The code for a Local Zone is its Region code followed by an identifier that indicates its physical location. For example, us-west-2-lax-1 in Los Angeles.

The following diagram illustrates the AWS Region us-west-2, two of its Availability Zones, and two of its Local Zones. The VPC spans the Availability Zones and one of the Local Zones. Each zone in the VPC has one subnet, and each subnet has an instance.

To use a Local Zone, you must first enable it. For more information, see the section called “Opt in to Local Zones” (p. 1354). Next, create a subnet in the Local Zone. Finally, launch resources in the Local Zone subnet, such as instances, so that your applications are close to your users.

Contents

- Available Local Zones (p. 1354)
- Opt in to Local Zones (p. 1354)
- Launch instances in a Local Zone (p. 1354)
Available Local Zones

You can use the Amazon EC2 console or a command line interface to determine which Local Zones are available for your account. For a complete list, see AWS Local Zones Locations.

To find your Local Zones using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, choose the Regions selector and then choose the parent Region.
3. On the navigation pane, choose EC2 Dashboard.
4. In the upper-right corner of the page, choose Account attributes, Zones.

To find your Local Zones using the AWS CLI

Use the describe-availability-zones command as follows to describe all Local Zones in the specified Region, even if they are not enabled. To describe only the Local Zones that you've enabled, omit the --all-availability-zones option.

```
aws ec2 describe-availability-zones --region region-name --filters Name=zone-type,Values=local-zone --all-availability-zones
```

Opt in to Local Zones

Before you can specify a Local Zone for a resource or service, you must opt in to Local Zones.

Consideration

Some AWS resources might not be available in all Regions. Make sure that you can create the resources that you need in the desired Regions or Local Zones before launching an instance in a specific Local Zone. For a list of services supported in each Local Zone see AWS Local Zones Features.

To opt in to Local Zones using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the upper-left corner of the page, select New EC2 Experience. You cannot complete this task using the old console experience.
3. From the navigation bar, choose the Regions selector and then choose the parent Region.
4. On the navigation pane, choose EC2 Dashboard.
5. In the upper-right corner of the page, choose Account attributes, Zones.
6. For the Local Zone to enable, choose Manage.
7. For Zone group, choose Enabled.
8. Choose Update zone group.

To opt in to Local Zones using the AWS CLI

Use the modify-availability-zone-group command.

Launch instances in a Local Zone

When you launch an instance, you can specify a subnet that is in a Local Zone. You also allocate an IP address from a network border group. A network border group is a unique set of Availability Zones, Local Zones, or Wavelength Zones from which AWS advertises IP addresses, for example, us-west-2-lax-1a.

You can allocate the following IP addresses from a network border group:
• Amazon-provided Elastic IPv4 addresses
• Amazon-provided IPv6 VPC addresses (available only in the Los Angeles zones)

For more information about how to launch an instance in a Local Zone, see Getting started with AWS Local Zones in the AWS Local Zones User Guide.

Wavelength Zones

AWS Wavelength enables developers to build applications that deliver ultra-low latencies to mobile devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks. Developers can extend a virtual private cloud (VPC) to one or more Wavelength Zones, and then use AWS resources like Amazon EC2 instances to run applications that require ultra-low latency and a connection to AWS services in the Region.

A Wavelength Zone is an isolated zone in the carrier location where the Wavelength infrastructure is deployed. Wavelength Zones are tied to a Region. A Wavelength Zone is a logical extension of a Region, and is managed by the control plane in the Region.

The code for a Wavelength Zone is its Region code followed by an identifier that indicates the physical location. For example, us-east-1-wl1-bos-wlz-1 in Boston.

The following diagram illustrates the AWS Region us-west-2, two of its Availability Zones, and a Wavelength Zone. The VPC spans the Availability Zones and the Wavelength Zone. Each zone in the VPC has one subnet, and each subnet has an instance.

To use a Wavelength Zone, you must first opt in to the Zone. For more information, see the section called "Enable Wavelength Zones" (p. 1356). Next, create a subnet in the Wavelength Zone. Finally, launch your resources in the Wavelength Zones subnet, so that your applications are closer to your end users.

Wavelength Zones are not available in every Region. For information about the Regions that support Wavelength Zones, see Available Wavelength Zones in the AWS Wavelength Developer Guide.

Contents
• Describe your Wavelength Zones (p. 1356)
• Enable Wavelength Zones (p. 1356)
• Launch instances in a Wavelength Zone (p. 1357)
Describe your Wavelength Zones

You can use the Amazon EC2 console or the command line interface to determine which Wavelength Zones are available for your account. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

To find your Wavelength Zones using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, choose the Regions selector and then choose the Region.
3. On the navigation pane, choose EC2 Dashboard.
4. In the upper-right corner of the page, choose Account attributes, Zones.

To find your Wavelength Zones using the AWS CLI

- Use the describe-availability-zones command as follows to describe the Wavelength Zones within the specified Region that are enabled for your account.

  aws ec2 describe-availability-zones --region region-name

- Use the describe-availability-zones command as follows to describe the Wavelength Zones regardless of the opt-in status.

  aws ec2 describe-availability-zones --all-availability-zones

Enable Wavelength Zones

Before you specify a Wavelength Zone for a resource or service, you must opt in to Wavelength Zones.

Considerations

- Some AWS resources are not available in all Regions. Make sure that you can create the resources that you need in the desired Region or Wavelength Zone before launching an instance in a specific Wavelength Zone.

To opt in to Wavelength Zone using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the upper-left corner of the page, select New EC2 Experience. You cannot complete this task using the old console experience.
3. From the navigation bar, choose the Regions selector and then choose the Region.
4. On the navigation pane, choose EC2 Dashboard.
5. In the upper-right corner of the page, choose Account attributes, Zones.
7. Choose Enable.
8. Choose Update zone group.

To enable Wavelength Zones using the AWS CLI

Use the modify-availability-zone-group command.

1356
Launch instances in a Wavelength Zone

When you launch an instance, you can specify a subnet which is in a Wavelength Zone. You also allocate a carrier IP address from a network border group, which is a unique set of Availability Zones, Local Zones, or Wavelength Zones from which AWS advertises IP addresses, for example, `us-east-1-wl1-bos-wlz-1`.

For information about how to launch an instance in a Wavelength Zone, see Get started with AWS Wavelength in the AWS Wavelength Developer Guide.

AWS Outposts

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to customer premises. By providing local access to AWS managed infrastructure, AWS Outposts enables customers to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs.

An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region. You can create subnets on your Outpost and specify them when you create AWS resources. Instances in Outpost subnets communicate with other instances in the AWS Region using private IP addresses, all within the same VPC.

The following diagram illustrates the AWS Region `us-west-2`, two of its Availability Zones, and an Outpost. The VPC spans the Availability Zones and the Outpost. The Outpost is in an on-premises customer data center. Each zone in the VPC has one subnet, and each subnet has an instance.

To begin using AWS Outposts, you must create an Outpost and order Outpost capacity. For more information about Outposts configurations, see our catalog. After your Outpost equipment is installed, the compute and storage capacity is available for you when you launch Amazon EC2 instances on your Outpost.

Launch instances on an Outpost

You can launch EC2 instances in the Outpost subnet that you created. Security groups control inbound and outbound traffic for instances with elastic network interfaces in an Outpost subnet, as they do for
instances in an Availability Zone subnet. To connect to an EC2 instance in an Outpost subnet, you can specify a key pair when you launch the instance, as you do for instances in an Availability Zone subnet.

The root volume for an instance on an Outpost rack must be 30 GB or smaller. You can specify data volumes in the block device mapping of the AMI or the instance to provide additional storage. To trim unused blocks from the boot volume, see How to Build Sparse EBS Volumes in the AWS Partner Network Blog.

We recommend that you increase the NVMe timeout for the root volume. For more information, see I/O operation timeout (p. 2338).

For information about how to create an Outpost, see Get started with AWS Outposts in the AWS Outposts User Guide.

Create a volume on an Outpost rack

AWS Outposts offers rack and server form factors. If your capacity is on an Outpost rack, you can create EBS volumes in the Outpost subnet that you created. When you create the volume, specify the Amazon Resource Name (ARN) of the Outpost.

The following create-volume command creates an empty 50 GB volume on the specified Outpost.

```
aws ec2 create-volume --availability-zone us-east-2a --outpost-arn arn:aws:outposts:us-east-2:123456789012:outpost/op-03e6fecad652a6138 --size 50
```

You can dynamically modify the size of your Amazon EBS gp2 volumes without detaching them. For more information about modifying a volume without detaching it, see Request modifications to your EBS volumes (p. 2306).

Amazon EC2 instance IP addressing

Amazon EC2 and Amazon VPC support both the IPv4 and IPv6 addressing protocols. By default, Amazon VPC uses the IPv4 addressing protocol; you can't disable this behavior. When you create a VPC, you must specify an IPv4 CIDR block (a range of private IPv4 addresses). You can optionally assign an IPv6 CIDR block to your VPC and assign IPv6 addresses from that block to instances in your subnets.

Contents
- Private IPv4 addresses (p. 1358)
- Public IPv4 addresses (p. 1359)
- Elastic IP addresses (IPv4) (p. 1360)
- IPv6 addresses (p. 1360)
- Work with the IPv4 addresses for your instances (p. 1361)
- Work with the IPv6 addresses for your instances (p. 1363)
- Multiple IP addresses (p. 1365)
- EC2 instance hostnames (p. 1373)
- Link-local addresses (p. 1374)

Private IPv4 addresses

A private IPv4 address is an IP address that's not reachable over the Internet. You can use private IPv4 addresses for communication between instances in the same VPC. For more information about the standards and specifications of private IPv4 addresses, see RFC 1918. We allocate private IPv4 addresses to instances using DHCP.
Note
You can create a VPC with a publicly routable CIDR block that falls outside of the private IPv4 address ranges specified in RFC 1918. However, for the purposes of this documentation, we refer to private IPv4 addresses (or 'private IP addresses') as the IP addresses that are within the IPv4 CIDR range of your VPC.

VPC subnets can be one of the following types:

- IPv4-only subnets: You can only create resources in these subnets with IPv4 addresses assigned to them.
- IPv6-only subnets: You can only create resources in these subnets with IPv6 addresses assigned to them.
- IPv4 and IPv6 subnets: You can create resources in these subnets with either IPv4 or IPv6 addresses assigned to them.

When you launch an EC2 instance into an IPv4-only or dual stack (IPv4 and IPv6) subnet, the instance receives a primary private IP address from the IPv4 address range of the subnet. For more information, see IP addressing in the Amazon VPC User Guide. If you don't specify a primary private IP address when you launch the instance, we select an available IP address in the subnet's IPv4 range for you. Each instance has a default network interface (eth0) that is assigned the primary private IPv4 address. You can also specify additional private IPv4 addresses, known as secondary private IPv4 addresses. Unlike primary private IP addresses, secondary private IP addresses can be reassigned from one instance to another. For more information, see Multiple IP addresses (p. 1365).

A private IPv4 address, regardless of whether it is a primary or secondary address, remains associated with the network interface when the instance is stopped and started, or hibernated and started, and is released when the instance is terminated.

Public IPv4 addresses

A public IP address is an IPv4 address that's reachable from the Internet. You can use public addresses for communication between your instances and the Internet.

When you launch an instance in a default VPC, we assign it a public IP address by default. When you launch an instance into a nondefault VPC, the subnet has an attribute that determines whether instances launched into that subnet receive a public IP address from the public IPv4 address pool. By default, we don't assign a public IP address to instances launched in a nondefault subnet.

You can control whether your instance receives a public IP address as follows:

- Modifying the public IPv4 addressing attribute of your subnet. For more information, see Modify the public IPv4 addressing attribute for your subnet in the Amazon VPC User Guide.
- Enabling or disabling the public IP addressing feature during launch, which overrides the subnet's public IP addressing attribute. For more information, see Assign a public IPv4 address during instance launch (p. 1363).

A public IP address is assigned to your instance from Amazon's pool of public IPv4 addresses, and is not associated with your AWS account. When a public IP address is disassociated from your instance, it is released back into the public IPv4 address pool, and you cannot reuse it.

You cannot manually associate or disassociate a public IP (IPv4) address from your instance. Instead, in certain cases, we release the public IP address from your instance, or assign it a new one:

- We release your instance's public IP address when it is stopped, hibernated, or terminated. Your stopped or hibernated instance receives a new public IP address when it is started.
• We release your instance's public IP address when you associate an Elastic IP address with it. When you disassociate the Elastic IP address from your instance, it receives a new public IP address.

• If the public IP address of your instance in a VPC has been released, it will not receive a new one if there is more than one network interface attached to your instance.

• If your instance's public IP address is released while it has a secondary private IP address that is associated with an Elastic IP address, the instance does not receive a new public IP address.

If you require a persistent public IP address that can be associated to and from instances as you require, use an Elastic IP address instead.

If you use dynamic DNS to map an existing DNS name to a new instance's public IP address, it might take up to 24 hours for the IP address to propagate through the Internet. As a result, new instances might not receive traffic while terminated instances continue to receive requests. To solve this problem, use an Elastic IP address. You can allocate your own Elastic IP address, and associate it with your instance. For more information, see Elastic IP addresses (p. 1392).

**Note**

• Starting on February 1, 2024, AWS will charge for all public IPv4 addresses, including public IPv4 addresses associated with running instances and Elastic IP addresses. For more information, see the Public IPv4 Address tab on the Amazon VPC pricing page.

• Instances that access other instances through their public NAT IP address are charged for regional or Internet data transfer, depending on whether the instances are in the same Region.

**Elastic IP addresses (IPv4)**

An Elastic IP address is a public IPv4 address that you can allocate to your account. You can associate it to and disassociate it from instances as you require. It's allocated to your account until you choose to release it. For more information about Elastic IP addresses and how to use them, see Elastic IP addresses (p. 1392).

We do not support Elastic IP addresses for IPv6.

**IPv6 addresses**

You can optionally associate an IPv6 CIDR block with your VPC and associate IPv6 CIDR blocks with your subnets. The IPv6 CIDR block for your VPC is automatically assigned from Amazon's pool of IPv6 addresses; you cannot choose the range yourself. For more information, see the following topics in the Amazon VPC User Guide:

- IP addressing for your VPCs and subnets
- Add an IPv6 CIDR block to your VPC
- Add an IPv6 CIDR block to your subnet

IPv6 addresses are globally unique and can be configured to remain private or reachable over the Internet. Your instance receives an IPv6 address if an IPv6 CIDR block is associated with your VPC and subnet, and if one of the following is true:

- Your subnet is configured to automatically assign an IPv6 address to an instance during launch. For more information, see Modify the IPv6 addressing attribute for your subnet.
- You assign an IPv6 address to your instance during launch.
- You assign an IPv6 address to the primary network interface of your instance after launch.
Work with the IPv4 addresses for your instances

You can assign a public IPv4 address to your instance when you launch it. You can view the IPv4 addresses for your instance in the console through either the Instances page or the Network Interfaces page.

Contents

- View the IPv4 addresses (p. 1361)
- Assign a public IPv4 address during instance launch (p. 1363)

View the IPv4 addresses

You can use the Amazon EC2 console to view the public and private IPv4 addresses of your instances. You can also determine the public IPv4 and private IPv4 addresses of your instance from within your instance by using instance metadata. For more information, see Instance metadata and user data (p. 1004).

The public IPv4 address is displayed as a property of the network interface in the console, but it’s mapped to the primary private IPv4 address through NAT. Therefore, if you inspect the properties of your network interface on your instance, for example, through ifconfig (Linux) or ipconfig (Windows), the public IPv4 address is not displayed. To determine your instance's public IPv4 address from an instance, use instance metadata.

To view the IPv4 addresses for an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and select your instance.
3. The following information is available on the Networking tab:
Work with the IPv4 addresses for your instances

- **Public IPv4 address** — The public IPv4 address. If you associated an Elastic IP address with the instance or the primary network interface, this is the Elastic IP address.
- **Private IPv4 address** — The private IPv4 address.
- **Secondary private IPv4 addresses** — Any secondary private IPv4 addresses.

4. Alternatively, under **Network interfaces** on the **Networking** tab, choose the interface ID for the primary network interface (for example, eni-123abc456def78901). The following information is available:
  - **Private IPv4 address** — The primary private IPv4 address.
  - **Public IPv4 address** — The public IPv4 address. If you associated an Elastic IP address with the instance or the primary network interface, this is the Elastic IP address.
  - **Secondary private IPv4 addresses** — Any secondary private IPv4 addresses.

**To view the IPv4 addresses for an instance using the command line**

You can use one of the following commands. For more information about these command line interfaces, see **Access Amazon EC2** (p. 5).

- **describe-instances** (AWS CLI)

**To determine your instance's IPv4 addresses using instance metadata**

1. Connect to your instance. For more information, see **Connect to your Linux instance** (p. 811).
2. Use the following command to access the private IP address:

   IMDSv2
   
   ```bash
   ```

   IMDSv1
   
   ```bash
   ```

3. Use the following command to access the public IP address:

   IMDSv2
   
   ```bash
   ```

   IMDSv1
   
   ```bash
   ```

If an Elastic IP address is associated with the instance, the value returned is that of the Elastic IP address.
Assign a public IPv4 address during instance launch

Each subnet has an attribute that determines whether instances launched into that subnet are assigned a public IP address. By default, nondefault subnets have this attribute set to false, and default subnets have this attribute set to true. When you launch an instance, a public IPv4 addressing feature is also available for you to control whether your instance is assigned a public IPv4 address; you can override the default behavior of the subnet's IP addressing attribute. The public IPv4 address is assigned from Amazon's pool of public IPv4 addresses, and is assigned to the network interface with the device index of eth0. This feature depends on certain conditions at the time you launch your instance.

Considerations

- You can't manually disassociate the public IP address from your instance after launch. Instead, it's automatically released in certain cases, after which you cannot reuse it. For more information, see Public IPv4 addresses (p. 1359). If you require a persistent public IP address that you can associate or disassociate at will, assign an Elastic IP address to the instance after launch instead. For more information, see Elastic IP addresses (p. 1392).
- You cannot auto-assign a public IP address if you specify more than one network interface. Additionally, you cannot override the subnet setting using the auto-assign public IP feature if you specify an existing network interface for eth0.
- The public IP addressing feature is only available during launch. However, whether you assign a public IP address to your instance during launch or not, you can associate an Elastic IP address with your instance after it's launched. For more information, see Elastic IP addresses (p. 1392). You can also modify your subnet's public IPv4 addressing behavior. For more information, see Modify the public IPv4 addressing attribute for your subnet.

To assign a public IPv4 address during instance launch using the console

Follow the procedure to launch an instance (p. 722), and when you configure Network Settings (p. 724), choose the option to Auto-assign Public IP.

To enable or disable the public IP addressing feature using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- Use the --associate-public-ip-address or the --no-associate-public-ip-address option with the run-instances command (AWS CLI)
- Use the -AssociatePublicIp parameter with the New-EC2Instance command (AWS Tools for Windows PowerShell)

Work with the IPv6 addresses for your instances

You can view the IPv6 addresses assigned to your instance, assign a public IPv6 address to your instance, or unassign an IPv6 address from your instance. You can view these addresses in the console through either the Instances page or the Network Interfaces page.

Contents

- View the IPv6 addresses (p. 1364)
- Assign an IPv6 address to an instance (p. 1364)
- Unassign an IPv6 address from an instance (p. 1365)
View the IPv6 addresses

You can use the Amazon EC2 console, AWS CLI, and instance metadata to view the IPv6 addresses for your instances.

To view the IPv6 addresses for an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance.
5. Alternatively, under Network interfaces on the Networking tab, choose the interface ID for the network interface (for example, eni-123abc456def78901). Locate IPv6 addresses.

To view the IPv6 addresses for an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- describe-instances (AWS CLI)

To view the IPv6 addresses for an instance using instance metadata

1. Connect to your instance. For more information, see Connect to your Linux instance (p. 811).
2. Use the following command to view the IPv6 address (you can get the MAC address from http://169.254.169.254/latest/meta-data/network/interfaces/macs/).

IMDSv2

```
```

IMDSv1

```
```

Assign an IPv6 address to an instance

If your VPC and subnet have IPv6 CIDR blocks associated with them, you can assign an IPv6 address to your instance during or after launch. The IPv6 address is assigned from the IPv6 address range of the subnet, and is assigned to the network interface with the device index of eth0.

To assign an IPv6 address during instance launch

Follow the procedure to launch an instance (p. 722), and when you configure Network Settings (p. 724), choose the option to Auto-assign IPv6 IP.

To assign an IPv6 address after launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select your instance, and choose **Actions, Networking, Manage IP addresses**.
4. Expand the network interface. Under **IPv6 addresses**, choose **Assign new IP address**. Enter an IPv6 address from the range of the subnet or leave the field blank to let Amazon choose an IPv6 address for you.
5. Choose **Save**.

**To assign an IPv6 address using the command line**

You can use one of the following commands. For more information about these command line interfaces, see **Access Amazon EC2** (p. 5).

- Use the --ipv6-addresses option with the **run-instances** command (AWS CLI)
- Use the Ipv6Addresses property for -NetworkInterface in the **New-EC2Instance** command (AWS Tools for Windows PowerShell)
- **assign-ipv6-addresses** (AWS CLI)
- **Register-EC2Ipv6AddressList** (AWS Tools for Windows PowerShell)

**Unassign an IPv6 address from an instance**

You can unassign an IPv6 address from an instance at any time.

**To unassign an IPv6 address from an instance using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select your instance, and choose **Actions, Networking, Manage IP addresses**.
4. Expand the network interface. Under **IPv6 addresses**, choose **Unassign** next to the IPv6 address.
5. Choose **Save**.

**To unassign an IPv6 address from an instance using the command line**

You can use one of the following commands. For more information about these command line interfaces, see **Access Amazon EC2** (p. 5).

- **unassign-ipv6-addresses** (AWS CLI)
- **Unregister-EC2Ipv6AddressList** (AWS Tools for Windows PowerShell).

**Multiple IP addresses**

You can specify multiple private IPv4 and IPv6 addresses for your instances. The number of network interfaces and private IPv4 and IPv6 addresses that you can specify for an instance depends on the instance type. For more information, see **IP addresses per network interface per instance type** (p. 1407).

It can be useful to assign multiple IP addresses to an instance in your VPC to do the following:

- Host multiple websites on a single server by using multiple SSL certificates on a single server and associating each certificate with a specific IP address.
- Operate network appliances, such as firewalls or load balancers, that have multiple IP addresses for each network interface.
- Redirect internal traffic to a standby instance in case your instance fails, by reassigning the secondary IP address to the standby instance.
How multiple IP addresses work

The following list explains how multiple IP addresses work with network interfaces:

- You can assign a secondary private IPv4 address to any network interface.
- You can assign multiple IPv6 addresses to a network interface that's in a subnet that has an associated IPv6 CIDR block.
- You must choose a secondary IPv4 address from the IPv4 CIDR block range of the subnet for the network interface.
- You must choose IPv6 addresses from the IPv6 CIDR block range of the subnet for the network interface.
- You associate security groups with network interfaces, not individual IP addresses. Therefore, each IP address you specify in a network interface is subject to the security group of its network interface.
- Multiple IP addresses can be assigned and unassigned to network interfaces attached to running or stopped instances.
- Secondary private IPv4 addresses that are assigned to a network interface can be reassigned to another one if you explicitly allow it.
- An IPv6 address cannot be reassigned to another network interface; you must first unassign the IPv6 address from the existing network interface.
- When assigning multiple IP addresses to a network interface using the command line tools or API, the entire operation fails if one of the IP addresses can't be assigned.
- Primary private IPv4 addresses, secondary private IPv4 addresses, Elastic IP addresses, and IPv6 addresses remain with a secondary network interface when it is detached from an instance or attached to an instance.
- Although you can't detach the primary network interface from an instance, you can reassign the secondary private IPv4 address of the primary network interface to another network interface.

The following list explains how multiple IP addresses work with Elastic IP addresses (IPv4 only):

- Each private IPv4 address can be associated with a single Elastic IP address, and vice versa.
- When a secondary private IPv4 address is reassigned to another interface, the secondary private IPv4 address retains its association with an Elastic IP address.
- When a secondary private IPv4 address is unassigned from an interface, an associated Elastic IP address is automatically disassociated from the secondary private IPv4 address.

Work with multiple IPv4 addresses

You can assign a secondary private IPv4 address to an instance, associate an Elastic IPv4 address with a secondary private IPv4 address, and unassign a secondary private IPv4 address.

Tasks

- Assign a secondary private IPv4 address (p. 1367)
- Configure the operating system on your instance to recognize secondary private IPv4 addresses (p. 1368)
- Associate an Elastic IP address with the secondary private IPv4 address (p. 1369)
Assign a secondary private IPv4 address

You can assign the secondary private IPv4 address to the network interface for an instance as you launch the instance, or after the instance is running. This section includes the following procedures.

- To assign a secondary private IPv4 address when launching an instance (p. 1367)
- To assign a secondary IPv4 address during launch using the command line (p. 1368)
- To assign a secondary private IPv4 address to a network interface (p. 1368)
- To assign a secondary private IPv4 to an existing instance using the command line (p. 1368)

New console

To assign a secondary private IPv4 address when launching an instance

1. Follow the procedure to launch an instance (p. 722), and when you configure Network Settings (p. 724), choose Advanced network configuration.
2. Under Secondary IP, choose Automatically assign to have Amazon automatically assign a secondary IPv4 address or choose Manually assign to manually enter a CIDR.
3. Complete the remaining steps to launch the instance (p. 722).

Old console

To assign a secondary private IPv4 address when launching an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance.
3. Select an AMI, then choose an instance type and choose Next: Configure Instance Details.
4. On the Configure Instance Details page, for Network, select a VPC and for Subnet, select a subnet.
5. In the Network Interfaces section, do the following, and then choose Next: Add Storage:
   - To add another network interface, choose Add Device. The console enables you to specify up to two network interfaces when you launch an instance. After you launch the instance, choose Network Interfaces in the navigation pane to add additional network interfaces. The total number of network interfaces that you can attach varies by instance type. For more information, see IP addresses per network interface per instance type (p. 1407).
     - Important
       When you add a second network interface, the system can no longer auto-assign a public IPv4 address. You will not be able to connect to the instance over IPv4 unless you assign an Elastic IP address to the primary network interface (eth0). You can assign the Elastic IP address after you complete the Launch wizard. For more information, see Work with Elastic IP addresses (p. 1394).
   - For each network interface, under Secondary IP addresses, choose Add IP, and then enter a private IP address from the subnet range, or accept the default Auto-assign value to let Amazon select an address.
6. On the next Add Storage page, you can specify volumes to attach to the instance besides the volumes specified by the AMI (such as the root device volume), and then choose Next: Add Tags.
7. On the Add Tags page, specify tags for the instance, such as a user-friendly name, and then choose Next: Configure Security Group.
8. On the **Configure Security Group** page, select an existing security group or create a new one. Choose **Review and Launch**.

9. On the **Review Instance Launch** page, review your settings, and then choose **Launch** to choose a key pair and launch your instance. If you're new to Amazon EC2 and haven't created any key pairs, the wizard prompts you to create one.

**Important**

After you have added a secondary private IP address to a network interface, you must connect to the instance and configure the secondary private IP address on the instance itself. For more information, see **Configure the operating system on your instance to recognize secondary private IPv4 addresses (p. 1368)**.

### To assign a secondary IPv4 address during launch using the command line

- You can use one of the following commands. For more information about these command line interfaces, see **Access Amazon EC2 (p. 5)**.

  - The **--secondary-private-ip-addresses** option with the **run-instances** command (AWS CLI)
  - Define **-NetworkInterface** and specify the **PrivateIpAddresses** parameter with the **New-EC2Instance** command (AWS Tools for Windows PowerShell).

### To assign a secondary IPv4 address to a network interface

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Network Interfaces**, and then select the network interface attached to the instance.
3. Choose **Actions, Manage IP Addresses**.
4. Under **IPv4 Addresses**, choose **Assign new IP**.
5. Enter a specific IPv4 address that’s within the subnet range for the instance, or leave the field blank to let Amazon select an IP address for you.
6. (Optional) Choose **Allow reassignment** to allow the secondary private IP address to be reassigned if it is already assigned to another network interface.
7. Choose **Yes, Update**.

Alternatively, you can assign a secondary private IPv4 address to an instance. Choose **Instances** in the navigation pane, select the instance, and then choose **Actions, Networking, Manage IP addresses**. You can configure the same information as you did in the steps above. The IP address is assigned to the primary network interface (eth0) for the instance.

### To assign a secondary private IPv4 to an existing instance using the command line

- You can use one of the following commands. For more information about these command line interfaces, see **Access Amazon EC2 (p. 5)**.

  - **assign-private-ip-addresses** (AWS CLI)
  - **Register-EC2PrivateIpAddress** (AWS Tools for Windows PowerShell)

### Configure the operating system on your instance to recognize secondary private IPv4 addresses

After you assign a secondary private IPv4 address to your instance, you need to configure the operating system on your instance to recognize the secondary private IP address.
• If you are using Amazon Linux, the ec2-net-utils package can take care of this step for you. It configures additional network interfaces that you attach while the instance is running, refreshes secondary IPv4 addresses during DHCP lease renewal, and updates the related routing rules. You can immediately refresh the list of interfaces by using the command `sudo service network restart` and then view the up-to-date list using `ip addr li`. If you require manual control over your network configuration, you can remove the ec2-net-utils package. For more information, see Configure your network interface using ec2-net-utils for Amazon Linux 2 (p. 1444).

• If you are using another Linux distribution, see the documentation for your Linux distribution. Search for information about configuring additional network interfaces and secondary IPv4 addresses. If the instance has two or more interfaces on the same subnet, search for information about using routing rules to work around asymmetric routing.

For information about configuring a Windows instance, see Configuring a secondary private IP address for your Windows instance in a VPC in the Amazon EC2 User Guide for Windows Instances.

Associate an Elastic IP address with the secondary private IPv4 address

To associate an Elastic IP address with a secondary private IPv4 address

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic IPs.
3. Choose Actions, and then select Associate address.
4. For Network interface, select the network interface, and then select the secondary IP address from the Private IP list.
5. Choose Associate.

To associate an Elastic IP address with a secondary private IPv4 address using the command line

• You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).
  • `associate-address` (AWS CLI)
  • `Register-EC2Address` (AWS Tools for Windows PowerShell)

View your secondary private IPv4 addresses

To view the private IPv4 addresses assigned to a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the network interface with private IP addresses to view.
4. On the Details tab in the details pane, check the Primary private IPv4 IP and Secondary private IPv4 IPs fields for the primary private IPv4 address and any secondary private IPv4 addresses assigned to the network interface.

To view the private IPv4 addresses assigned to an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance with private IPv4 addresses to view.
4. On the **Description** tab in the details pane, check the **Private IPs** and **Secondary private IPs** fields for the primary private IPv4 address and any secondary private IPv4 addresses assigned to the instance through its network interface.

**Unassign a secondary private IPv4 address**

If you no longer require a secondary private IPv4 address, you can unassign it from the instance or the network interface. When a secondary private IPv4 address is unassigned from a network interface, the Elastic IP address (if it exists) is also disassociated.

**To unassign a secondary private IPv4 address from an instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select an instance, choose **Actions, Networking, Manage IP addresses**.
4. Under **IPv4 Addresses**, choose **Unassign** for the IPv4 address to unassign.
5. Choose **Yes, Update**.

**To unassign a secondary private IPv4 address from a network interface**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Network Interfaces**.
3. Select the network interface, choose **Actions, Manage IP Addresses**.
4. Under **IPv4 Addresses**, choose **Unassign** for the IPv4 address to unassign.
5. Choose **Yes, Update**.

**To unassign a secondary private IPv4 address using the command line**

- You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](p. 5).
  - `unassign-private-ip-addresses` (AWS CLI)
  - `Unregister-EC2PrivatetIpAddress` (AWS Tools for Windows PowerShell)

**Work with multiple IPv6 addresses**

You can assign multiple IPv6 addresses to your instance, view the IPv6 addresses assigned to your instance, and unassign IPv6 addresses from your instance.

**Contents**

- [Assign multiple IPv6 addresses](p. 1370)
- [View your IPv6 addresses](p. 1372)
- [Unassign an IPv6 address](p. 1373)

**Assign multiple IPv6 addresses**

You can assign one or more IPv6 addresses to your instance during launch or after launch. To assign an IPv6 address to an instance, the VPC and subnet in which you launch the instance must have an associated IPv6 CIDR block.
New console

To assign multiple IPv6 addresses during launch

1. Follow the procedure to launch an instance (p. 722), and when you configure Network Settings (p. 724), choose Advanced network configuration.
2. To assign a secondary IPv6 address, under IPv6 IPs, choose Automatically assign to have Amazon automatically assign a secondary IPv6 address or choose Manually assign to manually enter a CIDR.
3. Complete the remaining steps to launch the instance (p. 722).

Old console

To assign multiple IPv6 addresses during launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the dashboard, choose Launch Instance.
3. Select an AMI, choose an instance type, and choose Next: Configure Instance Details. Ensure that you choose an instance type that support IPv6. For more information, see Instance types (p. 285).
4. On the Configure Instance Details page, select a VPC from the Network list, and a subnet from the Subnet list.
5. In the Network Interfaces section, do the following, and then choose Next: Add Storage:
   - To assign a single IPv6 address to the primary network interface (eth0), under IPv6 IPs, choose Add IP. To add a secondary IPv6 address, choose Add IP again. You can enter an IPv6 address from the range of the subnet, or leave the default Auto-assign value to let Amazon choose an IPv6 address from the subnet for you.
   - Choose Add Device to add another network interface and repeat the steps above to add one or more IPv6 addresses to the network interface. The console enables you to specify up to two network interfaces when you launch an instance. After you launch the instance, choose Network Interfaces in the navigation pane to add additional network interfaces. The total number of network interfaces that you can attach varies by instance type. For more information, see IP addresses per network interface per instance type (p. 1407).
6. Follow the next steps in the wizard to attach volumes and tag your instance.
7. On the Configure Security Group page, select an existing security group or create a new one. If you want your instance to be reachable over IPv6, ensure that your security group has rules that allow access from IPv6 addresses. For more information, see Security group rules for different use cases (p. 2037). Choose Review and Launch.
8. On the Review Instance Launch page, review your settings, and then choose Launch to choose a key pair and launch your instance. If you're new to Amazon EC2 and haven't created any key pairs, the wizard prompts you to create one.

You can use the Instances screen Amazon EC2 console to assign multiple IPv6 addresses to an existing instance. This assigns the IPv6 addresses to the primary network interface (eth0) for the instance. To assign a specific IPv6 address to the instance, ensure that the IPv6 address is not already assigned to another instance or network interface.

To assign multiple IPv6 addresses to an existing instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select your instance, choose Actions, Networking, Manage IP Addresses.

4. Under IPv6 Addresses, choose Assign new IP for each IPv6 address you want to add. You can specify an IPv6 address from the range of the subnet, or leave the Auto-assign value to let Amazon choose an IPv6 address for you.

5. Choose Yes, Update.

Alternatively, you can assign multiple IPv6 addresses to an existing network interface. The network interface must have been created in a subnet that has an associated IPv6 CIDR block. To assign a specific IPv6 address to the network interface, ensure that the IPv6 address is not already assigned to another network interface.

To assign multiple IPv6 addresses to a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select your network interface, choose Actions, Manage IP Addresses.
4. Under IPv6 Addresses, choose Assign new IP for each IPv6 address you want to add. You can specify an IPv6 address from the range of the subnet, or leave the Auto-assign value to let Amazon choose an IPv6 address for you.
5. Choose Yes, Update.

CLI overview

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

• Assign an IPv6 address during launch:
  • Use the --ipv6-addresses or --ipv6-address-count options with the run-instances command (AWS CLI)
  • Define -NetworkInterface and specify the Ipv6Addresses or Ipv6AddressCount parameters with the New-EC2Instance command (AWS Tools for Windows PowerShell).

• Assign an IPv6 address to a network interface:
  • assign-ipv6-addresses (AWS CLI)
  • Register-EC2Ipv6AddressList (AWS Tools for Windows PowerShell)

View your IPv6 addresses

You can view the IPv6 addresses for an instance or for a network interface.

To view the IPv6 addresses assigned to an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select your instance. In the details pane, review the IPv6 IPs field.

To view the IPv6 addresses assigned to a network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select your network interface. In the details pane, review the IPv6 IPs field.
CLI overview

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- View the IPv6 addresses for an instance:
  - `describe-instances` (AWS CLI)
- View the IPv6 addresses for a network interface:
  - `describe-network-interfaces` (AWS CLI)
  - `Get-EC2NetworkInterface` (AWS Tools for Windows PowerShell)

Unassign an IPv6 address

You can unassign an IPv6 address from the primary network interface of an instance, or you can unassign an IPv6 address from a network interface.

**To unassign an IPv6 address from an instance**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select your instance, choose Actions, Networking, Manage IP Addresses.
4. Under IPv6 Addresses, choose Unassign for the IPv6 address to unassign.
5. Choose Yes, Update.

**To unassign an IPv6 address from a network interface**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select your network interface, choose Actions, Manage IP Addresses.
4. Under IPv6 Addresses, choose Unassign for the IPv6 address to unassign.
5. Choose Save.

CLI overview

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- `unassign-ipv6-addresses` (AWS CLI)

EC2 instance hostnames

When you create an EC2 instance, AWS creates a hostname for that instance. For more information on the types of hostnames and how they're provisioned by AWS, see Amazon EC2 instance hostname types (p. 1374). Amazon provides a DNS server that resolves Amazon-provided hostnames to IPv4 and IPv6 addresses. The Amazon DNS server is located at the base of your VPC network range plus two. For more information, see DNS attributes for your VPC in the Amazon VPC User Guide.
Link-local addresses

Link-local addresses are well-known, non-routable IP addresses. Amazon EC2 uses addresses from the link-local address space to provide services that are accessible only from an EC2 instance. These services do not run on the instance, they run on the underlying host. When you access the link-local addresses for these services, you're communicating with either the Xen hypervisor or the Nitro controller.

Link-local address ranges

- IPv4 – 169.254.0.0/16 (169.254.0.0 to 169.254.255.255)
- IPv6 – fe80::/10

Services that you access using link-local addresses

- Instance Metadata Service (p. 1021)
- Amazon Route 53 Resolver (also known as the Amazon DNS server)
- Amazon Time Sync Service (p. 917)

Amazon EC2 instance hostname types

This section describes the Amazon EC2 instance guest OS hostname types available when you launch instances into your VPC subnets.

The hostname distinguishes the EC2 instances on your network. You may use the hostname of an instance if, for example, you want to run scripts to communicate with some or all of the instances on your network.

Contents

- Types of EC2 hostnames (p. 1374)
- Where you see Resource name and IP name (p. 1375)
- How to decide whether to choose Resource name or IP name (p. 1377)
- Modify Hostname type and DNS Hostname configurations (p. 1377)

Types of EC2 hostnames

There are two hostname types for the guest OS hostname when EC2 instances are launched in a VPC:

- **IP name**: The legacy naming scheme where, when you launch an instance, the *private IPv4 address* of the instance is included in the hostname of the instance. The IP name exists for the life of the EC2 instance. When used as the Private DNS hostname, it will only return the private IPv4 address (A record).

- **Resource name**: When you launch an instance, the *EC2 instance ID* is included in the hostname of the instance. The resource name exists for the life of the EC2 instance. When used as the Private DNS hostname, it can return both the private IPv4 address (A record) and/or the IPv6 Global Unicast Address (AAAA record).

The EC2 instance guest OS hostname type depends on the subnet settings:

- If the instance is launched into an IPv4-only subnet, you can select either IP name or resource name.
- If the instance is launched into a dual-stack (IPv4+IPv6) subnet, you can select either IP name or resource name.
If the instance is launched into an IPv6-only subnet, resource name is used automatically.

Contents

- IP name (p. 1375)
- Resource name (p. 1375)
- The difference between IP name and Resource name (p. 1375)

IP name

When you launch an EC2 instance with the Hostname type of IP name, the guest OS hostname is configured to use the private IPv4 address.

- Format for an instance in us-east-1: private-ipv4-address.ec2.internal
- Example: ip-10-24-34-0.ec2.internal
- Format for an instance in any other AWS Region: private-ipv4-address.region.compute.internal
- Example: ip-10-24-34-0.us-west-2.compute.internal

Resource name

When you launch EC2 instances in IPv6-only subnets, the Hostname type of Resource name is selected by default. When you launch an instance in IPv4-only or dual-stack (IPv4+IPv6) subnets, Resource name is an option that you can select. After you launch an instance, you can manage the hostname configuration. For more information, see Modify Hostname type and DNS Hostname configurations (p. 1377).

When you launch an EC2 instance with a Hostname type of Resource name, the guest OS hostname is configured to use the EC2 instance ID.

- Format for an instance in us-east-1: ec2-instance-id.ec2.internal
- Example: i-0123456789abcdef.ec2.internal
- Format for an instance in any other AWS Region: ec2-instance-id.region.compute.internal
- Example: i-0123456789abcdef.us-west-2.compute.internal

The difference between IP name and Resource name

DNS queries for both IP names and resource names coexist to ensure backward compatibility and to allow you to migrate from IP based-naming for hostnames to resource-based naming. For private DNS hostnames based on IP names, you cannot configure whether a DNS A record query for the instance is responded to or not. DNS A record queries are always responded to irrespective of the guest OS hostname settings. In contrast, for private DNS hostnames based on resource name, you can configure whether DNS A and/or DNS AAAA queries for the instance are responded to or not. You configure the response behavior when you launch an instance or modify a subnet. For more information, see Modify Hostname type and DNS Hostname configurations (p. 1377).

Where you see Resource name and IP name

This section describes where you see the hostname types resource name and IP name in the EC2 console.

Contents
When creating an EC2 instance

When you create an EC2 instance, depending on which type of subnet you select, Hostname type of Resource name might be available or it might be selected and not be modifiable. This section explains the scenarios in which you see the hostname types resource name and IP name.

Scenario 1

You create an EC2 instance in the wizard (see Launch an instance using the new launch instance wizard (p. 720)) and, when you configure the details, you choose a subnet that you configured to be IPv6-only.

In this case, the Hostname type of Resource name is selected automatically and is not modifiable. DNS Hostname options of Enable IP name IPv4 (A record) DNS requests and Enable resource-based IPv4 (A record) DNS requests are deselected automatically and are not modifiable. Enable resource-based IPv6 (AAAA record) DNS requests is selected by default but is modifiable. If selected, DNS requests to the resource name will resolve to the IPv6 address (AAAA record) of this EC2 instance.

Scenario 2

You create an EC2 instance in the wizard (see Launch an instance using the new launch instance wizard (p. 720)) and, when you configure the details, you choose a subnet configured with an IPv4 CIDR block or both an IPv4 and IPv6 CIDR block ("dual stack").

In this case, Enable IP name IPv4 (A record) DNS requests is selected automatically and can't be changed. This means that requests to the IP name will resolve to the IPv4 address (A record) of this EC2 instance.

The options default to the configurations of the subnet, but you can modify the options for this instance depending on the subnet settings:

- **Hostname type**: Determines whether you want the guest OS hostname of the EC2 instance to be the resource name or IP name. The default value is **IP name**.
- **Enable resource-based IPv4 (A record) DNS requests**: Determines whether requests to your resource name resolve to the private IPv4 address (A record) of this EC2 instance. This option is not selected by default.
- **Enable resource-based IPv6 (AAAA record) DNS requests**: Determines whether requests to your resource name resolve to the IPv6 GUA address (AAAA record) of this EC2 instance. This option is not selected by default.

When viewing the details of an existing EC2 instance

You can see the hostname values for an existing EC2 instance in the Details tab for the EC2 instance:

- **Hostname type**: The hostname in IP name or resource name format.
- **Private IP DNS name (IPv4 only)**: The IP name that will always resolve to the private IPv4 address of the instance.
- **Private resource DNS name**: The resource name that resolves to the DNS records selected for this instance.
- **Answer private resource DNS name**: The resource name resolves to IPv4 (A), IPv6 (AAAA) or IPv4 and IPv6 (A andAAAAA) DNS records.
In addition, if you connect to your EC2 instance directly over SSH and enter the `hostname` command, you'll see the hostname in either the IP name or resource name format.

### How to decide whether to choose Resource name or IP name

When you launch an EC2 instance (see [Launch an instance using the new launch instance wizard (p. 720)](launch_instance)), if you choose a Hostname type of Resource name, the EC2 instance launches with a hostname in the resource name format. In such cases, the DNS record for this EC2 instance can also point to the resource name. This gives you the flexibility to choose whether that hostname resolves to the IPv4 address, the IPv6 address, or both the IPv4 and IPv6 address of the instance. If you plan to use IPv6 in the future or if you are using dual-stack subnets today, it's best to use a Hostname type of Resource name so that you change DNS resolution for the hostnames of your instances without making any changes to the DNS records themselves. The resource name allows you to add and remove IPv4 and IPv6 DNS resolution on an EC2 instance.

If instead you choose a Hostname type of IP name, and use it as the DNS hostname, it can only resolve to the IPv4 address of the instance. It will not resolve to the IPv6 address of the instance even if the instance has both an IPv4 address and an IPv6 address associated with it.

### Modify Hostname type and DNS Hostname configurations

Follow the steps in this section to modify Hostname type and DNS Hostname configurations for subnets or EC2 instances after they've been launched.

#### Contents

- [Subnets](#) (p. 1377)
- [EC2 instances](#) (p. 1377)

#### Subnets

Modify the configurations for a subnet by selecting a subnet in the VPC console and choosing Actions, Edit subnet settings.

**Note**

Changing the subnet settings doesn't change the configuration of EC2 instances that are already launched in the subnet.

- **Hostname type**: Determines whether you want the default setting of the guest OS hostname of the EC2 instance launched in the subnet to be the resource name or IP name.
- **Enable DNS hostname IPv4 (A record) requests**: Determines whether DNS requests/queries to your resource name resolve to the private IPv4 address (A record) of this EC2 instance.
- **Enable DNS hostname IPv6 (AAAA record) requests**: Determines whether DNS requests/queries to your resource name resolve to the IPv6 address (AAAA record) of this EC2 instance.

#### EC2 instances

Follow the steps in this section to modify the Hostname type and DNS Hostname configurations for an EC2 instance.
Important

- To change the Use resource based naming as guest OS hostname setting, you must first stop the instance. To change the Answer DNS hostname IPv4 (A record) request or Answer DNS hostname IPv6 (AAAA record) requests settings, you don't have to stop the instance.
- To modify any of the settings for non-EBS backed EC2 instance types, you cannot stop the instance. You must terminate the instance and launch a new instance with the desired Hostname type and DNS Hostname configurations.

To modify the Hostname type and DNS Hostname configurations for an EC2 instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. If you're going to change the Use resource based naming as guest OS hostname setting, first stop the EC2 instance. Otherwise, skip this step.

   To stop the instance, select the instance and choose Instance state, Stop instance.
3. Select the instance and choose Actions, Instance settings, Change resource based naming options.
   - Use resource based naming as guest OS hostname: Determines whether you want the guest OS hostname of the EC2 instance to be the resource name or IP name.
   - Answer DNS hostname IPv4 (A record) requests: Determines whether DNS requests/queries to your resource name resolve to the private IPv4 address of this EC2 instance.
   - Answer DNS hostname IPv6 (AAAA record) requests: Determines whether DNS requests/queries to your resource name resolve to the IPv6 address (AAAA record) of this EC2 instance.
4. Choose Save.
5. If you stopped the instance, start it again.

Bring your own IP addresses (BYOIP) in Amazon EC2

You can bring part or all of your publicly routable IPv4 or IPv6 address range from your on-premises network to your AWS account. You continue to control the address range and you can advertise the address range on the internet through AWS. After you bring the address range to AWS, it appears in your AWS account as an address pool.

For a list of Regions where BYOIP is available, see Regional availability (p. 1392).

To see BYOIP information for Windows instances, switch to this page in the Amazon EC2 User Guide for Windows Instances guide: Bring your own IP addresses (BYOIP) in Amazon EC2.

Note

- The steps on this page describe how to bring your own IP address range for use in Amazon EC2 only.
- To bring your own IP address range for use in AWS Global Accelerator, see Bring your own IP addresses (BYOIP) in the AWS Global Accelerator Developer Guide.
- To bring your own IP address range for use with Amazon VPC IP Address Manager, see Tutorial: Bring your IP addresses to IPAM in the Amazon VPC IPAM User Guide.

Contents

- BYOIP definitions (p. 1379)
• **Requirements and quotas (p. 1379)**
• **Onboarding prerequisites for your BYOIP address range (p. 1380)**
• **Onboard your BYOIP (p. 1385)**
• **Work with your address range (p. 1388)**
• **Validate your BYOIP (p. 1389)**
• **Regional availability (p. 1392)**
• **Learn more (p. 1392)**

### BYOIP definitions

- **X.509 Self-sign certificate** — A certificate standard most commonly used to encrypt and authenticate data within a network. It is a certificate used by AWS to validate control over IP space from an RDAP record. For more information about X.509 certificates, see [RFC 3280](https://tools.ietf.org/html/rfc3280).

- **Autonomous System Number (ASN)** — A globally unique identifier that defines a group of IP prefixes run by one or more network operators that maintain a single, clearly-defined routing policy.

- **Regional Internet Registry (RIR)** — An organization that manages allocation and registration of IP addresses and ASNs within a region of the world.

- **Registry Data Access Protocol (RDAP)** — A read-only protocol to query current registration data within a RIR. Entries within the queried RIR database are referred to as "RDAP records". Certain record types need to be updated by customers via a RIR-provided mechanism. These records are queried by AWS to verify control of an address space in the RIR.

- **Route Origin Authorization (ROA)** — An object created by RIRs for customers to authenticate IP advertisement in particular autonomous systems. For an overview, see [Route Origin Authorizations (ROAs)](https://www.arin.net/roas) on the ARIN website.

- **Local Internet Registry (LIR)** — Organizations such as internet service providers that allocate a block of IP addresses from an RIR for their customers.

### Requirements and quotas

- The address range must be registered with your regional internet registry (RIR). BYOIP currently supports registration in the American Registry for Internet Numbers (ARIN), Réseaux IP Européens Network Coordination Centre (RIPE), or Asia-Pacific Network Information Centre (APNIC). It must be registered to a business or institutional entity and cannot be registered to an individual person.

- The most specific IPv4 address range that you can bring is /24.

- The most specific IPv6 address range that you can bring is /48 for CIDRs that are publicly advertisable, and /56 for CIDRs that are not publicly advertisable (p. 1387).

- ROAs are not required for CIDR ranges that are not publicly advertisable, but the RDAP records still need to be updated.

- You can bring each address range to one Region at a time.

- You can bring a total of five BYOIP IPv4 and IPv6 address ranges per Region to your AWS account. You cannot adjust the quotas for BYOIP CIDRs using the Service Quotas console, but you can request a quota increase by contacting the AWS Support Center as described in [AWS service quotas](https://aws.amazon.com/service-quotas) in the AWS General Reference.

- You cannot share your IP address range with other accounts using AWS RAM unless you use Amazon VPC IP Address Manager (IPAM) and integrate IPAM with AWS Organizations. For more information, see [Integrate IPAM with AWS Organizations](https://docs.aws.amazon.com/whitepapers/latest/ipam/integrating-aws-ipam-organizations.html) in the Amazon VPC IPAM User Guide.

- The addresses in the IP address range must have a clean history. We might investigate the reputation of the IP address range and reserve the right to reject an IP address range if it contains an IP address that has a poor reputation or is associated with malicious behavior.
• Legacy address space, the IPv4 address space that was distributed by the Internet Assigned Numbers Authority's (IANA) central registry prior to the formation of the Regional Internet Registry (RIR) system, still requires a corresponding ROA object.

• For LIRs, it is common that they use a manual process to update their records. This can take days to deploy depending on the LIR.

• A single ROA object and RDAP record are needed for a large CIDR block. You can bring multiple smaller CIDR blocks from that range to AWS, even across multiple Regions, using the single object and record.

• BYOIP is not supported for Local Zones, Wavelength Zones, or on AWS Outposts.

• Do not make any manual changes for BYOIP in RADb or any other IRR. BYOIP will automatically update RADb. Any manual changes that include the BYOIP ASN will cause the BYOIP provision operation to fail.

Onboarding prerequisites for your BYOIP address range

The onboarding process for BYOIP has two phases, for which you must perform three steps. These steps correspond to the steps depicted in the following diagram. We include manual steps in this documentation, but your RIR might offer managed services to help you with these steps.

Preparation phase

1. Create a private key (p. 1381) and use it to generate a self-signed X.509 certificate for authentication purposes. This certificate is only used during the provisioning phase.

RIR configuration phase

2. Upload the self-signed certificate (p. 1384) to your RDAP record comments.

3. Create a ROA object (p. 1385) in your RIR. The ROA defines the desired address range, the Autonomous System Numbers (ASNs) allowed to advertise the address range, and an expiration date to register with the Resource Public Key Infrastructure (RPKI) of your RIR.

   Note
   A ROA is not required for non-publicly advertisable IPv6 address space.
To bring on multiple non-contiguous address ranges, you must repeat this process with each address range. However, the preparation and RIR configuration steps don't need to be repeated if splitting a contiguous block across several different Regions.

Bringing on an address range has no effect on any address ranges that you brought on previously.

Before onboarding your address range, complete the following prerequisites. For some tasks, you run Linux commands. On Windows, you can use the Windows Subsystem for Linux to run the Linux commands.

1. Create a private key and generate an X.509 certificate

Use the following procedure to create a self-signed X.509 certificate and add it to the RDAP record for your RIR. This key pair is used to authenticate the address range with the RIR. The openssl commands require OpenSSL version 1.0.2 or later.

Copy the following commands and replace only the placeholder values (in colored italic text).

This procedure follows the best practice of encrypting your private RSA key and requiring a passphrase to access it.

1. Generate an RSA 2048-bit private key as shown in the following.
Onboarding prerequisites

$ openssl genpkey -aes256 -algorithm RSA -pkeyopt rsa_keygen_bits:2048 -out private-key.pem

The -aes256 parameter specifies the algorithm used to encrypt the private key. The command returns the following output, including prompts to set a passphrase:

```
......+++ 
.+.

Enter PEM pass phrase: xxxxxxx
Verifying - Enter PEM pass phrase: xxxxxxx
```

You can inspect the key using the following command:

```
openssl pkey -in private-key.pem -text
```

This returns a passphrase prompt and the contents of the key, which should be similar to the following:

```
Enter pass phrase for private-key.pem:

-----BEGIN PRIVATE KEY-----
MIIEvgIBADANBgkqhkiG9w0BAQEFAASCBKgwggSkAgEAAoIBAQDFBXHRI4HVKAhh3elciooiCZBTC3j1+YxsNTj3a4xKypVoGFWDGHZ5s44FCFLP00SV3+nQ74w96GOM7DPS3x90aKqOzB6n2YE2bEq5v5037KHM0n2ZLum3n2z20E0PM6v2FMs3B6xewlxRFA1nIvMsDWU7/00M9FvWiTwvsl0tJKk+a91K4+t03UdDR7so5WkX3fSwBw3gYldo37Brx815/y1v0CPNapy7ge2/Fiw3yA3xJBG6w6nU/F6H6Mrq4z4vkMRS01AhJNz2NPipeeooK+3K31lwgbgnOKd/z9svk8N/+HTUti1X0RFt6g+P1Jw5xWHRhG5mSn2BszVpuVdlAgMBAEECGgECAlju2j2h3jkV7kUv3Dcs3s2e67A5uDVjXmfox2BxgdupnFACnNqPtV6FxfT05PNUbKhxbj09ufEvFX115XnpzwukUHYc04zgbXFSbENYjyO0rz7Pn4BmM6b37P4hse6Dn1H83h0p4L8CQEBdBjvYF50xwymeBmpmc0jgh/HxsBAPwN6ZkICgULM1WiAZ3MRAZfPhHhpYaksUlKAbCBoVqCvJG059Wjnj3x7jT9PR0qVbH86ruIHB8D7C7Wjckb6xg+OIKrJL5Ewshb82jiH5rv263flWz/e0+HhEL5ZJzn2MY63xmi3qWNUOj/z3rmds2j1u0K61qDj1w1/C3j3x8j3y6P0aJQkV7JdWvnsUJv5SWDHZBHLvevJa1A0uq1jU1DarA8YitqX1NmCeh8GHyXuJ/v6V3C3mKdMrn1enOzn5s7QsndQ04z6iA0qlPm396q4wKtgoC7Apery90g1a/4/sj-b1+0x3yQ1pFd7/1c3aqaqtHe7PrwKbGQ0dc2zNyNT3+yjytf0kJEkVONk+xwUXzi9cL/O2Bqy5CIPC2Z7B5g0e18kwZw+x1pG6UBT6lm1EjLd0k59FyupN4dPvX55D0GgXq3xKv174usGeOBomF0p0HhkTKeWKbXy1XyiTo5085j1jEnnysIpGg028jir

-----END PRIVATE KEY-----
```

Private-Key: (2048 bit)

```c:
```
Keep your private key in a secure location when it is not in use.

2. Generate an X.509 certificate using the private key created in the previous step. In this example, the certificate expires in 365 days, after which time it cannot be trusted. Be sure to set the expiration appropriately. The `tr -d "\n"` command strips newline characters (line breaks) from the output.

You need to provide a Common Name when prompted, but the other fields can be left blank.

```
$ openssl req -new -x509 -key private-key.pem -days 365 | tr -d "\n" > certificate.pem
```

This results in output similar to the following:

Enter pass phrase for private-key.pem: xxxxxxx
You are about to be asked to enter information that will be incorporated into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) []:
State or Province Name (full name) []:
Locality Name (eg, city) []:
Organization Name (eg, company) []:
Organizational Unit Name (eg, section) []:
Common Name (eg, fully qualified host name) []: example.com
Email Address []:

Note
The Common Name is not needed for AWS provisioning. It can be any internal or public domain name.

You can inspect the certificate with the following command:

```
$ cat certificate.pem
```

The output should be a long, PEM-encoded string without line breaks, prefaced by `-----BEGIN CERTIFICATE-----` and followed by `-----END CERTIFICATE-----`.

2. Upload the X.509 certificate to the RDAP record in your RIR

Add the certificate that you previously created to the RDAP record for your RIR. Be sure to include the `-----BEGIN CERTIFICATE-----` and `-----END CERTIFICATE-----` strings before and after the encoded portion. All of this content must be on a single, long line. The procedure for updating RDAP depends on your RIR:
• For ARIN, use the Account Manager portal to add the certificate in the "Public Comments" section for the "Network Information" object representing your address range. Do not add it to the comments section for your organization.

• For RIPE, add the certificate as a new "descr" field to the "inetnum" or "inet6num" object representing your address range. These can usually be found in the "My Resources" section of the RIPE Database portal. Do not add it to the comments section for your organization or the "remarks" field of the above objects.

• For APNIC, email the certificate to helpdesk@apnic.net to manually add it to the "remarks" field for your address range. Send the email using the APNIC authorized contact for the IP addresses.

You can remove the certificate from your RIR’s record after the provisioning stage below has been completed.

3. Create a ROA object in your RIR

Create a ROA object to authorize the Amazon ASNs 16509 and 14618 to advertise your address range, as well as the ASNs that are currently authorized to advertise the address range. For the AWS GovCloud (US) Regions, authorize ASN 8987 instead of 16509 and 14618. You must set the maximum length to the size of the CIDR that you are bringing in. The most specific IPv4 prefix you can bring is /24. The most specific IPv6 address range that you can bring is /48 for CIDRs that are publicly advertisable and /56 for CIDRs that are not publicly advertisable.

Important
If you are creating a ROA object for Amazon VPC IP Address Manager (IPAM), when you create the ROAs, for IPv4 CIDRs you must set the maximum length of an IP address prefix to /24. For IPv6 CIDRs, if you are adding them to an advertisable pool, the maximum length of an IP address prefix must be /48. This ensures that you have full flexibility to divide your public IP address across AWS Regions. IPAM enforces the maximum length you set. For more information about BYOIP addresses to IPAM, see Tutorial: BYOIP address CIDRs to IPAM in the Amazon VPC IPAM User Guide.

It might take up to 24 hours for the ROA to become available to Amazon. For more information, consult your RIR:

• ARIN — ROA Requests
• RIPE — Managing ROAs
• APNIC — Route Management

When you migrate advertisements from an on-premises workload to AWS, you must create a ROA for your existing ASN before creating the ROAs for Amazon’s ASNs. Otherwise, you might see an impact to your existing routing and advertisements.

Important
For Amazon to advertise and continue advertising your IP address range, your ROAs with Amazon ASNs must be compliant with the above guidelines. If your ROAs are not compliant, Amazon reserves the right to stop advertising your IP address range.

Note
This step is not required for non-publicly advertisable IPv6 address space.

Onboard your BYOIP

The onboarding process for BYOIP has the following tasks depending on your needs:
Provision a publicly advertisable address range in AWS

When you provision an address range for use with AWS, you are confirming that you control the address range and are authorizing Amazon to advertise it. We also verify that you control the address range through a signed authorization message. This message is signed with the self-signed X.509 key pair that you used when updating the RDAP record with the X.509 certificate. AWS requires a cryptographically signed authorization message that it presents to the RIR. The RIR authenticates the signature against the certificate that you added to RDAP, and checks the authorization details against the ROA.

To provision the address range

1. Compose message

Compose the plaintext authorization message. The format of the message is as follows, where the date is the expiry date of the message:

```
1|aws|account|cidr|YYYYMMDD|SHA256|RSAPSS
```

Replace the account number, address range, and expiry date with your own values to create a message resembling the following:

```
text_message="1|aws|0123456789AB|198.51.100.0/24|20211231|SHA256|RSAPSS"
```

This is not to be confused with a ROA message, which has a similar appearance.

2. Sign message

Sign the plaintext message using the private key that you created previously. The signature returned by this command is a long string that you need to use in the next step.

```
import os
import base64
import hashlib
import json
import requests

message = json.dumps(text_message)

# Sign the message
signature = base64.b64encode(hashlib.sha256(message.encode('utf-8')).digest())

# Encode the signature
encoded_signature = base64.b64encode(signature)

# Format the signature
formatted_signature = encoded_signature.decode('utf-8')
```

3. Provision address

Use the AWS CLI `provision-byoip-cidr` command to provision the address range. The `--cidr-authorization-context` option uses the message and signature strings that you created previously.

```
aws ec2 provision-byoip-cidr --cidr address-range --cidr-authorization-context Message="$text_message",Signature="$signature" --region us-east-1
```
Provisioning an address range is an asynchronous operation, so the call returns immediately, but the address range is not ready to use until its status changes from pending-provision to provisioned.

4. **Monitor progress**

It can take up to one week to complete the provisioning process for publicly advertisable ranges. Use the `describe-byoip-cidrs` command to monitor progress, as in this example:

```bash
aws ec2 describe-byoip-cidrs --max-results 5 --region us-east-1
```

If there are issues during provisioning and the status goes to failed-provision, you must run the `provision-byoip-cidr` command again after the issues have been resolved.

---

**Provision an IPv6 address range that's not publicly advertisable**

By default, an address range is provisioned to be publicly advertisable to the internet. You can provision an IPv6 address range that will not be publicly advertisable. For routes that are not publicly advertisable, the provisioning process generally completes within minutes. When you associate an IPv6 CIDR block from a non-public address range with a VPC, the IPv6 CIDR can only be accessed through hybrid connectivity options that support IPv6, such as [AWS Direct Connect](https://aws.amazon.com/directconnect/), [AWS Site-to-Site VPN](https://aws.amazon.com/vpn/), or [Amazon VPC Transit Gateways](https://aws.amazon.com/vpc-transit/).

A ROA is not required to provision a non-public address range.

**Important**

- You can only specify whether an address range is publicly advertisable during provisioning. You cannot change the advertisable status later on.
- Amazon VPC doesn’t support [unique local address (ULA)](https://www.iana.org/assignments/ula-address-space) CIDRs. All VPCs must have unique IPv6 CIDRs. Two VPCs can’t have the same IPv6 CIDR range.

To provision an IPv6 address range that will not be publicly advertisable, use the following `provision-byoip-cidr` command.

```bash
aws ec2 provision-byoip-cidr --cidr address-range --cidr-authorization-context Message="$text_message",Signature="$signed_message" --no-publicly-advertisable --region us-east-1
```

---

**Advertise the address range through AWS**

After the address range is provisioned, it is ready to be advertised. You must advertise the exact address range that you provisioned. You can’t advertise only a portion of the provisioned address range.

If you provisioned an IPv6 address range that will not be publicly advertised, you do not need to complete this step.

We recommend that you stop advertising the address range from other locations before you advertise it through AWS. If you keep advertising your IP address range from other locations, we can’t reliably support it or troubleshoot issues. Specifically, we can’t guarantee that traffic to the address range will enter our network.

To minimize down time, you can configure your AWS resources to use an address from your address pool before it is advertised, and then simultaneously stop advertising it from the current location and start advertising it through AWS. For more information about allocating an Elastic IP address from your address pool, see [Allocate an Elastic IP address](p. 1394).
Limitations

- You can run the `advertise-byoip-cidr` command at most once every 10 seconds, even if you specify different address ranges each time.
- You can run the `withdraw-byoip-cidr` command at most once every 10 seconds, even if you specify different address ranges each time.

To advertise the address range, use the following `advertise-byoip-cidr` command.

```bash
aws ec2 advertise-byoip-cidr --cidr address-range --region us-east-1
```

To stop advertising the address range, use the following `withdraw-byoip-cidr` command.

```bash
aws ec2 withdraw-byoip-cidr --cidr address-range --region us-east-1
```

Deprovision the address range

To stop using your address range with AWS, first release any Elastic IP addresses and disassociate any IPv6 CIDR blocks that are still allocated from the address pool. Then stop advertising the address range, and finally, deprovision the address range.

You cannot deprovision a portion of the address range. If you want to use a more specific address range with AWS, deprovision the entire address range and provision a more specific address range.

(IPv4) To release each Elastic IP address, use the following `release-address` command.

```bash
aws ec2 release-address --allocation-id eipalloc-12345678abcabcabc --region us-east-1
```

(IPv6) To disassociate an IPv6 CIDR block, use the following `disassociate-vpc-cidr-block` command.

```bash
aws ec2 disassociate-vpc-cidr-block --association-id vpc-cidr-assoc-12345abcd1234abc1 --region us-east-1
```

To stop advertising the address range, use the following `withdraw-byoip-cidr` command.

```bash
aws ec2 withdraw-byoip-cidr --cidr address-range --region us-east-1
```

To deprovision the address range, use the following `deprovision-byoip-cidr` command.

```bash
aws ec2 deprovision-byoip-cidr --cidr address-range --region us-east-1
```

It can take up to a day to deprovision an address range.

Work with your address range

You can view and use the IPv4 and IPv6 address ranges that you've provisioned in your account.

IPv4 address ranges

You can create an Elastic IP address from your IPv4 address pool and use it with your AWS resources, such as EC2 instances, NAT gateways, and Network Load Balancers.

To view information about the IPv4 address pools that you've provisioned in your account, use the following `describe-public-ipv4-pools` command.
Validate your BYOIP

1. Validate the self-signed x.509 key pair

   Validate that the certificate has been uploaded and is valid via the whois command.

   For ARIN, use `whois -h whois.arin.net r + 2001:0DB8:6172::/48` to look up the RDAP record for your address range. Check the Public Comments section for the NetRange (network range) in the command output. The certificate should be added in the Public Comments section for the address range.

   You can inspect the Public Comments containing the certificate using the following command:

   ```
   whois -h whois.arin.net r + 2001:0DB8:6172::/48 | grep Comments | grep BEGIN
   ```

   This returns output with the contents of the key, which should be similar to the following:

   ```
   Public Comments:
   -----BEGIN CERTIFICATE-----
   ```
Validate your BYOIP

For RIPE, use whois -r -h whois.ripe.net `2001:0DB8:7269::/48` to look up the RDAP record for your address range. Check the descr section for the inetnum object (network range) in the command output. The certificate should be added as a new descr field for the address range.

For APNIC, use whois -r -h whois.apnic.net `2001:0DB8:6170::/48` to look up the RDAP record for your BYOIP address range. Check the remarks section for the inetnum object (network range) in the command output. The certificate should be added as a new remarks field for the address range.

--- END CERTIFICATE ---
You can inspect the remarks containing the certificate using the following command:

```
whois -h whois.apnic.net 2001:0DB8:6170::/48 | grep remarks | grep BEGIN
```

This returns output with the contents of the key, which should be similar to the following:

```
remarks:
-----BEGIN CERTIFICATE-----
MIID1zCCCAqgAwIBAgIUBkRPNSLrpQbRAFP8RDHSP+IITowDQYJKoZIhvcNAQEB
MBQowGgYDVQQDDBhBdWNrbGFuZDEcMBoGA1UEAECwTQwim9uIIFdJL1YbTZX2a
wL1czETM6BGA1UEwkwQlIP5VAgRgtbZEM6BGA1UEAwkwQlIP5VAgRgtbZEM6B
GA1UEAxwQUlIIP5VAgRgtbZEM6BGA1UEAxwQUlIIP5VAgRgtbZEM6BGA1UEAxwQ
uIIP5VAgRgtbZEM6BGA1UEAxwQUlIIP5VAgRgtbZEM6BGA1UEAxwQUlIIP5VAg
-----END CERTIFICATE-----
```

2. Validate the creation of a ROA object

Validate the successful creation of the ROA objects using the RIPEstat Data API. Be sure to test your address range against the Amazon ASNs 16509 and 14618, plus the ASNs that are currently authorized to advertise the address range.

You can inspect the ROA objects from different Amazon ASNs with your address range by using the following command:

```
curl --location --request GET "https://stat.ripe.net/data/rpki-validation/data.json?resource=ASN&prefix=CIDR"
```

In this example output, the response has a result of "status": "valid" for the Amazon ASN 16509. This indicates the ROA object for the address range was created successfully:

```
{
    "messages": [],
    "see_also": [],
    "version": "0.3",
    "data_call_name": "rpki-validation",
    "data_call_status": "supported",
    "cached": false,
    "data": {
        "validating_roas": [
            {
                "origin": "16509",
                "prefix": "2001:0DB8::/32",
                "max_length": 48,
                "validity": "valid"
            }
        ]
    }
}
```

---

1391
A status of “unknown” indicates the ROA object for the address range has not been created. A status of “invalid_asn” indicates that the ROA object for the address range was not created successfully.

Regional availability

The BYOIP feature is currently available in all commercial AWS Regions except for China Regions.

For more information, see the AWS Online Tech talk Deep Dive on Bring Your Own IP.

Elastic IP addresses

An Elastic IP address is a static IPv4 address designed for dynamic cloud computing. An Elastic IP address is allocated to your AWS account, and is yours until you release it. By using an Elastic IP address, you can mask the failure of an instance or software by rapidly remapping the address to another instance in your account. Alternatively, you can specify the Elastic IP address in a DNS record for your domain, so that your domain points to your instance. For more information, see the documentation for your domain registrar, or Set up dynamic DNS on your Amazon Linux instance (p. 995).

An Elastic IP address is a public IPv4 address, which is reachable from the internet. If your instance does not have a public IPv4 address, you can associate an Elastic IP address with your instance to enable communication with the internet. For example, this allows you to connect to your instance from your local computer.

Contents

- Elastic IP address pricing (p. 1393)
- Elastic IP address basics (p. 1393)
Elastic IP address basics

The following are the basic characteristics of an Elastic IP address:

• An Elastic IP address is static; it does not change over time.
• An Elastic IP address is for use in a specific Region only, and cannot be moved to a different Region.
• An Elastic IP address comes from Amazon's pool of IPv4 addresses, or from a custom IPv4 address pool that you have brought to your AWS account.
• To use an Elastic IP address, you first allocate one to your account, and then associate it with your instance or a network interface.
• When you associate an Elastic IP address with an instance, it is also associated with the instance's primary network interface. When you associate an Elastic IP address with a network interface that is attached to an instance, it is also associated with the instance.
• When you associate an Elastic IP address with an instance or its primary network interface, the instance's public IPv4 address (if it had one) is released back into Amazon's pool of public IPv4 addresses. You cannot reuse a public IPv4 address, and you cannot convert a public IPv4 address to an Elastic IP address. For more information, see Public IPv4 addresses (p. 1359).
• You can disassociate an Elastic IP address from a resource, and then associate it with a different resource. To avoid unexpected behavior, ensure that all active connections to the resource named in the existing association are closed before you make the change. After you have associated your Elastic IP address to a different resource, you can reopen your connections to the newly associated resource.
• A disassociated Elastic IP address remains allocated to your account until you explicitly release it. We impose a small hourly charge for Elastic IP addresses that are not associated with a running instance.
• When you associate an Elastic IP address with an instance that previously had a public IPv4 address, the public DNS host name of the instance changes to match the Elastic IP address.
• We resolve a public DNS host name to the public IPv4 address or the Elastic IP address of the instance outside the network of the instance, and to the private IPv4 address of the instance from within the network of the instance.
• When you allocate an Elastic IP address from an IP address pool that you have brought to your AWS account, it does not count toward your Elastic IP address limits. For more information, see Elastic IP address quota (p. 1404).
• When you associate an Elastic IP address with a network border group. This is the location from which we advertise the CIDR block. Setting the network border group limits the CIDR block to this group. If you do not specify the network border group, we set the border group containing all of the Availability Zones in the Region (for example, us-west-2).
• An Elastic IP address is for use in a specific network border group only.
Work with Elastic IP addresses

The following sections describe how you can work with Elastic IP addresses.

Tasks

- Allocate an Elastic IP address (p. 1394)
- Describe your Elastic IP addresses (p. 1395)
- Tag an Elastic IP address (p. 1396)
- Associate an Elastic IP address with an instance or network interface (p. 1396)
- Disassociate an Elastic IP address (p. 1397)
- Transfer Elastic IP addresses (p. 1398)
- Release an Elastic IP address (p. 1401)
- Recover an Elastic IP address (p. 1402)
- Use reverse DNS for email applications (p. 1402)

Allocate an Elastic IP address

You can allocate an Elastic IP address from Amazon's pool of public IPv4 addresses, or from a custom IP address pool that you have brought to your AWS account. For more information about bringing your own IP address range to your AWS account, see Bring your own IP addresses (BYOIP) in Amazon EC2 (p. 1378).

You can allocate an Elastic IP address using one of the following methods.

Console

To allocate an Elastic IP address

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network & Security, Elastic IPs.
3. Choose Allocate Elastic IP address.
4. (Optional) When you allocate an Elastic IP address (EIP), you choose the Network border group in which to allocate the EIP. A network border group is a collection of Availability Zones (AZs), Local Zones, or Wavelength Zones from which AWS advertises a public IP address. Local Zones and Wavelength Zones may have different network border groups than the AZs in a Region to ensure minimum latency or physical distance between the AWS network and the customers accessing the resources in these Zones.

   Important
   You must allocate an EIP in the same network border group as the AWS resource that will be associated with the EIP. An EIP in one network border group can only be advertised in zones in that network border group and not in any other zones represented by other network border groups.

   If you have Local Zones or Wavelength Zones enabled (for more information, see Enable a Local Zone or Enable Wavelength Zones), you can choose a network border group for AZs, Local Zones, or Wavelength Zones. Choose the network border group carefully as the EIP and the AWS resource it is associated with must reside in the same network border group. You can use the EC2 console to view the network border group that your Availability Zones, Local Zones, or Wavelength Zones are in (see Local Zones). Typically, all Availability Zones in a Region belong to the same network border group, whereas Local Zones or Wavelength Zones belong to their own separate network border groups.

   If you don't have Local Zones or Wavelength Zones enabled, when you allocate an EIP, the network border group that represents all of the AZs for the Region (such as us-west-2) is
predefined for you and you cannot change it. This means that the EIP that you allocate to this network border group will be advertised in all AZs in the Region you're in.

5. For **Public IPv4 address pool**, choose one of the following:

   - **Amazon's pool of IPv4 addresses**—If you want an IPv4 address to be allocated from Amazon's pool of IPv4 addresses.
   - **Public IPv4 address that you bring to your AWS account**—If you want to allocate an IPv4 address from an IP address pool that you have brought to your AWS account. This option is disabled if you do not have any IP address pools.
   - **Customer owned pool of IPv4 addresses**—If you want to allocate an IPv4 address from a pool created from your on-premises network for use with an AWS Outpost. This option is disabled if you do not have an AWS Outpost.

6. (Optional) Add or remove a tag.

   [Add a tag] Choose Add new tag and do the following:

   - For **Key**, enter the key name.
   - For **Value**, enter the key value.

   [Remove a tag] Choose Remove to the right of the tag's Key and Value.

7. Choose **Allocate**.

**AWS CLI**

**To allocate an Elastic IP address**

Use the `allocate-address` AWS CLI command.

**PowerShell**

**To allocate an Elastic IP address**

**Describe your Elastic IP addresses**

You can describe an Elastic IP address using one of the following methods.

**Console**

**To describe your Elastic IP addresses**

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address to view and choose **Actions, View details**.

**AWS CLI**

**To describe your Elastic IP addresses**

Use the `describe-addresses` AWS CLI command.

**PowerShell**

**To describe your Elastic IP addresses**

**Tag an Elastic IP address**

You can assign custom tags to your Elastic IP addresses to categorize them in different ways, for example, by purpose, owner, or environment. This helps you to quickly find a specific Elastic IP address based on the custom tags that you assigned to it.

Cost allocation tracking using Elastic IP address tags is not supported.

You can tag an Elastic IP address using one of the following methods.

**Console**

**To tag an Elastic IP address**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic IPs.
3. Select the Elastic IP address to tag and choose Actions, View details.
4. In the Tags section, choose Manage tags.
5. Specify a tag key and value pair.
6. (Optional) Choose Add tag to add additional tags.
7. Choose Save.

**AWS CLI**

**To tag an Elastic IP address**

Use the create-tags AWS CLI command.

```
aws ec2 create-tags --resources eipalloc-12345678 --tags Key=Owner,Value=TeamA
```

**PowerShell**

**To tag an Elastic IP address**

Use the New-EC2Tag AWS Tools for Windows PowerShell command.

The New-EC2Tag command needs a Tag parameter, which specifies the key and value pair to be used for the Elastic IP address tag. The following commands create the Tag parameter.

```
PS C:\> $tag = New-Object Amazon.EC2.Model.Tag
PS C:\> $tag.Key = "Owner"
PS C:\> $tag.Value = "TeamA"
```

```
PS C:\> New-EC2Tag -Resource eipalloc-12345678 -Tag $tag
```

**Associate an Elastic IP address with an instance or network interface**

If you're associating an Elastic IP address with your instance to enable communication with the internet, you must also ensure that your instance is in a public subnet. For more information, see Internet gateways in the Amazon VPC User Guide.
You can associate an Elastic IP address with an instance or network interface using one of the following methods.

**Console**

**To associate an Elastic IP address with an instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address to associate and choose **Actions, Associate Elastic IP address**.
4. For **Resource type**, choose **Instance**.
5. For instance, choose the instance with which to associate the Elastic IP address. You can also enter text to search for a specific instance.
6. (Optional) For **Private IP address**, specify a private IP address with which to associate the Elastic IP address.
7. Choose **Associate**.

**To associate an Elastic IP address with a network interface**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address to associate and choose **Actions, Associate Elastic IP address**.
4. For **Resource type**, choose **Network interface**.
5. For **Network interface**, choose the network interface with which to associate the Elastic IP address. You can also enter text to search for a specific network interface.
6. (Optional) For **Private IP address**, specify a private IP address with which to associate the Elastic IP address.
7. Choose **Associate**.

**AWS CLI**

**To associate an Elastic IP address**

Use the **associate-address** AWS CLI command.

**PowerShell**

**To associate an Elastic IP address**

Use the **Register-EC2Address** AWS Tools for Windows PowerShell command.

**Disassociate an Elastic IP address**

You can disassociate an Elastic IP address from an instance or network interface at any time. After you disassociate the Elastic IP address, you can reassociate it with another resource.

You can disassociate an Elastic IP address using one of the following methods.

**Console**

**To disassociate and reassociate an Elastic IP address**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address to disassociate, choose Actions, Disassociate Elastic IP address.
4. Choose Disassociate.

AWS CLI

To disassociate an Elastic IP address

Use the disassociate-address AWS CLI command.

PowerShell

To disassociate an Elastic IP address

Use the Unregister-EC2Address AWS Tools for Windows PowerShell command.

Transfer Elastic IP addresses

This section describes how to transfer Elastic IP addresses from one AWS account to another. Transferring Elastic IP addresses can be helpful in the following situations:

- **Organizational restructuring** – Use Elastic IP address transfers to quickly move workloads from one AWS account to another. You don't have to wait for new Elastic IP addresses to be allowlisted in your security groups and NACLs.
- **Centralized security administration** – Use a centralized AWS security account to track and transfer Elastic IP addresses that have been vetted for security compliance.
- **Disaster recovery** – Use Elastic IP address transfers to quickly remap IPs for public-facing internet workloads during emergency events.

There is no charge for transferring Elastic IP addresses.

Tasks

- Enable Elastic IP address transfer (p. 1398)
- Disable Elastic IP address transfer (p. 1399)
- Accept a transferred Elastic IP address (p. 1400)

Enable Elastic IP address transfer

This section describes how to accept a transferred Elastic IP address. Note the following limitations related to enabling Elastic IP addresses for transfer:

- You can transfer Elastic IP addresses from any AWS account (source account) to any other AWS account in the same AWS Region (transfer account).
- When you transfer an Elastic IP address, there is a two-step handshake between the AWS accounts. When the source account starts the transfer, the transfer accounts have seven days to accept the Elastic IP address transfer. During those seven days, the source account can view the pending transfer (for example in the AWS console or by using the describe-address-transfers AWS CLI command). After seven days, the transfer expires and ownership of the Elastic IP address returns to the source account.
- Accepted transfers are visible to the source account (for example in the AWS console or by using the describe-address-transfers AWS CLI command) for three days after the transfers have been accepted.
- AWS does not notify transfer accounts about pending Elastic IP address transfer requests. The owner of the source account must notify the owner of the transfer account that there is an Elastic IP address transfer request that they must accept.
- Any tags that are associated with an Elastic IP address being transferred are reset when the transfer is complete.
You cannot transfer Elastic IP addresses allocated from public IPv4 address pools that you bring to your AWS account – commonly referred to as Bring Your Own IP (BYOIP) address pools.

If you attempt to transfer an Elastic IP address that has a reverse DNS record associated with it, you can begin the transfer process, but the transfer account will not be able to accept the transfer until the associated DNS record is removed.

If you have enabled and configured AWS Outposts, you might have allocated Elastic IP addresses from a customer-owned IP address pool (CoIP). You cannot transfer Elastic IP addresses allocated from a CoIP. However, you can use AWS RAM to share a CoIP with another account. For more information, see Customer-owned IP addresses in the AWS Outposts User Guide.

You can use Amazon VPC IPAM to track the transfer of Elastic IP addresses to accounts in an organization from AWS Organizations. For more information, see View IP address history. If an Elastic IP address is transferred to an AWS account outside of the organization, the IPAM audit history of the Elastic IP address is lost.

These steps must be completed by the source account.

**Console**

To enable Elastic IP address transfer

1. Ensure that you’re using the source AWS account.
2. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
3. In the navigation pane, choose Elastic IPs.
4. Select one or more Elastic IP address to enable for transfer and choose Actions, Enable transfer.
5. If you are transferring multiple Elastic IP addresses, you’ll see the Transfer type option. Choose one of the following options:
   - Choose Single account if you are transferring the Elastic IP addresses to a single AWS account.
   - Choose Multiple accounts if you are transferring the Elastic IP addresses to multiple AWS accounts.
6. Under Transfer account ID, enter the IDs of the AWS accounts that you want to transfer the Elastic IP addresses to.
7. Confirm the transfer by entering enable in the text box.
8. Choose Submit.
9. To accept the transfer, see Accept a transferred Elastic IP address (p. 1400). To disable the transfer, see Disable Elastic IP address transfer (p. 1399).

**AWS CLI**

To enable Elastic IP address transfer

Use the enable-address-transfer command.

**PowerShell**

To enable Elastic IP address transfer

Use the Enable-EC2AddressTransfer command.

**Disable Elastic IP address transfer**

This section describes how to disable an Elastic IP transfer after the transfer has been enabled.
These steps must be completed by the source account that enabled the transfer.

**Console**

**To disable an Elastic IP address transfer**

1. Ensure that you’re using the source AWS account.
2. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
3. In the navigation pane, choose Elastic IPs.
4. In the resource list of Elastic IPs, ensure that you have the property enabled that shows the column **Transfer status**.
5. Select one or more Elastic IP address that have a **Transfer status** of **Pending**, and choose Actions, **Disable transfer**.
6. Confirm by entering **disable** in the text box.
7. Choose **Submit**.

**AWS CLI**

**To disable Elastic IP address transfer**

Use the **disable-address-transfer** command.

**PowerShell**

**To disable Elastic IP address transfer**

Use the **Disable-EC2AddressTransfer** command.

**Accept a transferred Elastic IP address**

This section describes how to accept a transferred Elastic IP address.

When you transfer an Elastic IP address, there is a two-step handshake between the AWS accounts. When the source account starts the transfer, the transfer accounts have seven days to accept the Elastic IP address transfer. During those seven days, the source account can view the pending transfer (for example in the AWS console or by using the **describe-address-transfers** AWS CLI command). After seven days, the transfer expires and ownership of the Elastic IP address returns to the source account.

When accepting transfers, note the following exceptions that might occur and how to resolve them:

- **AddressLimitExceeded**: If your transfer account has exceeded the Elastic IP address quota, the source account can enable Elastic IP address transfer, but this exception occurs when the transfer account tries to accept the transfer. By default, all AWS accounts are limited to 5 Elastic IP addresses per Region. See **Elastic IP address quota (p. 1404)** for instructions on increasing the limit.

- **InvalidTransfer.AddressCustomPtrSet**: If you or someone in your organization has configured the Elastic IP address that you are attempting to transfer to use reverse DNS lookup, the source account can enable transfer for the Elastic IP address, but this exception occurs when the transfer account tries to accept the transfer. To resolve this issue, the source account must remove the DNS record for the Elastic IP address. For more information, see **Use reverse DNS for email applications (p. 1402)**.

- **InvalidTransfer.AddressAssociated**: If an Elastic IP address is associated with an ENI or EC2 instance, the source account can enable transfer for the Elastic IP address, but this exception occurs when the transfer account tries to accept the transfer. To resolve this issue, the source account must disassociate the Elastic IP address. For more information, see **Disassociate an Elastic IP address (p. 1397)**.

For any other exceptions, contact AWS Support.
These steps must be completed by the transfer account.

**Console**

**To accept an Elastic IP address transfer**

1. Ensure that you're using the transfer account.
2. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
3. In the navigation pane, choose **Elastic IPs**.
4. Choose **Actions, Accept transfer**.
5. No tags that are associated with the Elastic IP address being transferred are transferred with the Elastic IP address when you accept the transfer. If you want to define a **Name** tag for the Elastic IP address that you are accepting, select **Create a tag with a key of 'Name' and a value that you specify**.
6. Enter the Elastic IP address that you want to transfer.
7. If you are accepting multiple transferred Elastic IP addresses, choose **Add address** to enter an additional Elastic IP address.
8. Choose **Submit**.

**AWS CLI**

**To accept an Elastic IP address transfer**

Use the `accept-address-transfer` command.

**PowerShell**

**To accept an Elastic IP address transfer**

Use the `Approve-EC2AddressTransfer` command.

**Release an Elastic IP address**

If you no longer need an Elastic IP address, we recommend that you release it using one of the following methods. The address to release must not be currently associated with an AWS resource, such as an EC2 instance, NAT gateway, or Network Load Balancer.

**Note**

If you contacted AWS support to set up reverse DNS for an Elastic IP (EIP) address, you can remove the reverse DNS, but you can't release the Elastic IP address because it's been locked by AWS support. To unlock the Elastic IP address, contact AWS Support. Once the Elastic IP address is unlocked, you can release the Elastic IP address.

**Console**

**To release an Elastic IP address**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address to release and choose **Actions, Release Elastic IP addresses**.
4. Choose **Release**.

**AWS CLI**

**To release an Elastic IP address**
Use the `release-address` AWS CLI command.

PowerShell

To release an Elastic IP address

Use the `Remove-EC2Address` AWS Tools for Windows PowerShell command.

## Recover an Elastic IP address

If you have released your Elastic IP address, you might be able to recover it. The following rules apply:

- You cannot recover an Elastic IP address if it has been allocated to another AWS account, or if it will result in your exceeding your Elastic IP address limit.
- You cannot recover tags associated with an Elastic IP address.
- You can recover an Elastic IP address using the Amazon EC2 API or a command line tool only.

### AWS CLI

To recover an Elastic IP address

Use the `allocate-address` AWS CLI command and specify the IP address using the `--address` parameter as follows.

```
aws ec2 allocate-address --domain vpc --address 203.0.113.3
```

### PowerShell

To recover an Elastic IP address

Use the `New-EC2Address` AWS Tools for Windows PowerShell command and specify the IP address using the `-Address` parameter as follows.

```
PS C:\> New-EC2Address -Address 203.0.113.3 -Domain vpc -Region us-east-1
```

### Use reverse DNS for email applications

If you intend to send email to third parties from an instance, we recommend that you provision one or more Elastic IP addresses and assign static reverse DNS records to the Elastic IP addresses that you use to send email. This can help you avoid having your email flagged as spam by some anti-spam organizations.

AWS works with ISPs and internet anti-spam organizations to reduce the chance that your email sent from these addresses will be flagged as spam.

#### Considerations

- Before you create a reverse DNS record, you must set a corresponding forward DNS record (record type A) that points to your Elastic IP address.
- If a reverse DNS record is associated with an Elastic IP address, the Elastic IP address is locked to your account and cannot be released from your account until the record is removed.
- **AWS GovCloud (US) Region**

  You can't create a reverse DNS record using the console or AWS CLI. AWS must assign the static reverse DNS records for you. Open Request to remove reverse DNS and email sending limitations and provide us with your Elastic IP addresses and reverse DNS records.
Create a reverse DNS record

To create a reverse DNS record, choose the tab that matches your preferred method.

**Console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address and choose **Actions, Update reverse DNS**.
4. For **Reverse DNS domain name**, enter the domain name.
5. Enter **update** to confirm.
6. Choose **Update**.

**AWS CLI**

Use the **modify-address-attribute** command in the AWS CLI, as shown in the following example:

```
aws ec2 modify-address-attribute --allocation-id eipalloc-abcd01234567890 --domain-name example.com
{
  "Addresses": [
  {
    "PublicIp": "192.0.2.0",
    "AllocationId": "eipalloc-abcd01234567890",
    "PtrRecord": "example.net."
    "PtrRecordUpdate": {
      "Value": "example.com.",
      "Status": "PENDING"
    }
  }
]
}
```

Remove a reverse DNS record

To remove a reverse DNS record, choose the tab that matches your preferred method.

**Console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Elastic IPs**.
3. Select the Elastic IP address and choose **Actions, Update reverse DNS**.
4. For **Reverse DNS domain name**, clear the domain name.
5. Enter **update** to confirm.
6. Choose **Update**.

**AWS CLI**

Use the **reset-address-attribute** command in the AWS CLI, as shown in the following example:

```
aws ec2 reset-address-attribute --allocation-id eipalloc-abcd01234567890 --domain-name
{
  "Addresses": [
  {
    "PublicIp": "192.0.2.0",
    "AllocationId": "eipalloc-abcd01234567890",
    "PtrRecord": "example.net."
    "PtrRecordUpdate": {
      "Value": "example.com.",
      "Status": "PENDING"
    }
  }
]
```
Elastic IP address quota

By default, all AWS accounts have a quota of five (5) Elastic IP addresses per Region, because public (IPv4) internet addresses are a scarce public resource. We strongly encourage you to use an Elastic IP address primarily for the ability to remap the address to another instance in the case of instance failure, and to use DNS hostnames for all other inter-node communication.

To verify how many Elastic IP addresses are in use

Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/ and choose Elastic IPs from the navigation pane.

To verify your current account quota for Elastic IP addresses

2. From the navigation bar (at the top of the screen), select a Region.
3. On the Dashboard, choose Amazon Elastic Compute Cloud (Amazon EC2).

   If Amazon Elastic Compute Cloud (Amazon EC2) is not listed on the Dashboard, choose AWS services, enter EC2 in the search field, and then choose Amazon Elastic Compute Cloud (Amazon EC2).
4. On the Amazon EC2 service quotas page, enter IP in the search field. The limit is EC2-VPC Elastic IPs. For more information, choose the limit.

If you think your architecture warrants additional Elastic IP addresses, you can request a quota increase directly from the Service Quotas console. To request a quota increase, choose Request increase at account-level. For more information, see Amazon EC2 service quotas (p. 2523).

Elastic network interfaces

An elastic network interface is a logical networking component in a VPC that represents a virtual network card. It can include the following attributes:

- A primary private IPv4 address from the IPv4 address range of your VPC
- A primary IPv6 address from the IPv6 address range of your VPC
- One or more secondary private IPv4 addresses from the IPv4 address range of your VPC
- One Elastic IP address (IPv4) per private IPv4 address
- One public IPv4 address
- One or more IPv6 addresses
Network interface basics

You can create and configure network interfaces and attach them to instances in the same Availability Zone. Your account might also have requester-managed network interfaces, which are created and managed by AWS services to enable you to use other resources and services. You cannot manage these network interfaces yourself. For more information, see Requester-managed network interfaces (p. 1447).

This AWS resource is referred to as a network interface in the AWS Management Console and the Amazon EC2 API. Therefore, we use "network interface" in this documentation instead of "elastic network interface". The term "network interface" in this documentation always means "elastic network interface".

Contents

• Network interface basics (p. 1405)
• Network cards (p. 1406)
• IP addresses per network interface per instance type (p. 1407)
• Work with network interfaces (p. 1435)
• Best practices for configuring network interfaces (p. 1443)
• Scenarios for network interfaces (p. 1445)
• Requester-managed network interfaces (p. 1447)
• Assign prefixes to Amazon EC2 network interfaces (p. 1448)

Network interface basics

You can create a network interface, attach it to an instance, detach it from an instance, and attach it to another instance. The attributes of a network interface follow it as it's attached or detached from an instance and reattached to another instance. When you move a network interface from one instance to another, network traffic is redirected to the new instance.

Primary network interface

Each instance has a default network interface, called the primary network interface. You cannot detach a primary network interface from an instance. You can create and attach additional network interfaces. The maximum number of network interfaces that you can use varies by instance type. For more information, see IP addresses per network interface per instance type (p. 1407).

Public IPv4 addresses for network interfaces

In a VPC, all subnets have a modifiable attribute that determines whether network interfaces created in that subnet (and therefore instances launched into that subnet) are assigned a public IPv4 address. For more information, see Subnet settings in the Amazon VPC User Guide. The public IPv4 address is assigned from Amazon's pool of public IPv4 addresses. When you launch an instance, the IP address is assigned to the primary network interface that's created.

When you create a network interface, it inherits the public IPv4 addressing attribute from the subnet. If you later modify the public IPv4 addressing attribute of the subnet, the network interface keeps the setting that was in effect when it was created. If you launch an instance and specify an existing network interface as the primary network interface, the public IPv4 address attribute is determined by this network interface.

For more information, see Public IPv4 addresses (p. 1359).

**Elastic IP addresses for network interface**

If you have an Elastic IP address, you can associate it with one of the private IPv4 addresses for the network interface. You can associate one Elastic IP address with each private IPv4 address.

If you disassociate an Elastic IP address from a network interface, you can release it back to the address pool. This is the only way to associate an Elastic IP address with an instance in a different subnet or VPC, as network interfaces are specific to subnets.

**IPv6 addresses for network interfaces**

If you associate IPv6 CIDR blocks with your VPC and subnet, you can assign one or more IPv6 addresses from the subnet range to a network interface. Each IPv6 address can be assigned to one network interface.

All subnets have a modifiable attribute that determines whether network interfaces created in that subnet (and therefore instances launched into that subnet) are automatically assigned an IPv6 address from the range of the subnet. For more information, see Subnet settings in the Amazon VPC User Guide. When you launch an instance, the IPv6 address is assigned to the primary network interface that's created.

For more information, see IPv6 addresses (p. 1360).

**Prefix Delegation**

A Prefix Delegation prefix is a reserved private IPv4 or IPv6 CIDR range that you allocate for automatic or manual assignment to network interfaces that are associated with an instance. By using Delegated Prefixes, you can launch services faster by assigning a range of IP addresses as a single prefix.

**Termination behavior**

You can set the termination behavior for a network interface that's attached to an instance. You can specify whether the network interface should be automatically deleted when you terminate the instance to which it's attached.

**Source/destination checking**

You can enable or disable source/destination checks, which ensure that the instance is either the source or the destination of any traffic that it receives. Source/destination checks are enabled by default. You must disable source/destination checks if the instance runs services such as network address translation, routing, or firewalls.

**Monitoring IP traffic**

You can enable a VPC flow log on your network interface to capture information about the IP traffic going to and from a network interface. After you've created a flow log, you can view and retrieve its data in Amazon CloudWatch Logs. For more information, see VPC Flow Logs in the Amazon VPC User Guide.

**Network cards**

Instances with multiple network cards provide higher network performance, including bandwidth capabilities above 100 Gbps and improved packet rate performance. Each network interface is attached to a network card. The primary network interface must be assigned to network card index 0.

If you enable Elastic Fabric Adapter (EFA) when you launch an instance that supports multiple network cards, all network cards are available. You can assign up to one EFA per network card. An EFA counts as a network interface.

The following instances support multiple network cards. All other instance types support one network card.
### IP addresses per network interface per instance type

The following tables list the maximum number of network interfaces per instance type, and the maximum number of private IPv4 addresses and IPv6 addresses per network interface. The limit for IPv6 addresses is separate from the limit for private IPv4 addresses per network interface. Not all instance types support IPv6 addressing.

You can use the `describe-instance-types` AWS CLI command to display information about an instance type, such as the supported network interfaces and IP addresses per interface. The following example displays this information for all C5 instances.

```bash
aws ec2 describe-instance-types --filters "Name=instance-type,Values=c5.*" --query "InstanceTypes[].{Type: InstanceType, MaxENI: NetworkInfo.MaximumNetworkInterfaces, IPv4addr: NetworkInfo.Ipv4AddressesPerInterface}" --output table
```

```
Work with network interfaces

You can work with network interfaces using the Amazon EC2 console or the command line.

Contents

- Create a network interface (p. 1435)
- View details about a network interface (p. 1436)
- Attach a network interface to an instance (p. 1437)
- Detach a network interface from an instance (p. 1438)
- Manage IP addresses (p. 1439)
- Modify network interface attributes (p. 1440)
- Add or edit tags (p. 1442)
- Delete a network interface (p. 1443)

Create a network interface

You can create a network interface in a subnet. You can't move the network interface to another subnet after it's created. You must attach a network interface to an instance in the same Availability Zone.

New console

To create a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Choose Create network interface.
4. (Optional) For Description, enter a descriptive name.
5. For Subnet, select a subnet. The options available in the subsequent steps change depending on the type of subnet you select (IPv4-only, IPv6-only, or dual-stack (IPv4 and IPv6)).
6. For Private IPv4 address, do one of the following:
   - Choose Auto-assign to allow Amazon EC2 to select an IPv4 address from the subnet.
   - Choose Custom and enter an IPv4 address that you select from the subnet.
7. (Subnets with IPv6 addresses only) For IPv6 address, do one of the following:
   - Choose None if you do not want to assign an IPv6 address to the network interface.
   - Choose Auto-assign to allow Amazon EC2 to select an IPv6 address from the subnet.
   - Choose Custom and enter an IPv6 address that you select from the subnet.
8. (Optional) If you're creating a network interface in a dual-stack or IPv6-only subnet, you have the option to Assign Primary IPv6 IP. This assigns a primary IPv6 global unicast address (GUA) to the network interface. Assigning a primary IPv6 address enables you to avoid disrupting traffic to instances or ENIs. Choose Enable if the instance that this ENI will be attached to relies on its IPv6 address not changing. AWS will automatically assign an IPv6 address associated with the ENI attached to your instance to be the primary IPv6 address. Once you enable an IPv6 GUA address to be a primary IPv6, you cannot disable it. When you enable an IPv6 GUA address to be a primary IPv6, the first IPv6 GUA will be made the primary IPv6 address until the instance is terminated or the network interface is detached. If you have multiple IPv6 addresses associated with an ENI attached to your instance and you enable a primary IPv6 address, the first IPv6 GUA address associated with the ENI becomes the primary IPv6 address.
9. (Optional) To create an Elastic Fabric Adapter, choose Elastic Fabric Adapter, Enable.
Work with network interfaces

10. (Optional) Under Advanced settings, for Idle connection tracking timeout, modify the default idle connection timeouts. For more information about these options, see Idle connection tracking timeout (p. 2027).

- UDP timeout: Timeout (in seconds) for idle UDP flows that have seen traffic only in a single direction or a single request-response transaction. Min: 30 seconds. Max: 60 seconds. Default: 30 seconds.

- UDP stream timeout: Timeout (in seconds) for idle UDP flows classified as streams which have seen more than one request-response transaction. Min: 60 seconds. Max: 180 seconds (3 minutes). Default: 180 seconds.

11. For Security groups, select one or more security groups.

12. (Optional) For each tag, choose Add new tag and enter a tag key and an optional tag value.

13. Choose Create network interface.

Old console

To create a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Choose Create Network Interface.
4. For Description, enter a descriptive name.
5. For Subnet, select the subnet.
6. For Private IP (or IPv4 Private IP), enter the primary private IPv4 address. If you don't specify an IPv4 address, we select an available private IPv4 address from within the selected subnet.
7. (IPv6 only) If you selected a subnet that has an associated IPv6 CIDR block, you can optionally specify an IPv6 address in the IPv6 IP field.
8. To create an Elastic Fabric Adapter, select Elastic Fabric Adapter.
9. For Security groups, select one or more security groups.
10. (Optional) Choose Add Tag and enter a tag key and a tag value.
11. Choose Yes, Create.

To create a network interface using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- create-network-interface (AWS CLI)
- New-EC2NetworkInterface (AWS Tools for Windows PowerShell)

View details about a network interface

You can view all the network interfaces in your account.

New console

To describe a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.
3. To view the details page for a network interface, select the ID of the network interface. Alternatively, to view information without leaving the network interfaces page, select the checkbox for the network interface.

Old console

**To describe a network interface using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Network Interfaces**.
3. Select the network interface.
4. To view the details, choose **Details**.

**To describe a network interface using the command line**

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](p. 5).

- `describe-network-interfaces` (AWS CLI)
- `Get-EC2NetworkInterface` (AWS Tools for Windows PowerShell)

**To describe a network interface attribute using the command line**

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](p. 5).

- `describe-network-interface-attribute` (AWS CLI)

**Attach a network interface to an instance**

You can attach a network interface to any instance in the same Availability Zone as the network interface, using either the **Instances** or **Network Interfaces** page of the Amazon EC2 console. Alternatively, you can specify existing network interfaces when you [launch instances](p. 720).

**Important**

For EC2 instances in an IPv6-only subnet, if you attach a secondary network interface to the instance, the private DNS hostname of the second network interface will resolve to the first IPv6 address on the instance's first network interface. For more information about EC2 instance private DNS hostnames, see [Amazon EC2 instance hostname types](p. 1374).

If the public IPv4 address on your instance is released, it does not receive a new one if there is more than one network interface attached to the instance. For more information about the behavior of public IPv4 addresses, see [Public IPv4 addresses](p. 1359).

**Instances page**

**To attach a network interface to an instance using the Instances page**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the checkbox for the instance.
4. Choose **Actions, Networking, Attach network interface**.
5. Select a network interface. If the instance supports multiple network cards, you can choose a network card.
6. Choose **Attach**.

**Network Interfaces page**

**To attach a network interface to an instance using the Network Interfaces page**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Network Interfaces**.
3. Select the checkbox for the network interface.
4. Choose **Actions, Attach**.
5. Choose an instance. If the instance supports multiple network cards, you can choose a network card.
6. Choose **Attach**.

**To attach a network interface to an instance using the command line**

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](p. 5).

- `attach-network-interface` (AWS CLI)
- `Add-EC2NetworkInterface` (AWS Tools for Windows PowerShell)

**Detach a network interface from an instance**

You can detach a secondary network interface that is attached to an EC2 instance at any time, using either the **Instances** or **Network Interfaces** page of the Amazon EC2 console.

If you try to detach a network interface that is attached to a resource from another service, such as an Elastic Load Balancing load balancer, a Lambda function, a WorkSpace, or a NAT gateway, you get an error that you do not have permission to access the resource. To find which service created the resource attached to a network interface, check the description of the network interface. If you delete the resource, then its network interface is deleted.

**Instances page**

**To detach a network interface from an instance using the Instances page**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the checkbox for the instance. Check the **Network interfaces** section of the **Networking** tab to verify that the network interface is attached to an instance as a secondary network interface.
4. Choose **Actions, Networking, Detach network interface**.
5. Select the network interface and choose **Detach**.

**Network Interfaces page**

**To detach a network interface from an instance using the Network Interfaces page**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Network Interfaces**.
3. Select the checkbox for the network interface. Check the Instance details section of the Details tab to verify that the network interface is attached to an instance as a secondary network interface.

4. Choose Actions, Detach.

5. When prompted for confirmation, choose Detach.

6. If the network interface fails to detach from the instance, choose Force detachment, Enable and then try again. We recommend that force detachment only as a last resort. Forcing a detachment can prevent you from attaching a different network interface on the same index until you restart the instance. It can also prevent the instance metadata from reflecting that the network interface was detached until you restart the instance.

To detach a network interface using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- detach-network-interface (AWS CLI)
- Dismount-EC2NetworkInterface (AWS Tools for Windows PowerShell)

Manage IP addresses

You can manage the following IP addresses for your network interfaces:

- Elastic IP addresses (one per private IPv4 address)
- IPv4 addresses
- IPv6 addresses
- Primary IPv6 address

To manage the Elastic IP addresses of a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the checkbox for the network interface.
4. To associate an Elastic IP address, do the following:
   a. Choose Actions, Associate address.
   b. For Elastic IP address, select the Elastic IP address.
   c. For Private IPv4 address, select the private IPv4 address to associate with the Elastic IP address.
   d. (Optional) Choose Allow the Elastic IP address to be reassociated if the network interface is currently associated with another instance or network interface.
   e. Choose Associate.
5. To disassociate an Elastic IP address, do the following:
   a. Choose Actions, Disassociate address.
   b. For Public IP address, select the Elastic IP address.
   c. Choose Disassociate.

To manage the IPv4 and IPv6 addresses of a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network Interfaces**.
3. Select the network interface.
4. Choose **Actions, Manage IP addresses**.
5. Expand the network interface.
6. For **IPv4 addresses**, modify the IP addresses as needed. To assign an IPv4 address, choose **Assign new IP address** and then specify an IPv4 address from the subnet range or let AWS choose one for you. To unassign an IPv4 address, choose **Unassign** next to the address.
7. For **IPv6 addresses**, modify the IP addresses as needed. To assign an IPv6 address, choose **Assign new IP address** and then specify an IPv6 address from the subnet range or let AWS choose one for you. To unassign an IPv6 address, choose **Unassign** next to the address.
8. (Optional) If your modifying a network interface in a dual-stack or IPv6-only subnet, you have the option to **Assign Primary IPv6 IP**. Assigning a primary IPv6 address enables you to avoid disrupting traffic to instances or ENIs. Choose **Enable** if the instance that this ENI will be attached to relies on its IPv6 address not changing. AWS will automatically assign an IPv6 address associated with the ENI attached to your instance to be the primary IPv6 address. Once you enable an IPv6 GUA address to be a primary IPv6, you cannot disable it. When you enable an IPv6 GUA address to be a primary IPv6, the first IPv6 GUA will be made the primary IPv6 address until the instance is terminated or the network interface is detached. If you have multiple IPv6 addresses associated with an ENI attached to your instance and you enable a primary IPv6 address, the first IPv6 GUA address associated with the ENI becomes the primary IPv6 address.
9. Choose **Save**.

**To manage the IP addresses of a network interface using the AWS CLI**

You can use one of the following commands. For more information about these command line interfaces, see *Access Amazon EC2* (p. 5).

- `assign-ipv6-addresses`
- `associate-address`
- `disassociate-address`
- `unassign-ipv6-addresses`

**To manage the IP addresses of a network interface using the Tools for Windows PowerShell**

You can use one of the following commands.

- `Register-EC2Address`
- `Register-EC2Ipv6AddressList`
- `Unregister-EC2Address`
- `Unregister-EC2Ipv6AddressList`

**Modify network interface attributes**

You can change the following network interface attributes:

- `Description` (p. 1440)
- `Security groups` (p. 1441)
- `Delete on termination` (p. 1441)
- `Source/destination check` (p. 1441)
To change the description of a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the checkbox for the network interface.
5. For Description, enter a description for the network interface.
6. Choose Save.

To change the security groups of a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the checkbox for the network interface.
4. Choose Actions, Change security groups.
5. For Associated security groups, select the security groups to use, and then choose Save.

The security group and network interface must be created for the same VPC. To change the security group for interfaces owned by other services, such as Elastic Load Balancing, do so through that service.

To change the termination behavior of a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the checkbox for the network interface.
4. Choose Actions, Change termination behavior.
5. Select or clear Delete on termination, Enable as needed, and then choose Save.

To change source/destination checking for a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the checkbox for the network interface.
5. Select or clear Source/destination check, Enable as needed, and then choose Save.

To change idle connection tracking timeouts:

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the checkbox for the network interface.
4. Choose Actions, Modify connection timeout.
5. Modify the idle connection tracking timeouts. For more information about these options, see Idle connection tracking timeout (p. 2027).
To modify network interface attributes using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- `modify-network-interface-attribute` (AWS CLI)
- `Edit-EC2NetworkInterfaceAttribute` (AWS Tools for Windows PowerShell)

Add or edit tags

Tags are metadata that you can add to a network interface. Tags are private and are only visible to your account. Each tag consists of a key and an optional value. For more information about tags, see Tag your Amazon EC2 resources (p. 2507).

New console

To add or edit tags for a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the checkbox for the network interface.
4. In Tags tab, choose Manage tags.
5. For each tag to create, choose Add new tag and enter a key and optional value. When you're done, choose Save.

Old console

To add or edit tags for a network interface using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the network interface.
4. In the details pane, choose Tags, Add/Edit Tags.
5. In the Add/Edit Tags dialog box, choose Create Tag for each tag to create, and enter a key and optional value. When you're done, choose Save.

To add or edit tags for a network interface using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).
Delete a network interface

Deleting a network interface releases all attributes associated with the interface and releases any private IP addresses or Elastic IP addresses to be used by another instance.

You cannot delete a network interface that is in use. First, you must [detach the network interface](p. 1438).

**New console**

To delete a network interface using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Network Interfaces**.
3. Select the checkbox for the network interface, and then choose **Actions, Delete**.
4. When prompted for confirmation, choose **Delete**.

**Old console**

To delete a network interface using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Network Interfaces**.
3. Select a network interface and choose **Delete**.
4. In the **Delete Network Interface** dialog box, choose **Yes, Delete**.

**To delete a network interface using the command line**

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](p. 5).

- `delete-network-interface` (AWS CLI)
- `Remove-EC2NetworkInterface` (AWS Tools for Windows PowerShell)

Best practices for configuring network interfaces

- You can attach a network interface to an instance when it's running (hot attach), when it's stopped (warm attach), or when the instance is being launched (cold attach).
- You can detach secondary network interfaces when the instance is running or stopped. However, you can't detach the primary network interface.
- You can move a secondary network interface from one instance to another, if the instances are in the same Availability Zone and VPC but in different subnets.
- When launching an instance using the CLI, API, or an SDK, you can specify the primary network interface and additional network interfaces.
- Launching an Amazon Linux or Windows Server instance with multiple network interfaces automatically configures interfaces, private IPv4 addresses, and route tables on the operating system of the instance.
A warm or hot attach of an additional network interface might require you to manually bring up the second interface, configure the private IPv4 address, and modify the route table accordingly. Instances running Amazon Linux or Windows Server automatically recognize the warm or hot attach and configure themselves.

You cannot attach another network interface to an instance (for example, a NIC teaming configuration) to increase or double the network bandwidth to or from the dual-homed instance.

If you attach two or more network interfaces from the same subnet to an instance, you might encounter networking issues such as asymmetric routing. If possible, use a secondary private IPv4 address on the primary network interface instead.

Configure your network interface using ec2-net-utils for Amazon Linux 2

Note
For AL2023, the amazon-ec2-net-utils package generates interface-specific configurations in the /run/systemd/network directory. For more information, see Networking service in the AWS Amazon Linux 2023 User Guide.

Amazon Linux 2 AMIs may contain additional scripts installed by AWS, known as ec2-net-utils. These scripts optionally automate the configuration of your network interfaces. These scripts are available for Amazon Linux 2 only.

Use the following command to install the package on Amazon Linux 2 if it's not already installed, or update it if it's installed and additional updates are available:

```
$ yum install ec2-net-utils
```

The following components are part of ec2-net-utils:

udev rules (/etc/udev/rules.d)

Identifies network interfaces when they are attached, detached, or reattached to a running instance, and ensures that the hotplug script runs (53-ec2-network-interfaces.rules). Maps the MAC address to a device name (75-persistent-net-generator.rules, which generates 70-persistent-net.rules).

hotplug script

DHCP script

Whenever the network interface receives a new DHCP lease, this script queries the instance metadata for Elastic IP addresses. For each Elastic IP address, it adds a rule to the routing policy database to ensure that outbound traffic from that address uses the correct network interface. It also adds each private IP address to the network interface as a secondary address.

ec2ifup ethN (/usr/sbin/)

Extends the functionality of the standard ifup. After this script rewrites the configuration files ifcfg-ethN and route-ethN, it runs ifup.

ec2ifdown ethN (/usr/sbin/)

Extends the functionality of the standard ifdown. After this script removes any rules for the network interface from the routing policy database, it runs ifdown.
**Scenarios for network interfaces**

Attaching multiple network interfaces to an instance is useful when you want to:

- Create a management network.
- Use network and security appliances in your Virtual Private Cloud (VPC).
- Create dual-homed instances with workloads/roles on distinct subnets.
- Create a low-budget, high-availability solution.

### Create a management network

This scenario describes how you can create a management network with network interfaces, given the following criteria and settings (image follows).

**Criteria**

- The primary network interface on the instance (`eth0`) handles public traffic.
- The secondary network interface on the instance (`eth1`) handles backend management traffic. It's connected to a separate subnet that has more restrictive access controls, and is located within the same Availability Zone (AZ) as the primary network interface.

**Settings**

- The primary network interface, which may or may not be behind a load balancer, has an associated security group that allows access to the server from the internet. For example, allow TCP port 80 and 443 from `0.0.0.0/0` or from the load balancer.
- The secondary network interface has an associated security group that allows SSH access only, initiated from one of the following locations:
  - An allowed range of IP addresses, either within the VPC, or from the internet.
  - A private subnet within the same AZ as the primary network interface.
• A virtual private gateway.

**Note**
To ensure failover capabilities, consider using a secondary private IPv4 for incoming traffic on a network interface. In the event of an instance failure, you can move the interface and/or secondary private IPv4 address to a standby instance.

**Use network and security appliances in your VPC**
Some network and security appliances, such as load balancers, network address translation (NAT) servers, and proxy servers prefer to be configured with multiple network interfaces. You can create and attach secondary network interfaces to instances that are running these types of applications and configure the additional interfaces with their own public and private IP addresses, security groups, and source/destination checking.

**Creating dual-homed instances with workloads/roles on distinct subnets**
You can place a network interface on each of your web servers that connects to a mid-tier network where an application server resides. The application server can also be dual-homed to a backend network (subnet) where the database server resides. Instead of routing network packets through the dual-homed instances, each dual-homed instance receives and processes requests on the front end, initiates a connection to the backend, and then sends requests to the servers on the backend network.
Creating dual-homed instances with workloads/roles on distinct VPCs within the same account

You can launch an EC2 instance in one VPC and attach a secondary ENI from another VPC (but in the same Availability Zone) to the instance. This enables you to create multi-homed instances across VPCs with different networking and security configurations. You cannot create multi-homed instances across VPCs across different AWS accounts.

You can use dual-homed instances across VPCs in the following use cases:

- **Overcome CIDR overlaps between two VPCs that can't be peered together**: You can leverage a secondary CIDR in a VPC and allow an instance to communicate across two non-overlapping IP ranges.
- **Connect multiple VPCs within a single account**: Enable communication between individual resources that would normally be separated by VPC boundaries.

Create a low budget high availability solution

If one of your instances serving a particular function fails, its network interface can be attached to a replacement or hot standby instance pre-configured for the same role in order to rapidly recover the service. For example, you can use a network interface as your primary or secondary network interface to a critical service such as a database instance or a NAT instance. If the instance fails, you (or more likely, the code running on your behalf) can attach the network interface to a hot standby instance. Because the interface maintains its private IP addresses, Elastic IP addresses, and MAC address, network traffic begins flowing to the standby instance as soon as you attach the network interface to the replacement instance. Users experience a brief loss of connectivity between the time the instance fails and the time that the network interface is attached to the standby instance, but no changes to the route table or your DNS server are required.

Requester-managed network interfaces

A requester-managed network interface is a network interface that an AWS service creates in your VPC on your behalf. The network interface is associated with a resource for another service, such as a DB instance from Amazon RDS, a NAT gateway, or an interface VPC endpoint from AWS PrivateLink.

Considerations

- You can view the requester-managed network interfaces in your account. You can add or remove tags, but you can't change other properties of a requester-managed network interface.
- You can't detach a requester-managed network interface.
- When you delete the resource associated with a requester-managed network interface, the AWS service detaches the network interface and deletes it. If the service detached a network interface but didn't delete it, you can delete the detached network interface.

To view requester-managed network interfaces using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Network & Security, Network Interfaces**.
3. Select the ID of the network interface to open its details page.
4. The following are the key fields that you can use to determine the purpose of the network interface:
   - **Description**: A description provided by the AWS service that created the interface. For example, "VPC Endpoint Interface vpc-089f2123488812123".
   - **Requester-managed**: Indicates whether the network interface is managed by AWS.
• **Requester ID**: The alias or AWS account ID of the principal or service that created the network interface. If you created the network interface, this is your AWS account ID. Otherwise, another principal or service created it.

**To view requester-managed network interfaces using the AWS CLI**

Use the `describe-network-interfaces` command as follows.

```bash
aws ec2 describe-network-interfaces --filters Name=requester-managed,Values=true
```

The following is example output that shows the key fields that you can use to determine the purpose of the network interface: Description and `InterfaceType`.

```json
{
   ...
   "Description": "VPC Endpoint Interface vpce-089f2123488812123",
   ...
   "InterfaceType": "vpc_endpoint",
   ...
   "NetworkInterfaceId": "eni-0d11e3ccd2c0e6c57",
   ...
   "RequesterId": "727180483921",
   "RequesterManaged": true,
   ...
}
```

**To view requester-managed network interfaces using the Tools for Windows PowerShell**

Use the `Get-EC2NetworkInterface` cmdlet as follows.

```powershell
Get-EC2NetworkInterface -Filter @{
   Name="requester-managed";
   Values="true"
}
```

The following is example output that shows the key fields that you can use to determine the purpose of the network interface: Description and `InterfaceType`.

```plaintext
Description        : VPC Endpoint Interface vpce-089f2123488812123
...
InterfaceType      : vpc_endpoint
...
NetworkInterfaceId : eni-0d11e3ccd2c0e6c57
...
RequesterId        : 727180483921
RequesterManaged   : True
...
```

**Assign prefixes to Amazon EC2 network interfaces**

You can assign a private IPv4 or IPv6 CIDR range, either automatically or manually, to your network interfaces. By assigning prefixes, you scale and simplify the management of applications, including container and networking applications that require multiple IP addresses on an instance. For more information about IPv4 and IPv6 addresses, see Amazon EC2 instance IP addressing (p. 1358).

The following assignment options are available:

• **Automatic assignment** — AWS chooses the prefix from your VPC subnet’s IPv4 or IPv6 CIDR block and assigns it to your network interface.
Assign prefixes

- **Manual Assignment** — You specify the prefix from your VPC subnet’s IPv4 or IPv6 CIDR block, and AWS verifies that the prefix is not already assigned to other resources before assigning it to your network interface.

Assigning prefixes has the following benefits:

- Increased IP addresses on a network interface — When you use a prefix, you assign a block of IP addresses as opposed to individual IP addresses. This increases the number of IP addresses for a network interface.
- Simplified VPC management for containers — In container applications, each container requires a unique IP address. Assigning prefixes to your instance simplifies the management of your VPCs, as you can launch and terminate containers without having to call Amazon EC2 APIs for individual IP assignments.

**Contents**

- Basics for assigning prefixes (p. 1449)
- Considerations and limits for prefixes (p. 1449)
- Work with prefixes (p. 1450)

**Basics for assigning prefixes**

- You can assign a prefix to new or existing network interfaces.
- To use prefixes, you assign a prefix to your network interface, attach the network interface to your instance, and then configure your operating system.
- When you choose the option to specify a prefix, the prefix must meet the following requirements:
  - The IPv4 prefix that you can specify is /28.
  - The IPv6 prefix that you can specify is /80.
  - The prefix is in the subnet CIDR of the network interface, and does not overlap with other prefixes or IP addresses assigned to existing resources in the subnet.
- You can assign a prefix to the primary or secondary network interface.
- You can assign an Elastic IP address to a network interface that has a prefix assigned to it.
- You can also assign an Elastic IP address to the IP address part of the assigned prefix.
- We resolve the private DNS host name of an instance to the primary private IPv4 address.
- We assign each private IPv4 address for a network interface, including those from prefixes, using the following format:
  - **us-east-1 Region**
    
    \[
    \text{ip-private-ipv4-address.ec2.internal}
    \]
  - **All other Regions**
    
    \[
    \text{ip-private-ipv4-address.region.compute.internal}
    \]

**Considerations and limits for prefixes**

Take the following into consideration when you use prefixes:

- Network interfaces with prefixes are supported with [instances built on the Nitro System (p. 295)](https://aws.amazon.com/about-aws/whats-new/).
• Prefixes for network interfaces are limited to IPv6 addresses and private IPv4 addresses.
• The maximum number of IP addresses that you can assign to a network interface depends on the instance type. Each prefix that you assign to a network interface counts as one IP address. For example, a c5.1large instance has a limit of 10 IPv4 addresses per network interface. Each network interface for this instance has a primary IPv4 address. If a network interface has no secondary IPv4 addresses, you can assign up to 9 prefixes to the network interface. For each additional IPv4 address that you assign to a network interface, you can assign one less prefix to the network interface. For more information, see IP addresses per network interface per instance type (p. 1407).
• Prefixes are included in source/destination checks.

Work with prefixes

You can use prefixes with your network interfaces as follows.

Tasks
• Assign prefixes during network interface creation (p. 1450)
• Assign prefixes to existing network interfaces (p. 1454)
• Configure your operating system for network interfaces with prefixes (p. 1457)
• View the prefixes assigned to your network interfaces (p. 1457)
• Remove prefixes from your network interfaces (p. 1459)

Assign prefixes during network interface creation

If you use the automatic assignment option, you can reserve a block of IP addresses in your subnet. AWS chooses the prefixes from this block. For more information, see Subnet CIDR reservations in the Amazon VPC User Guide.

After you have created the network interface, use the attach-network-interface AWS CLI command to attach the network interface to your instance. You must configure your operating system to work with network interfaces with prefixes. For more information, see Configure your operating system for network interfaces with prefixes (p. 1457).

Tasks
• Assign automatic prefixes during network interface creation (p. 1450)
• Assign specific prefixes during network interface creation (p. 1452)

Assign automatic prefixes during network interface creation

You can assign automatic prefixes during network interface creation using one of the following methods.

Console

To assign automatic prefixes during network interface creation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces and then choose Create network interface.
3. Specify a description for the network interface, select the subnet in which to create the network interface, and configure the private IPv4 and IPv6 addresses.
4. Expand Advanced settings and do the following:
   a. To automatically assign an IPv4 prefix, for IPv4 prefix delegation, choose Auto-assign. Then for Number of IPv4 prefixes, specify the number of prefixes to assign.
b. To automatically assign an IPv6 prefix, for IPv6 prefix delegation, choose Auto-assign. Then for Number of IPv6 prefixes, specify the number of prefixes to assign.

Note
IPv6 prefix delegation appears only if the selected subnet is enabled for IPv6.

5. Select the security groups to associate with the network interface and assign resource tags if needed.

6. Choose Create network interface.

AWS CLI

To assign automatic IPv4 prefixes during network interface creation

Use the create-network-interface command and set --ipv4-prefix-count to the number of prefixes that you want AWS to assign. In the following example, AWS assigns 1 prefix.

```
$ aws ec2 create-network-interface \
  --subnet-id subnet-047cfed18eEXAMPLE \
  --description "IPv4 automatic example" \
  --ipv4-prefix-count 1
```

Example output

```
{
  "NetworkInterface": {
    "AvailabilityZone": "us-west-2a",
    "Description": "IPv4 automatic example",
    "Groups": [
      {
        "GroupName": "default",
        "GroupId": "sg-044c2de2c4EXAMPLE"
      }
    ],
    "InterfaceType": "interface",
    "Ipv6Addresses": [],
    "MacAddress": "02:98:65:dd:18:47",
    "NetworkInterfaceId": "eni-02b80b4668EXAMPLE",
    "OwnerId": "123456789012",
    "PrivateIpAddress": "10.0.0.62",
    "PrivateIpAddresses": [
      {
        "Primary": true,
        "PrivateIpAddress": "10.0.0.62"
      }
    ],
    "Ipv4Prefixes": [
      {
        "Ipv4Prefix": "10.0.0.208/28"
      }
    ],
    "RequesterId": "AIDAIV5AJI5LXF5XXDPCO",
    "RequesterManaged": false,
    "SourceDestCheck": true,
    "Status": "pending",
    "SubnetId": "subnet-047cfed18eEXAMPLE",
    "TagSet": [],
    "VpcId": "vpc-0e12f52b21EXAMPLE"
  }
}
```

To assign automatic IPv6 prefixes during network interface creation
Use the `create-network-interface` command and set `--ipv6-prefix-count` to the number of prefixes that you want AWS to assign. In the following example, AWS assigns 1 prefix.

```
$ aws ec2 create-network-interface \
  --subnet-id subnet-047cfed18eEXAMPLE \
  --description "IPv6 automatic example" \
  --ipv6-prefix-count 1
```

Example output

```
{
    "NetworkInterface": {
        "AvailabilityZone": "us-west-2a",
        "Description": "IPv6 automatic example",
        "Groups": [
            {
                "GroupName": "default",
                "GroupId": "sg-044c2de2c4EXAMPLE"
            }
        ],
        "InterfaceType": "interface",
        "Ipv6Addresses": [],
        "MacAddress": "02:bb:e4:31:fe:09",
        "NetworkInterfaceId": "eni-006edbcfa4EXAMPLE",
        "OwnerId": "123456789012",
        "PrivateIpAddress": "10.0.0.73",
        "PrivateIpAddresses": [
            {
                "Primary": true,
                "PrivateIpAddress": "10.0.0.73"
            }
        ],
        "Ipv6Prefixes": [
            {
                "Ipv6Prefix": "2600:1f13:fc2:a700:1768::/80"
            }
        ],
        "RequesterId": "AIDAIV5AJI5LXF5XXDPCO",
        "RequesterManaged": false,
        "SourceDestCheck": true,
        "Status": "pending",
        "SubnetId": "subnet-047cfed18eEXAMPLE",
        "TagSet": [],
        "VpcId": "vpc-0e12f52b21EXAMPLE"
    }
}
```

Assign specific prefixes during network interface creation

You can assign specific prefixes during network interface creation using one of the following methods.

Console

**To assign specific prefixes during network interface creation**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Network Interfaces** and then choose **Create network interface**.
3. Specify a description for the network interface, select the subnet in which to create the network interface, and configure the private IPv4 and IPv6 addresses.
4. Expand **Advanced settings** and do the following:
a. To assign a specific IPv4 prefix, for **IPv4 prefix delegation**, choose **Custom**. Then choose **Add new prefix** and enter the prefix to use.
b. To assign a specific IPv6 prefix, for **IPv6 prefix delegation**, choose **Custom**. Then choose **Add new prefix** and enter the prefix to use.

**Note**

**IPv6 prefix delegation** appears only if the selected subnet is enabled for IPv6.

5. Select the security groups to associate with the network interface and assign resource tags if needed.

6. Choose **Create network interface**.

**AWS CLI**

**To assign specific IPv4 prefixes during network interface creation**

Use the **create-network-interface** command and set **--ipv4-prefixes** to the prefixes. AWS selects IP addresses from this range. In the following example, the prefix CIDR is **10.0.0.208/28**.

```
$ aws ec2 create-network-interface \
   --subnet-id subnet-047cfed18eEXAMPLE \
   --description "IPv4 manual example" \
   --ipv4-prefixes Ipv4Prefix=10.0.0.208/28
```

**Example output**

```
{
   "NetworkInterface": {
      "AvailabilityZone": "us-west-2a",
      "Description": "IPv4 manual example",
      "Groups": [
         {
            "GroupName": "default",
            "GroupId": "sg-044c2de2c4EXAMPLE"
         }
      ],
      "InterfaceType": "interface",
      "Ipv6Addresses": [],
      "MacAddress": "02:98:65:dd:18:47",
      "NetworkInterfaceId": "eni-02b80b4668EXAMPLE",
      "OwnerId": "123456789012",
      "PrivateIpAddress": "10.0.0.62",
      "PrivateIpAddresses": [
         {
            "Primary": true,
            "PrivateIpAddress": "10.0.0.62"
         }
      ],
      "Ipv4Prefixes": [
         {
            "Ipv4Prefix": "10.0.0.208/28"
         }
      ],
      "RequesterId": "AIDAIV5AJISLXF5XDP0C",
      "RequesterManaged": false,
      "SourceDestCheck": true,
      "Status": "pending",
      "SubnetId": "subnet-047cfed18eEXAMPLE",
      "TagSet": [],
      "VpcId": "vpc-0e12f52b21EXAMPLE"
   }
}
```
To assign specific IPv6 prefixes during network interface creation

Use the `create-network-interface` command and set `--ipv6-prefixes` to the prefixes. AWS selects IP addresses from this range. In the following example, the prefix CIDR is `2600:1f13:fc2:a700:1768::/80`.

```
$ aws ec2 create-network-interface
   --subnet-id subnet-047cfed18eEXAMPLE
   --description "IPv6 manual example"
   --ipv6-prefixes Ipv6Prefix=2600:1f13:fc2:a700:1768::/80
```

Example output

```
{
   "NetworkInterface": {
      "AvailabilityZone": "us-west-2a",
      "Description": "IPv6 automatic example",
      "Groups": [
         {
            "GroupName": "default",
            "GroupId": "sg-044c2de2c4EXAMPLE"
         }
      ],
      "InterfaceType": "interface",
      "Ipv6Addresses": [],
      "MacAddress": "02:bb:e4:31:fe:09",
      "NetworkInterfaceId": "eni-06edbcfa4EXAMPLE",
      "OwnerId": "123456789012",
      "PrivateIpAddress": "10.0.0.73",
      "PrivateIpAddresses": [
         {
            "Primary": true,
            "PrivateIpAddress": "10.0.0.73"
         }
      ],
      "Ipv6Prefixes": [
         {
            "Ipv6Prefix": "2600:1f13:fc2:a700:1768::/80"
         }
      ],
      "RequesterId": "AIDAIV5AJI5LXF5XXDPCO",
      "RequesterManaged": false,
      "SourceDestCheck": true,
      "Status": "pending",
      "SubnetId": "subnet-047cfed18eEXAMPLE",
      "TagSet": [],
      "VpcId": "vpc-0e12f52b21EXAMPLE"
   }
}
```

Assign prefixes to existing network interfaces

After you have assigned the prefixes, use the `attach-network-interface` AWS CLI command to attach the network interface to your instance. You must configure your operating system to work with network interfaces with prefixes. For more information, see Configure your operating system for network interfaces with prefixes (p. 1457).

Tasks
• Assign automatic prefixes to an existing network interface (p. 1455)
• Assign specific prefixes to an existing network interface (p. 1456)

Assign automatic prefixes to an existing network interface

You can assign automatic prefixes to an existing network interface using one of the following methods.

Console

To assign automatic prefixes to an existing network interface

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the network interface to which to assign the prefixes, and choose Actions, Manage prefixes.
4. To automatically assign an IPv4 prefix, for IPv4 prefix delegation, choose Auto-assign. Then for Number of IPv4 prefixes, specify the number of prefixes to assign.
5. To automatically assign an IPv6 prefix, for IPv6 prefix delegation, choose Auto-assign. Then for Number of IPv6 prefixes, specify the number of prefixes to assign.

Note
IPv6 prefix delegation appears only if the selected subnet is enabled for IPv6.
6. Choose Save.

AWS CLI

You can use the assign-ipv6-addresses command to assign IPv6 prefixes and the assign-private-ip-addresses command to assign IPv4 prefixes to existing network interfaces.

To assign automatic IPv4 prefixes to an existing network interface

Use the assign-private-ip-addresses command and set --ipv4-prefix-count to the number of prefixes that you want AWS to assign. In the following example, AWS assigns 1 IPv4 prefix.

```
$ aws ec2 assign-private-ip-addresses
   --network-interface-id eni-081fbb4095EXAMPLE
   --ipv4-prefix-count 1
```

Example output

```
{
   "NetworkInterfaceId": "eni-081fbb4095EXAMPLE",
   "AssignedIpv4Prefixes": [
      { "Ipv4Prefix": "10.0.0.176/28"
   ]
}
```

To assign automatic IPv6 prefixes to an existing network interface

Use the assign-ipv6-addresses command and set --ipv6-prefix-count to the number of prefixes that you want AWS to assign. In the following example, AWS assigns 1 IPv6 prefix.

```
$ aws ec2 assign-ipv6-addresses
```

1455
Assign specific prefixes to an existing network interface

You can assign specific prefixes to an existing network interface using one of the following methods.

**Console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Network Interfaces.
3. Select the network interface to which to assign the prefixes, and choose Actions, Manage prefixes.
4. To assign a specific IPv4 prefix, for IPv4 prefix delegation, choose Custom. Then choose Add new prefix and enter the prefix to use.
5. To assign a specific IPv6 prefix, for IPv6 prefix delegation, choose Custom. Then choose Add new prefix and enter the prefix to use.

   **Note**
   IPv6 prefix delegation appears only if the selected subnet is enabled for IPv6.
6. Choose Save.

**AWS CLI**

**Assign specific IPv4 prefixes to an existing network interface**

Use the `assign-private-ip-addresses` command and set --ipv4-prefixes to the prefix. AWS selects IPv4 addresses from this range. In the following example, the prefix CIDR is 10.0.0.208/28.

```
$ aws ec2 assign-private-ip-addresses \
--network-interface-id eni-081fbb4095EXAMPLE \
--ipv4-prefixes 10.0.0.208/28
```

**Example output**

```
{
    "AssignedIpv4Prefixes": [
        "10.0.0.208/28"
    ],
    "NetworkInterfaceId": "eni-081fbb4095EXAMPLE"
}
```
Assign specific IPv6 prefixes to an existing network interface

Use the `assign-ipv6-addresses` command and set `--ipv6-prefixes` to the prefix. AWS selects IPv6 addresses from this range. In the following example, the prefix CIDR is 2600:1f13:fc2:a700:18bb::/80.

```
$ aws ec2 assign-ipv6-addresses
  --network-interface-id eni-00d577338cEXAMPLE
  --ipv6-prefixes 2600:1f13:fc2:a700:18bb::/80
```

Example output

```
{
  "NetworkInterfaceId": "eni-00d577338cEXAMPLE",
  "AssignedIpv6Prefixes": [
    {
      "Ipv6Prefix": "2600:1f13:fc2:a700:18bb::/80"
    }
  ]
}
```

Configure your operating system for network interfaces with prefixes

Amazon Linux AMIs might contain additional scripts installed by AWS, known as `ec2-net-utils`. These scripts optionally automate the configuration of your network interfaces. They are available for Amazon Linux only.

If you are not using Amazon Linux, you can use a Container Network Interface (CNI) for Kubernetes plugin, or `dockerd` if you use Docker to manage your containers.

View the prefixes assigned to your network interfaces

You can view the prefixes assigned to your network interfaces using one of the following methods.

Console

**To view the automatic prefixes assigned to an existing network interface**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Select the network interface for which to view the prefixes and choose the Details tab.
4. The IPv4 Prefix Delegation field lists the assigned IPv4 prefixes, and the IPv6 Prefix Delegation field lists the assigned IPv6 prefixes.

AWS CLI

You can use the `describe-network-interfaces` AWS CLI command to view the prefixes assigned to your network interfaces.

```
$ aws ec2 describe-network-interfaces
```

Example output

```
{
```
"NetworkInterfaces": [
    {
        "AvailabilityZone": "us-west-2a",
        "Description": "IPv4 automatic example",
        "Groups": [

        "Status": "available",
        "SubnetId": "subnet-05eef9fb78EXAMPLE",
        "TagSet": [],
        "VpcId": "vpc-0e12f52b2146bf252"
    }
]
Remove prefixes from your network interfaces

You can remove prefixes from your network interfaces using one of the following methods.

**Console**

To remove the prefixes from a network interface

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Network Interfaces**.
3. Select the network interface from which to remove the prefixes and choose **Actions, Manage prefixes**.
4. Do one of the following:
   - To remove all assigned prefixes, for **IPv4 prefix delegation** and **IPv6 prefix delegation**, choose **Do not assign**.
   - To remove specific assigned prefixes, for **IPv4 prefix delegation** or **IPv6 prefix delegation**, choose **Custom** and then choose **Unassign** next to the prefixes to remove.

   **Note**  
   **IPv6 prefix delegation** appears only if the selected subnet is enabled for IPv6.
5. Choose **Save**.

**AWS CLI**

You can use the `unassign-ipv6-addresses` command to remove IPv6 prefixes and the `unassign-private-ip-addresses` commands to remove IPv4 prefixes from your existing network interfaces.

To remove IPv4 prefixes from a network interface

Use the `unassign-private-ip-addresses` command and set `--ipv4-prefix` to the address that you want to remove.

$ aws ec2 unassign-private-ip-addresses  
--network-interface-id eni-081fbb4095EXAMPLE  
--ipv4-prefixes 10.0.0.176/28

To remove IPv6 prefixes from a network interface

Use the `unassign-ipv6-addresses` command and set `--ipv6-prefix` to the address that you want to remove.

$ aws ec2 unassign-ipv6-addresses  
--network-interface-id eni-00d577338cEXAMPLE  
--ipv6-prefix 2600:1f13:fc2:a700:18bb::/80
Amazon Elastic Compute Cloud
User Guide for Linux Instances
Network bandwidth

Amazon EC2 instance network bandwidth

Instance bandwidth specifications apply to both inbound and outbound traffic for the instance. For example, if an instance specifies up to 10 Gbps of bandwidth, that means it has up to 10 Gbps of bandwidth for inbound traffic, and up to 10 Gbps for outbound traffic. The network bandwidth that’s available to an EC2 instance depends on several factors, as follows.

Multi-flow traffic

Bandwidth for aggregate multi-flow traffic available to an instance depends on the destination of the traffic.

- Within the Region – Traffic can utilize the full network bandwidth available to the instance.
- To other Regions, an internet gateway, Direct Connect, or local gateways (LGW) – Traffic can utilize up to 50% of the network bandwidth available to a current generation instance (p. 287) with a minimum of 32 vCPUs. Bandwidth for a current generation instance with less than 32 vCPUs is limited to 5 Gbps.

Single-flow traffic

Baseline bandwidth for single-flow traffic is limited to 5 Gbps when instances are not in the same cluster placement group (p. 1572). To reduce latency and increase single-flow bandwidth, try one of the following:

- Use a cluster placement group to achieve up to 10 Gbps bandwidth for instances within the same placement group.
- Set up multiple paths between two endpoints to achieve higher bandwidth with Multipath TCP (MPTCP).
- Configure ENA Express for eligible instances within the same subnet to achieve up to 25 Gbps between those instances.

Available instance bandwidth

The available network bandwidth of an instance depends on the number of vCPUs that it has. For example, an m5.8xlarge instance has 32 vCPUs and 10 Gbps network bandwidth, and an m5.16xlarge instance has 64 vCPUs and 20 Gbps network bandwidth. However, instances might not achieve this bandwidth; for example, if they exceed network allowances at the instance level, such as packet per second or number of tracked connections. How much of the available bandwidth the traffic can utilize depends on the number of vCPUs and the destination. For example, an m5.16xlarge instance has 64 vCPUs, so traffic to another instance in the Region can utilize the full bandwidth available (20 Gbps). However, traffic to another instance in a different Region can utilize only 50% of the bandwidth available (10 Gbps).

Typically, instances with 16 vCPUs or fewer (size 4xlarge and smaller) are documented as having "up to" a specified bandwidth; for example, "up to 10 Gbps". These instances have a baseline bandwidth. To meet additional demand, they can use a network I/O credit mechanism to burst beyond their baseline bandwidth. Instances can use burst bandwidth for a limited time, typically from 5 to 60 minutes, depending on the instance size.

An instance receives the maximum number of network I/O credits at launch. If the instance exhausts its network I/O credits, it returns to its baseline bandwidth. A running instance earns network I/O credits whenever it uses less network bandwidth than its baseline bandwidth. A stopped instance does not earn network I/O credits. Instance burst is on a best effort basis, even when the instance has credits available, as burst bandwidth is a shared resource.

There are separate network I/O credit buckets for inbound and outbound traffic.
Base and burst network performance

The following documentation describes the network performance for all instances, plus the baseline network bandwidth available for instances that can use burst bandwidth.

- **General purpose instances** (p. 314)
- **Compute optimized instances** (p. 364)
- **Memory optimized instances** (p. 386)
- **Storage optimized instances** (p. 416)
- **Accelerated computing instances** (p. 437)

**To view network performance using the AWS CLI**

You can use the `describe-instance-types` AWS CLI command to display information about an instance type. The following example displays network performance information for all C5 instances.

```
aws ec2 describe-instance-types --filters "Name=instance-type,Values=c5.*" --query "InstanceTypes[].[InstanceType, NetworkInfo.NetworkPerformance]" --output table
```

<table>
<thead>
<tr>
<th>DescribeInstanceTypes</th>
</tr>
</thead>
<tbody>
<tr>
<td>c5.4xlarge</td>
</tr>
<tr>
<td>c5.xlarge</td>
</tr>
<tr>
<td>c5.12xlarge</td>
</tr>
<tr>
<td>c5.24xlarge</td>
</tr>
<tr>
<td>c5.9xlarge</td>
</tr>
<tr>
<td>c5.2xlarge</td>
</tr>
<tr>
<td>c5.large</td>
</tr>
<tr>
<td>c5.metal</td>
</tr>
<tr>
<td>c5.18xlarge</td>
</tr>
</tbody>
</table>

**Monitor instance bandwidth**

You can use CloudWatch metrics to monitor instance network bandwidth and the packets sent and received. You can use the network performance metrics provided by the Elastic Network Adapter (ENA) driver to monitor when traffic exceeds the network allowances that Amazon EC2 defines at the instance level.

You can configure whether Amazon EC2 sends metric data for the instance to CloudWatch using one-minute periods or five-minute periods. It is possible that the network performance metrics would show that an allowance was exceeded and packets were dropped while the CloudWatch instance metrics do not. This can happen when the instance has a short spike in demand for network resources (known as a microburst), but the CloudWatch metrics are not granular enough to reflect these microsecond spikes.

**Learn more**

- **Instance metrics** (p. 1300)
- **Network performance metrics** (p. 1491)

**Enhanced networking on Linux**

Enhanced networking uses single root I/O virtualization (SR-IOV) to provide high-performance networking capabilities on **supported instance types** (p. 1462). SR-IOV is a method of device
virtualization that provides higher I/O performance and lower CPU utilization when compared to traditional virtualized network interfaces. Enhanced networking provides higher bandwidth, higher packet per second (PPS) performance, and consistently lower inter-instance latencies. There is no additional charge for using enhanced networking.

For information about the supported network speed for each instance type, see Amazon EC2 Instance Types.

Contents
- Enhanced networking support (p. 1462)
- Enable enhanced networking on your instance (p. 1462)
- Enable enhanced networking with the Elastic Network Adapter (ENA) on Linux instances (p. 1463)
- Improve network performance with ENA Express on Linux instances (p. 1472)
- Enable enhanced networking with the Intel 82599 VF interface on Linux instances (p. 1485)
- Operating system optimizations (p. 1491)
- Monitor network performance for your EC2 instance (p. 1491)
- Troubleshoot the Elastic Network Adapter (ENA) (p. 1497)
- Improve network latency for Linux based Amazon EC2 instances (p. 1506)

Enhanced networking support

All current generation (p. 287) instance types support enhanced networking, except for T2 instances.

You can enable enhanced networking using one of the following mechanisms:

Elastic Network Adapter (ENA)

The Elastic Network Adapter (ENA) supports network speeds of up to 100 Gbps for supported instance types.

All instance based on the Nitro system (p. 295) use ENA for enhanced networking. In addition, the following Xen instance types support ENA: H1, G3, m4.16xlarge, P2, P3, P3dn, and R4.

Intel 82599 Virtual Function (VF) interface

The Intel 82599 Virtual Function interface supports network speeds of up to 10 Gbps for supported instance types.

The following instance types use the Intel 82599 VF interface for enhanced networking: C3, C4, D2, I2, M4 (excluding m4.16xlarge), and R3.

For a summary of the enhanced networking mechanisms by instance type, see Summary of networking and storage features (p. 297).

Enable enhanced networking on your instance

If your instance type supports the Elastic Network Adapter for enhanced networking, follow the procedures in Enable enhanced networking with the Elastic Network Adapter (ENA) on Linux instances (p. 1463).

If your instance type supports the Intel 82599 VF interface for enhanced networking, follow the procedures in Enable enhanced networking with the Intel 82599 VF interface on Linux instances (p. 1485).
Enable enhanced networking with the Elastic Network Adapter (ENA) on Linux instances

Amazon EC2 provides enhanced networking capabilities through the Elastic Network Adapter (ENA). To use enhanced networking, you must install the required ENA module and enable ENA support.

Contents

- Requirements (p. 1463)
- Enhanced networking performance (p. 1463)
- Test whether enhanced networking is enabled (p. 1464)
- Enable enhanced networking on the Amazon Linux AMI (p. 1466)
- Enable enhanced networking on Ubuntu (p. 1467)
- Enable enhanced networking on Linux (p. 1468)
- Enable enhanced networking on Ubuntu with DKMS (p. 1470)
- Driver release notes (p. 1472)
- Troubleshoot (p. 1472)

Requirements

To prepare for enhanced networking using the ENA, set up your instance as follows:

- Launch an instance based on the Nitro system (p. 295).
- Launch the instance using a supported version of the Linux kernel and a supported distribution, so that ENA enhanced networking is enabled for your instance automatically. For more information, see ENA Linux Kernel Driver Release Notes.
- Ensure that the instance has internet connectivity.
- Use AWS CloudShell from the AWS Management Console, or install and configure the AWS CLI or the AWS Tools for Windows PowerShell on any computer you choose, preferably your local desktop or laptop. For more information, see Access Amazon EC2 (p. 5) or the AWS CloudShell User Guide.
- Enhanced networking cannot be managed from the Amazon EC2 console.
- If you have important data on the instance that you want to preserve, you should back that data up now by creating an AMI from your instance. Updating kernels and kernel modules, as well as enabling the enaSupport attribute, might render incompatible instances or operating systems unreachable. If you have a recent backup, your data will still be retained if this happens.

Note

We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints.

Enhanced networking performance

The following documentation provides a summary of the network performance for the instance types that support ENA enhanced networking:

- Network Performance for Accelerated Computing Instances (p. 437)
- Network Performance for Compute Optimized Instances (p. 373)
- Network Performance for General Purpose Instances (p. 314)
Test whether enhanced networking is enabled

The following AMIs include the required ENA module and have ENA support enabled:

- Amazon Linux 2023
- Amazon Linux 2
- Amazon Linux AMI 2018.03 and later
- Ubuntu 14.04 or later with Linux-aws kernel
  
  **Note**  
  AWS Graviton-based instance types require Ubuntu 18.04 or later with Linux-aws kernel

- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later

To test whether enhanced networking is already enabled, verify that the ena module is installed on your instance and that the enaSupport attribute is set. If your instance satisfies these two conditions, then the `ethtool -i ethn` command should show that the module is in use on the network interface.

**Kernel module (ena)**

To verify that the ena module is installed, use the `modinfo` command as shown in the following example.

```
[ec2-user ~]$ modinfo ena
version: 1.5.0g
license: GPL
description: Elastic Network Adapter (ENA)
author: Amazon.com, Inc. or its affiliates
srcversion: 692C7C68B8A9001CB3F31D0
alias: pci:v00001D0Fd0000EC21sv*sd*bc*sc*i*
alias: pci:v00001D0Fd0000EC20sv*sd*bc*sc*i*
alias: pci:v00001D0Fd0000EC20sv*sd*bc*sc*i*
alias: pci:v00001D0Fd00001EC2sv*sd*bc*sc*i*
depsends: retpoline: Y
intree: Y
name: ena
...
```

In the above Amazon Linux case, the ena module is installed.

```
ubuntu:~$ modinfo ena
ERROR: modinfo: could not find module ena
```

In the above Ubuntu instance, the module is not installed, so you must first install it. For more information, see [Enable enhanced networking on Ubuntu](p. 1467).
Instance attribute (enaSupport)

To check whether an instance has the enhanced networking enaSupport attribute set, use one of the following commands. If the attribute is set, the response is true.

- **describe-instances** (AWS CLI/AWS CloudShell)

  ```bash
  aws ec2 describe-instances --instance-ids instance_id --query "Reservations[].Instances[].EnaSupport"
  ```

- **Get-EC2Instance** (Tools for Windows PowerShell)

  ```powershell
  (Get-EC2Instance -InstanceId instance-id).Instances.EnaSupport
  ```

Image attribute (enaSupport)

To check whether an AMI has the enhanced networking enaSupport attribute set, use one of the following commands. If the attribute is set, the response is true.

- **describe-images** (AWS CLI/AWS CloudShell)

  ```bash
  aws ec2 describe-images --image-id ami_id --query "Images[].EnaSupport"
  ```

- **Get-EC2Image** (Tools for Windows PowerShell)

  ```powershell
  (Get-EC2Image -ImageId ami_id).EnaSupport
  ```

Network interface driver

Use the following command to verify that the ena module is being used on a particular interface, substituting the interface name that you want to check. If you are using a single interface (default), it this is eth0. If the operating system supports predictable network names (p. 1469), this could be a name like ens5.

In the following example, the ena module is not loaded, because the listed driver is vif.

```
[ec2-user ~]$ ethtool -i eth0
driver: vif
version: 0
firmware-version: 0
expansion-rom-version: 0
bus-info: vif-0
supports-statistics: no
supports-test: no
supports-eeprom-access: no
supports-register-dump: no
supports-priv-flags: no
```

In this example, the ena module is loaded and at the minimum recommended version. This instance has enhanced networking properly configured.

```
[ec2-user ~]$ ethtool -i eth0
driver: ena
version: 1.5.0g
firmware-version: 0
expansion-rom-version: 0
bus-info: 0000:00:05.0
supports-statistics: yes
```
Enable enhanced networking on the Amazon Linux AMI

Amazon Linux 2 and the latest versions of the Amazon Linux AMI include the module required for enhanced networking with ENA installed and have ENA support enabled. Therefore, if you launch an instance with an HVM version of Amazon Linux on a supported instance type, enhanced networking is already enabled for your instance. For more information, see Test whether enhanced networking is enabled (p. 1464).

If you launched your instance using an older Amazon Linux AMI and it does not have enhanced networking enabled already, use the following procedure to enable enhanced networking.

To enable enhanced networking on Amazon Linux AMI

1. Connect to your instance.
2. From the instance, run the following command to update your instance with the newest kernel and kernel modules, including ena:

   [ec2-user ~]$ sudo yum update

3. From your local computer, reboot your instance using the Amazon EC2 console or one of the following commands: reboot-instances (AWS CLI), Restart-EC2Instance (AWS Tools for Windows PowerShell).
4. Connect to your instance again and verify that the ena module is installed and at the minimum recommended version using the modinfo ena command from Test whether enhanced networking is enabled (p. 1464).
5. [EBS-backed instance] From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: stop-instances (AWS CLI), Stop-EC2Instance (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should stop the instance in the AWS OpsWorks console so that the instance state remains in sync.

   [Instance store-backed instance] You can't stop the instance to modify the attribute. Instead, proceed to this procedure: To enable enhanced networking on Amazon Linux AMI (instance store-backed instances) (p. 1467).
6. From your local computer, enable the enhanced networking attribute using one of the following commands:

   - modify-instance-attribute (AWS CLI)

     ```bash
     aws ec2 modify-instance-attribute --instance-id instance_id --ena-support
     ```

   - Edit-EC2InstanceAttribute (Tools for Windows PowerShell)

     ```powershell
     Edit-EC2InstanceAttribute -InstanceId instance_id -EnaSupport $true
     ```

7. (Optional) Create an AMI from the instance, as described in Create an Amazon EBS-backed Linux AMI (p. 173). The AMI inherits the enhanced networking enaSupport attribute from the instance. Therefore, you can use this AMI to launch another instance with enhanced networking enabled by default.
8. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: start-instances (AWS CLI), Start-EC2Instance (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should start the instance in the AWS OpsWorks console so that the instance state remains in sync.
9. Connect to your instance and verify that the ena module is installed and loaded on your network interface using the `ethtool -i ethn` command from Test whether enhanced networking is enabled (p. 1464).

   If you are unable to connect to your instance after enabling enhanced networking, see Troubleshoot the Elastic Network Adapter (ENA) (p. 1497).

To enable enhanced networking on Amazon Linux AMI (instance store-backed instances)

Follow the previous procedure until the step where you stop the instance. Create a new AMI as described in Create an instance store-backed Linux AMI (p. 178), making sure to enable the enhanced networking attribute when you register the AMI.

* register-image (AWS CLI)
  
  ```bash
  aws ec2 register-image --ena-support ...
  ```

* Register-EC2Image (AWS Tools for Windows PowerShell)
  
  ```powershell
  Register-EC2Image -EnaSupport $true ...
  ```

Enable enhanced networking on Ubuntu

The latest Ubuntu HVM AMIs include the module required for enhanced networking with ENA installed and have ENA support enabled. Therefore, if you launch an instance with the latest Ubuntu HVM AMI on a supported instance type, enhanced networking is already enabled for your instance. For more information, see Test whether enhanced networking is enabled (p. 1464).

If you launched your instance using an older AMI and it does not have enhanced networking enabled already, you can install the `linux-aws` kernel package to get the latest enhanced networking drivers and update the required attribute.

To install the `linux-aws` kernel package (Ubuntu 16.04 or later)

Ubuntu 16.04 and 18.04 ship with the Ubuntu custom kernel (`linux-aws` kernel package). To use a different kernel, contact AWS Support.

To install the `linux-aws` kernel package (Ubuntu Trusty 14.04)

1. Connect to your instance.
2. Update the package cache and packages.
   
   ```bash
   ubuntu:~$ sudo apt-get update & & sudo apt-get upgrade -y linux-aws
   ```

   **Important**
   
   If during the update process you are prompted to install `grub`, use `/dev/xvda` to install `grub` onto, and then choose to keep the current version of `/boot/grub/menu.lst`.

3. [EBS-backed instance] From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: stop-instances (AWS CLI), Stop-EC2Instance (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should stop the instance in the AWS OpsWorks console so that the instance state remains in sync.

   [Instance store-backed instance] You can't stop the instance to modify the attribute. Instead, proceed to this procedure: To enable enhanced networking on Ubuntu (instance store-backed instances) (p. 1468).
4. From your local computer, enable the enhanced networking attribute using one of the following commands:

- **modify-instance-attribute** (AWS CLI)
  
  ```shell
  aws ec2 modify-instance-attribute --instance-id instance_id --ena-support
  ```

- **Edit-EC2InstanceAttribute** (Tools for Windows PowerShell)
  
  ```powershell
  Edit-EC2InstanceAttribute -InstanceId instance-id -EnaSupport $true
  ```

5. (Optional) Create an AMI from the instance, as described in [Create an Amazon EBS-backed Linux AMI](p. 173). The AMI inherits the enhanced networking enaSupport attribute from the instance. Therefore, you can use this AMI to launch another instance with enhanced networking enabled by default.

6. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: **start-instances** (AWS CLI), **Start-EC2Instance** (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should start the instance in the AWS OpsWorks console so that the instance state remains in sync.

### To enable enhanced networking on Ubuntu (instance store-backed instances)

Follow the previous procedure until the step where you stop the instance. Create a new AMI as described in [Create an instance store-backed Linux AMI](p. 178), making sure to enable the enhanced networking attribute when you register the AMI.

- **register-image** (AWS CLI)
  
  ```shell
  aws ec2 register-image --ena-support ...
  ```

- **Register-EC2Image** (AWS Tools for Windows PowerShell)
  
  ```powershell
  Register-EC2Image -EnaSupport $true ...
  ```

### Enable enhanced networking on Linux

The latest AMIs for Red Hat Enterprise Linux, SUSE Linux Enterprise Server, and CentOS include the module required for enhanced networking with ENA and have ENA support enabled. Therefore, if you launch an instance with the latest AMI on a supported instance type, enhanced networking is already enabled for your instance. For more information, see [Test whether enhanced networking is enabled](p. 1464).

The following procedure provides the general steps for enabling enhanced networking on a Linux distribution other than Amazon Linux AMI or Ubuntu. For more information, such as detailed syntax for commands, file locations, or package and tool support, see the documentation for your Linux distribution.

### To enable enhanced networking on Linux

1. Connect to your instance.

2. Clone the source code for the ena module on your instance from GitHub at [https://github.com/amzn/amzn-drivers](https://github.com/amzn/amzn-drivers). (SUSE Linux Enterprise Server 12 SP2 and later include ENA 2.02 by default, so you are not required to download and compile the ENA driver. For SUSE Linux Enterprise Server 12 SP2 and later, you should file a request to add the driver version you want to the stock kernel).
3. Compile and install the ena module on your instance. These steps depend on the Linux distribution. For more information about compiling the module on Red Hat Enterprise Linux, see the AWS Knowledge Center article.

4. Run the `sudo depmod` command to update module dependencies.

5. Update `initramfs` on your instance to ensure that the new module loads at boot time. For example, if your distribution supports `dracut`, you can use the following command.

   ```
   dracut -f -v
   ```

6. Determine if your system uses predictable network interface names by default. Systems that use `systemd` or `udev` versions 197 or greater can rename Ethernet devices and they do not guarantee that a single network interface will be named eth0. This behavior can cause problems connecting to your instance. For more information and to see other configuration options, see Predictable Network Interface Names on the freedesktop.org website.

   a. You can check the `systemd` or `udev` versions on RPM-based systems with the following command.

      ```
      rpm -qa | grep -e '^systemd-\[0-9\]\+|^udev-\[0-9\]\+'
      systemd-208-11.el7_0.2.x86_64
      ```

      In the above Red Hat Enterprise Linux 7 example, the `systemd` version is 208, so predictable network interface names must be disabled.

   b. Disable predictable network interface names by adding the `net.ifnames=0` option to the GRUB_CMDLINE_LINUX line in `/etc/default/grub`.

      ```
      sudo sed -i '/^GRUB\_CMDLINE\_LINUX/s/"$/\ net\.ifnames\=0"/' /etc/default/grub
      ```

   c. Rebuild the grub configuration file.

      ```
      sudo grub2-mkconfig -o /boot/grub2/grub.cfg
      ```

7. [EBS-backed instance] From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: `stop-instances` (AWS CLI), `Stop-EC2Instance` (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should stop the instance in the AWS OpsWorks console so that the instance state remains in sync.

   [Instance store-backed instance] You can't stop the instance to modify the attribute. Instead, proceed to this procedure: To enable enhanced networking on Linux (instance store–backed instances) (p. 1470).

8. From your local computer, enable the enhanced networking enaSupport attribute using one of the following commands:

   - `modify-instance-attribute` (AWS CLI)

      ```
      aws ec2 modify-instance-attribute --instance-id instance_id --ena-support
      ```

   - `Edit-EC2InstanceAttribute` (Tools for Windows PowerShell)

      ```
      Edit-EC2InstanceAttribute -InstanceId instance_id -EnaSupport $true
      ```

9. (Optional) Create an AMI from the instance, as described in Create an Amazon EBS-backed Linux AMI (p. 173). The AMI inherits the enhanced networking enaSupport attribute from the instance.
Therefore, you can use this AMI to launch another instance with enhanced networking enabled by default.

**Important**
If your instance operating system contains an `/etc/udev/rules.d/70-persistent-net.rules` file, you must delete it before creating the AMI. This file contains the MAC address for the Ethernet adapter of the original instance. If another instance boots with this file, the operating system will be unable to find the device and `eth0` might fail, causing boot issues. This file is regenerated at the next boot cycle, and any instances launched from the AMI create their own version of the file.

10. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: `start-instances` (AWS CLI), `Start-EC2Instance` (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should start the instance in the AWS OpsWorks console so that the instance state remains in sync.

11. (Optional) Connect to your instance and verify that the module is installed.

If you are unable to connect to your instance after enabling enhanced networking, see [Troubleshoot the Elastic Network Adapter (ENA)](p. 1497).

**To enable enhanced networking on Linux (instance store–backed instances)**

Follow the previous procedure until the step where you stop the instance. Create a new AMI as described in [Create an instance store-backed Linux AMI](p. 178), making sure to enable the enhanced networking attribute when you register the AMI.

- `register-image` (AWS CLI)

```
aws ec2 register-image --ena-support ...
```

- `Register-EC2Image` (AWS Tools for Windows PowerShell)

```
Register-EC2Image -EnaSupport ...
```

**Enable enhanced networking on Ubuntu with DKMS**

This method is for testing and feedback purposes only. It is not intended for use with production deployments. For production deployments, see [Enable enhanced networking on Ubuntu](p. 1467).

**Important**
Using DKMS voids the support agreement for your subscription. It should not be used for production deployments.

**To enable enhanced networking with ENA on Ubuntu (EBS-backed instances)**

1. Follow steps 1 and 2 in [Enable enhanced networking on Ubuntu](p. 1467).

2. Install the `build-essential` packages to compile the kernel module and the `dkms` package so that your ena module is rebuilt every time your kernel is updated.

```
ubuntu:~$ sudo apt-get install -y build-essential dkms
```

3. Clone the source for the ena module on your instance from GitHub at [https://github.com/amzn/amzn-drivers](https://github.com/amzn/amzn-drivers).

```
ubuntu:~$ git clone https://github.com/amzn/amzn-drivers
```
4. Move the amzn-drivers package to the /usr/src/ directory so DKMS can find it and build it for each kernel update. Append the version number (you can find the current version number in the release notes) of the source code to the directory name. For example, version 1.0.0 is shown in the following example.

```bash
ubuntu:~$ sudo mv amzn-drivers /usr/src/amzn-drivers-1.0.0
```

5. Create the DKMS configuration file with the following values, substituting your version of ena.

Create the file.

```bash
ubuntu:~$ sudo touch /usr/src/amzn-drivers-1.0.0/dkms.conf
```

Edit the file and add the following values.

```bash
ubuntu:~$ sudo vim /usr/src/amzn-drivers-1.0.0/dkms.conf
PACKAGE_NAME="ena"
PATTERN_VERSION="1.0.0"
CLEAN="make -C kernel/linux/ena clean"
MAKE="make -C kernel/linux/ena/ BUILD_KERNEL=${kernelver}"
BUILT_MODULE_NAME[0]="ena"
BUILT_MODULE_LOCATION="kernel/linux/ena"
DEST_MODULE_LOCATION[0]="/updates"
DEST_MODULE_NAME[0]="ena"
AUTOINSTALL="yes"
```

6. Add, build, and install the ena module on your instance using DKMS.

Add the module to DKMS.

```bash
ubuntu:~$ sudo dkms add -m amzn-drivers -v 1.0.0
```

Build the module using the `dkms` command.

```bash
ubuntu:~$ sudo dkms build -m amzn-drivers -v 1.0.0
```

Install the module using `dkms`.

```bash
ubuntu:~$ sudo dkms install -m amzn-drivers -v 1.0.0
```

7. Rebuild initramfs so the correct module is loaded at boot time.

```bash
ubuntu:~$ sudo update-initramfs -u -k all
```

8. Verify that the ena module is installed using the modinfo ena command from Test whether enhanced networking is enabled (p. 1464).

```bash
ubuntu:~$ modinfo ena
filename:    /lib/modules/3.13.0-74-generic/updates/dkms/ena.ko
version:  1.0.0
license:  GPL
description: Elastic Network Adapter (ENA)
author:   Amazon.com, Inc. or its affiliates
srcversion:  9693C876C54CA64AE48F0CA
alias:    pci:v00001D0Fd0000EC21sv*sd*bc*sc*i*
alias:    pci:v00001D0Fd00000EC21sv*sd*bc*sc*i*
alias:    pci:v00001D0Fd00001EC21sv*sd*bc*sc*i*
alias:    pci:v00001D0Fd00000EC22sv*sd*bc*sc*i*
alias:    pci:v00001D0Fd00001EC22sv*sd*bc*sc*i*
```
### ENA Express

**depends:**

- `vermagic`: 3.13.0-74-generic SMP mod_unload modversions
- `parm`: `debug`: Debug level (0=none,...,16=all) (int)
- `parm`: `push_mode`: Descriptor / header push mode (0=automatic, 1=disable, 3=enable)
  - 0 - Automatically choose according to device capability (default)
  - 1 - Don't push anything to device memory
  - 3 - Push descriptors and header buffer to device memory (int)
- `parm`: `enable_wd`: Enable keepalive watchdog (0=disable, 1=enable, default=1) (int)
- `parm`: `enable_missing_tx_detection`: Enable missing Tx completions. (default=1) (int)
- `parm`: `numa_node_override_array`: Numa node override map (array of int)
- `parm`: `numa_node_override`: Enable/Disable numa node override (0=disable) (int)

### 9. Continue with Step 3 in Enable enhanced networking on Ubuntu (p. 1467).

### Driver release notes

For information about the versions of the Linux ENA driver, see the [ENA Linux kernel driver release notes](#).

### Troubleshoot

For troubleshooting information, see [Troubleshoot the Elastic Network Adapter (ENA) (p. 1497)](#).

### Improve network performance with ENA Express on Linux instances

ENA Express is powered by AWS Scalable Reliable Datagram (SRD) technology. SRD is a high performance network transport protocol that uses dynamic routing to increase throughput and minimize tail latency. With ENA Express, you can communicate between two EC2 instances in the same subnet.

#### Benefits of ENA Express

- Increases the maximum bandwidth a single flow can use from 5 Gbps to 25 Gbps within the subnet, up to the aggregate instance limit.
- Reduces tail latency of network traffic between EC2 instances, especially during periods of high network load.
- Detects and avoids congested network paths.
- Handles some tasks directly in the network layer, such as packet reordering on the receiving end, and most retransmits that are needed. This frees up the application layer for other work.

#### Note

If your application sends or receives a high volume of packets per second, and needs to optimize for latency most of the time, especially during periods when there is no congestion on the network, [Enhanced networking](#) might be a better fit for your network.

During periods of time when network traffic is light, you might notice a slight increase in packet latency (tens of microseconds) when the packet uses ENA Express. During those times, applications that prioritize specific network performance characteristics can benefit from ENA Express as follows:

- Processes can benefit from increased maximum single flow bandwidth from 5 Gbps to 25 Gbps within the same subnet, up to the aggregate instance limit. For example, if a specific instance type supports up to 12.5 Gbps, the single flow bandwidth is also limited to 12.5 Gbps.
- Longer running processes should experience reduced tail latency during periods of network congestion.
Processes can benefit from a smoother and more standard distribution for network response times.

Prerequisites

To ensure that ENA Express can operate effectively, update the following settings for your instance.

- If your instance uses jumbo frames, run the following command to set your maximum transmission unit (MTU) to 8900.

  ```
  [ec2-user ~]$ sudo ip link set dev eth0 mtu 8900
  ```

- Increase the receiver (Rx) ring size, as follows:

  ```
  [ec2-user ~]$ ethtool -G device rx 8192
  ```

- To maximize ENA Express bandwidth, configure your TCP queue limits as follows:

  1. Set the TCP small queue limit to 1MB or higher. This increases the amount of data that's queued for transmission on a socket.

     ```
     sudo sh -c 'echo 1048576 > /proc/sys/net/ipv4/tcp_limit_output_bytes'
     ```

  2. Disable byte queue limits on the eth device if they're enabled for your Linux distribution. This increases data queued for transmission for the device queue.

     ```
     sudo sh -c 'for txq in /sys/class/net/eth0/queues/tx-*; do echo max > ${txq}/byte_queue_limits/limit_min; done'
     ```

   **Note**

   The ENA driver for the Amazon Linux distribution disables byte queue limits by default.

How ENA Express works

ENA Express is powered by AWS Scalable Reliable Datagram (SRD) technology. It distributes packets for each network flow across different AWS network paths, and dynamically adjusts distribution when it detects signs of congestion. It also manages packet reordering on the receiving end.

To ensure that ENA Express can manage network traffic as intended, sending and receiving instances and the communication between them must meet all of the following requirements:

- Both sending and receiving instance types are supported. See the [Supported instance types for ENA Express](p. 1474) table for more information.

- Both sending and receiving instances must have ENA Express configured. If there are differences in the configuration, you can run into situations where traffic defaults to standard ENA transmission. The following scenario shows what can happen.

  **Scenario: Differences in configuration**

<table>
<thead>
<tr>
<th>Instance</th>
<th>ENA Express Enabled</th>
<th>UDP uses ENA Express</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instance 1</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Instance 2</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>
In this case, TCP traffic between the two instances can use ENA Express, as both instances have enabled it. However, since one of the instances does not use ENA Express for UDP traffic, communication between these two instances over UDP uses standard ENA transmission.

- The sending and receiving instances must run in the same subnet.
- The network path between the instances must not include middleware boxes. ENA Express doesn't currently support middleware boxes.
- To utilize full bandwidth potential, use driver version 2.2.9 or higher.
- To produce metrics, use driver version 2.8 or higher.

If any requirement is unmet, the instances use the standard TCP/UDP protocol but without SRD to communicate.

To ensure that your instance network driver is configured for optimum performance, review the recommended best practices for ENA drivers. These best practices apply to ENA Express, as well. For more information, see the ENA Linux Driver Best Practices and Performance Optimization Guide on the GitHub website.

**Note**
Amazon EC2 refers to the relationship between an instance and a network interface that’s attached to it as an attachment. ENA Express settings apply to the attachment. If the network interface is detached from the instance, the attachment no longer exists, and the ENA Express settings that applied to it are no longer in force. The same is true when an instance is terminated, even if the network interface remains.

**Supported instance types for ENA Express**

The following table contains instance types that support ENA Express.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Architecture</th>
</tr>
</thead>
<tbody>
<tr>
<td>m6a.48xlarge</td>
<td>x86_64</td>
</tr>

### List and view ENA Express settings

This section covers how to list and view ENA Express information from the AWS Management Console or from the AWS CLI. For more information, choose the tab that matches the method you'll use.

**Console**

This tab covers how to find information about your current ENA Express settings and to view instance type support in the AWS Management Console.

#### View instance type support

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the left navigation pane, choose **Instance types**.
3. Select an instance type to see the details for that instance. You can choose the **Instance type** link to open the detail page, or you can select the checkbox on the left side of the list to view details in the detail pane at the bottom of the page.
4. In the **Networking** tab or that section on the detail page, **ENA Express support** shows a true or false value to indicate if the instance type supports this feature.

#### View settings from the Network interface list

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the left navigation pane, choose **Network interfaces**.
3. Select a network interface to see the details for that instance. You can choose the **Network interface ID** link to open the detail page, or you can select the checkbox on the left side of the list to view details in the detail pane at the bottom of the page.
4. In the **Network interface attachment** section on the the **Details** tab or detail page, review settings for **ENA Express** and **ENA Express UDP**.

<td>arm64</td>
</tr>
</tbody>
</table>
View settings from instances

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances**.
3. Select an instance to see the details for that instance. You can choose the **Instance ID** link to open the detail page, or you can select the checkbox on the left side of the list to view details in the detail pane at the bottom of the page.
4. In the **Network interfaces** section on the **Networking** tab, scroll right to review settings for **ENA Express** and **ENA Express UDP**.

AWS CLI

This tab covers how to find information about your current ENA Express settings and to view instance type support in the AWS CLI.

Describe instance types

For information on instance type settings for a specific instance type, run the `describe-instance-types` command in the AWS CLI, and substitute the instance type as follows:

```
[ec2-user ~]$ aws ec2 describe-instance-types --instance-types m6i.metal
{
  "InstanceTypes": [
    {
      "InstanceType": "m6i.metal",
      "CurrentGeneration": true,
    },
    "NetworkInfo": {
      ...
      "EnaSrdSupported": true
    },
  ...
}
```

Describe network interfaces

For information on instance type settings, run the `describe-network-interfaces` command in the AWS CLI as follows:

```
[ec2-user ~]$ aws ec2 describe-network-interfaces
{
  "NetworkInterfaces": [
    {
      "Association": {
        ....IPs, DNS...
      },
      "Attachment": {
        "AttachTime": "2022-11-17T09:04:28+00:00",
        "AttachmentId": "eni-attach-0ab1c23456d78e9f0",
        "DeleteOnTermination": true,
        "DeviceIndex": 0,
        "NetworkCardIndex": 0,
        "InstanceId": "i-0abcd123e456fabcd",
        "InstanceOwnerId": "111122223333",
        "Status": "attached",
        "EnaSrdSpecification": {
          "EnaSrdEnabled": true
        }
      }
    }
  ]
```

PowerShell

This tab covers how to find information about your current ENA Express settings and to view instance type support using PowerShell.

**Describe instance types**

For information on instance type settings for a specific instance type, run the `Get-EC2InstanceType` Cmdlet with the Tools for PowerShell, and substitute the instance type as follows:

```powershell
PS C:\> Get-EC2InstanceType -InstanceType m6i.metal | ` Select-Object ` InstanceType, CurrentGeneration, @{Name = 'EnaSrdSupported'; Expression = { $_.NetworkInfo.EnaSrdSupported } } | ` Format-List
```

```
InstanceType      : m6i.metal
CurrentGeneration : True
EnaSrdSupported   : True
```

If ENA Express is enabled, a value of True is returned.

**Describe network interfaces**

For information on ENA Express settings for a networking interface, run the `Get-EC2NetworkInterface` Cmdlet with the Tools for PowerShell as follows:

```powershell
```

```
Association : 
NetworkInterfaceId : eni-0d1234e5f6a78901b
OwnerId : 111122223333
```
Configure ENA Express settings

You can configure ENA Express for supported EC2 instance types without needing to install any additional software. This section covers how to configure ENA Express from the AWS Management Console or from the AWS CLI. For more information, choose the tab that matches the method you'll use.

Console

This tab covers how to manage ENA Express settings for network interfaces that are attached to an instance.

Manage ENA Express from the Network interface list

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose Network interfaces.
3. Select a network interface that is attached to an instance. You can choose the Network interface ID link to open the detail page, or you can select the checkbox on the left side of the list.
4. Choose Manage ENA Express from the Action menu at the top right side of the page. This opens the Manage ENA Express dialog, with the selected network interface ID and current settings displayed.
   
   Note
   If the network interface you selected is not attached to an instance, this action does not appear in the menu.
5. To use ENA Express, select the Enable check box.
6. When ENA Express is enabled, you can configure UDP settings. To use ENA Express UDP, select the Enable check box.
7. To save your settings, choose Save.

Manage ENA Express from the Instance list

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose Instances.
3. Select the instance that you want to manage. You can choose the Instance ID to open the detail page, or you can select the checkbox on the left side of the list.
4. Select the Network interface to configure for your instance.
5. Choose Manage ENA Express from the Action menu at the top right side of the page.
6. To configure ENA Express for a network interface that's attached to your instance, select it from the Network interface list.
7. To use ENA Express for the selected network interface attachment, select the Enable check box.
8. When ENA Express is enabled, you can configure UDP settings. To use ENA Express UDP, select the Enable check box.
9. To save your settings, choose Save.
Configure ENA Express when you attach a network interface to an EC2 instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose Network interfaces.
3. Select a network interface that is not attached to an instance (Status is Available). You can choose the Network interface ID link to open the detail page, or you can select the checkbox on the left side of the list.
4. Select the Instance that you'll attach to.
5. To use ENA Express after you attach the network interface to the instance, select the Enable check box.
6. When ENA Express is enabled, you can configure UDP settings. To use ENA Express UDP, select the Enable check box.
7. To attach the network interface to the instance and save your ENA Express settings, choose Attach.

AWS CLI

This tab covers how to configure ENA Express settings in the AWS CLI.

Configure ENA Express when you attach a network interface

To configure ENA Express when you attach a network interface to an instance, run the attach-network-interface command in the AWS CLI, as shown in the following examples:

Example 1: Use ENA Express for TCP traffic, but not for UDP traffic

In this example, we configure EnaSrdEnabled as true, and we allow EnaSrdUdpEnabled to default to false.

```
[ec2-user ~]$ aws ec2 attach-network-interface --network-interface-id eni-0123f4567890a1b23 --instance-id i-0f1a234b5cd67e890 --device-index 1 --ena-srd-specification 'EnaSrdEnabled=true'
{
  "AttachmentId": "eni-attach-012c3d45e678f9012"
}
```

Example 2: Use ENA Express for both TCP traffic and UDP traffic

In this example, we configure both EnaSrdEnabled and EnaSrdUdpEnabled as true.

```
[ec2-user ~]$ aws ec2 attach-network-interface --network-interface-id eni-0123f4567890a1b23 --instance-id i-0f1a234b5cd67e890 --device-index 1 --ena-srd-specification 'EnaSrdEnabled=true,EnaSrdUdpSpecification={EnaSrdUdpEnabled=true}'
{
  "AttachmentId": "eni-attach-012c3d45e678f9012"
}
```

Update ENA Express settings for your network interface attachment

To update ENA Express settings for a network interface that's attached to an instance, run the modify-network-interface-attribute command in the AWS CLI, as shown in the following examples:

Example 1: Use ENA Express for TCP traffic, but not for UDP traffic

In this example, we configure EnaSrdEnabled as true, and we allow EnaSrdUdpEnabled to default to false if it has never been set previously.

```
[ec2-user ~]$ aws ec2 modify-network-interface-attribute --network-interface-id eni-0123f4567890a1b23 --modify-attribute-ena-srd-enabled --ena-srd-enabled=true
```

Example 2: Use ENA Express for both TCP traffic and UDP traffic

In this example, we configure both EnaSrdEnabled and EnaSrdUdpEnabled as true.

```
[ec2-user ~]$ aws ec2 modify-network-interface-attribute --network-interface-id eni-0123f4567890a1b23 --modify-attribute-ena-srd-enabled --ena-srd-enabled=true,EnaSrdUdpSpecification={EnaSrdUdpEnabled=true}
```

1481
**Example 2: Use ENA Express for both TCP traffic and UDP traffic**

In this example, we configure both `EnaSrdEnabled` and `EnaSrdUdpEnabled` as `true`.

```
```

**Example 3: Stop using ENA Express for UDP traffic**

In this example, we configure `EnaSrdUdpEnabled` as `false`.

```
```

---

**PowerShell**

This tab covers how to configure ENA Express settings using PowerShell.

**Configure ENA Express when you attach a network interface**

To configure ENA Express settings for a networking interface, run the `Add-EC2NetworkInterface` Cmdlet with the Tools for PowerShell as shown in the following examples:

**Example 1: Use ENA Express for TCP traffic, but not for UDP traffic**

In this example, we configure `EnaSrdEnabled` as `true`, and we allow `EnaSrdUdpEnabled` to default to `false`.

```
PS C:\> Add-EC2NetworkInterface -NetworkInterfaceId eni-0123f4567890a1b23 -InstanceId i-0f1a234b5cd67e890 -DeviceIndex 1 -EnaSrdSpecification_EnaSrdEnabled $true
eni-attach-012c3d45e678f9012
```

**Example 2: Use ENA Express for both TCP traffic and UDP traffic**

In this example, we configure both `EnaSrdEnabled` and `EnaSrdUdpEnabled` as `true`.

```
PS C:\> Add-EC2NetworkInterface -NetworkInterfaceId eni-0123f4567890a1b23 -InstanceId i-0f1a234b5cd67e890 -DeviceIndex 1 -EnaSrdSpecification_EnaSrdEnabled $true -EnaSrdUdpSpecification_EnaSrdUdpEnabled $true
eni-attach-012c3d45e678f9012
```

**Update ENA Express settings for your network interface attachment**

To update ENA Express settings for a network interface that's attached to an instance, run the `Add-EC2NetworkInterface` Cmdlet command in the Tools for PowerShell, as shown in the following examples:
Example 1: Use ENA Express for TCP traffic, but not for UDP traffic

In this example, we configure EnaSrdEnabled as true, and we allow EnaSrdUdpEnabled to default to false if it has never been set previously.

```
```

```
NetworkInterfaceId : eni-0123f4567890a1b23
EnaSrdEnabled      : True
EnaSrdUdpEnabled   : False
```

Example 2: Use ENA Express for both TCP traffic and UDP traffic

In this example, we configure both EnaSrdEnabled and EnaSrdUdpEnabled as true.

```
```

```
NetworkInterfaceId : eni-0123f4567890a1b23
EnaSrdEnabled      : True
EnaSrdUdpEnabled   : True
```

Example 3: Stop using ENA Express for UDP traffic

In this example, we configure EnaSrdUdpEnabled as false.

```
```

```
NetworkInterfaceId : eni-0123f4567890a1b23
EnaSrdEnabled      : True
EnaSrdUdpEnabled   : False
```
Configure ENA Express when you launch an EC2 instance

You can use one of the following methods to configure ENA Express for an AMI when you launch an instance from the AWS Management Console.

- You can configure ENA Express for your AMI when you launch an instance with the launch instance wizard. For configuration details, see Advanced network configuration in the Network settings (p. 724) for the launch instance wizard.
- You can configure ENA Express for your AMI when you use a launch template. For more information about launch template configuration, see Advanced network configuration in the Network settings (p. 746) for launch templates.

Monitor ENA Express performance

After you've enabled ENA Express for the network interface attachments on both the sending instance and receiving instance, you can use ENA Express metrics to help ensure that your instances take full advantage of the performance improvements that SRD technology provides.

To see a list of metrics that are filtered for ENA Express, run the following `ethtool` command for your network interface (shown here as `eth0`):

```
[ec2-user ~]$ ethtool -S eth0 | grep ena_srd
NIC statistics:
enet_srd_mode: 0
ena_srd_tx_pkts: 0
ena_srd_eligible_tx_pkts: 0
ena_srd_rx_pkts: 0
ena_srd_resource_utilization: 0
```

Verify ENA Express settings for an instance

To verify the current ENA Express settings for the network interface attachment on your instance, run the `ethtool` command to list ENA Express metrics, and take note of the value of the `ena_srd_mode` metric. Values are as follows:

- 0 = ENA Express off, UDP off
- 1 = ENA Express on, UDP off
- 2 = ENA Express off, UDP on

**Note**
This only happens when ENA Express was originally enabled, and UDP was configured to use it. The prior value is retained for UDP traffic.
- 3 = ENA Express on, UDP on

After you've enabled ENA Express for the network interface attachment on an instance, the sending instance initiates communication with the receiving instance, and SRD detects if ENA Express is operating on both the sending instance and the receiving instance. If ENA Express is operating, the communication can use SRD transmission. If ENA Express is not operating, the communication falls back to standard ENA transmission. To confirm if packet transmission is using SRD, you can compare the number of eligible packets (`ena_srd_eligible_tx_pkts` metric) to the number of SRD packets transmitted (`ena_srd_tx_pkts` metric) during a given time period.

You can monitor your SRD resource utilization using the the `ena_srd_resource_utilization` metric. If your instance is close to exhausting its SRD resources, you'll know it's time to scale out the instance.
Enable enhanced networking with the Intel 82599 VF interface on Linux instances

Amazon EC2 provides enhanced networking capabilities through the Intel 82599 VF interface, which uses the Intel ixgbevf driver.

Contents

- Requirements (p. 1485)
- Test whether enhanced networking is enabled (p. 1485)
- Enable enhanced networking on Amazon Linux (p. 1487)
- Enable enhanced networking on Ubuntu (p. 1488)
- Enable enhanced networking on other Linux distributions (p. 1489)
- Troubleshoot connectivity issues (p. 1491)

Requirements

To prepare for enhanced networking using the Intel 82599 VF interface, set up your instance as follows:

- Select from the following supported instance types: C3, C4, D2, I2, M4 (excluding m4.16xlarge), and R3.
- Launch the instance from an HVM AMI using Linux kernel version of 2.6.32 or later. The latest Amazon Linux HVM AMIs have the modules required for enhanced networking installed and have the required attributes set. Therefore, if you launch an Amazon EBS–backed, enhanced networking–supported instance using a current Amazon Linux HVM AMI, enhanced networking is already enabled for your instance.

  Warning
  Enhanced networking is supported only for HVM instances. Enabling enhanced networking with a PV instance can make it unreachable. Setting this attribute without the proper module or module version can also make your instance unreachable.

- Ensure that the instance has internet connectivity.
- Use AWS CloudShell from the AWS Management Console, or install and configure the AWS CLI or the AWS Tools for Windows PowerShell on any computer you choose, preferably your local desktop or laptop. For more information, see Access Amazon EC2 (p. 5) or the AWS CloudShell User Guide. Enhanced networking cannot be managed from the Amazon EC2 console.
- If you have important data on the instance that you want to preserve, you should back that data up now by creating an AMI from your instance. Updating kernels and kernel modules, as well as enabling the sriovNetSupport attribute, might render incompatible instances or operating systems unreachable. If you have a recent backup, your data will still be retained if this happens.

Test whether enhanced networking is enabled

Enhanced networking with the Intel 82599 VF interface is enabled if the ixgbevf module is installed on your instance and the sriovNetSupport attribute is set.

Instance attribute (sriovNetSupport)

To check whether an instance has the enhanced networking sriovNetSupport attribute set, use one of the following commands:
**AWS CLI**

`describe-instance-attribute` (AWS CLI/AWS CloudShell)

```
aws ec2 describe-instance-attribute --instance-id instance_id --attribute sriovNetSupport
```

**PowerShell**

`Get-EC2InstanceAttribute` (AWS Tools for Windows PowerShell)

```
Get-EC2InstanceAttribute -InstanceId instance-id -Attribute sriovNetSupport
```

If the attribute isn't set, `SriovNetSupport` is empty. If the attribute is set, the value is simple, as shown in the following example output.

```
"SriovNetSupport": {
  "Value": "simple"
},
```

**Image attribute (sriovNetSupport)**

To check whether an AMI already has the enhanced networking `sriovNetSupport` attribute set, use one of the following commands:

**AWS CLI**

`describe-images` (AWS CLI/AWS CloudShell)

```
aws ec2 describe-images --image-id ami_id --query "Images[].SriovNetSupport"
```

**PowerShell**

`Get-EC2Image` (AWS Tools for Windows PowerShell)

```
(Get-EC2Image -ImageId ami-id).SriovNetSupport
```

If the attribute isn't set, `SriovNetSupport` is empty. If the attribute is set, the value is simple.

**Network interface driver**

Use the following command to verify that the module is being used on a particular interface, substituting the interface name that you want to check. If you are using a single interface (default), this is `eth0`. If the operating system supports predictable network names (p. 1489), this could be a name like `ens5`.

In the following example, the `ixgbevf` module is not loaded, because the listed driver is `vif`.

```
[ec2-user ~]$ ethtool -i eth0
driver: vif
version:
firmware-version:
bus-info: vif-0
supports-statistics: yes
supports-test: no
supports-eeprom-access: no
```
In this example, the `ixgbevf` module is loaded. This instance has enhanced networking properly configured.

```
[ec2-user ~]$ ethtool -i eth0
driver: ixgbevf
driver: ixgbevf
version: 4.0.3
firmware-version: N/A
bus-info: 0000:00:03.0
supports-statistics: yes
supports-test: yes
supports-eeprom-access: no
supports-register-dump: yes
supports-priv-flags: no
```

### Enable enhanced networking on Amazon Linux

The latest Amazon Linux HVM AMIs have the `ixgbevf` module required for enhanced networking installed and have the required `sriovNetSupport` attribute set. Therefore, if you launch an instance type using a current Amazon Linux HVM AMI, enhanced networking is already enabled for your instance. For more information, see [Test whether enhanced networking is enabled](p. 1485).

If you launched your instance using an older Amazon Linux AMI and it does not have enhanced networking enabled already, use the following procedure to enable enhanced networking.

**Warning**

There is no way to disable the enhanced networking attribute after you’ve enabled it.

#### To enable enhanced networking

1. Connect to your instance.
2. From the instance, run the following command to update your instance with the newest kernel and kernel modules, including `ixgbevf`:

   ```
   [ec2-user ~]$ sudo yum update
   ```
3. From your local computer, reboot your instance using the Amazon EC2 console or one of the following commands: `reboot-instances` (AWS CLI), `Restart-EC2Instance` (AWS Tools for Windows PowerShell).
4. Connect to your instance again and verify that the `ixgbevf` module is installed and at the minimum recommended version using the `modinfo ixgbevf` command from [Test whether enhanced networking is enabled](p. 1485).
5. [EBS-backed instance] From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: `stop-instances` (AWS CLI), `Stop-EC2Instance` (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should stop the instance in the AWS OpsWorks console so that the instance state remains in sync.

   [Instance store-backed instance] You can’t stop the instance to modify the attribute. Instead, proceed to this procedure: [To enable enhanced networking (instance store-backed instances)](p. 1488).
6. From your local computer, enable the enhanced networking attribute using one of the following commands:

   AWS CLI

   ```
   modify-instance-attribute
   ```
   (AWS CLI/AWS CloudShell)
aws ec2 modify-instance-attribute --instance-id instance_id --sriov-net-support simple

PowerShell

Edit-EC2InstanceAttribute (AWS Tools for Windows PowerShell)

Edit-EC2InstanceAttribute -InstanceId instance_id -SriovNetSupport "simple"

7. (Optional) Create an AMI from the instance, as described in Create an Amazon EBS-backed Linux AMI (p. 173). The AMI inherits the enhanced networking attribute from the instance. Therefore, you can use this AMI to launch another instance with enhanced networking enabled by default.

8. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: start-instances (AWS CLI), Start-EC2Instance (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should start the instance in the AWS OpsWorks console so that the instance state remains in sync.

9. Connect to your instance and verify that the ixgbevf module is installed and loaded on your network interface using the ethtool -i ethn command from Test whether enhanced networking is enabled (p. 1485).

**To enable enhanced networking (instance store-backed instances)**

Follow the previous procedure until the step where you stop the instance. Create a new AMI as described in Create an instance store-backed Linux AMI (p. 178), making sure to enable the enhanced networking attribute when you register the AMI.

AWS CLI

register-image (AWS CLI/AWS CloudShell)

aws ec2 register-image --sriov-net-support simple ...

PowerShell

Register-EC2Image (AWS Tools for Windows PowerShell)

Register-EC2Image -SriovNetSupport "simple" ...

**Enable enhanced networking on Ubuntu**

Before you begin, check if enhanced networking is already enabled (p. 1485) on your instance.

The Quick Start Ubuntu HVM AMIs include the necessary drivers for enhanced networking. If you have a version of ixgbevf earlier than 2.16.4, you can install the linux-aws kernel package to get the latest enhanced networking drivers.

The following procedure provides the general steps for compiling the ixgbevf module on an Ubuntu instance.

**To install the linux-aws kernel package**

1. Connect to your instance.
2. Update the package cache and packages.
Important
If during the update process, you are prompted to install `grub`, use `/dev/xvda` to install `grub`, and then choose to keep the current version of `/boot/grub/menu.lst`.

Enable enhanced networking on other Linux distributions

Before you begin, check if enhanced networking is already enabled (p. 1485) on your instance. The latest Quick Start HVM AMIs include the necessary drivers for enhanced networking, therefore you do not need to perform additional steps.

The following procedure provides the general steps if you need to enable enhanced networking with the Intel 82599 VF interface on a Linux distribution other than Amazon Linux or Ubuntu. For more information, such as detailed syntax for commands, file locations, or package and tool support, see the specific documentation for your Linux distribution.

**To enable enhanced networking on Linux**

1. Connect to your instance.
2. Download the source for the `ixgbevf` module on your instance from Sourceforge at [https://sourceforge.net/projects/e1000/files/ixgbevf%20stable/](https://sourceforge.net/projects/e1000/files/ixgbevf%20stable/).
   
   Versions of `ixgbevf` earlier than 2.16.4, including version 2.14.2, do not build properly on some Linux distributions, including certain versions of Ubuntu.

3. Compile and install the `ixgbevf` module on your instance.
   
   **Warning**
   If you compile the `ixgbevf` module for your current kernel and then upgrade your kernel without rebuilding the driver for the new kernel, your system might revert to the distribution-specific `ixgbevf` module at the next reboot. This could make your system unreachable if the distribution-specific version is incompatible with enhanced networking.

4. Run the `sudo depmod` command to update module dependencies.
5. Update `initramfs` on your instance to ensure that the new module loads at boot time.
6. Determine if your system uses predictable network interface names by default. Systems that use `systemd` or `udev` versions 197 or greater can rename Ethernet devices and they do not guarantee that a single network interface will be named `eth0`. This behavior can cause problems connecting to your instance. For more information and to see other configuration options, see Predictable Network Interface Names on the freedesktop.org website.
   
   a. You can check the `systemd` or `udev` versions on RPM-based systems with the following command:

   ```bash
   [ec2-user ~]$ rpm -qa | grep -e '^systemd-[0-9]\+\|^udev-[0-9]\+'
systemd-208-11.el7_0.2.x86_64
   ```

   In the above Red Hat Enterprise Linux 7 example, the `systemd` version is 208, so predictable network interface names must be disabled.

   b. Disable predictable network interface names by adding the `net.ifnames=0` option to the `GRUB_CMDLINE_LINUX` line in `/etc/default/grub`.

   ```bash
   [ec2-user ~]$ sudo sed -i '/^GRUB_CMDLINE_LINUX/s/"$/ net.ifnames=0"/' /etc/default/grub
   ```
c. Rebuild the grub configuration file.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

7. [EBS-backed instance] From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: stop-instances (AWS CLI/AWS CloudShell), Stop-EC2Instance (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should stop the instance in the AWS OpsWorks console so that the instance state remains in sync.

   [Instance store-backed instance] You can't stop the instance to modify the attribute. Instead, proceed to this procedure: To enable enhanced networking (instance store–backed instances) (p. 1490).

8. From your local computer, enable the enhanced networking attribute using one of the following commands:

   AWS CLI
   
   modify-instance-attribute (AWS CLI/AWS CloudShell)

   ```
   aws ec2 modify-instance-attribute --instance-id instance_id --sriov-net-support simple
   ```

   PowerShell
   
   Edit-EC2InstanceAttribute (AWS Tools for Windows PowerShell)

   ```
   Edit-EC2InstanceAttribute -InstanceId instance_id -SriovNetSupport "simple"
   ```

9. (Optional) Create an AMI from the instance, as described in Create an Amazon EBS-backed Linux AMI (p. 173). The AMI inherits the enhanced networking attribute from the instance. Therefore, you can use this AMI to launch another instance with enhanced networking enabled by default.

   **Important**

   If your instance operating system contains an /etc/udev/rules.d/70-persistent-net.rules file, you must delete it before creating the AMI. This file contains the MAC address for the Ethernet adapter of the original instance. If another instance boots with this file, the operating system will be unable to find the device and eth0 might fail, causing boot issues. This file is regenerated at the next boot cycle, and any instances launched from the AMI create their own version of the file.

10. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: start-instances (AWS CLI), Start-EC2Instance (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should start the instance in the AWS OpsWorks console so that the instance state remains in sync.

11. (Optional) Connect to your instance and verify that the module is installed.

**To enable enhanced networking (instance store–backed instances)**

Follow the previous procedure until the step where you stop the instance. Create a new AMI as described in Create an instance store–backed Linux AMI (p. 178), making sure to enable the enhanced networking attribute when you register the AMI.

AWS CLI

register-image (AWS CLI/AWS CloudShell)

```
aws ec2 register-image --sriov-net-support simple ...
```
PowerShell

Register-EC2Image (AWS Tools for Windows PowerShell)

Register-EC2Image -SriovNetSupport "simple" ...  

Troubleshoot connectivity issues

If you lose connectivity while enabling enhanced networking, the ixgbevf module might be incompatible with the kernel. Try installing the version of the ixgbevf module included with the distribution of Linux for your instance.

If you enable enhanced networking for a PV instance or AMI, this can make your instance unreachable.

For more information, see How do I enable and configure enhanced networking on my EC2 instances?

Operating system optimizations

To achieve the maximum network performance on instances with enhanced networking, you might need to modify the default operating system configuration. For more information, see ENA Linux Driver Best Practices and Performance Optimization Guide on GitHub.

Monitor network performance for your EC2 instance

The Elastic Network Adapter (ENA) driver publishes network performance metrics from the instances where they are enabled. You can use these metrics to troubleshoot instance performance issues, choose the right instance size for a workload, plan scaling activities proactively, and benchmark applications to determine whether they maximize the performance available on an instance.

Amazon EC2 defines network maximums at the instance level to ensure a high-quality networking experience, including consistent network performance across instance sizes. AWS provides maximums for the following for each instance:

- **Bandwidth capability** – Each EC2 instance has a maximum bandwidth for aggregate inbound and outbound traffic, based on instance type and size. Some instances use a network I/O credit mechanism to allocate network bandwidth based on average bandwidth utilization. Amazon EC2 also has maximum bandwidth for traffic to AWS Direct Connect and the internet. For more information, see Amazon EC2 instance network bandwidth (p. 1460).

- **Packet-per-second (PPS) performance** – Each EC2 instance has a maximum PPS performance, based on instance type and size.

- **Connections tracked** – The security group tracks each connection established to ensure that return packets are delivered as expected. There is a maximum number of connections that can be tracked per instance. For more information, see Security group connection tracking (p. 2026)

- **Link-local service access** – Amazon EC2 provides a maximum PPS per network interface for traffic to services such as the DNS service, the Instance Metadata Service, and the Amazon Time Sync Service.

When the network traffic for an instance exceeds a maximum, AWS shapes the traffic that exceeds the maximum by queueing and then dropping network packets. You can monitor when traffic exceeds a maximum using the network performance metrics. These metrics inform you, in real time, of impact to network traffic and possible network performance issues.

Contents

- Requirements (p. 1492)
**Requirements**

The following requirements apply to Linux instances.

- Install ENA driver version 2.2.10 or later. To verify the installed version, use the `ethtool` command. In the following example, the version meets the minimum requirement.

  ```bash
  [ec2-user ~]$ ethtool -i eth0 | grep version
  version: 2.2.10
  ```

  To upgrade your ENA driver, see [Enhanced networking](p. 1463).

- To import these metrics to Amazon CloudWatch, install the CloudWatch agent. For more information, see [Collect network performance metrics](p. 1493) in the Amazon CloudWatch User Guide.

- In order to support `conntrack_allowance_available` metric, install ENA driver version 2.8.1.

**Metrics for the ENA driver**

The ENA driver delivers the following metrics to the instance in real time. They provide the cumulative number of packets queued or dropped on each network interface since the last driver reset.

The following metrics are available on Linux instances, FreeBSD instances, and DPDK environments.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Supported on</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bw_in_allowance_exceeded</code></td>
<td>The number of packets queued or dropped because the inbound aggregate bandwidth exceeded the maximum for the instance.</td>
<td>All instance types</td>
</tr>
<tr>
<td><code>bw_out_allowance_exceeded</code></td>
<td>The number of packets queued or dropped because the outbound aggregate bandwidth exceeded the maximum for the instance.</td>
<td>All instance types</td>
</tr>
<tr>
<td><code>conntrack_allowance_exceeded</code></td>
<td>The number of packets dropped because connection tracking exceeded the maximum for the instance and new connections could not be established. This can result in packet loss for traffic to or from the instance.</td>
<td>All instance types</td>
</tr>
<tr>
<td><code>conntrack_allowance_available</code></td>
<td>The number of tracked connections that can be established by the instance before hitting the Connections Tracked allowance of that instance type.</td>
<td>Nitro-based instance types (p. 295) only.</td>
</tr>
</tbody>
</table>
Network performance metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Supported on</th>
</tr>
</thead>
<tbody>
<tr>
<td>linklocal_allowance_exceeded</td>
<td>The number of packets dropped because the PPS of the traffic to local proxy services exceeded the maximum for the network interface. This impacts traffic to the DNS service, the Instance Metadata Service, and the Amazon Time Sync Service.</td>
<td>Not supported with FreeBSD instances or DPDK environments.</td>
</tr>
<tr>
<td>pps_allowance_exceeded</td>
<td>The number of packets queued or dropped because the bidirectional PPS exceeded the maximum for the instance.</td>
<td>All instance types</td>
</tr>
</tbody>
</table>

View the network performance metrics for your Linux instance

You can publish metrics to your favorite tools to visualize the metric data. For example, you can publish the metrics to Amazon CloudWatch using the CloudWatch agent. The agent enables you to select individual metrics and control publication.

You can also use the `ethtool` to retrieve the metrics for each network interface, such as eth0, as follows.

```
[ec2-user ~]$ ethtool -S eth0
  bw_in_allowance_exceeded: 0
  bw_out_allowance_exceeded: 0
  pps_allowance_exceeded: 0
  conntrack_allowance_exceeded: 0
  linklocal_allowance_exceeded: 0
  conntrack_allowance_available: 136812
```

Metrics for ENA Express

ENA Express is powered by AWS Scalable Reliable Datagram (SRD) technology. SRD is a high performance network transport protocol that uses dynamic routing to increase throughput and minimize tail latency. You can use ENA Express metrics to help ensure that your instances take full advantage of the performance improvements that SRD technology provides, for example:

- Evaluate your resources to ensure that they have sufficient capacity to establish more SRD connections.
- Identify where there are potential issues that prevent eligible outgoing packets from using SRD.
- Calculate the percentage of outgoing traffic that uses SRD for the instance.
- Calculate the percentage of incoming traffic that uses SRD for the instance.

**Note**
To produce metrics, use driver version 2.8 or higher.

The following ENA Express metrics are available using the `ethtool` command for Linux based instances.

- `ena_srd_mode` – Describes which ENA Express features are enabled. Values are as follows:
Network performance metrics

- 0 = ENA Express off, UDP off
- 1 = ENA Express on, UDP off
- 2 = ENA Express off, UDP on

**Note**
This only happens when ENA Express was originally enabled, and UDP was configured to use it. The prior value is retained for UDP traffic.

- 3 = ENA Express on, UDP on

**ena_srd_eligible_tx_pkts** – The number of network packets sent within a given time period that meet SRD requirements for eligibility, as follows:
- Both sending and receiving instance types are supported. See the [Supported instance types for ENA Express](p. 1474) table for more information.
- Both sending and receiving instances must have ENA Express configured.
- The sending and receiving instances must run in the same subnet.
- The network path between the instances must not include middleware boxes. ENA Express doesn't currently support middleware boxes.

**Note**
The ENA Express eligibility metric covers source and destination requirements, and the network between the two endpoints. Eligible packets can still be disqualified after they've already been counted. For example, if an eligible packet is over the maximum transmission unit (MTU) limit, it falls back to standard ENA transmission, though the packet is still reflected as eligible in the counter.

- **ena_srd_tx_pkts** – The number of SRD packets transmitted within a given time period.
- **ena_srd_rx_pkts** – The number of SRD packets received within a given time period.
- **ena_srd_resource_utilization** – The percentage of the maximum allowed memory utilization for concurrent SRD connections that the instance has consumed.

To see a list of metrics that are filtered for ENA Express, run the following `ethtool` command for your network interface (shown here as eth0):

```
[ec2-user ~]$ ethtool -S eth0 | grep ena_srd
NIC statistics:
  ena_srd_mode: 0
  ena_srd_tx_pkts: 0
  ena_srd_eligible_tx_pkts: 0
  ena_srd_rx_pkts: 0
  ena_srd_resource_utilization: 0
```

**Egress traffic (outgoing packets)**

To ensure that your egress traffic uses SRD as expected, compare the number of SRD eligible packets (`ena_srd_eligible_tx_pkts`) with the number of SRD packets sent (`ena_srd_tx_pkts`) over a given time period.

Significant differences between the number of eligible packets and the number of SRD packets sent are often caused by resource utilization issues. When the network card attached to the instance has used up its maximum resources, or if packets are over the MTU limit, eligible packets are not able to transmit via SRD, and must fall back to standard ENA transmission. Packets can also fall into this gap during live migrations or live droplet updates. Additional troubleshooting is required to determine the root cause.

**Note**
You can ignore occasional minor differences between the number of eligible packets and the number of SRD packets. This can happen when your instance establishes a connection to another instance for SRD traffic, for example.
To find out what percentage of your total egress traffic over a given time period uses SRD, compare the number of SRD packets sent (ena_srd_tx_pkts) to the total number of packets sent for the instance (NetworkPacketOut) during that time.

**Ingress traffic (incoming packets)**

To find out what percentage of your ingress traffic uses SRD, compare the number of SRD packets received (ena_srd_rx_pkts) over a given time period to the total number of packets received for the instance (NetworkPacketIn) during that time.

**Resource utilization**

Resource utilization is based on the number of concurrent SRD connections a single instance can hold at a given time. The resource utilization metric (ena_srd_resource_utilization) keeps track of your current utilization for the instance. As utilization approaches 100%, you can expect to see performance issues. ENA Express falls back from SRD to standard ENA transmission, and the possibility of dropped packets increases. High resource utilization is a sign that it's time to scale the instance out to improve network performance.

**Note**

When the network traffic for an instance exceeds a maximum, AWS shapes the traffic that exceeds the maximum by queueing and then dropping network packets.

**Persistence**

Egress and ingress metrics accrue while ENA Express is enabled for the instance. Metrics stop accruing if ENA Express is deactivated, but persist as long as the instance is still running. Metrics reset if the instance reboots or is terminated, or if the network interface is detached from the instance.

**Network performance metrics with the DPDK driver for ENA**

The ENA driver version 2.2.0 and later supports network metrics reporting. DPDK 20.11 includes the ENA driver 2.2.0 and is the first DPDK version to support this feature.

You can use an example application to view DPDK statistics. To start an interactive version of the example application, run the following command.

```
./app/dpdk-testpmd -- -i
```

Within this interactive session, you can enter a command to retrieve extended statistics for a port. The following example command retrieves the statistics for port 0.

```
show port xstats 0
```

The following is an example of an interactive session with the DPDK example application.

```
[root@ip-192.0.2.0 build]# ./app/dpdk-testpmd -- -i
EAL: Detected 4 lcore(s)

Metrics on instances running FreeBSD

Starting with version 2.3.0, the ENA FreeBSD driver supports collecting network performance metrics on instances running FreeBSD. To enable the collection of FreeBSD metrics, enter the following command
and set `interval` to a value between 1 and 3600. This specifies how often, in seconds, to collect FreeBSD metrics.

```
sysctl dev.ena.network_interface.eni_metrics.sample_interval=interval
```

For example, the following command sets the driver to collect FreeBSD metrics on network interface 1 every 10 seconds:

```
sysctl dev.ena.1.eni_metrics.sample_interval=10
```

To turn off the collection of FreeBSD metrics, you can run the preceding command and specify 0 as the `interval`.

Once you are collecting FreeBSD metrics, you can retrieve the latest set of collected metrics by running the following command.

```
sysctl dev.ena.network_interface.eni_metrics
```

**Troubleshoot the Elastic Network Adapter (ENA)**

The Elastic Network Adapter (ENA) is designed to improve operating system health and reduce the chances of long-term disruption because of unexpected hardware behavior and or failures. The ENA architecture keeps device or driver failures as transparent to the system as possible. This topic provides troubleshooting information for ENA.

If you are unable to connect to your instance, start with the Troubleshoot connectivity issues (p. 1497) section.

If you experience performance degradation after migrating to a sixth generation instance type, see the article What do I need to do before migrating my EC2 instance to a sixth generation instance to make sure that I get maximum network performance? in the AWS Knowledge Center.

If you are able to connect to your instance, you can gather diagnostic information by using the failure detection and recovery mechanisms that are covered in the later sections of this topic.

**Contents**

- Troubleshoot connectivity issues (p. 1497)
- Keep-alive mechanism (p. 1498)
- Register read timeout (p. 1499)
- Statistics (p. 1500)
- Driver error logs in syslog (p. 1504)
- Sub-optimal configuration notifications (p. 1505)

**Troubleshoot connectivity issues**

If you lose connectivity while enabling enhanced networking, the ena module might be incompatible with your instance’s current running kernel. This can happen if you install the module for a specific kernel version (without `dkms`, or with an improperly configured `dkms.conf` file) and then your instance kernel is updated. If the instance kernel that is loaded at boot time does not have the ena module properly installed, your instance will not recognize the network adapter and your instance becomes unreachable.
If you enable enhanced networking for a PV instance or AMI, this can also make your instance unreachable.

If your instance becomes unreachable after enabling enhanced networking with ENA, you can disable the enaSupport attribute for your instance and it will fall back to the stock network adapter.

**To disable enhanced networking with ENA (EBS-backed instances)**

1. From your local computer, stop the instance using the Amazon EC2 console or one of the following commands: `stop-instances` (AWS CLI), `Stop-EC2Instance` (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should stop the instance in the AWS OpsWorks console so that the instance state remains in sync.

   **Important**
   If you are using an instance store-backed instance, you can't stop the instance. Instead, proceed to To disable enhanced networking with ENA (instance store-backed instances) (p. 1498).

2. From your local computer, disable the enhanced networking attribute using the following command.

   ```bash
   $ aws ec2 modify-instance-attribute --instance-id instance_id --no-ena-support
   ```

3. From your local computer, start the instance using the Amazon EC2 console or one of the following commands: `start-instances` (AWS CLI), `Start-EC2Instance` (AWS Tools for Windows PowerShell). If your instance is managed by AWS OpsWorks, you should start the instance in the AWS OpsWorks console so that the instance state remains in sync.

4. (Optional) Connect to your instance and try reinstalling the ena module with your current kernel version by following the steps in Enable enhanced networking with the Elastic Network Adapter (ENA) on Linux instances (p. 1463).

**To disable enhanced networking with ENA (instance store-backed instances)**

If your instance is an instance store-backed instance, create a new AMI as described in Create an instance store-backed Linux AMI (p. 178). Be sure to disable the enhanced networking enaSupport attribute when you register the AMI.

```bash
$ aws ec2 register-image --no-ena-support ...
```

```bash
Register-EC2Image (AWS Tools for Windows PowerShell)
```

C:\> Register-EC2Image -EnaSupport $false ...

**Keep-alive mechanism**

The ENA device posts keep-alive events at a fixed rate (usually once every second). The ENA driver implements a watchdog mechanism, which checks for the presence of these keep-alive messages. If a message or messages are present, the watchdog is rearmed, otherwise the driver concludes that the device experienced a failure and then does the following:

- Dumps its current statistics to syslog
- Resets the ENA device
- Resets the ENA driver state
The above reset procedure may result in some traffic loss for a short period of time (TCP connections should be able to recover), but should not otherwise affect the user.

The ENA device may also indirectly request a device reset procedure, by not sending a keep-alive notification, for example, if the ENA device reaches an unknown state after loading an irrecoverable configuration.

Below is an example of the reset procedure:

```
[18509.800135] ena 0000:00:07.0 eth1: Keep alive watchdog timeout. // The watchdog process initiates a reset
[18509.815244] ena 0000:00:07.0 eth1: Trigger reset is on
[18509.825589] ena 0000:00:07.0 eth1: tx_timeout: 0 // The driver logs the current statistics
[18509.834253] ena 0000:00:07.0 eth1: io_suspend: 0
[18509.842674] ena 0000:00:07.0 eth1: io_resume: 0

[18512.775945] ena 0000:00:07.0: Device reset completed successfully // The reset process is complete
```

Register read timeout

The ENA architecture suggests a limited usage of memory mapped I/O (MMIO) read operations. MMIO registers are accessed by the ENA device driver only during its initialization procedure.

If the driver logs (available in `dmesg` output) indicate failures of read operations, this may be caused by an incompatible or incorrectly compiled driver, a busy hardware device, or hardware failure.

Intermittent log entries that indicate failures on read operations should not be considered an issue; the driver will retry them in this case. However, a sequence of log entries containing read failures indicate a driver or hardware problem.

Below is an example of driver log entry indicating a read operation failure due to a timeout:

```
[18599.800135] ena 0000:00:07.0 eth1: Keep alive watchdog timeout. // The watchdog process initiates a reset
[18599.815244] ena 0000:00:07.0 eth1: Trigger reset is on
[18599.825589] ena 0000:00:07.0 eth1: tx_timeout: 0 // The driver logs the current statistics
[18599.834253] ena 0000:00:07.0 eth1: io_suspend: 0
[18599.842674] ena 0000:00:07.0 eth1: io_resume: 0
[18599.850275] ena 0000:00:07.0 eth1: wd_expired: 1
[18599.857855] ena 0000:00:07.0 eth1: interface_up: 1
[18599.865415] ena 0000:00:07.0 eth1: interface_down: 0
[18599.873468] ena 0000:00:07.0 eth1: admin_q_pause: 0
[18599.881075] ena 0000:00:07.0 eth1: queue_0_tx_cnt: 0
[18599.888629] ena 0000:00:07.0 eth1: queue_0_tx_bytes: 0
[18599.895286] ena 0000:00:07.0 eth1: queue_0_rx_queue_stop: 0
.........
[18511.280972] ena 0000:00:07.0 eth1: free uncompleted tx skb qid 3 idx 0x7 // At the end of the down process, the driver discards incomplete packets.
[18511.420112] [ENA_COM: ena_com_validate_version] ena device version: 0.10 //The driver begins its up process
[18511.420119] [ENA_COM: ena_com_validate_version] ena controller version: 0.0.1 implementation version 1
[18512.252108] ena 0000:00:07.0: Device watchdog is Enabled
[18512.674877] ena 0000:00:07.0: irq 46 for MSI/MSI-X
[18512.674933] ena 0000:00:07.0: irq 47 for MSI/MSI-X
[18512.674990] ena 0000:00:07.0: irq 48 for MSI/MSI-X

```

1499
Statistics

If you experience insufficient network performance or latency issues, you should retrieve the device statistics and examine them. These statistics can be obtained using `ethtool` as follows.

```
[ec2-user ~]$ ethtool -S ethN
```

NIC statistics:

- `tx_timeout`: 0
- `suspend`: 0
- `resume`: 0
- `wd_expired`: 0
- `interface_up`: 1
- `interface_down`: 0
- `admin_q_pause`: 0
- `bw_in_allowance_exceeded`: 0
- `bw_out_allowance_exceeded`: 0
- `pps_allowance_exceeded`: 0
- `conntrack_allowance_available`: 450878
- `conntrack_allowance_exceeded`: 0
- `linklocal_allowance_exceeded`: 0
- `queue_0_tx_cnt`: 4329
- `queue_0_tx_bytes`: 1075749
- `queue_0_tx_queue_stop`: 0
- ...

The following command output parameters are described below:

- **tx_timeout**: N
  
  The number of times that the Netdev watchdog was activated.

- **suspend**: N
  
  The number of times the driver performed a suspend operation.

- **resume**: N
  
  The number of times the driver performed a resume operation.

- **wd_expired**: N
  
  The number of times that the driver did not receive the keep-alive event in the preceding three seconds.

- **interface_up**: N
  
  The number of times that the ENA interface was brought up.

- **interface_down**: N
  
  The number of times that the ENA interface was brought down.

- **admin_q_pause**: N
  
  The number of times the admin queue was not found in a running state.

- **bw_in_allowance_exceeded**: N
  
  The number of packets queued or dropped because the inbound aggregate bandwidth exceeded the maximum for the instance.
bw_out_allowance_exceeded: $N$

The number of packets queued or dropped because the outbound aggregate bandwidth exceeded the maximum for the instance.

pps_allowance_exceeded: $N$

The number of packets queued or dropped because the bidirectional PPS exceeded the maximum for the instance.

connttrack_allowance_available: $N$

The number of tracked connections that can be established by the instance before hitting the Connections Tracked allowance of that instance type. Only available for Nitro-based instances. Not supported with FreeBSD instances or DPDK environments.

connttrack_allowance_exceeded: $N$

The number of packets dropped because connection tracking exceeded the maximum for the instance and new connections could not be established. This can result in packet loss for traffic to or from the instance.

linklocal_allowance_exceeded: $N$

The number of packets dropped because the PPS of the traffic to local proxy services exceeded the maximum for the network interface. This impacts traffic to the DNS service, the Instance Metadata Service, and the Amazon Time Sync Service.

queue_{N}_tx_cnt: $N$

The number of transmitted packets for this queue.

queue_{N}_tx_bytes: $N$

The number of transmitted bytes for this queue.

queue_{N}_tx_queue_stop: $N$

The number of times that queue $N$ was full and stopped.

queue_{N}_tx_queue_wakeup: $N$

The number of times that queue $N$ resumed after being stopped.

queue_{N}_tx_dma_mapping_err: $N$

Direct memory access error count. If this value is not 0, it indicates low system resources.

queue_{N}_tx_linearize: $N$

The number of times SKB linearization was attempted for this queue.

queue_{N}_tx_linearize_failed: $N$

The number of times SKB linearization failed for this queue.

queue_{N}_tx_napi_comp: $N$

The number of times the napi handler called napi_complete for this queue.

queue_{N}_tx_tx_poll: $N$

The number of times the napi handler was scheduled for this queue.

queue_{N}_tx_doorbells: $N$

The number of transmission doorbells for this queue.

queue_{N}_tx_prepare_ctx_err: $N$

The number of times ena_com_prepare_tx failed for this queue.
Invalid req_id for this queue. The valid req_id is zero, minus the queue_size, minus 1.

The number of packets whose headers size are larger than llq entry for this queue.

The number of packets that were left uncompleted for this queue.

The number of times the tx interrupt was unmasked for this queue.

The number of received packets for this queue.

The number of received bytes for this queue.

The number of times the rx queue received a packet that is less than the rx_copybreak packet size for this queue.

The number of times the rx queue received a packet where the checksum was checked and was correct for this queue.

The number of times the driver did not succeed in refilling the empty portion of the rx queue with the buffers for this queue. If this value is not zero, it indicates low memory resources.

The number of times the rx queue had a bad checksum for this queue (only if rx checksum offload is supported).

The number of time that page allocation failed for this queue. If this value is not zero, it indicates low memory resources.

The number of time that SKB allocation failed for this queue. If this value is not zero, it indicates low system resources.

Direct memory access error count. If this value is not 0, it indicates low system resources.

Too many buffers per packet. If this value is not 0, it indicates the use of very small buffers.

The req_id for this queue is not valid. The valid req_id is from [0, queue_size - 1].

The number of times the rx queue was empty for this queue.

The number of times the rx queue received a packet whose checksum wasn't checked for this queue.
queue_N.rx_xdp_aborted: N
The number of times that an XDP packet was classified as XDP_ABORT.

queue_N.rx_xdp_drop: N
The number of times that an XDP packet was classified as XDP_DROP.

queue_N.rx_xdp_pass: N
The number of times that an XDP packet was classified as XDP_PASS.

queue_N.rx_xdp_tx: N
The number of times that an XDP packet was classified as XDP_TX.

queue_N.rx_xdp_invalid: N
The number of times that the XDP return code for the packet was not valid.

queue_N.rx_xdp_redirect: N
The number of times that an XDP packet was classified as XDP_REDIRECT.

queue_N.xdp_tx_cnt: N
The number of transmitted packets for this queue.

queue_N.xdp_tx_bytes: N
The number of transmitted bytes for this queue.

queue_N.xdp_tx_queue_stop: N
The number of times that this queue was full and stopped.

queue_N.xdp_tx_queue_wakeup: N
The number of times that this queue resumed after being stopped.

queue_N.xdp_tx_dma_mapping_err: N
Direct memory access error count. If this value is not 0, it indicates low system resources.

queue_N.xdp_tx_linearize: N
The number of times XDP buffer linearization was attempted for this queue.

queue_N.xdp_tx_linearize_failed: N
The number of times XDP buffer linearization failed for this queue.

queue_N.xdp_tx_napi_comp: N
The number of times the napi handler called napi_complete for this queue.

queue_N.xdp_tx_tx_poll: N
The number of times the napi handler was scheduled for this queue.

queue_N.xdp_tx_doorbells: N
The number of transmission doorbells for this queue.

queue_N.xdp_tx_prepare_ctx_err: N
The number of times ena_com_prepare_tx failed for this queue. This value should always be zero; if not, see the driver logs.

queue_N.xdp_tx_bad_req_id: N
The req_id for this queue is not valid. The valid req_id is from [0, queue_size - 1].

queue_N.xdp_tx_llq_buffer_copy: N
The number of packets that had their headers copied using llq buffer copy for this queue.
queue\_N\_xdp\_tx\_missed\_tx: N

The number of times a tx queue entry missed a completion timeout for this queue.

queue\_N\_xdp\_tx\_unmask\_interrupt: N

The number of times the tx interrupt was unmasked for this queue.

ena\_admin\_q\_aborted\_cmd: N

The number of admin commands that were aborted. This usually happens during the auto-recovery procedure.

ena\_admin\_q\_submitted\_cmd: N

The number of admin queue doorbells.

ena\_admin\_q\_completed\_cmd: N

The number of admin queue completions.

ena\_admin\_q\_out\_of\_space: N

The number of times that the driver tried to submit new admin command, but the queue was full.

ena\_admin\_q\_no\_completion: N

The number of times that the driver did not get an admin completion for a command.

Driver error logs in syslog

The ENA driver writes log messages to syslog during system boot. You can examine these logs to look for errors if you are experiencing issues. Below is an example of information logged by the ENA driver in syslog during system boot, along with some annotations for select messages.

Jun  3 22:37:46 ip-172-31-2-186 kernel: [ 478.416939] [ENA\_COM: ena\_com\_validate\_version] ena device version: 0.10

Jun  3 22:37:46 ip-172-31-2-186 kernel: [ 479.697433] [ENA\_COM: ena\_com\_set\_host\_attributes] Set host attribute isn't supported
Jun  3 22:37:46 ip-172-31-2-186 kernel: [ 479.701064] ena 0000:00:03.0: (unnamed net_device) (uninitialized): Cannot set host attributes
Jun  3 22:37:46 ip-172-31-2-186 kernel: [ 479.704017] ena 0000:00:03.0: Elastic Network Adapter (ENA) found at mem f3000000, mac addr 02:8a:3c:1e:13:b5 Queues 8

Which errors can I ignore?

The following warnings that may appear in your system's error logs can be ignored for the Elastic Network Adapter:
Set host attribute isn't supported

Host attributes are not supported for this device.

failed to alloc buffer for rx queue

This is a recoverable error, and it indicates that there may have been a memory pressure issue when the error was thrown.

Feature X isn't supported

The referenced feature is not supported by the Elastic Network Adapter. Possible values for X include:

- 10: RSS Hash function configuration is not supported for this device.
- 12: RSS Indirection table configuration is not supported for this device.
- 18: RSS Hash Input configuration is not supported for this device.
- 20: Interrupt moderation is not supported for this device.
- 27: The Elastic Network Adapter driver does not support polling the Ethernet capabilities from snmpd.

Failed to config AENQ

The Elastic Network Adapter does not support AENQ configuration.

Trying to set unsupported AENQ events

This error indicates an attempt to set an AENQ events group that is not supported by the Elastic Network Adapter.

Sub-optimal configuration notifications

The ENA device detects sub-optimal configuration settings in the driver that you can change. The device notifies the ENA driver and logs a warning to the console. The following example shows the format of the warning message.

```
Sub-optimal configuration notification code: 1. Refer to AWS ENA documentation for additional details and mitigation options.
```

The following list shows notification code details and recommended actions for sub-optimal configuration findings.

- **Code 1: ENA Express with wide LLQ configuration is not recommended**

  ENA Express ENI is configured with wide LLQ. This configuration is sub-optimal and could impact performance for ENA Express. We recommend that you disable wide LLQ settings when you use ENA Express ENIs as follows.

  ```
sudo rmmod ena && sudo modprobe ena force_large_llq_header=0
  ```

  For more information about optimal configuration for ENA Express, see [Improve network performance with ENA Express on Linux instances](p. 1472).

- **Code 2: ENA Express ENI with sub-optimal Tx queue depth is not recommended**

  ENA Express ENI is configured with sub-optimal Tx queue depth. This configuration could impact performance for ENA Express. We recommend that you enlarge all Tx queues to the maximum value for the network interface when you use ENA Express ENIs as follows.

  To obtain the maximum depth of the Tx queues:
Improve network latency on Linux instances

```
ethtool -g interface
```

To enlarge the Tx queues to the maximum depth:

```
ethtool -G interface tx depth
```

For more information about optimal configuration for ENA Express, see [Improve network performance with ENA Express on Linux instances](p. 1472).

### Improve network latency for Linux based Amazon EC2 instances

Network latency is the amount of time it takes for a packet of data to travel from its source to its destination. Applications that send data across the network depend on timely responses to provide a positive user experience. High network latency can lead to various issues, such as the following:

- Slow load times for web pages
- Video stream lag
- Difficulty accessing online resources

This section outlines steps that you can take to improve the network latency on Amazon EC2 instances that run on Linux. To achieve optimal latency, follow these steps to configure your instance, kernel, and ENA driver settings. For additional configuration guidance, see the [ENA Linux Driver Best Practices and Performance Optimization Guide](p. 1208) on GitHub.

**Note**

Steps and settings may vary slightly, depending on your specific network hardware, the AMI that you launched your instance from, and your application use case. Before you make any changes, thoroughly test and monitor your network performance to ensure that you're getting the desired results.

### Reduce network hops

Each hop that a data packet takes as it moves from router to router increases network latency. Typically, traffic must take multiple hops to reach your destination. There are two ways to reduce network hops for your Amazon EC2 instances, as follows:

- **Cluster placement group** – When you specify a [cluster placement group](p. 1572), Amazon EC2 launches instances that are in close proximity to each other, physically within the same Availability Zone (AZ) with tighter packing. The physical proximity of the instances in the group allows them to take advantage of high-speed connectivity, resulting in low latency and high single flow throughput.
- **Dedicated Host** – A [Dedicated Host](p. 612) is a physical server that's dedicated for your use. With a Dedicated Host, you can launch your instances to run on the same physical server. Communication between instances that run on the same Dedicated Host can happen without extra network hops.

### Linux kernel configuration

Linux kernel configuration can increase or decrease network latency. To achieve your latency optimization goals, it's important to fine-tune the Linux kernel configuration according to the specific requirements of your workload.
There are many configuration options for the Linux kernel that might help decrease network latency. The most impactful options are as follows.

- **Enable busy poll mode** – Busy poll mode reduces latency on the network receive path. When you enable busy poll mode, the socket layer code can directly poll the receive queue of a network device. The downside of busy polling is higher CPU usage in the host that comes from polling for new data in a tight loop. There are two global settings that control the number of microseconds to wait for packets for all interfaces.

  **busy_read**

  A low latency busy poll timeout for socket reads. This controls the number of microseconds to wait for the socket layer to read packets on the device queue. To enable the feature globally with the `sysctl` command, the Linux Kernel organization recommends a value of 50 microseconds. For more information, see `busy_read` in the *Linux kernel user’s and administrator’s guide*.

  ```sh
  sudo sysctl -w net.core.busy_read=50
  ```

  **busy_poll**

  A low latency busy poll timeout for poll and select. This controls the number of microseconds to wait for events. The recommended value is between 50-100 microseconds, depending on the number of sockets you're polling. The more sockets you add, the higher the number should be.

  ```sh
  sudo sysctl -w net.core.busy_poll=50
  ```

- **Configure CPU power states (C-states)** – C-states control the sleep levels that a core may enter when it's inactive. You might want to control C-states to tune your system for latency versus performance. In deeper C-states, the CPU is essentially “asleep” and can't respond to requests until it wakes up and transitions back to an active state. Putting cores to sleep takes time, and although a sleeping core allows more headroom for another core to boost to a higher frequency, it takes time for that sleeping core to wake back up and perform work.

  For example, if a core that's assigned to handle network packet interrupts is asleep, there might be a delay in servicing that interrupt. You can configure the system so that it doesn't use deeper C-states. However, while this configuration reduces the processor reaction latency, it also reduces the headroom available to other cores for Turbo Boost.

  To reduce the processor reaction latency, you can limit deeper C-states. For more information, see [High performance and low latency by limiting deeper C-states](#) (p. 912).

### ENA driver configuration

The ENA network driver enables communication between an instance and a network. The driver processes network packets and passes them on to the network stack or to the Nitro card. When a network packet comes in, the Nitro card generates an interrupt for the CPU to notify the software of an event.

**Interrupt**

An interrupt is a signal that a device or application sends to the processor. The interrupt tells the processor that an event has occurred or a condition has been met that requires immediate attention. Interrupts can handle time-sensitive tasks such as receiving data from a network interface, handling hardware events, or servicing requests from other devices.
Interrupt moderation

Interrupt moderation is a technique that reduces the number of interrupts a device generates by aggregating or delaying them. The purpose of interrupt moderation is to improve system performance by reducing the overhead associated with handling a large number of interrupts. Too many interrupts increase CPU usage, impacting the throughput adversely, while too few interrupts increase the latency.

Dynamic interrupt moderation

Dynamic interrupt moderation is an enhanced form of interrupt moderation that dynamically adjusts the interrupt rate based on the current system load and traffic patterns. It aims to strike a balance between reducing interrupt overhead and packets per second, or bandwidth.

Note

Dynamic interrupt moderation is enabled by default in some AMIs (but can be enabled or disabled in all AMIs).

To minimize network latency, it might be necessary to disable interrupt moderation. However, this can also increase the overhead of interrupt processing. It's important to find the right balance between reducing latency and minimizing overhead. ethtool commands can help you configure interrupt moderation. By default, rx-usecs is set to 20, and tx-usecs is set to 64.

To get the current interrupt modification configuration, use the following command.

```
$ ethtool -c interface | egrep "rx-usecs:|tx-usecs:|Adaptive RX"
Adaptive RX: on  TX: off
rx-usecs: 20
tx-usecs: 64
```

To disable interrupt modification and dynamic interrupt moderation, use the following command.

```
$ sudo ethtool -C interface adaptive-rx off rx-usecs 0 tx-usecs 0
```

Elastic Fabric Adapter

An Elastic Fabric Adapter (EFA) is a network device that you can attach to your Amazon EC2 instance to accelerate High Performance Computing (HPC) and machine learning applications. EFA enables you to achieve the application performance of an on-premises HPC cluster, with the scalability, flexibility, and elasticity provided by the AWS Cloud.

EFAs provide lower and more consistent latency and higher throughput than the TCP transport traditionally used in cloud-based HPC systems. It enhances the performance of inter-instance communication that is critical for scaling HPC and machine learning applications. It is optimized to work on the existing AWS network infrastructure and it can scale depending on application requirements.

EFAs integrate with Libfabric 1.7.0 and later and it supports Open MPI 3.1.3 and later and Intel MPI 2019 Update 5 and later for HPC applications, and Nvidia Collective Communications Library (NCCL) for machine learning applications.

Note

The OS-bypass capabilities of EFAs are not supported on Windows instances. If you attach an EFA to a Windows instance, the instance functions as an Elastic Network Adapter, without the added EFA capabilities.

Contents

• EFA basics (p. 1509)
EFA basics

An EFA is an Elastic Network Adapter (ENA) with added capabilities. It provides all of the functionality of an ENA, with an additional OS-bypass functionality. OS-bypass is an access model that allows HPC and machine learning applications to communicate directly with the network interface hardware to provide low-latency, reliable transport functionality.
Traditionally, HPC applications use the Message Passing Interface (MPI) to interface with the system's network transport. In the AWS Cloud, this has meant that applications interface with MPI, which then uses the operating system's TCP/IP stack and the ENA device driver to enable network communication between instances.

With an EFA, HPC applications use MPI or NCCL to interface with the Libfabric API. The Libfabric API bypasses the operating system kernel and communicates directly with the EFA device to put packets on the network. This reduces overhead and enables the HPC application to run more efficiently.

**Note**

Libfabric is a core component of the OpenFabrics Interfaces (OFI) framework, which defines and exports the user-space API of OFI. For more information, see the [Libfabric OpenFabrics website](#).

**Differences between EFAs and ENAs**

Elastic Network Adapters (ENAs) provide traditional IP networking features that are required to support VPC networking. EFAs provide all of the same traditional IP networking features as ENAs, and they also support OS-bypass capabilities. OS-bypass enables HPC and machine learning applications to bypass the operating system kernel and to communicate directly with the EFA device.

**Supported interfaces and libraries**

EFAs support the following interfaces and libraries:

- Open MPI 3.1.3 and later
- Open MPI 4.0 or newer is preferred for Graviton
- Intel MPI 2019 Update 5 and later
- NVIDIA Collective Communications Library (NCCL) 2.4.2 and later

**Supported instance types**

The following instance types support EFAs:

- General purpose: m5dn.24xlarge | m5dn.metal | m5n.24xlarge | m5n.metal | m5zn.12xlarge | m5zn.metal | m6a.48xlarge | m6a.metal | m6i.32xlarge | m6i.metal | m6id.32xlarge | m6id.metal | m6idn.32xlarge | m6idn.metal | m6in.32xlarge | m6in.metal | m7a.48xlarge | m7a.metal-48x1 | m7g.16xlarge | m7g.metal | m7gd.16xlarge | m7i.48xlarge | m7i.metal-48x1
- Compute optimized: c5n.9xlarge | c5n.18xlarge | c5n.metal | c6a.48xlarge | c6a.metal | c6g.16xlarge | c6g.metal | c6i.32xlarge | c6i.metal | c6id.32xlarge | c6id.metal | c6in.32xlarge | c6in.metal | c7a.48xlarge | c7a.metal-48x1 | c7g.16xlarge | c7g.metal | c7gd.16xlarge | c7gn.16xlarge | c7i.48xlarge | c7i.metal-48x1 | hc6a.48xlarge | hc7g.4xlarge | hc7g.8xlarge | hc7g.metal-12xlarge | hc7a.12xlarge | hc7a.24xlarge | hc7a.48xlarge | hc7a.96xlarge
- Memory optimized: hc6id.32xlarge | r5dn.24xlarge | r5dn.metal | r5n.24xlarge | r5n.metal | r6a.48xlarge | r6a.metal | r6i.32xlarge | r6i.metal | r6id.32xlarge | r6id.metal | r6in.32xlarge | r6in.metal | r6idn.32xlarge | r6idn.metal | r7a.48xlarge | r7a.metal-48x1 | r7g.16xlarge | r7g.metal | r7gd.16xlarge | r7i.48xlarge | r7i.metal-48x1 | r7iz.32xlarge | r7iz.metal-32x1 | x2i.32xlarge | x2i.metal | x2iedn.32xlarge | x2iedn.metal | x2iezn.12xlarge | x2iezn.metal
- Storage optimized: i3en.12xlarge | i3en.24xlarge | i3en.metal | i4g.16xlarge | i4i.32xlarge | i4i.metal | im4g.16xlarge
- Accelerated computing: dl1.24xlarge | dl2q.24xlarge | g4dn.8xlarge | g4dn.12xlarge | g4dn.16xlarge | g4dn.metal | g5.8xlarge | g5.12xlarge | g5.16xlarge | g5.24xlarge | g5.48xlarge | g5.96xlarge | g5c.48xlarge
To see the available instance types that support EFAs in a specific Region

The available instance types vary by Region. To see the available instance types that support EFAs in a Region, use the `describe-instance-types` command with the `--region` parameter. Include the `--filters` parameter to scope the results to the instance types that support EFA and the `--query` parameter to scope the output to the value of `InstanceType`.

```
aws ec2 describe-instance-types  --region us-east-1  --filters Name=network-info.efa-supported,Values=true  --query "InstanceTypes[*].[InstanceType]"  --output text | sort
```

Supported operating systems

The following operating systems support EFAs with Intel/AMD x86-based instance types:

- Amazon Linux 2023
- Amazon Linux 2
- CentOS 7
- RHEL 7, 8, and 9
- Debian 10 and 11
- Rocky Linux 8 and 9
- Ubuntu 20.04 and 22.04
- SUSE Linux Enterprise 15 SP2 and later
- OpenSUSE Leap 15.4 and later

**Note**

Ubuntu 20.04 supports peer direct support when used with dl1.24xlarge instances.

The following operating systems support EFAs with Arm-based (Graviton) instance types:

- Amazon Linux 2023
- Amazon Linux 2
- RHEL 8/9 and Rocky Linux 8/9
- Debian 10 and 11
- Ubuntu 20.04 and 22.04
- SUSE Linux Enterprise 15 SP2 and later

EFA limitations

EFAs have the following limitations:

- All P4d and P5 instance types support NVIDIA GPUDirect Remote Direct Memory Access (RDMA).
- EFA traffic between P4d/P4de/DL1 instances and other instance types is currently not supported.
- **Instance types that support multiple network cards (p. 1406)** can be configured with one EFA per network card. All other supported instance types support only one EFA per instance.
- For c7g.16xlarge, m7g.16xlarge and r7g.16xlarge Dedicated Instances and Dedicated Hosts are not supported when an EFA is attached.
- EFA OS-bypass traffic is limited to a single subnet. In other words, EFA traffic cannot be sent from one subnet to another. Normal IP traffic from the EFA can be sent from one subnet to another.
- EFA OS-bypass traffic is not routable. Normal IP traffic from the EFA remains routable.
- The EFA must be a member of a security group that allows all inbound and outbound traffic to and from the security group itself.
- EFA is not supported on AWS Outposts

## EFA pricing

EFA is available as an optional Amazon EC2 networking feature that you can enable on any supported instance at no additional cost.

### Get started with P5 instances and EFA

P5 instances deliver 3200 Gbps of networking bandwidth by using multiple EFA interfaces. P5 instances support 32 network cards. For more information about getting started with P5 instances, see Get started with P5 instances (p. 443).

We recommend that you define a single EFA network interface per network card. To configure these interfaces at launch we recommend the following settings:

- For network interface 0, specify device index 0
- For network interfaces 1 through 31, specify device index 1

If you are using the Amazon EC2 console, in the Launch Instance Wizard, choose Edit in the Network settings section. Expand Advanced network configuration and choose Add network interface to add the required number of network interfaces. For each network interface, for EFA, select Enable. For all network interfaces, except the primary network interface, for Device index, specify 1. Configure the remaining settings as needed.

If you are using the AWS CLI, use the run-instances command, for --network-interfaces, specify the required number of network interfaces. For each network interface, for InterfaceType, specify efa. For the primary network interface, for NetworkCardIndex and DeviceIndex specify 0. For the remaining network interfaces, for NetworkCardIndex specify a unique value from 1 to 31, and for DeviceIndex specify 1.

The following example command snippet shows a request with 32 EFA network interfaces.

```bash
$ aws --region $REGION ec2 run-instances \
  --instance-type p5.48xlarge \
  --count 1 \
  --key-name key_pair_name \
  --image-id ami_id \
  --network-interfaces "NetworkCardIndex=0,DeviceIndex=0,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa" \
  "NetworkCardIndex=1,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa" \
  "NetworkCardIndex=2,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa" \
  "NetworkCardIndex=3,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
```
"NetworkCardIndex=4,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=5,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=6,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=7,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=8,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=9,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=10,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=11,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=12,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=13,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=14,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=15,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=16,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=17,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=18,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=19,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=20,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=21,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=22,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=23,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=24,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
"NetworkCardIndex=25,DeviceIndex=1,Groups=security_group_id,SubnetId=subnet_id,InterfaceType=efa"
If you are using a launch template, specify the required number of network interfaces in the launch template. For each network interface, for `InterfaceType`, specify `efa`. For the primary network interface, for `NetworkCardIndex` and `DeviceIndex` specify `0`. For the remaining network interfaces, for `NetworkCardIndex` specify a unique value from `1` to `31`, and for `DeviceIndex` specify `1`. The following snippet shows an example with 3 network interfaces out of the possible 32 network interfaces.

```
"NetworkInterfaces": [
    {
        "NetworkCardIndex": 0,
        "DeviceIndex": 0,
        "InterfaceType": "efa",
        "AssociatePublicIpAddress": false,
        "Groups": [
            "security_group_id"
        ],
        "DeleteOnTermination": true
    },
    {
        "NetworkCardIndex": 1,
        "DeviceIndex": 1,
        "InterfaceType": "efa",
        "AssociatePublicIpAddress": false,
        "Groups": [
            "security_group_id"
        ],
        "DeleteOnTermination": true
    },
    {
        "NetworkCardIndex": 2,
        "DeviceIndex": 1,
        "InterfaceType": "efa",
        "AssociatePublicIpAddress": false,
        "Groups": [
            "security_group_id"
        ],
        "DeleteOnTermination": true
    }
...]
```

When launching a P5 instance with more than one network interface, you cannot auto-assign public IP addresses. However, you can attach an Elastic IP address to the primary network interface (`NetworkCardIndex=0, DeviceIndex=0`) after launch for internet connectivity. Both Ubuntu 20.04 and later and Amazon Linux 2 and later are configured to use the primary network interface for internet traffic when the instance is launched as recommended above.
Get started with EFA and MPI

This tutorial helps you to launch an EFA and MPI-enabled instance cluster for HPC workloads. In this tutorial, you will perform the following steps:

Contents

- Step 1: Prepare an EFA-enabled security group (p. 1515)
- Step 2: Launch a temporary instance (p. 1516)
- Step 3: Install the EFA software (p. 1517)
- Step 4: Disable ptrace protection (p. 1519)
- Step 5: (Optional) Install Intel MPI (p. 1520)
- Step 6: Confirm installation (p. 1522)
- Step 7: Install your HPC application (p. 1523)
- Step 8: Create an EFA-enabled AMI (p. 1523)
- Step 9: Launch EFA-enabled instances into a cluster placement group (p. 1523)
- Step 10: Terminate the temporary instance (p. 1525)
- Step 11: Enable passwordless SSH (p. 1525)

Step 1: Prepare an EFA-enabled security group

An EFA requires a security group that allows all inbound and outbound traffic to and from the security group itself. The following procedure creates a security group that allows all inbound and outbound traffic to and from itself, and that allows inbound SSH traffic from any IPv4 address for SSH connectivity.

**Important**

This security group is intended for testing purposes only. For your production environments, we recommend that you create an inbound SSH rule that allows traffic only from the IP address from which you are connecting, such as the IP address of your computer, or a range of IP addresses in your local network.

For other scenarios, see Security group rules for different use cases (p. 2037).

To create an EFA-enabled security group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups and then choose Create security group.
3. In the Create security group window, do the following:
   a. For Security group name, enter a descriptive name for the security group, such as EFA-enabled security group.
   b. (Optional) For Description, enter a brief description of the security group.
   c. For VPC, select the VPC into which you intend to launch your EFA-enabled instances.
   d. Choose Create security group.
4. Select the security group that you created, and on the Details tab, copy the Security group ID.
5. With the security group still selected, choose Actions, Edit inbound rules, and then do the following:
   a. Choose Add rule.
   b. For Type, choose All traffic.
   c. For Source type, choose Custom and paste the security group ID that you copied into the field.
d. Choose Add rule.
e. For Type, choose SSH.
f. For Source type, choose Anywhere-IPv4.
g. Choose Save rules.

6. With the security group still selected, choose Actions, Edit outbound rules, and then do the following:
   a. Choose Add rule.
   b. For Type, choose All traffic.
   c. For Destination type, choose Custom and paste the security group ID that you copied into the field.
   d. Choose Save rules.

**Step 2: Launch a temporary instance**

Launch a temporary instance that you can use to install and configure the EFA software components. You use this instance to create an EFA-enabled AMI from which you can launch your EFA-enabled instances.

**New console**

To launch a temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then choose Launch Instances to open the new launch instance wizard.
3. (Optional) In the Name and tags section, provide a name for the instance, such as EFA-instance. The name is assigned to the instance as a resource tag (Name=EFA-instance).
4. In the Application and OS Images section, select an AMI for one of the supported operating systems (p. 1511).
5. In the Instance type section, select a supported instance type (p. 1510).
6. In the Key pair section, select the key pair to use for the instance.
7. In the Network settings section, choose Edit, and then do the following:
   a. For Subnet, choose the subnet in which to launch the instance. If you do not select a subnet, you can't enable the instance for EFA.
   b. For Firewall (security groups), choose Select existing security group, and then select the security group that you created in the previous step.
   c. Expand the Advanced network configuration section, and for Elastic Fabric Adapter, select Enable.
8. In the Storage section, configure the volumes as needed.
9. In the Summary panel on the right, choose Launch instance.

**Old console**

To launch a temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance.
3. On the Choose an AMI page, choose Select for one of the supported operating systems (p. 1511).
4. On the **Choose an Instance Type** page, select one of the supported instance types (p. 1510) and then choose **Next: Configure Instance Details**.

5. On the **Configure Instance Details** page, do the following:
   a. For **Subnet**, choose the subnet in which to launch the instance. If you do not select a subnet, you can’t enable the instance for EFA.
   b. For **Elastic Fabric Adapter**, choose **Enable**.
   c. In the **Network Interfaces** section, for device **eth0**, choose **New network interface**.
   d. Choose **Next: Add Storage**.

6. On the **Add Storage** page, specify the volumes to attach to the instances in addition to the volumes that are specified by the AMI (such as the root device volume). Then choose **Next: Add Tags**.

7. On the **Add Tags** page, specify a tag that you can use to identify the temporary instance, and then choose **Next: Configure Security Group**.

8. On the **Configure Security Group** page, for **Assign a security group**, select **Select an existing security group**, and then select the security group that you created in **Step 1**.

9. On the **Review Instance Launch** page, review the settings, and then choose **Launch** to choose a key pair and to launch your instance.

**Step 3: Install the EFA software**

Install the EFA-enabled kernel, EFA drivers, Libfabric, and Open MPI stack that is required to support EFA on your temporary instance.

The steps differ depending on whether you intend to use EFA with Open MPI, with Intel MPI, or with Open MPI and Intel MPI.

**To install the EFA software**

1. Connect to the instance you launched. For more information, see [Connect to your Linux instance](p. 811).

2. To ensure that all of your software packages are up to date, perform a quick software update on your instance. This process may take a few minutes.

   - Amazon Linux 2, RHEL 7/8/9, CentOS 7, Rocky Linux 8/9
     
     
     ```
     $ sudo yum update -y
     ```

   - Ubuntu 20.04/22.04 and Debian 10/11
     
     ```
     $ sudo apt-get update && sudo apt-get upgrade -y
     ```

   - SUSE Linux Enterprise
     
     ```
     $ sudo zypper update -y
     ```

3. Reboot the instance and reconnect to it.

4. Download the EFA software installation files. The software installation files are packaged into a compressed tarball (.tar.gz) file. To download the latest stable version, use the following command.

   ```
   $ curl -O https://efa-installer.amazonaws.com/aws-efa-installer-1.29.0.tar.gz
   ```
You can also get the latest version by replacing the version number with `latest` in the preceding command.

5. **(Optional)** Verify the authenticity and integrity of the EFA tarball (.tar.gz) file. We recommend that you do this to verify the identity of the software publisher and to check that the file has not been altered or corrupted since it was published. If you do not want to verify the tarball file, skip this step.

   **Note**
   Alternatively, if you prefer to verify the tarball file by using an MD5 or SHA256 checksum instead, see [Verify the EFA installer using a checksum (p. 1555)](#).

   a. Download the public GPG key and import it into your keyring.

```
$ wget https://efa-installer.amazonaws.com/aws-efa-installer.key & gpg --import aws-efa-installer.key
```

   The command should return a key value. Make a note of the key value, because you need it in the next step.

   b. Verify the GPG key's fingerprint. Run the following command and specify the key value from the previous step.

```
$ gpg --fingerprint key_value
```

   The command should return a fingerprint that is identical to 4E90 91BC BB97 A96B 26B1 5E59 A054 80B1 DD2D 3CCC. If the fingerprint does not match, don't run the EFA installation script, and contact AWS Support.

   c. Download the signature file and verify the signature of the EFA tarball file.

```
$ wget https://efa-installer.amazonaws.com/aws-efa-installer-1.29.0.tar.gz.sig & gpg --verify ./aws-efa-installer-1.29.0.tar.gz.sig
```

   The following shows example output.

```
gpg: Signature made Wed 29 Jul 2020 12:50:13 AM UTC using RSA key ID DD2D3CCC
gpg: Good signature from "Amazon EC2 EFA <ec2-efa-maintainers@amazon.com>"
gpg: WARNING: This key is not certified with a trusted signature!
gpg: Primary key fingerprint: 4E90 91BC BB97 A96B 26B1 5E59 A054 80B1 DD2D 3CCC
```

   If the result includes *Good signature*, and the fingerprint matches the fingerprint returned in the previous step, proceed to the next step. If not, don't run the EFA installation script, and contact AWS Support.

6. Extract the files from the compressed .tar.gz file and navigate into the extracted directory.

```
$ tar -xf aws-efa-installer-1.29.0.tar.gz & cd aws-efa-installer
```

7. Install the EFA software. Do one of the following depending on your use case.

   **Note**
   If you are using a SUSE Linux operating system, you must additionally specify the `--skip-kmod` option to prevent kmod installation. By default, SUSE Linux does not allow out-of-tree kernel modules. As a result, EFA and NVIDIA GPUDirect support is currently not supported with SUSE Linux.

   - Open MPI and Intel MPI
If you intend to use an EFA with Open MPI and Intel MPI, you must install the EFA software with Libfabric and Open MPI, and you must complete Step 5: (Optional) Install Intel MPI. To install the EFA software with Libfabric and Open MPI, run the following command.

```
$ sudo ./efa_installer.sh -y
```

Libfabric is installed in the `/opt/amazon/efa` directory, while Open MPI is installed in the `/opt/amazon/openmpi` directory.

### Open MPI only

If you intend to use EFA with Open MPI only, you must install the EFA software with Libfabric and Open MPI, and you can skip Step 5: (Optional) Install Intel MPI. To install the EFA software with Libfabric and Open MPI, run the following command.

```
$ sudo ./efa_installer.sh -y
```

Libfabric is installed in the `/opt/amazon/efa` directory, while Open MPI is installed in the `/opt/amazon/openmpi` directory.

### Intel MPI only

If you intend to use EFA with Intel MPI only, you can install the EFA software without Libfabric and Open MPI. In this case, Intel MPI uses its embedded Libfabric. If you choose to do this, you must complete Step 5: (Optional) Install Intel MPI.

To install the EFA software without Libfabric and Open MPI, run the following command.

```
$ sudo ./efa_installer.sh -y --minimal
```

8. If the EFA installer prompts you to reboot the instance, do so and then reconnect to the instance. Otherwise, log out of the instance and then log back in to complete the installation.

### Step 4: Disable ptrace protection

To improve your HPC application's performance, Libfabric uses the instance's local memory for interprocess communications when the processes are running on the same instance.

The shared memory feature uses Cross Memory Attach (CMA), which is not supported with `ptrace protection`. If you are using a Linux distribution that has ptrace protection enabled by default, such as Ubuntu, you must disable it. If your Linux distribution does not have ptrace protection enabled by default, skip this step.

**To disable ptrace protection**

Do one of the following:

- To temporarily disable ptrace protection for testing purposes, run the following command.

  ```
  $ sudo sysctl -w kernel.yama.ptrace_scope=0
  ```

- To permanently disable ptrace protection, add `kernel.yama.ptrace_scope = 0` to `/etc/sysctl.d/10-ptrace.conf` and reboot the instance.
Step 5: *(Optional)* Install Intel MPI

**Important**
If you intend to only use Open MPI, skip this step. Perform this step only if you intend to use Intel MPI.

Intel MPI requires an additional installation and environment variable configuration.

**Prerequisites**
Ensure that the user performing the following steps has sudo permissions.

**To install Intel MPI**

1. To download the Intel MPI installation script, do the following
   a. Visit the [Intel website](#).
   b. In the **Intel MPI Library** section of the webpage, choose the link for the **Intel MPI Library for Linux Offline** installer.

2. Run the installation script that you downloaded in the previous step.

   ```
   $ sudo bash installation_script_name.sh
   ```

3. In the installer, choose **Accept & install**.
4. Read the Intel Improvement Program, choose the appropriate option, and then choose **Begin Installation**.
5. When the installation completes, choose **Close**.
6. By default, Intel MPI uses its embedded (internal) Libfabric. You can configure Intel MPI to use the Libfabric that ships with the EFA installer instead. Typically, the EFA installer ships with a later version of Libfabric than Intel MPI. In some cases, the Libfabric that ships with the EFA installer is more performant than that of Intel MPI. To configure Intel MPI to use the Libfabric that ships with the EFA installer, do one of the following depending on your shell.

   **bash shells**

   For **bash** shells, add the following statement to `/home/username/.bashrc` and `/home/username/.bash_profile`.

   ```
   export I_MPI_OFI_LIBRARY_INTERNAL=0
   ```

   **csh and tcsh shells**

   For **csh** and **tcsh** shells, add the following statement to `/home/username/.cshrc`.

   ```
   setenv I_MPI_OFI_LIBRARY_INTERNAL 0
   ```

7. Add the following **source** command to your shell script to source the `vars.sh` script from the installation directory to set up the compiler environment each time the instance starts. Do one of the following depending on your shell.

   **bash shells**

   For **bash** shells, add the following statement to `/home/username/.bashrc` and `/home/username/.bash_profile`.

   ```
   source /opt/intel/oneapi/mpi/latest/env/vars.sh
   ```
csh and tcsh shells

For **csh** and **tcsh** shells, add the following statement to `/home/username/.cshrc`.

```
source /opt/intel/oneapi/mpi/latest/env/vars.csh
```

8. By default, if EFA is not available due to a misconfiguration, Intel MPI defaults to the TCP/IP network stack, which might result in slower application performance. You can prevent this by setting `I_MPI_OFI_PROVIDER` to `efa`. This causes Intel MPI to fail with the following error if EFA is not available:

```
Abort (XXXXXX) on node 0 (rank 0 in comm 0): Fatal error in Pmpi_Init: OtherMPI error, MpiR_Init_thread (XXX)........:
MPID_Init (XXXX)...............:
MPIDI_OFI_mpi_init_hook (XXXX):
open_fabric (XXXX)...............:
find_provider (XXXX)............:
OFI fi_getinfo() failed (ofi_init.c:2684:find_provider:
```

Do one of the following depending on your shell.

bash shells

For **bash** shells, add the following statement to `/home/username/.bashrc` and `/home/username/.bash_profile`.

```
export I_MPI_OFI_PROVIDER=efa
```

csh and tcsh shells

For **csh** and **tcsh** shells, add the following statement to `/home/username/.cshrc`.

```
setenv I_MPI_OFI_PROVIDER efa
```

9. By default, Intel MPI doesn't print debugging information. You can specify different verbosity levels to control the debugging information. Possible values (in order of the amount of detail they provide) are: 0 (default), 1, 2, 3, 4, 5. Level 1 and higher prints the libfabric version and libfabric provider. Use `libfabric version` to check whether Intel MPI is using the internal Libfabric or the Libfabric that ships with the EFA installer. If it's using the internal Libfabric, the version is suffixed with `impi`. Use `libfabric provider` to check with Intel MPI is using EFA or the TCP/IP network. If it's using EFA, the value is `efa`. If it's using TCP/IP, the value is `tcp;ofi_rxm`.

To enable debugging information, do one of the following depending on your shell.

bash shells

For **bash** shells, add the following statement to `/home/username/.bashrc` and `/home/username/.bash_profile`.

```
export I_MPI_DEBUG=value
```

csh and tcsh shells

For **csh** and **tcsh** shells, add the following statement to `/home/username/.cshrc`.

```
setenv I_MPI_DEBUG value
```
10. By default, Intel MPI uses the operating system's shared memory (shm) for intra-node communication, and it uses Libfabric (ofi) only for inter-node communication. Generally, this configuration provides the best performance. However, in some cases the Intel MPI shm fabric can cause certain applications to hang indefinitely.

To resolve this issue, you can force Intel MPI to use Libfabric for both intra-node and inter-node communication. To do this, do one of the following depending on your shell.

bash shells

For **bash** shells, add the following statement to `/home/username/.bashrc` and `/home/username/.bash_profile`.

```
export I_MPI_FABRICS=ofi
```

csh and tcsh shells

For **csh and tcsh** shells, add the following statement to `/home/username/.cshrc`.

```
setenv I_MPI_FABRICS ofi
```

**Note**
The EFA Libfabric provider uses the operating system's shared memory for intra-node communication. This means that setting `I_MPI_FABRICS` to ofi yields similar performance to the default shm:ofi configuration.

11. Log out of the instance and then log back in.

**Note**
If you no longer want to use Intel MPI, remove the environment variables from the shell startup scripts.

**Step 6. Confirm installation**

**To confirm successful installation**

1. To confirm that MPI was successfully installed, run the following command:

```
$ which mpicc
```

- For Open MPI, the returned path should include `/opt/amazon/`
- For Intel MPI, the returned path should include `/opt/intel/`. If you do not get the expected output, ensure that you have sourced the Intel MPI `vars.sh` script.

2. To confirm that the EFA software components and Libfabric were successfully installed, run the following command.

```
$ fi_info -p efa -t FI_EP_RDM
```

The command should return information about the Libfabric EFA interfaces. The following example shows the command output.

```
provider: efa
  fabric: EFA-fe80::94:3dff:fe89:1b70
  domain: efa_0-rdm
```
Step 7: Install your HPC application

Install the HPC application on the temporary instance. The installation procedure varies depending on the specific HPC application. For more information, see Manage software on your Amazon Linux instance (p. 900).

Note
Refer to your HPC application’s documentation for installation instructions.

Step 8: Create an EFA-enabled AMI

After you have installed the required software components, you create an AMI that you can reuse to launch your EFA-enabled instances.

To create an AMI from your temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the temporary instance that you created and choose Actions, Image, Create image.
4. For Create image, do the following:
   a. For Image name, enter a descriptive name for the AMI.
   b. (Optional) For Image description, enter a brief description of the purpose of the AMI.
   c. Choose Create image.
5. In the navigation pane, choose AMIs.
6. Locate the AMI that you created in the list. Wait for the status to change from pending to available before continuing to the next step.

Step 9: Launch EFA-enabled instances into a cluster placement group

Launch your EFA-enabled instances into a cluster placement group using the EFA-enabled AMI that you created in Step 7, and the EFA-enabled security group that you created in Step 1.

Note
- It is not an absolute requirement to launch your EFA-enabled instances into a cluster placement group. However, we do recommend running your EFA-enabled instances in a cluster placement group as it launches the instances into a low-latency group in a single Availability Zone.
- To ensure that capacity is available as you scale your cluster’s instances, you can create a Capacity Reservation for your cluster placement group. For more information, see Capacity Reservations in cluster placement groups (p. 674).

New console

To launch a temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and then choose **Launch Instances** to open the new launch instance wizard.

3. *(Optional)* In the **Name and tags** section, provide a name for the instance, such as EFA-instance. The name is assigned to the instance as a resource tag (**Name=EFA-instance**).

4. In the **Application and OS Images** section, choose **My AMIs**, and then select the AMI that you created in the previous step.

5. In the **Instance type** section, select a supported instance type *(p. 1510)*.

6. In the **Key pair** section, select the key pair to use for the instance.

7. In the **Network settings** section, choose **Edit**, and then do the following:
   a. For **Subnet**, choose the subnet in which to launch the instance. If you do not select a subnet, you can't enable the instance for EFA.
   b. For **Firewall (security groups)**, choose **Select existing security group**, and then select the security group that you created in the previous step.
   c. Expand the **Advanced network configuration** section, and for **Elastic Fabric Adapter**, select **Enable**.

8. *(Optional)* In the **Storage** section, configure the volumes as needed.

9. In the **Advanced details** section, for **Placement group name**, select the cluster placement group into which to launch the instances. If you need to create a new cluster placement group, choose **Create new placement group**.

10. In the **Summary** panel on the right, for **Number of instances**, enter the number of EFA-enabled instances that you want to launch, and then choose **Launch instance**.

**Old console**

**To launch your EFA-enabled instances into a cluster placement group**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

2. Choose **Launch Instance**.

3. On the **Choose an AMI** page, choose **My AMIs**, find the AMI that you created in **Step 7**, and then choose **Select**.

4. On the **Choose an Instance Type** page, select one of the supported instance types *(p. 1510)* and then choose **Next: Configure Instance Details**.

5. On the **Configure Instance Details** page, do the following:
   a. For **Number of instances**, enter the number of EFA-enabled instances that you want to launch.
   b. For **Network** and **Subnet**, select the VPC and subnet into which to launch the instances.
   c. For **Placement group**, select **Add instance to placement group**.
   d. For **Placement group name**, select **Add to a new placement group**, enter a descriptive name for the placement group, and then for **Placement group strategy**, select **cluster**.
   e. For **EFA**, choose **Enable**.
   f. In the **Network Interfaces** section, for device **eth0**, choose **New network interface**. You can optionally specify a primary IPv4 address and one or more secondary IPv4 addresses. If you're launching the instance into a subnet that has an associated IPv6 CIDR block, you can optionally specify a primary IPv6 address and one or more secondary IPv6 addresses.
   g. Choose **Next: Add Storage**.

6. On the **Add Storage** page, specify the volumes to attach to the instances in addition to the volumes specified by the AMI (such as the root device volume), and then choose **Next: Add Tags**.

7. On the **Add Tags** page, specify tags for the instances, such as a user-friendly name, and then choose **Next: Configure Security Group**.
8. On the Configure Security Group page, for Assign a security group, select Select an existing security group, and then select the security group that you created in Step 1.

10. On the Review Instance Launch page, review the settings, and then choose Launch to choose a key pair and to launch your instances.

Step 10: Terminate the temporary instance

At this point, you no longer need the temporary instance that you launched. You can terminate the instance to stop incurring charges for it.

To terminate the temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the temporary instance that you created and then choose Actions, Instance state, Terminate instance.
4. When prompted for confirmation, choose Terminate.

Step 11: Enable passwordless SSH

To enable your applications to run across all of the instances in your cluster, you must enable passwordless SSH access from the leader node to the member nodes. The leader node is the instance from which you run your applications. The remaining instances in the cluster are the member nodes.

To enable passwordless SSH between the instances in the cluster

1. Select one instance in the cluster as the leader node, and connect to it.
2. Disable strictHostKeyChecking and enable ForwardAgent on the leader node. Open ~/.ssh/config using your preferred text editor and add the following.

```
Host *
  ForwardAgent yes
Host *
  StrictHostKeyChecking no
```
3. Generate an RSA key pair.

```
$ ssh-keygen -t rsa -N "" -f ~/.ssh/id_rsa
```
4. The key pair is created in the $HOME/.ssh/ directory.
5. Change the permissions of the private key on the leader node.

```
$ chmod 600 ~/.ssh/id_rsa
chmod 600 ~/.ssh/config
```
6. For each member node in the cluster, do the following:
   a. Connect to the instance.
   b. Open ~/.ssh/authorized_keys using your preferred text editor and add the public key that you copied earlier.
7. To test that the passwordless SSH is functioning as expected, connect to your leader node and run
the following command.

```
$ ssh member_node_private_ip
```

You should connect to the member node without being prompted for a key or password.

## Get started with EFA and NCCL

The NVIDIA Collective Communications Library (NCCL) is a library of standard collective communication
routines for multiple GPUs across a single node or multiple nodes. NCCL can be used together with EFA,
Libfabric, and MPI to support various machine learning workloads. For more information, see the [NCCL](#)
website.

**Note**

- NCCL with EFA is supported with p3dn.24xlarge, p4d.24xlarge, and p5.48xlarge
  instances only.
- Only NCCL 2.4.2 and later is supported with EFA.

The following tutorials help you to launch an EFA and NCCL-enabled instance cluster for machine
learning workloads.

- [Use a base AMI (p. 1526)](#)
- [Use an AWS Deep Learning AMI (p. 1545)](#)

## Use a base AMI

The following steps help you to get started with Elastic Fabric Adapter using an AMI for one of the
supported operating systems (p. 1511).

**Note**

- Only the p3dn.24xlarge, p4d.24xlarge, p5.48xlarge instance types are supported.
- Only Amazon Linux 2, RHEL 7/8/9, CentOS 7, Rocky Linux 8/9, and Ubuntu 20.04 base AMIs
  are supported.

**Contents**

- [Step 1: Prepare an EFA-enabled security group (p. 1527)](#)
- [Step 2: Launch a temporary instance (p. 1527)](#)
- [Step 3: Install Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN (p. 1528)](#)
- [Step 4: Install GDRCopy (p. 1536)](#)
- [Step 5: Install the EFA software (p. 1537)](#)
- [Step 6: Install NCCL (p. 1539)](#)
- [Step 7: Install the aws-ofi-nccl plugin (p. 1539)](#)
- [Step 8: Install the NCCL tests (p. 1540)](#)
- [Step 9: Test your EFA and NCCL configuration (p. 1541)](#)
- [Step 10: Install your machine learning applications (p. 1542)](#)
- [Step 11: Create an EFA and NCCL-enabled AMI (p. 1542)](#)
- [Step 12: Terminate the temporary instance (p. 1542)](#)
Step 1: Prepare an EFA-enabled security group

An EFA requires a security group that allows all inbound and outbound traffic to and from the security group itself. The following procedure creates a security group that allows all inbound and outbound traffic to and from itself, and that allows inbound SSH traffic from any IPv4 address for SSH connectivity.

**Important**

This security group is intended for testing purposes only. For your production environments, we recommend that you create an inbound SSH rule that allows traffic only from the IP address from which you are connecting, such as the IP address of your computer, or a range of IP addresses in your local network.

For other scenarios, see Security group rules for different use cases (p. 2037).

**To create an EFA-enabled security group**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups and then choose Create security group.
3. In the Create security group window, do the following:
   a. For Security group name, enter a descriptive name for the security group, such as EFA-enabled security group.
   b. (Optional) For Description, enter a brief description of the security group.
   c. For VPC, select the VPC into which you intend to launch your EFA-enabled instances.
   d. Choose Create security group.
4. Select the security group that you created, and on the Details tab, copy the Security group ID.
5. With the security group still selected, choose Actions, Edit inbound rules, and then do the following:
   a. Choose Add rule.
   b. For Type, choose All traffic.
   c. For Source type, choose Custom and paste the security group ID that you copied into the field.
   d. Choose Add rule.
   e. For Type, choose SSH.
   f. For Source type, choose Anywhere-IPv4.
   g. Choose Save rules.
6. With the security group still selected, choose Actions, Edit outbound rules, and then do the following:
   a. Choose Add rule.
   b. For Type, choose All traffic.
   c. For Destination type, choose Custom and paste the security group ID that you copied into the field.
   d. Choose Save rules.

**Step 2: Launch a temporary instance**

Launch a temporary instance that you can use to install and configure the EFA software components. You use this instance to create an EFA-enabled AMI from which you can launch your EFA-enabled instances.
New console

To launch a temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then choose Launch Instances to open the new launch instance wizard.
3. (Optional) In the Name and tags section, provide a name for the instance, such as EFA-instance. The name is assigned to the instance as a resource tag (Name=EFA-instance).
4. In the Application and OS Images section, select an AMI for one of the supported operating systems (p. 1511).
5. In the Instance type section, select either p3dn.24xlarge, p4d.24xlarge, or p5d.48xlarge.
6. In the Key pair section, select the key pair to use for the instance.
7. In the Network settings section, choose Edit, and then do the following:
   a. For Subnet, choose the subnet in which to launch the instance. If you do not select a subnet, you can't enable the instance for EFA.
   b. For Firewall (security groups), choose Select existing security group, and then select the security group that you created in the previous step.
   c. Expand the Advanced network configuration section, and for Elastic Fabric Adapter, select Enable.
8. In the Storage section, configure the volumes as needed.

   Note
   You must provision an additional 10 to 20 GiB of storage for the Nvidia CUDA Toolkit. If you do not provision enough storage, you will receive an insufficient disk space error when attempting to install the Nvidia drivers and CUDA toolkit.
9. In the Summary panel on the right, choose Launch instance.

Step 3: Install Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN

Amazon Linux 2

To install the Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN

1. To ensure that all of your software packages are up to date, perform a quick software update on your instance.

   $ sudo yum upgrade -y && sudo reboot

   After the instance has rebooted, reconnect to it.
2. Install the utilities that are needed to install the Nvidia GPU drivers and the Nvidia CUDA toolkit.

   $ sudo yum groupinstall 'Development Tools' -y
3. Disable the nouveau open source drivers.
   a. Install the required utilities and the kernel headers package for the version of the kernel that you are currently running.

   $ sudo yum install -y wget kernel-devel-$uname -r kernel-headers-$uname -r
   b. Add nouveau to the /etc/modprobe.d/blacklist.conf deny list file.
Get started with EFA and NCCL

```
$ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
blacklist vga16fb
blacklist nouveau
blacklist rivafb
blacklist nvidiafb
blacklist rivatv
EOF
```

c. Append `GRUB_CMDLINE_LINUX="rdblacklist=nouveau"` to the grub file and rebuild the Grub configuration.

```
$ echo 'GRUB_CMDLINE_LINUX="rdblacklist=nouveau"' | sudo tee -a /etc/default/grub
& sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

4. Reboot the instance and reconnect to it.

5. Prepare the required repositories

   a. Install the EPEL repository for DKMS and enable any optional repos for your Linux distribution.

```
```

   b. Install the CUDA repository public GPG key.

```
$ distribution='rhel7'
```

   c. Set up the CUDA network repository and update the repository cache.

```
$ ARCH=($ /bin/arch ) \n& sudo yum-config-manager --add-repo http://developer.download.nvidia.com/compute/cuda/repos/$distribution/${ARCH}/cuda-$distribution.repo \n& sudo yum clean expire-cache
```

   d. *(Kernel version 5.10 only)* Perform these steps only if you are using Amazon Linux 2 with kernel version 5.10. If you are using Amazon Linux 2 with kernel version 4.12, skip these steps. To check your kernel version, run `uname -r`.

   i. Add the amzn2-nvidia repository. Create a new repo file named `/etc/yum.repos.d/amzn2-nvidia.repo`, and using your preferred text editor, add the following to the file.

```
[amzn2-nvidia]
name=Amazon Linux 2 Nvidia repository
mirrorlist=http://amazonlinux.{}.awsregion.{}.awsdomain/{}/releasever/amzn2-nvidia/$target/$basearch/mirror.list
priority=20
gpgcheck=0
gpgkey=https://developer.download.nvidia.com/compute/cuda/repos/rhel7/x86_64/7fa2af80.pub
enabled=1
metadata_expire=300
mirrorlist_expire=300
report_instanceid=yes
```

   ii. Install the system-release-nvidia package from the repo you added in the previous step.
$ sudo yum install system-release-nvidia

iii. Create the Nvidia driver configuration file named /etc/dkms/nvidia.conf.

```
$ sudo mkdir -p /etc/dkms 
&& echo "MAKE[0]="'make' -j2 module SYSSRC="${kernel_source_dir} 
IGNORE_XEN_PRESENCE=1 IGNORE_PREEMPT_RT_PRESENCE=1 IGNORE_CC_MISMATCH=1 
CC=/usr/bin/gcc10-gcc" | sudo tee /etc/dkms/nvidia.conf
```

6. Install the Nvidia GPU drivers, NVIDIA CUDA toolkit, and cuDNN.

```
$ sudo yum clean all 
&& sudo yum -y install kmod-nvidia-latest-dkms nvidia-driver-latest-dkms 
&& sudo yum -y install cuda-drivers-fabricmanager cuda libcudnn8-devel
```

7. Reboot the instance and reconnect to it.

8. (p4d.24xlarge and p5.48xlarge instances only) Start the Nvidia Fabric Manager service, and ensure that it starts automatically when the instance starts. Nvidia Fabric Manager is required for NV Switch Management.

```
$ sudo systemctl enable nvidia-fabricmanager && sudo systemctl start nvidia-fabricmanager
```

9. Ensure that the CUDA paths are set each time that the instance starts.

   • For `bash` shells, add the following statements to `/home/username/.bashrc` and `/home/username/.bash_profile`.

     ```
     export PATH=/usr/local/cuda/bin:$PATH
     export LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:
     $LD_LIBRARY_PATH
     ```

   • For `tcsh` shells, add the following statements to `/home/username/.cshrc`.

     ```
     setenv PATH=/usr/local/cuda/bin:$PATH
     setenv LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:
     $LD_LIBRARY_PATH
     ```

10. To confirm that the Nvidia GPU drivers are functional, run the following command.

    ```
    $ nvidia-smi -q | head
    ```

The command should return information about the Nvidia GPUs, Nvidia GPU drivers, and Nvidia CUDA toolkit.

CentOS 7

**To install the Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN**

1. To ensure that all of your software packages are up to date, perform a quick software update on your instance.

    ```
    $ sudo yum upgrade -y && sudo reboot
    ```

After the instance has rebooted, reconnect to it.
2. Install the utilities that are needed to install the Nvidia GPU drivers and the Nvidia CUDA toolkit.

```bash
$ sudo yum groupinstall 'Development Tools' -y 
&& sudo yum install -y tar bzip2 make automake pciutils elfutils-libelf-devel
libglvnd-devel iptables firewalld vim bind-utils
```

3. To use the Nvidia GPU driver, you must first disable the nouveau open source drivers.
   a. Install the required utilities and the kernel headers package for the version of the kernel that you are currently running.

```bash
$ sudo yum install -y wget kernel-devel-$(uname -r) kernel-headers-$(uname -r)
```

   b. Add nouveau to the `/etc/modprobe.d/blacklist.conf` deny list file.

```bash
$ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
blacklist vga16fb
blacklist nouveau
blacklist rivafb
blacklist nvidiafb
blacklist rivatv
EOF
```

   c. Open `/etc/default/grub` using your preferred text editor and add the following.

```bash
GRUB_CMDLINE_LINUX="rdblacklist=nouveau"
```

   d. Rebuild the Grub configuration.

```bash
$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

4. Reboot the instance and reconnect to it.

5. Install the Nvidia GPU drivers, NVIDIA CUDA toolkit, and cuDNN.
   a. Install the EPEL repository for DKMS and enable any optional repos for your Linux distribution.

```bash
```

   b. Install the CUDA repository public GPG key.

```bash
$ DISTRIBUTION='rhel7'
```

   c. Set up the CUDA network repository and update the repository cache.

```bash
$ ARCH=$( /bin/arch ) 
&& sudo yum clean expire-cache
```

   d. Install the NVIDIA, CUDA drivers and cuDNN.

```bash
$ sudo yum clean all \ 
&& sudo yum -y install cuda-drivers-fabricmanager cuda libcudnn8-devel
```

6. Reboot the instance and reconnect to it.
7. (p4d.24xlarge and p5.48xlarge instances only) Start the Nvidia Fabric Manager service, and ensure that it starts automatically when the instance starts. Nvidia Fabric Manager is required for NV Switch Management.

```
$ sudo systemctl start nvidia-fabricmanager \
& sudo systemctl enable nvidia-fabricmanager
```

8. Ensure that the CUDA paths are set each time that the instance starts.

- For bash shells, add the following statements to `/home/username/.bashrc` and `/home/username/.bash_profile`.

```
export PATH=/usr/local/cuda/bin:$PATH
export LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:
$LD_LIBRARY_PATH
```

- For tcsh shells, add the following statements to `/home/username/.cshrc`.

```
setenv PATH=/usr/local/cuda/bin:$PATH
setenv LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:
$LD_LIBRARY_PATH
```

9. To confirm that the Nvidia GPU drivers are functional, run the following command.

```
$ nvidia-smi -q | head
```

The command should return information about the Nvidia GPUs, Nvidia GPU drivers, and Nvidia CUDA toolkit.

RHEL 7/8/9 and Rocky Linux 8/9

**To install the Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN**

1. To ensure that all of your software packages are up to date, perform a quick software update on your instance.

```
$ sudo yum upgrade -y && sudo reboot
```

After the instance has rebooted, reconnect to it.

2. Install the utilities that are needed to install the Nvidia GPU drivers and the Nvidia CUDA toolkit.

```
$ sudo yum groupinstall 'Development Tools' -y
```

3. To use the Nvidia GPU driver, you must first disable the nouveau open source drivers.

   a. Install the required utilities and the kernel headers package for the version of the kernel that you are currently running.

```
$ sudo yum install -y wget kernel-devel-$uname -r kernel-headers-$uname -r
```

   b. Add nouveau to the `/etc/modprobe.d/blacklist.conf` deny list file.

```
$ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
blacklist vga16fb
blacklist nouveau
blacklist rivafb
EOF
```
Amazon Elastic Compute Cloud
User Guide for Linux Instances
Get started with EFA and NCCL

blacklist nvidiafb
blacklist rivatv
EOF

c. Open /etc/default/grub using your preferred text editor and add the following.

```
GRUB_CMDLINE_LINUX="rd blacklist=nouveau"
```
d. Rebuild the Grub configuration.

```
$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

4. Reboot the instance and reconnect to it.

5. Install the Nvidia GPU drivers, NVIDIA CUDA toolkit, and cuDNN.

a. Install the EPEL repository for DKMS and enable any optional repos for your Linux distribution.

   - **RHEL 7**

   ```
   ```

   - **RHEL 8 and Rocky Linux 8/9**

   ```
   ```

   - **RHEL 9**

   ```
   ```

b. Install the CUDA repository public GPG key.

```
$ distribution=$(./etc/os-release;echo $ID`rpm -E "%{?rhel}%{?fedora}"")
```
c. Set up the CUDA network repository and update the repository cache.

```
$ ARCH=$( /bin/arch ) \
   && sudo yum clean expire-cache
```
d. Install the NVIDIA, CUDA drivers and cuDNN.

```
$ sudo yum clean all \ 
   && sudo yum -y install cuda-drivers-fabricmanager cuda libcudnn8-devel
```

6. Reboot the instance and reconnect to it.

7. (p4d.24xlarge and p5.48xlarge instances only) Start the Nvidia Fabric Manager service, and ensure that it starts automatically when the instance starts. Nvidia Fabric Manager is required for NV Switch Management.

```
$ sudo systemctl start nvidia-fabricmanager \ 
   && sudo systemctl enable nvidia-fabricmanager
```

8. Ensure that the CUDA paths are set each time that the instance starts.
For `bash` shells, add the following statements to `/home/username/.bashrc` and `/home/username/.bash_profile`.

```bash
export PATH=/usr/local/cuda/bin:$PATH
export LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:$LD_LIBRARY_PATH
```

For `tcsh` shells, add the following statements to `/home/username/.cshrc`.

```bash
setenv PATH=/usr/local/cuda/bin:$PATH
setenv LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:$LD_LIBRARY_PATH
```

9. To confirm that the Nvidia GPU drivers are functional, run the following command.

```bash
$ nvidia-smi -q | head
```

The command should return information about the Nvidia GPUs, Nvidia GPU drivers, and Nvidia CUDA toolkit.

Ubuntu 20.04

**To install the Nvidia GPU drivers, Nvidia CUDA toolkit, and cuDNN**

1. To ensure that all of your software packages are up to date, perform a quick software update on your instance.

   ```bash
   $ sudo apt-get update && sudo apt-get upgrade -y
   ```

2. Install the utilities that are needed to install the Nvidia GPU drivers and the Nvidia CUDA toolkit.

   ```bash
   $ sudo apt-get update && sudo apt-get install build-essential -y
   ```

3. To use the Nvidia GPU driver, you must first disable the `nouveau` open source drivers.

   a. Install the required utilities and the kernel headers package for the version of the kernel that you are currently running.

   ```bash
   $ sudo apt-get install -y gcc make linux-headers-$\{(uname -r)\}
   ```

   b. Add `nouveau` to the `/etc/modprobe.d/blacklist.conf` deny list file.

   ```bash
   $ cat << EOF | sudo tee --append /etc/modprobe.d/blacklist.conf
   blacklist vga16fb
   blacklist nouveau
   blacklist rivafb
   blacklist nvidiafb
   blacklist rivatv
   EOF
   ```

   c. Open `/etc/default/grub` using your preferred text editor and add the following.

   ```bash
   GRUB_CMDLINE_LINUX="rd blacklist=nouveau"
   ```

   d. Rebuild the Grub configuration.
$ sudo update-grub

4. Reboot the instance and reconnect to it.
5. Add the CUDA repository and install the Nvidia GPU drivers, NVIDIA CUDA toolkit, and cuDNN.

```bash
$ sudo apt-key adv --fetch-keys http://developer.download.nvidia.com/compute/machine-learning/repos/ubuntu2004/x86_64/7fa2af80.pub
&& sudo dpkg -i /tmp/deeplearning.deb
&& sudo apt-key adv --fetch-keys http://developer.download.nvidia.com/compute/cuda/repos/ubuntu2004/x86_64/3bf863cc.pub
&& sudo apt update
&& sudo apt install nvidia-dkms-515
&& sudo apt install -o Dpkg::Options::='--force-overwrite' cuda-drivers cuda-toolkit-12-3 libcudnn8 libcudnn8-dev -y
```

6. Reboot the instance and reconnect to it.
7. (p4d.24xlarge and p5.48xlarge instances only) Install the Nvidia Fabric Manager.
   a. You must install the version of the Nvidia Fabric Manager that matches the version of the Nvidia kernel module that you installed in the previous step.

   Run the following command to determine the version of the Nvidia kernel module.

   ```bash
   $ cat /proc/driver/nvidia/version | grep "Kernel Module"
   ```

   The following is example output.

   ```
   NVRM version: NVIDIA UNIX x86_64 Kernel Module 450.42.01 Tue Jun 15 21:26:37 UTC 2021
   ```

   In the example above, major version 450 of the kernel module was installed. This means that you need to install Nvidia Fabric Manager version 450.

   b. Install the Nvidia Fabric Manager. Run the following command and specify the major version identified in the previous step.

   ```bash
   $ sudo apt install -o Dpkg::Options::='--force-overwrite' nvidia-fabricmanager-major_version_number
   ```

   For example, if major version 450 of the kernel module was installed, use the following command to install the matching version of Nvidia Fabric Manager.

   ```bash
   $ sudo apt install -o Dpkg::Options::='--force-overwrite' nvidia-fabricmanager-450
   ```

   c. Start the service, and ensure that it starts automatically when the instance starts. Nvidia Fabric Manager is required for NV Switch Management.
$ sudo systemctl start nvidia-fabricmanager && sudo systemctl enable nvidia-fabricmanager

8. Ensure that the CUDA paths are set each time that the instance starts.
   - For bash shells, add the following statements to `/home/username/.bashrc` and `/home/username/.bash_profile`.

      ```bash
      export PATH=/usr/local/cuda/bin:$PATH
      export LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:
      $LD_LIBRARY_PATH
      ```

   - For tcsh shells, add the following statements to `/home/username/.cshrc`.

      ```bash
      setenv PATH=/usr/local/cuda/bin:$PATH
      setenv LD_LIBRARY_PATH=/usr/local/cuda/lib64:/usr/local/cuda/extras/CUPTI/lib64:
      $LD_LIBRARY_PATH
      ```

9. To confirm that the Nvidia GPU drivers are functional, run the following command.

   $ nvidia-smi -q | head

   The command should return information about the Nvidia GPUs, Nvidia GPU drivers, and Nvidia CUDA toolkit.

**Step 4: Install GDRCopy**

Install GDRCopy to improve the performance of Libfabric. For more information about GDRCopy, see the [GDRCopy repository](https://github.com/NVIDIA/gdrcopy).

**Amazon Linux 2, CentOS 7, RHEL 7/8/9, and Rocky Linux 8/9**

**To install GDRCopy**

1. Install the required dependencies.

   $ sudo yum -y install dkms rpm-build make check check-devel subunit subunit-devel

2. Download and extract the GDRCopy package.

   $ wget https://github.com/NVIDIA/gdrcopy/archive/refs/tags/v2.3.tar.gz 
   && tar xf v2.3.tar.gz ; cd gdrcopy-2.3/packages

3. Build the GDRCopy RPM package.

   $ CUDA=/usr/local/cuda ./build-rpm-packages.sh

4. Install the GDRCopy RPM package.

   $ sudo rpm -Uvh gdrcopy-kmod-2.3-1dkms.noarch*.rpm 
   && sudo rpm -Uvh gdrcopy-2.3-1.x86_64*.rpm 
   && sudo rpm -Uvh gdrcopy-devel-2.3-1.noarch*.rpm
Ubuntu 20.04

**To install GDRCopy**

1. Install the required dependencies.

   ```bash
   $ sudo apt -y install build-essential devscripts debhelper check libsubunit-dev fakeroot pkg-config dkms
   ```

2. Download and extract the GDRCopy package.

   ```bash
   $ wget https://github.com/NVIDIA/gdrcopy/archive/refs/tags/v2.3.tar.gz 
   && tar xf v2.3.tar.gz ; cd gdrcopy-2.3/packages
   ```

3. Build the GDRCopy RPM package.

   ```bash
   $ CUDA=/usr/local/cuda ./build-deb-packages.sh
   ```

4. Install the GDRCopy RPM package.

   ```bash
   $ sudo dpkg -i gdrdrv-dkms_2.3-1_amd64.*.deb 
   && sudo dpkg -i libgdrapi_2.3-1_amd64.*.deb 
   && sudo dpkg -i gdrcopy-tests_2.3-1_amd64.*.deb 
   && sudo dpkg -i gdrcopy_2.3-1_amd64.*.deb
   ```

**Step 5: Install the EFA software**

Install the EFA-enabled kernel, EFA drivers, Libfabric, and Open MPI stack that is required to support EFA on your temporary instance.

**To install the EFA software**

1. Connect to the instance you launched. For more information, see [Connect to your Linux instance](p. 811).

2. Download the EFA software installation files. The software installation files are packaged into a compressed tarball (.tar.gz) file. To download the latest stable version, use the following command.

   ```bash
   $ curl -O https://efa-installer.amazonaws.com/aws-efa-installer-1.29.0.tar.gz
   ```

   You can also get the latest version by replacing the version number with latest in the preceding command.

3. (Optional) Verify the authenticity and integrity of the EFA tarball (.tar.gz) file. We recommend that you do this to verify the identity of the software publisher and to check that the file has not been altered or corrupted since it was published. If you do not want to verify the tarball file, skip this step.

   **Note**

   Alternatively, if you prefer to verify the tarball file by using an MD5 or SHA256 checksum instead, see [Verify the EFA installer using a checksum](p. 1555).

   a. Download the public GPG key and import it into your keyring.

   ```bash
   $ wget https://efa-installer.amazonaws.com/aws-efa-installer.key && gpg --import aws-efa-installer.key
   ```
The command should return a key value. Make a note of the key value, because you need it in the next step.

b. Verify the GPG key's fingerprint. Run the following command and specify the key value from the previous step.

```
$ gpg --fingerprint key_value
```

The command should return a fingerprint that is identical to 4E90 91BC BB97 A96B 26B1 5E59 A054 80B1 DD2D 3CCC. If the fingerprint does not match, don't run the EFA installation script, and contact AWS Support.

c. Download the signature file and verify the signature of the EFA tarball file.

```
$ wget https://efa-installer.amazonaws.com/aws-efa-installer-1.29.0.tar.gz.sig && gpg --verify ./aws-efa-installer-1.29.0.tar.gz.sig
```

The following shows example output.

```
gpg: Signature made Wed 29 Jul 2020 12:50:13 AM UTC using RSA key ID DD2D3CCC
gpg: Good signature from "Amazon EC2 EFA <ec2-efa-maintainers@amazon.com>"
gpg: WARNING: This key is not certified with a trusted signature!
gpg:     There is no indication that the signature belongs to the owner.
Primary key fingerprint: 4E90 91BC BB97 A96B 26B1 5E59 A054 80B1 DD2D 3CCC
```

If the result includes Good signature, and the fingerprint matches the fingerprint returned in the previous step, proceed to the next step. If not, don't run the EFA installation script, and contact AWS Support.

4. Extract the files from the compressed .tar.gz file and navigate into the extracted directory.

```
$ tar -xf aws-efa-installer-1.29.0.tar.gz && cd aws-efa-installer
```

5. Run the EFA software installation script.

```
$ sudo ./efa_installer.sh -y
```

Libfabric is installed in the /opt/amazon/efa directory, while Open MPI is installed in the /opt/amazon/openmpi directory.

6. If the EFA installer prompts you to reboot the instance, do so and then reconnect to the instance. Otherwise, log out of the instance and then log back in to complete the installation.

7. Confirm that the EFA software components were successfully installed.

```
$ fi_info -p efa -t FI_EP_RDM
```

The command should return information about the Libfabric EFA interfaces. The following example shows the command output.

```
• p3dn.24xlarge with single network interface
```

```bash
provider: efa
fabric: EFA-e80::94:3dff:fe89:1b70
domain: efa_0-rdm
version: 2.0
type: FI_EP_RDM
```
Step 6: Install NCCL

Install NCCL. For more information about NCCL, see the NCCL repository.

To install NCCL

1. Navigate to the /opt directory.

   
   ```sh
   $ cd /opt
   ```

2. Clone the official NCCL repository to the instance and navigate into the local cloned repository.

   ```sh
   $ sudo git clone https://github.com/NVIDIA/nccl.git && cd nccl
   ```

3. Build and install NCCL and specify the CUDA installation directory.

   ```sh
   $ sudo make -j src.build CUDA_HOME=/usr/local/cuda
   ```

Step 7: Install the aws-ofi-nccl plugin

The aws-ofi-nccl plugin maps NCCL’s connection-oriented transport APIs to Libfabric’s connection-less reliable interface. This enables you to use Libfabric as a network provider while running NCCL-based applications. For more information about the aws-ofi-nccl plugin, see the aws-ofi-nccl repository.

To install the aws-ofi-nccl plugin

1. Navigate to your home directory.
2. *(Amazon Linux 2 and Ubuntu 20.04 only)* Install the required utilities.

   - **Amazon Linux 2**
     
     $ sudo yum install hwloc-devel
   
   - **Ubuntu 20.04**
     
     $ sudo apt-get install libhwloc-dev

3. Download the aws-ofi-nccl plugin files. The files are packaged into a compressed tarball (.tar.gz).

   $ wget https://github.com/aws/aws-ofi-nccl/releases/download/v1.7.4-aws/aws-ofi-nccl-1.7.4-aws.tar.gz

4. Extract the files from the compressed .tar.gz file and navigate into the extracted directory.

   $ tar -xf aws-ofi-nccl-1.7.4-aws.tar.gz && cd aws-ofi-nccl-1.7.4-aws

5. To generate the make files, run the configure script and specify the MPI, Libfabric, NCCL, and CUDA installation directories.

   $ ./configure --prefix=/opt/aws-ofi-nccl --with-mpi=/opt/amazon/openmpi 
   --with-libfabric=/opt/amazon/efa 
   --with-cuda=/usr/local/cuda 
   --enable-platform-aws

6. Add the Open MPI directory to the PATH variable.

   $ export PATH=/opt/amazon/openmpi/bin/:$PATH

7. Install the aws-ofi-nccl plugin.

   $ make && sudo make install

---

**Step 8: Install the NCCL tests**

Install the NCCL tests. The NCCL tests enable you to confirm that NCCL is properly installed and that it is operating as expected. For more information about the NCCL tests, see the [nccl-tests repository](#).

**To install the NCCL tests**

1. Navigate to your home directory.

   $ cd $HOME

2. Clone the official nccl-tests repository to the instance and navigate into the local cloned repository.

   $ git clone https://github.com/NVIDIA/nccl-tests.git && cd nccl-tests

3. Add the Libfabric directory to the LD_LIBRARY_PATH variable.

   - Amazon Linux, Amazon Linux 2, RHEL, Rocky Linux 8/9, and CentOS
$ export LD_LIBRARY_PATH=/opt/amazon/efa/lib64:$LD_LIBRARY_PATH

• Ubuntu 20.04

$ export LD_LIBRARY_PATH=/opt/amazon/efa/lib:$LD_LIBRARY_PATH

4. Install the NCCL tests and specify the MPI, NCCL, and CUDA installation directories.

$ make MPI=1 MPI_HOME=/opt/amazon/openmpi NCCL_HOME=/opt/nccl/build CUDA_HOME=/usr/local/cuda

Step 9: Test your EFA and NCCL configuration

Run a test to ensure that your temporary instance is properly configured for EFA and NCCL.

To test your EFA and NCCL configuration

1. Create a host file that specifies the hosts on which to run the tests. The following command creates a host file named `my-hosts` that includes a reference to the instance itself.

IMDSv2

```
```

IMDSv1

```
```

2. Run the test and specify the host file (`--hostfile`) and the number of GPUs to use (`-n`). The following command runs the `all_reduce_perf` test on 8 GPUs on the instance itself, and specifies the following environment variables.

• `FI_EFA_USE_DEVICE_RDMA=1`—(p4d.24xlarge only) uses the device's RDMA functionality for one-sided and two-sided transfer.

• `NCCL_DEBUG=INFO`—enables detailed debugging output. You can also specify `VERSION` to print only the NCCL version at the start of the test, or `WARN` to receive only error messages.

For more information about the NCCL test arguments, see the [NCCL Tests README](#) in the official nccl-tests repository.

• p3dn.24xlarge

```
$ /opt/amazon/openmpi/bin/mpirun \
-x LD_LIBRARY_PATH=/opt/nccl/build/lib:/usr/local/cuda/lib64:/opt/amazon/efa/lib:/opt/amazon/openmpi/lib:/opt/aws-ofi-nccl/lib:$LD_LIBRARY_PATH \
-x NCCL_DEBUG=INFO \
--hostfile my-hosts -n 8 -N 8 \n--mca pml ^cm --mca btl tcp,self --mca btl_tcp_if_exclude lo,docker0 --bind-to none \
$HOME/nccl-tests/build/all_reduce_perf -b 8 -e 1G -f 2 -g 1 -c 1 -n 100
```

• p4d.24xlarge and p5.48xlarge
$ /opt/amazon/openmpi/bin/mpirun \
   -x FI_EFA_USE_DEVICE_RDMA=1 \
   -x LD_LIBRARY_PATH=/opt/nccl/build/lib:/usr/local/cuda/lib64:/opt/amazon/efa/lib:/opt/amazon/openmpi/lib:/opt/aws-ofi-nccl/lib:$LD_LIBRARY_PATH \
   -x NCCL_DEBUG=INFO \ 
   --hostfile my-hosts -n 8 -N 8 \ 
   --mca pml ^cm --mca btl tcp,self --mca btl_tcp_if_exclude lo,docker0 --bind-to none \ 
   $HOME/nccl-tests/build/all_reduce_perf -b 8 -e 1G -f 2 -g 1 -c 1 -n 100

3. You can confirm that EFA is active as the underlying provider for NCCL when the NCCL_DEBUG log is printed.

| ip-192-168-2-54:14:14 [0] NCCL INFO NET/OFI Selected Provider is efa* |

### Step 10: Install your machine learning applications

Install the machine learning applications on the temporary instance. The installation procedure varies depending on the specific machine learning application. For more information about installing software on your Linux instance, see [Managing Software on Your Linux Instance](#).

**Note**

Refer to your machine learning application's documentation for installation instructions.

### Step 11: Create an EFA and NCCL-enabled AMI

After you have installed the required software components, you create an AMI that you can reuse to launch your EFA-enabled instances.

**To create an AMI from your temporary instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the temporary instance that you created and choose **Actions, Image, Create image**.
4. For **Create image**, do the following:
   a. For **Image name**, enter a descriptive name for the AMI.
   b. (Optional) For **Image description**, enter a brief description of the purpose of the AMI.
   c. Choose **Create image**.
5. In the navigation pane, choose **AMIs**.
6. Locate the AMI that you created in the list. Wait for the status to change from pending to available before continuing to the next step.

### Step 12: Terminate the temporary instance

At this point, you no longer need the temporary instance that you launched. You can terminate the instance to stop incurring charges for it.
To terminate the temporary instance

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the temporary instance that you created and then choose **Actions**, **Instance state**, **Terminate instance**.
4. When prompted for confirmation, choose **Terminate**.

Step 13: Launch EFA and NCCL-enabled instances into a cluster placement group

Launch your EFA and NCCL-enabled instances into a cluster placement group using the EFA-enabled AMI and the EFA-enabled security group that you created earlier.

**Note**

- It is not an absolute requirement to launch your EFA-enabled instances into a cluster placement group. However, we do recommend running your EFA-enabled instances in a cluster placement group as it launches the instances into a low-latency group in a single Availability Zone.

- To ensure that capacity is available as you scale your cluster’s instances, you can create a Capacity Reservation for your cluster placement group. For more information, see [Capacity Reservations in cluster placement groups](p. 674).

New console

**To launch a temporary instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**, and then choose **Launch Instances** to open the new launch instance wizard.
3. *(Optional)* In the **Name and tags** section, provide a name for the instance, such as **EFA-instance**. The name is assigned to the instance as a resource tag (Name=EFA-instance).
4. In the **Application and OS Images** section, choose **My AMIs**, and then select the AMI that you created in the previous step.
5. In the **Instance type** section, select either p3dn.24xlarge or p4d.24xlarge.
6. In the **Key pair** section, select the key pair to use for the instance.
7. In the **Network settings** section, choose **Edit**, and then do the following:
   a. For **Subnet**, choose the subnet in which to launch the instance. If you do not select a subnet, you can’t enable the instance for EFA.
   b. For **Firewall (security groups)**, choose **Select existing security group**, and then select the security group that you created in the previous step.
   c. Expand the **Advanced network configuration** section, and for **Elastic Fabric Adapter**, select **Enable**.
8. *(Optional)* In the **Storage** section, configure the volumes as needed.
9. In the **Advanced details** section, for **Placement group name**, select the cluster placement group into which to launch the instance. If you need to create a new cluster placement group, choose **Create new placement group**.
10. In the **Summary** panel on the right, for **Number of instances**, enter the number of EFA-enabled instances that you want to launch, and then choose **Launch instance**.
Old console

To launch your EFA and NCCL-enabled instances into a cluster placement group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance.
3. On the Choose an AMI page, choose My AMIs, find the AMI that you created earlier, and then choose Select.
4. On the Choose an Instance Type page, select p3dn.24xlarge and then choose Next: Configure Instance Details.
5. On the Configure Instance Details page, do the following:
   a. For Number of instances, enter the number of EFA and NCCL-enabled instances that you want to launch.
   b. For Network and Subnet, select the VPC and subnet into which to launch the instances.
   c. For Placement group, select Add instance to placement group.
   d. For Placement group name, select Add to a new placement group, and then enter a descriptive name for the placement group. Then for Placement group strategy, select cluster.
   e. For EFA, choose Enable.
   f. In the Network Interfaces section, for device eth0, choose New network interface. You can optionally specify a primary IPv4 address and one or more secondary IPv4 addresses. If you are launching the instance into a subnet that has an associated IPv6 CIDR block, you can optionally specify a primary IPv6 address and one or more secondary IPv6 addresses.
   g. Choose Next: Add Storage.
6. On the Add Storage page, specify the volumes to attach to the instances in addition to the volumes specified by the AMI (such as the root device volume). Then choose Next: Add Tags.
7. On the Add Tags page, specify tags for the instances, such as a user-friendly name, and then choose Next: Configure Security Group.
8. On the Configure Security Group page, for Assign a security group, select Select an existing security group, and then select the security group that you created earlier.
10. On the Review Instance Launch page, review the settings, and then choose Launch to choose a key pair and to launch your instances.

Step 14: Enable passwordless SSH

To enable your applications to run across all of the instances in your cluster, you must enable passwordless SSH access from the leader node to the member nodes. The leader node is the instance from which you run your applications. The remaining instances in the cluster are the member nodes.

To enable passwordless SSH between the instances in the cluster

1. Select one instance in the cluster as the leader node, and connect to it.
2. Disable strictHostKeyChecking and enable ForwardAgent on the leader node. Open ~/.ssh/config using your preferred text editor and add the following.

<table>
<thead>
<tr>
<th>Host *</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
<tr>
<td>ForwardAgent yes</td>
</tr>
<tr>
<td>Host *</td>
</tr>
<tr>
<td>StrictHostKeyChecking no</td>
</tr>
</tbody>
</table>
3. Generate an RSA key pair.

   $ ssh-keygen -t rsa -N "" -f ~/.ssh/id_rsa

   The key pair is created in the $HOME/.ssh/ directory.

4. Change the permissions of the private key on the leader node.

   $ chmod 600 ~/.ssh/id_rsa
   chmod 600 ~/.ssh/config

5. Open ~/.ssh/id_rsa.pub using your preferred text editor and copy the key.

6. For each member node in the cluster, do the following:

   a. Connect to the instance.
   b. Open ~/.ssh/authorized_keys using your preferred text editor and add the public key that you copied earlier.

7. To test that the passwordless SSH is functioning as expected, connect to your leader node and run the following command.

   $ ssh member_node_private_ip

   You should connect to the member node without being prompted for a key or password.

Use an AWS Deep Learning AMI

The following steps help you to get started with one of the following AWS Deep Learning AMIs:

- Deep Learning AMI (Amazon Linux 2)
- Deep Learning AMI (Ubuntu 20.04)

For more information, see the AWS Deep Learning AMI User Guide.

Note
Only the p3dn.24xlarge and p4d.24xlarge instance types are supported.

Contents

- Step 1: Prepare an EFA-enabled security group (p. 1545)
- Step 2: Launch a temporary instance (p. 1546)
- Step 3: Test your EFA and NCCL configuration (p. 1547)
- Step 4: Install your machine learning applications (p. 1549)
- Step 5: Create an EFA and NCCL-enabled AMI (p. 1549)
- Step 6: Terminate the temporary instance (p. 1549)
- Step 7: Launch EFA and NCCL-enabled instances into a cluster placement group (p. 1549)
- Step 8: Enable passwordless SSH (p. 1551)

Step 1: Prepare an EFA-enabled security group

An EFA requires a security group that allows all inbound and outbound traffic to and from the security group itself. The following procedure creates a security group that allows all inbound and outbound traffic to and from itself, and that allows inbound SSH traffic from any IPv4 address for SSH connectivity.
Important
This security group is intended for testing purposes only. For your production environments, we recommend that you create an inbound SSH rule that allows traffic only from the IP address from which you are connecting, such as the IP address of your computer, or a range of IP addresses in your local network.

For other scenarios, see Security group rules for different use cases (p. 2037).

To create an EFA-enabled security group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups and then choose Create security group.
3. In the Create security group window, do the following:
   a. For Security group name, enter a descriptive name for the security group, such as EFA-enabled security group.
   b. (Optional) For Description, enter a brief description of the security group.
   c. For VPC, select the VPC into which you intend to launch your EFA-enabled instances.
   d. Choose Create security group.
4. Select the security group that you created, and on the Details tab, copy the Security group ID.
5. With the security group still selected, choose Actions, Edit inbound rules, and then do the following:
   a. Choose Add rule.
   b. For Type, choose All traffic.
   c. For Source type, choose Custom and paste the security group ID that you copied into the field.
   d. Choose Add rule.
   e. For Type, choose SSH.
   f. For Source type, choose Anywhere-IPv4.
   g. Choose Save rules.
6. With the security group still selected, choose Actions, Edit outbound rules, and then do the following:
   a. Choose Add rule.
   b. For Type, choose All traffic.
   c. For Destination type, choose Custom and paste the security group ID that you copied into the field.
   d. Choose Save rules.

Step 2: Launch a temporary instance

Launch a temporary instance that you can use to install and configure the EFA software components. You use this instance to create an EFA-enabled AMI from which you can launch your EFA-enabled instances.

To launch a temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then choose Launch Instances to open the new launch instance wizard.
3. (Optional) In the Name and tags section, provide a name for the instance, such as EFA-instance. The name is assigned to the instance as a resource tag (Name=EFA-instance).
4. In the Application and OS Images section, select a supported AWS Deep Learning AMI Version 25.0 or later.

5. In the Instance type section, select either p3dn.24xlarge or p4d.24xlarge.

6. In the Key pair section, select the key pair to use for the instance.

7. In the Network settings section, choose Edit, and then do the following:
   a. For Subnet, choose the subnet in which to launch the instance. If you do not select a subnet, you can't enable the instance for EFA.
   b. For Firewall (security groups), choose Select existing security group, and then select the security group that you created in the previous step.
   c. Expand the Advanced network configuration section, and for Elastic Fabric Adapter, select Enable.

8. In the Storage section, configure the volumes as needed.

   Note
   You must provision an additional 10 to 20 GiB of storage for the Nvidia CUDA Toolkit. If you do not provision enough storage, you will receive an insufficient disk space error when attempting to install the Nvidia drivers and CUDA toolkit.

9. In the Summary panel on the right, choose Launch instance.

Old console

To launch a temporary instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. Choose Launch Instance.

3. On the Choose an AMI page, choose a supported AWS Deep Learning AMI Version 25.0 or later.

4. On the Choose an Instance Type page, select p3dn.24xlarge or p4d.24xlarge and then choose Next: Configure Instance Details.

5. On the Configure Instance Details page, do the following:
   a. For Subnet, choose the subnet in which to launch the instance. If you do not select a subnet, you can't enable the instance for EFA.
   b. For Elastic Fabric Adapter, choose Enable.
   c. In the Network Interfaces section, for device eth0, choose New network interface.
   d. Choose Next: Add Storage.

6. On the Add Storage page, specify the volumes to attach to the instances, in addition to the volumes specified by the AMI (such as the root device volume). Then choose Next: Add Tags.

7. On the Add Tags page, specify a tag that you can use to identify the temporary instance, and then choose Next: Configure Security Group.

8. On the Configure Security Group page, for Assign a security group, select Select an existing security group. Then select the security group that you created in Step 1.

9. On the Review Instance Launch page, review the settings, and then choose Launch to choose a key pair and to launch your instance.

Step 3: Test your EFA and NCCL configuration

Run a test to ensure that your temporary instance is properly configured for EFA and NCCL.
To test your EFA and NCCL configuration

1. Create a host file that specifies the hosts on which to run the tests. The following command creates a host file named `my-hosts` that includes a reference to the instance itself.

IMDSv2

```
```

IMDSv1

```
```

2. Run the test and specify the host file (`--hostfile`) and the number of GPUs to use (`-n`). The following command runs the `all_reduce_perf` test on 8 GPUs on the instance itself, and specifies the following environment variables.

- `FI_EFA_USE_DEVICE_RDMA=1` (p4d.24xlarge only) uses the device's RDMA functionality for one-sided and two-sided transfer.
- `NCCL_DEBUG=INFO` enables detailed debugging output. You can also specify `VERSION` to print only the NCCL version at the start of the test, or `WARN` to receive only error messages.

For more information about the NCCL test arguments, see the NCCL Tests README in the official nccl-tests repository.

- p3dn.24xlarge

```
$ /opt/amazon/openmpi/bin/mpirun \ 
   -x LD_LIBRARY_PATH=/opt/nccl/build/lib:/usr/local/cuda/lib64:/opt/amazon/efa/\ 
   -x /opt/amazon/openmpi/lib:/opt/aws-ofi-nccl/lib:$LD_LIBRARY_PATH \ 
   -x NCCL_DEBUG=INFO \ 
   --hostfile my-hosts -n 8 -N 8 \ 
   --mca pml ^cm --mca btl tcp,self --mca btl_tcp_if_exclude lo,docker0 --bind-to none \ 
   $HOME/nccl-tests/build/all_reduce_perf -b 8 -e 1G -f 2 -g 1 -c 1 -n 100
```

- p4d.24xlarge

```
$ /opt/amazon/openmpi/bin/mpirun \ 
   -x FI_EFA_USEDEVICE_RDMA=1 \ 
   -x LD_LIBRARY_PATH=/opt/nccl/build/lib:/usr/local/cuda/lib64:/opt/amazon/efa/\ 
   -x /opt/amazon/openmpi/lib:/opt/aws-ofi-nccl/lib:$LD_LIBRARY_PATH \ 
   --hostfile my-hosts -n 8 -N 8 \ 
   --mca pml ^cm --mca btl tcp,self --mca btl_tcp_if_exclude lo,docker0 --bind-to none \ 
   $HOME/nccl-tests/build/all_reduce_perf -b 8 -e 1G -f 2 -g 1 -c 1 -n 100
```

3. You can confirm that EFA is active as the underlying provider for NCCL when the `NCCL_DEBUG` log is printed.

```
ip-192-168-2-54:14:14 [0] NCCL INFO NET/OFI Selected Provider is efa*
```

The following additional information is displayed when using a p4d.24xlarge instance.

1548
Step 4: Install your machine learning applications

Install the machine learning applications on the temporary instance. The installation procedure varies depending on the specific machine learning application. For more information about installing software on your Linux instance, see Managing Software on Your Linux Instance.

Note
Refer to your machine learning application's documentation for installation instructions.

Step 5: Create an EFA and NCCL-enabled AMI

After you have installed the required software components, you create an AMI that you can reuse to launch your EFA-enabled instances.

**To create an AMI from your temporary instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Instances.
3. Select the temporary instance that you created and choose Actions, Image, Create image.
4. For Create image, do the following:
   a. For Image name, enter a descriptive name for the AMI.
   b. (Optional) For Image description, enter a brief description of the purpose of the AMI.
   c. Choose Create image.
5. In the navigation pane, choose AMIs.
6. Locate the AMI that you created in the list. Wait for the status to change from pending to available before continuing to the next step.

Step 6: Terminate the temporary instance

At this point, you no longer need the temporary instance that you launched. You can terminate the instance to stop incurring charges for it.

**To terminate the temporary instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Instances.
3. Select the temporary instance that you created and then choose Actions, Instance state, Terminate instance.
4. When prompted for confirmation, choose Terminate.

Step 7: Launch EFA and NCCL-enabled instances into a cluster placement group

Launch your EFA and NCCL-enabled instances into a cluster placement group using the EFA-enabled AMI and the EFA-enabled security group that you created earlier.

Note

- It is not an absolute requirement to launch your EFA-enabled instances into a cluster placement group. However, we do recommend running your EFA-enabled instances in a cluster...
placement group as it launches the instances into a low-latency group in a single Availability Zone.

- To ensure that capacity is available as you scale your cluster’s instances, you can create a Capacity Reservation for your cluster placement group. For more information, see Capacity Reservations in cluster placement groups (p. 674).

New console

**To launch a temporary instance**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and then choose **Launch Instances** to open the new launch instance wizard.
3. *(Optional)* In the **Name and tags** section, provide a name for the instance, such as EFA-instance. The name is assigned to the instance as a resource tag (Name=EFA-instance).
4. In the **Application and OS Images** section, choose **My AMIs**, and then select the AMI that you created in the previous step.
5. In the **Instance type** section, select either p3dn.24xlarge or p4d.24xlarge.
6. In the **Key pair** section, select the key pair to use for the instance.
7. In the **Network settings** section, choose **Edit**, and then do the following:
   a. For **Subnet**, choose the subnet in which to launch the instance. If you do not select a subnet, you can't enable the instance for EFA.
   b. For **Firewall (security groups)**, choose **Select existing security group**, and then select the security group that you created in the previous step.
   c. Expand the **Advanced network configuration** section, and for **Elastic Fabric Adapter**, select **Enable**.
8. *(Optional)* In the **Storage** section, configure the volumes as needed.
9. In the **Advanced details** section, for **Placement group name**, select the cluster placement group into which to launch the instance. If you need to create a new cluster placement group, choose **Create new placement group**.
10. In the **Summary** panel on the right, for **Number of instances**, enter the number of EFA-enabled instances that you want to launch, and then choose **Launch instance**.

Old console

**To launch your EFA and NCCL-enabled instances into a cluster placement group**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose **Launch Instance**.
3. On the **Choose an AMI** page, choose **My AMIs**, find the AMI that you created earlier, and then choose **Select**.
4. On the **Choose an Instance Type** page, select p3dn.24xlarge and then choose **Next: Configure Instance Details**.
5. On the **Configure Instance Details** page, do the following:
   a. For **Number of instances**, enter the number of EFA and NCCL-enabled instances that you want to launch.
   b. For **Network** and **Subnet**, select the VPC and subnet into which to launch the instances.
   c. For **Placement group**, select **Add instance to placement group**.
d. For Placement group name, select Add to a new placement group, and then enter a descriptive name for the placement group. Then for Placement group strategy, select cluster.

e. For EFA, choose Enable.

f. In the Network Interfaces section, for device eth0, choose New network interface. You can optionally specify a primary IPv4 address and one or more secondary IPv4 addresses. If you are launching the instance into a subnet that has an associated IPv6 CIDR block, you can optionally specify a primary IPv6 address and one or more secondary IPv6 addresses.

g. Choose Next: Add Storage.

6. On the Add Storage page, specify the volumes to attach to the instances in addition to the volumes specified by the AMI (such as the root device volume). Then choose Next: Add Tags.

7. On the Add Tags page, specify tags for the instances, such as a user-friendly name, and then choose Next: Configure Security Group.

8. On the Configure Security Group page, for Assign a security group, select Select an existing security group, and then select the security group that you created earlier.

10. On the Review Instance Launch page, review the settings, and then choose Launch to choose a key pair and to launch your instances.

Step 8: Enable passwordless SSH

To enable your applications to run across all of the instances in your cluster, you must enable passwordless SSH access from the leader node to the member nodes. The leader node is the instance from which you run your applications. The remaining instances in the cluster are the member nodes.

To enable passwordless SSH between the instances in the cluster

1. Select one instance in the cluster as the leader node, and connect to it.

2. Disable strictHostKeyChecking and enable ForwardAgent on the leader node. Open ~/.ssh/config using your preferred text editor and add the following.

   ```
   Host *
     ForwardAgent yes
   Host *
     StrictHostKeyChecking no
   ```

3. Generate an RSA key pair.

   ```
   $ ssh-keygen -t rsa -N "" -f ~/.ssh/id_rsa
   ```

   The key pair is created in the $HOME/.ssh/ directory.

4. Change the permissions of the private key on the leader node.

   ```
   $ chmod 600 ~/.ssh/id_rsa
   chmod 600 ~/.ssh/config
   ```

5. Open ~/.ssh/id_rsa.pub using your preferred text editor and copy the key.

6. For each member node in the cluster, do the following:

   a. Connect to the instance.

   b. Open ~/.ssh/authorized_keys using your preferred text editor and add the public key that you copied earlier.
7. To test that the passwordless SSH is functioning as expected, connect to your leader node and run the following command.

```
$ ssh member_node_private_ip
```

You should connect to the member node without being prompted for a key or password.

## Work with EFA

You can create, use, and manage an EFA much like any other elastic network interface in Amazon EC2. However, unlike elastic network interfaces, EFAs cannot be attached to or detached from an instance in a running state.

### EFA requirements

To use an EFA, you must do the following:

- Choose one of the supported instance types (p. 1510).
- Use an AMI for one of the supported operating systems (p. 1511).
- Install the EFA software components. For more information, see Step 3: Install the EFA software (p. 1517) and Step 5: (Optional) Install Intel MPI (p. 1520).
- Use a security group that allows all inbound and outbound traffic to and from the security group itself. For more information, see Step 1: Prepare an EFA-enabled security group (p. 1515).

### Contents

- Create an EFA (p. 1552)
- Attach an EFA to a stopped instance (p. 1553)
- Attach an EFA when launching an instance (p. 1553)
- Add an EFA to a launch template (p. 1553)
- Manage IP addresses for an EFA (p. 1554)
- Change the security group for an EFA (p. 1554)
- Detach an EFA (p. 1554)
- View EFAs (p. 1554)
- Delete an EFA (p. 1554)

## Create an EFA

You can create an EFA in a subnet in a VPC. You can't move the EFA to another subnet after it's created, and you can only attach it to stopped instances in the same Availability Zone.

### To create a new EFA using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Network Interfaces.
3. Choose Create Network Interface.
4. For Description, enter a descriptive name for the EFA.
5. For Subnet, select the subnet in which to create the EFA.
6. For **Private IP**, enter the primary private IPv4 address. If you don’t specify an IPv4 address, we select an available private IPv4 address from the selected subnet.

7. For **IPv6 only**, if you selected a subnet that has an associated IPv6 CIDR block, you can optionally specify an IPv6 address in the **IPv6 IP** field.

8. For **Security groups**, select one or more security groups.

9. For **EFA**, choose **Enabled**.

10. Choose **Yes, Create**.

**To create a new EFA using the AWS CLI**

Use the `create-network-interface` command and for `interface-type`, specify efa, as shown in the following example.

```
aws ec2 create-network-interface --subnet-id subnet-01234567890 --description example_efa --interface-type efa
```

**Attach an EFA to a stopped instance**

You can attach an EFA to any supported instance that is in the **stopped** state. You cannot attach an EFA to an instance that is in the **running** state. For more information about the supported instance types, see [Supported instance types](p. 1510).

You attach an EFA to an instance in the same way that you attach a network interface to an instance. For more information, see [Attach a network interface to an instance](p. 1437).

**Attach an EFA when launching an instance**

**To attach an existing EFA when launching an instance (AWS CLI)**

Use the `run-instances` command and for **NetworkInterfaceId**, specify the ID of the EFA, as shown in the following example.

```
aws ec2 run-instances --image-id ami_id --count 1 --instance-type c5n.18xlarge --key-name my_key_pair --network-interfaces DeviceIndex=0,NetworkInterfaceId=efa_id,Groups=sg_id,SubnetId=subnet_id
```

**To attach a new EFA when launching an instance (AWS CLI)**

Use the `run-instances` command and for **InterfaceType**, specify efa, as shown in the following example.

```
aws ec2 run-instances --image-id ami_id --count 1 --instance-type c5n.18xlarge --key-name my_key_pair --network-interfaces DeviceIndex=0,InterfaceType=efa,Groups=sg_id,SubnetId=subnet_id
```

**Add an EFA to a launch template**

You can create a launch template that contains the configuration information needed to launch EFA-enabled instances. To create an EFA-enabled launch template, create a new launch template and specify a supported instance type, your EFA-enabled AMI, and an EFA-enabled security group. For more information, see [Get started with EFA and MPI](p. 1515).

You can leverage launch templates to launch EFA-enabled instances with other AWS services, such as [AWS Batch](http://aws.amazon.com/batch) or [AWS ParallelCluster](http://aws.amazon.com/parallelcluster).
Monitor an EFA

For more information about creating launch templates, see Create a launch template (p. 743).

Manage IP addresses for an EFA

You can change the IP addresses associated with an EFA. If you have an Elastic IP address, you can associate it with an EFA. If your EFA is provisioned in a subnet that has an associated IPv6 CIDR block, you can assign one or more IPv6 addresses to the EFA.

You assign an Elastic IP (IPv4) and IPv6 address to an EFA in the same way that you assign an IP address to an elastic network interface. For more information, see Managing IP addresses (p. 1439).

Change the security group for an EFA

You can change the security group that is associated with an EFA. To enable OS-bypass functionality, the EFA must be a member of a security group that allows all inbound and outbound traffic to and from the security group itself.

You change the security group that is associated with an EFA in the same way that you change the security group that is associated with an elastic network interface. For more information, see Changing the security group (p. 1441).

Detach an EFA

To detach an EFA from an instance, you must first stop the instance. You cannot detach an EFA from an instance that is in the running state.

You detach an EFA from an instance in the same way that you detach an elastic network interface from an instance. For more information, see Detach a network interface from an instance (p. 1438).

View EFAs

You can view all of the EFAs in your account.

You view EFAs in the same way that you view elastic network interfaces. For more information, see View details about a network interface (p. 1436).

Delete an EFA

To delete an EFA, you must first detach it from the instance. You cannot delete an EFA while it is attached to an instance.

You delete EFAs in the same way that you delete elastic network interfaces. For more information, see Delete a network interface (p. 1443).

Monitor an EFA

You can use the following features to monitor the performance of your Elastic Fabric Adapters.

Amazon VPC flow logs

You can create an Amazon VPC Flow Log to capture information about the traffic going to and from an EFA. Flow log data can be published to Amazon CloudWatch Logs and Amazon S3. After you create a flow log, you can retrieve and view its data in the chosen destination. For more information, see VPC Flow Logs in the Amazon VPC User Guide.
Verify the EFA installer using a checksum

You create a flow log for an EFA in the same way that you create a flow log for an elastic network interface. For more information, see Create a flow log in the Amazon VPC User Guide.

In the flow log entries, EFA traffic is identified by the srcAddress and destAddress, which are both formatted as MAC addresses, as shown in the following example.

```
version  accountId  eniId  srcAddress   destAddress  sourcePort  destPort
protocol packets  bytes  start      end      action  log-status
2          3794755123  eni-10000001 01:23:45:67:89:ab 05:23:45:67:89:ab -      -      -
9          5689  1521232534  1524512343  ACCEPT  OK
```

Amazon CloudWatch

Amazon CloudWatch provides metrics that enable you to monitor your EFAs in real time. You can collect and track metrics, create customized dashboards, and set alarms that notify you or take actions when a specified metric reaches a threshold that you specify. For more information, see Monitor your instances using CloudWatch (p. 1298).

Verify the EFA installer using a checksum

You can optionally verify the EFA tarball (.tar.gz file) using an MD5 or SHA256 checksum. We recommend that you do this to verify the identity of the software publisher and to check that the application has not been altered or corrupted since it was published.

To verify the tarball

Use the md5sum utility for the MD5 checksum, or the sha256sum utility for the SHA256 checksum, and specify the tarball filename. You must run the command from the directory in which you saved the tarball file.

- **MD5**

  ```
  $ md5sum tarball_filename.tar.gz
  ```

- **SHA256**

  ```
  $ sha256sum tarball_filename.tar.gz
  ```

The commands should return a checksum value in the following format.

```
checksum_value  tarball_filename.tar.gz
```

Compare the checksum value returned by the command with the checksum value provided in the table below. If the checksums match, then it is safe to run the installation script. If the checksums do not match, do not run the installation script, and contact AWS Support.

For example, the following command verifies the EFA 1.9.4 tarball using the SHA256 checksum.

```bash
$ sha256sum aws-efa-installer-1.9.4.tar.gz
```

```
1009b5182693490d908ef0ed2c1dd4f813cc310a5d2062ce9619c4c12b5a7f14 aws-efa-
installer-1.9.4.tar.gz
```
The following table lists the checksums for recent versions of EFA.

</table>
Amazon EC2 instance topology

Use the DescribeInstanceTopology API to manage high performance computing (HPC) and machine learning (ML) compute infrastructure at scale while optimizing job placement. HPC and ML jobs are sensitive to latency and throughput. You can use the DescribeInstanceTopology API to detect the location of your instances, and then use this information to optimize HPC and ML jobs by running them on instances that are physically closer to each other.

**Note**

You can use the DescribeInstanceTopology API to detect the location of your existing instances, but you can't use it to choose to launch a new instance physically close to an existing instance. To influence instance placement, you can use [Capacity Reservations in cluster placement groups](p. 674).

There is no additional cost for using the DescribeInstanceTopology API.

**Contents**

- **How it works** (p. 1560)
- **Prerequisites** (p. 1563)
- **Required IAM permissions** (p. 1564)
- **Limitations** (p. 1564)
- **Examples** (p. 1564)

## How it works

Every EC2 instance connects to a node set. A node set comprises three network nodes, with each node representing a different layer in the AWS network. The network layers are arranged in a hierarchy of 3 or more layers. The node set provides the top-down view of this hierarchy, with the bottom layer connected closest to an instance.
The information about the node set is called the *instance topology*, and is returned by the DescribeInstanceTopology API.

The following diagram provides a visual representation that you can use to understand the API output. A description of the diagram follows.

In the preceding diagram, **NN1 – NN7** identify the network nodes in this example. The numerals i, ii, and iii identify the different network layers in this example. The numbers 1, 2, 3, and 4 identify the EC2 instances in this example. Instances connect to a node in the bottom layer, identified by iii in this example. More than one instance can connect to the same node.

In the diagram, instance 1 connects to network node 4 (NN4) in layer iii. NN4 connects to network node 2 (NN2) in layer ii, and NN2 connects to network node 1 (NN1) in layer i, which is the top of the network hierarchy in this example. The network node set comprises NN1, NN2, and NN4, expressed hierarchically from the upper layers to the bottom layer.

Instance 2 also connects to network node 4 (NN4). Instance 1 and instance 2 share the same network node set: NN1, NN2, and NN4.

Instance 3 connects to network node 5 (NN5). NN5 connects to NN2, and NN2 connects to NN1. The network node set for instance 3 is NN1, NN2, and NN5.

Instance 4 connects to network node 6 (NN6). Its network node set is NN1, NN3, and NN6.

When considering the proximity of instances 1, 2, and 3, instances 1 and 2 are closer to each other because they connect to the same network node (NN4), while instance 3 is further away because it connects to a different network node (NN5).

When considering the proximity of all the instances in this diagram, instances 1, 2, and 3 are closer to each other than they are to instance 4 because they share NN2 in their network node set.

As a general rule, if the network node connected to any two instances is the same, these instances are physically close to each other, as is the case with instances 1 and 2. Furthermore, the fewer the number of hops between network nodes, the closer the instances are to each other. For example, instances 1 and 3 have fewer hops to a common network node (NN2) than they have to the network node (NN1) they have in common with instance 4, and are therefore closer to each other than they are to instance 4.

There are no instances running under network node 7 (NN7) in this example, and therefore the API output won't include NN7.

How to interpret the output

The output of the DescribeInstanceTopology API provides a hierarchical view of the underlying network topology for an instance.

The following example output corresponds to the network topology information of the four instances in the preceding diagram. Comments are included in the example output for the purposes of this example.
The following information in the output is important to note:

- **NetworkNodes** describes the network node set of an instance.
- In each network node set, the network nodes are listed in hierarchical order from top to bottom.
- The network node that is connected to the instance is the last network node in the list (the bottom layer).
- To work out which instances are close to each other, first find common network nodes in the bottom layer. If there are no common network nodes in the bottom layer, then find common network nodes in the upper layers.

In the following example output, `i-1111111111example` and `i-2222222222example` are located closest to each other compared to the other instances in this example because they have the network node `nn-4444444444example` in common in the bottom layer.

```
{
  "Instances": [
    {
      "InstanceId": "i-1111111111example",  //Corresponds to instance 1
      "InstanceType": "p4d.24xlarge",
      "GroupName": "ML-group",
      "NetworkNodes": [
        "nn-1111111111example",           //Corresponds to NN1 in layer i
        "nn-2222222222example",           //Corresponds to NN2 in layer ii
        "nn-4444444444example"            //Corresponds to NN3 in layer iii -
        bottom layer, connected to the instance
      ],
      "ZoneId": "usw2-az2",
      "AvailabilityZone": "us-west-2a"
    },
    {
      "InstanceId": "i-2222222222example",  //Corresponds to instance 2
      "InstanceType": "p4d.24xlarge",
      "NetworkNodes": [
        "nn-1111111111example",           //Corresponds to NN1 - layer i
        "nn-2222222222example",           //Corresponds to NN2 - layer ii
        "nn-4444444444example"            //Corresponds to NN4 - layer iii -
        connected to instance
      ],
      "ZoneId": "usw2-az2",
      "AvailabilityZone": "us-west-2a"
    },
    {
      "InstanceId": "i-3333333333example",  //Corresponds to instance 3
      "InstanceType": "trn1.32xlarge",
      "NetworkNodes": [
        "nn-1111111111example",           //Corresponds to NN1 - layer i
        "nn-2222222222example",           //Corresponds to NN2 - layer ii
        "nn-5555555555example"           //Corresponds to NN5 - layer iii -
        connected to instance
      ],
      "ZoneId": "usw2-az2",
      "AvailabilityZone": "us-west-2a"
    },
    {
      "InstanceId": "i-4444444444example",  //Corresponds to instance 4
      "InstanceType": "trn1.2xlarge",
      "NetworkNodes": [
        "nn-1111111111example",           //Corresponds to NN1 - layer i
        "nn-3333333333example",           //Corresponds to NN3 - layer ii
        "nn-6666666666example"           //Corresponds to NN6 - layer iii -
        connected to instance
      ],
    }
  ]
}
```
Prerequisites

To describe the topology of your instances using the DescribeInstanceTopology API, the instances must meet the following prerequisites:

- AWS Regions (p. 1563)
- Instance types (p. 1563)
- Instance state (p. 1564)

AWS Regions

Supported in the following AWS Regions:

- US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon)
- Asia Pacific (Seoul), Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt), Europe (Ireland), Europe (Stockholm)

Instance types

Supported instance types:

- hpc6a.48xlarge | hpc6id.32xlarge | hpc7a.12xlarge | hpc7a.24xlarge | hpc7a.48xlarge | hpc7a.96xlarge | hpc7g.4xlarge | hpc7g.8xlarge | hpc7g.16xlarge
- p3dn.24xlarge | p4d.24xlarge | p4de.24xlarge | p5.48xlarge
- trn1.2xlarge | trn1.32xlarge | trn1n.32xlarge

To see the available instance types in a specific Region

The available instance types vary by Region. To see if an instance type is available in a Region, use the describe-instance-types-offerings command with the --region parameter. Include the --filters parameter to scope the results to the instance family or instance type that you're interested in and the --query parameter to scope the output to the value of InstanceType.

```bash
aws ec2 describe-instance-type-offerings
  --region us-east-2
  --filters 'Name=instance-type, Values=trn1*' 
  --query 'InstanceTypeOfferings[].InstanceType'
```

Expected output

```json
[
  "trn1.2xlarge",
  "trn1.32xlarge",
  "trn1n.32xlarge"
]
```
Instance state

Instances must be in the running state. You can't get instance topology information for instances that are in another state.

Required IAM permissions

To use the DescribeInstanceTopology API, the following IAM permission is required:

- ec2:DescribeInstanceTopology

Limitations

When using the DescribeInstanceTopology API, the following limitations apply:

- Only the instance topology of running instances is available.
- Each instance topology view is unique per account.
- Only supported when using the AWS API, AWS CLI, or SDK.

Examples

To describe your EC2 instance topology, you can use the describe-instance-topology CLI command with or without parameters or filters.

When you use the describe-instance-topology command without parameters or filters, the response includes all your instances that match the supported instance types for this command in the specified Region. You can specify the Region by including the --region parameter, or by setting a default Region. For more information about setting a default Region, see Specify the Region for a resource (p. 1348).

You can include parameters to return instances that match specified instance IDs or placement group names. You can also include filters to return instances that match a specified instance type or instance family, or instances in a specified Availability Zone or Local Zone. You can include a single parameter or filter, or a combination of parameters and filters.

The output is paginated, with up to 20 instances per page by default. You can specify up to 100 instances per page using the --max-results parameter.

For more information, see describe-instance-topology in the AWS CLI Command Reference.

Examples

- Example 1 - No parameters or filters (p. 1565)
- Example 2 – instance-type filter (p. 1566)
  - Example 2a – Exact match filter for a specified instance type (p. 1566)
  - Example 2b – Wild card filter for an instance family (p. 1566)
  - Example 2c – Combined instance family and exact match filters (p. 1567)
- Example 3 – zone-id filter (p. 1568)
  - Example 3a – Availability Zone filter (p. 1568)
  - Example 3b – Local Zone filter (p. 1568)
  - Example 3c – Combined Availability Zone and Local Zone filters (p. 1569)
- Example 4 – Combined instance-type and zone-id filters (p. 1570)
- Example 5 – Placement group name parameter (p. 1570)
Example 1 - No parameters or filters

To describe the instance topology of all your instances

Use the `describe-instance-topology` CLI command without specifying any parameters or filters.

```
aws ec2 describe-instance-topology --region us-west-2
```

The response returns only the instances that match the supported instance types for this API. The instances can be in different Availability Zones, Local Zones (ZoneId), and placement groups (GroupName). If an instance is not in a placement group, the GroupName field does not appear in the output. In the following example output, only one instance is in a placement group.

Example output

```
{
  "Instances": [
  {
    "InstanceId": "i-11111111example",
    "InstanceType": "p4d.24xlarge",
    "GroupName": "my-ml-cpg",
    "NetworkNodes": [
      "nn-11111111example",
      "nn-22222222example",
      "nn-33333333example"
    ],
    "ZoneId": "usw2-az2",
    "AvailabilityZone": "us-west-2a"
  },
  {
    "InstanceId": "i-22222222example",
    "InstanceType": "p4d.24xlarge",
    "NetworkNodes": [
      "nn-11111111example",
      "nn-22222222example",
      "nn-33333333example"
    ],
    "ZoneId": "usw2-az2",
    "AvailabilityZone": "us-west-2a"
  },
  {
    "InstanceId": "i-33333333example",
    "InstanceType": "trn1.32xlarge",
    "NetworkNodes": [
      "nn-12121212example",
      "nn-12111211example",
      "nn-13111331example"
    ],
    "ZoneId": "usw2-az4",
    "AvailabilityZone": "us-west-2d"
  },
  {
    "InstanceId": "i-44444444example",
    "InstanceType": "trn1.2xlarge",
    "NetworkNodes": [
      "nn-11111111example",
      "nn-54343434example",
      "nn-1235301234example"
    ],
    "ZoneId": "usw2-az2"
  }
  ]
}
```
Example 2 – instance-type filter

You can filter by a specified instance type (exact match) or filter by an instance family (using a wildcard). You can also combine a specified instance type filter and instance family filter.

Example 2a – Exact match filter for a specified instance type

**To describe the instance topology of all your instances that match a specified instance type**

Use the `describe-instance-topology` CLI command with the `instance-type` filter. In this example, the output is filtered for `trn1n.32xlarge` instances. The response will return only the instances that match the specified instance type.

```
aws ec2 describe-instance-topology \
  --region us-west-2 \
  --filters Name=instance-type,Values=trn1n.32xlarge
```

**Example output**

```
{
  "Instances": [
    {
      "InstanceId": "i-2222222222example",
      "InstanceType": "trn1n.32xlarge",
      "NetworkNodes": [
        "nn-1111111111example",
        "nn-2222222222example",
        "nn-3333333333example"
      ],
      "ZoneId": "usw2-az2",
      "AvailabilityZone": "us-west-2a"
    },
    {
      "InstanceId": "i-2222222222example",
      "InstanceType": "trn1n.32xlarge",
      "NetworkNodes": [
        "nn-4444444444example",
        "nn-5555555555example",
        "nn-6666666666example"
      ],
      "ZoneId": "usw2-az3",
      "AvailabilityZone": "us-west-2a"
    }
  ],
  "NextToken": "SomeEncryptedToken"
}
```

Example 2b – Wild card filter for an instance family

**To describe the instance topology of all your instances that match an instance family**

Use the `describe-instance-topology` CLI command with the `instance-type` filter. In this example, the output is filtered for `trn1*` instances. The response will return only the instances that match the specified instance family.

```
aws ec2 describe-instance-topology \
  --region us-west-2 \
  --filters Name=instance-type,Values=trn1*
```

**Example output**

```
{
  "Instances": [
    {
      "InstanceId": "i-2222222222example",
      "InstanceType": "trn1n.32xlarge",
      "NetworkNodes": [
        "nn-1111111111example",
        "nn-2222222222example",
        "nn-3333333333example"
      ],
      "ZoneId": "usw2-az2",
      "AvailabilityZone": "us-west-2a"
    },
    {
      "InstanceId": "i-2222222222example",
      "InstanceType": "trn1n.32xlarge",
      "NetworkNodes": [
        "nn-4444444444example",
        "nn-5555555555example",
        "nn-6666666666example"
      ],
      "ZoneId": "usw2-az3",
      "AvailabilityZone": "us-west-2a"
    }
  ],
  "NextToken": "SomeEncryptedToken"
}
```
Example 2c – Combined instance family and exact match filters

To describe the instance topology of all your instances that match an instance family or specified instance type

Use the `describe-instance-topology` CLI command with the `instance-type` filter. In this example, the output is filtered for `pd4d*` or `trn1n.32xlarge` instances. The response will return the instances that match any of the specified filters.

```bash
aws ec2 describe-instance-topology \
  --region us-west-2 \
  --filters "Name=instance-type,Values=p4d*,trn1n.32xlarge"
```

Example output

```json
{
  "Instances": [
    {
      "InstanceId": "i-1111111111example",
      "InstanceType": "p4d.24xlarge",
      "GroupName": "ML-group",
      "NetworkNodes": [
        "nn-1111111111example",
        "nn-2222222222example",
        "nn-3333333333example"
      ],
      "ZoneId": "usw2-az2",
      "AvailabilityZone": "us-west-2a"
    },
    {
      "InstanceId": "i-3333333333example",
      "InstanceType": "trn1n.32xlarge",
      "NetworkNodes": [
        "nn-1111111111example",
        "nn-2222222222example",
        "nn-3333333333example"
      ],
      "ZoneId": "usw2-az2",
      "AvailabilityZone": "us-west-2a"
    },
    {
      "InstanceId": "i-4444444444example",
      "InstanceType": "trn1n.32xlarge",
      "NetworkNodes": [
        "nn-1111111111example",
        "nn-2222222222example",
        "nn-3333333333example"
      ],
      "ZoneId": "usw2-az2",
      "AvailabilityZone": "us-west-2a"
    }
  ],
  "NextToken": "SomeEncryptedToken"
}
```
Example 3 – zone-id filter

You can use the zone-id filter to filter by an Availability Zone or Local Zone. You can also combine an Availability Zone filter and Local Zone filter.

Example 3a – Availability Zone filter

To describe the instance topology of all your instances that match a specified Availability Zone

Use the describe-instance-topology CLI command with the zone-id filter. In this example, the output is filtered for the us-west-2a Availability Zone. The response will return only the instances that match the specified Availability Zone.

aws ec2 describe-instance-topology \
  --region us-west-2 \
  --filters Name=zone-id,Values="us-west-2a"

Example output

```
{
  "Instances": [
    {
      "InstanceId": "i-2222222222example",
      "InstanceType": "trn1n.32xlarge",
      "NetworkNodes": [
        "nn-111111111example",
        "nn-222222222example",
        "nn-634343434example"
      ],
      "ZoneId": "usw2-az2",
      "AvailabilityZone": "us-west-2a"
    }
  ],
  "NextToken": "SomeEncryptedToken"
}
```

Example 3b – Local Zone filter

To describe the instance topology of all your instances that match a specified Local Zone

Use the describe-instance-topology CLI command with the zone-id filter. In this example, the output is filtered for the usw2-az2 Local Zone. The response will return only the instances that match the specified Local Zone.

aws ec2 describe-instance-topology \
  --region us-west-2 \
  --filters Name=zone-id,Values="us-west-2a"
Example output

```
{
   "Instances": [
      {
         "InstanceId": "i-1111111111example",
         "InstanceType": "p4d.24xlarge",
         "GroupName": "ML-group",
         "NetworkNodes": [
            "nn-1111111111example",
            "nn-2222222222example",
            "nn-3333333333example"
         ],
         "ZoneId": "usw2-az2",
         "AvailabilityZone": "us-west-2a"
      }
   ],
   "NextToken": "SomeEncryptedToken"
}
```

Example 3c – Combined Availability Zone and Local Zone filters

To describe the instance topology of all your instances that match a specified Availability Zone or Local Zone

Use the `describe-instance-topology` CLI command with the `zone-id` filter. In this example, the output is filtered for the `us-west-2a` Availability Zone and `usw2-az2` Local Zone. The response will return the instances that match any of the specified filters.

```
aws ec2 describe-instance-topology \
   --region us-west-2 \
   --filters "Name=zone-id,Values=us-west-2a,usw2-az2"
```

Example output

```
{
   "Instances": [
      {
         "InstanceId": "i-1111111111example",
         "InstanceType": "p4d.24xlarge",
         "GroupName": "ML-group",
         "NetworkNodes": [
            "nn-1111111111example",
            "nn-2222222222example",
            "nn-3333333333example"
         ],
         "ZoneId": "usw2-az2",
         "AvailabilityZone": "us-west-2a"
      },
      {
         "InstanceId": "i-2222222222example",
         "InstanceType": "trn1n.32xlarge",
         "NetworkNodes": [
            "nn-1111111111example",
            "nn-2222222222example",
            "nn-3214313214example"
         ],
         "ZoneId": "usw2-az2",
         "AvailabilityZone": "us-west-2a"
      }
   ]
}
```
Example 4 – Combined instance-type and zone-id filters

You can combine all the filters in a single command.

To describe the instance topology of all your instances that match a specified instance type, instance family, Availability Zone, or Local Zone

Use the describe-instance-topology CLI command with the instance-type and zone-id filters. In this example, the output is filtered for the p4d* instance family, trn1n.32xlarge instance type, us-west-2a Availability Zone, and usw2-az2 Local Zone. The response will return the instances that match p4d* or trn1n.32xlarge instances in the us-west-2a or usw2-az2 zones.

```
aws ec2 describe-instance-topology
  --region us-west-2
  --filters "Name=instance-type,Values=p4d*,trn1n.32xlarge" "Name=zone-id,Values=us-west-2a,usw2-az2"
```

Example output

```
{
  "Instances": [
    {
      "InstanceId": "i-1111111111example",
      "InstanceType": "p4d.24xlarge",
      "GroupName": "ML-group",
      "NetworkNodes": [
        "nn-1111111111example",
        "nn-2222222222example",
        "nn-3333333333example"
      ],
      "ZoneId": "usw2-az2",
      "AvailabilityZone": "us-west-2a"
    },
    {
      "InstanceId": "i-2222222222example",
      "InstanceType": "trn1n.32xlarge",
      "NetworkNodes": [
        "nn-1111111111example",
        "nn-2222222222example",
        "nn-3214313214example"
      ],
      "ZoneId": "usw2-az2",
      "AvailabilityZone": "us-west-2a"
    }
  ],
  "NextToken": "SomeEncryptedToken"
}
```

Example 5 – Placement group name parameter

To describe the instance topology of all your instances in a specified placement group

Use the describe-instance-topology CLI command with the group-names parameter. In the following example, the instances can be in the ML-group or HPC-group placement group. The response will return instances that are in either of the placement groups.

```bash
aws ec2 describe-instance-topology
  --region us-west-2
  --filter "Name=instance-type,Values=p4d*,trn1n.32xlarge" "Name=group-names,Values=ML-group,HPC-group"
```
aws ec2 describe-instance-topology \
  --region us-west-2  \
  --group-names ML-group HPC-group

Example output

```
{
  "Instances": [
    {
      "InstanceId": "i-1111111111example",
      "InstanceType": "p4d.24xlarge",
      "GroupName": "ML-group",
      "NetworkNodes": [
        "nn-1111111111example",
        "nn-2222222222example",
        "nn-3333333333example"
      ],
      "ZoneId": "usw2-az2",
      "AvailabilityZone": "us-west-2a"
    },
    {
      "InstanceId": "i-2222222222example",
      "InstanceType": "trn1n.32xlarge",
      "GroupName": "HPC-group",
      "NetworkNodes": [
        "nn-1111111111example",
        "nn-2222222222example",
        "nn-3214313214example"
      ],
      "ZoneId": "usw2-az2",
      "AvailabilityZone": "us-west-2a"
    }
  ],
  "NextToken": "SomeEncryptedToken"
}
```

Example 6 – Instance IDs

To describe the instance topology of specified instances

Use the `describe-instance-topology` CLI command with the `--instance-ids` parameter. The response will return the instances that match the specified instance IDs.

```
aws ec2 describe-instance-topology \
  --region us-west-2  \
  --instance-ids i-1111111111example i-2222222222example

Example output

```
{
  "Instances": [
    {
      "InstanceId": "i-1111111111example",
      "InstanceType": "p4d.24xlarge",
      "GroupName": "ML-group",
      "NetworkNodes": [
        "nn-1111111111example",
        "nn-2222222222example",
        "nn-3333333333example"
      ],
      "ZoneId": "usw2-az2"
    }
  ]
```
Placement groups

To meet the needs of your workload, you can launch a group of interdependent EC2 instances into a placement group to influence their placement.

Depending on the type of workload, you can create a placement group using one of the following placement strategies:

- **Cluster** – Packs instances close together inside an Availability Zone. This strategy enables workloads to achieve the low-latency network performance necessary for tightly-coupled node-to-node communication that is typical of high-performance computing (HPC) applications.
- **Partition** – Spreads your instances across logical partitions such that groups of instances in one partition do not share the underlying hardware with groups of instances in different partitions. This strategy is typically used by large distributed and replicated workloads, such as Hadoop, Cassandra, and Kafka.
- **Spread** – Strictly places a small group of instances across distinct underlying hardware to reduce correlated failures.

Placement groups are optional. If you don’t launch your instances into a placement group, EC2 tries to place the instances in such a way that all of your instances are spread out across the underlying hardware to minimize correlated failures.

There is no charge for creating a placement group.

Placement strategies

You can create a placement group using one of the following placement strategies.

**Placement strategies:**

- [Cluster placement groups (p. 1572)](#)
- [Partition placement groups (p. 1573)](#)
- [Spread placement groups (p. 1574)](#)

**Cluster placement groups**

A cluster placement group is a logical grouping of instances within a single Availability Zone. A cluster placement group can span peered virtual private networks (VPCs) in the same Region. Instances in the
same cluster placement group enjoy a higher per-flow throughput limit for TCP/IP traffic and are placed in the same high-bisection bandwidth segment of the network.

The following image shows instances that are placed into a cluster placement group.

Cluster placement groups are recommended for applications that benefit from low network latency, high network throughput, or both. They are also recommended when the majority of the network traffic is between the instances in the group. To provide the lowest latency and the highest packet-per-second network performance for your placement group, choose an instance type that supports enhanced networking. For more information, see Enhanced Networking (p. 1461).

We recommend that you launch your instances in the following way:

- Use a single launch request to launch the number of instances that you need in the placement group.
- Use the same instance type for all instances in the placement group.

If you try to add more instances to the placement group later, or if you try to launch more than one instance type in the placement group, you increase your chances of getting an insufficient capacity error.

If you stop an instance in a placement group and then start it again, it still runs in the placement group. However, the start fails if there isn't enough capacity for the instance.

If you receive a capacity error when launching an instance in a placement group that already has running instances, stop and start all of the instances in the placement group, and try the launch again. Starting the instances may migrate them to hardware that has capacity for all of the requested instances.

**Partition placement groups**

Partition placement groups help reduce the likelihood of correlated hardware failures for your application. When using partition placement groups, Amazon EC2 divides each group into logical segments called partitions. Amazon EC2 ensures that each partition within a placement group has its own set of racks. Each rack has its own network and power source. No two partitions within a placement group share the same racks, allowing you to isolate the impact of hardware failure within your application.

The following image is a simple visual representation of a partition placement group in a single Availability Zone. It shows instances that are placed into a partition placement group with three partitions—Partition 1, Partition 2, and Partition 3. Each partition comprises multiple instances. The instances in a partition do not share racks with the instances in the other partitions, allowing you to contain the impact of a single hardware failure to only the associated partition.
Partition placement groups can be used to deploy large distributed and replicated workloads, such as HDFS, HBase, and Cassandra, across distinct racks. When you launch instances into a partition placement group, Amazon EC2 tries to distribute the instances evenly across the number of partitions that you specify. You can also launch instances into a specific partition to have more control over where the instances are placed.

A partition placement group can have partitions in multiple Availability Zones in the same Region. A partition placement group can have a maximum of seven partitions per Availability Zone. The number of instances that can be launched into a partition placement group is limited only by the limits of your account.

In addition, partition placement groups offer visibility into the partitions — you can see which instances are in which partitions. You can share this information with topology-aware applications, such as HDFS, HBase, and Cassandra. These applications use this information to make intelligent data replication decisions for increasing data availability and durability.

If you start or launch an instance in a partition placement group and there is insufficient unique hardware to fulfill the request, the request fails. Amazon EC2 makes more distinct hardware available over time, so you can try your request again later.

**Spread placement groups**

A spread placement group is a group of instances that are each placed on distinct hardware.

Spread placement groups are recommended for applications that have a small number of critical instances that should be kept separate from each other. Launching instances in a spread level placement group reduces the risk of simultaneous failures that might occur when instances share the same equipment. Spread level placement groups provide access to distinct hardware, and are therefore suitable for mixing instance types or launching instances over time.

If you start or launch an instance in a spread placement group and there is insufficient unique hardware to fulfill the request, the request fails. Amazon EC2 makes more distinct hardware available over time, so you can try your request again later. Placement groups can spread instances across racks or hosts. You can use host level spread placement groups only with AWS Outposts.

**Rack spread level placement groups**

The following image shows seven instances in a single Availability Zone that are placed into a spread placement group. The seven instances are placed on seven different racks, each rack has its own network and power source.
A rack spread placement group can span multiple Availability Zones in the same Region. For rack spread level placement groups, you can have a maximum of seven running instances per Availability Zone per group.

**Host level spread placement groups**

Host spread level placement groups are only available with AWS Outposts. For host spread level placement groups, there are no restrictions for running instances per Outposts. For more information, see the section called “Placement groups on AWS Outposts” (p. 1588).

## Placement group rules and limitations

**Topics**

- General rules and limitations (p. 1575)
- Cluster placement group rules and limitations (p. 1575)
- Partition placement group rules and limitations (p. 1576)
- Spread placement group rules and limitations (p. 1576)

### General rules and limitations

Before you use placement groups, be aware of the following rules:

- You can create a maximum of 500 placement groups per account in each Region.
- The name that you specify for a placement group must be unique within your AWS account for the Region.
- You can't merge placement groups.
- An instance can be launched in one placement group at a time; it cannot span multiple placement groups.
- On-Demand Capacity Reservation (p. 661) and zonal Reserved Instances (p. 505) provide a capacity reservation for EC2 instances in a specific Availability Zone. The capacity reservation can be used by instances in a placement group. When using a cluster placement group with capacity reservation, it is recommended that you reserve capacity within the cluster placement group. For more information, see Capacity Reservations in cluster placement groups.

- Zonal Reserved Instances (p. 505) provide a capacity reservation for instances in a specific Availability Zone. The capacity reservation can be used by instances in a placement group. However, it is not possible to explicitly reserve capacity in a placement group using a zonal Reserved Instance.
- You can't launch Dedicated Hosts in placement groups.
- You can't launch a Spot Instance that is configured to stop or hibernate on interruption in a placement group.

### Cluster placement group rules and limitations

The following rules apply to cluster placement groups:

- The following instance types are supported:
  - Current generation (p. 287) instances, except for burstable performance (p. 330) instances (for example, T2), Mac1 instances (p. 485), and M7i-flex instances.
  - The following previous generation (p. 294) instances: A1, C3, C4, G2, I2, M4, R3, and R4.
  - A cluster placement group can't span multiple Availability Zones.
• The maximum network throughput speed of traffic between two instances in a cluster placement group is limited by the slower of the two instances. For applications with high-throughput requirements, choose an instance type with network connectivity that meets your requirements.

• For instances that are enabled for enhanced networking, the following rules apply:
  • Instances within a cluster placement group can use up to 10 Gbps for single-flow traffic. Instances that are not within a cluster placement group can use up to 5 Gbps for single-flow traffic.
  • Traffic to and from Amazon S3 buckets within the same Region over the public IP address space or through a VPC endpoint can use all available instance aggregate bandwidth.
  • You can launch multiple instance types into a cluster placement group. However, this reduces the likelihood that the required capacity will be available for your launch to succeed. We recommend using the same instance type for all instances in a cluster placement group.
  • Network traffic to the internet and over an AWS Direct Connect connection to on-premises resources is limited to 5 Gbps.

Partition placement group rules and limitations

The following rules apply to partition placement groups:

• A partition placement group supports a maximum of seven partitions per Availability Zone. The number of instances that you can launch in a partition placement group is limited only by your account limits.

• When instances are launched into a partition placement group, Amazon EC2 tries to evenly distribute the instances across all partitions. Amazon EC2 doesn’t guarantee an even distribution of instances across all partitions.

• A partition placement group with Dedicated Instances can have a maximum of two partitions.

• Capacity Reservations do not reserve capacity in a partition placement group.

Spread placement group rules and limitations

The following rules apply to spread placement groups:

• A rack spread placement group supports a maximum of seven running instances per Availability Zone. For example, in a Region with three Availability Zones, you can run a total of 21 instances in the group, with seven instances in each Availability Zone. If you try to start an eighth instance in the same Availability Zone and in the same spread placement group, the instance will not launch. If you need more than seven instances in an Availability Zone, we recommend that you use multiple spread placement groups. Using multiple spread placement groups does not provide guarantees about the spread of instances between groups, but it does help ensure the spread for each group, thus limiting the impact from certain classes of failures.

• Spread placement groups are not supported for Dedicated Instances.

• Host level spread placement groups are only supported for placement groups on AWS Outposts. There are no restrictions for the number of running instances with host level spread placement groups.

• Capacity Reservations do not reserve capacity in a spread placement group.

Work with placement groups

Contents

• Create a placement group (p. 1577)
• Tag a placement group (p. 1578)
• Launch instances in a placement group (p. 1580)
Create a placement group

You can create a placement group using one of the following methods.

Console

To create a placement group using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Placement Groups.
3. Choose Create placement group.
4. Specify a name for the group.
5. Choose the placement strategy for the group.
   - If you choose Spread, choose the spread level.
   - Rack - no restrictions
   - Host - only for Outposts
   - If you choose Partition, choose the number of partitions within the group.
6. To tag the placement group, choose Add tag, and then enter a key and value. Choose Add tag for each tag that you want to add.
7. Choose Create group.

AWS CLI

To create a placement group using the AWS CLI

Use the create-placement-group command. The following example creates a placement group named my-cluster that uses the cluster placement strategy, and it applies a tag with a key of purpose and a value of production.

```bash
aws ec2 create-placement-group \
   --group-name my-cluster \ 
   --strategy cluster \ 
   --tag-specifications 'ResourceType=placement-group,Tags={Key=purpose,Value=production}'
```

To create a partition placement group using the AWS CLI

Use the create-placement-group command. Specify the --strategy parameter with the value partition, and specify the --partition-count parameter with the desired number of partitions. In this example, the partition placement group is named HDFS-Group-A and is created with five partitions.

```bash
aws ec2 create-placement-group \
   --group-name HDFS-Group-A \ 
   --strategy partition \ 
   --partition-count 5
```
PowerShell

**To create a placement group using the AWS Tools for Windows PowerShell**

Use the `New-EC2PlacementGroup` command.

**Tag a placement group**

To help categorize and manage your existing placement groups, you can tag them with custom metadata. For more information about how tags work, see Tag your Amazon EC2 resources (p. 2507).

When you tag a placement group, the instances that are launched into the placement group are not automatically tagged. You need to explicitly tag the instances that are launched into the placement group. For more information, see Add a tag when you launch an instance (p. 2515).

You can view, add, and delete tags using one of the following methods.

**Console**

**To view, add, or delete a tag for an existing placement group**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Placement Groups**.
3. Select a placement group, and then choose **Actions, Manage tags**.
4. The **Manage tags** screen displays any tags that are assigned to the placement group.
   - To add a tag, choose **Add tag**, and then enter the tag key and value. You can add up to 50 tags per placement group. For more information, see Tag restrictions (p. 2512).
   - To delete a tag, choose **Remove** next to the tag that you want to delete.
5. Choose **Save**.

**AWS CLI**

**To view placement group tags**

Use the `describe-tags` command to view the tags for the specified resource. In the following example, you describe the tags for all of your placement groups.

```
aws ec2 describe-tags \
   --filters Name=resource-type,Values=placement-group
```

```json
{
   "Tags": [
      {
         "Key": "Environment",
         "ResourceId": "pg-0123456789EXAMPLE",
         "ResourceType": "placement-group",
         "Value": "Production"
      },
      {
         "Key": "Environment",
         "ResourceId": "pg-9876543210EXAMPLE",
         "ResourceType": "placement-group",
         "Value": "Production"
      }
   ]
}
```
You can also use the `describe-tags` command to view the tags for a placement group by specifying its ID. In the following example, you describe the tags for `pg-0123456789EXAMPLE`.

```
aws ec2 describe-tags \
  --filters Name=resource-id,Values=pg-0123456789EXAMPLE
```

```
{
  "Tags": [
    {
      "Key": "Environment",
      "ResourceId": "pg-0123456789EXAMPLE",
      "ResourceType": "placement-group",
      "Value": "Production"
    }
  ]
}
```

You can also view the tags of a placement group by describing the placement group.

Use the `describe-placement-groups` command to view the configuration of the specified placement group, which includes any tags that were specified for the placement group.

```
aws ec2 describe-placement-groups \
  --group-name my-cluster
```

```
{
  "PlacementGroups": [
    {
      "GroupName": "my-cluster",
      "State": "available",
      "Strategy": "cluster",
      "GroupId": "pg-0123456789EXAMPLE",
      "Tags": [
        {
          "Key": "Environment",
          "Value": "Production"
        }
      ]
    }
  ]
}
```

To tag an existing placement group using the AWS CLI

You can use the `create-tags` command to tag existing resources. In the following example, the existing placement group is tagged with Key=Cost-Center and Value=CC-123.

```
aws ec2 create-tags \
  --resources pg-0123456789EXAMPLE \
  --tags Key=Cost-Center,Value=CC-123
```

To delete a tag from a placement group using the AWS CLI

You can use the `delete-tags` command to delete tags from existing resources. For examples, see Examples in the AWS CLI Command Reference.
PowerShell

To view placement group tags
Use the `Get-EC2Tag` command.

To describe the tags for a specific placement group
Use the `Get-EC2PlacementGroup` command.

To tag an existing placement group
Use the `New-EC2Tag` command.

To delete a tag from a placement group
Use the `Remove-EC2Tag` command.

Launch instances in a placement group

You can launch an instance into a placement group if the placement group rules and limitations are met (p. 1575) using one of the following methods.

Console

To launch instances into a placement group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the EC2 console dashboard, in the Launch instance box, choose Launch instance. Complete the form as directed, taking care to do the following:
   • Under Instance type, select an instance type that can be launched into a placement group.
   • In the Summary box, under Number of instances, enter the total number of instances that you need in this placement group, because you might not be able to add instances to the placement group later.
   • Under Advanced details, for Placement group name, you can choose to add the instances to a new or existing placement group. If you choose a placement group with a partition strategy, for Target partition, choose the partition in which to launch the instances.

AWS CLI

To launch instances into a placement group

Use the `run-instances` command and specify the placement group name using the `--placement "GroupName = my-cluster"` parameter. In this example, the placement group is named my-cluster.

```
aws ec2 run-instances --placement "GroupName = my-cluster"
```

To launch instances into a specific partition of a partition placement group using the AWS CLI

Use the `run-instances` command and specify the placement group name and partition using the `--placement "GroupName = HDFS-Group-A, PartitionNumber = 3"` parameter. In this example, the placement group is named HDFS-Group-A and the partition number is 3.

```
aws ec2 run-instances --placement "GroupName = HDFS-Group-A, PartitionNumber = 3"
```
To launch instances into a placement group using AWS Tools for Windows PowerShell

Use the `New-EC2Instance` command and specify the placement group name using the `-Placement.GroupName` parameter.

Describe instances in a placement group

You can view the placement information of your instances using one of the following methods. You can also filter partition placement groups by the partition number using the AWS CLI.

Console

**To view the placement group and partition number of an instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Instances.
3. Select the instance.
4. On the Details tab, under Host and placement group, find Placement group. If the instance is not in a placement group, the field is empty. Otherwise, it contains the name of the placement group name. If the placement group is a partition placement group, Partition number contains the partition number for the instance.

AWS CLI

**To view the partition number for an instance in a partition placement group**

Use the `describe-instances` command and specify the `--instance-id` parameter.

```bash
aws ec2 describe-instances --instance-id i-0123a456700123456
```

The response contains the placement information, which includes the placement group name and the partition number for the instance.

```json
"Placement": {
    "AvailabilityZone": "us-east-1c",
    "GroupName": "HDFS-Group-A",
    "PartitionNumber": 3,
    "Tenancy": "default"
}
```

**To filter instances for a specific partition placement group and partition number**

Use the `describe-instances` command and specify the `--filters` parameter with the placement-group-name and placement-partition-number filters. In this example, the placement group is named HDFS-Group-A and the partition number is 7.

```bash
aws ec2 describe-instances --filters "Name = placement-group-name, Values = HDFS-Group-A" "Name = placement-partition-number, Values = 7"
```

The response lists all the instances that are in the specified partition within the specified placement group. The following is example output showing only the instance ID, instance type, and placement information for the returned instances.
Change the placement group for an instance

You can change the placement group for an instance as follows:

- Move an existing instance to a placement group
- Move an instance from one placement group to another

Before you can move the instance, the instance must be in the stopped state.

Console

To move an instance to a placement group

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance, and then choose **Instance state**, **Stop instance**.
4. With the instance selected, choose **Actions**, **Instance settings**, **Modify instance placement**.
5. For **Placement group**, choose the placement group to move the instance to.
6. Choose **Save**.

AWS CLI

To move an instance to a placement group

1. Stop the instance using the `stop-instances` command.
2. Use the `modify-instance-placement` command and specify the name of the placement group to move the instance to.

```bash
aws ec2 modify-instance-placement --instance-id i-0123a456700123456
```
--group-name MySpreadGroup

3. Start the instance using the start-instances command.

PowerShell

To move an instance to a placement group using the AWS Tools for Windows PowerShell

1. Stop the instance using the Stop-EC2Instance command.
2. Use the Edit-EC2InstancePlacement command and specify the name of the placement group to which to move the instance.
3. Start the instance using the Start-EC2Instance command.

Remove an instance from a placement group

You can remove an instance from a placement group using one of the following methods.

Before you can remove an instance from a placement group, the instance must be in the stopped state.

Console

To remove an instance from a placement group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, and then choose Instance state, Stop instance.
4. With the instance selected, choose Actions, Instance settings, Modify instance placement.
5. For Placement group, choose None.
6. Choose Save.

AWS CLI

To remove an instance from a placement group

1. Stop the instance using the stop-instances command.
2. Use the modify-instance-placement command and specify an empty string for the placement group name.

    aws ec2 modify-instance-placement \
        --instance-id i-0123a456700123456 \
        --group-name ""

3. Start the instance using the start-instances command.

PowerShell

To remove an instance from a placement group using the AWS Tools for Windows PowerShell

1. Stop the instance using the Stop-EC2Instance command.
2. Use the Edit-EC2InstancePlacement command and specify an empty string for the placement group name.
3. Start the instance using the Start-EC2Instance command.
Delete a placement group

If you need to replace a placement group or no longer need one, you can delete it. You can delete a
placement group using one of the following methods.

Prerequisite

Before you can delete a placement group, it must contain no instances. You can terminate (p. 806) all
instances that you launched in the placement group, move (p. 1582) instances to another placement
group, or remove (p. 1583) instances from the placement group.

Console

To delete a placement group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Placement Groups.
3. Select the placement group and choose Actions, Delete.
4. When prompted for confirmation, enter Delete and then choose Delete.

AWS CLI

To delete a placement group

Use the delete-placement-group command and specify the placement group name to delete the
placement group. In this example, the placement group name is my-cluster.

aws ec2 delete-placement-group --group-name my-cluster

PowerShell

To delete a placement group using the AWS Tools for Windows PowerShell

Use the Remove-EC2PlacementGroup command to delete the placement group.

Share a placement group

Placement group sharing allows you to influence the placement of interdependent instances that are
owned by separate AWS accounts. You can share a placement group across multiple AWS accounts or
within your AWS Organizations. You can launch instances in a shared placement group.

A placement group owner can share a placement group with:

- Specific AWS accounts inside or outside of its AWS organization
- An organizational unit inside its AWS organization
- Its entire AWS organization

Note

The AWS account from which you want to share a placement group must have the following
permissions in the IAM policy.

- ec2:PutResourcePolicy
- ec2:DeleteResourcePolicy

Topics
• **Rules and limitations (p. 1585)**
• **Share across Availability Zones (p. 1585)**
• **Share a placement group (p. 1585)**
• **Identify a shared placement group (p. 1586)**
• **Launch an instance in a shared placement group (p. 1586)**
• **Unshare a shared placement group (p. 1587)**

**Rules and limitations**

The following rules and limitations apply when you share a placement group or when a placement group is shared with you.

- To share a placement group, you must own it in your AWS account. You cannot share a placement group that has been shared with you.
- When you share a partition or spread placement group, the placement group limits do not change. A shared partition placement group supports a maximum of seven partitions per Availability Zone, and a shared spread placement group supports a maximum of seven running instances per Availability Zone.
- To share a placement group with your AWS organization or an organizational unit in your AWS organization, you must enable sharing with AWS Organizations. For more information, see [Sharing your AWS resources](#).
- You are responsible for managing the instances owned by you in a shared placement group.
- You cannot view or modify instances and capacity reservations that are associated with a shared placement group but not owned by you.

**Share across Availability Zones**

To ensure that resources are distributed across the Availability Zones for a Region, we independently map Availability Zones to names for each account. This could lead to Availability Zone naming differences across accounts. For example, the Availability Zone `us-east-1a` for your AWS account might not have the same location as `us-east-1a` for another AWS account.

To identify the location of your Dedicated Hosts relative to your accounts, you must use the *Availability Zone ID* (AZ ID). The Availability Zone ID is a unique and consistent identifier for an Availability Zone across all AWS accounts. For example, `use1-az1` is an Availability Zone ID for the `us-east-1` Region and it is the same location in every AWS account.

To view the *Availability Zone IDs for the Availability Zones in your account*:

2. The Availability Zone IDs for the current Region are displayed under *Your AZ ID* in the right panel.

**Share a placement group**

To share a placement group, you must add it to a resource share. A resource share is an AWS RAM resource that lets you share your resources across AWS accounts. A resource share specifies the resources to share, and the consumers with whom they are shared.

If you are part of an organization in AWS Organizations sharing within your organization is enabled, consumers in your organization are granted access to the shared placement group.

If the placement group is shared with an AWS account outside of your organization, the AWS account owner will receive an invitation to join the resource share. They can access the shared placement group after accepting the invitation.
You can share a placement group across AWS accounts using https://console.aws.amazon.com/ram or AWS CLI.

AWS RAM console

To share a placement group you own using https://console.aws.amazon.com/ram, see Creating a resource share.

AWS CLI

To share a placement group you own, use the create-resource-share command.

Identify a shared placement group

You can identify a placement group shared that is shared with you via https://console.aws.amazon.com/ec2/ or AWS CLI.

Amazon EC2 console

2. In the left navigation pane, choose Placement Groups.
3. The Placement Groups screen on the right lists all the placement groups owned by you and shared with you. The Amazon Resource Name (ARN) of a placement group contains the details of its owner.

AWS CLI

The describe-placement-groups command lists all the placement groups owned by you and shared with you. The Amazon Resource Name (ARN) of a placement group contains the details of its owner.

Launch an instance in a shared placement group

Important
You must specify the Placement Group Group Id to launch an instance in a shared placement group.

You can use the Placement Group Name only if you are the owner of the placement group being shared. We recommend using the Placement Group Group Id to avoid potential placement group name collisions between AWS accounts.

You can find the Group Id of a placement group using the describe-placement-groups command or in the https://console.aws.amazon.com/ec2/ on the Placement Groups screen under Network & Security.

Amazon EC2 Console

To launch instances into a placement group using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Choose Launch Instance. Complete the wizard as directed, taking care to do the following:
   • On the Choose an Instance Type page, select an instance type that can be launched into a placement group.
• On the Configure Instance Details page, the following fields are applicable to placement groups:
  • For Number of instances, enter the total number of instances that you need in this placement group, because you might not be able to add instances to the placement group later.
  • For Placement group, select the Add instance to placement group check box. If you do not see Placement group on this page, verify that you have selected an instance type that can be launched into a placement group. Otherwise, this option is not available.
  • For Placement group name, you can choose to add the instances to an existing placement group or to a new placement group that you create.
  • For Placement group strategy, choose the appropriate strategy. If you choose partition, for Target partition, choose Auto distribution to have Amazon EC2 do a best effort to distribute the instances evenly across all the partitions in the group. Alternatively, specify the partition in which to launch the instances.

AWS CLI

To launch instances in a shared placement group

Use the run-instances command and specify the placement group Group Id.

```
aws ec2 run-instances --placement "GroupId = pg-01234567891011121"
```

To launch instances into a specific partition of a shared partition placement group

Use the run-instances command and specify the Group Id and PartitionNumber of the shared placement group.

```
aws ec2 run-instances --placement "GroupId = pg-01234567891011121, PartitionNumber = 3"
```

Tip

Use VPC peering to connect instances owned by separate AWS accounts and get the full latency benefits offered by shared cluster placement groups. For more information, see What is VPC peering?

Unshare a shared placement group

The placement group owner can unshare a shared placement group at any time.

When you unshare a shared placement group, the following changes will take effect.

• The AWS accounts with which a placement group was shared will no longer be able to launch instances or reserve capacity.
• If your instances were running in a shared placement group, they will be disassociated from the placement group but continue to run normally in your AWS account.
• If you had capacity reservations in a shared placement group, they will be disassociated from the placement group but you will continue to have access to them in your AWS account.

You can unshare a shared placement group using one of the following methods.

AWS RAM console

To unshare a shared placement group using https://console.aws.amazon.com/ram, see Deleting a resource share.
AWS CLI

To unshare a shared placement group using AWS Command Line Interface, use the `disassociate-resource-share` command.

Placement groups on AWS Outposts

AWS Outposts is a fully managed service that extends AWS infrastructure, services, APIs, and tools to customer premises. By providing local access to AWS managed infrastructure, AWS Outposts enables customers to build and run applications on premises using the same programming interfaces as in AWS Regions, while using local compute and storage resources for lower latency and local data processing needs.

An Outpost is a pool of AWS compute and storage capacity deployed at a customer site. AWS operates, monitors, and manages this capacity as part of an AWS Region.

You can create placement groups on Outposts that you have created in your account. This allows you to spread out instances across underlying hardware on an Outpost at your site. You create and use placement groups on Outposts in the same way that you create and use placement groups in regular Availability Zones. When you create a placement group with a spread strategy on an Outpost, you can choose to have the placement group spread instances across hosts or racks. Spreading instances across hosts allows you to use a spread strategy with a single rack Outpost.

Prerequisite

You must have an Outpost installed at your site. For more information, see Create an Outpost and order Outpost capacity in the AWS Outposts User Guide.

To use a placement group on an Outpost

1. Create a subnet on the Outpost. For more information, see Create a subnet in the AWS Outposts User Guide.
2. Create a placement group in the associated Region of the Outpost. If you create a placement group with a spread strategy, you can choose host or rack spread level to determine how the group will spread instances across the underlying hardware on your Outpost. For more information, see the section called “Create a placement group” (p. 1577).
3. Launch an instance into the placement group. For Subnet choose the subnet that you created in Step 1, and for Placement group name, select the placement group that you created in Step 2. For more information, see Launch an instance on the Outpost in the AWS Outposts User Guide.

Network maximum transmission unit (MTU) for your EC2 instance

The maximum transmission unit (MTU) of a network connection is the size, in bytes, of the largest permissible packet that can be passed over the connection. The larger the MTU of a connection, the more data that can be passed in a single packet. Ethernet frames consist of the packet, or the actual data you are sending, and the network overhead information that surrounds it.

Ethernet frames can come in different formats, and the most common format is the standard Ethernet v2 frame format. It supports 1500 MTU, which is the largest Ethernet packet size supported over most of the internet. The maximum supported MTU for an instance depends on its instance type.

The following rules apply to instances that are in Wavelength Zones:
Jumbo frames (9001 MTU)

Jumbo frames allow more than 1500 bytes of data by increasing the payload size per packet, and thus increasing the percentage of the packet that is not packet overhead. Fewer packets are needed to send the same amount of usable data. However, traffic is limited to a maximum MTU of 1500 in the following cases:

• Traffic over an internet gateway
• Traffic over an inter-region VPC peering connection
• Traffic over VPN connections
• Traffic outside of a given AWS Region for EC2-Classic

If packets are over 1500 bytes, they are fragmented, or they are dropped if the Don’t Fragment flag is set in the IP header.

Jumbo frames should be used with caution for internet-bound traffic or any traffic that leaves a VPC. Packets are fragmented by intermediate systems, which slows down this traffic. To use jumbo frames inside a VPC and not slow traffic that’s bound for outside the VPC, you can configure the MTU size by route, or use multiple elastic network interfaces with different MTU sizes and different routes.

For instances that are collocated inside a cluster placement group, jumbo frames help to achieve the maximum network throughput possible, and they are recommended in this case. For more information, see Placement groups (p. 1572).

You can use jumbo frames for traffic between your VPCs and your on-premises networks over AWS Direct Connect. For more information, and for how to verify Jumbo Frame capability, see Setting Network MTU in the AWS Direct Connect User Guide.

All Amazon EC2 instance types support 1500 MTU and all current generation instance types support jumbo frames. The following previous generation instance types support jumbo frames: A1, C3, G2, I2, M3, and R3.

For more information about supported MTU sizes for transit gateways, see MTU in the Amazon VPC Transit Gateways User Guide.
For more information about supported MTU sizes for Local Zones, see Considerations in the AWS Local Zones User Guide.

Path MTU Discovery

Path MTU Discovery (PMTUD) is used to determine the path MTU between two devices. The path MTU is the maximum packet size that's supported on the path between the originating host and the receiving host. When there is a difference in the MTU size in the network between two hosts, PMTUD enables the receiving host to respond to the originating host with an ICMP message. This ICMP message instructs the originating host to use the lowest MTU size along the network path and to resend the request. Without this negotiation, packet drop can occur because the request is too large for the receiving host to accept.

For IPv4, when a host sends a packet that's larger than the MTU of the receiving host or that's larger than the MTU of a device along the path, the receiving host or device drops the packet, and then returns the following ICMP message: Destination Unreachable: Fragmentation Needed and Don't Fragment was Set (Type 3, Code 4). This instructs the transmitting host to split the payload into multiple smaller packets, and then retransmit them.

The IPv6 protocol does not support fragmentation in the network. When a host sends a packet that's larger than the MTU of the receiving host or that's larger than the MTU of a device along the path, the receiving host or device drops the packet, and then returns the following ICMP message: ICMPv6 Packet Too Big (PTB) (Type 2). This instructs the transmitting host to split the payload into multiple smaller packets, and then retransmit them.

Connections made through some components, like NAT gateways and load balancers, are automatically tracked (p. 2026). This means that security group tracking (p. 2026) is automatically enabled for your outbound connection attempts. If connections are automatically tracked or if your security group rules allow inbound ICMP traffic, you can receive PMTUD responses.

Note that ICMP traffic can be blocked even if the traffic is allowed at the security group level, such as if you have a network access control list entry that denies ICMP traffic to the subnet.

Important
Path MTU Discovery does not guarantee that jumbo frames will not be dropped by some routers. An internet gateway in your VPC will forward packets up to 1500 bytes only. 1500 MTU packets are recommended for internet traffic.

Check the path MTU between two hosts

You can check the path MTU between two hosts using the tracepath command, which is part of the iputils package that is available by default on many Linux distributions, including Amazon Linux.

To check path MTU using tracepath

Use the following command to check the path MTU between your EC2 instance and another host. You can use a DNS name or an IP address as the destination. If the destination is another EC2 instance, verify that the security group allows inbound UDP traffic. This example checks the path MTU between an EC2 instance and amazon.com.

```
[ec2-user ~]$ tracepath amazon.com
17: [LOCALHOST] pmtu 9001
  1: ip-172-31-16-1.us-west-1.compute.internal (172.31.16.1) 0.187ms pmtu 1500
     1: no reply
     2: no reply
     3: no reply
  4: 100.64.16.241 (100.64.16.241) 0.574ms pmtu 1500
     4: 100.64.16.241 (100.64.16.241) 0.574ms pmtu 1500
  5: 72.21.222.221 (72.21.222.221) 84.447ms asymm 21
     5: 72.21.222.221 (72.21.222.221) 84.447ms asymm 21
  6: 205.251.229.97 (205.251.229.97) 79.970ms asymm 19
     6: 205.251.229.97 (205.251.229.97) 79.970ms asymm 19
  7: 72.21.222.194 (72.21.222.194) 96.546ms asymm 16
     7: 72.21.222.194 (72.21.222.194) 96.546ms asymm 16
```
In this example, the path MTU is 1500.

**Check and set the MTU on your Linux instance**

Some instances are configured to use jumbo frames, and others are configured to use standard frame sizes. You may want to use jumbo frames for network traffic within your VPC or you may want to use standard frames for internet traffic. Whatever your use case, we recommend verifying that your instance will behave the way you expect it to. You can use the procedures in this section to check your network interface's MTU setting and modify it if needed.

**To check the MTU setting on a Linux instance**

You can check the current MTU value using the following `ip` command. Note that in the example output, `mtu 9001` indicates that this instance uses jumbo frames.

```
[ec2-user ~]$ ip link show eth0
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 9001 qdisc pfifo_fast state UP mode DEFAULT
   group default qlen 1000
   link/ether 02:90:c0:b7:9e:d1 brd ff:ff:ff:ff:ff:ff
```

**To set the MTU value on a Linux instance**

1. You can set the MTU value using the `ip` command. The following command sets the desired MTU value to 1500, but you could use 9001 instead.

```
[ec2-user ~]$ sudo ip link set dev eth0 mtu 1500
```

2. (Optional) To persist your network MTU setting after a reboot, modify the following configuration files, based on your operating system type.

   - For Amazon Linux 2, add the following line to the `/etc/sysconfig/network-scripts/ifcfg-eth0` file:

   ```
   MTU=1500
   ```

   Add the following line to the `/etc/dhcp/dhclient.conf` file:

   ```
   request subnet-mask, broadcast-address, time-offset, routers, domain-name, domain-name-search, domain-name-servers, host-name, nis-domain, nis-servers, ntp-servers;
   ```

   - For Amazon Linux, add the following lines to your `/etc/dhcp/dhclient-eth0.conf` file.

   ```
   interface "eth0" {
       supersede interface-mtu 1500;
   }
   ```

   - For other Linux distributions, consult their specific documentation.

3. (Optional) Reboot your instance and verify that the MTU setting is correct.
Troubleshoot

If you experience connectivity issues between your EC2 instance and an Amazon Redshift cluster when using jumbo frames, see Queries Appear to Hang in the Amazon Redshift Management Guide.

Virtual private clouds

Amazon Virtual Private Cloud (Amazon VPC) enables you to define a virtual network in your own logically isolated area within the AWS cloud, known as a virtual private cloud or VPC. You can create AWS resources, such as Amazon EC2 instances, into the subnets of your VPC. Your VPC closely resembles a traditional network that you might operate in your own data center, with the benefits of using scalable infrastructure from AWS. You can configure your VPC; you can select its IP address range, create subnets, and configure route tables, network gateways, and security settings. You can connect instances in your VPC to the internet or to your own data center.

Your default VPCs

When you create your AWS account, we create a default VPC in each Region. A default VPC is a VPC that is already configured and ready for you to use. For example, there is a default subnet for each Availability Zone in each default VPC, an internet gateway attached to the VPC, and there’s a route in the main route table that sends all traffic (0.0.0.0/0) to the internet gateway. Alternatively, you can create your own VPC and configure it to meet your needs.
Create additional VPCs

Use the following procedure to create a VPC with the subnets, gateways, and routing configuration that you need.

To create a VPC

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Choose Create VPC.
3. Under Resources to create, choose VPC and more.
4. For Name tag auto-generation, enter a name for the VPC.
5. For IPv4 CIDR block, either keep the default suggestion, enter the CIDR block required by your application or network.
6. For Number of Availability Zones, choose 2, so that you can launch instances in multiple Availability Zones to ensure high availability.
7. If your instances must be accessible from the internet, do one of the following:
   • If your instances can be in a public subnet, select a nonzero value for **Number of public subnets**. Keep both options under **DNS options** selected. You can optionally add private subnets now or later on.
   • If your instances must be in a private subnet, select 0 for **Number of public subnets**. For **Number of private subnets**, select a number depending on your needs (the possible values correspond to 1 or 2 private subnets per Availability Zone). For **NAT gateways**, if your instances in both Availability Zones send or receive a significant volume of traffic across Availability Zones, select **1 per AZ**. Otherwise, select **In 1 AZ** and launch instances that send or receive cross-zone traffic in the same Availability Zone as the NAT gateway.

8. Expand **Customize subnet CIDR blocks**. Either keep the default suggestions, or enter a CIDR block for each subnet. For more information, see **Subnet CIDR blocks** in the Amazon VPC User Guide.

9. Review the **Preview** pane, which shows the VPC resources that will be created based on your selections.

10. Choose **Create VPC**.

### Access the internet from your instances

Instances launched into a default subnet have access to the internet, as the VPC is configured to assign public IP addresses and DNS hostnames, and the main route table is configured with a route to an internet gateway attached to the VPC.

For the subnets that you create in your VPCs, do one of the following to ensure that instances that you launch in these subnets have access to the internet:

- Configure an internet gateway. For more information, see **Connect to the internet using an internet gateway** in the Amazon VPC User Guide.
- Configure a public NAT gateway. For more information, see **Access the internet from a private subnet** in the Amazon VPC User Guide.

### SSH access to your instances

To connect to an instance, you must authorize SSH traffic to the instance from your network. You must also specify a key pair when you launch the instance and specify the .pem file when you connect to the instance. For more information, see **Locate the private key and set permissions** (p. 814).

### Shared subnets

When launching EC2 instances into shared VPC subnets, note the following:

- Participants can run instances in a shared VPC subnet by passing in the shared subnet ID. If participants want to pass in a security group ID or network interface ID when they run an instance, the participant must own the security group or network interface.
- Participants can start, stop, terminate, and describe instances that they've created in a shared VPC subnet. Participants cannot start, stop, terminate, or describe instances created by the VPC owner in a shared VPC subnet.
- VPC owners cannot start, stop, terminate, or describe instances created by participants in a shared VPC subnet.

For more information see, **Share your VPC with other accounts** in the Amazon VPC User Guide.
IPv6-only subnets

An EC2 instance launched in an IPv6-only subnet receives an IPv6 address but not an IPv4 address. Any instances that you launch into an IPv6-only subnet must be instances built on the Nitro System (p. 295).
Code examples for Amazon EC2 using AWS SDKs

The following code examples show how to use Amazon EC2 with an AWS software development kit (SDK).

*Actions* are code excerpts from larger programs and must be run in context. While actions show you how to call individual service functions, you can see actions in context in their related scenarios and cross-service examples.

*Scenarios* are code examples that show you how to accomplish a specific task by calling multiple functions within the same service.

For a complete list of AWS SDK developer guides and code examples, see *Using Amazon EC2 with an AWS SDK* (p. 22). This topic also includes information about getting started and details about previous SDK versions.

Get started

Hello Amazon EC2

The following code examples show how to get started using Amazon EC2.

.NET

AWS SDK for .NET

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
namespace EC2Actions;
public class HelloEc2
{
    /// <summary>
    /// HelloEc2 lists the existing security groups for the default users.
    /// </summary>
    /// <param name="args">Command line arguments</param>
    /// <returns>A Task object.</returns>
    static async Task Main(string[] args)
    {
        // Set up dependency injection for Amazon Elastic Compute Cloud (Amazon EC2).
            .ConfigureServices((_, services) =>
                services.AddAWSService<IAmazonEC2>()
                .AddTransient<EC2Wrapper>()
            )
            .Build();
        // Set up credentials
        var credentials = await host.UseSerilog().RunExceptionCaptureTask(async c =>
```

1596
.Build();

// Now the client is available for injection.
var ec2Client = host.Services.GetRequiredService<IAmazonEC2>();

var request = new DescribeSecurityGroupsRequest
{
    MaxResults = 10,
};

// Retrieve information about up to 10 Amazon EC2 security groups.
var response = await ec2Client.DescribeSecurityGroupsAsync(request);

// Now print the security groups returned by the call to
// DescribeSecurityGroupsAsync.
Console.WriteLine("Security Groups:");
response.SecurityGroups.ForEach(group =>
{
    Console.WriteLine($"Security group: {group.GroupName} ID:
{group.GroupId}"));
});

• For API details, see DescribeSecurityGroups in AWS SDK for .NET API Reference.

C++

SDK for C++

Note
There’s more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Code for the CMakeLists.txt CMake file.

```cmake
# Set the minimum required version of CMake for this project.
cmake_minimum_required(VERSION 3.13)

# Set the AWS service components used by this project.
set(SERVICE_COMPONENTS ec2)

# Set this project's name.
project("hello_ec2")

# Set the C++ standard to use to build this target.
# At least C++ 11 is required for the AWS SDK for C++.
set(CMAKE_CXX_STANDARD 11)

# Use the MSVC variable to determine if this is a Windows build.
set(WINDOWS_BUILD ${MSVC})

if (WINDOWS_BUILD) # Set the location where CMake can find the installed libraries
    string(REPLACE ";" ";aws-cpp-sdk-all;" SYSTEM_MODULE_PATH
    ";${CMAKE_SYSTEM_PREFIX_PATH}/aws-cpp-sdk-all"
    list(APPEND CMAKE_PREFIX_PATH ${SYSTEM_MODULE_PATH}))
endif()

# Find the AWS SDK for C++ package.
find_package(AWSSDK REQUIRED COMPONENTS ${SERVICE_COMPONENTS})
```
if (WINDOWS_BUILD)

     # Copy relevant AWS SDK for C++ libraries into the current binary directory
     # for running and debugging.

     # set(BIN_SUB_DIR "/*/Debug") # If you are building from the command line, you
     # may need to uncomment this

     AWSSDK_CPY_DYN_LIBS(SERVICE_COMPONENTS ""
        ${CMAKE_CURRENT_BINARY_DIR} ${BIN_SUB_DIR})
endif()

add_executable(${PROJECT_NAME}
    hello_ec2.cpp)

target_link_libraries(${PROJECT_NAME}
    ${AWSSDK_LINK_LIBRARIES})

Code for the hello_ec2.cpp source file.

#include <aws/core/Aws.h>
#include <aws/ec2/EC2Client.h>
#include <aws/ec2/model/DescribeInstancesRequest.h>
#include <iomanip>
#include <iostream>

/*

Actions for Amazon EC2 using AWS SDKs

The following code examples demonstrate how to perform individual Amazon EC2 actions with AWS SDKs. These excerpts call the Amazon EC2 API and are code excerpts from larger programs that must be run in context. Each example includes a link to GitHub, where you can find instructions for setting up and running the code.

The following examples include only the most commonly used actions. For a complete list, see the Amazon Elastic Compute Cloud (Amazon EC2) API Reference.
Examples

- **Add tags to Amazon EC2 resources using an AWS SDK (p. 1604)**
- **Allocate an Elastic IP address for Amazon EC2 using an AWS SDK (p. 1606)**
- **Associate an Elastic IP address with an Amazon EC2 instance using an AWS SDK (p. 1613)**
- **Create a Amazon Virtual Private Cloud (Amazon VPC) (p. 1619)**
- **Create an Amazon EC2 launch template using an AWS SDK (p. 1620)**
- **Create a route table in Amazon Virtual Private Cloud (Amazon VPC) and associate it with a subnet (p. 1625)**
- **Create an Amazon EC2 security group using an AWS SDK (p. 1628)**
- **Create a security key pair for Amazon EC2 using an AWS SDK (p. 1639)**
- **Associate an Elastic IP address with an Amazon EC2 instance using an AWS SDK (p. 1647)**
- **Create and run an Amazon EC2 instance using an AWS SDK (p. 1649)**
- **Delete an Amazon EC2 launch template using an AWS SDK (p. 1660)**
- **Delete an Amazon EC2 security group using an AWS SDK (p. 1662)**
- **Delete an Amazon EC2 security key pair using an AWS SDK (p. 1667)**
- **Delete the Amazon EBS snapshot using an AWS SDK (p. 1672)**
- **Describe the Availability Zones for your account using an AWS SDK (p. 1673)**
- **Describes the Regions for your account using an AWS SDK (p. 1676)**
- **Describes the status of Amazon EC2 instances using an AWS SDK (p. 1685)**
- **Describe Amazon EC2 instances using an AWS SDK (p. 1687)**
- **Describe one or more Amazon EBS snapshots using an AWS SDK (p. 1702)**
- **Disable detailed monitoring for an Amazon EC2 instance using an AWS SDK (p. 1705)**
- **Disassociate an Elastic IP address from an Amazon EC2 instance using an AWS SDK (p. 1707)**
- **Enables monitoring for a running Amazon EC2 instance using an AWS SDK (p. 1711)**
- **Get data about Amazon Machine Images using an AWS SDK (p. 1714)**
- **Get data about an Amazon EC2 security group using an AWS SDK (p. 1717)**
- **Get data about Amazon EC2 instance types using an AWS SDK (p. 1724)**
- **Get data about the instance profile associated with an Amazon EC2 instance using an AWS SDK (p. 1730)**
- **Get details about Elastic IP addresses using an AWS SDK (p. 1733)**
- **Get the default VPC using an AWS SDK (p. 1737)**
- **Get the default subnets for a VPC using an AWS SDK (p. 1740)**
- **List Amazon EC2 security key pairs using an AWS SDK (p. 1745)**
- **Reboot an Amazon EC2 instance using an AWS SDK (p. 1750)**
- **Release an Elastic IP address using an AWS SDK (p. 1755)**
- **Replace the instance profile associated with an Amazon EC2 instance using an AWS SDK (p. 1760)**
- **Set inbound rules for an Amazon EC2 security group using an AWS SDK (p. 1763)**
- **Start an Amazon EC2 instance using an AWS SDK (p. 1773)**
- **Stop an Amazon EC2 instance using an AWS SDK (p. 1780)**
- **Terminate an Amazon EC2 instance using an AWS SDK (p. 1788)**

Add tags to Amazon EC2 resources using an AWS SDK

The following code examples show how to add tags to Amazon EC2 resources.
C++

SDK for C++

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```cpp
Aws::EC2::EC2Client ec2Client(clientConfiguration);
Aws::EC2::Model::Tag nameTag;
nameTag.SetKey("Name");
nameTag.SetValue(instanceName);

Aws::EC2::Model::CreateTagsRequest createRequest;
createRequest.AddResources(instanceID);
createRequest.AddTags(nameTag);

Aws::EC2::Model::CreateTagsOutcome createOutcome = ec2Client.CreateTags(createRequest);
if (!createOutcome.IsSuccess()) {
    std::cerr << "Failed to tag ec2 instance " << instanceID << " with name " << instanceName << ": " << createOutcome.GetError().GetMessage() << std::endl;
    return false;
}
```

- For API details, see CreateTags in AWS SDK for C++ API Reference.

CLI

AWS CLI

To add a tag to a resource

The following create-tags example adds the tag Stack=production to the specified image, or overwrites an existing tag for the AMI where the tag key is Stack.

```
aws ec2 create-tags --resources ami-1234567890abcdef0 --tags Key=Stack,Value=production
```

To add tags to multiple resources

The following create-tags example adds (or overwrites) two tags for an AMI and an instance. One of the tags has a key (webserver) but no value (value is set to an empty string). The other tag has a key (stack) and a value (Production).

```
aws ec2 create-tags --resources ami-1a2b3c4d i-1234567890abcdef0 --tags Key=webserver,Value= Key=stack,Value=Production
```

To add tags containing special characters

The following create-tags example adds the tag [Group]=test for an instance. The square brackets ([ and ]) are special characters, and must be escaped. The following examples also use the line continuation character appropriate for each environment.
Allocate an Elastic IP address

If you are using Windows, surround the element that has special characters with double quotes ("), and then precede each double quote character with a backslash (\) as follows:

```bash
aws ec2 create-tags ^
   --resources i-1234567890abcdef0 ^
   --tags Key="[Group]\",Value=test
```

If you are using Windows PowerShell, element the value that has special characters with double quotes ("), precede each double quote character with a backslash (\), and then surround the entire key and value structure with single quotes (') as follows:

```bash
aws ec2 create-tags `^
   --resources i-1234567890abcdef0 `^
   --tags 'Key="[Group]\",Value=test'
```

If you are using Linux or OS X, surround the element that has special characters with double quotes ("), and then surround the entire key and value structure with single quotes (') as follows:

```bash
aws ec2 create-tags \\n   --resources i-1234567890abcdef0 \\n   --tags 'Key="[Group]\",Value=test'
```

- For API details, see CreateTags in AWS CLI Command Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Amazon EC2 with an AWS SDK (p. 22). This topic also includes information about getting started and details about previous SDK versions.

### Allocate an Elastic IP address for Amazon EC2 using an AWS SDK

The following code examples show how to allocate an Elastic IP address for Amazon EC2.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with instances (p. 1871)

#### .NET

**AWS SDK for .NET**

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
/// <summary>
/// Allocate an Elastic IP address.
/// </summary>
/// <returns>The allocation Id of the allocated address.</returns>
public async Task<string> AllocateAddress()
```
Allocate an Elastic IP address

```javascript
{  
    var request = new AllocateAddressRequest();
    var response = await _amazonEC2.AllocateAddressAsync(request);
    return response.AllocationId;
}
```

- For API details, see [AllocateAddress](#) in AWS SDK for .NET API Reference.

C++

SDK for C++

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```cpp
Aws::EC2::EC2Client ec2Client(clientConfiguration);

Aws::EC2::Model::AllocateAddressRequest request;
request.SetDomain(Aws::EC2::Model::DomainType::vpc);
const Aws::EC2::Model::AllocateAddressOutcome outcome = ec2Client.AllocateAddress(request);
if (!outcome.IsSuccess()) {
    std::cerr << "Failed to allocate Elastic IP address:" << outcome.GetError().GetMessage() << std::endl;
    return false;
}

allocationId = outcome.GetResult().GetAllocationId();
```

- For API details, see [AllocateAddress](#) in AWS SDK for C++ API Reference.

CLI

AWS CLI

**Example 1: To allocate an Elastic IP address from Amazon's address pool**

The following `allocate-address` example allocates an Elastic IP address. Amazon EC2 selects the address from Amazon's address pool.

```bash
aws ec2 allocate-address
```

Output:

```json
{
    "PublicIp": "70.224.234.241",
    "AllocationId": "eipalloc-01435ba59eEXAMPLE",
    "PublicIpv4Pool": "amazon",
    "NetworkBorderGroup": "us-west-2",
    "Domain": "vpc"
}
```
Allocate an Elastic IP address

For more information, see Elastic IP addresses in the Amazon EC2 User Guide.

Example 2: To allocate an Elastic IP address and associate it with a network border group

The following allocate-address example allocates an Elastic IP address and associates it with the specified network border group.

```bash
aws ec2 allocate-address \
  --network-border-group us-west-2-lax-1
```

Output:

```
{
  "PublicIp": "70.224.234.241",
  "AllocationId": "eipalloc-e03dd489ceEXAMPLE",
  "PublicIpv4Pool": "amazon",
  "NetworkBorderGroup": "us-west-2-lax-1",
  "Domain": "vpc"
}
```

For more information, see Elastic IP addresses in the Amazon EC2 User Guide.

Example 3: To allocate an Elastic IP address from an address pool that you own

The following allocate-address example allocates an Elastic IP address from an address pool that you have brought to your Amazon Web Services account. Amazon EC2 selects the address from the address pool.

```bash
aws ec2 allocate-address \
  --public-ipv4-pool ipv4pool-ec2-1234567890abcdef0
```

Output:

```
{
  "AllocationId": "eipalloc-02463d08ceEXAMPLE",
  "NetworkBorderGroup": "us-west-2",
  "CustomerOwnedIp": "18.218.95.81",
  "CustomerOwnedIpv4Pool": "ipv4pool-ec2-1234567890abcdef0",
  "Domain": "vpc"
  "NetworkBorderGroup": "us-west-2",
}
```

For more information, see Elastic IP addresses in the Amazon EC2 User Guide.

- For API details, see AllocateAddress in AWS CLI Command Reference.

CLI

AWS CLI

To associate an Elastic IP addresses in EC2-Classic

This example associates an Elastic IP address with an instance in EC2-Classic. If the command
succeeds, no output is returned.

Command:

aws ec2 associate-address --instance-id i-07ffe74c7330ebf53 --public-ip
198.51.100.0

To associate an Elastic IP address in EC2-VPC

This example associates an Elastic IP address with an instance in a VPC.

Command:

aws ec2 associate-address --instance-id i-0b263919b6498b123 --allocation-id
eipalloc-64d5890a

Output:

{
    "AssociationId": "eipassoc-2bebb745"
}

This example associates an Elastic IP with a private IP address that's associated with a network
interface.

Command:

aws ec2 associate-address --allocation-id eipalloc-64d5890a --network-interface-id
eni-1a2b3c4d

This example associates an Elastic IP with a private IP address that's associated with a network
interface.
Command:

```
aws ec2 associate-address --allocation-id eipalloc-64d5890a --network-interface-id eni-1a2b3c4d --private-ip-address 10.0.0.85
```

- For API details, see `AssociateAddress` in *AWS CLI Command Reference*.

Create a Amazon Virtual Private Cloud (Amazon VPC)

The following code example shows how to create a Amazon Virtual Private Cloud (Amazon VPC).

Ruby

SDK for Ruby

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```ruby
require "aws-sdk-ec2"

# Creates a virtual private cloud (VPC) in
# Amazon Virtual Private Cloud (Amazon VPC) and then tags
# the VPC.
#
# @param ec2_resource [Aws::EC2::Resource] An initialized
#   Amazon Elastic Compute Cloud (Amazon EC2) resource object.
# @param cidr_block [String] The IPv4 CIDR block for the subnet.
# @param tag_key [String] The key portion of the tag for the VPC.
# @param tag_value [String] The value portion of the tag for the VPC.
# @return [Boolean] true if the VPC was created and tagged;
#   otherwise, false.
# @example
#   exit 1 unless vpc_created_and_tagged?(    
#     Aws::EC2::Resource.new(region: 'us-west-2'),
#     '10.0.0.0/24',
#     'my-key',
#     'my-value'
#   )
#   
#   def vpc_created_and_tagged?(ec2_resource, cidr_block, tag_key, tag_value)
#     vpc = ec2_resource.create_vpc(cidr_block: cidr_block)
#     
#     # Create a public DNS by enabling DNS support and DNS hostnames.
#     vpc.modify_attribute(enable_dns_support: { value: true })
#     vpc.modify_attribute(enable_dns_hostnames: { value: true })
#     
#     vpc.create_tags(tags: [{ key: tag_key, value: tag_value }])
#     puts "Created VPC with ID '#{vpc.id}' and tagged with key "    
#         "#{tag_key}' and value '#{tag_value}'."
#     return true
#     rescue StandardError => e
#     puts "#{e.message}"
#     return false
#   end
#   
#   # Full example call:
#   def run_me
#     cidr_block = ""
#     tag_key = ""
#     tag_value = ""
#     region = ""
#     # Print usage information and then stop.
#     if ARGV[0] == "--help" || ARGV[0] == "-h"
```
puts "Usage: ruby ec2-ruby-example-create-vpc.rb " \
"CIDR_BLOCK TAG_KEY TAG_VALUE REGION"
# Replace us-west-2 with the AWS Region you're using for Amazon EC2.
puts "Example: ruby ec2-ruby-example-create-vpc.rb " \
"10.0.0.0/24 my-key my-value us-west-2"
exit 1
# If no values are specified at the command prompt, use these default values.
elsif ARGV.count.zero?
cidr_block = "10.0.0.0/24"
tag_key = "my-key"
tag_value = "my-value"
# Replace us-west-2 with the AWS Region you're using for Amazon EC2.
region = "us-west-2"
# Otherwise, use the values as specified at the command prompt.
else
cidr_block = ARGV[0]
tag_key = ARGV[1]
tag_value = ARGV[2]
region = ARGV[3]
end
ec2_resource = Aws::EC2::Resource.new(region: region)
if vpc_created_and_tagged?(ec2_resource,
cidr_block,
tag_key,
tag_value)
  puts "VPC created and tagged."
else
  puts "VPC not created or not tagged."
end
run_me if $PROGRAM_NAME == __FILE__

• For API details, see CreateVpc in AWS SDK for Ruby API Reference.

For a complete list of AWS SDK developer guides and code examples, see Using Amazon EC2 with an AWS SDK (p. 22). This topic also includes information about getting started and details about previous SDK versions.

Create an Amazon EC2 launch template using an AWS SDK

The following code examples show how to create an Amazon EC2 launch template.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

• Build and manage a resilient service (p. 1794)

CLI

AWS CLI

Example 1: To create a launch template
The following `create-launch-template` example creates a launch template that specifies the subnet in which to launch the instance, assigns a public IP address and an IPv6 address to the instance, and creates a tag for the instance.

```
aws ec2 create-launch-template \
  --launch-template-name TemplateForWebServer \
  --version-description WebVersion1 \
  --launch-template-data '{"NetworkInterfaces": [{"AssociatePublicIpAddress":true,"DeviceIndex":0,"Ipv6AddressCount":1,"SubnetId":"subnet-7b16de0c"}],"ImageId":"ami-8c1be5f6","InstanceType":"t2.small","TagSpecifications": [{"ResourceType":"instance","Tags": [{"Key":"purpose","Value":"webserver"}]]}'}
```

Output:

```
{
  "LaunchTemplate": {
    "LatestVersionNumber": 1,
    "LaunchTemplateId": "lt-01238c059e3466abc",
    "LaunchTemplateName": "TemplateForWebServer",
    "DefaultVersionNumber": 1,
    "CreatedBy": "arn:aws:iam::123456789012:user/Bob",
    "CreateTime": "2019-01-27T09:13:24.000Z"
  }
}
```

For more information, see Launching an Instance from a Launch Template in the Amazon Elastic Compute Cloud User Guide. For information about quoting JSON-formatted parameters, see Quoting Strings in the AWS Command Line Interface User Guide.

**Example 2: To create a launch template for Amazon EC2 Auto Scaling**

The following `create-launch-template` example creates a launch template with multiple tags and a block device mapping to specify an additional EBS volume when an instance launches. Specify a value for Groups that corresponds to security groups for the VPC that your Auto Scaling group will launch instances into. Specify the VPC and subnets as properties of the Auto Scaling group.

```
aws ec2 create-launch-template \
  --launch-template-name TemplateForAutoScaling \
  --version-description AutoScalingVersion1 \
  --launch-template-data '{"NetworkInterfaces": [{"DeviceIndex":0,"AssociatePublicIpAddress":true,"Groups": ["sg-7c227019,sg-903004f8"],"DeleteOnTermination":true}],"ImageId":"ami-b42209de","InstanceType":"m4.large","TagSpecifications": [{"ResourceType":"instance","Tags": [{"Key":"environment","Value":"production"},{"Key":"purpose","Value":"webserver"}],"ResourceType":"volume","Tags": [{"Key":"environment","Value":"production"},{"Key":"cost-center","Value":"cc123"}],"BlockDeviceMappings": [{"DeviceName":"/dev/sda1","Ebs": {"VolumeSize":100}}]}}' --region us-east-1
```

Output:

```
{
  "LaunchTemplate": {
    "LatestVersionNumber": 1,
    "LaunchTemplateId": "lt-0123c79c33a54e0abc",
    "LaunchTemplateName": "TemplateForAutoScaling",
    "DefaultVersionNumber": 1,
    "CreatedBy": "arn:aws:iam::123456789012:user/Bob",
    "CreateTime": "2019-04-30T09:13:24.000Z"
  }
}
```
Create a launch template

For more information, see Creating a Launch Template for an Auto Scaling Group in the Amazon EC2 Auto Scaling User Guide. For information about quoting JSON-formatted parameters, see Quoting Strings in the AWS Command Line Interface User Guide.

Example 3: To create a launch template that specifies encryption of EBS volumes

The following `create-launch-template` example creates a launch template that includes encrypted EBS volumes created from an unencrypted snapshot. It also tags the volumes during creation. If encryption by default is disabled, you must specify the "Encrypted" option as shown in the following example. If you use the "KmsKeyId" option to specify a customer managed CMK, you also must specify the "Encrypted" option even if encryption by default is enabled.

```bash
aws ec2 create-launch-template \
--launch-template-name TemplateForEncryption \
--launch-template-data file://config.json
```

Contents of `config.json`:

```json
{
   "BlockDeviceMappings": [
      {
         "DeviceName": "/dev/sda1",
         "Ebs": {
            "VolumeType": "gp2",
            "DeleteOnTermination": true,
            "SnapshotId": "snap-066877671789bd71b",
            "Encrypted": true,
            "KmsKeyId": "arn:aws:kms:us-east-1:012345678910:key/abcd1234-a123-456a-a12b-a123b4cd56ef"
         }
      }
   ],
   "ImageId": "ami-00068cd7555f543d5",
   "InstanceType": "c5.large",
   "TagSpecifications": [
      {
         "ResourceType": "volume",
         "Tags": [
            {
               "Key": "encrypted",
               "Value": "yes"
            }
         ]
      }
   ]
}
```

Output:

```json
{
   "LaunchTemplate": {
      "LatestVersionNumber": 1,

Python

SDK for Python (Boto3)

**Note**
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

This example creates a launch template that includes an instance profile that grants specific permissions to the instance, and a user data Bash script that runs on the instance after it starts.

```python
class AutoScaler:
    
    """
    Encapsulates Amazon EC2 Auto Scaling and EC2 management actions.
    """

    def __init__(
```
Create a launch template

```python
self,
resource_prefix,
inst_type,
ami_param,
autoscaling_client,
ec2_client,
ssm_client,
iam_client,
):
    
    :param resource_prefix: The prefix for naming AWS resources that are
created by this class.
    :param inst_type: The type of EC2 instance to create, such as t3.micro.
    :param ami_param: The Systems Manager parameter used to look up the AMI
that is
created.
    :param ssm_client: A Boto3 Systems Manager client.
    :param iam_client: A Boto3 IAM client.
    
    self.inst_type = inst_type
    self.ami_param = ami_param
    self.autoscaling_client = autoscaling_client
    self.ec2_client = ec2_client
    self.ssm_client = ssm_client
    self.iam_client = iam_client
    
    self.launch_template_name = f"{resource_prefix}-template"
    self.group_name = f"{resource_prefix}-group"
    self.instance_policy_name = f"{resource_prefix}-pol"
    self.instance_role_name = f"{resource_prefix}-role"
    self.instance_profile_name = f"{resource_prefix}-prof"
    self.bad_creds_policy_name = f"{resource_prefix}-bc-pol"
    self.bad_creds_role_name = f"{resource_prefix}-bc-role"
    self.bad_creds_profile_name = f"{resource_prefix}-bc-prof"
    self.key_pair_name = f"{resource_prefix}-key-pair"
    
    def create_template(self, server_startup_script_file, instance_policy_file):
        ""
        Creates an Amazon EC2 launch template to use with Amazon EC2 Auto Scaling.
        The
        launch template specifies a Bash script in its user data field that runs
        after
        the instance is started. This script installs Python packages and starts a
        Python web server on the instance.
        :param server_startup_script_file: The path to a Bash script file that is
run
        when an instance starts.
        :param instance_policy_file: The path to a file that defines a permissions
policy
        to create and attach to the instance profile.
        :return: Information about the newly created template.
        ""
        template = {}
        try:
            self.create_key_pair(self.key_pair_name)
            self.create_instance_profile(
                instance_policy_file,
                self.instance_policy_name,
                self.instance_role_name,
                self.instance_profile_name,
            )
            with open(server_startup_script_file) as file:
                start_server_script = file.read()
```
Create a route table in Amazon Virtual Private Cloud (Amazon VPC) and associate it with a subnet

The following code example shows how to create route table and associate with Amazon EC2 subnet.

Ruby

```ruby
require "aws-sdk-ec2"

ami_latest = self.ssm_client.get_parameter(Name=self.ami_param)
ami_id = ami_latest["Parameter"]
lt_response = self.ec2_client.create_launch_template(
    LaunchTemplateName=self.launch_template_name,
    LaunchTemplateData={
        "InstanceType": self.inst_type,
        "ImageId": ami_id,
        "IamInstanceProfile": {"Name": self.instance_profile_name},
        "UserData": base64.b64encode(
            start_server_script.encode(encoding="utf-8")
        ).decode(encoding="utf-8"),
        "KeyName": self.key_pair_name,
    },
)
template = lt_response["LaunchTemplate"]
log.info("Created launch template %s for AMI %s on %s.",
    self.launch_template_name,
    ami_id,
    self.inst_type,
)
except ClientError as err:
    if (err.response["Error"]
        "Code"
    ) == "InvalidLaunchTemplateName.AlreadyExistsException"
    ): log.info("Launch template %s already exists, nothing to do.",
        self.launch_template_name,
    )
    else:
        raise AutoScalerError(f"Couldn't create launch template {self.launch_template_name}:
            {err}.
    )
    return template
```

Create an Amazon EC2 security group using an AWS SDK

The following code examples show how to create an Amazon EC2 security group.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with instances (p. 1871)

.NET

AWS SDK for .NET

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
/// <summary>
/// Create an Amazon EC2 security group.
/// </summary>
/// <param name="groupName">The name for the new security group.</param>
/// <param name="groupDescription">A description of the new security group.</param>
/// <returns>The group Id of the new security group.</returns>
public async Task<string> CreateSecurityGroup(string groupName, string groupDescription)
{
    var response = await _amazonEC2.CreateSecurityGroupAsync(new CreateSecurityGroupRequest(groupName, groupDescription));
    return response.GroupId;
}
```

• For API details, see CreateSecurityGroup in AWS SDK for .NET API Reference.

C++

SDK for C++

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```cpp
Aws::EC2::EC2Client ec2Client(clientConfiguration);

Aws::EC2::Model::CreateSecurityGroupRequest request;
request.SetGroupName(groupName);
request.SetDescription(description);
request.SetVpcId(vpcID);

const Aws::EC2::Model::CreateSecurityGroupOutcome outcome = ec2Client.CreateSecurityGroup(request);
if (!outcome.IsSuccess()) {

```

1628
std::cerr << "Failed to create security group:" << outcome.GetError().GetMessage() << std::endl;
return false;
}
std::cout << "Successfully created security group named " << groupName << std::endl;

• For API details, see CreateSecurityGroup in AWS SDK for C++ API Reference.

CLI

AWS CLI

To create a security group for EC2-Classic
This example creates a security group named MySecurityGroup.

Command:

aws ec2 create-security-group --group-name MySecurityGroup --description "My security group"

Output:

{
  "GroupId": "sg-903004f8"
}

To create a security group for EC2-VPC
This example creates a security group named MySecurityGroup for the specified VPC.

Command:

aws ec2 create-security-group --group-name MySecurityGroup --description "My security group" --vpc-id vpc-1a2b3c4d

Output:

{
  "GroupId": "sg-903004f8"
}

For more information, see Using Security Groups in the AWS Command Line Interface User Guide.

• For API details, see CreateSecurityGroup in AWS CLI Command Reference.

Create a security key pair

1. **For API details, see** [CreateKeyPair](https://docs.aws.amazon.com/sdk-for-cpp/api/latest/class Aws::EC2::Model::CreateKeyPairRequest.html) in **AWS SDK for C++ API Reference**.

**CLI**

**AWS CLI**

**To create a key pair**

This example creates a key pair named `MyKeyPair`.

**Command:**

```bash
aws ec2 create-key-pair --key-name MyKeyPair
```

The output is an ASCII version of the private key and key fingerprint. You need to save the key to a file.

For more information, see Using Key Pairs in the [AWS Command Line Interface User Guide](https://docs.aws.amazon.com/cli/latest/index.html).

- **For API details, see** [CreateKeyPair](https://docs.aws.amazon.com/cli/latest/index.html) in **AWS CLI Command Reference**.

Create and tag a subnet in Amazon Virtual Private Cloud (Amazon VPC)

The following code example shows how to create an Amazon EC2 subnet.

Ruby

SDK for Ruby

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```ruby
require "aws-sdk-ec2"

# Creates a subnet within a virtual private cloud (VPC) in
# Amazon Virtual Private Cloud (Amazon VPC) and then tags
# the subnet.
#
# Prerequisites:
#
# - A VPC in Amazon VPC.
#
# @param ec2_resource [Aws::EC2::Resource] An initialized
#   Amazon Elastic Compute Cloud (Amazon EC2) resource object.
# @param vpc_id [String] The ID of the VPC for the subnet.
# @param cidr_block [String] The IPv4 CIDR block for the subnet.
# @param availability_zone [String] The ID of the Availability Zone
#   for the subnet.
# @param tag_key [String] The key portion of the tag for the subnet.
# @param tag_value [String] The value portion of the tag for the subnet.
```

For a complete list of AWS SDK developer guides and code examples, see Using Amazon EC2 with an AWS SDK (p. 22). This topic also includes information about getting started and details about previous SDK versions.

Create and run an Amazon EC2 instance using an AWS SDK

The following code examples show how to create and run an Amazon EC2 instance.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

• Get started with instances (p. 1871)

.NET

AWS SDK for .NET

Note
There’s more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

/// <summary>
/// Create and run an EC2 instance.
/// </summary>
/// <param name="ImageId">The image Id of the image used as a basis for the
Create and run an instance

```csharp
public async Task<string> RunInstances(string imageId, string instanceType,
string keyName, string groupId)
{
    var request = new RunInstancesRequest
    {
        ImageId = imageId,
        InstanceType = instanceType,
        KeyName = keyName,
        MinCount = 1,
        MaxCount = 1,
        SecurityGroupIds = new List<string> { groupId }
    };
    var response = await _amazonEC2.RunInstancesAsync(request);
    return response.Reservation.Instances[0].InstanceId;
}
```

• For API details, see `RunInstances` in *AWS SDK for .NET API Reference*.

### C++

**SDK for C++**

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the *AWS Code Examples Repository*.

```cpp
Aws::EC2::EC2Client ec2Client(clientConfiguration);

Aws::EC2::Model::RunInstancesRequest runRequest;
runRequest.SetImageId(amiId);
runRequest.SetInstanceType(Aws::EC2::Model::InstanceType::t1_micro);
runRequest.SetMinCount(1);
runRequest.SetMaxCount(1);
Aws::EC2::Model::RunInstancesOutcome runOutcome = ec2Client.RunInstances(
runRequest);
if (!runOutcome.IsSuccess()) {
    std::cerr << "Failed to launch EC2 instance " << instanceName << " based on ami " << amiId << ":" << runOutcome.GetError().GetMessage() << std::endl;
    return false;
}

const Aws::Vector<Aws::EC2::Model::Instance> &instances = runOutcome.GetResult().GetInstances();
if (instances.empty()) {
    std::cerr << "Failed to launch EC2 instance " << instanceName << " based on ami " << amiId << ":" << runOutcome.GetError().GetMessage() << std::endl;
    return false;
}

instanceID = instances[0].GetInstanceId();
```
Create and run an instance

• For API details, see RunInstances in AWS SDK for C++ API Reference.

CLI

AWS CLI

Example 1: To launch an instance into a default subnet

The following run-instances example launches a single instance of type t2.micro into the default subnet for the current Region and associates it with the default subnet for the default VPC for the Region. The key pair is optional if you do not plan to connect to your instance using SSH (Linux) or RDP (Windows).

```
aws ec2 run-instances \
   --image-id ami-0abcdef1234567890 \n   --instance-type t2.micro \n   --key-name MyKeyPair
```

Output:

```
{
   "Instances": [
      {"AmiLaunchIndex": 0,
       "ImageId": "ami-0abcdef1234567890",
       "InstanceId": "i-1231231230abcdef0",
       "InstanceType": "t2.micro",
       "KeyName": "MyKeyPair",
       "LaunchTime": "2018-05-10T08:05:20.000Z",
       "Monitoring": {
          "State": "disabled"
       },
       "Placement": {
          "AvailabilityZone": "us-east-2a",
          "GroupName": "",
          "Tenancy": "default"
       },
       "PrivateDnsName": "ip-10-0-0-157.us-east-2.compute.internal",
       "PrivateIpAddress": "10.0.0.157",
       "ProductCodes": [],
       "PublicDnsName": "",
       "State": {
          "Code": 0,
          "Name": "pending"
       },
       "StateTransitionReason": "",
       "SubnetId": "subnet-04a636d18e83cfacb",
       "VpcId": "vpc-1234567890abcdef0",
       "Architecture": "x86_64",
       "BlockDeviceMappings": [],
       "ClientToken": "",
       "EbsOptimized": false,
       "Hypervisor": "xen",
       "NetworkInterfaces": [
          { "Attachment": {
             "AttachTime": "2018-05-10T08:05:20.000Z",
             "AttachmentId": "eni-attach-0e325c07e928a0405",
             "DeleteOnTermination": true,
          }
        ]
      ]
    }
```
Example 2: To launch an instance into a non-default subnet and add a public IP address

The following `run-instances` example requests a public IP address for an instance that you're launching into a nondefault subnet. The instance is associated with the specified security group.

```
aws ec2 run-instances \
  --image-id ami-0abcdef1234567890 \
  --instance-type t2.micro \
  --subnet-id subnet-08fc749671b2d077c \
  --security-group-ids sg-0b0384b66d7d692f9 \
  --associate-public-ip-address \
  --key-name MyKeyPair
```

For an example of the output for `run-instances`, see Example 1.

Example 3: To launch an instance with additional volumes

The following `run-instances` example uses a block device mapping, specified in `mapping.json`, to attach additional volumes at launch. A block device mapping can specify EBS volumes, instance store volumes, or both EBS volumes and instance store volumes.

```
aws ec2 run-instances \
  --image-id ami-0abcdef1234567890 \
  --instance-type t2.micro \
  --subnet-id subnet-08fc749671b2d077c \
  --security-group-ids sg-0b0384b66d7d692f9 \
  --key-name MyKeyPair \
  --block-device-mappings file://mapping.json
```

Contents of `mapping.json`. This example adds `/dev/sdh` an empty EBS volume with a size of 100 GiB.

```
[
  {
    "DeviceName": "/dev/sdh",
    "Ebs": {
      "VolumeSize": 100
    }
  }
]
```

Contents of `mapping.json`. This example adds `ephemeral1` as an instance store volume.

```
[
  {
    "DeviceName": "/dev/sdc",
    "VirtualName": "ephemeral1"
  }
]
```

For an example of the output for `run-instances`, see Example 1.

For more information about block device mappings, see `Block device mapping` in the Amazon EC2 User Guide.

Example 4: To launch an instance and add tags on creation
The following `run-instances` example adds a tag with a key of `webserver` and value of `production` to the instance. The command also applies a tag with a key of `cost-center` and a value of `cc123` to any EBS volume that's created (in this case, the root volume).

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --instance-type t2.micro \
    --count 1 \
    --subnet-id subnet-08fc749671b2d077c \
    --key-name MyKeyPair \
    --security-group-ids sg-0b0584b66d7d692f9 \
    --tag-specifications
    'ResourceType=instance,Tags=[{Key=webserver,Value=production}]'
    'ResourceType=volume,Tags=[{Key=cost-center,Value=cc123}]'
```

For an example of the output for `run-instances`, see Example 1.

**Example 5: To launch an instance with user data**

The following `run-instances` example passes user data in a file called `my_script.txt` that contains a configuration script for your instance. The script runs at launch.

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --instance-type t2.micro \
    --count 1 \
    --subnet-id subnet-08fc749671b2d077c \
    --key-name MyKeyPair \
    --security-group-ids sg-0b0584b66d7d692f9 \
    --user-data file://my_script.txt
```

For an example of the output for `run-instances`, see Example 1.

For more information about instance user data, see Working with instance user data in the Amazon EC2 User Guide.

**Example 6: To launch a burstable performance instance**

The following `run-instances` example launches a t2.micro instance with the unlimited credit option. When you launch a T2 instance, if you do not specify `--credit-specification`, the default is the standard credit option. When you launch a T3 instance, the default is the unlimited credit option.

```
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --instance-type t2.micro \
    --count 1 \
    --subnet-id subnet-08fc749671b2d077c \
    --key-name MyKeyPair \
    --security-group-ids sg-0b0584b66d7d692f9 \
    --credit-specification CpuCredits=unlimited
```

For an example of the output for `run-instances`, see Example 1.

For more information about burstable performance instances, see Burstable performance instances in the Amazon EC2 User Guide.
• For API details, see RunInstances in AWS CLI Command Reference.

## Delete an Amazon EC2 security group using an AWS SDK

The following code examples show how to delete an Amazon EC2 security group.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Get started with instances](https://docs.aws.amazon.com/elasticloadbalancing/latest/elbiloadbalancerusersguide/GettingStarted.html) (p. 1871)

### .NET

**AWS SDK for .NET**

*Note*

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/aws-samples/aws-code-examples).
Delete a security group

C++

SDK for C++

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```cpp
Aws::EC2::EC2Client ec2Client(clientConfiguration);
Aws::EC2::Model::DeleteSecurityGroupRequest request;
request.SetGroupId(securityGroupID);
auto outcome = ec2Client.DeleteSecurityGroup(request);

if (!outcome.IsSuccess()) {
    std::cerr << "Failed to delete security group " << securityGroupID << ":" << outcome.GetError().GetMessage() << std::endl;
} else {
    std::cout << "Successfully deleted security group " << securityGroupID << std::endl;
}
```

For API details, see `DeleteSecurityGroup` in AWS SDK for C++ API Reference.

CLI

AWS CLI

[EC2-Classic] To delete a security group

This example deletes the security group named MySecurityGroup. If the command succeeds, no output is returned.

Command:

```
aws ec2 delete-security-group --group-name MySecurityGroup
```

[EC2-VPC] To delete a security group

This example deletes the security group with the ID sg-903004f8. Note that you can't reference a security group for EC2-VPC by name. If the command succeeds, no output is returned.

Command:

```
aws ec2 delete-security-group --group-id sg-903004f8
```
Delete a security group

For more information, see Using Security Groups in the AWS Command Line Interface User Guide.

- For API details, see DeleteSecurityGroup in AWS CLI Command Reference.

Java

SDK for Java 2.x

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

## Describe the Availability Zones for your account using an AWS SDK

The following code examples show how to describe Amazon EC2 Availability Zones.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- [Build and manage a resilient service (p. 1794)](https://aws.amazon.com/documentation/)

### C++

#### SDK for C++

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://aws.amazon.com/code-examples/).

```cpp
Aws::EC2::EC2Client ec2Client(clientConfiguration);
Aws::EC2::Model::DescribeAvailabilityZonesRequest describe_request;
auto describe_outcome = ec2Client.DescribeAvailabilityZones(describe_request);

if (describe_outcome.IsSuccess()) {
    std::cout << std::left <<
        std::setw(32) << "ZoneName" <<
        std::setw(20) << "State" <<
        std::setw(32) << "Region" << std::endl;
    const auto &zones =
        describe_outcome.GetResult().GetAvailabilityZones();
    for (const auto &zone: zones) {
        Aws::String stateString =
            Aws::EC2::Model::AvailabilityZoneStateMapper::GetNameForAvailabilityZoneState(
                zone.GetState());
        std::cout << std::left <<
            std::setw(32) << zone.GetZoneName() <<
            std::setw(20) << stateString <<
            std::setw(32) << zone.GetRegionName() << std::endl;
    }
} else {
    std::cerr << "Failed to describe availability zones:" <<
        describe_outcome.GetError().GetMessage() << std::endl;
    result = false;
}
```
• For API details, see DescribeAvailabilityZones in AWS SDK for C++ API Reference.

CLI

AWS CLI

To describe your Availability Zones

The following example describe-availability-zones displays details for the Availability Zones that are available to you. The response includes Availability Zones only for the current Region. In this example, it uses the profiles default us-west-2 (Oregon) Region.

aws ec2 describe-availability-zones

Output:

```json
{
   "AvailabilityZones": [
   {
      "State": "available",
      "OptInStatus": "opt-in-not-required",
      "Messages": [],
      "RegionName": "us-west-2",
      "ZoneName": "us-west-2a",

**Describes the Regions for your account using an AWS SDK**

The following code examples show how to describe Amazon EC2 Regions.

**C++**

**SDK for C++**

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
Describe Regions

```cpp
Aws::EC2::EC2Client ec2Client(clientConfiguration);

Aws::EC2::Model::DescribeRegionsRequest request;
auto outcome = ec2Client.DescribeRegions(request);
bool result = true;
if (outcome.IsSuccess()) {
    std::cout << std::left <<
    std::setw(32) << "RegionName" <<
    std::setw(64) << "Endpoint" << std::endl;

    const auto &regions = outcome.GetResult().GetRegions();
    for (const auto &region: regions) {
        std::cout << std::left <<
        std::setw(32) << region.GetRegionName() <<
        std::setw(64) << region.GetEndpoint() << std::endl;
    }
} else {
    std::cerr << "Failed to describe regions:" <<
    outcome.GetError().GetMessage() << std::endl;
    result = false;
}
```

- For API details, see DescribeRegions in AWS SDK for C++ API Reference.

CLI

**AWS CLI**

**Example 1: To describe all of your enabled Regions**

The following describe-regions example describes all of the Regions that are enabled for your account.

```
aws ec2 describe-regions
```

**Output:**

```json
{
    "Regions": [
        {
            "Endpoint": "ec2.eu-north-1.amazonaws.com",
            "RegionName": "eu-north-1",
            "OptInStatus": "opt-in-not-required"
        },
        {
            "Endpoint": "ec2.eu-west-3.amazonaws.com",
            "RegionName": "eu-west-3",
            "OptInStatus": "opt-in-not-required"
        },
        {
            "Endpoint": "ec2.eu-west-2.amazonaws.com",
            "RegionName": "eu-west-2",
            "OptInStatus": "opt-in-not-required"
        }
    ]
}
```
Describe Regions

1678
Example 2: To describe enabled Regions with an endpoint whose name contains a specific string

The following describe-regions example describes all Regions that you have enabled that have the string "us" in the endpoint.

```bash
aws ec2 describe-regions \
   --filters "Name=endpoint,Values=*us*"
```

Output:

```
{
"Regions": [
{
   "Endpoint": "ec2.us-east-1.amazonaws.com",
   "RegionName": "us-east-1"
},
{
   "Endpoint": "ec2.us-east-2.amazonaws.com",
   "RegionName": "us-east-2"
},
{
   "Endpoint": "ec2.us-west-1.amazonaws.com",
   "RegionName": "us-west-1"
},
{
   "Endpoint": "ec2.us-west-2.amazonaws.com",
   "RegionName": "us-west-2"
]
}
```

Example 3: To describe all Regions

The following describe-regions example describes all available Regions, including Regions that are disabled.

```bash
aws ec2 describe-regions \
   --all-regions
```

Output:

```
{
"Regions": [
{
   "Endpoint": "ec2.eu-north-1.amazonaws.com",
   "RegionName": "eu-north-1",
   "OptInStatus": "opt-in-not-required"
},
{
   "Endpoint": "ec2.ap-south-1.amazonaws.com",
   "RegionName": "ap-south-1"
}
}
```
"RegionName": "ap-south-1",
"OptInStatus": "opt-in-not-required"
},
{
"Endpoint": "ec2.eu-west-3.amazonaws.com",
"RegionName": "eu-west-3",
"OptInStatus": "opt-in-not-required"
},
{
"Endpoint": "ec2.eu-west-2.amazonaws.com",
"RegionName": "eu-west-2",
"OptInStatus": "opt-in-not-required"
},
{
"Endpoint": "ec2.eu-west-1.amazonaws.com",
"RegionName": "eu-west-1",
"OptInStatus": "opt-in-not-required"
},
{
"Endpoint": "ec2.ap-northeast-3.amazonaws.com",
"RegionName": "ap-northeast-3",
"OptInStatus": "opt-in-not-required"
},
{
"Endpoint": "ec2.me-south-1.amazonaws.com",
"RegionName": "me-south-1",
"OptInStatus": "not-opted-in"
},
{
"Endpoint": "ec2.ap-northeast-2.amazonaws.com",
"RegionName": "ap-northeast-2",
"OptInStatus": "opt-in-not-required"
},
{
"Endpoint": "ec2.ap-northeast-1.amazonaws.com",
"RegionName": "ap-northeast-1",
"OptInStatus": "opt-in-not-required"
},
{
"Endpoint": "ec2.sa-east-1.amazonaws.com",
"RegionName": "sa-east-1",
"OptInStatus": "opt-in-not-required"
},
{
"Endpoint": "ec2.ca-central-1.amazonaws.com",
"RegionName": "ca-central-1",
"OptInStatus": "not-opted-in"
},
{
"Endpoint": "ec2.ap-east-1.amazonaws.com",
"RegionName": "ap-east-1",
"OptInStatus": "not-opted-in"
},
{
"Endpoint": "ec2.ap-southeast-1.amazonaws.com",
"RegionName": "ap-southeast-1",
"OptInStatus": "opt-in-not-required"
},
{
"Endpoint": "ec2.ap-southeast-2.amazonaws.com",
"RegionName": "ap-southeast-2",
"OptInStatus": "opt-in-not-required"
},
{
"Endpoint": "ec2.eu-central-1.amazonaws.com",
"RegionName": "eu-central-1",
"OptInStatus": "opt-in-not-required"
}
For more information, see Regions and Zones in the Amazon EC2 User Guide.

Example 4: To list the Region names only

The following describe-regions example uses the --query parameter to filter the output and return only the names of the Regions as text.

```bash
aws ec2 describe-regions \
  --all-regions \
  --query "Regions[].{Name:RegionName}" \
  --output text
```

Output:

```
eu-north-1
ap-south-1
eu-west-3
eu-west-2
eu-west-1
ap-northeast-3
ap-northeast-2
me-south-1
ap-northeast-1
sa-east-1
can-central-1
ap-east-1
ap-southeast-1
ap-southeast-2
eu-central-1
us-east-1
us-east-2
us-west-1
us-west-2
```

For more information, see Regions and Zones in the Amazon EC2 User Guide.

- For API details, see DescribeRegions in AWS CLI Command Reference.
**JavaScript**

**SDK for JavaScript (v3)**

Example 2: To filter for instances with the specified type

The following describe-instances example uses filters to scope the results to instances of the specified type.

```bash
aws ec2 describe-instances \
--filters Name=instance-type,Values=m5.large
```

For example output, see Example 1.

For more information, see [List and filter using the CLI](https://docs.aws.amazon.com/cli/latest/reference/ec2/describe-instances.html) in the *Amazon EC2 User Guide*.

Example 3: To filter for instances with the specified type and Availability Zone

The following describe-instances example uses multiple filters to scope the results to instances with the specified type that are also in the specified Availability Zone.
aws ec2 describe-instances \
  --filters Name=instance-type,Values=t2.micro,t3.micro Name=availability-zone,Values=us-east-2c

For example output, see Example 1.

**Example 4: To filter for instances with the specified type and Availability Zone using a JSON file**

The following describe-instances example uses a JSON input file to perform the same filtering as the previous example. When filters get more complicated, they can be easier to specify in a JSON file.

aws ec2 describe-instances \
  --filters file://filters.json

Contents of filters.json:

```json
[
  {
    "Name": "instance-type",
    "Values": ["t2.micro", "t3.micro"]
  },
  {
    "Name": "availability-zone",
    "Values": ["us-east-2c"]
  }
]
```

For example output, see Example 1.

**Example 5: To filter for instances with the specified Owner tag**

The following describe-instances example uses tag filters to scope the results to instances that have a tag with the specified tag key (Owner), regardless of the tag value.

aws ec2 describe-instances \
  --filters "Name=tag-key,Values=Owner"

For example output, see Example 1.

**Example 6: To filter for instances with the specified my-team tag value**

The following describe-instances example uses tag filters to scope the results to instances that have a tag with the specified tag value (my-team), regardless of the tag key.

aws ec2 describe-instances \
  --filters "Name=tag-value,Values=my-team"

For example output, see Example 1.

**Example 7: To filter for instances with the specified Owner tag and my-team value**

The following describe-instances example uses tag filters to scope the results to instances that have the specified tag (Owner=my-team).
For example output, see Example 1.

**Example 8: To display only instance and subnet IDs for all instances**

The following `describe-instances` examples use the --query parameter to display only the instance and subnet IDs for all instances, in JSON format.

Linux and macOS:

```
aws ec2 describe-instances \
--query Reservations[*].Instances[*].{Instance:InstanceId,Subnet:SubnetId} \
--output json
```

Windows:

```
aws ec2 describe-instances ^
--query "Reservations[*].Instances[*].{Instance:InstanceId,Subnet:SubnetId}" ^
--output json
```

Output:

```
[
  {
    "Instance": "i-057750d42936e468a",
    "Subnet": "subnet-069beee9b12030077"
  },
  {
    "Instance": "i-001efd250faaa6ffa",
    "Subnet": "subnet-0b715c6b7db68927a"
  },
  {
    "Instance": "i-027552a73f021f3bd",
    "Subnet": "subnet-0250c25a1f4e15235"
  }
...
]
```

**Example 9: To filter instances of the specified type and only display their instance IDs**

The following `describe-instances` example uses filters to scope the results to instances of the specified type and the --query parameter to display only the instance IDs.

```
aws ec2 describe-instances \
--filters "Name=instance-type,Values=t2.micro" \
--query "Reservations[*].Instances[*].[InstanceId]" \
--output text
```

Output:

```
i-031c0dc19de2fb70c
```
Example 10: To filter instances of the specified type and only display their instance IDs, Availability Zone, and the specified tag value

The following describe-instances examples display the instance ID, Availability Zone, and the value of the Name tag for instances that have a tag with the name tag-key, in table format.

Linux and macOS:

```
aws ec2 describe-instances \
--filters Name=tag-key,Values=Name \n--query 'Reservations[*].Instances[*].\
{Instance:InstanceId,AZ:Placement.AvailabilityZone,Name:Tags[?Key==`Name`]|\n[0].Value} ' \
--output table
```

Example 11: To describe instances in a partition placement group

The following describe-instances example describes the specified instance. The output includes the placement information for the instance, which contains the placement group name and the partition number for the instance.

```
aws ec2 describe-instances \
--instance-ids i-0123a456700123456 \
--query "Reservations[*].Instances[*].Placement"
```

Output:

```
[
```
```
Describe instances

```json
[
    {
        "AvailabilityZone": "us-east-1c",
        "GroupName": "HDFS-Group-A",
        "PartitionNumber": 3,
        "Tenancy": "default"
    }
]
```

For more information, see [Describing instances in a placement group](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/using-placement-group-filtering.html) in the Amazon EC2 User Guide.

Example 12: To filter to instances with the specified placement group and partition number

The following `describe-instances` example filters the results to only those instances with the specified placement group and partition number.

```bash
aws ec2 describe-instances
    --filters "Name=placement-group-name,Values=HDFS-Group-A" "Name=placement-partition-number,Values=7"
```

The following shows only the relevant information from the output.

```json
"Instances": [
    {
        "InstanceId": "i-0123a456700123456",
        "InstanceType": "r4.large",
        "Placement": {
            "AvailabilityZone": "us-east-1c",
            "GroupName": "HDFS-Group-A",
            "PartitionNumber": 7,
            "Tenancy": "default"
        }
    },
    {
        "InstanceId": "i-9876a543210987654",
        "InstanceType": "r4.large",
        "Placement": {
            "AvailabilityZone": "us-east-1c",
            "GroupName": "HDFS-Group-A",
            "PartitionNumber": 7,
            "Tenancy": "default"
        }
    }
],
```

For more information, see [Describing instances in a placement group](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/using-placement-group-filtering.html) in the Amazon EC2 User Guide.

Example 13: To filter to instances that are configured to allow access to tags from instance metadata

The following `describe-instances` example filters the results to only those instances that are configured to allow access to instance tags from instance metadata.

```bash
aws ec2 describe-instances
    --filters "Name=metadata-options.instance-metadata-tags,Values=enabled"
```

1696
--query "Reservations[*].Instances[*].InstanceId" \
--output text

The following shows the expected output.

i-1234567890abcdefg
i-abcdefg1234567890
i-11111111aaaaaaaaa
i-aaaaaaaa111111111

For more information, see [Work with instance tags in instance metadata](link) in the [Amazon EC2 User Guide](link).

Describe one or more Amazon EBS snapshots using an AWS SDK

The following code examples show how to describe Amazon EBS snapshots.

**CLI**

**AWS CLI**

**Example 1: To describe a snapshot**

The following describe-snapshots example describes the specified snapshot.

```bash
aws ec2 describe-snapshots \ --snapshot-ids snap-1234567890abcdef0
```

**Output:**

```json
{
  "Snapshots": [
    {
      "Description": "This is my snapshot",
      "Encrypted": false,
      "VolumeId": "vol-049df61146c4d7901",
      "State": "completed",
      "VolumeSize": 8,
      "StartTime": "2019-02-28T21:28:32.000Z",
      "Progress": "100%",
      "OwnerId": "012345678910",
      "SnapshotId": "snap-01234567890abcdef",
      "Tags": [
        {
          "Key": "Stack",
          "Value": "test"
        }
      ]
    }
  ]
}
```

For more information, see Amazon EBS snapshots in the Amazon EC2 User Guide.
Example 2: To describe snapshots based on filters

The following describe-snapshots example uses filters to scope the results to snapshots owned by your AWS account that are in the pending state. The example uses the --query parameter to display only the snapshot IDs and the time the snapshot was started.

```bash
aws ec2 describe-snapshots \
  --owner-ids self \
  --filters Name=status,Values=pending \
  --query "Snapshots[*].{ID:SnapshotId,Time:StartTime}"
```

Output:

```
[
  {
    "ID": "snap-1234567890abcdef0",
    "Time": "2019-08-04T12:48:18.000Z"
  },
  {
    "ID": "snap-066877671789bd71b",
    "Time": "2019-08-04T02:45:16.000Z"
  },
  ...
]
```

The following describe-snapshots example uses filters to scope the results to snapshots created from the specified volume. The example uses the --query parameter to display only the snapshot IDs.

```bash
aws ec2 describe-snapshots \
  --filters Name=volume-id,Values=049df61146c4d7901 \
  --query "Snapshots[*].[SnapshotId]" \
  --output text
```

Output:

```
snap-1234567890abcdef0
snap-08637175a712c3fb9
...
```

For additional examples using filters, see Listing and filtering your resources in the Amazon EC2 User Guide.

Example 3: To describe snapshots based on tags

The following describe-snapshots example uses tag filters to scope the results to snapshots that have the tag Stack=Prod.

```bash
aws ec2 describe-snapshots \
  --filters Name=tag:Stack,Values=prod
```

For an example of the output for describe-snapshots, see Example 1.

For additional examples using tag filters, see Working with tags in the Amazon EC2 User Guide.
Example 4: To describe snapshots based on age

The following `describe-snapshots` example uses JMESPath expressions to describe all snapshots created by your AWS account before the specified date. It displays only the snapshot IDs.

```
aws ec2 describe-snapshots \
  --owner-ids 012345678910 \
  --query "Snapshots[?(StartTime<'2020-03-31')].[SnapshotId]"
```

For additional examples using filters, see Listing and filtering your resources in the Amazon EC2 User Guide.

Example 5: To view only archived snapshots

The following `describe-snapshots` example lists only snapshots that are stored in the archive tier.

```
aws ec2 describe-snapshots \
  --filters "Name=storage-tier,Values=archive"
```

Output:

```
{
  "Snapshots": [
    {
      "Description": "Snap A",
      "Encrypted": false,
      "VolumeId": "vol-01234567890aaaaaa",
      "State": "completed",
      "VolumeSize": 8,
      "StartTime": "2021-09-07T21:00:00.000Z",
      "Progress": "100%",
      "OwnerId": "123456789012",
      "SnapshotId": "snap-01234567890aaaaaa",
      "StorageTier": "archive",
      "Tags": []
    }
  ]
}
```

For more information, see View archived snapshots in the Amazon Elastic Compute Cloud User Guide.

- For API details, see DescribeSnapshots in AWS CLI Command Reference.

Rust

SDK for Rust

Note

Shows the state of a snapshot.

```rust
async fn show_state(client: &Client, id: &str) -> Result<(), Error> {
```
let resp = client
  .describe_snapshots()
  .filters(Filter::builder().name("snapshot-id").values(id).build())
  .send()
  .await?

println!("State: 
         
         ");
resp.snapshots().first().unwrap().state().unwrap().as_ref()
Ok()}

async fn show_snapshots(client: &Client) -> Result<(), Error> {
    // "self" represents your account ID.
    // You can list the snapshots for any account by replacing
    // "self" with that account ID.
    let resp = client.describe_snapshots().owner_ids("self").send().await?;
    let snapshots = resp.snapshots();
    let length = snapshots.len();

    for snapshot in snapshots {
        println!("ID:          
                 
                 ");
        println!("Description: 
                 
                 ");
        println!("State:       
                 
                 ");
        println!();
    }

    println!();
    println!("Found {} snapshot(s)", length);
    println!();
    Ok()}

• For API details, see DescribeSnapshots in AWS SDK for Rust API reference.

Disable detailed monitoring for an Amazon EC2 instance using an AWS SDK

The following code examples show how to disable detailed monitoring on an Amazon EC2 instance.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

• Get started with instances (p. 1871)
C++

SDK for C++

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```cpp
Aws::EC2::EC2Client ec2Client(clientConfiguration);
Aws::EC2::Model::UnmonitorInstancesRequest unrequest;
unrequest.AddInstanceIds(instanceId);
unrequest.SetDryRun(true);

auto undryRunOutcome = ec2Client.UnmonitorInstances(unrequest);
if (undryRunOutcome.IsSuccess()) {
    std::cerr
    << "Failed dry run to disable monitoring on instance. A dry run should trigger an error."
    << std::endl;
    return false;
} else if (undryRunOutcome.GetError().GetErrorType() !=
    Aws::EC2::EC2Errors::DRY_RUN_OPERATION) {
    std::cout << "Failed dry run to disable monitoring on instance " <<
        instanceId << ": " << undryRunOutcome.GetError().GetMessage() <<
        std::endl;
    return false;
}

unrequest.SetDryRun(false);
auto unmonitorInstancesOutcome = ec2Client.UnmonitorInstances(unrequest);
if (!unmonitorInstancesOutcome.IsSuccess()) {
    std::cout << "Failed to disable monitoring on instance " <<
        instanceId << ": " << unmonitorInstancesOutcome.GetError().GetMessage() <<
        std::endl;
} else {
    std::cout << "Successfully disable monitoring on instance " <<
        instanceId << std::endl;
}
```

• For API details, see UnmonitorInstances in AWS SDK for C++ API Reference.

CLI

AWS CLI

To disable detailed monitoring for an instance

This example command disables detailed monitoring for the specified instance.

Command:

```
aws ec2 unmonitor-instances --instance-ids i-1234567890abcdef0
```

Output:

```
{
```
Disassociate an Elastic IP address from an instance

For API details, see UnmonitorInstances in AWS CLI Command Reference.

JavaScript

SDK for JavaScript (v3)

Note

There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```javascript
import { UnmonitorInstancesCommand } from '@aws-sdk/client-ec2';
import { client } from '../libs/client.js';

export const main = async () => {
  const command = new UnmonitorInstancesCommand({
    InstanceIds: ['i-09a3dfe7ae00e853f'],
  });

  try {
    const { InstanceMonitorings } = await client.send(command);
    const instanceMonitoringsList = InstanceMonitorings.map(
      (im) => 
        `• Detailed monitoring state for ${im.InstanceId} is ${im.Monitoring.State}.`,
    );
    console.log("Monitoring status:");
    console.log(instanceMonitoringsList.join("\n"));
  } catch (err) {
    console.error(err);
  }
};
```

Disassociate an Elastic IP address from an Amazon EC2 instance using an AWS SDK

The following code examples show how to disassociate an Elastic IP address from an Amazon EC2 instance.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:
Disassociate an Elastic IP address from an instance

- **Get started with instances (p. 1871)**

**.NET**

**AWS SDK for .NET**

**Note**
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
/// <summary>
/// Disassociate an Elastic IP address from an EC2 instance.
/// </summary>
/// <param name="associationId">The association Id.</param>
/// <returns>A Boolean value indicating the success of the action.</returns>
public async Task<bool> DisassociateIp(string associationId)
{
    var response = await _amazonEC2.DisassociateAddressAsync(
        new DisassociateAddressRequest { AssociationId = associationId });
    return response.HttpStatusCode == HttpStatusCode.OK;
}
```

- For API details, see [DisassociateAddress](https://docs.aws.amazon.com/sdk-for-net/v3/api/aws殖awssdk.core.html) in **AWS SDK for .NET API Reference**.

**CLI**

**AWS CLI**

**To disassociate an Elastic IP addresses in EC2-Classic**

This example disassociates an Elastic IP address from an instance in EC2-Classic. If the command succeeds, no output is returned.

Command:

```bash
aws ec2 disassociate-address --public-ip 198.51.100.0
```

**To disassociate an Elastic IP address in EC2-VPC**

This example disassociates an Elastic IP address from an instance in a VPC. If the command succeeds, no output is returned.

Command:

```bash
aws ec2 disassociate-address --association-id eipassoc-2bebb745
```

- For API details, see [DisassociateAddress](https://docs.aws.amazon.com/cli/latest/reference/ec2/disassociate-address.html) in **AWS CLI Command Reference**.

**Java**

**SDK for Java 2.x**

**Note**
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
Disassociate an Elastic IP address from an instance

```java
public static void disassociateAddress(Ec2Client ec2, String associationId) {
    try {
        DisassociateAddressRequest addressRequest =
            DisassociateAddressRequest.builder()
                .associationId(associationId)
                .build();
        ec2.disassociateAddress(addressRequest);
        System.out.println("You successfully disassociated the address!");
    } catch (Ec2Exception e) {
        System.err.println(e.awsErrorDetails().errorMessage());
        System.exit(1);
    }
}
```

For API details, see [DisassociateAddress](https://docs.aws.amazon.com/AWSJavaSDK/latest/api/com/amazonaws/services/ec2/model/DisassociateAddressRequest.html) in [AWS SDK for Java 2.x API Reference](https).

### JavaScript SDK for JavaScript (v3)

**Note**
There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https).

```javascript
import { DisassociateAddressCommand } from '@aws-sdk/client-ec2';
import { client } from '../libs/client.js';

// Disassociate an Elastic IP address from an instance.
export const main = async () => {
    const command = new DisassociateAddressCommand({
        // You can also use PublicIp, but that is for EC2 classic which is being retired.
        AssociationId: "ASSOCIATION_ID",
    });
    try {
        await client.send(command);
        console.log("Successfully disassociated address");
    } catch (err) {
        console.error(err);
    }
};
```

Enable monitoring

- For API details, see `DisassociateAddress` in *AWS SDK for Python (Boto3) API Reference*.

For a complete list of AWS SDK developer guides and code examples, see *Using Amazon EC2 with an AWS SDK* (p. 22). This topic also includes information about getting started and details about previous SDK versions.

**Enables monitoring for a running Amazon EC2 instance using an AWS SDK**

The following code examples show how to enable monitoring for a running Amazon EC2 instance.

**C++

**SDK for C++**

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the *AWS Code Examples Repository*.

```cpp
Aws::EC2::EC2Client ec2Client(clientConfiguration);
Aws::EC2::Model::MonitorInstancesRequest request;
request.AddInstanceIds(instanceId);
request.SetDryRun(true);

auto dry_run_outcome = ec2Client.MonitorInstances(request);
if (dry_run_outcome.IsSuccess()) {
    std::cerr
        << "Failed dry run to enable monitoring on instance. A dry run should trigger an error."
        << std::endl;
    return false;
} else if (dry_run_outcome.GetError().GetType() != Aws::EC2::EC2Errors::DRY_RUN_OPERATION) {
    std::cerr << "Failed dry run to enable monitoring on instance " << instanceId << ": " << dry_run_outcome.GetError().GetMessage() << std::endl;
    return false;
}
request.SetDryRun(false);
auto monitorInstancesOutcome = ec2Client.MonitorInstances(request);
if (!monitorInstancesOutcome.IsSuccess()) {
    std::cerr << "Failed to enable monitoring on instance " << instanceId << ": " << monitorInstancesOutcome.GetError().GetMessage() << std::endl;
} else {
    std::cout << "Successfully enabled monitoring on instance " << instanceId << std::endl;
}
```

- For API details, see `MonitorInstances` in *AWS SDK for C++ API Reference*. 
Enable monitoring

**CLI**

**AWS CLI**

To enable detailed monitoring for an instance

This example command enables detailed monitoring for the specified instance.

Command:

```
aws ec2 monitor-instances --instance-ids i-1234567890abcdef0
```

Output:

```
{
    "InstanceMonitorings": [
        {
            "InstanceId": "i-1234567890abcdef0",
            "Monitoring": {
                "State": "pending"
            }
        }
    ]
}
```

- For API details, see [MonitorInstances](#) in **AWS CLI Command Reference**.

**JavaScript**

**SDK for JavaScript (v3)**

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](#).

```
import { MonitorInstancesCommand } from '@aws-sdk/client-ec2';
import { client } from '../libs/client.js';

// Turn on detailed monitoring for the selected instance.
// By default, metrics are sent to Amazon CloudWatch every 5 minutes.
// For a cost you can enable detailed monitoring which sends metrics every minute.
export const main = async () => {
  const command = new MonitorInstancesCommand({
    InstanceIds: ['INSTANCE_ID'],
  });

  try {
    const { InstanceMonitorings } = await client.send(command);
    const instancesBeingMonitored = InstanceMonitorings.map(
      (im) => `• Detailed monitoring state for ${im.InstanceId} is
      ${im.Monitoring.State}.`,
    );
    console.log("Monitoring status:");
    console.log(instancesBeingMonitored.join("\n"));
  } catch (err) {
    console.error(err);
  }
```

AWS SDK (p. 22). This topic also includes information about getting started and details about previous
SDK versions.

Get data about Amazon Machine Images using an
AWS SDK

The following code examples show how to get data about Amazon Machine Images (AMIs).

Action examples are code excerpts from larger programs and must be run in context. You can see this
action in context in the following code example:

• Get started with instances (p. 1871)

CLI

AWS CLI

Example 1: To describe an AMI

The following describe-images example describes the specified AMI in the specified Region.

aws ec2 describe-images \
  --region us-east-1 \
  --image-ids ami-1234567890EXAMPLE

Output:

{  
  "Images": [
    
    "VirtualizationType": "hvm",
    "Description": "Provided by Red Hat, Inc.",
    "PlatformDetails": "Red Hat Enterprise Linux",
    "EnaSupport": true,
    "Hypervisor": "xen",
    "State": "available",
    "SriovNetSupport": "simple",
    "ImageId": "ami-1234567890EXAMPLE",
    "UsageOperation": "RunInstances:0010",
    "BlockDeviceMappings": [
      
      "DeviceName": "/dev/sda1",
    ]
  ]
}
For more information, see Amazon Machine Images (AMI) in the Amazon EC2 User Guide.

**Example 2: To describe AMIs based on filters**

The following describe-images example describes Windows AMIs provided by Amazon that are backed by Amazon EBS.

```
aws ec2 describe-images \
  --owners amazon \
  --filters "Name=platform,Values=windows" "Name=root-device-type,Values=ebs"
```

For an example of the output for describe-images, see Example 1.

For additional examples using filters, see Listing and filtering your resources in the Amazon EC2 User Guide.

**Example 3: To describe AMIs based on tags**

The following describe-images example describes all AMIs that have the tag `Type=Custom`. The example uses the --query parameter to display only the AMI IDs.

```
aws ec2 describe-images \
  --filters "Name=tag:Type,Values=Custom" \
  --query 'Images[*].[ImageId]' \
  --output text
```

Output:

```
ami-1234567890EXAMPLE
ami-0abcdef1234567890
```

For additional examples using tag filters, see Working with tags in the Amazon EC2 User Guide.

- For API details, see DescribeImages in AWS CLI Command Reference.
JavaScript

**SDK for JavaScript (v3)**

**Note**
There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](https://github.com/awsdocs/aws-code-examples).

```javascript
import { paginateDescribeImages } from '@aws-sdk/client-ec2';
import { client } from '../libs/client.js';

// List at least the first i386 image available for EC2 instances.
export const main = async () => {
  // The paginate function is a wrapper around the base command.
  const paginator = paginateDescribeImages({
    client, pageSize: 25
  });
  // Without limiting the page size, this call can take a long time. pageSize is just sugar for
  // the MaxResults property in the base command.
  { client, pageSize: 25 },
  // There are almost 70,000 images available. Be specific with your filtering
  // to increase efficiency.
  // See https://docs.aws.amazon.com/AWSJavaScriptSDK/v3/latest/clients/client-ec2/interfaces/describeimagescommandinput.html#filters
  Filters: [{ Name: "architecture", Values: ["x86_64"] }],
};

try {
  const arm64Images = [];
  for await (const page of paginator) {
    if (page.Images.length) {
      arm64Images.push(...page.Images);
      // Once we have at least 1 result, we can stop.
      if (arm64Images.length >= 1) {
        break;
      }
    }
  }
  console.log(arm64Images);
} catch (err) {
  console.error(err);
}
```

- For API details, see [DescribeImages](https://docs.aws.amazon.com/AWSJavaScriptSDK/v3/latest/clients/client-ec2/interfaces/describeimagescommandinput.html) in AWS SDK for JavaScript API Reference.

AWS CLI

Example 1: To describe a security group

The following describe-security-groups example describes the specified security group.

```
aws ec2 describe-security-groups \
   --group-ids sg-903004f8
```

Output:

```
{
   "SecurityGroups": [
      {
         "IpPermissionsEgress": [
            {
               "IpProtocol": "-1",
               "IpRanges": [
                  {
                     "CidrIp": "0.0.0.0/0"
                  }
               ],
               "UserIdGroupPairs": [],
               "PrefixListIds": []
            }
         ],
         "Description": "My security group",
         "Tags": [
            {
               "Value": "SG1",
               "Key": "Name"
            }
         ],
         "IpPermissions": [
            {
               "IpProtocol": "-1",
               "IpRanges": [],
               "UserIdGroupPairs": [
                  {
                     "UserId": "123456789012",
                     "GroupId": "sg-903004f8"
                  }
               ],
               "PrefixListIds": []
            },
            {
               "PrefixListIds": [],
               "FromPort": 22,
               "IpRanges": [
                  {
                     "Description": "Access from NY office",
                     "CidrIp": "203.0.113.0/24"
                  }
               ],
               "ToPort": 22,
               "IpProtocol": "tcp",
               "UserIdGroupPairs": []
            }
         ],
         "GroupName": "MySecurityGroup",
         "VpcId": "vpc-1a2b3c4d",
         "GroupId": "sg-903004f8"
      }
   ]
}
```
Example 2: To describe security groups that have specific rules

The following `describe-security-groups` example uses filters to scope the results to security groups that have a rule that allows SSH traffic (port 22) and a rule that allows traffic from all addresses (`0.0.0.0/0`). The example uses the `--query` parameter to display only the names of the security groups. Security groups must match all filters to be returned in the results; however, a single rule does not have to match all filters. For example, the output returns a security group with a rule that allows SSH traffic from a specific IP address and another rule that allows HTTP traffic from all addresses.

```
aws ec2 describe-security-groups \
  --filters Name=ip-permission.from-port,Values=22 Name=ip-permission.to-port,Values=22 Name=ip-permission.cidr,Values='0.0.0.0/0' \
  --query "SecurityGroups[*].[GroupName]" \
  --output text
```

Output:

```
default
my-security-group
web-servers
launch-wizard-1
```

Example 3: To describe security groups based on tags

The following `describe-security-groups` example uses filters to scope the results to security groups that include `test` in the security group name, and that have the tag `Test=To-delete`. The example uses the `--query` parameter to display only the names and IDs of the security groups.

```
aws ec2 describe-security-groups \
  --filters Name=group-name,Values=*test* Name=tag:Test,Values=To-delete \
  --query "SecurityGroups[*].{Name:GroupName,ID:GroupId}"
```

Output:

```
[
  {
    "Name": "testfornewinstance",
    "ID": "sg-33bb22aa"
  },
  {
    "Name": "newgrouptest",
    "ID": "sg-1a2b3c4d"
  }
]
```

For additional examples using tag filters, see Working with tags in the Amazon EC2 User Guide.

Get data about Amazon EC2 instance types using an AWS SDK

The following code examples show how to get data about Amazon EC2 instance types.
Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with instances (p. 1871)

.NET

AWS SDK for .NET

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```csharp
/// <summary>
/// Describe the instance types available.
/// </summary>
/// <returns>A list of instance type information.</returns>
public async Task<List<InstanceTypeInfo>>
    DescribeInstanceTypes(ArchitectureValues architecture)
{
    var request = new DescribeInstanceTypesRequest();
    var filters = new List<Filter>
    { new Filter("processor-info.supported-architecture", new List<string>
       { architecture.ToString() })
    ;
    filters.Add(new Filter("instance-type", new() { "*.micro", "*.small" }));
    request.Filters = filters;
    var instanceTypes = new List<InstanceTypeInfo>();
    var paginator = _amazonEC2.Paginators.DescribeInstanceTypes(request);
    await foreach (var instanceType in paginator.InstanceTypes)
    {
        instanceTypes.Add(instanceType);
    }
    return instanceTypes;
}
```

- For API details, see DescribeInstanceTypes in AWS SDK for .NET API Reference.

CLI

AWS CLI

Example 1: To describe an instance type

The following describe-instance-types example displays details for the specified instance type.

```bash
aws ec2 describe-instance-types \
   --instance-types t2.micro
```

Output:

```json
{
   "InstanceTypes": [
   {
      "InstanceType": "t2.micro",
```
Example 2: To filter the available instance types

You can specify a filter to scope the results to instance types that have a specific characteristic. The following `describe-instance-types` example lists the instance types that support hibernation.
aws ec2 describe-instance-types --filters Name=hibernation-supported,Values=true --query InstanceTypes[].InstanceType

Output:

```
[
    "m5.8xlarge",
    "r3.large",
    "c3.8xlarge",
    "r5.large",
    "m4.4xlarge",
    "c4.large",
    "m5.xlarge",
    "m4.xlarge",
    "c3.large",
    "c4.8xlarge",
    "c4.4xlarge",
    "c5.xlarge",
    "c5.12xlarge",
    "r5.4xlarge",
    "c5.4xlarge"
]
```

- For API details, see DescribeInstanceTypes in AWS CLI Command Reference.

Java

**SDK for Java 2.x**

**Note**

There’s more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
// Get a list of instance types.
public static String getInstanceTypes(Ec2Client ec2) {
    String instanceType="";
    try {
        List<Filter> filters = new ArrayList<>();
        Filter filter = Filter.builder()
            .name("processor-info.supported-architecture")
            .values("arm64")
            .build();

        filters.add(filter);
        DescribeInstanceTypesRequest typesRequest = DescribeInstanceTypesRequest.builder()
            .filters(filters)
            .maxResults(10)
            .build();

        DescribeInstanceTypesResponse response = ec2.describeInstanceTypes(typesRequest);
        List<InstanceTypeInfo> instanceTypes = response.instanceTypes();
        for (InstanceTypeInfo type : instanceTypes) {
            System.out.println("The memory information of this type is "+type.memoryInfo().sizeInMiB());
            System.out.println("Network information is "+type.networkInfo().toString());
            instanceType = type.instanceType().toString();
        }
    }

    return instanceType;
}
```

        Gets data about the profile associated with an instance.
Get details about Elastic IP addresses

```python
try:
    response = self.ec2_client.describe_iam_instance_profile_associations(
        Filters=[["Name": "instance-id", "Values": [instance_id]]
    )
except ClientError as err:
    raise AutoScalerError("Couldn't get instance profile association for instance {instance_id}: {err}"
) else:
    return response["IamInstanceProfileAssociations"]
```

- For API details, see [DescribeIamInstanceProfileAssociations](http://aws.amazon.com) in [AWS SDK for Python (Boto3) API Reference](http://aws.amazon.com).

For a complete list of AWS SDK developer guides and code examples, see [Using Amazon EC2 with an AWS SDK](http://aws.amazon.com) (p. 22). This topic also includes information about getting started and details about previous SDK versions.

**Get details about Elastic IP addresses using an AWS SDK**

The following code examples show how to get details about Elastic IP addresses.

**C++**

```cpp
// SDK for C++
```

**Note**

There's more on GitHub. Find the complete example and learn how to set up and run in the [AWS Code Examples Repository](http://aws.amazon.com).
For API details, see DescribeAddresses in AWS SDK for C++ API Reference.

CLI

AWS CLI

Example 1: To retrieve details about all of your Elastic IP addresses

The following describe-addresses example displays details about your Elastic IP addresses.

```bash
aws ec2 describe-addresses
```

Output:

```
{
  "Addresses": [
    {
      "InstanceId": "i-1234567890abcdef0",
      "PublicIp": "198.51.100.0",
      "PublicIpv4Pool": "amazon",
      "Domain": "standard"
    },
    {
      "Domain": "vpc",
      "PublicIpv4Pool": "amazon",
      "InstanceId": "i-1234567890abcdef0",
      "NetworkInterfaceId": "eni-12345678",
      "AssociationId": "eipassoc-12345678",
      "NetworkInterfaceOwnerId": "123456789012",
      "PublicIp": "203.0.113.0",
      "AllocationId": "eipalloc-12345678",
      "PrivateIpAddress": "10.0.1.241"
    }
  ]
}
```
Example 3: To retrieve details about an Elastic IP address specified by allocation ID

The following `describe-addresses` example displays details about the Elastic IP address with the specified allocation ID, which is associated with an instance in EC2-VPC.

```bash
aws ec2 describe-addresses \
  --allocation-ids eipalloc-282d9641
```

Output:

```json
{
  "Addresses": [
    {
      "Domain": "vpc",
      "PublicIpv4Pool": "amazon",
      "InstanceId": "i-1234567890abcdef0",
      "NetworkInterfaceId": "eni-1a2b3c4d",
      "AssociationId": "eipassoc-123abc12",
      "NetworkInterfaceOwnerId": "1234567891012",
      "PublicIp": "203.0.113.25",
      "AllocationId": "eipalloc-282d9641",
      "PrivateIpAddress": "10.251.50.12"
    }
  ]
}
```

Example 4: To retrieve details about an Elastic IP address specified by its VPC private IP address

The following `describe-addresses` example displays details about the Elastic IP address associated with a particular private IP address in EC2-VPC.

```bash
aws ec2 describe-addresses \
  --filters "Name=private-ip-address,Values=10.251.50.12"
```

Example 5: To retrieve details about Elastic IP addresses in EC2-Classic

The following `describe-addresses` example displays details about your Elastic IP addresses for use in EC2-Classic.

```bash
aws ec2 describe-addresses \
  --filters "Name=domain,Values=standard"
```

Output:

```json
{
  "Addresses": [
```

1735
Example 6: To retrieve details about an Elastic IP addresses specified by its public IP address

The following describe-addresses example displays details about the Elastic IP address with the value `203.0.110.25`, which is associated with an instance in EC2-Classic.

```bash
aws ec2 describe-addresses \
--public-ips 203.0.110.25
```

Output:

```
{
  "Addresses": [
    {
      "InstanceId": "i-1234567890abcdef0",
      "PublicIp": "203.0.110.25",
      "PublicIpv4Pool": "amazon",
      "Domain": "standard"
    }
  ]
}
```

- For API details, see [DescribeAddresses](#) in AWS CLI Command Reference.

      "OwnerId": "111122223333",
      "AssignIpv6AddressOnCreation": false,
      "Ipv6CidrBlockAssociationSet": [],
      "CustomerOwnedIpv4Pool": "pool-2EXAMPLE",
      "SubnetArn": "arn:aws:ec2:us-east-2:111122223333:subnet/subnet-0bb1c79de3EXAMPLE",
      "EnableDns64": false,
      "Ipv6Native": false,
      "PrivateDnsNameOptionsOnLaunch": {
        "HostnameType": "ip-name",
        "EnableResourceNameDnsARecord": false,
        "EnableResourceNameDnsAAAARecord": false
      }
    },
    {
      "AvailabilityZone": "us-east-1d",
      "AvailabilityZoneId": "use1-az2",
      "AvailableIpAddressCount": 4089,
      "CidrBlock": "172.31.80.0/20",
      "DefaultForAz": true,
      "MapPublicIpOnLaunch": true,
      "MapCustomerOwnedIpOnLaunch": false,
      "State": "available",
      "SubnetId": "subnet-8EXAMPLE",
      "VpcId": "vpc-3EXAMPLE",
      "OwnerId": "111122223333",
      "AssignIpv6AddressOnCreation": false,
      "Ipv6CidrBlockAssociationSet": [],
      "Tags": [
        {
          "Key": "Name",
```
Get the default subnets for a VPC

Example 2: To describe the subnets of a specific VPC

The following `describe-subnets` example uses a filter to retrieve details for the subnets of the specified VPC.

```
aws ec2 describe-subnets \n  --filters "Name=vpc-id,Values=vpc-3EXAMPLE"
```

Output:

```json
{
  "Subnets": [
  {
    "AvailabilityZone": "us-east-1d",
    "AvailabilityZoneId": "use1-az2",
    "AvailableIpAddressCount": 4089,
    "CidrBlock": "172.31.80.0/20",
    "DefaultForAz": true,
    "MapPublicIpOnLaunch": true,
    "MapCustomerOwnedIpOnLaunch": false,
    "State": "available",
    "SubnetId": "subnet-8EXAMPLE",
    "VpcId": "vpc-3EXAMPLE",
    "OwnerId": "1111222233333",
    "AssignIpv6AddressOnCreation": false,
    "Ipv6CidrBlockAssociationSet": [],
    "Tags": [
    {
      "Key": "Name",
      "Value": "MySubnet"
    }
    ],
    "EnableDns64": false,
    "Ipv6Native": false,
    "PrivateDnsNameOptionsOnLaunch": {
      "HostnameType": "ip-name",
      "EnableResourceNameDnsARecord": false,
      "EnableResourceNameDnsAAAARecord": false
    }
  }
  ]
}
```
For more information, see Working with VPCs and Subnets in the AWS VPC User Guide.

**Example 3: To describe the subnets with a specific tag**

The following `describe-subnets` example uses a filter to retrieve the details of those subnets with the tag `CostCenter=123` and the `--query` parameter to display the subnet IDs of the subnets with this tag.

```bash
aws ec2 describe-subnets
  --filters "Name=tag:CostCenter,Values=123"
  --query "Subnets[*].SubnetId"
  --output text
```

Output:

```
subnet-0987a87c8b37348ef
subnet-02a95061c45f372ee
subnet-03f720e7de2788d73
```

For more information, see Working with VPCs and Subnets in the Amazon VPC User Guide.

For a complete list of AWS SDK developer guides and code examples, see Using Amazon EC2 with an AWS SDK (p. 22). This topic also includes information about getting started and details about previous SDK versions.

Set inbound rules for an Amazon EC2 security group using an AWS SDK

The following code examples show how to set inbound rules for an Amazon EC2 security group.

Action examples are code excerpts from larger programs and must be run in context. You can see this action in context in the following code example:

- Get started with instances (p. 1871)

.NET

AWS SDK for .NET

Note
There’s more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.
/// <summary>
/// Authorize the local computer ingress to EC2 instances associated
/// with the virtual private cloud (VPC) security group.
/// </summary>
/// <param name="groupName">The name of the security group.</param>
/// <returns>A Boolean value indicating the success of the action.</returns>
public async Task<bool> AuthorizeSecurityGroupIngress(string groupName) {
    // Get the IP address for the local computer.
    var ipAddress = await GetIpAddress();
    Console.WriteLine("Your IP address is: {0}", ipAddress);
    var ipRanges = new List<IpRange> { new IpRange { CidrIp = ipAddress } };
    var permission = new IpPermission {
        Ipv4Ranges = ipRanges,
        IpProtocol = "tcp",
        FromPort = 22,
        ToPort = 22
    };
    var permissions = new List<IpPermission> { permission };
    var response = await _amazonEC2.AuthorizeSecurityGroupIngressAsync(
        new AuthorizeSecurityGroupIngressRequest(groupName, permissions));
    return response.HttpStatusCode == HttpStatusCode.OK;
}

/// <summary>
/// Authorize the local computer for ingress to
/// the Amazon EC2 SecurityGroup.
/// </summary>
/// <returns>The IPv4 address of the computer running the scenario.</returns>
private static async Task<string> GetIpAddress() {
    var httpClient = new HttpClient();
    // The IP address is returned with a new line character on the end. Trim off the whitespace and return the value to the caller.
    return ipString.Trim();
}

CLI

AWS CLI

Example 1: To add a rule that allows inbound SSH traffic

The following authorize-security-group-ingress example adds a rule that allows
inbound traffic on TCP port 22 (SSH).

aws ec2 authorize-security-group-ingress \\
--group-id sg-1234567890abcdef0 \\
--protocol tcp \\
--port 22 \\
--cidr 203.0.113.0/24

Output:

{
  "Return": true,
  "SecurityGroupRules": [
    {
      "SecurityGroupRuleId": "sgr-01afa97ef3e1bedfc",
      "GroupId": "sg-1234567890abcdef0",
      "GroupOwnerId": "123456789012",
      "IsEgress": false,
      "IpProtocol": "tcp",
      "FromPort": 22,
      "ToPort": 22,
      "CidrIpv4": "203.0.113.0/24"
    }
  ]
}

1765
Example 2: To add a rule that allows inbound HTTP traffic from another security group

The following authorize-security-group-ingress example adds a rule that allows inbound access on TCP port 80 from the source security group sg-1a2b3c4d. The source group must be in the same VPC or in a peer VPC (requires a VPC peering connection). Incoming traffic is allowed based on the private IP addresses of instances that are associated with the source security group (not the public IP address or Elastic IP address).

```
aws ec2 authorize-security-group-ingress \
  --group-id sg-1234567890abcdef0 \
  --protocol tcp \
  --port 80 \
  --source-group sg-1a2b3c4d
```

Output:

```
{
  "Return": true,
  "SecurityGroupRules": [
    {
      "SecurityGroupRuleId": "sgr-01f4be99110f638a7",
      "GroupId": "sg-1234567890abcdef0",
      "GroupOwnerId": "123456789012",
      "IsEgress": false,
      "IpProtocol": "tcp",
      "FromPort": 80,
      "ToPort": 80,
      "ReferencedGroupInfo": {
        "GroupId": "sg-1a2b3c4d",
        "UserId": "123456789012"
      }
    }
  ]
}
```

Example 3: To add multiple rules in the same call

The following authorize-security-group-ingress example uses the ip-permissions parameter to add two inbound rules, one that enables inbound access on TCP port 3389 (RDP) and the other that enables ping/ICMP.

```
aws ec2 authorize-security-group-ingress --group-id sg-1234567890abcdef0 --ip-permissions 
IpProtocol=tcp,FromPort=3389,ToPort=3389,IpRanges="[{CidrIp=172.31.0.0/16}]"
IpProtocol=icmp,FromPort=-1,ToPort=-1,IpRanges="[{CidrIp=172.31.0.0/16}]"
```

Output:

```
{
  "Return": true,
  "SecurityGroupRules": [
    {
      "SecurityGroupRuleId": "sgr-00e06e5d3690f29f3",
      "GroupId": "sg-1234567890abcdef0",
      "GroupOwnerId": "123456789012",
      "IsEgress": false,
      "IpProtocol": "tcp",
      "FromPort": 3389,
      "ToPort": 3389,
      "CidrIpv4": "172.31.0.0/16"
    },
    {
      "SecurityGroupRuleId": "sgr-01f4be99110f638a7",
      "GroupId": "sg-1234567890abcdef0",
      "GroupOwnerId": "123456789012",
      "IsEgress": false,
      "IpProtocol": "tcp",
      "FromPort": 80,
      "ToPort": 80,
      "ReferencedGroupInfo": {
        "GroupId": "sg-1a2b3c4d",
        "UserId": "123456789012"
      }
    }
  ]
}
```
Example 4: To add a rule for ICMP traffic

The following authorize-security-group-ingress example uses the ip-permissions parameter to add an inbound rule that allows the ICMP message Destination Unreachable: Fragmentation Needed and Don't Fragment was Set (Type 3, Code 4) from anywhere.

```bash
aws ec2 authorize-security-group-ingress --group-id sg-1234567890abcdef0 --ip-permissions IpProtocol=icmp,FromPort=3,ToPort=4,IpRanges="[{CidrIp=0.0.0.0/0}]"
```

Output:

```json
{
  "Return": true,
  "SecurityGroupRules": [
    {
      "SecurityGroupRuleId": "sgr-0de3811019069b787",
      "GroupId": "sg-1234567890abcdef0",
      "GroupOwnerId": "123456789012",
      "IsEgress": false,
      "IpProtocol": "icmp",
      "FromPort": 3,
      "ToPort": 4,
      "CidrIpv4": "0.0.0.0/0"
    }
  ]
}
```

Example 5: To add a rule for IPv6 traffic

The following authorize-security-group-ingress example uses the ip-permissions parameter to add an inbound rule that allows SSH access (port 22) from the IPv6 range 2001:db8:1234:1a00::/64.

```bash
aws ec2 authorize-security-group-ingress --group-id sg-1234567890abcdef0 --ip-permissions IpProtocol=tcp,FromPort=22,ToPort=22,Ipv6Ranges="[{CidrIpv6=2001:db8:1234:1a00::/64}]"
```

Output:

```json
{
  "Return": true,
  "SecurityGroupRules": [
    {
      "SecurityGroupRuleId": "sgr-0455bc68b60805563",
      "GroupId": "sg-1234567890abcdef0",
      "GroupOwnerId": "123456789012",
      "IsEgress": false,
      "IpProtocol": "tcp",
      "FromPort": 22,
      "ToPort": 22,
      "CidrIpv6": "2001:db8:1234:1a00::/64"
    }
  ]
}
```
Example 6: To add a rule for ICMPv6 traffic

The following `authorize-security-group-ingress` example uses the `ip-permissions` parameter to add an inbound rule that allows ICMPv6 traffic from anywhere.

```
aws ec2 authorize-security-group-ingress --group-id sg-1234567890abcdef0 --ip-permissions
IpProtocol=icmpv6,Ipv6Ranges="[{CidrIpv6=::/0}]"
```

Output:

```
{
"Return": true,
"SecurityGroupRules": [
  {
    "SecurityGroupRuleId": "sgr-0a4b612d9363ab6327",
    "GroupId": "sg-1234567890abcdef0",
    "GroupOwnerId": "123456789012",
    "IsEgress": false,
    "IpProtocol": "icmpv6",
    "FromPort": -1,
    "ToPort": -1,
    "CidrIpv6": "::/0"
  }
]
}
```

Example 7: Add a rule with a description

The following `authorize-security-group-ingress` example uses the `ip-permissions` parameter to add an inbound rule that allows RDP traffic from the specified IPv4 address range. The rule includes a description to help you identify it later.

```
aws ec2 authorize-security-group-ingress --group-id sg-1234567890abcdef0 --ip-permissions
IpProtocol=tcp,FromPort=3389,ToPort=3389,IpRanges="[{CidrIp=203.0.113.0/24,Description='RDP access from NY office'}]"
```

Output:

```
{
"Return": true,
"SecurityGroupRules": [
  {
    "SecurityGroupRuleId": "sgr-0397bbcc01e974db3",
    "GroupId": "sg-1234567890abcdef0",
    "GroupOwnerId": "123456789012",
    "IsEgress": false,
    "IpProtocol": "tcp",
    "FromPort": 3389,
    "ToPort": 3389,
    "CidrIpv4": "203.0.113.0/24",
    "Description": "RDP access from NY office"
  }
]
}
```
Example 8: To add an inbound rule that uses a prefix list

The following authorize-security-group-ingress example uses the ip-permissions parameter to add an inbound rule that allows all traffic for the CIDR ranges in the specified prefix list.

```bash
aws ec2 authorize-security-group-ingress --group-id sg-04a351bfe432d4e71 --ip-permissions IpProtocol=all,PrefixListIds="[PrefixListId=pl-002dc3ec097de1514]"
```

Output:

```
{
  "Return": true,
  "SecurityGroupRules": [
    {
      "SecurityGroupRuleId": "sgr-09c74b32f677c6c7c",
      "GroupId": "sg-1234567890abcdef0",
      "GroupOwnerId": "123456789012",
      "IsEgress": false,
      "IpProtocol": "-1",
      "FromPort": -1,
      "ToPort": -1,
      "PrefixListId": "pl-0721453c7ac4ec009"
    }
  ]
}
```

CLI

AWS CLI

**Example 1: To stop an Amazon EC2 instance**

The following `stop-instances` example stops the specified Amazon EBS-backed instance.

```
aws ec2 stop-instances \
  --instance-ids i-1234567890abcdef0
```

Output:

```
{
  "StoppingInstances": [ 
    {
      "InstanceId": "i-1234567890abcdef0",
      "CurrentState": {
        "Code": 64,
        "Name": "stopping"
      },
      "PreviousState": {
        "Code": 16,
        "Name": "running"
      }
    }
  ]
}
```

For more information, see [Stop and Start Your Instance](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/stop-start.html) in the *Amazon Elastic Compute Cloud User Guide*.

**Example 2: To hibernate an Amazon EC2 instance**

The following `stop-instances` example hibernates Amazon EBS-backed instance if the instance is enabled for hibernation and meets the hibernation prerequisites. After the instance is put into hibernation the instance is stopped.

```
aws ec2 stop-instances \
  --instance-ids i-1234567890abcdef0 \
  --hibernate
```

Output:

```
{
  "StoppingInstances": [ 
    {
      "CurrentState": {
        "Code": 64,
        "Name": "stopping"
      },
      "InstanceId": "i-1234567890abcdef0",
      "PreviousState": {
        "Code": 16,
        "Name": "running"
      }
    }
  ]
}
```
Stop an instance

Terminate an instance

```cpp
Aws::EC2::EC2Client ec2Client(clientConfiguration);

Aws::EC2::Model::TerminateInstancesRequest request;
request.SetInstanceIds({instanceID});

Aws::EC2::Model::TerminateInstancesOutcome outcome =
ec2Client.TerminateInstances(request);
if (outcome.IsSuccess()) {
    std::cout << "Ec2 instance '" << instanceID << "," << std::endl;
}
else {
    std::cerr << "Failed to terminate ec2 instance " << instanceID << "," << 
    outcome.GetError().GetMessage() << std::endl;
    return false;
}
```

- For API details, see `TerminateInstances` in *AWS SDK for C++ API Reference*.

**CLI**

**AWS CLI**

**To terminate an Amazon EC2 instance**

This example terminates the specified instance.

Command:

```bash
aws ec2 terminate-instances --instance-ids i-1234567890abcdef0
```

Output:

```
{
"TerminatingInstances": [
    {
        "InstanceId": "i-1234567890abcdef0",
        "CurrentState": {
            "Code": 32,
            "Name": "shutting-down"
        },
        "PreviousState": {
            "Code": 16,
            "Name": "running"
        }
    }
]
```

Scenarios for Amazon EC2 using AWS SDKs

The following code examples show you how to implement common scenarios in Amazon EC2 with AWS SDKs. These scenarios show you how to accomplish specific tasks by calling multiple functions within Amazon EC2. Each scenario includes a link to GitHub, where you can find instructions on how to set up and run the code.

Examples

• **Build and manage a resilient service using an AWS SDK (p. 1794)**
• **Get started with Amazon EC2 instances using an AWS SDK (p. 1871)**

**Build and manage a resilient service using an AWS SDK**

The following code examples show how to create a load-balanced web service that returns book, movie, and song recommendations. The example shows how the service responds to failures, and how to restructure the service for more resilience when failures occur.

• Use an Amazon EC2 Auto Scaling group to create Amazon Elastic Compute Cloud (Amazon EC2) instances based on a launch template and to keep the number of instances in a specified range.
• Handle and distribute HTTP requests with Elastic Load Balancing.
• Monitor the health of instances in an Auto Scaling group and forward requests only to healthy instances.
• Run a Python web server on each EC2 instance to handle HTTP requests. The web server responds with recommendations and health checks.
• Simulate a recommendation service with an Amazon DynamoDB table.
• Control web server response to requests and health checks by updating AWS Systems Manager parameters.

For API details, see [TerminateInstances](https://docs.aws.amazon.com/sdk-for-ruby/api/AWS/EC2/Examples/TerminateInstances.html) in *AWS SDK for Ruby API Reference*. For a complete list of AWS SDK developer guides and code examples, see [Using Amazon EC2 with an AWS SDK (p. 22)](https://docs.aws.amazon.com/sdk-for-ruby/api/AWS/EC2/Examples/UsingAmazonEC2.html). This topic also includes information about getting started and details about previous SDK versions.

"));
    paramHelper.put(paramHelper.tableName, "this-is-not-a-table");
    System.out.println("\nNow, sending a GET request to the load balancer endpoint returns a
failure code. But, the service reports as
healthy to the load balancer because shallow health checks don't check for
failure of the recommendation service.
"));
    demoChoices(loadBalancer);
    System.out.println("Instead of failing when the recommendation service fails, the web service
can return a static response.
While this is not a perfect solution, it presents the customer with a
somewhat better experience than failure.
"));
    paramHelper.put(paramHelper.failureResponse, "static");
}
Now, sending a GET request to the load balancer endpoint returns a static response. The service still reports as healthy because health checks are still shallow.

demoChoices(loadBalancer);

System.out.println("Let's reinstate the recommendation service.");
paramHelper.put(paramHelper.tableName, paramHelper.dyntable);

System.out.println("Let's also substitute bad credentials for one of the instances in the target group so that it can't access the DynamoDB recommendation table. We will get an instance id value.");

LaunchTemplateCreator templateCreator = new LaunchTemplateCreator();
AutoScaler autoScaler = new AutoScaler();

//Create a new instance profile based on badCredsProfileName.
templateCreator.createInstanceProfile(policyFile, policyName, badCredsProfileName, roleName);
String badInstanceId = autoScaler.getBadInstance(autoScalingGroupName);
System.out.println("The bad instance id values used for this demo is "+badInstanceId);

String profileAssociationId = autoScaler.getInstanceProfile(badInstanceId);
System.out.println("The association Id value is "+profileAssociationId);
System.out.println("Replacing the profile for instance " + badInstanceId + " with a profile that contains bad credentials");
autoScaler.replaceInstanceProfile(badInstanceId, badCredsProfileName, profileAssociationId);

System.out.println("Now, sending a GET request to the load balancer endpoint returns either a recommendation or a static response, depending on which instance is selected by the load balancer.");
demoChoices(loadBalancer);

System.out.println("Let's implement a deep health check. For this demo, a deep health check tests whether the web service can access the DynamoDB table that it depends on for recommendations. Note that the deep health check is only for ELB routing and not for Auto Scaling instance health. This kind of deep health check is not recommended for Auto Scaling instance health, because it risks accidental termination of all instances in the Auto Scaling group when a dependent service fails.");

System.out.println("By implementing deep health checks, the load balancer can detect when one of the instances is failing and take that instance out of rotation.");
paramHelper.put(paramHelper.healthCheck, "deep");
System.out.println(""
Now, checking target health indicates that the instance with bad credentials is unhealthy. Note that it might take a minute or two for the load balancer to detect the unhealthy instance. Sending a GET request to the load balancer endpoint always returns a recommendation, because the load balancer takes unhealthy instances out of its rotation.

```
System.out.println("Because the instances in this demo are controlled by an auto scaler, the simplest way to fix an unhealthy instance is to terminate it and let the auto scaler start a new instance to replace it.
";
autoScaler.terminateInstance(badInstanceId);
```

Even while the instance is terminating and the new instance is starting, sending a GET request to the web service continues to get a successful recommendation response because the load balancer routes requests to the healthy instances. After the replacement instance starts and reports as healthy, it is included in the load balancing rotation. Note that terminating and replacing an instance typically takes several minutes, during which time you can see the changing health check status until the new instance is running and healthy.

```
System.out.println("If the recommendation service fails now, deep health checks mean all instances report as unhealthy.");
paramHelper.put(paramHelper.tableName, "this-is-not-a-table");
```

demoChoices(loadBalancer);

```
paramHelper.reset();
```
