Cold HDD (sc1) volumes provide low-cost magnetic storage that defines performance in terms of throughput rather than IOPS. With a lower throughput limit than st1, sc1 is a good fit for large, sequential cold-data workloads. If you require infrequent access to your data and are looking to save costs, sc1 provides inexpensive block storage. Bootable sc1 volumes are not supported.
Cold HDD (sc1) volumes, though similar to Throughput Optimized HDD (st1) volumes, are designed to support *infrequently accessed* data.

**Note**

This volume type is optimized for workloads involving large, sequential I/O, and we recommend that customers with workloads performing small, random I/O use gp2. For more information, see [Inefficiency of small read/writes on HDD (p. 1791)].

Cold HDD (sc1) volumes attached to EBS-optimized instances are designed to offer consistent performance, delivering at least 90 percent of the expected throughput performance 99 percent of the time in a given year.

**Throughput credits and burst performance**

Like gp2, sc1 uses a burst bucket model for performance. Volume size determines the baseline throughput of your volume, which is the rate at which the volume accumulates throughput credits. Volume size also determines the burst throughput of your volume, which is the rate at which you can spend credits when they are available. Larger volumes have higher baseline and burst throughput. The more credits your volume has, the longer it can drive I/O at the burst level.

Subject to throughput and throughput-credit caps, the available throughput of an sc1 volume is expressed by the following formula:

\[
(Volume \ size) \times (Credit \ accumulation \ rate \ per \ TiB) = Throughput
\]

For a 1-TiB sc1 volume, burst throughput is limited to 80 MiB/s, the bucket fills with credits at 12 MiB/s, and it can hold up to 1 TiB-worth of credits.

Larger volumes scale these limits linearly, with throughput capped at a maximum of 250 MiB/s. After the bucket is depleted, throughput is limited to the baseline rate of 12 MiB/s per TiB.

On volume sizes ranging from 0.125 TiB to 16 TiB, baseline throughput varies from 1.5 MiB/s to a maximum of 192 MiB/s, which is reached at 16 TiB as follows:

\[
12 \frac{MiB/s}{TiB} \times \frac{16}{1} = 192 \frac{MiB/s}{1}
\]

Burst throughput varies from 10 MiB/s to a cap of 250 MiB/s, which is reached at 3.125 TiB as follows:

\[
80 \frac{MiB/s}{TiB} \times \frac{3.125}{1} = 250 \frac{MiB/s}{1}
\]
The following table states the full range of base and burst throughput values for sc1:

<table>
<thead>
<tr>

The following diagram plots the table values:
Note
When you create a snapshot of a Cold HDD (sc1) volume, performance may drop as far as the volume's baseline value while the snapshot is in progress.

For information about using CloudWatch metrics and alarms to monitor your burst bucket balance, see Monitor the burst bucket balance for volumes (p. 1792).

Performance considerations when using HDD volumes

For optimal throughput results using HDD volumes, plan your workloads with the following considerations in mind.

Comparing Throughput Optimized HDD and Cold HDD

The st1 and sc1 bucket sizes vary according to volume size, and a full bucket contains enough tokens for a full volume scan. However, larger st1 and sc1 volumes take longer for the volume scan to complete because of per-instance and per-volume throughput limits. Volumes attached to smaller instances are limited to the per-instance throughput rather than the st1 or sc1 throughput limits.

Both st1 and sc1 are designed for performance consistency of 90 percent of burst throughput 99 percent of the time. Non-compliant periods are approximately uniformly distributed, targeting 99 percent of expected total throughput each hour.

In general, scan times are expressed by this formula:

\[
\text{Volume size} \div \text{Throughput} = \text{Scan time}
\]

For example, taking the performance consistency guarantees and other optimizations into account, an st1 customer with a 5-TiB volume can expect to complete a full volume scan in 2.91 to 3.27 hours.

- Optimal scan time

\[
\frac{5 \text{ TiB}}{500 \text{ MiB/s}} = \frac{5 \text{ TiB}}{0.00047684 \text{ TiB/s}} = 10,486 \text{ seconds} = 2.91 \text{ hours}
\]

- Maximum scan time

\[
\frac{2.91 \text{ hours}}{(0.90)(0.99)} = 3.27 \text{ hours}
\]

Similarly, an sc1 customer with a 5-TiB volume can expect to complete a full volume scan in 5.83 to 6.54 hours.

- Optimal scan time

\[
\frac{5 \text{ TiB}}{250 \text{ MiB/s}} = \frac{5 \text{ TiB}}{0.000238418 \text{ TiB/s}} = 20972 \text{ seconds} = 5.83 \text{ hours}
\]

- Maximum scan time

\[
5.83 \text{ hours}
\]
The following table shows ideal scan times for volumes of various size, assuming full buckets and sufficient instance throughput.

<table>
<thead>
<tr>
<th>Volume size (TiB)</th>

</tbody>
</table>

* These scan times assume an average queue depth (rounded to the nearest whole number) of four or more when performing 1 MiB of sequential I/O.

Therefore if you have a throughput-oriented workload that needs to complete scans quickly (up to 500 MiB/s), or requires several full volume scans a day, use st1. If you are optimizing for cost, your data is relatively infrequently accessed, and you don't need more than 250 MiB/s of scanning performance, then use sc1.

Inefficiency of small read/writes on HDD

The performance model for st1 and sc1 volumes is optimized for sequential I/Os, favoring high-throughput workloads, offering acceptable performance on workloads with mixed IOPS and throughput, and discouraging workloads with small, random I/O.

For example, an I/O request of 1 MiB or less counts as a 1 MiB I/O credit. However, if the I/Os are sequential, they are merged into 1 MiB I/O blocks and count only as a 1 MiB I/O credit.
Monitor the burst bucket balance for volumes

You can monitor the burst bucket level for st1 and sc1 volumes using the Amazon EBS BurstBalance metric available in Amazon CloudWatch. This metric shows the throughput credits for st1 and sc1 remaining in the burst bucket. For more information about the BurstBalance metric and other metrics related to I/O, see I/O characteristics and monitoring (p. 2030). CloudWatch also allows you to set an alarm that notifies you when the BurstBalance value falls to a certain level. For more information, see Creating CloudWatch Alarms.

Constraints on the size and configuration of an EBS volume

The size of an Amazon EBS volume is constrained by the physics and arithmetic of block data storage, as well as by the implementation decisions of operating system (OS) and file system designers. AWS imposes additional limits on volume size to safeguard the reliability of its services.

The following sections describe the most important factors that limit the usable size of an EBS volume and offer recommendations for configuring your EBS volumes.

Contents

- Storage capacity (p. 1792)
- Service limitations (p. 1792)
- Partitioning schemes (p. 1793)
- Data block sizes (p. 1794)

Storage capacity

The following table summarizes the theoretical and implemented storage capacities for the most commonly used file systems on Amazon EBS, assuming a 4,096 byte block size.

<table>
<thead>
<tr>
<th>Partitioning scheme</th>
<th>Max addressable blocks</th>
<th>Theoretical max size (blocks x block size)</th>
<th>Ext4 implemented max size*</th>
<th>XFS implemented max size**</th>
<th>NTFS implemented max size</th>
<th>Max supported by EBS</th>
</tr>
</thead>
<tbody>
<tr>

<td>256 TiB</td>
<td>64 TiB †</td>
</tr>
</tbody>
</table>

** [https://access.redhat.com/solutions/1532](https://access.redhat.com/solutions/1532)

† io2 Block Express volumes support up to 64 TiB for GPT partitions. For more information, see io2 Block Express volumes (p. 1783).

Service limitations

Amazon EBS abstracts the massively distributed storage of a data center into virtual hard disk drives. To an operating system installed on an EC2 instance, an attached EBS volume appears to be a physical hard
disk drive containing 512-byte disk sectors. The OS manages the allocation of data blocks (or clusters) onto those virtual sectors through its storage management utilities. The allocation is in conformity with a volume partitioning scheme, such as master boot record (MBR) or GUID partition table (GPT), and within the capabilities of the installed file system (ext4, NTFS, and so on).

EBS is not aware of the data contained in its virtual disk sectors; it only ensures the integrity of the sectors. This means that AWS actions and OS actions are independent of each other. When you are selecting a volume size, be aware of the capabilities and limits of both, as in the following cases:

- EBS currently supports a maximum volume size of 64 TiB. This means that you can create an EBS volume as large as 64 TiB, but whether the OS recognizes all of that capacity depends on its own design characteristics and on how the volume is partitioned.
- Linux boot volumes may use either the MBR or GPT partitioning scheme. The AMI you launch an instance from determines the boot mode parameter and subsequently which partition scheme can be used for the boot volume. MBR supports boot volumes up to 2047 GiB (2 TiB - 1 GiB). GPT with GRUB 2 supports boot volumes 2 TiB or larger. If your Linux AMI uses MBR, your boot volume is limited to 2047 GiB, but your non-boot volumes do not have this limit. For more information, see Make an Amazon EBS volume available for use on Linux (p. 1803) and Set the boot mode of an AMI.

Partitioning schemes

Among other impacts, the partitioning scheme determines how many logical data blocks can be uniquely addressed in a single volume. For more information, see Data block sizes (p. 1794). The common partitioning schemes in use are Master Boot Record (MBR) and GUID partition table (GPT). The important differences between these schemes can be summarized as follows.

MBR

MBR uses a 32-bit data structure to store block addresses. This means that each data block is mapped with one of \(2^{32}\) possible integers. The maximum addressable size of a volume is given by the following formula:

\[
2^{32} \times \text{Block size}
\]

The block size for MBR volumes is conventionally limited to 512 bytes. Therefore:

\[
2^{32} \times 512 \text{ bytes} = 2 \text{ TiB}
\]

Engineering workarounds to increase this 2-TiB limit for MBR volumes have not met with widespread industry adoption. Consequently, Linux and Windows never detect an MBR volume as being larger than 2 TiB even if AWS shows its size to be larger.

GPT

GPT uses a 64-bit data structure to store block addresses. This means that each data block is mapped with one of \(2^{64}\) possible integers. The maximum addressable size of a volume is given by the following formula:

\[
2^{64} \times \text{Block size}
\]

The block size for GPT volumes is commonly 4,096 bytes. Therefore:

\[
2^{64} \times 4,096 \text{ bytes} = 2^{64} \times 2^{12} \text{ bytes}
\]
= 2^8 × 2^6 bytes
= 64 ZiB

Real-world computer systems don't support anything close to this theoretical maximum. Implemented file-system size is currently limited to 50 TiB for ext4 and 256 TiB for NTFS.

**Data block sizes**

Data storage on a modern hard drive is managed through *logical block addressing*, an abstraction layer that allows the operating system to read and write data in logical blocks without knowing much about the underlying hardware. The OS relies on the storage device to map the blocks to its physical sectors. EBS advertises 512-byte sectors to the operating system, which reads and writes data to disk using data blocks that are a multiple of the sector size.

The industry default size for logical data blocks is currently 4,096 bytes (4 KiB). Because certain workloads benefit from a smaller or larger block size, file systems support non-default block sizes that can be specified during formatting. Scenarios in which non-default block sizes should be used are outside the scope of this topic, but the choice of block size has consequences for the storage capacity of the volume. The following table shows storage capacity as a function of block size:

<table>
<thead>
<tr>
<th>Block size</th>
<th>Max volume size</th>
</tr>
</thead>
<tbody>
<tr>
<td>4 KiB (default)</td>
<td>16 TiB</td>
</tr>
<tr>
<td>8 KiB</td>
<td>32 TiB</td>
</tr>
<tr>
<td>16 KiB</td>
<td>64 TiB</td>
</tr>
<tr>
<td>32 KiB</td>
<td>128 TiB</td>
</tr>
<tr>
<td>64 KiB (maximum)</td>
<td>256 TiB</td>
</tr>
</tbody>
</table>

The EBS-imposed limit on volume size (64 TiB) is currently equal to the maximum size enabled by 16-KiB data blocks.

**Create an Amazon EBS volume**

You can create an Amazon EBS volume and then attach it to any EC2 instance in the same Availability Zone. If you create an encrypted EBS volume, you can only attach it to supported instance types. For more information, see [Supported instance types](p. 1977).

If you are creating a volume for a high-performance storage scenario, you should make sure to use a Provisioned IOPS SSD volume (io1 or io2) and attach it to an instance with enough bandwidth to support your application, such as an EBS-optimized instance. The same advice holds for Throughput Optimized HDD (st1) and Cold HDD (sc1) volumes. For more information, see [Amazon EBS–optimized instances](p. 1998).

Empty EBS volumes receive their maximum performance the moment that they are available and do not require initialization (formerly known as pre-warming). However, storage blocks on volumes that were created from snapshots must be initialized (pulled down from Amazon S3 and written to the volume) before you can access the block. This preliminary action takes time and can cause a significant increase in the latency of an I/O operation the first time each block is accessed. Volume performance is achieved after all blocks have been downloaded and written to the volume. For most applications, amortizing this cost over the lifetime of the volume is acceptable. To avoid this initial performance hit in a production environment, you can force immediate initialization of the entire volume or enable fast snapshot restore. For more information, see [Initialize Amazon EBS volumes](p. 2033).
Important

If you create an io2 volume with a size greater than 16 TiB or with IOPS greater than 64,000 in a Region where EBS Block Express is supported, the volume automatically runs on Block Express. io2 Block Express volumes can be attached to supported instances only. For more information, see io2 Block Express volumes.

Methods of creating a volume

- Create and attach EBS volumes when you launch instances by specifying a block device mapping. For more information, see Launch an instance using the new launch instance wizard (p. 676) and Block device mappings (p. 2101).
- Create an empty EBS volume and attach it to a running instance. For more information, see Create an empty volume (p. 1795) below.
- Create an EBS volume from a previously created snapshot and attach it to a running instance. For more information, see Create a volume from a snapshot (p. 1796) below.

Create an empty volume

Empty volumes receive their maximum performance the moment that they are available and do not require initialization.

You can create an empty EBS volume using one of the following methods.

Console

To create an empty EBS volume using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Choose Create volume.
4. For Volume type, choose the type of volume to create. For more information, see Amazon EBS volume types (p. 1775).
5. For Size, enter the size of the volume, in GiB. For more information, see Constraints on the size and configuration of an EBS volume (p. 1792).
6. (io1, io2, and gp3 only) For IOPS, enter the maximum number of input/output operations per second (IOPS) that the volume should provide.
7. (gp3 only) For Throughput, enter the throughput that the volume should provide, in MiB/s.
8. For Availability Zone, choose the Availability Zone in which to create the volume. A volume can be attached only to an instance that is in the same Availability Zone.
9. For Snapshot ID, keep the default value (Don't create volume from a snapshot).
10. (io1 and io2 only) To enable the volume for Amazon EBS Multi-Attach, select Enable Multi-Attach. For more information, see Attach a volume to multiple instances with Amazon EBS Multi-Attach (p. 1799).
11. Set the encryption status for the volume.

If your account is enabled for encryption by default (p. 1797), then encryption is automatically enabled and you can't disable it. You can choose the KMS key to use to encrypt the volume.

If your account is not enabled for encryption by default, encryption is optional. To encrypt the volume, for Encryption, choose Encrypt this volume and then select the KMS key to use to encrypt the volume.

Note

Encrypted volumes can be attached only to instances that support Amazon EBS encryption. For more information, see Amazon EBS encryption (p. 1975).
12. (Optional) To assign custom tags to the volume, in the Tags section, choose Add tag, and then enter a tag key and value pair. For more information, see Tag your Amazon EC2 resources (p. 2154).

13. Choose Create volume.

   **Note**
   The volume is ready for use when the Volume state is available.

14. To use the volume, attach it to an instance. For more information, see Attach an Amazon EBS volume to an instance (p. 1797).

AWS CLI

**To create an empty EBS volume using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- create-volume (AWS CLI)
- New-EC2Volume (AWS Tools for Windows PowerShell)

The volume is ready for use when the state is available.

**Create a volume from a snapshot**

Volumes created from snapshots load lazily in the background. This means that there is no need to wait for all of the data to transfer from Amazon S3 to your EBS volume before the instance can start accessing an attached volume and all its data. If your instance accesses data that hasn't yet been loaded, the volume immediately downloads the requested data from Amazon S3, and then continues loading the rest of the volume data in the background. Volume performance is achieved after all blocks are downloaded and written to the volume. To avoid the initial performance hit in a production environment, see Initialize Amazon EBS volumes (p. 2033).

New EBS volumes that are created from encrypted snapshots are automatically encrypted. You can also encrypt a volume on-the-fly while restoring it from an unencrypted snapshot. Encrypted volumes can only be attached to instance types that support EBS encryption. For more information, see Supported instance types (p. 1977).

You can create a volume from a snapshot using one of the following methods.

**Console**

**To create an EBS volume from a snapshot using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Choose Create volume.
4. For Volume type, choose the type of volume to create. For more information, see Amazon EBS volume types (p. 1775).
5. For Size, enter the size of the volume, in GiB. For more information, see Constraints on the size and configuration of an EBS volume (p. 1792).
6. (io1, io2, and gp3 only) For IOPS, enter the maximum number of input/output operations per second (IOPS) that the volume should provide.
7. (gp3 only) For Throughput, enter the throughput that the volume should provide, in MiB/s.
8. For **Availability Zone**, choose the Availability Zone in which to create the volume. A volume can be attached only to instances that are in the same Availability Zone.

9. For **Snapshot ID**, select the snapshot from which to create the volume.

10. Set the encryption status for the volume.

    If the selected snapshot is encrypted, or if your account is enabled for encryption by default (p. 1979), then encryption is automatically enabled and you can't disable it. You can choose the KMS key to use to encrypt the volume.

    If the selected snapshot is unencrypted and your account is not enabled for encryption by default, encryption is optional. To encrypt the volume, for **Encryption**, choose **Encrypt this volume** and then select the KMS key to use to encrypt the volume.

    **Note**
    Encrypted volumes can be attached only to instances that support Amazon EBS encryption. For more information, see Amazon EBS encryption (p. 1975).

11. (Optional) To assign custom tags to the volume, in the **Tags** section, choose **Add tag**, and then enter a tag key and value pair. For more information, see Tag your Amazon EC2 resources (p. 2154).

12. Choose **Create Volume**.

    **Note**
    The volume is ready for use when the **Volume state** is **available**.

13. To use the volume, attach it to an instance. For more information, see Attach an Amazon EBS volume to an instance (p. 1797).

**AWS CLI**

To create an EBS volume from a snapshot using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- `create-volume` (AWS CLI)
- `New-EC2Volume` (AWS Tools for Windows PowerShell)

The volume is ready for use when the state is available.

**Attach an Amazon EBS volume to an instance**

You can attach an available EBS volume to one or more of your instances that is in the same Availability Zone as the volume.

For information about adding EBS volumes to your instance at launch, see Instance block device mapping (p. 2106).

**Prerequisites**

- Determine how many volumes that you can attach to your instance. For more information, see Instance volume limits (p. 2091).
- Determine whether you can attach your volume to multiple instances and enable Multi-Attach. For more information, see Attach a volume to multiple instances with Amazon EBS Multi-Attach (p. 1799).
- If a volume is encrypted, you can attach it only to an instance that supports Amazon EBS encryption. For more information, see Supported instance types (p. 1977).
• If a volume has an AWS Marketplace product code:
  • You can attach a volume only to a stopped instance.
  • You must be subscribed to the AWS Marketplace code that is on the volume.
  • The instance's configuration, such as its type and operating system, must support that specific AWS
    Marketplace code. For example, you cannot take a volume from a Windows instance and attach it to
    a Linux instance.
  • AWS Marketplace product codes are copied from the volume to the instance.

  **Important**
  If you attach an io2 volume to an instance that supports Block Express, the volume always runs
  on Block Express. For more information, see [io2 Block Express volumes](#).

You can attach a volume to an instance using one of the following methods.

**Console**

To attach an EBS volume to an instance using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Volumes**.
3. Select the volume to attach and choose **Actions, Attach volume**.
   
   **Note**
   You can attach only volumes that are in the **Available** state.
4. For **Instance**, enter the ID of the instance or select the instance from the list of options.
   
   **Note**
   • The volume must be attached to an instance in the same Availability Zone.
   • If the volume is encrypted, it can only be attached to instance types that
     support Amazon EBS encryption. For more information, see [Amazon EBS
     encryption](#).
5. For **Device name**, enter a supported device name for the volume. This device name is used by
   Amazon EC2. The block device driver for the instance might assign a different device name when
   mounting the volume. For more information, see [Device names on Linux instances](#).
6. Choose **Attach volume**.
7. Connect to the instance and mount the volume. For more information, see [Make an Amazon EBS
   volume available for use on Linux](#).

**AWS CLI**

To attach an EBS volume to an instance using the command line

You can use one of the following commands. For more information about these command line
interfaces, see [Access Amazon EC2](#).

• **attach-volume** (AWS CLI)
• **Add-EC2Volume** (AWS Tools for Windows PowerShell)

  **Note**
  In some situations, you may find that a volume other than the volume attached to `/dev/xvda`
  or `/dev/sda` has become the root volume of your instance. This can happen when you have
  attached the root volume of another instance, or a volume created from the snapshot of a root
volume, to an instance with an existing root volume. For more information, see Boot from the wrong volume.

Attach a volume to multiple instances with Amazon EBS Multi-Attach

Amazon EBS Multi-Attach enables you to attach a single Provisioned IOPS SSD (io1 or io2) volume to multiple instances that are in the same Availability Zone. You can attach multiple Multi-Attach enabled volumes to an instance or set of instances. Each instance to which the volume is attached has full read and write permission to the shared volume. Multi-Attach makes it easier for you to achieve higher application availability in clustered Linux applications that manage concurrent write operations.

Contents
- Considerations and limitations (p. 448)
- Performance (p. 1800)
- Work with Multi-Attach (p. 1800)
- Monitor a Multi-Attach enabled volume (p. 1803)
- Pricing and billing (p. 654)

Considerations and limitations

- Multi-Attach enabled volumes can be attached to up to 16 Linux instances built on the Nitro System (p. 282) that are in the same Availability Zone. You can attach a volume that is Multi-Attach enabled to Windows instances, but the operating system does not recognize the data on the volume that is shared between the instances, which can result in data inconsistency.
- Multi-Attach is supported exclusively on Provisioned IOPS SSD (io1 and io2) volumes (p. 1781).
- Multi-Attach for io1 volumes is available in the following Regions only: US East (N. Virginia), US West (N. California), US West (Oregon), and Asia Pacific (Seoul).
- Multi-Attach for io2 and io2 Block Express volumes is available in all Regions that support those volumes types.
- You can’t attach a Multi-Attach enabled io2 volume to instance types that support Block Express and instance types that do not support Block Express at the same time. For more information, see io2 Block Express volumes (p. 1783).
- io1 volumes with Multi-Attach enabled are not supported with instance types that support io2 Block Express. To use Multi-Attach with these instance types, you must use io2 volumes.
- Standard file systems, such as XFS and EXT4, are not designed to be accessed simultaneously by multiple servers, such as EC2 instances. Using Multi-Attach with a standard file system can result in data corruption or loss, so this is not safe for production workloads. You can use a clustered file system to ensure data resiliency and reliability for production workloads.
- Multi-Attach enabled volumes do not support I/O fencing. I/O fencing protocols control write access in a shared storage environment to maintain data consistency. Your applications must provide write ordering for the attached instances to maintain data consistency.
- Multi-Attach enabled volumes can’t be created as boot volumes.
- Multi-Attach enabled volumes can be attached to one block device mapping per instance.
- Multi-Attach can’t be enabled during instance launch using either the Amazon EC2 console or RunInstances API.
- Multi-Attach enabled volumes that have an issue at the Amazon EBS infrastructure layer are unavailable to all attached instances. Issues at the Amazon EC2 or networking layer might impact only some attached instances.
- The following table shows volume modification support for Multi-Attach enabled io1 and io2 volumes after creation.
### Modify volume type

<table>
<thead>
<tr>
<th></th>
<th>io2 volumes</th>
<th>io1 volumes</th>

<td>x</td>
</tr>
</tbody>
</table>

* You can't enable or disable Multi-Attach while the volume is attached to an instance.

### Performance

Each attached instance is able to drive its maximum IOPS performance up to the volume's maximum provisioned performance. However, the aggregate performance of all of the attached instances can't exceed the volume's maximum provisioned performance. If the attached instances' demand for IOPS is higher than the volume's Provisioned IOPS, the volume will not exceed its provisioned performance.

For example, say you create an io2 Multi-Attach enabled volume with 50,000 Provisioned IOPS and you attach it to an m5.8xlarge instance and a c5.12xlarge instance. The m5.8xlarge and c5.12xlarge instances support a maximum of 30,000 and 40,000 IOPS respectively. Each instance can drive its maximum IOPS as it is less than the volume's Provisioned IOPS of 50,000. However, if both instances drive I/O to the volume simultaneously, their combined IOPS can't exceed the volume's provisioned performance of 50,000 IOPS. The volume will not exceed 50,000 IOPS.

To achieve consistent performance, it is best practice to balance I/O driven from attached instances across the sectors of a Multi-Attach enabled volume.

### Work with Multi-Attach

Multi-Attach enabled volumes can be managed in much the same way that you would manage any other Amazon EBS volume. However, in order to use the Multi-Attach functionality, you must enable it for the volume. When you create a new volume, Multi-Attach is disabled by default.

### Contents

- [Enable Multi-Attach](#) (p. 1800)
- [Disable Multi-Attach](#) (p. 1802)
- [Attach a volume to instances](#) (p. 1802)
- [Delete on termination](#) (p. 1802)

#### Enable Multi-Attach

You can enable Multi-Attach for io1 and io2 volumes during creation.

Use one of the following methods to enable Multi-Attach for an io1 or io2 volume during creation.
To enable Multi-Attach during volume creation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Choose Create volume.
4. For Volume type, choose Provisioned IOPS SSD (io1) or Provisioned IOPS SSD (io2).
5. For Size and IOPS, choose the required volume size and the number of IOPS to provision.
6. For Availability Zone, choose the same Availability Zone that the instances are in.
7. For Amazon EBS Multi-Attach, choose Enable Multi-Attach.
8. (Optional) For Snapshot ID, choose the snapshot from which to create the volume.
9. Set the encryption status for the volume.
   - If the selected snapshot is encrypted, or if your account is enabled for encryption by default (p. 1979), then encryption is automatically enabled and you can't disable it. You can choose the KMS key to use to encrypt the volume.
   - If the selected snapshot is unencrypted and your account is not enabled for encryption by default, encryption is optional. To encrypt the volume, for Encryption, choose Encrypt this volume and then select the KMS key to use to encrypt the volume.

   **Note**
   You can attach encrypted volumes only to instances that support Amazon EBS encryption. For more information, see Amazon EBS encryption (p. 1975).

10. (Optional) To assign custom tags to the volume, in the Tags section, choose Add tag, and then enter a tag key and value pair. For more information, see Tag your Amazon EC2 resources (p. 2154).
11. Choose Create volume.

Command line

To enable Multi-Attach during volume creation

Use the `create-volume` command and specify the `--multi-attach-enabled` parameter.

```
$ aws ec2 create-volume --volume-type io2 --multi-attach-enabled --size 100 --iops 2000
--region us-west-2 --availability-zone us-west-2b
```

You can also enable Multi-Attach for io2 volumes after they have been created only if they are not attached to any instances.

**Note**
You can't enable Multi-Attach for io1 volumes after creation.

Use one of the following methods to enable Multi-Attach for an Amazon EBS volume after it has been created.

Console

To enable Multi-Attach after creation

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Select the volume and choose Actions, Modify volume.
4. For Amazon EBS Multi-Attach, choose Enable Multi-Attach.
5. Choose Modify.

Command line

**To enable Multi-Attach after creation**

Use the modify-volume command and specify the --multi-attach-enabled parameter.

```
$ aws ec2 modify-volume --volume-id vol-1234567890abcdef0 --multi-attach-enabled
```

**Disable Multi-Attach**

You can disable Multi-Attach for an io2 volume only if it is attached to no more than one instance.

**Note**

You can’t disable Multi-Attach for io1 volumes after creation.

Use one of the following methods to disable Multi-Attach for an io2 volume.

**Console**

**To disable Multi-Attach after creation**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Select the volume and choose Actions, Modify volume.
4. For Amazon EBS Multi-Attach, clear Enable Multi-Attach.
5. Choose Modify.

Command line

**To disable Multi-Attach after creation**

Use the modify-volume command and specify the --no-multi-attach-enabled parameter.

```
$ aws ec2 modify-volume --volume-id vol-1234567890abcdef0 --no-multi-attach-enabled
```

**Attach a volume to instances**

You attach a Multi-Attach enabled volume to an instance in the same way that you attach any other EBS volume. For more information, see [Attach an Amazon EBS volume to an instance](p. 1797).

**Delete on termination**

Multi-Attach enabled volumes are deleted on instance termination if the last attached instance is terminated and if that instance is configured to delete the volume on termination. If the volume is attached to multiple instances that have different delete on termination settings in their volume block device mappings, the last attached instance's block device mapping setting determines the delete on termination behavior.

To ensure predictable delete on termination behavior, enable or disable delete on termination for all of the instances to which the volume is attached.
By default, when a volume is attached to an instance, the delete on termination setting for the block device mapping is set to false. If you want to turn on delete on termination for a Multi-Attach enabled volume, modify the block device mapping.

If you want the volume to be deleted when the attached instances are terminated, enable delete on termination in the block device mapping for all of the attached instances. If you want to retain the volume after the attached instances have been terminated, disable delete on termination in the block device mapping for all of the attached instances. For more information, see Preserve Amazon EBS volumes on instance termination (p. 750).

You can modify an instance's delete on termination setting at launch or after it has launched. If you enable or disable delete on termination during instance launch, the settings apply only to volumes that are attached at launch. If you attach a volume to an instance after launch, you must explicitly set the delete on termination behavior for that volume.

You can modify an instance's delete on termination setting using the command line tools only.

To modify the delete on termination setting for an existing instance

Use the modify-instance-attribute command and specify the DeleteOnTermination attribute in the --block-device-mappings option.

```
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --block-device-mappings file://mapping.json
```

Specify the following in mapping.json.

```
[
    {
        "DeviceName": "/dev/sdf",
        "Ebs": {
            "DeleteOnTermination": true|false
        }
    }
]
```

Monitor a Multi-Attach enabled volume

You can monitor a Multi-Attach enabled volume using the CloudWatch Metrics for Amazon EBS volumes. For more information, see Amazon CloudWatch metrics for Amazon EBS (p. 2043).

Data is aggregated across all of the attached instances. You can't monitor metrics for individual attached instances.

Pricing and billing

There are no additional charges for using Amazon EBS Multi-Attach. You are billed the standard charges that apply to Provisioned IOPS SSD (io1 and io2) volumes. For more information, see Amazon EBS pricing.

Make an Amazon EBS volume available for use on Linux

After you attach an Amazon EBS volume to your instance, it is exposed as a block device. You can format the volume with any file system and then mount it. After you make the EBS volume available for use, you can access it in the same ways that you access any other volume. Any data written to this file system is written to the EBS volume and is transparent to applications using the device.
You can take snapshots of your EBS volume for backup purposes or to use as a baseline when you create another volume. For more information, see Amazon EBS snapshots (p. 1825).

If the EBS volume you are preparing for use is greater than 2 TiB, you must use a GPT partitioning scheme to access the entire volume. For more information, see Constraints on the size and configuration of an EBS volume (p. 1792).

You can get directions for volumes on a Windows instance from Make a volume available for use on Windows in the Amazon EC2 User Guide for Windows Instances.

Format and mount an attached volume

Suppose that you have an EC2 instance with an EBS volume for the root device, /dev/xvda, and that you have just attached an empty EBS volume to the instance using /dev/sdf. Use the following procedure to make the newly attached volume available for use.

To format and mount an EBS volume on Linux

1. Connect to your instance using SSH. For more information, see Connect to your Linux instance (p. 757).
2. The device could be attached to the instance with a different device name than you specified in the block device mapping. For more information, see Device names on Linux instances (p. 2099). Use the lsblk command to view your available disk devices and their mount points (if applicable) to help you determine the correct device name to use. The output of lsblk removes the /dev/ prefix from full device paths.

The following is example output for an instance built on the Nitro System (p. 282), which exposes EBS volumes as NVMe block devices. The root device is /dev/nvme0n1, which has two partitions named nvme0n1p1 and nvme0n1p128. The attached volume is /dev/nvme1n1, which has no partitions and is not yet mounted.

```
[ec2-user ~]$ lsblk
NAME       MAJ:MIN  RM SIZE RO TYPE MOUNTPOINT
nvme1n1    259:0    0  10G  0 disk
nvme0n1    259:1    0   8G  0 disk
-nvme0n1p1  259:2    0   8G  0 part /
-nvme0n1p128  259:3    0  1M  0 part
```

The following is example output for a T2 instance. The root device is /dev/xvda, which has one partition named xvda1. The attached volume is /dev/xvdf, which has no partitions and is not yet mounted.

```
[ec2-user ~]$ lsblk
NAME       MAJ:MIN  RM SIZE RO TYPE MOUNTPOINT
xvda       202:0    0   8G  0 disk
-xvda1 202:1    0   8G  0 part /
xvdf       202:80   0  10G  0 disk
```

3. Determine whether there is a file system on the volume. New volumes are raw block devices, and you must create a file system on them before you can mount and use them. Volumes that were created from snapshots likely have a file system on them already; if you create a new file system on top of an existing file system, the operation overwrites your data.

Use one or both of the following methods to determine whether there is a file system on the volume:

- Use the file -s command to get information about a specific device, such as its file system type. If the output shows simply data, as in the following example output, there is no file system on the device
If the device has a file system, the command shows information about the file system type. For example, the following output shows a root device with the XFS file system.

```
[ec2-user ~]$ sudo file -s /dev/xvdf
/dev/xvdf: data
```

If the device has a file system, the command shows information about the file system type. For example, the following output shows a root device with the XFS file system.

```
[ec2-user ~]$ sudo file -s /dev/xvda1
/dev/xvda1: SGI XFS filesystem data (blksz 4096, inosz 512, v2 dirs)
```

• Use the `lsblk -f` command to get information about all of the devices attached to the instance.

```
[ec2-user ~]$ sudo lsblk -f
```

For example, the following output shows that there are three devices attached to the instances — `nvme1n1`, `nvme0n1`, and `nvme2n1`. The first column lists the devices and their partitions. The FSTYPE column shows the file system type for each device. If the column is empty for a specific device, it means that the device does not have a file system. In this case, device `nvme1n1` and partition `nvme0n1p1` on device `nvme0n1` are both formatted using the XFS file system, while device `nvme2n1` and partition `nvme0n1p128` on device `nvme0n1` do not have file systems.

<table>
<thead>
<tr>
<th>NAME</th>
<th>FSTYPE</th>
<th>LABEL</th>
<th>UUID</th>
<th>MOUNTPOINT</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvme1n1</td>
<td>xfs</td>
<td></td>
<td>7f939f28-6dccc-4315-8c42-6806080b94dd</td>
<td></td>
</tr>
<tr>
<td>nvme0n1</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>#nvme0n1p1</td>
<td>xfs</td>
<td></td>
<td>90e29211-2de8-4967-b0fb-16f51a6e464c</td>
<td>/</td>
</tr>
<tr>
<td>#nvme0n1p128</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>nvme2n1</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If the output from these commands show that there is no file system on the device, you must create one.

4. (Conditional) If you discovered that there is a file system on the device in the previous step, skip this step. If you have an empty volume, use the `mkfs -t` command to create a file system on the volume.

**Warning**
Do not use this command if you’re mounting a volume that already has data on it (for example, a volume that was created from a snapshot). Otherwise, you’ll format the volume and delete the existing data.

```
[ec2-user ~]$ sudo mkfs -t xfs /dev/xvdf
```

If you get an error that `mkfs.xfs` is not found, use the following command to install the XFS tools and then repeat the previous command:

```
[ec2-user ~]$ sudo yum install xfsprogs
```

5. Use the `mkdir` command to create a mount point directory for the volume. The mount point is where the volume is located in the file system tree and where you read and write files to after you mount the volume. The following example creates a directory named `/data`.

```
[ec2-user ~]$ sudo mkdir /data
```

6. Mount the volume or partition at the mount point directory you created in the previous step.

If the volume has no partitions, use the following command and specify the device name to mount the entire volume.
Amazon Elastic Compute Cloud
User Guide for Linux Instances
EBS volumes

[ec2-user ~]$ sudo mount /dev/xvdf /data

If the volume has partitions, use the following command and specify the partition name to mount a partition.

[ec2-user ~]$ sudo mount /dev/xvdf1 /data

7. Review the file permissions of your new volume mount to make sure that your users and applications can write to the volume. For more information about file permissions, see File security at The Linux Documentation Project.

8. The mount point is not automatically preserved after rebooting your instance. To automatically mount this EBS volume after reboot, see Automatically mount an attached volume after reboot (p. 1806).

Automatically mount an attached volume after reboot

To mount an attached EBS volume on every system reboot, add an entry for the device to the /etc/fstab file.

You can use the device name, such as /dev/xvdf, in /etc/fstab, but we recommend using the device's 128-bit universally unique identifier (UUID) instead. Device names can change, but the UUID persists throughout the life of the partition. By using the UUID, you reduce the chances that the system becomes unbootable after a hardware reconfiguration. For more information, see Identify the EBS device (p. 1995).

To mount an attached volume automatically after reboot

1. (Optional) Create a backup of your /etc/fstab file that you can use if you accidentally destroy or delete this file while editing it.

[ec2-user ~]$ sudo cp /etc/fstab /etc/fstab.orig

2. Use the blkid command to find the UUID of the device. Make a note of the UUID of the device that you want to mount after reboot. You'll need it in the following step.

For example, the following command shows that there are two devices mounted to the instance, and it shows the UUIDs for both devices.

[ec2-user ~]$ sudo blkid
/dev/xvda1: LABEL="/" UUID="ca774df7-756d-4261-a3f1-76038323e572" TYPE="xfs"
PARTLABEL="Linux" PARTUUID="02dcd367-e07c-4f2e-9a72-a53f8f299c10"
/dev/xvdf: UUID="aebf131c-6957-451e-8d34-ec978d9581ae" TYPE="xfs"

For Ubuntu 18.04 use the lsblk command.

[ec2-user ~]$ sudo lsblk -o "+UUID"

3. Open the /etc/fstab file using any text editor, such as nano or vim.

[ec2-user ~]$ sudo vim /etc/fstab

4. Add the following entry to /etc/fstab to mount the device at the specified mount point. The fields are the UUID value returned by blkid (or lsblk for Ubuntu 18.04), the mount point, the file system, and the recommended file system mount options. For more information about the required fields, run man fstab to open the fstab manual.
In the following example, we mount the device with UUID aebf131c-6957-451e-8d34-ec978d9581ae to mount point /data and we use the xfs file system. We also use the defaults and nofail flags. We specify 0 to prevent the file system from being dumped, and we specify 2 to indicate that it is a non-root device.

```
UUID=aebf131c-6957-451e-8d34-ec978d9581ae /data xfs defaults,nofail 0 2
```

**Note**

If you ever boot your instance without this volume attached (for example, after moving the volume to another instance), the nofail mount option enables the instance to boot even if there are errors mounting the volume. Debian derivatives, including Ubuntu versions earlier than 16.04, must also add the nobootwait mount option.

5. To verify that your entry works, run the following commands to unmount the device and then mount all file systems in /etc/fstab. If there are no errors, the /etc/fstab file is OK and your file system will mount automatically after it is rebooted.

```
[ec2-user ~]$
mount -a
```

If you receive an error message, address the errors in the file.

**Warning**

Errors in the /etc/fstab file can render a system unbootable. Do not shut down a system that has errors in the /etc/fstab file.

If you are unsure how to correct errors in /etc/fstab and you created a backup file in the first step of this procedure, you can restore from your backup file using the following command.

```
[ec2-user ~]$
mv /etc/fstab.orig /etc/fstab
```

**View information about an Amazon EBS volume**

You can view descriptive information about your EBS volumes. For example, you can view information about all volumes in a specific Region or view detailed information about a single volume, including its size, volume type, whether the volume is encrypted, which master key was used to encrypt the volume, and the specific instance to which the volume is attached.

You can get additional information about your EBS volumes, such as how much disk space is available, from the operating system on the instance.

**View volume information**

You can view information about a volume using one of the following methods.

**Console**

**To view information about a volume using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Volumes**.
3. To reduce the list, you can filter your volumes using tags and volume attributes. Choose the filter field, select a tag or volume attribute, and then select the filter value.
4. To view more information about a volume, choose its ID.
To view the EBS volumes that are attached to an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance.
4. On the Storage tab, the Block devices section lists the volumes that are attached to the instance. To view information about a specific volume, choose its ID in the Volume ID column.

AWS CLI

To view information about an EBS volume using the command line

You can use one of the following commands to view volume attributes. For more information, see Access Amazon EC2 (p. 5).

- `describe-volumes` (AWS CLI)
- `Get-EC2Volume` (AWS Tools for Windows PowerShell)

Amazon EC2 Global View

You can use Amazon EC2 Global View to view your volumes across all Regions for which your AWS account is enabled. For more information, see List and filter resources across Regions using Amazon EC2 Global View (p. 2152).

Volume state

Volume state describes the availability of an Amazon EBS volume. You can view the volume state in the State column on the Volumes page in the console, or by using the `describe-volumes` AWS CLI command.

The possible volume states are:

- creating
  - The volume is being created.
- available
  - The volume is not attached to an instance.
- in-use
  - The volume is attached to an instance.
- deleting
  - The volume is being deleted.
- deleted
  - The volume is deleted.
- error
  - The underlying hardware related to your EBS volume has failed, and the data associated with the volume is unrecoverable. For information about how to restore the volume or recover the data on the volume, see My EBS volume has a status of ‘error’.

View volume metrics

You can get additional information about your EBS volumes from Amazon CloudWatch. For more information, see Amazon CloudWatch metrics for Amazon EBS (p. 2043).
View free disk space

You can get additional information about your EBS volumes, such as how much disk space is available, from the Linux operating system on the instance. For example, use the following command:

```
[ec2-user ~]$ df -hT /dev/xvda1
```

<table>
<thead>
<tr>
<th>Filesystem</th>
<th>Type</th>
<th>Size</th>
<th>Used</th>
<th>Avail</th>
<th>Use%</th>
<th>Mounted on</th>
</tr>
</thead>
<tbody>
<tr>
<td>/dev/xvda1</td>
<td>xfs</td>
<td>8.0G</td>
<td>1.2G</td>
<td>6.9G</td>
<td>15%</td>
<td>/</td>
</tr>
</tbody>
</table>

Tip

You can also use the CloudWatch agent to collect disk space usage metrics from an Amazon EC2 instance without connecting to the instance. For more information, see Create the CloudWatch agent configuration file and Installing the CloudWatch agent in the Amazon CloudWatch User Guide. If you need to monitor disk space usage for multiple instances, you can install and configure the CloudWatch agent on those instances using Systems Manager. For more information, see Installing the CloudWatch agent using Systems Manager.

For information about viewing free disk space on a Windows instance, see View free disk space in the Amazon EC2 User Guide for Windows Instances.

Replace a volume using a previous snapshot

Amazon EBS snapshots are the preferred backup tool on Amazon EC2 because of their speed, convenience, and cost. When creating a volume from a snapshot, you recreate its state at a specific point in time with the data saved up to that specific point intact. By attaching a volume created from a snapshot to an instance, you can duplicate data across Regions, create test environments, replace a damaged or corrupted production volume in its entirety, or retrieve specific files and directories and transfer them to another attached volume. For more information, see Amazon EBS snapshots (p. 1825).

You can use one of the following procedure to replace an Amazon EBS volume with another volume created from a previous snapshot of that volume. You must detach the current volume and then attach the new volume.

**Note**

Amazon EBS volumes can only be attached to instances in the same Availability Zone.

**Console**

**To replace a volume**

1. Create a volume from the snapshot and write down the ID of the new volume. For more information, see Create a volume from a snapshot (p. 1796).
2. On the Instances page, select the instance on which to replace the volume and write down the instance ID.

   With the instance still selected, choose the Storage tab. In the Block devices section, find the volume to replace and write down the device name for the volume, for example /dev/sda1.

   Choose the volume ID.
3. On the Volumes screen, select the volume and choose Actions, Detach volume, Detach.
4. Select the new volume that you created in step 1 and choose Actions, Attach volume.

   For **Instance** and **Device name**, enter the instance ID and device name that you wrote down in Step 2, and then choose Attach volume.
5. Connect to your instance and mount the volume. For more information, see Make an Amazon EBS volume available for use on Linux (p. 1803).
Replace a root volume

Amazon EC2 enables you to replace the root Amazon EBS volume for a running instance while retaining the following:

- Data stored on instance store volumes — Instance store volumes remain attached to the instance after the root volume has been restored.
- Data stored on data (non-root) Amazon EBS volumes — Non-root Amazon EBS volumes remain attached to the instance after the root volume has been restored.
- Network configuration — All network interfaces remain attached to the instance and they retain their IP addresses, identifiers, and attachment IDs. When the instance becomes available, all pending network traffic is flushed. Additionally, the instance remains on the same physical host, so it retains its public and private IP addresses and DNS name.
- IAM policies — IAM profiles and policies (such as tag-based policies) that are associated with the instance are retained and enforced.

Topics

- How does it work? (p. 1810)
- Replace a root volume (p. 1813)
- View root volume replacement tasks (p. 1814)

How does it work?

When you replace the root volume for an instance, a new (replacement) root volume is restored in one of the following ways:

- **To the initial launch state** — the volume is restored to its initial state at instance launch. For more information, see Restore a root volume to its launch state (p. 1811).
- **From a snapshot** from the same lineage as the current root volume — this allows you to fix issues, such as root volume corruption or guest operating system network configuration errors. For more information, see Replace a root volume using a snapshot (p. 1811).
- **From an AMI** that has the same key attributes as the instance — this allows you to perform operating system and application patching or upgrades. For more information, see Replace a root volume using an AMI (p. 1811).

The original root volume is detached from the instance, and the new root volume is attached to the instance in its place. The instance's block device mapping is updated to reflect the ID of the replacement root volume. You can choose whether or not to keep the original root volume after the root volume replacement process has completed. If you choose delete the original root volume after the replacement process completes, the original root volume is automatically deleted and becomes unrecoverable. If you choose to keep the original root volume after the process completes, the volume remains provisioned in your account; you must manually delete it when you no longer need it.

If the root volume replacement task fails, the instance is rebooted and the original root volume remains attached to the instance.

Considerations for root volume replacement

- The instance must be in the running state.
- The instance is automatically rebooted during the process. The contents of the memory (RAM) is erased during the reboot. No manual reboots are required.
- You can't replace the root volume if it is an instance store volume. Only instances with Amazon EBS root volumes are supported.
You can replace the root volume for all virtualized instance types and EC2 Mac bare metal instances. All other bare metal instance types are not supported.

Amazon EC2 Mac bare metal instances support restoring a root volume to its launch state and replacing a root volume using a snapshot. Amazon EC2 Mac bare metal instances do not currently support replacing a root volume using an AMI.

You can use any snapshot that belongs to the same lineage as any of the instance's previous root volumes.

If Amazon EBS encryption by default is enabled for the account and Region, and you perform a root volume replacement using an unencrypted snapshot or AMI, the replacement root volume that is created is unencrypted. To create an encrypted replacement root volume, you should consider using an AMI with an encrypted root volume.

**Topics**

- **Restore a root volume to its launch state** *(p. 1811)*
- **Replace a root volume using a snapshot** *(p. 1811)*
- **Replace a root volume using an AMI** *(p. 1811)*

**Restore a root volume to its launch state**

You can perform a root volume replacement that replaces an instance's root volume with a replacement root volume that is restored to the original root volume's launch state. The replacement volume is automatically restored from the snapshot that was used to create the original volume during the instance launch.

The replacement root volume gets the same type, size, and delete on termination attributes as the original root volume.

**Replace a root volume using a snapshot**

You can perform a root volume replacement that replaces an instance's root volume with a replacement volume that is restored to a specific snapshot. This enables you to restore the root volume for an instance to a specific snapshot that you previously created from that root volume.

The replacement root volume gets the same type, size, and delete on termination attributes as the original root volume.

**Considerations for using a snapshot**

- You can only use snapshots that belong to the same lineage as the instance's current root volume.
- You can't use snapshot copies created from snapshots that were taken from the root volume.
- After successfully replacing the root volume, snapshots taken from the original root volume can still be used to replace the new (replacement) root volume.

**Replace a root volume using an AMI**

You can perform a root volume replacement using an AMI that you own or an AMI that is shared with you. The AMI must have the same product code, billing information, architecture type, and virtualization type as that of the instance.

If the instance is enabled for NitroTPM, ENA, or sriov-net, then you must use an AMI that supports those features. If the instance is not enabled for NitroTPM, ENA, or sriov-net, then you can select an AMI that does not support those features, or you can select an AMI that does support them, in which case support is added to the instance.
You can select an AMI with a different boot mode than that of the instance, as long as the instance supports the boot mode of the AMI. If the instance does not support the boot mode, the request fails. If the instance supports the boot mode, the new boot mode is propagated to the instance and its UEFI data is updated accordingly. If you manually modified the boot order or added a private UEFI Secure Boot key to load private kernel modules, the changes are lost during root volume replacement.

The replacement root volume gets the same volume type and delete on termination attribute as the original root volume, and it gets the size of the AMI root volume block device mapping.

**Note**
The size of the AMI root volume block device mapping must be equal to or greater than the size of the original root volume. If the size of the AMI root volume block device mapping is smaller than the size of the original root volume, the request fails.

After the root volume replacement task completes, the following new and updated information is reflected when you describe the instance using the console, AWS CLI or AWS SDKs:

- New AMI ID
- New volume ID for the root volume
- Updated boot mode configuration (if changed by the AMI)
- Updated NitroTPM configuration (if enabled by the AMI)
- Updated ENA configuration (if enabled by the AMI)
- Updated sriov-net configuration (if enabled by the AMI)

The new AMI ID is also reflected in the instance metadata.

**Considerations for using an AMI:**

- If you use an AMI that has multiple block device mappings, only the root volume of the AMI is used. The other (non-root) volumes are ignored.
- You can only use this feature if you have permissions to the AMI and its associated root volume snapshot. You cannot use this feature with AWS Marketplace AMIs.
- You can only use an AMI without a product code only if the instance does not have a product code.
- You can't specify the encryption status for the replacement root volume. The following table summarizes the possible encryption outcomes.

<table>
<thead>
<tr>
<th>Original root volume</th>
<th>AMI block device mapping</th>
<th>Replacement root volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encrypted</td>
<td>Unencrypted</td>
<td>The request fails</td>
</tr>
<tr>
<td>Encrypted</td>
<td>Encrypted</td>
<td>Encrypted</td>
</tr>
<tr>
<td>Unencrypted</td>
<td>Unencrypted</td>
<td>Unencrypted</td>
</tr>
<tr>
<td>Unencrypted</td>
<td>Encrypted</td>
<td>Encrypted</td>
</tr>
</tbody>
</table>

- The size of the AMI root volume block device mapping must be equal to or greater than the size of the original root volume. If the size of the AMI root volume block device mapping is smaller than the size of the original root volume, the request fails.
- The instance identity documents for the instance are automatically updated.
- If the instance supports NitroTPM, the NitroTPM data for the instance is reset and new keys are generated.
Replace a root volume

When you replace the root volume for an instance, a root volume replacement task is created. You can use the root volume replacement task to monitor the progress and outcome of the replacement process. For more information, see View root volume replacement tasks (p. 1814).

You can replace the root volume for an instance using one of the following methods.

Note
If you use the Amazon EC2 console, the functionality is available in the new console only.

New console

To replace the root volume

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance for which to replace the root volume and choose Actions, Monitor and troubleshoot, Replace root volume.

Note
The Replace root volume action is disabled if the selected instance is not in the running state.

4. In the Replace root volume screen, do one of the following:
   - To restore the replacement root volume to its initial launch state, choose Create replacement task without selecting a snapshot.
   - To restore the replacement root volume to a specific snapshot, for Snapshot, select the snapshot to use, and then choose Create replacement task.
   - To restore the replacement root volume using an AMI, for AMI, select the AMI to use, and then choose Create replacement task.
5. To delete the original root volume after the replacement task completes, select Delete replaced root volume.

AWS CLI

To restore the replacement root volume to the launch state

Use the create-replace-root-volume-task command. For --instance-id, specify the ID of the instance for which to replace the root volume. Omit the --snapshot-id --image-id parameters. To delete the original root volume after it has been replaced, include --delete-replaced-root-volume and specify true.

```
$ aws ec2 create-replace-root-volume-task --instance-id instance_id --delete-replaced-root-volume true
```

For example:

```
$ aws ec2 create-replace-root-volume-task --instance-id i-1234567890abcdef0 --delete-replaced-root-volume true
```

To restore the replacement root volume to a specific snapshot

Use the create-replace-root-volume-task command. For --instance-id, specify the ID of the instance for which to replace the root volume. For --snapshot-id, specify the ID of the snapshot
to use. To delete the original root volume after it has been replaced, include --delete-replaced-root-volume and specify true.

```bash
$ aws ec2 create-replace-root-volume-task --instance-id instance_id --snapshot-id snapshot_id --delete-replaced-root-volume true
```

For example:

```bash
$ aws ec2 create-replace-root-volume-task --instance-id i-1234567890abcdef0 --snapshot-id snap-9876543210abcdef0 --delete-replaced-root-volume true
```

**To restore the replacement root volume using an AMI**

Use the `create-replace-root-volume-task` command. For --instance-id, specify the ID of the instance for which to replace the root volume. For --image-id, specify the ID of the AMI to use. To delete the original root volume after it has been replaced, include --delete-replaced-root-volume and specify true.

```bash
$ aws ec2 create-replace-root-volume-task --instance-id instance_id --image-id ami_id --delete-replaced-root-volume true
```

For example:

```bash
$ aws ec2 create-replace-root-volume-task --instance-id i-01234567890abcdef --image-id ami-09876543210abcdef --delete-replaced-root-volume true
```

**View root volume replacement tasks**

When you replace the root volume for an instance, a root volume replacement task is created. The root volume replacement task transitions through the following states during the process:

- pending — the replacement volume is being created.
- in-progress — the original volume is being detached and the replacement volume is being attached.
- succeeded — the replacement volume has been successfully attached to the instance and the instance is available.
- failing — the replacement task is in the process of failing.
- failed — the replacement task has failed, but the original root volume is still attached.
- failing-detached — the replacement task is in the process of failing and the instance might not have a root volume attached.
- failed-detached — the replacement task has failed and the instance doesn't have a root volume attached.

You can view the root volume replacement tasks for an instance using one of the following methods.

**Note**

If you use the Amazon EC2 console, the functionality is available in the new console only.

**Console**

**To view the root volume replacement tasks**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance for which to view the root volume replacement tasks, and then choose the **Storage** tab.
4. In the **Storage** tab, expand **Recent root volume replacement tasks**.

**AWS CLI**

**To view the status of a root volume replacement task**

Use the `describe-replace-root-volume-tasks` command and specify the IDs of the root volume replacement tasks to view.

```
$ aws ec2 describe-replace-root-volume-tasks --replace-root-volume-task-ids task_id_1 task_id_2
```

For example:

```
$ aws ec2 describe-replace-root-volume-tasks --replace-root-volume-task-ids replacevol-1234567890abcdef0
```

```json
{
  "ReplaceRootVolumeTasks": [
    {
      "ReplaceRootVolumeTaskId": "replacevol-1234567890abcdef0",
      "InstanceId": "i-1234567890abcdef0",
      "TaskState": "succeeded",
      "StartTime": "2020-11-06 13:09:54.0",
      "CompleteTime": "2020-11-06 13:10:14.0",
      "SnapshotId": "snap-01234567890abcdef",
      "DeleteReplacedRootVolume": "True"
    }
  ]
}
```

Alternatively, specify the `instance-id` filter to filter the results by instance.

```
$ aws ec2 describe-replace-root-volume-tasks --filters Name=instance-id,Values=instance_id
```

For example:

```
$ aws ec2 describe-replace-root-volume-tasks --filters Name=instance-id,Values=i-1234567890abcdef0
```

**Monitor the status of your volumes**

Amazon Web Services (AWS) automatically provides data that you can use to monitor your Amazon Elastic Block Store (Amazon EBS) volumes.
For additional monitoring information, see Amazon CloudWatch metrics for Amazon EBS (p. 2043) and EventBridge for Amazon EBS (p. 2049).

**EBS volume status checks**

Volume status checks enable you to better understand, track, and manage potential inconsistencies in the data on an Amazon EBS volume. They are designed to provide you with the information that you need to determine whether your Amazon EBS volumes are impaired, and to help you control how a potentially inconsistent volume is handled.

Volume status checks are automated tests that run every 5 minutes and return a pass or fail status. If all checks pass, the status of the volume is **ok**. If a check fails, the status of the volume is **impaired**. If the status is **insufficient-data**, the checks may still be in progress on the volume. You can view the results of volume status checks to identify any impaired volumes and take any necessary actions.

When Amazon EBS determines that a volume's data is potentially inconsistent, the default is that it disables I/O to the volume from any attached EC2 instances, which helps to prevent data corruption. After I/O is disabled, the next volume status check fails, and the volume status is **impaired**. In addition, you'll see an event that lets you know that I/O is disabled, and that you can resolve the impaired status of the volume by enabling I/O to the volume. We wait until you enable I/O to give you the opportunity to decide whether to continue to let your instances use the volume, or to run a consistency check using a command, such as `fsck`, before doing so.

**Note**

Volume status is based on the volume status checks, and does not reflect the volume state. Therefore, volume status does not indicate volumes in the error state (for example, when a volume is incapable of accepting I/O.) For information about volume states, see Volume state (p. 1808).

If the consistency of a particular volume is not a concern, and you'd prefer that the volume be made available immediately if it's impaired, you can override the default behavior by configuring the volume to automatically enable I/O. If you enable the Auto-Enable IO volume attribute (autoEnableIO in the API), the volume status check continues to pass. In addition, you'll see an event that lets you know that the volume was determined to be potentially inconsistent, but that its I/O was automatically enabled. This enables you to check the volume's consistency or replace it at a later time.

The I/O performance status check compares actual volume performance to the expected performance of a volume. It alerts you if the volume is performing below expectations. This status check is available only for Provisioned IOPS SSD (io1 and io2) and General Purpose SSD (gp3) volumes that are attached to an instance. The status check is not valid for General Purpose SSD (gp2), Throughput Optimized HDD (st1), Cold HDD (sc1), or Magnetic (standard) volumes. The I/O performance status check is performed once every minute, and CloudWatch collects this data every 5 minutes. It might take up to 5 minutes from the moment that you attach an io1 or io2 volume to an instance for the status check to report the I/O performance status.

**Important**

While initializing Provisioned IOPS SSD volumes that were restored from snapshots, the performance of the volume may drop below 50 percent of its expected level, which causes the volume to display a warning state in the I/O Performance status check. This is expected, and you can ignore the warning state on Provisioned IOPS SSD volumes while you are initializing them. For more information, see Initialize Amazon EBS volumes (p. 2033).

The following table lists statuses for Amazon EBS volumes.

<table>
<thead>
<tr>
<th>Volume status</th>
<th>I/O enabled status</th>
<th>I/O performance status (io1, io2, and gp3 volumes only)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ok</td>
<td>Enabled (I/O Enabled or I/O Auto-Enabled)</td>
<td>Normal (Volume performance is as expected)</td>
</tr>
<tr>
<td>Volume status</td>
<td>I/O enabled status</td>
<td>I/O performance status (io1, io2, and gp3 volumes only)</td>
</tr>
<tr>
<td>-------------------</td>
<td>--------------------------------------------------------</td>
<td>--------------------------------------------------------</td>
</tr>
<tr>
<td>warning</td>
<td>Enabled (I/O Enabled or I/O Auto-Enabled)</td>
<td>Degraded (Volume performance is below expectations)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Severely Degraded (Volume performance is well below expectations)</td>
</tr>
<tr>
<td>impaired</td>
<td>Enabled (I/O Enabled or I/O Auto-Enabled)</td>
<td>Stalled (Volume performance is severely impacted)</td>
</tr>
<tr>
<td></td>
<td>Disabled (Volume is offline and pending recovery, or is waiting for the user to enable I/O)</td>
<td>Not Available (Unable to determine I/O performance because I/O is disabled)</td>
</tr>
<tr>
<td>insufficient-data</td>
<td>Enabled (I/O Enabled or I/O Auto-Enabled)</td>
<td>Insufficient Data</td>
</tr>
<tr>
<td></td>
<td>Insufficient Data</td>
<td></td>
</tr>
</tbody>
</table>

You can view and work with status checks using the following methods.

**Console**

**To view status checks**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Volumes.
   
   The Volume status column displays the operational status of each volume.
3. To view the status details of a specific volume, select it in the grid and choose the Status checks tab.
4. If you have a volume with a failed status check (status is impaired), see Work with an impaired volume (p. 1819).

Alternatively, you can choose Events in the navigator to view all the events for your instances and volumes. For more information, see EBS volume events (p. 1817).

**AWS CLI**

**To view volume status information**

Use one of the following commands.

- `describe-volume-status` (AWS CLI)
- `Get-EC2VolumeStatus` (AWS Tools for Windows PowerShell)

For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

**EBS volume events**

When Amazon EBS determines that a volume's data is potentially inconsistent, it disables I/O to the volume from any attached EC2 instances by default. This causes the volume status check to fail, and creates a volume status event that indicates the cause of the failure.
To automatically enable I/O on a volume with potential data inconsistencies, change the setting of the **Auto-Enabled IO** volume attribute (autoEnableIO in the API). For more information about changing this attribute, see [Work with an impaired volume (p. 1819)](https://console.aws.amazon.com/ec2/).

Each event includes a start time that indicates the time at which the event occurred, and a duration that indicates how long I/O for the volume was disabled. The end time is added to the event when I/O for the volume is enabled.

Volume status events include one of the following descriptions:

**Awaiting Action: Enable I/O**

Volume data is potentially inconsistent. I/O is disabled for the volume until you explicitly enable it. The event description changes to **IO Enabled** after you explicitly enable I/O.

**IO Enabled**

I/O operations were explicitly enabled for this volume.

**IO Auto-Enabled**

I/O operations were automatically enabled on this volume after an event occurred. We recommend that you check for data inconsistencies before continuing to use the data.

**Normal**

For io1, io2, and gp3 volumes only. Volume performance is as expected.

**Degraded**

For io1, io2, and gp3 volumes only. Volume performance is below expectations.

**Severely Degraded**

For io1, io2, and gp3 volumes only. Volume performance is well below expectations.

**Stalled**

For io1, io2, and gp3 volumes only. Volume performance is severely impacted.

You can view events for your volumes using the following methods.

**Console**

**To view events for your volumes**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Events. All instances and volumes that have events are listed.
3. You can filter by volume to view only volume status. You can also filter on specific status types.
4. Select a volume to view its specific event.

**AWS CLI**

**To view events for your volumes**

Use one of the following commands.

- [describe-volume-status](https://awscli.amazonaws.com/v2/documentation/api/1.15.257/) (AWS CLI)

For more information about these command line interfaces, see [Access Amazon EC2 (p. 5)](https://console.aws.amazon.com/ec2/).
If you have a volume where I/O is disabled, see Work with an impaired volume (p. 1819). If you have a volume where I/O performance is below normal, this might be a temporary condition due to an action you have taken (for example, creating a snapshot of a volume during peak usage, running the volume on an instance that cannot support the I/O bandwidth required, accessing data on the volume for the first time, etc.).

**Work with an impaired volume**

Use the following options if a volume is impaired because the volume's data is potentially inconsistent.

**Options**

- **Option 1: Perform a consistency check on the volume attached to its instance** (p. 1819)
- **Option 2: Perform a consistency check on the volume using another instance** (p. 1819)
- **Option 3: Delete the volume if you no longer need it** (p. 1820)

**Option 1: Perform a consistency check on the volume attached to its instance**

The simplest option is to enable I/O and then perform a data consistency check on the volume while the volume is still attached to its Amazon EC2 instance.

**To perform a consistency check on an attached volume**

1. Stop any applications from using the volume.
2. Enable I/O on the volume. Use one of the following methods.
   - **Console**
     1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
     2. In the navigation pane, choose Events.
     3. Select the volume on which to enable I/O operations.
     4. Choose Actions, Enable I/O.
   - **AWS CLI**
     To enable I/O for a volume with the command line

     You can use one of the following commands to view event information for your Amazon EBS volumes. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

     - `enable-volume-io` (AWS CLI)
     - `Enable-EC2VolumeIOPowerShell` (AWS Tools for Windows PowerShell)

3. Check the data on the volume.
   a. Run the `fsck` command.
   b. (Optional) Review any available application or system logs for relevant error messages.
   c. If the volume has been impaired for more than 20 minutes, you can contact the AWS Support Center. Choose Troubleshoot, and then in the Troubleshoot Status Checks dialog box, choose Contact Support to submit a support case.

**Option 2: Perform a consistency check on the volume using another instance**

Use the following procedure to check the volume outside your production environment.
Important
This procedure may cause the loss of write I/Os that were suspended when volume I/O was disabled.

To perform a consistency check on a volume in isolation

1. Stop any applications from using the volume.
2. Detach the volume from the instance. For more information, see Detach an Amazon EBS volume from a Linux instance (p. 1821).
3. Enable I/O on the volume. Use one of the following methods.

   Console
   1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   2. In the navigation pane, choose Events.
   3. Select the volume that you detached in the previous step.
   4. Choose Actions, Enable I/O.

AWS CLI

To enable I/O for a volume with the command line

You can use one of the following commands to view event information for your Amazon EBS volumes. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- `enable-volume-io` (AWS CLI)
- `Enable-EC2VolumeIO` (AWS Tools for Windows PowerShell)

4. Attach the volume to another instance. For more information, see Launch your instance (p. 675) and Attach an Amazon EBS volume to an instance (p. 1797).

5. Check the data on the volume.
   a. Run the `fsck` command.
   b. (Optional) Review any available application or system logs for relevant error messages.
   c. If the volume has been impaired for more than 20 minutes, you can contact the AWS Support Center. Choose Troubleshoot, and then in the troubleshooting dialog box, choose Contact Support to submit a support case.

Option 3: Delete the volume if you no longer need it

If you want to remove the volume from your environment, simply delete it. For information about deleting a volume, see Delete an Amazon EBS volume (p. 1823).

If you have a recent snapshot that backs up the data on the volume, you can create a new volume from the snapshot. For more information, see Create a volume from a snapshot (p. 1796).

Work with the Auto-Enabled IO volume attribute

When Amazon EBS determines that a volume's data is potentially inconsistent, it disables I/O to the volume from any attached EC2 instances by default. This causes the volume status check to fail, and creates a volume status event that indicates the cause of the failure. If the consistency of a particular volume is not a concern, and you prefer that the volume be made available immediately if it's impaired, you can override the default behavior by configuring the volume to automatically enable I/O. If you enable the Auto-Enabled IO volume attribute (autoEnableIO in the API), I/O between the volume and the instance is automatically re-enabled and the volume's status check will pass. In addition, you'll see
an event that lets you know that the volume was in a potentially inconsistent state, but that its I/O was automatically enabled. When this event occurs, you should check the volume's consistency and replace it if necessary. For more information, see EBS volume events (p. 1817).

You can view and modify the **Auto-Enabled IO** attribute of a volume using one of the following methods.

**New console**

**To view the Auto-Enabled IO attribute of a volume**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Volumes**.
3. Select the volume and choose the **Status checks** tab.

   The *Auto-enabled I/O* field displays the current setting (**Enabled** or **Disabled**) for the selected volume.

**To modify the Auto-Enabled IO attribute of a volume**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Volumes**.
3. Select the volume and choose **Actions**, Manage auto-enabled I/O.
4. To automatically enable I/O for an impaired volume, select the **Auto-enable I/O for impaired volumes** check box. To disable the feature, clear the check box.
5. Choose **Update**.

**AWS CLI**

**To view the autoEnableIO attribute of a volume**

Use one of the following commands.

- `describe-volume-attribute` (AWS CLI)
- `Get-EC2VolumeAttribute` (AWS Tools for Windows PowerShell)

**To modify the autoEnableIO attribute of a volume**

Use one of the following commands.

- `modify-volume-attribute` (AWS CLI)
- `Edit-EC2VolumeAttribute` (AWS Tools for Windows PowerShell)

For more information about these command line interfaces, see [Access Amazon EC2](p. 5)

**Detach an Amazon EBS volume from a Linux instance**

You need to detach an Amazon Elastic Block Store (Amazon EBS) volume from an instance before you can attach it to a different instance or delete it. Detaching a volume does not affect the data on the volume.

For information about detaching volumes from a Windows instance, see [Detach a volume from a Windows instance](in the Amazon EC2 User Guide for Windows Instances).
Considerations

- You can detach an Amazon EBS volume from an instance explicitly or by terminating the instance. However, if the instance is running, you must first unmount the volume from the instance.
- If an EBS volume is the root device of an instance, you must stop the instance before you can detach the volume.
- You can reattach a volume that you detached (without unmounting it), but it might not get the same mount point. If there were writes to the volume in progress when it was detached, the data on the volume might be out of sync.
- After you detach a volume, you are still charged for volume storage as long as the storage amount exceeds the limit of the AWS Free Tier. You must delete a volume to avoid incurring further charges. For more information, see [Delete an Amazon EBS volume](p. 1823).

Unmount and detach a volume

Use the following procedures to unmount and detach a volume from an instance. This can be useful when you need to attach the volume to a different instance or when you need to delete the volume.

Steps

- **Step 1: Unmount the volume**
  - From your Linux instance, use the following command to unmount the /dev/sdh device.

```
[ec2-user ~]$ sudo umount -d /dev/sdh
```

- **Step 2: Detach the volume from the instance**
  - To detach the volume from the instance, use one of the following methods:

  **Console**

  **To detach an EBS volume using the console**

  1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
  2. In the navigation pane, choose Volumes.
  3. Select the volume to detach and choose Actions, Detach volume.
  4. When prompted for confirmation, choose Detach.

  **Command line**

  **To detach an EBS volume from an instance using the command line**

  After unmounting the volume, you can use one of the following commands to detach it. For more information about these command line interfaces, see [Access Amazon EC2](p. 5).
Troubleshoot

The following are common problems encountered when detaching volumes, and how to resolve them.

**Note**
To guard against the possibility of data loss, take a snapshot of your volume before attempting to unmount it. Forced detachment of a stuck volume can cause damage to the file system or the data it contains or an inability to attach a new volume using the same device name, unless you reboot the instance.

- If you encounter problems while detaching a volume through the Amazon EC2 console, it can be helpful to use the `describe-volumes` CLI command to diagnose the issue. For more information, see `describe-volumes`.
- If your volume stays in the detaching state, you can force the detachment by choosing **Force Detach**. Use this option only as a last resort to detach a volume from a failed instance, or if you are detaching a volume with the intention of deleting it. The instance doesn't get an opportunity to flush file system caches or file system metadata. If you use this option, you must perform the file system check and repair procedures.
- If you've tried to force the volume to detach multiple times over several minutes and it stays in the detaching state, you can post a request for help to **AWS re:Post**. To help expedite a resolution, include the volume ID and describe the steps that you've already taken.
- When you attempt to detach a volume that is still mounted, the volume can become stuck in the busy state while it is trying to detach. The following output from `describe-volumes` shows an example of this condition:

```json
"Volumes": [  
    {  
        "AvailabilityZone": "us-west-2b",  
        "Attachments": [  
            {  
                "AttachTime": "2016-07-21T23:44:52.000Z",  
                "InstanceId": "i-fedc9876",  
                "VolumeId": "vol-1234abcd",  
                "State": "busy",  
                "DeleteOnTermination": false,  
                "Device": "/dev/sdf"  
            }  
            ...  
        ]  
    }  
]
```

When you encounter this state, detachment can be delayed indefinitely until you unmount the volume, force detachment, reboot the instance, or all three.

Delete an Amazon EBS volume

You can delete an Amazon EBS volume that you no longer need. After deletion, its data is gone and the volume can't be attached to any instance. So before deletion, you can store a snapshot of the volume, which you can use to re-create the volume later.

**Note**
You can't delete a volume if it's attached to an instance. To delete a volume, you must first detach it. For more information, see [Detach an Amazon EBS volume from a Linux instance](p. 1821).
You can check if a volume is attached to an instance. In the console, on the **Volumes** page, you can view the state of your volumes.

- If a volume is attached to an instance, it’s in the **in-use** state.
- If a volume is detached from an instance, it’s in the **available** state. You can delete this volume.

You can delete an EBS volume using one of the following methods.

**Console**

**To delete an EBS volume using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Volumes**.
3. Select the volume to delete and choose **Actions, Delete volume**.
   
   **Note**
   If **Delete volume** is greyed out, the volume is attached to an instance. You must detach the volume from the instance before it can be deleted.
4. In the confirmation dialog box, choose **Delete**.

**AWS CLI**

**To delete an EBS volume using the command line**

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2](p. 5).

- **delete-volume** (AWS CLI)
- **Remove-EC2Volume** (AWS Tools for Windows PowerShell)

**Fault testing on Amazon EBS**

Use AWS Fault Injection Simulator and the Pause I/O action to temporarily stop I/O between an Amazon EBS volume and the instances to which it is attached to test how your workloads handle I/O interruptions. With AWS FIS, you can use controlled experiments to test your architecture and monitoring, such as Amazon CloudWatch alarms and OS timeout configurations, and improve resiliency to storage faults.

For more information about AWS FIS, see the [AWS Fault Injection Simulator User Guide](p).

**Considerations**

Keep in mind the following considerations for pausing volume I/O:

- You can pause I/O for all Amazon EBS volume types that are attached to [instances built on the Nitro System](p. 282).
- You can pause I/O for the root volume.
- You can pause I/O for Multi-Attach enabled volumes. If you pause I/O for a Multi-Attach enabled volume, I/O is paused between the volume and all of the instances to which it is attached.
- To test your OS timeout configuration, set the experiment duration equal to or greater than the value specified for `nvme_core.io_timeout`. For more information, see [I/O operation timeout](p. 1997).
- If you drive I/O to a volume that has I/O paused, the following happens:
Amazon Elastic Compute Cloud  
User Guide for Linux Instances  
EBS snapshots

- The volume's status transitions to impaired within 120 seconds. For more information, see Monitor the status of your volumes (p. 1815).
- The CloudWatch metrics for queue length (VolumeQueueLength) will be non-zero. Any alarms or monitoring should monitor for a non-zero queue depth. For more information see Volume metrics for volumes attached to all instance types (p. 2043).
- The CloudWatch metrics for VolumeReadOps or VolumeWriteOps will be 0, which indicates that the volume is no longer processing I/O.

Limitations

Keep in mind the following limitations for pausing volume I/O:

- Instance store volumes are not supported.
- Xen-based instances types are not supported.
- You can't pause I/O for volumes created on an Outpost in AWS Outposts, in an AWS Wavelength Zone, or in a Local Zone.

You can perform a basic experiment from the Amazon EC2 console, or you can perform more advanced experiments using the AWS FIS console. For more information about performing advanced experiments using the AWS FIS console, see Tutorials for AWS FIS in the AWS Fault Injection Simulator User Guide.

To perform a basic experiment using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Select the volume for which to pause I/O and choose Actions, Fault injection, Pause volume I/O.
4. For Duration, enter the duration for which to pause I/O between the volume and the instances. The field next to the Duration dropdown list shows the duration in ISO 8601 format.
5. In the Service access section, select the IAM service role for AWS FIS to assume to perform the experiment. You can use either the default role, or an existing role that you created. For more information, see Create an IAM role for AWS FIS experiments.
6. Choose Pause volume I/O. When prompted, enter start in the confirmation field and choose Start experiment.
7. Monitor the progress and impact of your experiment. For more information, see Monitoring AWS FIS in the AWS FIS User Guide.

Amazon EBS snapshots

You can back up the data on your Amazon EBS volumes to Amazon S3 by taking point-in-time snapshots. Snapshots are incremental backups, which means that only the blocks on the device that have changed after your most recent snapshot are saved. This minimizes the time required to create the snapshot and saves on storage costs by not duplicating data.

Important

AWS does not automatically back up data stored on your Amazon EBS volumes. For data resiliency and disaster recovery, it remains your responsibility to create regular backups using Amazon EBS snapshots, or to set up automatic snapshot creation using Amazon Data Lifecycle Manager (p. 1913) or AWS Backup.

Each snapshot contains all of the information that is needed to restore your data (from the moment when the snapshot was taken) to a new EBS volume. When you create an EBS volume based on a snapshot, the new volume begins as an exact replica of the original volume that was used to create the snapshot. The replicated volume loads data in the background so that you can begin using it.
immediately. If you access data that hasn't been loaded yet, the volume immediately downloads the requested data from Amazon S3, and then continues loading the rest of the volume's data in the background. For more information, see Create Amazon EBS snapshots (p. 1830).

When you delete a snapshot, only the data unique to that snapshot is removed. For more information, see Delete an Amazon EBS snapshot (p. 1834).

**Snapshot events**

You can track the status of your EBS snapshots through CloudWatch Events. For more information, see EBS snapshot events (p. 2052).

**Multi-volume snapshots**

Snapshots can be used to create a backup of critical workloads, such as a large database or a file system that spans across multiple EBS volumes. Multi-volume snapshots allow you to take exact point-in-time, data coordinated, and crash-consistent snapshots across multiple EBS volumes attached to an EC2 instance. You are no longer required to stop your instance or to coordinate between volumes to ensure crash consistency, because snapshots are automatically taken across multiple EBS volumes. For more information, see the steps for creating a multi-volume EBS snapshot under Create Amazon EBS snapshots (p. 1830).

**Snapshot pricing**

Charges for your snapshots are based on the amount of data stored. Because snapshots are incremental, deleting a snapshot might not reduce your data storage costs. Data referenced exclusively by a snapshot is removed when that snapshot is deleted, but data referenced by other snapshots is preserved. For more information, see Amazon Elastic Block Store Volumes and Snapshots in the AWS Billing User Guide.

**Contents**

- Amazon EBS local snapshots on Outposts (p. 1871)
- Use EBS direct APIs to access the contents of an EBS snapshot (p. 1881)
- Automate the snapshot lifecycle (p. 1913)

**How snapshots work**

The first snapshot that you create from a volume is always a full snapshot. It includes all of the data blocks written to the volume at the time of creating the snapshot. Subsequent snapshots of the same volume are incremental snapshots. They include only changed and new data blocks written to the volume since the last snapshot was created.

The size of a full snapshot is determined by the size of the data being backed up, not the size of the source volume. Similarly, the storage costs associated with a full snapshot is determined by the size of the snapshot, not the size of the source volume. For example, you create the first snapshot of a 200 GiB
Amazon EBS volume that contains only 50 GiB of data. This results in a full snapshot that is 50 GiB in size, and you are billed for 50 GiB snapshot storage.

Similarly, the size and storage costs of an incremental snapshot are determined by the size of any data that was written to the volume since the previous snapshot was created. Continuing this example, if you create a second snapshot of the 200 GiB volume after changing 20 GiB of data and adding 10 GiB of data, the incremental snapshot is 30 GiB in size. You are then billed for that additional 30 GiB snapshot storage.

For more information about snapshot pricing, see Amazon EBS pricing.

**Important**

When you archive an incremental snapshot, it is converted to a full snapshot that includes all of the blocks written to the volume at the time that the snapshot was created. It is then moved to the Amazon EBS Snapshots Archive tier. Snapshots in the archive tier are billed at a different rate from snapshots in the standard tier. For more information, see Pricing and billing (p. 1842).

The following sections show how an EBS snapshot captures the state of a volume at a point in time, and how subsequent snapshots of a changing volume create a history of those changes.

### Multiple snapshots of the same volume

The diagram in this section shows Volume 1, which is 15 GiB in size, at three points in time. A snapshot is taken of each of these three volume states. The diagram specifically shows the following:

- **In State 1**, the volume has 10 GiB of data. Snap A is the first snapshot taken of the volume. Snap A is a full snapshot and the entire 10 GiB of data is backed up.

- **In State 2**, the volume still contains 10 GiB of data, but only 4 GiB have changed after Snap A was taken. Snap B is an incremental snapshot. It needs to back up only the 4 GiB that changed. The other 6 GiB of unchanged data, which are already backed up in Snap A, are referenced by Snap B rather than being backed up again. This is indicated by the dashed arrow.

- **In State 3**, 2 GiB of data have been added to the volume, for a total of 12 GiB, after Snap B was taken. Snap C is an incremental snapshot. It needs to back up only the 2 GiB that were added after Snap B was taken. As shown by the dashed arrows, Snap C also references the 4 GiB of data stored in Snap B, and the 6 GiB of data stored in Snap A.

- The total storage required for the three snapshots is 16 GiB total. This accounts for 10 GiB for Snap A, 4 GiB for Snap B, and 2 GiB for Snap C.
Incremental snapshots of different volumes

The diagram in this section shows how incremental snapshots can be taken from different volumes.

1. **Vol 1**, which is 14 GiB in size, has 10 GiB of data. Because **Snap A** is the first snapshot taken of the volume, it is a full snapshot and the entire 10 GiB of data is backed up.
2. **Vol 2** is created from **Snap A**, so it is an exact replica of **Vol 1** at the time the snapshot was taken.
3. Over time, 4 GiB of data is added to **Vol 2** and the total size of its data is 14 GiB.
4. **Snap B** is taken from **Vol 2**. For **Snap B**, only the 4 GiB of data that was added after the volume was created from **Snap A** is backed up. The other 10 GiB of unchanged data, which is already stored in **Snap A**, is referenced by **Snap B** instead of being backed up again.

**Snap B** is an incremental snapshot of **Snap A**, even though it was created from a different volume.
Important
The diagram assumes that you own Vol 1 and Snap A, and that Vol 2 is encrypted with the same
KMS key as Vol 1. If Vol 1 was owned by another AWS account and that account took Snap A
and shared it with you, then Snap B would be a full snapshot. Or, if Vol 2 was encrypted with a
different KMS key than Vol 1, then Snap B would be a full snapshot.

For more information about how data is managed when you delete a snapshot, see Delete an Amazon
EBS snapshot (p. 1834).

Copy and share snapshots

You can share a snapshot across AWS accounts by modifying its access permissions. You can make copies
of your own snapshots as well as snapshots that have been shared with you. For more information, see
Share an Amazon EBS snapshot (p. 1864).

A snapshot is constrained to the AWS Region where it was created. After you create a snapshot of an EBS
volume, you can use it to create new volumes in the same Region. For more information, see Create a
volume from a snapshot (p. 1796). You can also copy snapshots across Regions, making it possible to use
multiple Regions for geographical expansion, data center migration, and disaster recovery. You can copy
any accessible snapshot that has a completed status. For more information, see Copy an Amazon EBS
snapshot (p. 1836).
Encryption support for snapshots

EBS snapshots fully support EBS encryption.

- Snapshots of encrypted volumes are automatically encrypted.
- Volumes that you create from encrypted snapshots are automatically encrypted.
- Volumes that you create from an unencrypted snapshot that you own or have access to can be encrypted on-the-fly.
- When you copy an unencrypted snapshot that you own, you can encrypt it during the copy process.
- When you copy an encrypted snapshot that you own or have access to, you can reencrypt it with a different key during the copy process.
- The first snapshot you take of an encrypted volume that has been created from an unencrypted snapshot is always a full snapshot.
- The first snapshot you take of a reencrypted volume, which has a different CMK compared to the source snapshot, is always a full snapshot.

Complete documentation of possible snapshot encryption scenarios is provided in Create Amazon EBS snapshots (p. 1830) and in Copy an Amazon EBS snapshot (p. 1836).

For more information, see Amazon EBS encryption (p. 1975).

Create Amazon EBS snapshots

You can create a point-in-time snapshot of an EBS volume and use it as a baseline for new volumes or for data backup. If you make periodic snapshots of a volume, the snapshots are incremental—the new snapshot saves only the blocks that have changed since your last snapshot.

Snapshots occur asynchronously; the point-in-time snapshot is created immediately, but the status of the snapshot is pending until the snapshot is complete (when all of the modified blocks have been transferred to Amazon S3), which can take several hours for large initial snapshots or subsequent snapshots where many blocks have changed. While it is completing, an in-progress snapshot is not affected by ongoing reads and writes to the volume.

You can take a snapshot of an attached volume that is in use. However, snapshots only capture data that has been written to your Amazon EBS volume at the time the snapshot command is issued. This might exclude any data that has been cached by any applications or the operating system. If you can pause any file writes to the volume long enough to take a snapshot, your snapshot should be complete. However, if you can't pause all file writes to the volume, you should unmount the volume from within the instance, issue the snapshot command, and then remount the volume to ensure a consistent and complete snapshot. You can remount and use your volume while the snapshot status is pending.

To make snapshot management easier, you can tag your snapshots during creation or add tags afterward. For example, you can apply tags describing the original volume from which the snapshot was created, or the device name that was used to attach the original volume to an instance. For more information, see Tag your Amazon EC2 resources (p. 2154).

Snapshot encryption

Snapshots that are taken from encrypted volumes are automatically encrypted. Volumes that are created from encrypted snapshots are also automatically encrypted. The data in your encrypted volumes and any associated snapshots is protected both at rest and in motion. For more information, see Amazon EBS encryption (p. 1975).

By default, only you can create volumes from snapshots that you own. However, you can share your unencrypted snapshots with specific AWS accounts, or you can share them with the entire AWS community by making them public. For more information, see Share an Amazon EBS snapshot (p. 1864).
You can share an encrypted snapshot only with specific AWS accounts. For others to use your shared, encrypted snapshot, you must also share the CMK key that was used to encrypt it. Users with access to your encrypted snapshot must create their own personal copy of it and then use that copy. Your copy of a shared, encrypted snapshot can also be re-encrypted using a different key. For more information, see Share an Amazon EBS snapshot (p. 1864).

Multi-volume snapshots

You can create multi-volume snapshots, which are point-in-time snapshots for all, or some, of the volumes attached to an instance.

By default, when you create multi-volume snapshots from an instance, Amazon EBS creates snapshots of all the volumes (root and data (non-root)) that are attached to the instance. However, you can choose to create snapshots of a subset of the volumes that are attached to the instance.

You can tag your multi-volume snapshots as you would a single volume snapshot. We recommend you tag your multiple volume snapshots to manage them collectively during restore, copy, or retention. You can also choose to automatically copy tags from the source volume to the corresponding snapshots. This helps you to set the snapshot metadata, such as access policies, attachment information, and cost allocation, to match the source volume.

After the snapshots are created, each snapshot is treated as an individual snapshot. You can perform all snapshot operations, such as restore, delete, and copy across Regions or accounts, just as you would with a single volume snapshot.

Multi-volume, crash-consistent snapshots are typically restored as a set. It is helpful to identify the snapshots that are in a crash-consistent set by tagging your set with the instance ID, name, or other relevant details.

After creating your snapshots, they appear in your EC2 console created at the exact point-in-time.

If any one snapshot for the multi-volume snapshot set fails, all of the other snapshots display an error status and a createSnapshots CloudWatch event with a result of failed is sent to your AWS account. For more information, see Create snapshots (createSnapshots) (p. 2053).

Amazon Data Lifecycle Manager

You can create snapshot lifecycle policies to automate the creation and retention of snapshots of individual volumes and multi-volume snapshots of instances. For more information, see Amazon Data Lifecycle Manager (p. 1913).

Considerations

The following considerations apply to creating snapshots:

- When you create a snapshot for an EBS volume that serves as a root device, we recommend that you stop the instance before taking the snapshot.
- You cannot create snapshots from instances for which hibernation is enabled, or from hibernated instances. If you create a snapshot or AMI from an instance that is hibernated or has hibernation enabled, you might not be able to connect to a new instance that is launched from the AMI, or from an AMI that was created from the snapshot.
- Although you can take a snapshot of a volume while a previous snapshot of that volume is in the pending status, having multiple pending snapshots of a volume can result in reduced volume performance until the snapshots complete.
- There is a limit of one pending snapshot for a single st1 or sc1 volume, or five pending snapshots for a single volume of the other volume types. If you receive a ConcurrentSnapshotLimitExceeded error while trying to create multiple concurrent snapshots of the same volume, wait for one or more of the pending snapshots to complete before creating another snapshot of that volume.
• When a snapshot is created from a volume with an AWS Marketplace product code, the product code is propagated to the snapshot.
• When creating multi-volume snapshot sets from instances, you can specify up to 40 data (non-root) volumes to exclude.

Create a snapshot

To create a snapshot from the specified volume, use one of the following methods.

Console

To create a snapshot using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots, Create snapshot.
3. For Resource type, choose Volume.
4. For Volume ID, select the volume from which to create the snapshot.
   The Encryption field indicates the selected volume's encryption status. If the selected volume is encrypted, the snapshot is automatically encrypted using the same KMS key. If the selected volume is unencrypted, the snapshot is not encrypted.
5. (Optional) For Description, enter a brief description for the snapshot.
6. (Optional) To assign custom tags to the snapshot, in the Tags section, choose Add tag, and then enter the key-value pair. You can add up to 50 tags.
7. Choose Create snapshot.

AWS CLI

To create a snapshot using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

• create-snapshot (AWS CLI)
• New-EC2Snapshot (AWS Tools for Windows PowerShell)

Create a multi-volume snapshot

When you create a multi-volume snapshot set from an instance, you can choose whether to copy the tags from the source volume to the corresponding snapshot. You can specify whether to create a snapshot of the root volume. You can also specify whether to create snapshots of all the data (non-root) volumes that are attached to the instance, or whether to create snapshots of a subset of those volumes.

Considerations

• Multi-volume snapshots support up to 40 EBS volumes for each instance.

To create a snapshot from the volumes of an instance, use one of the following methods.

Console

To create multi-volume snapshots using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Snapshots, Create snapshot**.

3. For **Resource type**, choose **Instance**.

4. For **Description**, enter a brief description for the snapshots. This description is applied to all of the snapshots.

5. (Optional) By default, Amazon EBS creates a snapshot of the instance's root volume. If you do not want to create a snapshot of the instance's root volume, select **Exclude root volume**.

6. (Optional) By default, Amazon EBS creates snapshots of all the data (non-root) volumes attached to the instance. If you want to create snapshots of a subset of the data (non-root) volumes attached to the instance, select **Exclude specific data volumes**. The **Attached data volumes** section lists all of the data volumes that are currently attached to the selected instance.

   In the **Attached data volumes** section, select the data volumes for which you do **not** want to create snapshots. Only the volumes that remain unselected will be included in the multi-volume snapshot set. You can exclude up to 40 volumes.

7. (Optional) To automatically copy tags from the source volumes to the corresponding snapshots, for **Copy tags from source volume**, select **Copy tags**. This sets snapshot metadata—such as access policies, attachment information, and cost allocation—to match the source volume.

8. (Optional) To assign additional custom tags to the snapshots, in the **Tags** section, choose **Add tag**, and then enter the key-value pair. You can add up to 50 tags.

9. Choose **Create snapshot**.

   During snapshot creation, the snapshots are managed together. If one of the snapshots in the volume set fails, the other snapshots are moved to error status for the volume set. You can monitor the progress of your snapshots using **CloudWatch Events**. After the snapshot creation process completes, CloudWatch generates an event that contains the status and all of the relevant snapshot details for the affected instance.

**Command line**

**AWS CLI**

To create multi-volume snapshots using the AWS CLI, use the `create-snapshots` command.

If you do not want to create a snapshot of the root volume, for **--instance-specification ExcludeBootVolume**, specify `true`. If you do not want to create snapshots of all the data (non-root) volumes attached to the instance, for **--instance-specification ExcludeDataVolumes**, specify the IDs of the data volumes for which you do not want to create snapshots. You can specify up to 40 volumes to exclude.

**AWS Tools for Windows PowerShell**

To create multi-volume snapshots using the Tools for Windows PowerShell, use the `New-EC2SnapshotBatch` command.

If you do not want to create a snapshot of the root volume, for `- InstanceSpecification_ExcludeBootVolume`, specify `1`. If you do not want to create snapshots of all the data (non-root) volumes attached to the instance, for `- InstanceSpecification_ExcludeDataVolumes`, specify the IDs of the data volumes for which you do not want to create snapshots. You can specify up to 40 volumes to exclude.

If all of the snapshots complete successfully, a `createSnapshots CloudWatch` event with a result of `succeeded` is sent to your AWS account. If any one snapshot for the multi-volume snapshot set fails, all of the other snapshots display an error status and a `createSnapshots CloudWatch` event.
with a result of failed is sent to your AWS account. For more information, see Create snapshots (createSnapshots) (p. 2053).

Work with EBS snapshots

You can copy snapshots, share snapshots, and create volumes from snapshots. For more information, see the following:

- Copy an Amazon EBS snapshot (p. 1836)
- Share an Amazon EBS snapshot (p. 1864)
- Create a volume from a snapshot (p. 1796)

Delete an Amazon EBS snapshot

After you no longer need an Amazon EBS snapshot of a volume, you can delete it. Deleting a snapshot has no effect on the volume. Deleting a volume has no effect on the snapshots made from it.

Incremental snapshot deletion

If you make periodic snapshots of a volume, the snapshots are incremental. This means that only the blocks on the device that have changed after your most recent snapshot are saved in the new snapshot. Even though snapshots are saved incrementally, the snapshot deletion process is designed so that you need to retain only the most recent snapshot in order to create volumes.

If data was present on a volume held in an earlier snapshot or series of snapshots, and that data is subsequently deleted from the volume later on, the data is still considered to be unique data of the earlier snapshots. Unique data is only deleted from the sequence of snapshots if all snapshots that reference the unique data are deleted.

When you delete a snapshot, only the data that is referenced exclusively by that snapshot is removed. Unique data is only deleted if all of the snapshots that reference it are deleted. Deleting previous snapshots of a volume does not affect your ability to create volumes from later snapshots of that volume.

Deleting a snapshot might not reduce your organization's data storage costs. Other snapshots might reference that snapshot's data, and referenced data is always preserved. If you delete a snapshot containing data being used by a later snapshot, costs associated with the referenced data are allocated to the later snapshot. For more information about how snapshots store data, see How snapshots work (p. 1826) and the following example.

In the following diagram, Volume 1 is shown at three points in time. A snapshot has captured each of the first two states, and in the third, a snapshot has been deleted.

- In State 1, the volume has 10 GiB of data. Because Snap A is the first snapshot taken of the volume, the entire 10 GiB of data must be copied.
- In State 2, the volume still contains 10 GiB of data, but 4 GiB have changed. Snap B needs to copy and store only the 4 GiB that changed after Snap A was taken. The other 6 GiB of unchanged data, which are already copied and stored in Snap A, are referenced by Snap B rather than (again) copied. This is indicated by the dashed arrow.
- In state 3, the volume has not changed since State 2, but Snapshot A has been deleted. The 6 GiB of data stored in Snapshot A that were referenced by Snapshot B have now been moved to Snapshot B, as shown by the heavy arrow. As a result, you are still charged for storing 10 GiB of data; 6 GiB of unchanged data preserved from Snap A and 4 GiB of changed data from Snap B.

Deleting a snapshot with some of its data referenced by another snapshot
Considerations

The following considerations apply to deleting snapshots:

- You can't delete a snapshot of the root device of an EBS volume used by a registered AMI. You must first deregister the AMI before you can delete the snapshot. For more information, see Deregister your AMI (p. 219).

- You can't delete a snapshot that is managed by the AWS Backup service using Amazon EC2. Instead, use AWS Backup to delete the corresponding recovery points in the backup vault. For more information, see Deleting backups in the AWS Backup Developer Guide.

- You can create, retain, and delete snapshots manually, or you can use Amazon Data Lifecycle Manager to manage your snapshots for you. For more information, see Amazon Data Lifecycle Manager (p. 1913).

- Although you can delete a snapshot that is still in progress, the snapshot must complete before the deletion takes effect. This might take a long time. If you are also at your concurrent snapshot limit, and you attempt to take an additional snapshot, you might get a ConcurrentSnapshotLimitExceeded error. For more information, see the Service Quotas for Amazon EBS in the Amazon Web Services General Reference.

- If you delete a snapshot that matches an Recycle Bin retention rule, the snapshot is retained in the Recycle Bin instead of being immediately deleted. For more information, see Recycle Bin (p. 2114).

Delete a snapshot

To delete a snapshot, use one of the following methods.
Console

**To delete a snapshot using the console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots.
3. Select the snapshot to delete, and then choose Actions, Delete snapshot.
4. Choose Delete.

AWS CLI

**To delete a snapshot using the command line**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- `delete-snapshot` (AWS CLI)
- `Remove-EC2Snapshot` (AWS Tools for Windows PowerShell)

Delete a multi-volume snapshot

To delete multi-volume snapshots, retrieve all of the snapshots for your multi-volume snapshot set using the tag you applied to the set when you created the snapshots. Then, delete the snapshots individually.

You will not be prevented from deleting individual snapshots in the multi-volume snapshot set. If you delete a snapshot while it is in the pending state, only that snapshot is deleted. The other snapshots in the multi-volume snapshot set still complete successfully.

Copy an Amazon EBS snapshot

With Amazon EBS, you can create point-in-time snapshots of volumes, which we store for you in Amazon S3. After you create a snapshot and it has finished copying to Amazon S3 (when the snapshot status is completed), you can copy it from one AWS Region to another, or within the same Region. Amazon S3 server-side encryption (256-bit AES) protects a snapshot's data in transit during a copy operation. The snapshot copy receives an ID that is different from the ID of the original snapshot.

To copy multi-volume snapshots to another AWS Region, retrieve the snapshots using the tag you applied to the multi-volume snapshot set when you created it. Then individually copy the snapshots to another Region.

If you would like another account to be able to copy your snapshot, you must either modify the snapshot permissions to allow access to that account or make the snapshot public so that all AWS accounts can copy it. For more information, see Share an Amazon EBS snapshot (p. 1864).

For information about copying an Amazon RDS snapshot, see Copying a DB Snapshot in the Amazon RDS User Guide.

Use cases

- Geographic expansion: Launch your applications in a new AWS Region.
- Migration: Move an application to a new Region, to enable better availability and to minimize cost.
- Disaster recovery: Back up your data and logs across different geographical locations at regular intervals. In case of disaster, you can restore your applications using point-in-time backups stored in the secondary Region. This minimizes data loss and recovery time.
- Encryption: Encrypt a previously unencrypted snapshot, change the key with which the snapshot is encrypted, or create a copy that you own in order to create a volume from it (for encrypted snapshots that have been shared with you).
Data retention and auditing requirements: Copy your encrypted EBS snapshots from one AWS account to another to preserve data logs or other files for auditing or data retention. Using a different account helps prevent accidental snapshot deletions, and protects you if your main AWS account is compromised.

Contents

- Prerequisites (p. 1837)
- Considerations (p. 1837)
- Pricing (p. 1837)
- Incremental snapshot copying (p. 1838)
- Encryption and snapshot copying (p. 1838)
- Copy a snapshot (p. 1839)

Prerequisites

- You can copy any accessible snapshots that have a completed status, including shared snapshots and snapshots that you have created.
- You can copy AWS Marketplace, VM Import/Export, and Storage Gateway snapshots, but you must verify that the snapshot is supported in the destination Region.
- To copy an encrypted snapshot, your user must have the following permissions to use Amazon EBS encryption.
  - kms:DescribeKey
  - kms:CreateGrant
  - kms:GenerateDataKey
  - kms:ReEncrypt
  - kms:Decrypt
- To copy an encrypted snapshot shared from another AWS account, you must have permissions to use customer managed key that was used to encrypt the snapshot. For more information, see Share a KMS key (p. 1866).

Considerations

- There is a limit of 20 concurrent snapshot copy requests per destination Region. If you exceed this quota, you receive a ResourceLimitExceeded error. If you receive this error, wait for one or more of the copy requests to complete before making a new snapshot copy request.
- User-defined tags are not copied from the source snapshot to the new snapshot. You can add user-defined tags during or after the copy operation. For more information, see Tag your Amazon EC2 resources (p. 2154).
- Snapshots created by a snapshot copy operation have an arbitrary volume ID, such as vol-ffff or vol-ffffffff. These arbitrary volume IDs should not be used for any purpose.
- Resource-level permissions specified for the snapshot copy operation apply only to the new snapshot. You cannot specify resource-level permissions for the source snapshot. For an example, see Example: Copying snapshots (p. 1681).

Pricing

- For pricing information about copying snapshots across AWS Regions and accounts, see Amazon EBS Pricing.
• Snapshot copy operations within a single account and Region do not copy any actual data and therefore are cost-free as long as the encryption status of the snapshot copy does not change.
- If you copy a snapshot and encrypt it to a new KMS key, a complete (non-incremental) copy is created. This results in additional storage costs.
- If you copy a snapshot to a new Region, a complete (non-incremental) copy is created. This results in additional storage costs. Subsequent copies of the same snapshot are incremental.

**Incremental snapshot copying**

Whether a snapshot copy is incremental is determined by the most recently completed snapshot copy. When you copy a snapshot across Regions or accounts, the copy is an incremental copy if the following conditions are met:

- The snapshot was copied to the destination Region or account previously.
- The most recent snapshot copy still exists in the destination Region or account.
- All copies of the snapshot in the destination Region or account are either unencrypted or were encrypted using the same KMS key.

If the most recent snapshot copy was deleted, the next copy is a full copy, not an incremental copy. If a copy is still pending when you start a another copy, the second copy starts only after the first copy finishes.

Incremental snapshot copying reduces the time required to copy snapshots and saves on data transfer and storage costs by not duplicating data.

We recommend that you tag your snapshots with the volume ID and creation time so that you can keep track of the most recent snapshot copy of a volume in the destination Region or account.

To see whether your snapshot copies are incremental, check the `copySnapshot` CloudWatch event.

**Encryption and snapshot copying**

When you copy a snapshot, you can encrypt the copy or you can specify a KMS key that is different than the original, and the resulting copied snapshot uses the new KMS key. However, changing the encryption status of a snapshot during a copy operation could result in a full (not incremental) copy, which might incur greater data transfer and storage charges. For more information, see [Incremental snapshot copying](p. 1838).

To copy an encrypted snapshot shared from another AWS account, you must have permissions to use the snapshot and the customer managed key (CMK) that was used to encrypt the snapshot. When using an encrypted snapshot that was shared with you, we recommend that you re-encrypt the snapshot by copying it using a KMS key that you own. This protects you if the original KMS key is compromised, or if the owner revokes it, which could cause you to lose access to any encrypted volumes that you created using the snapshot. For more information, see [Share an Amazon EBS snapshot](p. 1864).

You apply encryption to EBS snapshot copies by setting the `Encrypted` parameter to `true`. (The `Encrypted` parameter is optional if [encryption by default](p. 1979) is enabled).

Optionally, you can use `KmsKeyId` to specify a custom key to use to encrypt the snapshot copy. (The `Encrypted` parameter must also be set to `true`, even if encryption by default is enabled.) If `KmsKeyId` is not specified, the key that is used for encryption depends on the encryption state of the source snapshot and its ownership.

The following table describes the encryption outcomes for each possible combination of settings when copying snapshots that you own and snapshots that are shared with you.
**This is a customer managed key specified for the copy action. This customer managed key is used instead of the default customer managed key for the AWS account and Region.**

**Copy a snapshot**

To copy a snapshot, use one of the following methods.

**Console**

To copy a snapshot using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots.
3. Select the snapshot to copy, and then choose Actions, Copy snapshot.
4. For Description, enter a brief description for the snapshot copy.

   By default, the description includes information about the source snapshot so that you can identify a copy from the original. You can change this description as needed.
5. For Destination Region, select the Region in which to create the snapshot copy.
6. Specify the encryption status for the snapshot copy.

   If the source snapshot is encrypted, or if your account is enabled for encryption by default (p. 1979), then the snapshot copy is automatically encrypted and you can’t change its encryption status.

   If the source snapshot is unencrypted and your account is not enabled for encryption by default, encryption is optional. To encrypt the snapshot copy, for Encryption, select Encrypt this snapshot. Then, for KMS key, select the KMS key to use to encrypt the snapshot in the destination Region.
7. Choose Copy snapshot.
AWS CLI

To copy a snapshot using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- **copy-snapshot** (AWS CLI)
- **Copy-EC2Snapshot** (AWS Tools for Windows PowerShell)

To check for failure

If you attempt to copy an encrypted snapshot without having permissions to use the encryption key, the operation fails silently. The error state is not displayed in the console until you refresh the page. You can also check the state of the snapshot from the command line, as in the following example.

```
aws ec2 describe-snapshots --snapshot-id snap-0123abcd
```

If the copy failed because of insufficient key permissions, you see the following message: "StateMessage": "Given key ID is not accessible".

When copying an encrypted snapshot, you must have **DescribeKey** permissions on the default CMK. Explicitly denying these permissions results in copy failure. For information about managing CMK keys, see Authentication and access control for AWS KMS.

Archive Amazon EBS snapshots

Amazon EBS Snapshots Archive is a new storage tier that you can use for low-cost, long-term storage of your rarely-accessed snapshots that do not need frequent or fast retrieval.

By default, when you create a snapshot, it is stored in the Amazon EBS Snapshot Standard tier (standard tier). Snapshots stored in the standard tier are incremental. This means that only the blocks on the volume that have changed after your most recent snapshot are saved.

When you archive a snapshot, the incremental snapshot is converted to a full snapshot, and it is moved from the standard tier to the Amazon EBS Snapshots Archive tier (archive tier). Full snapshots include all of the blocks that were written to the volume at the time when the snapshot was created.

When you need to access an archived snapshot, you can restore it from the archive tier to the standard tier, and then use it in the same way that you use any other snapshot in your account.

Amazon EBS Snapshots Archive offers up to 75 percent lower snapshot storage costs for snapshots that you plan to store for 90 days or longer and that you rarely need to access.

Some typical use cases include:

- Archiving the only snapshot of a volume, such as end-of-project snapshots
- Archiving full, point-in-time incremental snapshots for compliance reasons.
- Archiving monthly, quarterly, or yearly incremental snapshots.

Topics

- **Considerations and limitations** (p. 1841)
- **Pricing and billing** (p. 1842)
Considerations and limitations

Considerations

- The minimum archive period is 90 days. If you delete or permanently restore an archived snapshot before the minimum archive period of 90 days, you are billed for remaining days in the archive tier, rounded to the nearest hour. For more information, see Pricing and billing (p. 1842).
- It can take up to 72 hours to restore an archived snapshot from the archive tier to the standard tier, depending on the size of the snapshot.
- Archived snapshots are always full snapshots. A full snapshot contains all the blocks written to the volume at the time the snapshot was created. The full snapshot will likely be larger than the incremental snapshot from which it was created. However, if you have only one incremental snapshot of a volume on the standard tier, the size of the full snapshot in the archive tier will be the same size as the snapshot in standard tier. This is because the first snapshot taken of a volume is always a full snapshot.
- Archiving is recommended for monthly, quarterly, or yearly snapshots. Archiving daily incremental snapshots of a single volume can lead to higher costs when compared to keeping them in the standard tier.
- When a snapshot is archived, the data of the snapshot that is referenced by other snapshots in the snapshot lineage are retained in the standard tier. Data and storage costs associated with the referenced data that is retained on the standard tier are allocated to the next snapshot in the lineage. This ensures that subsequent snapshots in the lineage are not affected by the archival.
- If you delete an archived snapshot that matches a Recycle Bin retention rule, the archived snapshot is retained in the Recycle Bin for the retention period defined in the retention rule. To use the snapshot, you must first recover it from the Recycle Bin and then restore it from the archive tier. For more information, see Recycle Bin (p. 2114) and Pricing and billing (p. 1842).

Limitations

- You can archive snapshots that are in the completed state only.
- You can archive only snapshots that you own in your account. To archive a snapshot that is shared with you, first copy the snapshot to your account and then archive the snapshot copy.
- You can't archive a snapshot of the root device volume of a registered AMI.
- You can't archive snapshots that are associated with an Amazon EBS-backed AMI.
- You can't cancel the snapshot archive or snapshot restore process after it has been started.
- You can't share archived snapshots. If you archive a snapshot that you have shared with other accounts, the accounts with which the snapshot is shared lose access after the snapshot is archived.
- You can't copy an archived snapshot. If you need to copy an archived snapshot, you must first restore it.
- You can't enable fast snapshot restore for an archived snapshot. Fast snapshot restore is automatically disabled when a snapshot is archived. If you need to use fast snapshot restore, you must manually enable it after restoring the snapshot.
- You can't archive snapshots that were created by AWS Backup.
**Pricing and billing**

Archived snapshots are billed at a rate of $0.0125 per GB-month. For example, if you archive a 100 GiB snapshot, you are billed $1.25 (100 GiB * $0.0125) per month.

Snapshot restores are billed at a rate of $0.03 per GB of data restored. For example, if you restore a 100 GiB snapshot from the archive tier, you are billed one time for $3 (100 GiB * $0.03).

After the snapshot is restored to the standard tier, the snapshot is billed at the standard rate for snapshots of $0.05 per GB-month.

For more information, see [Amazon EBS pricing](https://aws.amazon.com/ebs/pricing/).

**Billing for the minimum archive period**

The minimum archive period is 90 days. If you delete or permanently restore an archived snapshot before the minimum archive period of 90 days, you are billed a pro-rated charge equal to the archive tier storage charge for the remaining days, rounded to the nearest hour. For example, if you delete or permanently restore an archived snapshot after 40 days, you are billed for the remaining 50 days of the minimum archive period.

*Note*
Temporarily restoring an archived snapshot before the minimum archive period of 90 days does not incur this charge.

**Temporary restores**

When you temporarily restore a snapshot, the snapshot is restored from the archive tier to the standard tier, and a copy of the snapshot remains in the archive tier. You are billed for both the snapshot in the standard tier and the snapshot copy in the archive tier for the duration of the temporary restore period. When the temporarily restored snapshot is removed from the standard tier, you are no longer billed for it, and you are billed for the snapshot in the archive tier only.

**Permanent restores**

When you permanently restore a snapshot, the snapshot is restored from the archive tier to the standard tier, and the snapshot is deleted from the archive tier. You are billed for the snapshot in the standard tier only.

**Deleting snapshots**

If you delete a snapshot while it is being archived, you are billed for the snapshot data that has already been moved to the archive tier. This data is subject to the minimum archive period of 90 days and billed accordingly upon deletion. For example, if you archive a 100 GiB snapshot, and you delete the snapshot after only 40 GiB has been archived, you are billed $1.50 for the minimum archive period of 90 days for the 40 GiB that has already been archived ($0.0125 per GB-month * 40 GB * (90 days * 24 hours) / (24 hours/day * 30-day month)).

If you delete a snapshot while it is being restored from the archive tier, you are billed for the snapshot restore for the full size of the snapshot (snapshot size * $0.03). For example, if you restore a 100 GiB snapshot from the archive tier, and you delete the snapshot at any point before the snapshot restore completes, you are billed $3 (100 GiB snapshot size * $0.03).

**Recycle Bin**

Archived snapshots are billed at the rate for archived snapshots while they are in the Recycle Bin. Archived snapshots that are in the Recycle Bin are subject to the minimum archive period of 90 days and
they are billed accordingly if they are deleted by Recycle Bin before the minimum archive period. In other words, if a retention rule deletes an archived snapshot from the Recycle Bin before the minimum period of 90 days, you are billed for the remaining days.

If you delete a snapshot that matches a retention rule while the snapshot is being archived, the archived snapshot is retained in the Recycle Bin for the retention period defined in the retention rule. It is billed at the rate for archived snapshots.

If you delete a snapshot that matches a retention rule while the snapshot is being restored, the restored snapshot is retained in the Recycle Bin for the remainder of the retention period, and billed at the standard snapshot rate. To use the restored snapshot, you must first recover it from the Recycle Bin.

For more information, see Recycle Bin (p. 2114).

**Cost tracking**

Archived snapshots appear in the AWS Cost and Usage Report with their same resource ID and Amazon Resource Name (ARN). For more information, see the AWS Cost and Usage Report User Guide.

You can use the following usage types to identify the associated costs:

- **SnapshotArchiveStorage** — fee for monthly data storage
- **SnapshotArchiveRetrieval** — one-time fee for snapshot restores
- **SnapshotArchiveEarlyDelete** — fee for deleting or permanently restoring a snapshot before the minimum archive period (90 days)

**Quotas**

This section describes the default quotas for archived and in-progress snapshots.

<table>
<thead>
<tr>
<th>Quota</th>
<th>Default quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Archived snapshots per volume</td>
<td>25</td>
</tr>
<tr>
<td>Concurrent 25 in-progress snapshot archives per account</td>
<td></td>
</tr>
<tr>
<td>Concurrent 5 in-progress snapshot restores per account</td>
<td></td>
</tr>
</tbody>
</table>

If you need more than the default limits, complete the AWS Support Center Create case form to request a limit increase.
Guidelines and best practices for archiving snapshots

This section provides some guidelines and best practices for archiving snapshots.

Topics
- **Archiving the only snapshot of a volume** (p. 1844)
- **Archiving incremental snapshots of a single volume** (p. 1844)
- **Archiving full snapshots for compliance reasons** (p. 1845)
- **Determining the reduction in standard tier storage costs** (p. 1846)

Archiving the only snapshot of a volume

When you have only one snapshot of a volume, the snapshot is always the same size as the blocks written to the volume at the time the snapshot was created. When you archive such a snapshot, the snapshot in the standard tier is converted to an equivalent-sized full snapshot and it is moved from the standard tier to the archive tier.

Archiving these snapshots can help you save with lower storage costs. If you no longer need the source volume, you can delete the volume for further storage cost savings.

Archiving incremental snapshots of a single volume

When you archive an incremental snapshot, the snapshot is converted to a full snapshot and it is moved to the archive tier. For example, in the following image, if you archive **Snap B**, the snapshot is converted to a full snapshot that is 10 GiB in size and moved to the archive tier. Similarly, if you archive **Snap C**, the size of the full snapshot in the archive tier is 14 GiB.
If you are archiving snapshots to reduce your storage costs in the standard tier, you should not archive the first snapshot in a set of incremental snapshots. These snapshots are referenced by subsequent snapshots in the snapshot lineage. In most cases, archiving these snapshots will not reduce storage costs.

**Note**

You should not archive the last snapshot in a set of incremental snapshots. The last snapshot is the most recent snapshot taken of a volume. You will need this snapshot in the standard tier if you want to create volumes from it in the case of a volume corruption or loss.

If you archive a snapshot that contains data that is referenced by a later snapshot in the lineage, the data storage and storage costs associated with the referenced data are allocated to the later snapshot in the lineage. In this case, archiving the snapshot will not reduce data storage or storage costs. For example, in the preceding image, if you archive `Snap B`, its 4 GiB of data is attributed to `Snap C`. In this case, your overall storage costs will increase because you incur storage costs for the full version of `Snap B` in the archive tier, and your storage costs for the standard tier remain unchanged.

If you archive `Snap C`, your standard tier storage will decrease by 4 GiB because the data is not referenced by any other snapshots later in the lineage. And your archive tier storage will increase by 14 GiB because the snapshot is converted to a full snapshot.

**Archiving full snapshots for compliance reasons**

You might need to create full backups of volumes on a monthly, quarterly, or yearly basis for compliance reasons. For these backups, you might need standalone snapshots without backward or forward
references to other snapshots in the snapshot lineage. Snapshots archived with EBS Snapshots Archive are full snapshots, and they do not have any references to other snapshots in the lineage. Additionally, you will likely need to retain these snapshots for compliance reasons for several years. EBS Snapshots Archive makes it cost-effective to archive these full snapshots for long-term retention.

**Determining the reduction in standard tier storage costs**

If you want to archive an incremental snapshot to reduce your storage costs, you should consider the size of the full snapshot in the archive tier and the reduction in storage in the standard tier. This section explains how to do this.

**Important**

The API responses are data accurate at the point-in-time when the APIs are called. API responses can differ as the data associated with a snapshot changes as a result of changes in the snapshot lineage.

To determine the reduction in storage and storage costs in the standard tier, use the following steps.

1. Check the size of the full snapshot. To determine the full size of the snapshot, use the `list-snapshot-blocks` command. For `--snapshot-id`, specify the ID of the snapshot that you want to archive.

   ```bash
   $ aws ebs list-snapshot-blocks --snapshot-id snapshot_id
   ``

   This returns information about all of the blocks in the specified snapshot. The `BlockIndex` of the last block returned by the command indicates the number of blocks in the snapshot. The number of blocks multiplied by 512 KiB, which is the snapshot block size, gives you a close approximation of the size of the full snapshot in the archive tier (blocks * 512 KiB = full snapshot size).

   For example, the following command lists the blocks for snapshot `snap-01234567890abcdef`.

   ```bash
   $ aws ebs list-snapshot-blocks --snapshot-id snap-01234567890abcdef
   ``

   The following is the command output, with some blocks omitted. The following output indicates that the snapshot includes about 16,383 blocks of data. This approximates to a full snapshot size of about 8 GiB (16,383 * 512 KiB = 7.99 GiB).

   ```json
   {   "VolumeSize": 8,
    "Blocks": [
     {   "BlockToken": "ABgBAeShfaSRwG+iWUg2pwnnCU/
          YMnV7fgxLbCwFEBEUmuqac5RmoyVat",
        "BlockIndex": 0 },
     {   "BlockToken": "ABgBATdTONyThPUAbQhbUQXsn5TGoY/
          J17GfE83j9WN7siupav0Tw9E1KpFh",
        "BlockIndex": 1 },
     {   "BlockToken": "EBEUmuqXsn5TGoY/QwmmCU/YNnV74eKE2TSn5TGoY/
          E83j9WQhqUQXsn5T",
        "BlockIndex": 4 },
     ......
     {   "BlockToken": "yThPUAbQhb5V8xpwnnCU/
          YMnV74eKE2TSFY1ksKP/4r05y47WEdTONyThPUA",
        "BlockIndex": 12890 }
   }
   ```
2. Find the source volume from which the snapshot that you want to archive was created. Use the `describe-snapshots` command. For `--snapshot-id`, specify the ID of the snapshot that you want to archive. The `VolumeId` response parameter indicates the ID of the source volume.

   ```bash
   $ aws ec2 describe-snapshots --snapshot-id snapshot_id
   ```

   For example, the following command returns information about snapshot snap-09c9114207084f0d9.

   ```bash
   $ aws ec2 describe-snapshots --snapshot-id snap-09c9114207084f0d9
   ```

   The following is the command output, which indicates that snapshot snap-09c9114207084f0d9 was created from volume vol-0f3e2c292c52b85c3.

   ```json
   {   "Snapshots": [     {         "Description": "",         "Tags": [],         "Encrypted": false,         "VolumeId": "vol-0f3e2c292c52b85c3",         "State": "completed",         "VolumeSize": 8,         "StartTime": "2021-11-16T08:29:49.840Z",         "Progress": "100%",         "OwnerId": "123456789012",         "SnapshotId": "snap-09c9114207084f0d9"     }   ] }
   ```

3. Find all of the snapshots created from the source volume. Use the `describe-snapshots` command. Specify the `volume-id` filter, and for the filter value, specify the volume ID from the previous step.

   ```bash
   $ aws ec2 describe-snapshots --filters "Name=volume-id, Values=volume_id"
   ```

   For example, the following command returns all snapshots created from volume vol-0f3e2c292c52b85c3.

   ```bash
   $ aws ec2 describe-snapshots --filters "Name=volume-id, Values=vol-0f3e2c292c52b85c3"
   ```
The following is the command output, which indicates that three snapshots were created from volume vol-0f3e2c292c52b85c3.

```
{
    "Snapshots": [
    {
        "Description": "",
        "Tags": [],
        "Encrypted": false,
        "VolumeId": "vol-0f3e2c292c52b85c3",
        "State": "completed",
        "VolumeSize": 8,
        "StartTime": "2021-11-14T08:57:39.300Z",
        "Progress": "100%",
        "OwnerId": "123456789012",
        "SnapshotId": "snap-08ca60083f86816b0"
    },
    {
        "Description": "",,
        "Tags": [],
        "Encrypted": false,
        "VolumeId": "vol-0f3e2c292c52b85c3",
        "State": "completed",
        "VolumeSize": 8,
        "StartTime": "2021-11-15T08:29:49.840Z",
        "Progress": "100%",
        "OwnerId": "123456789012",
        "SnapshotId": "snap-09c9114207084f0d9"
    },
    {
        "Description": "01",
        "Tags": [],
        "Encrypted": false,
        "VolumeId": "vol-0f3e2c292c52b85c3",
        "State": "completed",
        "VolumeSize": 8,
        "StartTime": "2021-11-16T07:50:08.042Z",
        "Progress": "100%",
        "OwnerId": "123456789012",
        "SnapshotId": "snap-024f49fe8dd853fa8"
    }
    ]
}
```

4. Using the output from the previous command, sort the snapshots by their creation times, from earliest to newest. The `StartTime` response parameter for each snapshot indicates its creation time, in UTC time format.

For example, the snapshots returned in the previous step arranged by creation time, from earliest to newest, is as follows:

1. `snap-08ca60083f86816b0` (earliest – created before the snapshot that you want to archive)
2. `snap-09c9114207084f0d9` (the snapshot to archive)
3. `snap-024f49fe8dd853fa8` (newest – created after the snapshot that you that want to archive)

5. Identify the snapshots that were created immediately before and after the snapshot that you want to archive. In this case, you want to archive snapshot `snap-09c9114207084f0d9`, which was the second incremental snapshot created in the set of three snapshots. Snapshot `snap-08ca60083f86816b0` was created immediately before, and snapshot `snap-024f49fe8dd853fa8` was created immediately after.
6. Find the unreferenced data in the snapshot that you want to archive. First, find the blocks that are different between the snapshot that was created immediately before the snapshot that you want to archive, and the snapshot that you want to archive. Use the `list-changed-blocks` command. For `--first-snapshot-id`, specify the ID of the snapshot that was created immediately before the snapshot that you want to archive. For `--second-snapshot-id`, specify the ID of the snapshot that you want to archive.

```
$ aws ebs list-changed-blocks --first-snapshot-id snapshot_created_before --second-snapshot-id snapshot_to_archive
```

For example, the following command shows the block indexes for the blocks that are different between snapshot snap-08ca60083f86816b0 (the snapshot created before the snapshot you want to archive), and snapshot snap-09c9114207084f0d9 (the snapshot you want to archive).

```
$ aws ebs list-changed-blocks --first-snapshot-id snap-08ca60083f86816b0 --second-snapshot-id snap-09c9114207084f0d9
```

The following shows the command output, with some blocks omitted.

```json
{
"BlockSize": 524288,
"ChangedBlocks": [
  {
    "FirstBlockToken": "ABgBAX6y+WH6Rm9y5zq1vYeTCmEzGm7T0jNZG1cDizFq1r0VeFbWXsH3W4z/",
    "SecondBlockToken": "ABgBASyx8bHHbTEnRu+9USLxYK/8IU70dbHIuFqUJQkTwK5qkJP8NSGyNB",
    "BlockIndex": 4
  },
  {
    "FirstBlockToken": "ABgBAcFL+EfmQmlNgstqrFnYgsAxFX4SD5kLKNY00CHG8Wc3Jnppn90E9XX1",
    "SecondBlockToken": "ABgBArX0m6aBAt3EBy+8fCSESmpig7csKjbO20cd08m2iNJV2Ue+cRwUqF",
    "BlockIndex": 5
  },
  {
    "FirstBlockToken": "ABgBAVBAfJmbP/eRHgh7vnnJLwiyiNUi3MKZmEMxs2wC3AmM/fc6yCOAmbHicity",
    "SecondBlockToken": "ABgBAwemwWkHTrchZmsFM7GbAYX1f7c1tcn2nppz4wYItZrAo1M72fpXU0Yv",
    "BlockIndex": 13
  },
  {
    "FirstBlockToken": "ABgBAQ6xwuf6z095L6DpRoVRVnOqPxm9z7Wf60+i1tZ0dwPgN39ijztLn",
    "SecondBlockToken": "ABgBAUdBitiwCI7c6hGst6cckkCWe6bMRc1nV+bKjVi/u/9UEStcW7CD9w4j2t",
    "BlockIndex": 14
  },
  {
    "FirstBlockToken": "ABgBAZBfEvEHS1a5XTXxSE3mBZ6bGmEIkxpljzmgSHICGlFmZCyJXz4t3",
    "SecondBlockToken": "ABgBAVWr7QuQQBNAP2TtmNkgSAe5kAQVC1dnpc91zB1NmSFW9ou11beXWy",
    "BlockIndex": 15
  },
  ...
  {
    "SecondBlockToken": "ABgBAeHwXPL+z3DBLjdhwjdAM9+CpgV5V5Q3zEea+ku50P498hjntAgMhLg",
```

1849
Next, use the same command to find blocks that are different between the snapshot that you want to archive and the snapshot that was created immediately after it. For `--first-snapshot-id`, specify the ID of the snapshot that you want to archive. For `--second-snapshot-id`, specify the ID of the snapshot that was created immediately after the snapshot that you want to archive.

```
$ aws ebs list-changed-blocks --first-snapshot-id snapshot_to_archive --second-snapshot-id snapshot_created_after
```

For example, the following command shows the block indexes of the blocks that are different between snapshot snap-09c9114207084f0d9 (the snapshot that you want to archive) and snapshot snap-024f49fe8dd853fa8 (the snapshot created after the snapshot that you want to archive).

```
$ aws ebs list-changed-blocks --first-snapshot-id snap-09c9114207084f0d9 --second-snapshot-id snap-024f49fe8dd853fa8
```

The following shows the command output, with some blocks omitted.

```
{
   "BlockIndex": 13171,
   { "SecondBlockToken": 
   "ABgBAVax0bHHBnTERu+9USLxYK/81UT0dbSnkDk0gqwRFSFGWA7HYbkkAy5Y", 
   "BlockIndex": 13172,
   { "SecondBlockToken": "ABgBAeL0mtX6aBAt3EBu+8jFCESMpig7cscsmI4ufnQJT3XBm/ 
   +pJSG/19ESwtt7Hd8GHaUqkVx56Zf3", 
   "BlockIndex": 13174
   },
   { "SecondBlockToken": "ABgBAXtGvUhsTjjUqiwkXfXzyR2GPeii/
   +pJSG/19ESwtt7Hd8GHaUqkVx56Zf3", 
   "BlockIndex": 13175
   },
   "ExpiryTime": 1637648751.813,
   "VolumeSize": 8
}
```
7. Compare the output returned by both commands in the previous step. If the same block index appears in both command outputs, it indicates that the block contains unreferenced data.

For example, the command output in the previous step indicates that blocks 4, 5, 13, and 14 are unique to snapshot snap-09c9114207084f0d9 and that they are not referenced by any other snapshots in the snapshot lineage.

To determine the reduction in standard tier storage, multiply the number of blocks that appear in both command outputs by 512 KiB, which is the snapshot block size.
For example, if 9,950 block indexes appear in both command outputs, it indicates that you will decrease standard tier storage by around 4.85 GiB (9,950 blocks * 512 KiB = 4.85 GiB).

8. Determine the storage costs for storing the unreferenced blocks in the standard tier for 90 days. Compare this value with the cost of storing the full snapshot, described in from step 1, in the archive tier. You can determine your costs savings by comparing the values, assuming that you do not restore the full snapshot from the archive tier during the minimum 90-day period. For more information, see Pricing and billing (p. 1842).

Required IAM permissions

By default, users don't have permission to use snapshot archiving. To allow users to use snapshot archiving, you must create IAM policies that grant permission to use specific resources and API actions. For more information, see Creating IAM policies in the IAM User Guide.

To use snapshot archiving, users need the following permissions.

• ec2:DescribeSnapshotTierStatus
• ec2:ModifySnapshotTier
• ec2:RestoreSnapshotTier

Console users might need additional permissions such as ec2:DescribeSnapshots.

To archive and restore encrypted snapshots, the following additional AWS KMS permissions are required.

• kms:CreateGrant
• kms:Decrypt
• kms:DescribeKey

The following is an example IAM policy that gives IAM users permission to archive, restore, and view encrypted and unencrypted snapshots. It includes the ec2:DescribeSnapshots permission for console users. If some permissions are not needed, you can remove them from the policy.

Tip
To follow the principle of least privilege, do not allow full access to kms:CreateGrant. Instead, use the kms:GrantIsForAWSResource condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service, as shown in the following example.

```json
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "ec2:DescribeSnapshotTierStatus",
      "ec2:ModifySnapshotTier",
      "ec2:RestoreSnapshotTier",
      "ec2:DescribeSnapshots",
      "kms:CreateGrant",
      "kms:Decrypt",
      "kms:DescribeKey"
    ],
    "Resource": "*",
    "Condition": {
      "Bool": {
        "kms:GrantIsForAWSResource": true
```
To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center (successor to AWS Single Sign-On):
  
  Create a permission set. Follow the instructions in [Create a permission set](https://docs.aws.amazon.com/iam/latest/userguide/idc-create-permission-set.html) in the *AWS IAM Identity Center (successor to AWS Single Sign-On)* User Guide.

- Users managed in IAM through an identity provider:
  
  Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider (federation)](https://docs.aws.amazon.com/iam/latest/userguide/idc-create-role.html) in the *IAM User Guide*.

- IAM users:
  
  - Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](https://docs.aws.amazon.com/iam/latest/userguide/creating-role.html) in the *IAM User Guide*.
  
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user (console)](https://docs.aws.amazon.com/iam/latest/userguide/iam-users-console.html) in the *IAM User Guide*.

### Work with snapshot archiving

**Topics**

- [Archive a snapshot](#)
- [Restore an archived snapshot](#)
- [Modify the restore period or restore type for a temporarily restored snapshot](#)
- [View archived snapshots](#)

### Archive a snapshot

You can archive any snapshot that is in the completed state and that you own in your account. You can't archive snapshots that are in the pending or error states, or snapshots that are shared with you. For more information, see [Considerations and limitations](https://docs.aws.amazon.com/elasticblockstore/latest/ebs/considerations.html).

Archived snapshots retain their snapshot ID, encryption status, AWS Identity and Access Management (IAM) permissions, owner information, and resource tags. However, fast snapshot restore and snapshot sharing are automatically disabled after the snapshot is archived.

You can continue to use the snapshot while the archive is in process. As soon as the snapshot tiering status reaches the archival-complete state, you can no longer use the snapshot.

You can archive a snapshot using one of the following methods.

#### Console

**To archive a snapshot**

Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

1. In the navigation pane, choose **Snapshots**.
2. In the list of snapshots, select the snapshot to archive and then choose **Actions, Archive snapshot**.
3. To confirm, choose **Archive snapshot**.
AWS CLI

To archive a snapshot

Use the `modify-snapshot-tier` AWS CLI command. For `--snapshot-id`, specify the ID of the snapshot to archive. For `--storage-tier`, specify archive.

```
$ aws ec2 modify-snapshot-tier
   --snapshot-id snapshot_id
   --storage-tier archive
```

For example, the following command archives snapshot `snap-01234567890abcedf`.

```
$ aws ec2 modify-snapshot-tier
   --snapshot-id snap-01234567890abcedf
   --storage-tier archive
```

The following is the command output. The `TieringStartTime` response parameter indicates the date and time at which the archive process was started, in UTC time format (YYYY-MM-DDTHH:MM:SSZ).

```
{
   "SnapshotId": "snap-01234567890abcedf",
   "TieringStartTime": "2021-09-15T16:44:37.574Z"
}
```

Restore an archived snapshot

Before you can use an archived snapshot, you must first restore it to the standard tier. The restored snapshot has the same snapshot ID, encryption status, IAM permissions, owner information, and resource tags that it had before it was archived. After it is restored, you can use it in the same way that you use any other snapshot in your account. The restored snapshot is always a full snapshot.

When you restore a snapshot, you can choose to restore it **permanently** or **temporarily**.

If you restore a snapshot permanently, the snapshot is moved from the archive tier to the standard tier permanently. The snapshot remains restored and ready for use until you manually re-archive it or you manually delete it. When you permanently restore a snapshot, the snapshot is removed from the archive tier.

If you restore a snapshot temporarily, the snapshot is copied from the archive tier to the standard tier for a restore period that you specify. The snapshot remains restored and ready for use for the restore period only. During the restore period, a copy of the snapshot remains in the archive tier. After the period expires, the snapshot is automatically removed from the standard tier. You can increase or decrease the restore period or change the restore type to permanent at any time during the restore period. For more information, see [Modify the restore period or restore type for a temporarily restored snapshot](p. 1856).

You can restore an archived snapshot using one of the following methods.

Console

**To restore a snapshot from the archive**

Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

1. In the navigation pane, choose **Snapshots**.
2. In the list of snapshots, select the archived snapshot to restore, and then choose **Actions**, **Restore snapshot from archive**.
3. Specify the type of restore to perform. For **Restore type**, do one of the following:
   - To restore the snapshot permanently, select **Permanent**.
   - To restore the snapshot temporarily, select **Temporary**, and then for **Temporary restore period**, enter the number of days for which to restore the snapshot.

4. To confirm, choose **Restore snapshot**.

AWS CLI

**To permanently restore an archived snapshot**

Use the `restore-snapshot-tier` AWS CLI command. For `--snapshot-id`, specify the ID of the snapshot to restore, and include the `--permanent-restore` option.

```bash
aws ec2 restore-snapshot-tier \
--snapshot-id snapshot_id \
--permanent-restore
```

For example, the following command permanently restores snapshot `snap-01234567890abcedf`.

```bash
aws ec2 restore-snapshot-tier \
--snapshot-id snap-01234567890abcedf \
--permanent-restore
```

The following is the command output.

```json
{
   "SnapshotId": "snap-01234567890abcedf",
   "IsPermanentRestore": true
}
```

**To temporarily restore an archived snapshot**

Use the `restore-snapshot-tier` AWS CLI command. Omit the `--permanent-restore` option. For `--snapshot-id`, specify the ID of the snapshot to restore, and for `--temporary-restore-days`, specify the number of days for which to restore the snapshot.

`--temporary-restore-days` must be specified in days. The allowed range is 1 - 180. If you do not specify a value, it defaults to 1 day.

```bash
aws ec2 restore-snapshot-tier \
--snapshot-id snapshot_id \
--temporary-restore-days number_of_days
```

For example, the following command temporarily restores snapshot `snap-01234567890abcedf` for a restore period of 5 days.

```bash
aws ec2 restore-snapshot-tier \
--snapshot-id snap-01234567890abcedf \
--temporary-restore-days 5
```

The following is the command output.

```json
{
   "SnapshotId": "snap-01234567890abcedf",
   "RestoreDuration": 5,
   "IsPermanentRestore": false
}
```
Modify the restore period or restore type for a temporarily restored snapshot

When you restore a snapshot temporarily, you must specify the number of days for which the snapshot is to remain restored in your account. After the restore period expires, the snapshot is automatically removed from the standard tier.

You can change the restore period for a temporarily restored snapshot at any time. You can choose to either increase or decrease the restore period, or you can change the restore type from temporary to permanent.

If you change the restore period, the new restore period is effective from the current date. For example, if you specify a new restore period of 5 days, the snapshot will remain restored for five days from the current date.

Note
You can end a temporary restore early by setting the restore period to 1 day.

If you change the restore type from temporary to permanent, the snapshot copy is deleted from the archive tier, and the snapshot remains available in your account until you manually re-archive it or delete it.

You can modify the restore period for a snapshot using one of the following methods.

Console

To modify the restore period or restore type

Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

1. In the navigation pane, choose Snapshots.
2. In the list of snapshots, select the snapshot that you previously temporarily restored, and then choose Actions, Restore snapshot from archive.
3. For Restore type, do one of the following:
   - To change the restore type from temporary to permanent, select Permanent.
   - To increase or decrease the restore period, keep Temporary, and then for Temporary restore period, enter the new restore period in days.
4. To confirm, choose Restore snapshot.

AWS CLI

To modify the restore period or change the restore type

Use the restore-snapshot-tier AWS CLI command. For --snapshot-id, specify the ID of the snapshot that you previously temporarily restored. To change the restore type from temporary to permanent, specify --permanent-restore and omit --temporary-restore-days. To increase or decrease the restore period, omit --permanent-restore and for --temporary-restore-days, specify the new restore period in days.

Example: Increase or decrease the restore period

The following command changes the restore period for snapshot snap-01234567890abcedf to 10 days.

$ aws ec2 restore-snapshot-tier \

bash

--snapshot-id snap-01234567890abcedf
--temporary-restore-days 10

The following is the command output.

```
{
   "SnapshotId": "snap-01234567890abcedf",
   "RestoreDuration": 10,
   "IsPermanentRestore": false
}
```

**Example: Change restore type to permanent**

The following command changes the restore type for snapshot snap-01234567890abcedf from temporary to permanent.

```
$ aws ec2 restore-snapshot-tier \ 
   --snapshot-id snap-01234567890abcedf 
   --permanent-restore
```

The following is the command output.

```
{
   "SnapshotId": "snap-01234567890abcedf",
   "IsPermanentRestore": true
}
```

**View archived snapshots**

You can view storage tier information for snapshots using one of the following methods.

**Console**

**To view storage tier information for a snapshot**

Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

1. In the navigation pane, choose Snapshots.
2. In the list of snapshots, select the snapshot and choose the Storage tier tab.

   The tab provides the following information:

   - **Last tier change started on** — The date and time when the last archive or restore was started.
   - **Tier change progress** — The progress of the last archive or restore action, as a percentage.
   - **Storage tier** — The storage tier for the snapshot. Always archive for archived snapshots, and standard for snapshots stored on the standard tier, including temporarily restored snapshots.
   - **Tiering status** — The status of the last archive or restore action.
   - **Archive completed on** — The date and time when the archive completed.
   - **Temporary restore expires on** — The date and time when a temporarily restored snapshot is set to expire.

**AWS CLI**

**To view archival information about an archived snapshot**
Use the `describe-snapshot-tier-status` AWS CLI command. Specify the `snapshot-id` filter, and for the filter value, specify the snapshot ID. Alternatively, to view all archived snapshots, omit the filter.

```
$ aws ec2 describe-snapshot-tier-status --filters "Name=snapshot-id, Values=snapshot_id"
```

The output includes the following response parameters:

- **Status** — The status of the snapshot. Always completed for archived snapshots. Only snapshots that are in the completed state can be archived.
- **LastTieringStartTime** — The date and time that the archival process started, in UTC time format (YYYY-MM-DDTHH:MM:SSZ).
- **LastTieringOperationState** — The current state of the archival process. Possible states include: `archival-in-progress` | `archival-completed` | `archival-failed` | `permanent-restore-in-progress` | `permanent-restore-completed` | `permanent-restore-failed` | `temporary-restore-in-progress` | `temporary-restore-completed` | `temporary-restore-failed`
- **LastTieringProgress** — The progress of the snapshot archival process, as a percentage.
- **StorageTier** — The storage tier for the snapshot. Always archive for archived snapshots, and standard for snapshots stored on the standard tier, including temporarily restored snapshots.
- **ArchivalCompleteTime** — The date and time that the archival process completed, in UTC time format (YYYY-MM-DDTHH:MM:SSZ).

**Example**

The following command displays information about snapshot snap-01234567890abcedf.

```
$ aws ec2 describe-snapshot-tier-status --filters "Name=snapshot-id, Values=snap-01234567890abcedf"
```

The following is the command output.

```
{
   "SnapshotTierStatuses": [
   {
      "Status": "completed",
      "ArchivalCompleteTime": "2021-09-15T17:33:16.147Z",
      "LastTieringProgress": 100,
      "Tags": [],
      "VolumeId": "vol-01234567890abcedf",
      "LastTieringOperationState": "archival-completed",
      "StorageTier": "archive",
      "OwnerId": "123456789012",
      "SnapshotId": "snap-01234567890abcedf",
      "LastTieringStartTime": "2021-09-15T16:44:37.574Z"
   }
   ]
}
```

To view archived and standard tier snapshots

Use the `describe-snapshot` AWS CLI command. For `--snapshot-ids`, specify the ID of the snapshot view.

```
$ aws ec2 describe-snapshots --snapshot-ids snapshot_id
```
For example, the following command displays information about snapshot snap-01234567890abcedf.

```
$ aws ec2 describe-snapshots --snapshot-ids snap-01234567890abcedf
```

The following is the command output. The `StorageTier` response parameter indicates whether the snapshot is currently archived. `archive` indicates that the snapshot is currently archived and stored in the archive tier, and `standard` indicates that the snapshot is currently not archived and that it is stored in the standard tier.

In the following example output, only Snap A is archived. Snap B and Snap C are not archived.

Additionally, the `RestoreExpiryTime` response parameter is returned only for snapshots that are temporarily restored from the archive. It indicates when temporarily restored snapshots are to be automatically removed from the standard tier. It is **not** returned for snapshots that are permanently restored.

In the following example output, Snap C is temporarily restored, and it will be automatically removed from the standard tier at 2021-09-19T21:00:00.000Z (September 19, 2021 at 21:00 UTC).

```
{
    "Snapshots": [
        {
            "Description": "Snap A",
            "Encrypted": false,
            "VolumeId": "vol-01234567890aaaaaa",
            "State": "completed",
            "VolumeSize": 8,
            "StartTime": "2021-09-07T21:00:00.000Z",
            "Progress": "100%",
            "OwnerId": "123456789012",
            "SnapshotId": "snap-01234567890aaaaaa",
            "StorageTier": "archive",
            "Tags": []
        },
        {
            "Description": "Snap B",
            "Encrypted": false,
            "VolumeId": "vol-09876543210bbbbbb",
            "State": "completed",
            "VolumeSize": 10,
            "StartTime": "2021-09-14T21:00:00.000Z",
            "Progress": "100%",
            "OwnerId": "123456789012",
            "SnapshotId": "snap-09876543210bbbbbb",
            "StorageTier": "standard",
            "RestoreExpiryTime": "2019-09-19T21:00:00.000Z",
            "Tags": []
        },
        {
            "Description": "Snap C",
            "Encrypted": false,
            "VolumeId": "vol-054321543210cccccc",
            "State": "completed",
            "VolumeSize": 12,
            "StartTime": "2021-08-01T21:00:00.000Z",
            "Progress": "100%",
            "OwnerId": "123456789012",
            "SnapshotId": "snap-054321543210cccccc",
            "StorageTier": "standard",
            "Tags": []
        }
    ]
}
```
To view only snapshots that are stored in the archive tier or the standard tier

Use the `describe-snapshot` AWS CLI command. Include the `--filter` option, for the filter name, specify `storage-tier`, and for the filter value specify either `archive` or `standard`.

```
$ aws ec2 describe-snapshots --filters "Name=storage-tier,Values=archive|standard"
```

For example, the following command displays only archived snapshots.

```
$ aws ec2 describe-snapshots --filters "Name=storage-tier,Values=archive"
```

Monitor snapshot archiving

Amazon EBS emits events related to snapshot archiving actions. You can use AWS Lambda and Amazon CloudWatch Events to handle event notifications programmatically. Events are emitted on a best effort basis. For more information, see the Amazon CloudWatch Events User Guide.

The following events are available:

- `archiveSnapshot` — Emitted when a snapshot archive action succeeds or fails.

The following is an example of an event that is emitted when a snapshot archive action succeeds.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "2021-05-25T13:12:22Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
    ],
    "detail": {
        "event": "archiveSnapshot",
        "result": "succeeded",
        "cause": "",
        "request-id": "123456789",
        "snapshot-id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",
        "startTime": "2021-05-25T13:12:22Z",
        "endTime": "2021-05-45T15:30:00Z",
        "recycleBinExitTime": "2021-10-45T15:30:00Z"
    }
}
```

The following is an example of an event that is emitted when a snapshot archive action fails.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "2021-05-25T13:12:22Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
    ],
    "detail": {
        "event": "archiveSnapshot",
        "result": "failed",
        "cause": "",
        "request-id": "123456789",
        "snapshot-id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",
        "startTime": "2021-05-25T13:12:22Z",
        "endTime": "2021-05-45T15:30:00Z",
        "recycleBinExitTime": "2021-10-45T15:30:00Z"
    }
}
```
• **permanentRestoreSnapshot** — Emitted when a permanent restore action succeeds or fails.

The following is an example of an event that is emitted when a permanent restore action succeeds.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "2021-05-25T13:12:22Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
    ],
    "detail": {
        "event": "permanentRestoreSnapshot",
        "result": "succeeded",
        "cause": "",
        "request-id": "1234567890",
        "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",
        "startTime": "2021-05-25T13:12:22Z",
        "endTime": "2021-10-45T15:30:00Z"
    }
}
```

The following is an example of an event that is emitted when a permanent restore action fails.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "2021-05-25T13:12:22Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
    ],
    "detail": {
        "event": "permanentRestoreSnapshot",
        "result": "failed",
        "cause": "Source snapshot ID is not valid",
        "request-id": "1234567890",
        "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",
        "startTime": "2021-05-25T13:12:22Z",
        "endTime": "2021-05-45T15:30:00Z",
        "recycleBinExitTime": "2021-10-45T15:30:00Z"
    }
}
```
• **temporaryRestoreSnapshot** — Emitted when a temporary restore action succeeds or fails.

The following is an example of an event that is emitted when a temporary restore action succeeds.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "2021-05-25T13:12:22Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
    ],
    "detail": {
        "event": "temporaryRestoreSnapshot",
        "result": "succeeded",
        "cause": "",
        "request-id": "1234567890",
        "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",
        "startTime": "2021-05-25T13:12:22Z",
        "endTime": "2021-05-45T15:30:00Z",
        "restoreExpiryTime": "2021-06-45T15:30:00Z",
        "recycleBinExitTime": "2021-10-45T15:30:00Z"
    }
}
```

The following is an example of an event that is emitted when a temporary restore action fails.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "2021-05-25T13:12:22Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
    ],
    "detail": {
        "event": "temporaryRestoreSnapshot",
        "result": "failed",
        "cause": "Source snapshot ID is not valid",
        "request-id": "1234567890",
        "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",
        "startTime": "2021-05-25T13:12:22Z",
        "endTime": "2021-05-45T15:30:00Z",
        "recycleBinExitTime": "2021-10-45T15:30:00Z"
    }
}
```

• **restoreExpiry** — Emitted when the restore period for a temporarily restored snapshot expires.

The following is an example.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "123456789012",
}```
View Amazon EBS snapshot information

You can view detailed information about your snapshots using one of the following methods.

Console

To view snapshot information using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots.
3. To view only your snapshots that you own, in the top-left corner of the screen, choose Owned by me. You can also filter the list of snapshots using tags and other snapshot attributes. In the Filter field, select the attribute field, and then select or enter the attribute value. For example, to view only encrypted snapshots, select Encryption, and then enter true.
4. To view more information about a specific snapshot, choose its ID in the list.

AWS CLI

To view snapshot information using the command line

You can use one of the following command line interfaces, see Access Amazon EC2 (p. 5).

- describe-snapshots (AWS CLI)
- Get-EC2Snapshot (AWS Tools for Windows PowerShell)

Example Example 1: Filter based on tags

The following command describes the snapshots with the tag Stack=production.

```
aws ec2 describe-snapshots --filters Name=tag:Stack,Values=production
```

Example Example 2: Filter based on volume

The following command describes the snapshots created from the specified volume.

```
aws ec2 describe-snapshots --filters Name=volume-id,Values=vol-049df61146c4d7901
```
Example Example 3: Filter based on snapshot age

With the AWS CLI, you can use JMESPath to filter results using expressions. For example, the following command displays the IDs of all snapshots created by your AWS account (represented by 123456789012) before the specified date (represented by 2020-03-31). If you do not specify the owner, the results include all public snapshots.

```
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[?(StartTime<='2020-03-31')].[SnapshotId]" --output text
```

The following command displays the IDs of all snapshots created in the specified date range.

```
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[?(StartTime>='2019-01-01') && (StartTime<='2019-12-31')].[SnapshotId]" --output text
```

Share an Amazon EBS snapshot

You can modify the permissions of a snapshot if you want to share it with other AWS accounts. You can share snapshots publicly with all other AWS accounts, or you can share them privately with individual AWS accounts that you specify. Users that you have authorized can use the snapshots that you share to create their own EBS volumes, while your original snapshot remains unaffected.

**Important**

When you share a snapshot, you are giving others access to all of the data on the snapshot. Share snapshots only with people that you trust with all of your snapshot data.

**Topics**

- Before you share a snapshot (p. 1864)
- Share a snapshot (p. 1864)
- Share a KMS key (p. 1866)
- View snapshots that are shared with you (p. 1867)
- Use snapshots that are shared with you (p. 1868)
- Determine the use of snapshots that you share (p. 1868)

Before you share a snapshot

The following considerations apply to sharing snapshots:

- Snapshots are constrained to the Region in which they were created. To share a snapshot with another Region, copy the snapshot to that Region and then share the copy. For more information, see Copy an Amazon EBS snapshot (p. 1836).
- You can’t share snapshots that are encrypted with the default AWS managed key. You can only share snapshots that are encrypted with a customer managed key. For more information, see Creating Keys in the AWS Key Management Service Developer Guide.
- You can share only unencrypted snapshots publicly.
- When you share an encrypted snapshot, you must also share the customer managed key used to encrypt the snapshot. For more information, see Share a KMS key (p. 1866).

Share a snapshot

You can share a snapshot using one of the methods described in the section.
Console

To share a snapshot

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots.
3. Select the snapshot to share, and then choose Actions, Modify permissions.
4. Specify the snapshot's permissions. Current setting indicates the snapshot's current sharing permissions.
   - To share the snapshot publicly with all AWS accounts, choose Public.
   - To share the snapshot privately with specific AWS accounts, choose Private. Then, in the Sharing accounts section, choose Add account, and enter the 12-digit account ID (without hyphens) of the account to share with.
5. Choose Save changes.

AWS CLI

The permissions for a snapshot are specified using the createVolumePermission attribute of the snapshot. To make a snapshot public, set the group to all. To share a snapshot with a specific AWS account, set the user to the ID of the AWS account.

To share a snapshot publicly

Use one of the following commands.

- **modify-snapshot-attribute** (AWS CLI)
  
  For --attribute, specify createVolumePermission. For --operation-type, specify add. For --group-names, specify all.
  
  $ aws ec2 modify-snapshot-attribute --snapshot-id 1234567890abcdef0 --attribute createVolumePermission --operation-type add --group-names all

- **Edit-EC2SnapshotAttribute** (AWS Tools for Windows PowerShell)
  
  For -Attribute, specify CreateVolumePermission. For -OperationType, specify Add. For -GroupName, specify all.
  
  PS C:\> Edit-EC2SnapshotAttribute -SnapshotId 1234567890abcdef0 -Attribute CreateVolumePermission -OperationType Add -GroupName all

To share a snapshot privately

Use one of the following commands.

- **modify-snapshot-attribute** (AWS CLI)
  
  For --attribute, specify createVolumePermission. For --operation-type, specify add. For --user-ids, specify the 12-digit IDs of the AWS accounts with which to share the snapshots.
  
  $ aws ec2 modify-snapshot-attribute --snapshot-id 1234567890abcdef0 --attribute createVolumePermission --operation-type add --user-ids 123456789012

- **Edit-EC2SnapshotAttribute** (AWS Tools for Windows PowerShell)
For -Attribute, specify CreateVolumePermission. For -OperationType, specify Add. For
UserId, specify the 12-digit IDs of the AWS accounts with which to share the snapshots.

```
PS C:\>  Edit-EC2SnapshotAttribute -SnapshotId 1234567890abcdef0 -Attribute
CreateVolumePermission -OperationType Add -UserId 123456789012
```

### Share a KMS key

When you share an encrypted snapshot, you must also share the customer managed key used to encrypt
the snapshot. You can apply cross-account permissions to a customer managed key either when it is
created or at a later time.

Users of your shared customer managed key who are accessing encrypted snapshots must be granted
permissions to perform the following actions on the key:

- `kms:DescribeKey`
- `kms:CreateGrant`
- `kms:GenerateDataKey`
- `kms:ReEncrypt`
- `kms:Decrypt`

**Tip**

To follow the principle of least privilege, do not allow full access to `kms:CreateGrant`. Instead,
use the `kms:GrantIsForAWSResource` condition key to allow the user to create grants on the
KMS key only when the grant is created on the user's behalf by an AWS service.

For more information about controlling access to a customer managed key, see [Using key policies in
AWS KMS](https://docs.aws.amazon.com/kms/latest/developerguide/key-policy-when-used.html)
in the AWS KMS Developer Guide.

### To share customer managed key using the AWS KMS console

2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. Choose **Customer managed keys** in the navigation pane.
4. In the **Alias** column, choose the alias (text link) of the customer managed key that you used to
   encrypt the snapshot. The key details open in a new page.
5. In the **Key policy** section, you see either the **policy view** or the **default view**. The policy view displays
   the key policy document. The default view displays sections for **Key administrators**, **Key deletion**, **Key Use**, and **Other AWS accounts**. The default view displays if you created the policy in the console
   and have not customized it. If the default view is not available, you'll need to manually edit the
   policy in the policy view. For more information, see [Viewing a Key Policy (Console)](https://docs.aws.amazon.com/kms/latest/developerguide/key-policy-console.html)
in the AWS KMS Developer Guide.

Use either the policy view or the default view, depending on which view you can access, to add one
or more AWS account IDs to the policy, as follows:

- **(Policy view)** Choose **Edit**. Add one or more AWS account IDs to the following statements:
  "Allow use of the key" and "Allow attachment of persistent resources". Choose **Save changes**. In the following example, the AWS account ID 444455556666 is added
to the policy.
View snapshots that are shared with you

You can view snapshots that are shared with you using one of the following methods.

Console

To view shared snapshots using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots.
3. Filter the listed snapshots. In the top-left corner of the screen, choose one of the following options:
   - Private snapshots — To view only snapshots that are shared with you privately.
   - Public snapshots — To view only snapshots that are shared with you publicly.

AWS CLI

To view snapshot permissions using the command line

Use one of the following commands:

- describe-snapshot-attribute (AWS CLI)
- Get-EC2SnapshotAttribute (AWS Tools for Windows PowerShell)
Use snapshots that are shared with you

To use a shared unencrypted snapshot

Locate the shared snapshot by ID or description. For more information, see View snapshots that are shared with you (p. 1867). You can use this snapshot as you would any other snapshot that you own in your account. For example, you can create a volume from the snapshot or copy it to a different Region.

To use a shared encrypted snapshot

Locate the shared snapshot by ID or description. For more information, see View snapshots that are shared with you (p. 1867). Create a copy of the shared snapshot in your account, and encrypt the copy with a KMS key that you own. You can then use the copy to create volumes or you can copy it to different Regions.

Determine the use of snapshots that you share

You can use AWS CloudTrail to monitor whether a snapshot that you have shared with others is copied or used to create a volume. The following events are logged in CloudTrail:

- SharedSnapshotCopyInitiated — A shared snapshot is being copied.
- SharedSnapshotVolumeCreated — A shared snapshot is being used to create a volume.

For more information about using CloudTrail, see Log Amazon EC2 and Amazon EBS API calls with AWS CloudTrail (p. 1246).

Recover snapshots from the Recycle Bin

Recycle Bin is a data recovery feature that enables you to restore accidentally deleted Amazon EBS snapshots and EBS-backed AMIs. When using Recycle Bin, if your resources are deleted, they are retained in the Recycle Bin for a time period that you specify before being permanently deleted.

You can restore a resource from the Recycle Bin at any time before its retention period expires. After you restore a resource from the Recycle Bin, the resource is removed from the Recycle Bin and you can use it in the same way that you use any other resource of that type in your account. If the retention period expires and the resource is not restored, the resource is permanently deleted from the Recycle Bin and it is no longer available for recovery.

Snapshots in the Recycle Bin are billed at the same rate as regular snapshots in your account. There are no additional charges for using Recycle Bin and retention rules. For more information, see Amazon EBS pricing.

For more information, see Recycle Bin (p. 2114).

Topics

- Permissions for working with snapshots in the Recycle Bin (p. 1868)
- View snapshots in the Recycle Bin (p. 1870)
- Restore snapshots from the Recycle Bin (p. 1870)

Permissions for working with snapshots in the Recycle Bin

By default, users don't have permission to work with snapshots that are in the Recycle Bin. To allow users to work with these resources, you must create IAM policies that grant permission to use specific resources and API actions. Once the policies are created, you must add permissions to your users, groups, or roles.

To view and recover snapshots that are in the Recycle Bin, users must have the following permissions:
• `ec2:ListSnapshotsInRecycleBin`
• `ec2:RestoreSnapshotFromRecycleBin`

To manage tags for snapshots in the Recycle Bin, users need the following additional permissions.

• `ec2:CreateTags`
• `ec2:DeleteTags`

To use the Recycle Bin console, users need the `ec2:DescribeTags` permission.

The following is an example IAM policy. It includes the `ec2:DescribeTags` permission for console users, and it includes the `ec2:CreateTags` and `ec2:DeleteTags` permissions for managing tags. If the permissions are not needed, you can remove them from the policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:ListSnapshotsInRecycleBin",
        "ec2:RestoreSnapshotFromRecycleBin"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CreateTags",
        "ec2:DeleteTags",
        "ec2:DescribeTags"
      ],
    }
  ]
}
```

To provide access, add permissions to your users, groups, or roles:

• Users and groups in AWS IAM Identity Center (successor to AWS Single Sign-On):

  Create a permission set. Follow the instructions in Create a permission set in the AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide.

• Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in Creating a role for a third-party identity provider (federation) in the IAM User Guide.

• IAM users:

  • Create a role that your user can assume. Follow the instructions in Creating a role for an IAM user in the IAM User Guide.
  
  • (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the IAM User Guide.

For more information about the permissions needed to use Recycle Bin, see Permissions for working with Recycle Bin and retention rules (p. 2118).
View snapshots in the Recycle Bin

While a snapshot is in the Recycle Bin, you can view limited information about it, including:

- The ID of the snapshot.
- The snapshot description.
- The ID of the volume from which the snapshot was created.
- The date and time when the snapshot was deleted and it entered Recycle Bin.
- The date and time when the retention period expires. The snapshot will be permanently deleted from the Recycle Bin at this time.

You can view the snapshots in the Recycle Bin using one of the following methods.

Recycle Bin console

To view snapshots in the Recycle Bin using the console

1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation pane, choose Recycle Bin.
3. The grid lists all of the snapshots that are currently in the Recycle Bin. To view the details for a specific snapshot, select it in the grid and choose Actions, View details.

AWS CLI

To view snapshots in the Recycle Bin using the AWS CLI

Use the list-snapshots-in-recycle-bin AWS CLI command. Include the --snapshot-id option to view a specific snapshot. Or omit the --snapshot-id option to view all snapshots in the Recycle Bin.

$ aws ec2 list-snapshots-in-recycle-bin --snapshot-id snapshot_id

For example, the following command provides information about snapshot snap-01234567890abcdef in the Recycle Bin.

$ aws ec2 list-snapshots-in-recycle-bin --snapshot-id snap-01234567890abcdef

Example output:

```
{
   "SnapshotRecycleBinInfo": [
   {
       "Description": "Monthly data backup snapshot",
       "RecycleBinEnterTime": "2021-12-01T13:00:00.000Z",
       "RecycleBinExitTime": "2021-12-15T13:00:00.000Z",
       "VolumeId": "vol-abcdef09876543210",
       "SnapshotId": "snap-01234567890abcdef"
   }
   ]
}
```

Restore snapshots from the Recycle Bin

You can't use a snapshot in any way while it is in the Recycle Bin. To use the snapshot, you must first restore it. When you restore a snapshot from the Recycle Bin, the snapshot is immediately available for
use, and it is removed from the Recycle Bin. You can use a restored snapshot in the same way that you use any other snapshot in your account.

You can restore a snapshot from the Recycle Bin using one of the following methods.

Recycle Bin console

To restore a snapshot from the Recycle Bin using the console

1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation pane, choose Recycle Bin.
3. The grid lists all of the snapshots that are currently in the Recycle Bin. Select the snapshot to restore and choose Recover.
4. When prompted, choose Recover.

AWS CLI

To restore a deleted snapshot from the Recycle Bin using the AWS CLI

Use the restore-snapshot-from-recycle-bin AWS CLI command. For --snapshot-id, specify the ID of the snapshot to restore.

```
$ aws ec2 restore-snapshot-from-recycle-bin --snapshot-id snapshot_id
```

For example, the following command restores snapshot snap-01234567890abcdef from the Recycle Bin.

```
$ aws restore-snapshot-from-recycle-bin --snapshot-id snap-01234567890abcdef
```

The command returns no output on success.

Amazon EBS local snapshots on Outposts

Amazon EBS snapshots are a point-in-time copy of your EBS volumes.

By default, snapshots of EBS volumes on an Outpost are stored in Amazon S3 in the Region of the Outpost. You can also use Amazon EBS local snapshots on Outposts to store snapshots of volumes on an Outpost locally in Amazon S3 on the Outpost itself. This ensures that the snapshot data resides on the Outpost, and on your premises. In addition, you can use AWS Identity and Access Management (IAM) policies and permissions to set up data residency enforcement policies to ensure that snapshot data does not leave the Outpost. This is especially useful if you reside in a country or region that is not yet served by an AWS Region and that has data residency requirements.

This topic provides information about working with Amazon EBS local snapshots on Outposts. For more information about Amazon EBS snapshots and about working with snapshots in an AWS Region, see Amazon EBS snapshots (p. 1825).

For more information about AWS Outposts, see AWS Outposts Features and the AWS Outposts User Guide. For pricing information, see AWS Outposts pricing.

Topics
- Frequently asked questions (p. 1872)
- Prerequisites (p. 1873)
- Considerations (p. 448)
Frequently asked questions

1. What are local snapshots?

By default, Amazon EBS snapshots of volumes on an Outpost are stored in Amazon S3 in the Region of the Outpost. If the Outpost is provisioned with Amazon S3 on Outposts, you can choose to store the snapshots locally on the Outpost itself. Local snapshots are incremental, which means that only the blocks of the volume that have changed after your most recent snapshot are saved. You can use these snapshots to restore a volume on the same Outpost as the snapshot at any time. For more information about Amazon EBS snapshots, see Amazon EBS snapshots (p. 1825).

2. Why should I use local snapshots?

Snapshots are a convenient way of backing up your data. With local snapshots, all of your snapshot data is stored locally on the Outpost. This means that it does not leave your premises. This is especially useful if you reside in a country or region that is not yet served by an AWS Region and that has residency requirements.

Additionally, using local snapshots can help to reduce the bandwidth used for communication between the Region and the Outpost in bandwidth constrained environments.

3. How do I enforce snapshot data residency on Outposts?

You can use AWS Identity and Access Management (IAM) policies to control the permissions that principals (AWS accounts, IAM users, and IAM roles) have when working with local snapshots and to enforce data residency. You can create a policy that prevents principals from creating snapshots from Outpost volumes and instances and storing the snapshots in an AWS Region. Currently, copying snapshots and images from an Outpost to a Region is not supported. For more information, see Controlling access with IAM (p. 1874).

4. Are multi-volume, crash-consistent local snapshots supported?

Yes, you can create multi-volume, crash-consistent local snapshots from instances on an Outpost.

5. How do I create local snapshots?

You can create snapshots manually using the AWS Command Line Interface (AWS CLI) or the Amazon EC2 console. For more information see, Working with local snapshots (p. 1875). You can also automate the lifecycle of local snapshots using Amazon Data Lifecycle Manager. For more information see, Automate snapshots on an Outpost (p. 1880).

6. Can I create, use, or delete local snapshots if my Outpost loses connectivity to its Region?

No. The Outpost must have connectivity with its Region as the Region provides the access, authorization, logging, and monitoring services that are critical for your snapshots' health. If there is no connectivity, you can't create new local snapshots, create volumes or launch instances from existing local snapshots, or delete local snapshots.

7. How quickly is Amazon S3 storage capacity made available after deleting local snapshots?

Amazon S3 storage capacity becomes available within 72 hours after deleting local snapshots and the volumes that reference them.

8. How can I ensure that I do not run out of Amazon S3 capacity on my Outpost?

We recommend that you use Amazon CloudWatch alarms to monitor your Amazon S3 storage capacity, and delete snapshots and volumes that you no longer need to avoid running out of storage capacity. If you are using Amazon Data Lifecycle Manager to automate the lifecycle of local snapshots, ensure that your snapshot retention policies do not retain snapshots for longer than is needed.
9. What happens if I run out of local Amazon S3 capacity on my Outposts?

If you run out of local Amazon S3 capacity on your Outposts, Amazon Data Lifecycle Manager will not be able to successfully create local snapshots on the Outposts. Amazon Data Lifecycle Manager will attempt to create the local snapshots on the Outposts, but the snapshots immediately transition to the error state and they are eventually deleted by Amazon Data Lifecycle Manager. We recommend that you use the SnapshotsCreateFailed Amazon CloudWatch metric to monitor your snapshot lifecycle policies for snapshot creation failures. For more information, see Monitor your policies using Amazon CloudWatch (p. 1956).

10. Can I use local snapshots and AMIs backed by local snapshots with Spot Instances and Spot Fleet?

No, you can't use local snapshots or AMIs backed by local snapshots to launch Spot Instances or a Spot Fleet.

11. Can I use local snapshots and AMIs backed by local snapshots with Amazon EC2 Auto Scaling?

Yes, you can use local snapshots and AMIs backed by local snapshots to launch Auto Scaling groups in a subnet that is on the same Outpost as the snapshots. The Amazon EC2 Auto Scaling group service-linked role must have permission to use the KMS key used to encrypt the snapshots.

You can't use local snapshots or AMIs backed by local snapshots to launch Auto Scaling groups in an AWS Region.

Prerequisites

To store snapshots on an Outpost, you must have an Outpost that is provisioned with Amazon S3 on Outposts. For more information about Amazon S3 on Outposts, see Using Amazon S3 on Outposts in the Amazon Simple Storage Service User Guide.

Considerations

Keep the following in mind when working with local snapshots.

- Outposts must have connectivity to their AWS Region to use local snapshots.
- Snapshot metadata is stored in the AWS Region associated with the Outpost. This does not include any snapshot data.
- Snapshots stored on Outposts are encrypted by default. Unencrypted snapshots are not supported. Snapshots that are created on an Outpost and snapshots that are copied to an Outpost are encrypted using the default KMS key for the Region or a different KMS key that you specify at the time of the request.
- When you create a volume on an Outpost from a local snapshot, you cannot re-encrypt the volume using a different KMS key. Volumes created from local snapshots must be encrypted using the same KMS key as the source snapshot.
- After you delete local snapshots from an Outpost, the Amazon S3 storage capacity used by the deleted snapshots becomes available within 72 hours. For more information, see Delete local snapshots (p. 1880).
- You can't export local snapshots from an Outpost.
- You can't enable fast snapshot restore for local snapshots.
- EBS direct APIs are not supported with local snapshots.
- You can't copy local snapshots or AMIs from an Outpost to an AWS Region, from one Outpost to another, or within an Outpost. However, you can copy snapshots from an AWS Region to an Outpost. For more information, see Copy snapshots from an AWS Region to an Outpost (p. 1878).
- When copying a snapshot from an AWS region to an Outpost, the data is transferred over the service link. Copying multiple snapshots simultaneously could impact other services running on the Outpost.
- You can't share local snapshots.
You must use IAM policies to ensure that your data residency requirements are met. For more information, see Controlling access with IAM (p. 1874).

Local snapshots are incremental backups. Only the blocks in the volume that have changed after your most recent snapshot are saved. Each local snapshot contains all of the information that is needed to restore your data (from the moment when the snapshot was taken) to a new EBS volume. For more information, see How snapshots work (p. 1826).

You can't use IAM policies to enforce data residency for CopySnapshot and CopyImage actions.

Controlling access with IAM

You can use AWS Identity and Access Management (IAM) policies to control the permissions that principals (AWS accounts, IAM users, and IAM roles) have when working with local snapshots. The following are example policies that you can use to grant or deny permission to perform specific actions with local snapshots.

Important

Copying snapshots and images from an Outpost to a Region is currently not supported. As a result, you currently can't use IAM policies to enforce data residency for CopySnapshot and CopyImage actions.

Topics

- Enforce data residency for snapshots (p. 1874)
- Prevent principals from deleting local snapshots (p. 1875)

Enforce data residency for snapshots

The following example policy prevents all principals from creating snapshots from volumes and instances on Outpost arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef and storing the snapshot data in an AWS Region. Principals can still create local snapshots. This policy ensures that all snapshots remain on the Outpost.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": [
                "ec2:CreateSnapshot",
                "ec2:CreateSnapshots"
            ],
            "Resource": "arn:aws:ec2:us-east-1::snapshot/*",
            "Condition": {
                "StringEquals": {
                    "ec2:SourceOutpostArn": "arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef"
                },
                "Null": {
                    "ec2:OutpostArn": "true"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateSnapshot",
                "ec2:CreateSnapshots"
            ],
            "Resource": "*"
        }
    ]
}
```
Prevent principals from deleting local snapshots

The following example policy prevents all principals from deleting local snapshots that are stored on Outpost arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Deny",
         "Action": [
            "ec2:DeleteSnapshot"
         ],
         "Resource": "arn:aws:ec2:us-east-1::snapshot/*",
         "Condition": {
            "StringEquals": {
               "ec2:OutpostArn": "arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0"
            }
         }
      },
      {
         "Effect": "Allow",
         "Action": [
            "ec2:DeleteSnapshot"
         ],
         "Resource": "*"
      }
   ]
}
```

Working with local snapshots

The following sections explain how to use local snapshots.

**Topics**
- Rules for storing snapshots (p. 1875)
- Create local snapshots from volumes on an Outpost (p. 1876)
- Create multi-volume local snapshots from instances on an Outpost (p. 1877)
- Create AMIs from local snapshots (p. 1878)
- Copy snapshots from an AWS Region to an Outpost (p. 1878)
- Copy AMIs from an AWS Region to an Outpost (p. 1879)
- Create volumes from local snapshots (p. 1880)
- Launch instances from AMIs backed by local snapshots (p. 271)
- Delete local snapshots (p. 1880)
- Automate snapshots on an Outpost (p. 1880)

Rules for storing snapshots

The following rules apply to snapshot storage:

- If the most recent snapshot of a volume is stored on an Outpost, then all successive snapshots must be stored on the same Outpost.
• If the most recent snapshot of a volume is stored in an AWS Region, then all successive snapshots must be stored in the same Region. To start creating local snapshots from that volume, do the following:

1. Create a snapshot of the volume in the AWS Region.
2. Copy the snapshot to the Outpost from the AWS Region.
3. Create a new volume from the local snapshot.
4. Attach the volume to an instance on the Outpost.

For the new volume on the Outpost, the next snapshot can be stored on the Outpost or in the AWS Region. All successive snapshots must then be stored in that same location.

• Local snapshots, including snapshots created on an Outpost and snapshots copied to an Outpost from an AWS Region, can be used only to create volumes on the same Outpost.

• If you create a volume on an Outpost from a snapshot in a Region, then all successive snapshots of that new volume must be in the same Region.

• If you create a volume on an Outpost from a local snapshot, then all successive snapshots of that new volume must be on the same Outpost.

Create local snapshots from volumes on an Outpost

You can create local snapshots from volumes on your Outpost. You can choose to store the snapshots on the same Outpost as the source volume, or in the Region for the Outpost.

Local snapshots can be used to create volumes on the same Outpost only.

You can create local snapshots from volumes on an Outpost using one of the following methods.

Console

To create local snapshots from volumes on an Outpost

Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

1. In the navigation pane, choose Volumes.
2. Select the volume on the Outpost, and choose Actions, Create Snapshot.
3. (Optional) For Description, enter a brief description for the snapshot.
4. For Snapshot destination, choose AWS Outpost. The snapshot will be created on the same Outpost as the source volume. The Outpost ARN field shows the Amazon Resource Name (ARN) of the destination Outpost.
5. (Optional) Choose Add Tag to add tags to your snapshot. For each tag, provide a tag key and a tag value.
6. Choose Create Snapshot.

Command line

To create local snapshots from volumes on an Outpost

Use the create-snapshot command. Specify the ID of the volume from which to create the snapshot, and the ARN of the destination Outpost on which to store the snapshot. If you omit the Outpost ARN, the snapshot is stored in the AWS Region for the Outpost.

For example, the following command creates a local snapshot of volume vol-1234567890abcdef0, and stores the snapshot on Outpost arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0.
Create multi-volume local snapshots from instances on an Outpost

You can create crash-consistent multi-volume local snapshots from instances on your Outpost. You can choose to store the snapshots on the same Outpost as the source instance, or in the Region for the Outpost.

Multi-volume local snapshots can be used to create volumes on the same Outpost only.

You can create multi-volume local snapshots from instances on an Outpost using one of the following methods.

Console

To create multi-volume local snapshots from instances on an Outpost

Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

1. In the navigation pane, choose Snapshots.
2. Choose Create Snapshot.
3. For Select resource type, choose Instance.
4. For Instance ID, select the instance on the Outpost from which to create the snapshots.
5. (Optional) For Description, enter a brief description for the snapshots.
6. For Snapshot destination, choose AWS Outpost. The snapshots will be created on the same Outpost as the source instance. The Outpost ARN shows the ARN of the destination Outpost.
7. To exclude the instance's root volume from the multi-volume snapshot set, select Exclude root volume. If you do this, Amazon EBS will not create a snapshot of the instance's root volume.
8. To exclude specific data volumes from the multi-volume snapshot set, select Exclude specific data volumes. The Attached data volumes section lists all of the data volumes that are currently attached to the selected instance.

   In the Attached data volumes section, deselect the data volumes to exclude from the multi-volume snapshot set. Only the volumes that remain selected will be included in the multi-volume snapshot set.

9. (Optional) To automatically copy tags from the source volumes to the corresponding snapshots, for Copy tags from source volume, select Copy tags. This sets snapshot metadata—such as access policies, attachment information, and cost allocation—to match the source volume.
10. (Optional) To assign additional custom tags to the snapshots, in the Tags section, choose Add tag, and then enter the key-value pair. You can add up to 50 tags.
11. Choose Create Snapshot.

   During snapshot creation, the snapshots are managed together. If one of the snapshots in the volume set fails, the other snapshots in the volume set are moved to error status.

Command line

To create multi-volume local snapshots from instances on an Outpost

Use the create-snapshots command. Specify the ID of the instance from which to create the snapshots, and the ARN of the destination Outpost on which to store the snapshots. If you omit the Outpost ARN, the snapshots are stored in the AWS Region for the Outpost.
For example, the following command creates snapshots of the volumes attached to instance i-1234567890abcdef0 and stores the snapshots on Outpost arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0.

```
$ aws ec2 create-snapshots --instance-specification InstanceId=i-1234567890abcdef0 --outpost-arn arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0 --description "multi-volume local snapshots"
```

Create AMIs from local snapshots

You can create Amazon Machine Images (AMIs) using a combination of local snapshots and snapshots that are stored in the Region of the Outpost. For example, if you have an Outpost in us-east-1, you can create an AMI with data volumes that are backed by local snapshots on that Outpost, and a root volume that is backed by a snapshot in the us-east-1 Region.

**Note**

- You can't create AMIs that include backing snapshots stored across multiple Outposts.
- You can't currently create AMIs directly from instances on an Outposts using `CreateImage` API or the Amazon EC2 console for Outposts that are enabled with Amazon S3 on Outposts.
- AMIs that are backed by local snapshots can be used to launch instances on the same Outpost only.

**To create an AMI on an Outpost from snapshots in a Region**

1. Copy the snapshots from the Region to the Outpost. For more information, see [Copy snapshots from an AWS Region to an Outpost](p. 1878).
2. Use the Amazon EC2 console or the `register-image` command to create the AMI using the snapshot copies on the Outpost. For more information, see [Creating an AMI from a snapshot](p. 1879).

**To create an AMI on an Outpost from an instance on an Outpost**

1. Create snapshots from the instance on the Outpost and store the snapshots on the Outpost. For more information, see [Create multi-volume local snapshots from instances on an Outpost](p. 1877).
2. Use the Amazon EC2 console or the `register-image` command to create the AMI using the local snapshots. For more information, see [Creating an AMI from a snapshot](p. 1879).

**To create an AMI in a Region from an instance on an Outpost**

1. Create snapshots from the instance on the Outpost and store the snapshots in the Region. For more information, see [Create local snapshots from volumes on an Outpost](p. 1876) or [Create multi-volume local snapshots from instances on an Outpost](p. 1877).
2. Use the Amazon EC2 console or the `register-image` command to create the AMI using the snapshot copies in the Region. For more information, see [Creating an AMI from a snapshot](p. 1879).

**Copy snapshots from an AWS Region to an Outpost**

You can copy snapshots from an AWS Region to an Outpost. You can do this only if the snapshots are in the Region for the Outpost. If the snapshots are in a different Region, you must first copy the snapshot to the Region for the Outpost, and then copy it from that Region to the Outpost.

**Note**

You can't copy local snapshots from an Outpost to a Region, from one Outpost to another, or within the same Outpost.

1878
You can copy snapshots from a Region to an Outpost using one of the following methods.

Console

**To copy a snapshot from an AWS Region to an Outpost**

Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

1. In the navigation pane, choose Snapshots.
2. Select the snapshot in the Region, and choose Actions, Copy.
3. For Destination Region, choose the Region for the destination Outpost.
4. For Snapshot Destination, choose AWS Outpost.

The Snapshot Destination field only appears if you have Outposts in the selected destination Region. If the field does not appear, you do not have any Outposts in the selected destination Region.

5. For Destination Outpost ARN, enter the ARN of the Outpost to which to copy the snapshot.
6. (Optional) For Description, enter a brief description of the copied snapshot.
7. Encryption is enabled by default for the snapshot copy. Encryption cannot be disabled. For KMS key, choose the KMS key to use.
8. Choose Copy.

Command line

**To copy a snapshot from a Region to an Outpost**

Use the `copy-snapshot` command. Specify the ID of the snapshot to copy, the Region from which to copy the snapshot, and the ARN of the destination Outpost.

For example, the following command copies snapshot snap-1234567890abcdef0 from the us-east-1 Region to Outpost arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0.

```
$ aws ec2 copy-snapshot --source-region us-east-1 --source-snapshot-id snap-1234567890abcdef0 --destination-outpost-arn arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0 --description "Local snapshot copy"
```

**Copy AMIs from an AWS Region to an Outpost**

You can copy AMIs from an AWS Region to an Outpost. When you copy an AMI from a Region to an Outpost, all of the snapshots associated with the AMI are copied from the Region to the Outpost.

You can copy an AMI from a Region to an Outpost only if the snapshots associated with the AMI are in the Region for the Outpost. If the snapshots are in a different Region, you must first copy the AMI to the Region for the Outpost, and then copy it from that Region to the Outpost.

**Note**

You can't copy an AMI from an Outpost to a Region, from one Outpost to another, or within an Outpost.

You can copy AMIs from a Region to an Outpost using the AWS CLI only.

Command line

**To copy an AMI from a Region to an Outpost**
Use the `copy-image` command. Specify the ID of the AMI to copy, the source Region, and the ARN of the destination Outpost.

For example, the following command copies AMI `ami-1234567890abcdef0` from the `us-east-1` Region to Outpost ARN `arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0`.

```
$ aws ec2 copy-image --source-region us-east-1 --source-image-id ami-1234567890abcdef0 --name "Local AMI copy" --destination-outpost-arn arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0
```

Create volumes from local snapshots

You can create volumes on Outposts from local snapshots. Volumes must be created on the same Outpost as the source snapshots. You cannot use local snapshots to create volumes in the Region for the Outpost.

When you create a volume from a local snapshot, you cannot re-encrypt the volume using different KMS key. Volumes created from local snapshots must be encrypted using the same KMS key as the source snapshot.

For more information, see Create a volume from a snapshot (p. 1796).

Launch instances from AMIs backed by local snapshots

You can launch instances from AMIs that are backed by local snapshots. You must launch instances on the same Outpost as the source AMI. For more information, see Launch an instance on your Outpost in the AWS Outposts User Guide.

Delete local snapshots

You can delete local snapshots from an Outpost. After you delete a snapshot from an Outpost, the Amazon S3 storage capacity used by the deleted snapshot becomes available within 72 hours after deleting the snapshot and the volumes that reference that snapshot.

Because Amazon S3 storage capacity does not become available immediately, we recommend that you use Amazon CloudWatch alarms to monitor your Amazon S3 storage capacity. Delete snapshots and volumes that you no longer need to avoid running out of storage capacity.

For more information about deleting snapshots, see Delete a snapshot (p. 1835).

Automate snapshots on an Outpost

You can create Amazon Data Lifecycle Manager snapshot lifecycle policies that automatically create, copy, retain, and delete snapshots of your volumes and instances on an Outpost. You can choose whether to store the snapshots in a Region or whether to store them locally on an Outpost. Additionally, you can automatically copy snapshots that are created and stored in an AWS Region to an Outpost.

The following table shows provides and Overview of the supported features.

<table>
<thead>
<tr>
<th>Resource location</th>
<th>Snapshot destination</th>
<th>Cross-region copy</th>
<th>Fast snapshot restore</th>
<th>Cross-account sharing</th>
</tr>
</thead>
<tbody>

<td>Outpost</td>
<td>x</td>
<td>x</td>
<td>x</td>
</tr>
</tbody>
</table>
Considerations

- Only Amazon EBS snapshot lifecycle policies are currently supported. EBS-backed AMI policies and Cross-account sharing event policies are not supported.
- If a policy manages snapshots for volumes or instances in a Region, then snapshots are created in the same Region as the source resource.
- If a policy manages snapshots for volumes or instances on an Outpost, then snapshots can be created on the source Outpost, or in the Region for that Outpost.
- A single policy can't manage both snapshots in a Region and snapshots on an Outpost. If you need to automate snapshots in a Region and on an Outpost, you must create separate policies.
- Fast snapshot restore is not supported for snapshots created on an Outpost, or for snapshots copied to an Outpost.
- Cross-account sharing is not supported for snapshots created on an Outpost.

For more information about creating a snapshot lifecycle that manages local snapshots, see Automating snapshot lifecycles (p. 1916).

Use EBS direct APIs to access the contents of an EBS snapshot

You can use the Amazon Elastic Block Store (Amazon EBS) direct APIs to create EBS snapshots, write data directly to your snapshots, read data on your snapshots, and identify the differences or changes between two snapshots. If you're an independent software vendor (ISV) who offers backup services for Amazon EBS, the EBS direct APIs make it more efficient and cost-effective to track incremental changes on your EBS volumes through snapshots. This can be done without having to create new volumes from snapshots, and then use Amazon Elastic Compute Cloud (Amazon EC2) instances to compare the differences.

You can create incremental snapshots directly from data on-premises into EBS volumes and the cloud to use for quick disaster recovery. With the ability to write and read snapshots, you can write your on-premises data to an EBS snapshot during a disaster. Then after recovery, you can restore it back to AWS or on-premises from the snapshot. You no longer need to build and maintain complex mechanisms to copy data to and from Amazon EBS.

This user guide provides an overview of the elements that make up the EBS direct APIs, and examples of how to use them effectively. For more information about the actions, data types, parameters, and errors of the APIs, see the EBS direct APIs reference. For more information about the supported AWS Regions, endpoints, and service quotas for the EBS direct APIs, see Amazon EBS Endpoints and Quotas in the AWS General Reference.

Contents

- Understand the EBS direct APIs (p. 1881)
- IAM permissions for EBS direct APIs (p. 1883)
- Use EBS direct APIs (p. 1887)
- Pricing for EBS direct APIs (p. 1905)
- Using interface VPC endpoints with EBS direct APIs (p. 1906)
- Log API Calls for EBS direct APIs with AWS CloudTrail (p. 1906)
- Frequently asked questions (p. 1912)

Understand the EBS direct APIs

The following are the key elements that you should understand before getting started with the EBS direct APIs.
Snapshots

Snapshots are the primary means to back up data from your EBS volumes. With the EBS direct APIs, you can also back up data from your on-premises disks to snapshots. To save storage costs, successive snapshots are incremental, containing only the volume data that changed since the previous snapshot. For more information, see Amazon EBS snapshots (p. 1825).

Note

EBS direct APIs does not support public snapshots and local snapshots on Outposts.

Blocks

A block is a fragment of data within a snapshot. Each snapshot can contain thousands of blocks. All blocks in a snapshot are of a fixed size.

Block indexes

A block index is a logical index in units of 512 KiB blocks. To identify the block index, divide the logical offset of the data in the logical volume by the block size (logical offset of data/524288). The logical offset of the data must be 512 KiB aligned.

Block tokens

A block token is the identifying hash of a block within a snapshot, and it is used to locate the block data. Block tokens returned by EBS direct APIs are temporary. They change on the expiry timestamp specified for them, or if you run another ListSnapshotBlocks or ListChangedBlocks request for the same snapshot.

Checksum

A checksum is a small-sized datum derived from a block of data for the purpose of detecting errors that were introduced during its transmission or storage. The EBS direct APIs use checksums to validate data integrity. When you read data from an EBS snapshot, the service provides Base64-encoded SHA256 checksums for each block of data transmitted, which you can use for validation. When you write data to an EBS snapshot, you must provide a Base64 encoded SHA256 checksum for each block of data transmitted. The service validates the data received using the checksum provided. For more information, see Use checksums (p. 1899) later in this guide.

Encryption

Encryption protects your data by converting it into unreadable code that can be deciphered only by people who have access to the KMS key used to encrypt it. You can use the EBS direct APIs to read and write encrypted snapshots, but there are some limitations. For more information, see Use encryption (p. 1897) later in this guide.

API actions

The EBS direct APIs consists of six actions. There are three read actions and three write actions. The read actions are:

- **ListSnapshotBlocks** — returns the block indexes and block tokens of blocks in the specified snapshot
- **ListChangedBlocks** — returns the block indexes and block tokens of blocks that are different between two specified snapshots of the same volume and snapshot lineage.
- **GetSnapshotBlock** — returns the data in a block for the specified snapshot ID, block index, and block token.

The write actions are:

- **StartSnapshot** — starts a snapshot, either as an incremental snapshot of an existing one or as a new snapshot. The started snapshot remains in a pending state until it is completed using the CompleteSnapshot action.
• **PutSnapshotBlock** — adds data to a started snapshot in the form of individual blocks. You must specify a Base64-encoded SHA256 checksum for the block of data transmitted. The service validates the checksum after the transmission is completed. The request fails if the checksum computed by the service doesn’t match what you specified.

• **CompleteSnapshot** — completes a started snapshot that is in a pending state. The snapshot is then changed to a completed state.

### IAM permissions for EBS direct APIs

A user must have the following policies to use the EBS direct APIs. For more information, see [Changing permissions for a user](#).

For more information about the EBS direct APIs resources, actions, and condition context keys for use in IAM permission policies, see [Actions, resources, and condition keys for Amazon Elastic Block Store](#) in the Service Authorization Reference.

**Important**

Be cautious when assigning the following policies to users. By assigning these policies, you might give access to a user who is denied access to the same resource through the Amazon EC2 APIs, such as the CopySnapshot or CreateVolume actions.

#### Permissions to read snapshots

The following policy allows the `read` EBS direct APIs to be used on all snapshots in a specific AWS Region. In the policy, replace `<Region>` with the Region of the snapshot.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ebs:ListSnapshotBlocks",
        "ebs:ListChangedBlocks",
        "ebs:GetSnapshotBlock"
      ],
      "Resource": "arn:aws:ec2:<Region>::snapshot/*"
    }
  ]
}
```

The following policy allows the `read` EBS direct APIs to be used on snapshots with a specific key-value tag. In the policy, replace `<Key>` with the key value of the tag, and `<Value>` with the value of the tag.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ebs:ListSnapshotBlocks",
        "ebs:ListChangedBlocks",
        "ebs:GetSnapshotBlock"
      ],
      "Resource": "arn:aws:ec2:*::snapshot/*",
      "Condition": {
        "StringEqualsIgnoreCase": {
          "aws:ResourceTag/<Key>": "<Value>
        }
      }
    }
  ]
}
```
The following policy allows all of the read EBS direct APIs to be used on all snapshots in the account only within a specific time range. This policy authorizes use of the EBS direct APIs based on the `aws:CurrentTime` global condition key. In the policy, be sure to replace the date and time range shown with the date and time range for your policy.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ebs:ListSnapshotBlocks",
            "ebs:ListChangedBlocks",
            "ebs:GetSnapshotBlock"
         ],
         "Resource": "arn:aws:ec2:*::snapshot/*",
         "Condition": {
            "DateGreaterThan": {
               "aws:CurrentTime": "2018-05-29T00:00:00Z"
            },
            "DateLessThan": {
               "aws:CurrentTime": "2020-05-29T23:59:59Z"
            }
         }
      }
   ]
}
```

For more information, see [Changing permissions for a user](https://docs.aws.amazon.com/IAM/latest/UserGuide/reference_policies_elements.html) in the IAM User Guide.

### Permissions to write snapshots

The following policy allows the write EBS direct APIs to be used on all snapshots in a specific AWS Region. In the policy, replace `<Region>` with the Region of the snapshot.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ebs:StartSnapshot",
            "ebs:PutSnapshotBlock",
            "ebs:CompleteSnapshot"
         ],
         "Resource": "arn:aws:ec2:<Region>::snapshot/*"
      }
   ]
}
```

The following policy allows the write EBS direct APIs to be used on snapshots with a specific key-value tag. In the policy, replace `<Key>` with the key value of the tag, and `<Value>` with the value of the tag.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ebs:StartSnapshot",
            "ebs:PutSnapshotBlock",
            "ebs:CompleteSnapshot"
         ],
         "Resource": "arn:aws:ec2:*::snapshot/*"
      }
   ]
}
```
The following policy allows all of the EBS direct APIs to be used. It also allows the StartSnapshot action only if a parent snapshot ID is specified. Therefore, this policy blocks the ability to start new snapshots without using a parent snapshot.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ebs:*",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:ParentSnapshot": "arn:aws:ec2:*::snapshot/*"
                }
            }
        }
    ]
}
```

The following policy allows all of the EBS direct APIs to be used. It also allows only the user tag key to be created for a new snapshot. This policy also ensures that the user has access to create tags. The StartSnapshot action is the only action that can specify tags.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ebs:*",
            "Resource": "*",
            "Condition": {
                "ForAllValues:StringEquals": {
                    "aws:TagKeys": "user"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "ec2:CreateTags",
            "Resource": "*"
        }
    ]
}
```
The following policy allows all of the write EBS direct APIs to be used on all snapshots in the account only within a specific time range. This policy authorizes use of the EBS direct APIs based on the aws:CurrentTime global condition key. In the policy, be sure to replace the date and time range shown with the date and time range for your policy.

```json
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Effect": "Allow",  
      "Action": [  
        "ebs:StartSnapshot",  
        "ebs:PutSnapshotBlock",  
        "ebs:CompleteSnapshot"  
      ],  
      "Resource": "arn:aws:ec2:*::snapshot/*",  
      "Condition": {  
        "DateGreaterThan": {  
          "aws:CurrentTime": "2018-05-29T00:00:00Z"  
        },  
        "DateLessThan": {  
          "aws:CurrentTime": "2020-05-29T23:59:59Z"  
        }  
      }  
    }  
  ]}
```

For more information, see [Changing permissions for a user](https://docs.aws.amazon.com/IAM/latest/UserGuide/index.html) in the IAM User Guide.

**Permissions to use AWS KMS keys**

The following policy grants permission to decrypt an encrypted snapshot using a specific KMS key. It also grants permission to encrypt new snapshots using the default KMS key for EBS encryption. In the policy, replace `<Region>` with the Region of the KMS key, `<AccountId>` with the ID of the AWS account of the KMS key, and `<KeyId>` with the ID of the KMS key.

**Note**

By default, all principals in the account have access to the default AWS managed KMS key for Amazon EBS encryption, and they can use it for EBS encryption and decryption operations. If you are using a customer managed key, you must create a new key policy or modify the existing key policy for the customer managed key to grant the principal access to the customer managed key. For more information, see [Key policies in AWS KMS](https://docs.aws.amazon.com/kms/latest/developerguide/key-policies.html) in the AWS Key Management Service Developer Guide.

**Tip**

To follow the principle of least privilege, do not allow full access to kms:CreateGrant. Instead, use the kms:GrantIsForAWSResource condition key to allow the user to create grants on the KMS key only when the grant is created on the user’s behalf by an AWS service, as shown in the following example.

```json
{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Sid": "VisualEditor0",  
      "Effect": "Allow",  
      "Action": [  
        "kms:Encrypt",  
        "kms:Decrypt",  
        "kms:GenerateDataKey",  
        "kms:GenerateDataKeyWithoutPlaintext"  
      ],  
      "Resource": [  
        "arn:aws:kms:*:*:key/<KeyId>"  
      ],  
      "Condition": {  
        "StringEquals": {  
          "kms:GrantIsForAWSResource": "true"  
        },  
        "StringEqualsIfExists": {  
          "kms:GrantIsForAWSResource": "true"  
        }  
      }  
    }  
  ]}
```
Use EBS direct APIs

The following topics show how to read and write snapshots using the EBS direct APIs. You can read and write snapshots using the AWS CLI, AWS APIs, and AWS SDKs only. For more information, see:

- Installing the AWS CLI and Configuring the AWS CLI
- EBS direct APIs Reference
- AWS SDKs

Important
The EBS direct APIs require an AWS Signature Version 4 signature. For more information, see Use Signature Version 4 signing (p. 1899).

Topics
- Read snapshots with EBS direct APIs (p. 1887)
- Write snapshots with EBS direct APIs (p. 1893)
- Use encryption (p. 1897)
- Use Signature Version 4 signing (p. 1899)
- Use checksums (p. 1899)
- Idempotency for StartSnapshot API (p. 1900)
- Error retries (p. 1900)
- Optimize performance (p. 1902)
- EBS direct APIs service endpoints (p. 1902)

Read snapshots with EBS direct APIs

The following steps describe how to use the EBS direct APIs to read snapshots:

1. Use the ListSnapshotBlocks action to view all block indexes and block tokens of blocks in a snapshot. Or use the ListChangedBlocks action to view only the block indexes and block tokens of blocks that are different between two snapshots of the same volume and snapshot lineage. These actions help you identify the block tokens and block indexes of blocks for which you might want to get data.
2. Use the GetSnapshotBlock action, and specify the block index and block token of the block for which you want to get data.

The following examples show how to read snapshots using the EBS direct APIs.
Topics

- **List blocks in a snapshot (p. 1888)**
- **List blocks that are different between two snapshots (p. 1889)**
- **Get block data from a snapshot (p. 1892)**

**List blocks in a snapshot**

**AWS CLI**

The following `list-snapshot-blocks` example command returns the block indexes and block tokens of blocks that are in snapshot `snap-0987654321`. The `--starting-block-index` parameter limits the results to block indexes greater than 1000, and the `--max-results` parameter limits the results to the first 100 blocks.

```
aws ebs list-snapshot-blocks --snapshot-id snap-0987654321 --starting-block-index 1000 --max-results 100
```

The following example response for the previous command lists the block indexes and block tokens in the snapshot. Use the `get-snapshot-block` command and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.

```
{
  "Blocks": [
    {
      "BlockIndex": 1001,
      "BlockToken": "AAABAV3/PNhXOnVdMYHUqPssetaSvjLB1dtIGfbJv5OJ0sX855EzGTWos4a4"
    },
    {
      "BlockIndex": 1002,
      "BlockToken": "AAABATGQIgwRI0WwIuqIMjCA/Sy7e/YoQFZnHejzGNvJkauzNgzeII3YHBfQ8"
    },
    {
      "BlockIndex": 1007,
      "BlockToken": "AAABAZ9CTuQtUvp/dXqRW4d07e0g7Z3jvn6H1w5099duM8Miw6yQayzF2c"
    },
    {
      "BlockIndex": 1012,
      "BlockToken": "AAABATGQIgwRI0WwIuqIMjCA/Sy7e/YoQFZnHejzGNvJkauzNgzeII3YHBfQ8"
    },
    {
      "BlockIndex": 1030,
      "BlockToken": "AAABAAyvPax6mv+iGWdTUjQtFWouQ7Dqz6nSD9L+CbXnvpksAw6jID523d"
    },
    {
      "BlockIndex": 1031,
      "BlockToken": "AAABATGQIgwRI0WwIuqIMjCA/Sy7e/YoQFZnHejzGNvJkauzNgzeII3YHBfQ8"
    },
    ...
  ],
  "ExpiryTime": 1576287332.806,
  "VolumeSize": 32212254720,
  "BlockSize": 524288
}
```
The following **ListSnapshotBlocks** example request returns the block indexes and block tokens of blocks that are in snapshot snap-0acEXAMPLEcf41648. The `startingBlockIndex` parameter limits the results to block indexes greater than 1000, and the `maxResults` parameter limits the results to the first 100 blocks.

```
GET /snapshots/snap-0acEXAMPLEcf41648/blocks?maxResults=100&startingBlockIndex=1000
```

The following example response for the previous request lists the block indexes and block tokens in the snapshot. Use the `GetSnapshotBlock` action and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.

```
HTTP/1.1 200 OK
x-amzn-RequestId: d6e5017c-70a8-4539-8830-57f5557f3f27
Content-Type: application/json

        },
        {
            "BlockIndex": 3073,
            "BlockToken": "AAUBAQt9zpBEvTo2HINAfFawTo0wlPjbIsQ0l1x6JUN/0+iMQl0NtNbnX4"
        },
        ...
    ],
    "ExpiryTime": 1.59298379649E9,
    "VolumeSize": 3
}
```

**List blocks that are different between two snapshots**

Keep the following in mind when making **paginated requests** to list the changed blocks between two snapshots:

- The response can include one or more empty ChangedBlocks arrays. For example:
• Snapshot 1 — full snapshot with 1000 blocks with block indexes 0 - 999.
• Snapshot 2 — incremental snapshot with only one changed block with block index 999.

Listing the changed blocks for these snapshots with StartingBlockIndex = 0 and MaxResults = 100 returns an empty array of ChangedBlocks. You must request the remaining results using nextToken until the changed block is returned in the tenth result set, which includes blocks with block indexes 900 - 999.

• The response can skip unwritten blocks in the snapshots. For example:
  • Snapshot 1 — full snapshot with 1000 blocks with block indexes 2000 - 2999.
  • Snapshot 2 — incremental snapshot with only one changed block with block index 2000.

Listing the changed blocks for these snapshots with StartingBlockIndex = 0 and MaxResults = 100, the response skips block indexes 0 - 1999 and includes block index 2000. The response will not include empty ChangedBlocks arrays.

AWS CLI

The following list-changed-blocks example command returns the block indexes and block tokens of blocks that are different between snapshots snap-1234567890 and snap-0987654321. The --starting-block-index parameter limits the results to block indexes greater than 0, and the --max-results parameter limits the results to the first 500 blocks.

```
aws ebs list-changed-blocks --first-snapshot-id snap-1234567890 --second-snapshot-id snap-0987654321 --starting-block-index 0 --max-results 500
```

The following example response for the previous command shows that block indexes 0, 6000, 6001, 6002, and 6003 are different between the two snapshots. Additionally, block indexes 6001, 6002, and 6003 exist only in the first snapshot ID specified, and not in the second snapshot ID because there is no second block token listed in the response.

Use the get-snapshot-block command and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.

```json
{
   "ChangedBlocks": [
      {
         "BlockIndex": 0,
         "FirstBlockToken": "AAABAVahm9SOGO0Di00RySzn2ZjGjWfKN3uygGiSQQYVwesbZbBn2dGpmC",
         "SecondBlockToken": "AAABAf8o0o6UFi1rDbSGIRaCEdDyBu9T1vtCQxxwKV8qUPQP7vcM6IWGSz"
      },
      {
         "BlockIndex": 6000,
         "FirstBlockToken": "AAABAbYSiZvJ0/R9tz8su18dSzeclJN4kkazK8inFXVIqntPkdavFLfCMQsKe",
         "SecondBlockToken": "AAABAZnqTdzFMKrp5aMsDv1vqE/3jJzi2crq2eFDCgHmyNF777e1D9oVR"
      },
      {
         "BlockIndex": 6001,
         "FirstBlockToken": "AAABASBpSJ2UDIPxJnCt6zun4/T4sU2Sbn8jBSQ6FRXHFaIAeB0hJoR"
      },
      {
         "BlockIndex": 6002,
         "FirstBlockToken": "AAABASqX4/NWjvNceoMVu1jcRd0Dnw5wNnesu1UkoP62CrXvn47BY5435aw"
      }
   ]
}
```
The following **ListChangedBlocks** example request returns the block indexes and block tokens of blocks that are different between snapshots snap-0acEXAMPLEcf41648 and snap-0c9EXAMPLE1b30e2f. The startingBlockIndex parameter limits the results to block indexes greater than 0, and the maxResults parameter limits the results to the first 500 blocks.

```
GET /snapshots/snap-0c9EXAMPLE1b30e2f/changedblocks?
    firstSnapshotId=snap-0acEXAMPLEcf41648&maxResults=500&startingBlockIndex=0
```

The following example response for the previous request shows that block indexes 0, 3072, 6002, and 6003 are different between the two snapshots. Additionally, block indexes 6002, and 6003 exist only in the first snapshot ID specified, and not in the second snapshot ID because there is no second block token listed in the response.

Use the GetSnapshotBlock action and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.
Get block data from a snapshot

AWS CLI

The following `get-snapshot-block` example command returns the data in the block index 6001 with block token AAABASmJ0O5JxAOce25rF4P1sdRtyIDsX12tFEDunnePYUK0f4PBROuICb2A" in snapshot snap-1234567890. The binary data is output to the data file in the C:\Temp directory on a Windows computer. If you run the command on a Linux or Unix computer, replace the output path with /tmp/data to output the data to the data file in the /tmp directory.

```
aws ebs get-snapshot-block --snapshot-id snap-1234567890 --block-index 6001 --block-token AAABASmJ0O5JxAOce25rF4P1sdRtyIDsX12tFEDunnePYUK0f4PBROuICb2A C:/Temp/data
```

The following example response for the previous command shows the size of the data returned, the checksum to validate the data, and the algorithm of the checksum. The binary data is automatically saved to the directory and file you specified in the request command.

```
{
    "DataLength": "524288",
    "Checksum": "cf0Y6/Fn0oFa4VyjQPOa/iD0zhTf1PTKzxGv20KowXc=",
    "ChecksumAlgorithm": "SHA256"
}
```

AWS API

The following `GetSnapshotBlock` example request returns the data in the block index 3072 with block token AAUBARGCaufCqBR2CG8tEkPYGGK5v3vqvojJ2xKDi3l1jDFiytUXbLXYgTmkid, in snapshot snap-0c9EXAMPLE1b30e2f.

```
GET /snapshots/snap-0c9EXAMPLE1b30e2f/blocks/3072?
blockToken=AAUBARGCaufCqBR2CG8tEkPYGGK5v3vqvojJ2xKDi3l1jDFiytUXbLXYgTmkid HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
User-Agent: <User agent parameter>
X-Amz-Date: 20200617T232838Z
Authorization: <Authentication parameter>
```

The following example response for the previous request shows the size of the data returned, the checksum to validate the data, and the algorithm used to generate the checksum. The binary data is transmitted in the body of the response and is represented as `BlockData` in the following example.

```
HTTP/1.1 200 OK
x-amzn-RequestId: 2d0db2fb-bd88-474d-a137-81c4e57d7b9f
x-amzn-Data-Length: 524288
x-amzn-Checksum: Vc0Y2j3gg8bUL9I6GQu1ZoriTudzQRb0M1hcy7bdEsw=
```
Write snapshots with EBS direct APIs

The following steps describe how to use the EBS direct APIs to write incremental snapshots:

1. Use the StartSnapshot action and specify a parent snapshot ID to start a snapshot as an incremental snapshot of an existing one, or omit the parent snapshot ID to start a new snapshot. This action returns the new snapshot ID, which is in a pending state.

2. Use the PutSnapshotBlock action and specify the ID of the pending snapshot to add data to it in the form of individual blocks. You must specify a Base64-encoded SHA256 checksum for the block of data transmitted. The service computes the checksum of the data received and validates it with the checksum that you specified. The action fails if the checksums don't match.

3. When you're done adding data to the pending snapshot, use the CompleteSnapshot action to start an asynchronous workflow that seals the snapshot and moves it to a completed state.

Repeat these steps to create a new, incremental snapshot using the previously created snapshot as the parent.

For example, in the following diagram, snapshot A is the first new snapshot started. Snapshot A is used as the parent snapshot to start snapshot B. Snapshot B is used as the parent snapshot to start and create snapshot C. Snapshots A, B, and C are incremental snapshots. Snapshot A is used to create EBS volume 1. Snapshot D is created from EBS volume 1. Snapshot D is an incremental snapshot of A; it is not an incremental snapshot of B or C.

The following examples show how to write snapshots using the EBS direct APIs.

Topics
- Start a snapshot (p. 1894)
- Put data into a snapshot (p. 1895)
- Complete a snapshot (p. 1896)
Start a snapshot

AWS CLI

The following `start-snapshot` example command starts an 8 GiB snapshot, using snapshot snap-123EXAMPLE1234567 as the parent snapshot. The new snapshot will be an incremental snapshot of the parent snapshot. The snapshot moves to an error state if there are no put or complete requests made for the snapshot within the specified 60 minute timeout period. The 550e8400-e29b-41d4-a716-446655440000 client token ensures idempotency for the request. If the client token is omitted, the AWS SDK automatically generates one for you. For more information about idempotency, see [Idempotency for StartSnapshot API](p. 1900).

```bash
aws ebs start-snapshot --volume-size 8 --parent-snapshot snap-123EXAMPLE1234567 --timeout 60 --client-token 550e8400-e29b-41d4-a716-446655440000
```

The following example response for the previous command shows the snapshot ID, AWS account ID, status, volume size in GiB, and size of the blocks in the snapshot. The snapshot is started in a pending state. Specify the snapshot ID in subsequent `PutSnapshotBlock` commands to write data to the snapshot, then use the `CompleteSnapshot` command to complete the snapshot and change its status to completed.

```
{
    "SnapshotId": "snap-0aaEXAMPLEe306d62",
    "OwnerId": "111122223333",
    "Status": "pending",
    "VolumeSize": 8,
    "BlockSize": 524288
}
```

AWS API

The following `StartSnapshot` example request starts an 8 GiB snapshot, using snapshot snap-123EXAMPLE1234567 as the parent snapshot. The new snapshot will be an incremental snapshot of the parent snapshot. The snapshot moves to an error state if there are no put or complete requests made for the snapshot within the specified 60 minute timeout period. The 550e8400-e29b-41d4-a716-446655440000 client token ensures idempotency for the request. If the client token is omitted, the AWS SDK automatically generates one for you. For more information about idempotency, see [Idempotency for StartSnapshot API](p. 1900).

```http
POST /snapshots HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
User-Agent: <User agent parameter>
X-Amz-Date: 20200618T040724Z
Authorization: <Authentication parameter>

{
    "VolumeSize": 8,
    "ParentSnapshot": "snap-123EXAMPLE1234567",
    "ClientToken": "550e8400-e29b-41d4-a716-446655440000",
    "Timeout": 60
}
```

The following example response for the previous request shows the snapshot ID, AWS account ID, status, volume size in GiB, and size of the blocks in the snapshot. The snapshot is started in a pending state. Specify the snapshot ID in a subsequent `PutSnapshotBlock` request to write data to the snapshot.

```
HTTP/1.1 201 Created
```

1894
Put data into a snapshot

AWS CLI

The following put-snapshot example command writes 524288 Bytes of data to block index 1000 on snapshot snap-0aaEXEMPLEe306d62. The Base64 encoded QOD3gmEQOXATfJx2Aa34W4FU2nZGyXfqtUukt0w8DM= checksum was generated using the SHA256 algorithm. The data that is transmitted is in the /tmp/data file.

```
aws ebs put-snapshot-block --snapshot-id snap-0aaEXEMPLEe306d62 --block-index 1000 --data-length 524288 --block-data /tmp/data --checksum QOD3gmEQOXATfJx2Aa34W4FU2nZGyXfqtUukt0w8DM= --checksum-algorithm SHA256
```

The following example response for the previous command confirms the data length, checksum, and checksum algorithm for the data received by the service.

```
{
  "DataLength": "524288",
  "Checksum": "QOD3gmEQOXATfJx2Aa34W4FU2nZGyXfqtUukt0w8DM=",
  "ChecksumAlgorithm": "SHA256"
}
```

AWS API

The following PutSnapshot example request writes 524288 Bytes of data to block index 1000 on snapshot snap-052EXAMPLEc85d8dd. The Base64 encoded QOD3gmEQOXATfJx2Aa34W4FU2nZGyXfqtUukt0w8DM= checksum was generated using the SHA256 algorithm. The data is transmitted in the body of the request and is represented as BlockData in the following example.

```
PUT /snapshots/snap-052EXAMPLEc85d8dd/blocks/1000 HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
x-amzn-Data-Length: 524288
x-amzn-Checksum: QOD3gmEQOXATfJx2Aa34W4FU2nZGyXfqtUukt0w8DM=

Authorization: <Authentication parameter>
```

1895
BlockData

The following is example response for the previous request confirms the data length, checksum, and checksum algorithm for the data received by the service.

HTTP/1.1 201 Created
x-amzn-RequestId: 643ac797-7e0c-4aad-0-6417-97b77b43c57b
x-amz-Checksum: Q0D3gmE0QXATFjx2AA34W6FU2n2G6YxFqtsUuKt0w8DM=
x-amz-Checksum-Algorithm: SHA256
Content-Type: application/json
Content-Length: 2
Date: Thu, 18 Jun 2020 04:22:12 GMT
Connection: keep-alive
{}

Complete a snapshot

AWS CLI

The following **complete-snapshot** example command completes snapshot snap-0aaEXAMPLEe306d62. The command specifies that 5 blocks were written to the snapshot. The 6D3nmwi5f2F0w1h7xX8Qprrr8FzDX8aacd0cA3KC3c checksum represents the checksum for the complete set of data written to a snapshot. For more information about checksums, see Use checksums (p. 1899) earlier in this guide.

```bash
aws ebs complete-snapshot --snapshot-id snap-0aaEXAMPLEe306d62 --changed-blocks-count 5 --checksum 6D3nmwi5f2F0w1h7xX8Qprrr8FzDX8aacd0cA3KC3c --checksum-algorithm SHA256 --checksum-aggregation-method LINEAR
```

The following is an example response for the previous command.

```
{
    "Status": "pending"
}
```

AWS API

The following **CompleteSnapshot** example request completes snapshot snap-052EXAMPLEec85d8dd. The command specifies that 5 blocks were written to the snapshot. The 6D3nmwi5f2F0w1h7xX8Qprrr8FzDX8aacd0cA3KC3c checksum represents the checksum for the complete set of data written to a snapshot.

```http
POST /snapshots/completion/snap-052EXAMPLEec85d8dd HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
x-amz-ChangedBlocksCount: 5
x-amz-Checksum: 6D3nmwi5f2F0w1h7xX8Qprrr8FzDX8aacd0cA3KC3c
x-amz-Checksum-Algorithm: SHA256
x-amz-Checksum-Aggregation-Method: LINEAR
User-Agent: <User agent parameter>
X-Amz-Date: 20200618T043158Z
Authorization: <Authentication parameter>
```

The following is an example response for the previous request.

```
HTTP/1.1 202 Accepted
x-amzn-RequestId: 06cba5b5-b731-49de-af40-80333ac3a117
```
Use encryption

When you start a new snapshot using `StartSnapshot`, the encryption status depends on the values that you specify for `Encrypted`, `KmsKeyArn`, and `ParentSnapshotId`, and whether your AWS account is enabled for encryption by default (p. 1979).

**Note**

- You might need additional IAM permissions to use the EBS direct APIs with encryption. For more information, see Permissions to use AWS KMS keys (p. 1886).
- If Amazon EBS encryption by default is enabled on your AWS account, you can't create unencrypted snapshots.
- If Amazon EBS encryption by default is enabled on your AWS account, you cannot start a new snapshot using an unencrypted parent snapshot. You must first encrypt the parent snapshot by copying it. For more information, see Copy an Amazon EBS snapshot (p. 1836).

**Topics**

- Encryption outcomes: Unencrypted parent snapshot (p. 1897)
- Encryption outcomes: Encrypted parent snapshot (p. 1898)
- Encryption outcomes: No parent snapshot (p. 1898)

**Encryption outcomes: Unencrypted parent snapshot**

The following table describes the encryption outcome for each possible combination of settings when specifying an unencrypted parent snapshot.

<table>
<thead>
<tr>
<th>ParentSnapshot</th>
<th>Encrypted</th>
<th>KmsKeyArn</th>
<th>Encryption by default</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unencrypted</td>
<td>Omitted</td>
<td>Omitted</td>
<td>Enabled</td>
<td>The request fails with ValidationException.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Disabled</td>
<td>The snapshot is unencrypted.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Specified</td>
<td>Enabled</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Specified</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Specified</td>
<td>Disabled</td>
</tr>
<tr>
<td>Unencrypted</td>
<td>True</td>
<td>Omitted</td>
<td>Enabled</td>
<td>The request fails with ValidationException.</td>
</tr>

<td></td>
<td>Disabled</td>
<td></td>
</tr>
</tbody>
</table>

1897
### Encryption outcomes: Encrypted parent snapshot

The following table describes the encryption outcome for each possible combination of settings when specifying an encrypted parent snapshot.

<table>
<thead>
<tr>
<th>ParentSnapshot</th>
<th>Encrypted</th>
<th>KmsKeyArn</th>
<th>Encryption by default</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encrypted</td>
<td>Omitted</td>
<td>Omitted</td>
<td>Enabled</td>
<td>The snapshot is encrypted using the same KMS key as the parent snapshot.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Enabled</td>
<td>The request fails with ValidationException.</td>
</tr>
<tr>
<td></td>
<td>Specified</td>
<td></td>
<td>Enabled</td>
<td>The request fails with ValidationException.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Enabled</td>
<td>The request fails with ValidationException.</td>
</tr>
<tr>
<td></td>
<td>False</td>
<td>Omitted</td>
<td>Enabled</td>
<td>The request fails with ValidationException.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Enabled</td>
<td>The request fails with ValidationException.</td>
</tr>
</tbody>
</table>

### Encryption outcomes: No parent snapshot

The following tables describe the encryption outcome for each possible combination of settings when not using a parent snapshot.

<table>
<thead>
<tr>
<th>ParentSnapshot</th>
<th>Encrypted</th>
<th>KmsKeyArn</th>
<th>Encryption by default</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Omitted</td>
<td>True</td>
<td>Omitted</td>
<td>Enabled</td>
<td>The snapshot is encrypted using the default KMS key for your account. *</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Enabled</td>
<td>The request fails with ValidationException.</td>
</tr>
<tr>
<td></td>
<td>Specified</td>
<td></td>
<td>Enabled</td>
<td>The request fails with ValidationException.</td>
</tr>
<tr>
<td>Omitted</td>
<td>False</td>
<td>Omitted</td>
<td>Enabled</td>
<td>The request fails with ValidationException.</td>
</tr>
</tbody>
</table>
ParentSnapshot | Encrypted | KmsKeyArn | Encryption by default | Result
---|---|---|---|---
Disabled | The snapshot is unencrypted. | Specified | Enabled | The request fails with ValidationException. | Disabled
Omitted | The snapshot is unencrypted. | Specified | Enabled | The snapshot is encrypted using the default KMS key for your account. * | Disabled
specified | The snapshot is encrypted using the KMS key specified for KmsKeyArn. | Omitted | Omitted | Disabled

* This default KMS key could be a customer managed key or the default AWS managed KMS key for Amazon EBS encryption.

Use Signature Version 4 signing

Signature Version 4 is the process to add authentication information to AWS requests sent by HTTP. For security, most requests to AWS must be signed with an access key, which consists of an access key ID and secret access key. These two keys are commonly referred to as your security credentials. For information about how to obtain credentials for your account, see Understanding and getting your credentials.

If you intend to manually create HTTP requests, you must learn how to sign them. When you use the AWS Command Line Interface (AWS CLI) or one of the AWS SDKs to make requests to AWS, these tools automatically sign the requests for you with the access key that you specify when you configure the tools. When you use these tools, you don’t need to learn how to sign requests yourself.

For more information, see Signing AWS requests with Signature Version 4 in the AWS General Reference.

Use checksums

The GetSnapshotBlock action returns data that is in a block of a snapshot, and the PutSnapshotBlock action adds data to a block in a snapshot. The block data that is transmitted is not signed as part of the Signature Version 4 signing process. As a result, checksums are used to validate the integrity of the data as follows:

- When you use the GetSnapshotBlock action, the response provides a Base64-encoded SHA256 checksum for the block data using the x-amz-Checksum header, and the checksum algorithm using the x-amz-Checksum-Algorithm header. Use the returned checksum to validate the integrity of the data. If the checksum that you generate doesn’t match what Amazon EBS provided, you should consider the data not valid and retry your request.
- When you use the PutSnapshotBlock action, your request must provide a Base64-encoded SHA256 checksum for the block data using the x-amz-Checksum header, and the checksum algorithm using the x-amz-Checksum-Algorithm header. The checksum that you provide is validated against a checksum generated by Amazon EBS to validate the integrity of the data. If the checksums do not correspond, the request fails.
- When you use the CompleteSnapshot action, your request can optionally provide an aggregate Base64-encoded SHA256 checksum for the complete set of data added to the snapshot. Provide the checksum using the x-amz-Checksum header, the checksum algorithm using the x-amz-Checksum-Algorithm header, and the checksum aggregation method using the x-amz-Checksum-Aggregation-Method header. To generate the aggregated checksum using the linear aggregation method, arrange...
the checksums for each written block in ascending order of their block index, concatenate them to form a single string, and then generate the checksum on the entire string using the SHA256 algorithm.

The checksums in these actions are part of the Signature Version 4 signing process.

**Idempotency for StartSnapshot API**

Idempotency ensures that an API request completes only once. With an idempotent request, if the original request completes successful, the subsequent retries return the result from the original successful request and they have no additional effect.

The **StartSnapshot** API supports idempotency using a *client token*. A client token is a unique string that you specify when you make an API request. If you retry an API request with the same client token and the same request parameters after it has completed successfully, the result of the original request is returned. If you retry a request with the same client token, but change one or more of the request parameters, the **ConflictException** error is returned.

If you do not specify your own client token, the AWS SDKs automatically generates a client token for the request to ensure that it is idempotent.

A client token can be any string that includes up to 64 ASCII characters. You should not reuse the same client tokens for different requests.

**To make an idempotent StartSnapshot request with your own client token using the API**

Specify the `ClientToken` request parameter.

```
POST /snapshots HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
User-Agent: <User agent parameter>
X-Amz-Date: 20200618T040724Z
Authorization: <Authentication parameter>
{
    "VolumeSize": 8,
    "ParentSnapshot": "snap-123EXAMPLE1234567",
    "ClientToken": "550e8400-e29b-41d4-a716-446655440000",
    "Timeout": 60
}
```

**To make an idempotent StartSnapshot request with your own client token using the AWS CLI**

Specify the `-client-token` request parameter.

```
$ aws ebs start-snapshot --region us-east-2 --volume-size 8 --parent-snapshot snap-123EXAMPLE1234567 --timeout 60 --client-token 550e8400-e29b-41d4-a716-446655440000
```

**Error retries**

The **AWS SDKs** implement automatic retry logic for requests that return error responses. You can configure the retry settings for the AWS SDKs. For more information, see your SDK's documentation.

You can configure the **AWS CLI** to automatically retry some failed requests. For more information about configuring retries for the AWS CLI, see **AWS CLI retries** in the **AWS Command Line Interface User Guide**.

The **AWS Query API** does not support retry logic for failed requests. If you are using HTTP or HTTPS requests, you must implement retry logic in your client application.

For more information, see **Error retries and exponential backoff in AWS** in the **AWS General Reference**.
The following table shows the possible API error responses. Some API errors are retryable. Your client application should always retry failed requests that receive a retryable error.

<table>
<thead>
<tr>
<th>Error</th>
<th>Response code</th>
<th>Description</th>
<th>Thrown by</th>
<th>Retryable?</th>
</tr>
</thead>
<tbody>
<tr>
<td>InternalServerException</td>
<td>500</td>
<td>The request failed due to a network or AWS server-side issue.</td>
<td>All APIs</td>
<td>Yes</td>
</tr>
<tr>
<td>ThrottlingException</td>
<td>400</td>
<td>The number of API requests has exceeded the maximum allowed API request throttling limit for the account.</td>
<td>All APIs</td>
<td>Yes</td>
</tr>
<tr>
<td>RequestThrottleException</td>
<td>400</td>
<td>The number of API requests has exceeded the maximum allowed API request throttling limit for the snapshot.</td>
<td>GetSnapshotBlock, PutSnapshotBlock</td>
<td>Yes</td>
</tr>
<tr>
<td>ValidationException</td>
<td>400, 403</td>
<td>The provided data block was not readable.</td>
<td>PutSnapshotBlock</td>
<td>Yes</td>
</tr>
<tr>
<td>ValidationException</td>
<td>400</td>
<td>The request syntax is malformed, or the input does not satisfy the constraints specified by the AWS service.</td>
<td>All APIs</td>
<td>No</td>
</tr>
<tr>
<td>ResourceNotFoundException</td>
<td>404</td>
<td>The specified snapshot ID does not exist.</td>
<td>All APIs</td>
<td>No</td>
</tr>
<tr>
<td>ConflictException</td>
<td>409</td>
<td>The specified client token was previously used in a similar request that had different request parameters. For more information, see Idempotency for StartSnapshot API (p. 1900).</td>
<td>StartSnapshot</td>
<td>No</td>
</tr>
<tr>
<td>AccessDeniedException</td>
<td>403</td>
<td>You do not have permission</td>
<td>All APIs</td>
<td>No</td>
</tr>
</tbody>
</table>

1901
Optimize performance

You can run API requests concurrently. Assuming PutSnapshotBlock latency is 100ms, then a thread can process 10 requests in one second. Furthermore, assuming your client application creates multiple threads and connections (for example, 100 connections), it can make 1000 (10 * 100) requests per second in total. This will correspond to a throughput of around 500 MB per second.

The following list contains few things to look for in your application:

- Is each thread using a separate connection? If the connections are limited on the application then multiple threads will wait for the connection to be available and you will notice lower throughput.
- Is there any wait time in the application between two put requests? This will reduce the effective throughput of a thread.
- The bandwidth limit on the instance – If bandwidth on the instance is shared by other applications, it could limit the available throughput for PutSnapshotBlock requests.

Be sure to take note of other workloads that might be running in the account to avoid bottlenecks. You should also build retry mechanisms into your EBS direct APIs workflows to handle throttling, timeouts, and service unavailability.

Review the EBS direct APIs service quotas to determine the maximum API requests that you can run per second. For more information, see Amazon Elastic Block Store Endpoints and Quotas in the AWS General Reference.

EBS direct APIs service endpoints

An endpoint is a URL that serves as an entry point for an AWS web service. EBS direct APIs supports the following endpoint types:

- IPv4 endpoints
- Dual-stack endpoints that support both IPv4 and IPv6
- FIPS endpoints
When you make a request, you can specify the endpoint and Region to use. If you do not specify an endpoint, the IPv4 endpoint is used by default. To use a different endpoint type, you must specify it in your request. For examples of how to do this, see Specifying endpoints (p. 1904).

For more information about Regions, see Regions and Availability Zones in the Amazon EC2 User Guide for Linux Instances. For a list of endpoints for EBS direct APIs, see Endpoints for the EBS direct APIs in the Amazon Web Services General Reference.

Topics
- IPv4 endpoints (p. 1903)
- Dual-stack (IPv4 and IPv6) endpoints (p. 1903)
- FIPS endpoints (p. 1904)
- Specifying endpoints (p. 1904)

IPv4 endpoints

IPv4 endpoints support IPv4 traffic only. IPv4 endpoints are available for all Regions.

If you specify the general endpoint, ebs.amazonaws.com, we use the endpoint for us-east-1. To use a different Region, specify its associated endpoint. For example, if you specify ebs.us-east-2.amazonaws.com as the endpoint, we direct your request to the us-east-2 endpoint.

IPv4 endpoint names use the following naming convention:

- ebs.region.amazonaws.com

For example, the IPv4 endpoint name for the us-west-1 Region is ebs.us-west-1.amazonaws.com. For a list of endpoints for EBS direct APIs, see Endpoints for the EBS direct APIs in the Amazon Web Services General Reference.

Pricing

You are not charged for data transferred directly between EBS direct APIs and Amazon EC2 instances using an IPv4 endpoint in the same Region. However, if there are intermediate services, such as AWS PrivateLink endpoints, NAT Gateway, or Amazon VPC Transit Gateways, you are charged their associated costs.

Dual-stack (IPv4 and IPv6) endpoints

Dual-stack endpoints support both IPv4 and IPv6 traffic. Dual-stack endpoints are available for all Regions.

To use IPv6, you must use a dual-stack endpoint. When you make a request to a dual-stack endpoint, the endpoint URL resolves to an IPv6 or an IPv4 address, depending on the protocol used by your network and client.

EBS direct APIs supports only regional dual-stack endpoints, which means that you must specify the Region as part of the endpoint name. Dual-stack endpoint names use the following naming convention:

- ebs.region.api.aws

For example, the dual-stack endpoint name for the eu-west-1 Region is ebs.eu-west-1.api.aws. For a list of endpoints for EBS direct APIs, see Endpoints for the EBS direct APIs in the Amazon Web Services General Reference.

Pricing
You are not charged for data transferred directly between EBS direct APIs and Amazon EC2 instances using a dual-stack endpoint in the same Region. However, if there are intermediate services, such as AWS PrivateLink endpoints, NAT Gateway, or Amazon VPC Transit Gateways, you are charged their associated costs.

**FIPS endpoints**

EBS direct APIs provides FIPS-validated IPv4 and dual-stack (IPv4 and IPv6) endpoints for the following Regions:

- **us-east-1** — US East (N. Virginia)
- **us-east-2** — US East (Ohio)
- **us-west-1** — US West (N. California)
- **us-west-2** — US West (Oregon)
- **ca-central-1** — Canada (Central)

**FIPS IPv4 endpoints** use the following naming convention: `ebs-fips.region.amazonaws.com`. For example, the FIPS IPv4 endpoint for `us-east-1` is `ebs-fips.us-east-1.amazonaws.com`.

**FIPS dual-stack endpoints** use the following naming convention: `ebs-fips.region.api.aws`. For example, the FIPS dual-stack endpoint for `us-east-1` is `ebs-fips.us-east-1.api.aws`.

For more information about FIPS endpoints see, [FIPS endpoints](#) in the *Amazon Web Services General Reference*.

**Specifying endpoints**

This section provides some examples of how to specify an endpoint when making a request.

**AWS CLI**

The following examples show how to specify an endpoint for the `us-east-2` Region using the AWS CLI.

- **Dual-stack**
  
  ```bash
  aws ebs list-snapshot-blocks --snapshot-id snap-0987654321 --starting-block-index 1000 --endpoint-url https://ebs.us-east-2.api.aws
  ```

- **IPv4**
  
  ```bash
  aws ebs list-snapshot-blocks --snapshot-id snap-0987654321 --starting-block-index 1000 --endpoint-url https://ebs.us-east-2.amazonaws.com
  ```

**AWS SDK for Java 2.x**

The following examples show how to specify an endpoint for the `us-east-2` Region using the AWS SDK for Java 2.x.

- **Dual-stack**
  
  ```java
  AwsClientBuilder.EndpointConfiguration config = new
  AwsClientBuilder.EndpointConfiguration("https://ebs.us-east-2.api.aws", "us-
  east-2");
  AmazonEBS ebs = AmazonEBSClientBuilder.standard()
  .withEndpointConfiguration(config)
  .build();
  ```
**IPv4**

```java
AwsClientBuilder.EndpointConfiguration config = new
AmazonEBS ebs = AmazonEBSClientBuilder.standard()
    .withEndpointConfiguration(config)
    .build();
```

AWS SDK for Go

The following examples show how to specify an endpoint for the us-east-2 Region using the AWS SDK for Go.

- **Dual-stack**

```go
sess := session.Must(session.NewSession())
svc := ebs.New(sess, &aws.Config{
    Region: aws.String(endpoints.UsEast1RegionID),
    Endpoint: aws.String("https://ebs.us-east-2.api.aws")
})
```

- **IPv4**

```go
sess := session.Must(session.NewSession())
svc := ebs.New(sess, &aws.Config{
    Region: aws.String(endpoints.UsEast1RegionID),
    Endpoint: aws.String("https://ebs.us-east-2.amazonaws.com")
})
```

**Pricing for EBS direct APIs**

**Topics**

- Pricing for APIs (p. 1905)
- Networking costs (p. 1905)

**Pricing for APIs**

The price that you pay to use the EBS direct APIs depends on the requests you make. For more information, see [Amazon EBS pricing](#).

- **ListChangedBlocks** and ListSnapshotBlocks APIs are charged per request. For example, if you make 100,000 ListSnapshotBlocks API requests in a Region that charges $0.0006 per 1,000 requests, you will be charged $0.06 ($0.0006 per 1,000 requests x 100).

- **GetSnapshotBlock** is charged per block returned. For example, if you make 100,000 GetSnapshotBlock API requests in a Region that charges $0.003 per 1,000 blocks returned, you will be charged $0.30 ($0.003 per 1,000 blocks returned x 100).

- **PutSnapshotBlock** is charged per block written. For example, if you make 100,000 PutSnapshotBlock API requests in a Region that charges $0.006 per 1,000 blocks written, you will be charged $0.60 ($0.006 per 1,000 blocks written x 100).

**Networking costs**

**Data transfer costs**
Data transferred directly between EBS direct APIs and Amazon EC2 instances in the same AWS Region is free when using non-FIPS endpoints. For more information, see AWS service endpoints. If other AWS services are in the path of your data transfer, you will be charged their associated data processing costs. These services include, but are not limited to, PrivateLink endpoints, NAT Gateway and Transit Gateway.

**VPC interface endpoints**

If you are using EBS direct APIs from Amazon EC2 instances or AWS Lambda functions in private subnets, you can use VPC interface endpoints, instead of using NAT gateways, to reduce network data transfer costs. For more information, see Using interface VPC endpoints with EBS direct APIs (p. 1906).

**Using interface VPC endpoints with EBS direct APIs**

You can establish a private connection between your VPC and EBS direct APIs by creating an interface VPC endpoint, powered by AWS PrivateLink. You can access EBS direct APIs as if it were in your VPC, without using an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC don't need public IP addresses to communicate with EBS direct APIs.

We create an endpoint network interface in each subnet that you enable for the interface endpoint.

For more information, see Access AWS services through AWS PrivateLink in the AWS PrivateLink Guide.

**Considerations for EBS direct APIs VPC endpoints**

Before you set up an interface VPC endpoint for EBS direct APIs, review Considerations in the AWS PrivateLink Guide.

VPC endpoint policies are not supported for EBS direct APIs. By default, full access to EBS direct APIs is allowed through the endpoint. However, you can control access to the interface endpoint using security groups.

**Create an interface VPC endpoint for EBS direct APIs**

You can create a VPC endpoint for EBS direct APIs using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see Create a VPC endpoint in the AWS PrivateLink Guide.

Create a VPC endpoint for EBS direct APIs using the following service name:

- com.amazonaws.<region>.ebs

If you enable private DNS for the endpoint, you can make API requests to EBS direct APIs using its default DNS name for the Region, for example, ebs.us-east-1.amazonaws.com.

**Log API Calls for EBS direct APIs with AWS CloudTrail**

The EBS direct APIs service is integrated with AWS CloudTrail. CloudTrail is a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls performed in EBS direct APIs as events. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon Simple Storage Service (Amazon S3) bucket. If you don't configure a trail, you can still view the most recent management events in the CloudTrail console in Event history. Data events are not captured in Event history. You can use the information collected by CloudTrail to determine the request that was made to EBS direct APIs, the IP address from which the request was made, who made the request, when it was made, and additional details.

For more information about CloudTrail, see the AWS CloudTrail User Guide.

**EBS direct APIs Information in CloudTrail**

CloudTrail is enabled on your AWS account when you create the account. When supported event activity occurs in EBS direct APIs, that activity is recorded in a CloudTrail event along with other AWS service
events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](#).

For an ongoing record of events in your AWS account, including events for EBS direct APIs, create a trail. A trail enables CloudTrail to deliver log files to an S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- [Overview for Creating a Trail](#)
- [CloudTrail Supported Services and Integrations](#)
- [Configuring Amazon SNS Notifications for CloudTrail](#)
- [Receiving CloudTrail Log Files from Multiple Regions](#) and [Receiving CloudTrail Log Files from Multiple Accounts](#)

**Supported API actions**

For EBS direct APIs, you can use CloudTrail to log two types of events:

- **Management events** — Management events provide visibility into management operations that are performed on snapshots in your AWS account. The following API actions are logged by default as management events in trails:
  - [StartSnapshot](#)
  - [CompleteSnapshot](#)

  For more information about logging management events, see [Logging management events for trails](#) in the *CloudTrail User Guide*.

- **Data events** — These events provide visibility into the snapshot operations performed on or within a snapshot. The following API actions can optionally be logged as data events in trails:
  - [ListSnapshotBlocks](#)
  - [ListChangedBlocks](#)
  - [GetSnapshotBlock](#)
  - [PutSnapshotBlock](#)

  Data events are not logged by default when you create a trail. You can use only **advanced event selectors** to record data events on EBS direct API calls. For more information, see [Logging data events for trails](#) in the *CloudTrail User Guide*.

  **Note**
  
  If you perform an action on a snapshot that is shared with you, data events are not sent to the AWS account that owns the snapshot.

**Identity information**

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the [CloudTrail userIdentityElement](#).
Understand EBS direct APIs Log File Entries

A trail is a configuration that enables delivery of events as log files to an S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following are example CloudTrail log entries.

StartSnapshot

```json
{

PutSnapshotBlock
Frequently asked questions

Can a snapshot be accessed using the EBS direct APIs if it has a pending status?

No. The snapshot can be accessed only if it has a completed status.

Are the block indexes returned by the EBS direct APIs in numerical order?

Yes. The block indexes returned are unique, and in numerical order.

Can I submit a request with a MaxResults parameter value of under 100?

No. The minimum MaxResult parameter value you can use is 100. If you submit a request with a MaxResult parameter value of under 100, and there are more than 100 blocks in the snapshot, then the API will return at least 100 results.

Can I run API requests concurrently?

You can run API requests concurrently. Be sure to take note of other workloads that might be running in the account to avoid bottlenecks. You should also build retry mechanisms into your EBS direct APIs workflows to handle throttling, timeouts, and service unavailability. For more information, see Optimize performance (p. 1902).

Review the EBS direct APIs service quotas to determine the API requests that you can run per second. For more information, see Amazon Elastic Block Store Endpoints and Quotas in the AWS General Reference.

When running the ListChangedBlocks action, is it possible to get an empty response even though there are blocks in the snapshot?

Yes. If the changed blocks are scarce in the snapshot, the response may be empty but the API will return a next page token value. Use the next page token value to continue to the next page of results. You can confirm that you have reached the last page of results when the API returns a next page token value of null.

If the NextToken parameter is specified together with a StartingBlockIndex parameter, which of the two is used?

The NextToken is used, and the StartingBlockIndex is ignored.

How long are the block tokens and next tokens valid?

Block tokens are valid for seven days, and next tokens are valid for 60 minutes.

Are encrypted snapshots supported?

Yes. Encrypted snapshots can be accessed using the EBS direct APIs.

To access an encrypted snapshot, the user must have access to the KMS key used to encrypt the snapshot, and the AWS KMS decrypt action. See the IAM permissions for EBS direct APIs (p. 1883) section earlier in this guide for the AWS KMS policy to assign to a user.
Are public snapshots supported?

Public snapshots are not supported.

Are Amazon EBS local snapshots on Outposts supported?

Amazon EBS local snapshots on Outposts are not supported.

Does list snapshot block return all block indexes and block tokens in a snapshot, or only those that have data written to them?

It returns only block indexes and tokens that have data written to them.

Can I get a history of the API calls made by the EBS direct APIs on my account for security analysis and operational troubleshooting purposes?

Yes. To receive a history of EBS direct APIs API calls made on your account, turn on AWS CloudTrail in the AWS Management Console. For more information, see Log API Calls for EBS direct APIs with AWS CloudTrail (p. 1906).

Automate the snapshot lifecycle

You can use Amazon Data Lifecycle Manager to automate the creation, retention, and deletion of snapshots that you use to back up your Amazon EBS volumes.

For more information, see Amazon Data Lifecycle Manager (p. 1913).

Amazon Data Lifecycle Manager

You can use Amazon Data Lifecycle Manager to automate the creation, retention, and deletion of EBS snapshots and EBS-backed AMIs. When you automate snapshot and AMI management, it helps you to:

- Protect valuable data by enforcing a regular backup schedule.
- Create standardized AMIs that can be refreshed at regular intervals.
- Retain backups as required by auditors or internal compliance.
- Reduce storage costs by deleting outdated backups.
- Create disaster recovery backup policies that back up data to isolated accounts.

When combined with the monitoring features of Amazon CloudWatch Events and AWS CloudTrail, Amazon Data Lifecycle Manager provides a complete backup solution for Amazon EC2 instances and individual EBS volumes at no additional cost.

Important
Amazon Data Lifecycle Manager cannot be used to manage snapshots or AMIs that are created by any other means.
Amazon Data Lifecycle Manager cannot be used to automate the creation, retention, and deletion of instance store-backed AMIs.

Contents

- AWS Identity and Access Management (p. 1947)
- Monitor the lifecycle of snapshots and AMIs (p. 1955)
How Amazon Data Lifecycle Manager works

The following are the key elements of Amazon Data Lifecycle Manager.

Elements

- Snapshots (p. 1914)
- EBS-backed AMIs (p. 1914)
- Target resource tags (p. 1914)
- Amazon Data Lifecycle Manager tags (p. 1914)
- Lifecycle policies (p. 1915)
- Policy schedules (p. 1915)

Snapshots

Snapshots are the primary means to back up data from your EBS volumes. To save storage costs, successive snapshots are incremental, containing only the volume data that changed since the previous snapshot. When you delete one snapshot in a series of snapshots for a volume, only the data that's unique to that snapshot is removed. The rest of the captured history of the volume is preserved. For more information, see Amazon EBS snapshots (p. 1825).

EBS-backed AMIs

An Amazon Machine Image (AMI) provides the information that's required to launch an instance. You can launch multiple instances from a single AMI when you need multiple instances with the same configuration. Amazon Data Lifecycle Manager supports EBS-backed AMIs only. EBS-backed AMIs include a snapshot for each EBS volume that's attached to the source instance. For more information, see Amazon Machine Images (AMI) (p. 108).

Target resource tags

Amazon Data Lifecycle Manager uses resource tags to identify the resources to back up. When you create a snapshot or EBS-backed AMI policy, you can specify multiple target resource tags. All resources of the specified type (instance or volume) that have at least one of the specified target resource tags will be targeted by the policy. For example, if you create a snapshot policy that targets volumes and you specify purpose=prod, costcenter=prod, and environment=live as target resource tags, then the policy will target all volumes that have any of those tag-key value pairs.

If you want to run multiple policies on a resource, you can assign multiple tags to the target resource, and then create separate policies that each target a specific resource tag.

You can't use the \ or = characters in a tag key. Target resource tags are case sensitive. For more information, see Tag your Amazon EC2 resources (p. 2154).

Amazon Data Lifecycle Manager tags

Amazon Data Lifecycle Manager applies the following system tags to all snapshots and AMIs created by a policy, to distinguish them from snapshots and AMIs created by any other means:

- aws:dlm:lifecycle-policy-id
- aws:dlm:lifecycle-schedule-name
- aws:dlm:expirationTime — For snapshots created by an age-based schedule. Indicates when the snapshot is to be deleted from the standard tier.
- aws:dlm:managed
- aws:dlm:archived — For snapshots that were archived by a schedule.
You can also specify custom tags to be applied to snapshots and AMIs on creation. You can't use the \ or = characters in a tag key.

The target tags that Amazon Data Lifecycle Manager uses to associate volumes with a snapshot policy can optionally be applied to snapshots created by the policy. Similarly, the target tags that are used to associate instances with an AMI policy can optionally be applied to AMIs created by the policy.

Lifecycle policies

A lifecycle policy consists of these core settings:

- **Policy type**—Defines the type of resources that the policy can manage. Amazon Data Lifecycle Manager supports the following types of lifecycle policies:
  - Snapshot lifecycle policy—Used to automate the lifecycle of EBS snapshots. These policies can target individual EBS volumes or all EBS volumes attached to an instance.
  - EBS-backed AMI lifecycle policy—Used to automate the lifecycle of EBS-backed AMIs and their backing snapshots. These policies can target instances only.
  - Cross-account copy event policy—Used to automate snapshot copies across accounts. Use this policy type in conjunction with an EBS snapshot policy that shares snapshots across accounts.

- **Resource type**—Defines the type of resources that are targeted by the policy. Snapshot lifecycle policies can target instances or volumes. Use VOLUME to create snapshots of individual volumes, or use INSTANCE to create multi-volume snapshots of all of the volumes that are attached to an instance. For more information, see Multi-volume snapshots (p. 1831). AMI lifecycle policies can target instances only. One AMI is created that includes snapshots of all of the volumes that are attached to the target instance.

- **Target tags**—Specifies the tags that must be assigned to an EBS volume or an Amazon EC2 instance for it to be targeted by the policy.

- **Policy schedules** (Snapshot and AMI policies only)—Define when snapshots or AMIs are to be created and how long to retain them for. For more information, see Policy schedules (p. 1915).

For example, you could create a policy with settings similar to the following:

- Manages all EBS volumes that have a tag with a key of account and a value of finance.
- Creates snapshots every 24 hours at 0900 UTC.
- Retains only the five most recent snapshots.
- Starts snapshot creation no later than 0959 UTC each day.

Policy schedules

Policy schedules define when snapshots or AMIs are created by the policy. Policies can have up to four schedules—one mandatory schedule, and up to three optional schedules.

Adding multiple schedules to a single policy lets you create snapshots or AMIs at different frequencies using the same policy. For example, you can create a single policy that creates daily, weekly, monthly, and yearly snapshots. This eliminates the need to manage multiple policies.

For each schedule, you can define the frequency, fast snapshot restore settings (snapshot lifecycle policies only), cross-Region copy rules, and tags. The tags that are assigned to a schedule are automatically assigned to the snapshots or AMIs that are created when the schedule is initiated. In addition, Amazon Data Lifecycle Manager automatically assigns a system-generated tag based on the schedule's frequency to each snapshot or AMI.

Each schedule is initiated individually based on its frequency. If multiple schedules are initiated at the same time, Amazon Data Lifecycle Manager creates only one snapshot or AMI and applies the retention
settings of the schedule that has the highest retention period. The tags of all of the initiated schedules are applied to the snapshot or AMI.

- (Snapshot lifecycle policies only) If more than one of the initiated schedules is enabled for fast snapshot restore, then the snapshot is enabled for fast snapshot restore in all of the Availability Zones specified across all of the initiated schedules. The highest retention settings of the initiated schedules is used for each Availability Zone.

- If more than one of the initiated schedules is enabled for cross-Region copy, the snapshot or AMI is copied to all Regions specified across all of the initiated schedules. The highest retention period of the initiated schedules is applied.

**Quotas**

Your AWS account has the following quotas related to Amazon Data Lifecycle Manager:

<table>
<thead>
<tr>
<th>Description</th>
<th>Quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lifecycle policies per Region</td>
<td>100</td>
</tr>
<tr>
<td>Tags per resource</td>
<td>45</td>
</tr>
</tbody>
</table>

**Automate snapshot lifecycles**

The following procedure shows you how to use Amazon Data Lifecycle Manager to automate Amazon EBS snapshot lifecycles.

**Topics**

- Create a snapshot lifecycle policy (p. 1916)
- Considerations for snapshot lifecycle policies (p. 1925)
- Additional resources (p. 1929)

**Create a snapshot lifecycle policy**

Use one of the following procedures to create a snapshot lifecycle policy.

**Console**

**To create a snapshot policy**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Elastic Block Store, Lifecycle Manager, and then choose Create lifecycle policy.
3. On the Select policy type screen, choose EBS snapshot policy and then choose Next.
4. In the Target resources section, do the following:
   a. For Target resource types, choose the type of resource to back up. Choose Volume to create snapshots of individual volumes, or choose Instance to create multi-volume snapshots from the volumes attached to an instance.
   b. (For AWS Outpost customers only) For Target resource location, specify where the target resources are located.

   - If the target resources are located in an AWS Region, choose AWS Region. Amazon Data Lifecycle Manager backs up all resources of the specified type that have matching target
tags in the current Region only. If the resource is located in a Region, snapshots created by the policy will be stored in the same Region.

- If the target resources are located on an Outpost in your account, choose AWS Outpost. Amazon Data Lifecycle Manager backs up all resources of the specified type that have matching target tags across all of the Outposts in your account. If the resource is located on an Outpost, snapshots created by the policy can be stored in the same Region or on the same Outpost as the resource.
- If you do not have any Outposts in your account, this option is hidden and AWS Region is selected for you.

c. For **Target resource tags**, choose the resource tags that identify the volumes or instances to back up. Only resources that have the specified tag key and value pairs are backed up by the policy.

5. For **Description**, enter a brief description for the policy.

6. For **IAM role**, choose the IAM role that has permissions to manage snapshots and to describe volumes and instances. To use the default role provided by Amazon Data Lifecycle Manager, choose **Default role**. Alternatively, to use a custom IAM role that you previously created, choose **Choose another role** and then select the role to use.

7. For **Policy tags**, add the tags to apply to the lifecycle policy. You can use these tags to identify and categorize your policies.

8. For **Policy status**, choose **Enable** to start the policy runs at the next scheduled time, or **Disable policy** to prevent the policy from running. If you do not enable the policy now, it will not start creating snapshots until you manually enable it after creation.

9. (Only for policies that target instances) By default, Amazon Data Lifecycle Manager will create snapshots of all the volumes attached to targeted instances. However, you can choose to create snapshots of a subset of the attached volumes. In the **Parameters** section, do the following:

   - If you do not want to create snapshots of the root volumes attached to the targeted instances, select **Exclude root volume**. If you select this option, only the data (non-root) volumes that are attached to targeted instances will be included in the multi-volume snapshot sets.
   - If you want to create snapshots of a subset of the data (non-root) volumes attached to the targeted instances, select **Exclude specific data volumes**, and then specify the tags that are to be used to identify the data volumes that should not be snapshotted. Amazon Data Lifecycle Manager will not create snapshots of data volumes that have any of the specified tags. Amazon Data Lifecycle Manager will create snapshots only of data volumes that do not have any of the specified tags.

10. Choose **Next**.

11. On the **Configure schedule** screen, configure the policy schedules. A policy can have up to 4 schedules. Schedule 1 is mandatory. Schedules 2, 3, and 4 are optional. For each policy schedule that you add, do the following:

   a. In the **Schedule details** section do the following:

      i. For **Schedule name**, specify a descriptive name for the schedule.
      
      ii. For **Frequency** and the related fields, configure the interval between policy runs. You can configure policy runs on a daily, weekly, monthly, or yearly schedule. Alternatively, choose **Custom cron expression** to specify an interval of up to one year. For more information, see [Cron expressions](#) in the *Amazon CloudWatch Events User Guide*.

      **Note**

      If you need to enable **snapshot archiving** for the schedule, then you must select either the **monthly** or **yearly** frequency, or you must specify a cron expression with a creation frequency of at least 28 days.

      If specify a monthly frequency that creates snapshots on a specific day in a specific week (for example, the second Thursday of the month), then for
count-based schedule, the retention count for the archive tier must be 4 or more.

iii. For **Starting at**, specify the time at which the policy runs are scheduled to start. The first policy run starts within an hour after the scheduled time. The time must be entered in the hh:mm UTC format.

iv. For **Retention type**, specify the retention policy for snapshots created by the schedule. You can retain snapshots based on either their total count or their age.

- (Count-based retention) If you do not enable snapshot archiving, the range is 1 to 1000. If you enable snapshot archiving, the range is 0 to 1000. If you specify a count of 0, snapshots are archived immediately after creation.
- (Age-based retention) If you do not enable snapshot archiving, the range is 1 day to 100 years. If you enable snapshot archiving, the range is 0 days to 100 years. If you specify 0 days, snapshots are archived immediately after creation.

**Note**

- All schedules must have the same retention type (age-based or count-based). You can specify the retention type for Schedule 1 only. Schedules 2, 3, and 4 inherit the retention type from Schedule 1. Each schedule can have its own retention count or period.
- If you enable fast snapshot restore, cross-Region copy, or snapshot sharing, then you must specify a retention count of 1 or more, or a retention period of 1 day or longer.
- If you enable snapshot archiving, this retention rule determines how long the snapshot remains in the standard tier before being archived. Once the standard tier retention threshold is met, the snapshot is converted to a full snapshot and it is moved to the archive tier.

v. (For AWS Outposts customers only) For **Snapshot destination**, specify the destination for snapshots created by the policy.

- If the policy targets resources in a Region, snapshots must be created in the same Region. AWS Region is selected for you.
- If the policy targets resources on an Outpost, you can choose to create snapshots on the same Outpost as the source resource, or in the Region that is associated with the Outpost.
- If you do not have any Outposts in your account, this option is hidden and AWS Region is selected for you.

b. In the **Tagging** section, do the following:

i. To copy all of the user-defined tags from the source volume to the snapshots created by the schedule, select **Copy tags from source**.

ii. To specify additional tags to assign to snapshots created by this schedule, choose **Add tags**.

c. (Only for policies that target volumes) In the **Snapshot archiving** section, do the following:

**Note**

You can enable snapshot archiving for only one schedule in a policy.

i. To enable snapshot archiving for the schedule, select **Archive snapshots created by this schedule**.
Note
You can enable snapshot archiving only if the snapshot creation frequency is monthly or yearly, or if you specify a cron expression with a creation frequency of at least 28 days.

ii. Specify the retention rule for snapshots in the archive tier.

- For **count-based schedules**, specify the number of snapshots to retain in the archive tier. When the retention threshold is reached, the oldest snapshot is permanently deleted from the archive tier. For example, if you specify 3, the schedule will retain a maximum of 3 snapshots in the archive tier. When the fourth snapshot is archived, the oldest of the three existing snapshots in the archive tier is deleted.

- For **age-based schedules**, specify the time period for which to retain snapshots in the archive tier. When the retention threshold is reached, the oldest snapshot is permanently deleted from the archive tier. For example, if you specify 120 days, the schedule will automatically delete snapshots from the archive tier when they reach that age.

**Important**
The minimum retention period for archived snapshots is 90 days. You must specify a retention rule that retains the snapshot for at least 90 days.

d. To enable fast snapshot restore for snapshots created by the schedule, in the **Fast snapshot restore** section, select **Enable fast snapshot restore**. If you enable fast snapshot restore, you must choose the Availability Zones in which to enable it. If the schedule uses an age-based retention schedule, you must specify the period for which to enable fast snapshot restore for each snapshot. If the schedule uses count-based retention, you must specify the maximum number of snapshots to enable for fast snapshot restore.

If the schedule creates snapshots on an Outpost, you can't enable fast snapshot restore. Fast snapshot restore is not supported with local snapshots that are stored on an Outpost.

**Note**
You are billed for each minute that fast snapshot restore is enabled for a snapshot in a particular Availability Zone. Charges are pro-rated with a minimum of one hour.

e. To copy snapshots created by the schedule to an Outpost or to a different Region, in the **Cross-Region copy** section, select **Enable cross-Region copy**.

If the schedule creates snapshots in a Region, you can copy the snapshots to up to three additional Regions or Outposts in your account. You must specify a separate cross-Region copy rule for each destination Region or Outpost.

For each Region or Outpost, you can choose different retention policies and you can choose whether to copy all tags or no tags. If the source snapshot is encrypted, or if encryption by default is enabled, the copied snapshots are encrypted. If the source snapshot is unencrypted, you can enable encryption. If you do not specify a KMS key, the snapshots are encrypted using the default KMS key for EBS encryption in each destination Region. If you specify a KMS key for the destination Region, then the selected IAM role must have access to the KMS key.

**Note**
You must ensure that you do not exceed the number of concurrent snapshot copies per Region.

If the policy creates snapshots on an Outpost, then you can't copy the snapshots to a Region or to another Outpost and the cross-Region copy settings are not available.
Cross-account sharing

1. In the Cross-account sharing, configure the policy to automatically share the snapshots created by the schedule with other AWS accounts. Do the following:

   a. To enable sharing with other AWS accounts, select Enable cross-account sharing.
   b. To add the accounts with which to share the snapshots, choose Add account, enter the 12-digit AWS account ID, and choose Add.
   c. To automatically unshare shared snapshots after a specific period, select Unshare automatically. If you choose to automatically unshare shared snapshots, the period after which to automatically unshare the snapshots cannot be longer than the period for which the policy retains its snapshots. For example, if the policy's retention configuration retains snapshots for a period of 5 days, you can configure the policy to automatically unshare shared snapshots after periods up to 4 days. This applies to policies with age-based and count-based snapshot retention configurations.

2. If you do not enable automatic unsharing, the snapshot is shared until it is deleted.

   **Note**
   You can only share snapshots that are unencrypted or that are encrypted using a customer managed key. You can't share snapshots that are encrypted with the default EBS encryption KMS key. If you share encrypted snapshots, then you must also share the KMS key that was used to encrypt the source volume with the target accounts. For more information, see [Allowing users in other accounts to use a KMS key](https://docs.aws.amazon.com/awssdk/latest/userguide/API_KMS_Access.html) in the AWS Key Management Service (KMS) User Guide.

3. To add additional schedules, choose Add another schedule, which is located at the top of the screen. For each additional schedule, complete the fields as described previously in this topic.

4. After you have added the required schedules, choose Review policy.

5. Review the policy summary, and then choose Create policy.

**Command line**

Use the `create-lifecycle-policy` command to create a snapshot lifecycle policy. For PolicyType, specify EBS_SNAPSHOT_MANAGEMENT.

**Note**
To simplify the syntax, the following examples use a JSON file, policyDetails.json, that includes the policy details.

**Example 1—Snapshot lifecycle policy with two schedules**

This example creates a snapshot lifecycle policy that creates snapshots of all volumes that have a tag key of costcenter with a value of 115. The policy includes two schedules. The first schedule creates a snapshot every day at 03:00 UTC. The second schedule creates a weekly snapshot every Friday at 17:00 UTC.

```
aws dlm create-lifecycle-policy \
  --description "My volume policy" \
  --state ENABLED \
  --execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \
  --policy-details file://policyDetails.json
```

The following is an example of the policyDetails.json file.

```
{
  "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
  "ResourceTypes": ["Amazon Elastic Block Store Volume"
}
"VOLUME",
"
"TargetTags": [{
"Key": "costcenter",
"Value": "115"
}],
"Schedules": [{
"Name": "DailySnapshots",
"TagsToAdd": [{
"Key": "type",
"Value": "myDailySnapshot"
}],
"CreateRule": {
"Interval": 24,
"IntervalUnit": "HOURS",
"Times": [
"03:00"
],
"RetainRule": {
"Count": 5
},
"CopyTags": false
},{
"Name": "WeeklySnapshots",
"TagsToAdd": [{
"Key": "type",
"Value": "myWeeklySnapshot"
}],
"CreateRule": {
"CronExpression": "cron(0 17 ? * FRI *)"
},
"RetainRule": {
"Count": 5
},
"CopyTags": false
}]
}

If the request succeeds, the command returns the ID of the newly created policy. The following is example output.

```
{
   "PolicyId": "policy-0123456789abcdef0"
}
```

Example 2—Snapshot lifecycle policy that targets instances and creates snapshots of a subset of data (non-root) volumes

This example creates a snapshot lifecycle policy that creates multi-volume snapshot sets from instances tagged with `code=production`. The policy includes only one schedule. The schedule does not create snapshots of the data volumes that are tagged with `code=temp`.

```
aws dlm create-lifecycle-policy \
   --description "My volume policy" \
   --state ENABLED \
   --execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \
   --policy-details file://policyDetails.json
```

The following is an example of the `policyDetails.json` file.
Example 3—Snapshot lifecycle policy that automates local snapshots of Outpost resources

This example creates a snapshot lifecycle policy that creates snapshots of volumes tagged with team=dev across all of your Outposts. The policy creates the snapshots on the same Outposts as the source volumes. The policy creates snapshots every 12 hours starting at 00:00 UTC.

```
aws dlm create-lifecycle-policy
  --description "My local snapshot policy"
  --state ENABLED
  --execution-role-arn arn:aws:iam::123456789012:role/AWSDataLifecycleManagerDefaultRole
  --policy-details file://policyDetails.json
```

The following is an example of the policyDetails.json file.

```
{
  "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
  "ResourceTypes": [ "VOLUME" ],
  "TargetTags": [{
    "Key": "team",
    "Value": "dev"
  }],
  "Parameters": {
    "ExcludeResourceTags": [{
      "Key": "code",
      "Value": "temp"
    }]
  },
  "Schedules": [{
    "Name": "DailySnapshots",
    "TagsToAdd": [{
      "Key": "type",
      "Value": "myDailySnapshot"
    }],
    "CreateRule": {
      "Interval": 24,
      "IntervalUnit": "HOURS",
      "Times": [ "03:00" ]
    },
    "RetainRule": {
      "Count": 5
    },
    "CopyTags": false
  }]
}
```
"TargetTags": [{
    "Key": "team",
    "Value": "dev"
}]
},
"Schedules": [{
    "Name": "on-site backup",
    "CreateRule": {
        "Interval": 12,
        "IntervalUnit": "HOURS",
        "Times": [
            "00:00"
        ],
        "Location": [
            "OUTPOST_LOCAL"
        ]
    },
    "RetainRule": {
        "Count": 1
    },
    "CopyTags": false
}]
]

Example 4—Snapshot lifecycle policy that creates snapshots in a Region and copies them to an Outpost

The following example policy creates snapshots of volumes that are tagged with `team=dev`. Snapshots are created in the same Region as the source volume. Snapshots are created every 12 hours starting at 00:00 UTC, and retains a maximum of 1 snapshot. The policy also copies the snapshots to Outpost `arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0`, encrypts the copied snapshots using the default encryption KMS key, and retains the copies for 1 month.

```
aws dlm create-lifecycle-policy \
    --description "Copy snapshots to Outpost" \
    --state ENABLED \
    --execution-role-arn \
    arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \
    --policy-details file://policyDetails.json
```

The following is an example of the `policyDetails.json` file.

```
{
    "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
    "ResourceTypes": "VOLUME",
    "ResourceLocations": "CLOUD",
    "TargetTags": [{
        "Key": "team",
        "Value": "dev"
    }],
    "Schedules": [{
        "Name": "on-site backup",
        "CopyTags": false,
        "CreateRule": {
            "Interval": 12,
            "IntervalUnit": "HOURS",
            "Times": [
                "00:00"
            ],
            "Location": "CLOUD"
        },
        "RetainRule": {
            "Count": 1
        }
    }]
}
```
Example 5—Snapshot lifecycle policy with an archive-enabled, age-based schedule

This example creates a snapshot lifecycle policy that targets volumes tagged with `Name=Prod`. The policy has one age-based schedule that creates snapshots on the first day of each month at 09:00. The schedule retains each snapshot in the standard tier for one day, after which it moves them to the archive tier. Snapshots are stored in the archive tier for 90 days before being deleted.

```
aws dlm create-lifecycle-policy
  --description "Copy snapshots to Outpost"
  --state ENABLED
  --execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole
  --policy-details file://policyDetails.json
```

The following is an example of the `policyDetails.json` file.

```
{
  "ResourceTypes": [ "VOLUME"],
  "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
  "Schedules": [ 
    { 
      "Name": "sched1",
      "TagsToAdd": [ 
        {"Key":"createdby","Value":"dlm"}
      ],
      "CreateRule": { 
        "CronExpression": "cron(0 9 1 * ? *)"
      },
      "CopyTags": true,
      "RetainRule": { 
        "Interval": 1,
        "IntervalUnit": "DAYS"
      },
      "ArchiveRule": { 
        "RetainRule":{ 
          "RetentionArchiveTier": { 
            "Interval": 90,
            "IntervalUnit": "DAYS"
          }
        }
      }
    }
  ],
  "TargetTags": [ 
    { 
      "Key": "Name",
      "Value": "Prod"
    }
  ]
}
```
Example 6—Snapshot lifecycle policy with an archive-enabled, count-based schedule

This example creates a snapshot lifecycle policy that targets volumes tagged with Purpose=Test. The policy has one count-based schedule that creates snapshots on the first day of each month at 09:00. The schedule archives snapshots immediately after creation and retains a maximum of three snapshots in the archive tier.

```
aws dlm create-lifecycle-policy \
  --description "Copy snapshots to Outpost" \
  --state ENABLED \
  --execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \
  --policy-details file://policyDetails.json
```

The following is an example of the `policyDetails.json` file.

```
{
  "ResourceTypes": [ "VOLUME"],
  "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
  "Schedules": [
    {
      "Name": "sched1",
      "TagsToAdd": ["Key":"createdby" ,"Value":"dlm"],
      "CreateRule": {
        "CronExpression": "cron(0 9 1 * ? *)"
      },
      "CopyTags": true,
      "RetainRule": {
        "Count": 0
      },
      "ArchiveRule": {
        "RetainRule": {
          "RetentionArchiveTier": {
            "Count": 3
          }
        }
      }
    }
  ],
  "TargetTags": [
    {"Key": "Purpose",
     "Value": "Test"}
  ]
}
```

Considerations for snapshot lifecycle policies

The following general considerations apply to snapshot lifecycle policies:

- Snapshot lifecycle policies target only instances or volumes that are in the same Region as the policy.
- The first snapshot creation operation starts within one hour after the specified start time. Subsequent snapshot creation operations start within one hour of their scheduled time.
• You can create multiple policies to back up a volume or instance. For example, if a volume has two tags, where tag $A$ is the target for policy $A$ to create a snapshot every 12 hours, and tag $B$ is the target for policy $B$ to create a snapshot every 24 hours, Amazon Data Lifecycle Manager creates snapshots according to the schedules for both policies. Alternatively, you can achieve the same result by creating a single policy that has multiple schedules. For example, you can create a single policy that targets only tag $A$, and specify two schedules — one for every 12 hours and one for every 24 hours.

• Target resource tags are case sensitive.

• If you remove the target tags from a resource that is targeted by a policy, Amazon Data Lifecycle Manager no longer manages existing snapshots in the standard tier and archive tier; you must manually delete them if they are no longer needed.

• If you create a policy that targets instances, and new volumes are attached to a target instance after the policy has been created, the newly-added volumes are included in the backup at the next policy run. All volumes attached to the instance at the time of the policy run are included.

• If you create a policy with a custom cron-based schedule that is configured to create only one snapshot, the policy will not automatically delete that snapshot when the retention threshold is reached. You must manually delete the snapshot if it is no longer needed.

• If you create an age-based policy where the retention period is shorter than the creation frequency, Amazon Data Lifecycle Manager will always retain the last snapshot until the next one is created. For example, if an age-based policy creates one snapshot every month with a retention period of seven days, Amazon Data Lifecycle Manager will retain each snapshot for one month, even though the retention period is seven days.

The following considerations apply to snapshot archiving (p. 1840):

• You can enable snapshot archiving only for snapshot policies that target volumes.

• You can specify an archiving rule for only one schedule for each policy.

• If you are using the console, you can enable snapshot archiving only if the schedule has a monthly or yearly creation frequency, or if the schedule has a cron expression with a creation frequency of at least 28 days.

If you are using the AWS CLI, AWS API, or AWS SDK, you can enable snapshot archiving only if the schedule has a cron expression with a creation frequency of at least 28 days.

• The minimum retention period in the archive tier is 90 days.

• When a snapshot is archived, it is converted to a full snapshot when it is moved to the archive tier. This could result in higher snapshot storage costs. For more information, see Pricing and billing (p. 1842).

• Fast snapshot restore and snapshot sharing are disabled for snapshots when they are archived.

• If, in the case of a leap year, your retention rule results in an archive retention period of less than 90 days, Amazon Data Lifecycle Manager will always retain the last snapshot until the next one is created.

• If you manually archive a snapshot created by Amazon Data Lifecycle Manager, and the snapshot is still archived when the schedule's retention threshold is reached, Amazon Data Lifecycle Manager no longer manages that snapshot. However, if you restore the snapshot to the standard tier before the schedule's retention threshold is reached, the schedule will continue to manage the snapshot as per the retention rules.

• If you permanently or temporarily restore a snapshot archived by Amazon Data Lifecycle Manager to the standard tier, and the snapshot is still in the standard tier when the schedule's retention threshold is reached, Amazon Data Lifecycle Manager no longer manages the snapshot. However, if you re-archive the snapshot before the schedule's retention threshold is reached, the schedule will delete the snapshot when the retention threshold is met.

• Snapshots archived by Amazon Data Lifecycle Manager count towards your Archived snapshots per volume and In-progress snapshot archives per account quotas.

• If a schedule is unable to archive a snapshot after retrying for 24 hours, the snapshot remains in the standard tier and it is scheduled for deletion based on the time that it would have been deleted.
from the archive tier. For example, if the schedule archives snapshots for 120 days, it remains in the standard tier for 120 days after the failed archiving before being permanently deleted. For count-based schedules, the snapshot does not count towards the schedule's retention count.

- Snapshots must be archived in the same Region in which they were created. If you enabled cross-Region copy and snapshot archiving, Amazon Data Lifecycle Manager does not archive the snapshot copy.
- Snapshots archived by Amazon Data Lifecycle Manager are tagged with the `aws:dlm:archived=true` system tag. Additionally, snapshots created by an archive-enabled, age-based schedule are tagged with the `aws:dlm:expirationTime` system tag, which indicates the date and time at which the snapshot is scheduled to be archived.

The following considerations apply to excluding root volumes and data (non-root) volumes:

- If you choose to exclude boot volumes and you specify tags that consequently exclude all of the additional data volumes attached to an instance, then Amazon Data Lifecycle Manager will not create any snapshots for the affected instance, and it will emit a `SnapshotsCreateFailed` CloudWatch metric. For more information, see Monitor your policies using CloudWatch.

The following considerations apply to deleting volumes or terminating instances targeted by snapshot lifecycle policies:

- If you delete a volume or terminate an instance targeted by a policy with a count-based retention schedule, Amazon Data Lifecycle Manager no longer manages snapshots in the standard tier and archive tier that were created from the deleted volume or instance. You must manually delete those earlier snapshots if they are no longer needed.
- If you delete a volume or terminate an instance targeted by a policy with an age-based retention schedule, the policy continues to delete snapshots from the standard tier and archive tier that were created from the deleted volume or instance on the defined schedule, up to, but not including, the last snapshot. You must manually delete the last snapshot if it is no longer needed.

The following considerations apply to snapshot lifecycle policies and fast snapshot restore (p. 1988):

- Amazon Data Lifecycle Manager can enable fast snapshot restore only for snapshots with a size of 16 TiB or less. For more information, see Amazon EBS fast snapshot restore (p. 1988).
- A snapshot that is enabled for fast snapshot restore remains enabled even if you delete or disable the policy, disable fast snapshot restore for the policy, or disable fast snapshot restore for the Availability Zone. You must disable fast snapshot restore for these snapshots manually.
- If you enable fast snapshot restore for a policy and you exceed the maximum number of snapshots that can be enabled for fast snapshot restore, Amazon Data Lifecycle Manager creates snapshots as scheduled but does not enable them for fast snapshot restore. After a snapshot that is enabled for fast snapshot restore is deleted, the next snapshot that Amazon Data Lifecycle Manager creates is enabled for fast snapshot restore.
- When fast snapshot restore is enabled for a snapshot, it takes 60 minutes per TiB to optimize the snapshot. We recommend that you configure your schedules so that each snapshot is fully optimized before Amazon Data Lifecycle Manager creates the next snapshot.
- If you enable fast snapshot restore for a policy that targets instances, Amazon Data Lifecycle Manager enables fast snapshot restore for each snapshot in the multi-volume snapshot set individually. If Amazon Data Lifecycle Manager fails to enable fast snapshot restore for one of the snapshots in the multi-volume snapshot set, it will still attempt to enable fast snapshot restore for the remaining snapshots in the snapshot set.
- You are billed for each minute that fast snapshot restore is enabled for a snapshot in a particular Availability Zone. Charges are pro-rated with a minimum of one hour. For more information, see Pricing and Billing (p. 1993).
Note
Depending on the configuration of your lifecycle policies, you could have multiple snapshots enabled for fast snapshot restore in multiple Availability Zones simultaneously.

The following considerations apply to snapshot lifecycle policies and Multi-Attach (p. 1799) enabled volumes:

- When creating a lifecycle policy that targets instances that have the same Multi-Attach enabled volume, Amazon Data Lifecycle Manager initiates a snapshot of the volume for each attached instance. Use the timestamp tag to identify the set of time-consistent snapshots that are created from the attached instances.

The following considerations apply to sharing snapshots across accounts:

- You can only share snapshots that are unencrypted or that are encrypted using a customer managed key.
- You can't share snapshots that are encrypted with the default EBS encryption KMS key.
- If you share encrypted snapshots, you must also share the KMS key that was used to encrypt the source volume with the target accounts. For more information, see Allowing users in other accounts to use a KMS key in the AWS Key Management Service Developer Guide.

The following considerations apply to snapshots policies and snapshot archiving (p. 1840):

- If you manually archive a snapshot that was created by a policy, and that snapshot is in the archive tier when the policy's retention threshold is reached, Amazon Data Lifecycle Manager will not delete the snapshot. Amazon Data Lifecycle Manager does not manage snapshots while they are stored in the archive tier. If you no longer need snapshots that are stored in the archive tier, you must manually delete them.

The following considerations apply to snapshot policies and Recycle Bin (p. 2114):

- If Amazon Data Lifecycle Manager deletes a snapshot and sends it to the Recycle Bin when the policy's retention threshold is reached, you manually restore the snapshot from the Recycle Bin, you must manually delete that snapshot when it is no longer needed. Amazon Data Lifecycle Manager will no longer manage the snapshot.
- If you manually delete a snapshot that was created by a policy, and that snapshot is in the Recycle Bin when the policy's retention threshold is reached, Amazon Data Lifecycle Manager will not delete the snapshot. Amazon Data Lifecycle Manager does not manage the snapshots while they are stored in the Recycle Bin.

If the snapshot is restored from the Recycle Bin before the policy's retention threshold is reached, Amazon Data Lifecycle Manager will delete the snapshot when the policy's retention threshold is reached.

If the snapshot is restored from the Recycle Bin after the policy's retention threshold is reached, Amazon Data Lifecycle Manager will no longer delete the snapshot. You must manually delete the snapshot when it is no longer needed.

The following considerations apply to snapshot lifecycle policies that are in the error state:

- For policies with age-based retention schedules, snapshots that are set to expire while the policy is in the error state are retained indefinitely. You must delete the snapshots manually. When you re-
enable the policy, Amazon Data Lifecycle Manager resumes deleting snapshots as their retention periods expire.

- For policies with count-based retention schedules, the policy stops creating and deleting snapshots while it is in the error state. When you re-enable the policy, Amazon Data Lifecycle Manager resumes creating snapshots, and it resumes deleting snapshots as the retention threshold is met.

Additional resources

For more information, see the Automating Amazon EBS snapshot and AMI management using Amazon Data Lifecycle Manager AWS storage blog.

Automate AMI lifecycles

The following procedure shows you how to use Amazon Data Lifecycle Manager to automate EBS-backed AMI lifecycles.

Topics

- Create an AMI lifecycle policy (p. 1929)
- Considerations for AMI lifecycle policies (p. 1933)
- Additional resources (p. 1935)

Create an AMI lifecycle policy

Use one of the following procedures to create an AMI lifecycle policy.

Console

To create an AMI policy

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic Block Store, Lifecycle Manager, and then choose Create lifecycle policy.
3. On the Select policy type screen, choose EBS-backed AMI policy, and then choose Next.
4. In the Target resources section, for Target resource tags, choose the resource tags that identify the volumes or instances to back up. The policy backs up only the resources that have the specified tag key and value pairs.
5. For Description, enter a brief description for the policy.
6. For IAM role, choose the IAM role that has permissions to manage AMIs and snapshot and to describe instances. To use the default role provided by Amazon Data Lifecycle Manager, choose Default role. Alternatively, to use a custom IAM role that you previously created, choose Choose another role, and then select the role to use.
7. For Policy tags, add the tags to apply to the lifecycle policy. You can use these tags to identify and categorize your policies.
8. For Policy status after creation, choose Enable policy to start running the policy at the next scheduled time, or Disable policy to prevent the policy from running. If you do not enable the policy now, it will not start creating AMIs until you manually enable it after creation.
9. In the Instance reboot section, indicate whether instances should be rebooted before AMI creation. To prevent the targeted instances from being rebooted, choose No. Choosing No could cause data consistency issues. To reboot instances before AMI creation, choose Yes. Choosing this ensures data consistency, but could result in multiple targeted instances rebooting simultaneously.
10. Choose Next.
11. On the **Configure schedule** screen, configure the policy schedules. A policy can have up to four schedules. Schedule 1 is mandatory. Schedules 2, 3, and 4 are optional. For each policy schedule that you add, do the following:

   a. In the **Schedule details** section do the following:

      i. For **Schedule name**, specify a descriptive name for the schedule.

      ii. For **Frequency** and the related fields, configure the interval between policy runs. You can configure policy runs on a daily, weekly, monthly, or yearly schedule. Alternatively, choose **Custom cron expression** to specify an interval of up to one year. For more information, see [Cron expressions](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/CloudWatch-CronExpressions.html) in the *Amazon CloudWatch Events User Guide*.

      iii. For **Starting at**, specify the time to start the policy runs. The first policy run starts within an hour after the time that you schedule. You must enter the time in the `hh:mm` UTC format.

      iv. For **Retention type**, specify the retention policy for AMIs created by the schedule. You can retain AMIs based on either their total count or their age.

         - For count-based retention, the range is 1 to 1000. After the maximum count is reached, the oldest AMI is deregistered when a new one is created.

         - For age-based retention, the range is 1 day to 100 years. After the retention period of each AMI expires, it is deregistered.

         **Note**
         
         All schedules must have the same retention type. You can specify the retention type for Schedule 1 only. Schedules 2, 3, and 4 inherit the retention type from Schedule 1. Each schedule can have its own retention count or period.

   b. In the **Tagging** section, do the following:

      i. To copy all of the user-defined tags from the source instance to the AMIs created by the schedule, select **Copy tags from source**.

      ii. By default, AMIs created by the schedule are automatically tagged with the ID of the source instance. To prevent this automatic tagging from happening, for **Variable tags**, remove the `instance-id:$(instance-id)` tile.

      iii. To specify additional tags to assign to AMIs created by this schedule, choose **Add tags**.

   c. To deprecate AMIs when they should no longer be used, in the **AMI deprecation** section, select **Enable AMI deprecation for this schedule** and then specify the AMI deprecation rule. The AMI deprecation rule specifies when AMIs are to be deprecated.

      If the schedule uses count-based AMI retention, you must specify the number of oldest AMIs to deprecate. The deprecation count must be less than or equal to the schedule's AMI retention count, and it can't be greater than 1000. For example, if the schedule is configured to retain a maximum of 5 AMIs, then you can configure the scheduled to deprecate up to 5 oldest AMIs.

      If the schedule uses age-based AMI retention, you must specify the period after which AMIs are to be deprecated. The deprecation count must be less than or equal to the schedule's AMI retention period, and it can't be greater than 10 years (120 months, 520 weeks, or 3650 days). For example, if the schedule is configured to retain AMIs for 10 days, then you can configure the scheduled to deprecate AMIs after periods up to 10 days after creation.

   d. To copy AMIs created by the schedule to different Regions, in the **Cross-Region copy** section, select **Enable cross-Region copy**. You can copy AMIs to up to three additional Regions in your account. You must specify a separate cross-Region copy rule for each destination Region.

      For each destination Region, you can specify the following:

1930
• A retention policy for the AMI copy. When the retention period expires, the copy in the destination Region is automatically deregistered.

• Encryption status for the AMI copy. If the source AMI is encrypted, or if encryption by default is enabled, the copied AMIs are always encrypted. If the source AMI is unencrypted and encryption by default is disabled, you can optionally enable encryption. If you do not specify a KMS key, the AMIs are encrypted using the default KMS key for EBS encryption in each destination Region. If you specify a KMS key for the destination Region, then the selected IAM role must have access to the KMS key.

• A deprecation rule for the AMI copy. When the deprecation period expires, the AMI copy is automatically deprecated. The deprecation period must be less than or equal to the copy retention period, and it can't be greater than 10 years.

• Whether to copy all tags or no tags from the source AMI.

Note
Do not exceed the number of concurrent AMI copies per Region.

e. To add additional schedules, choose Add another schedule, which is located at the top of the screen. For each additional schedule, complete the fields as described previously in this topic.

f. After you have added the required schedules, choose Review policy.

12. Review the policy summary, and then choose Create policy.

Command line
Use the create-lifecycle-policy command to create an AMI lifecycle policy. For PolicyType, specify IMAGE_MANAGEMENT.

Note
To simplify the syntax, the following examples use a JSON file, policyDetails.json, that includes the policy details.

Example 1: Age-based retention and AMI deprecation

This example creates an AMI lifecycle policy that creates AMIs of all instances that have a tag key of purpose with a value of production without rebooting the targeted instances. The policy includes one schedule that creates an AMI every day at 01:00 UTC. The policy retains AMIs for 2 days and deprecates them after 1 day. It also copies the tags from the source instance to the AMIs that it creates.

```bash
aws dlm create-lifecycle-policy \
--description "My AMI policy" \
--state ENABLED \
--execution-role-arn \narn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRoleForAMIManagement \n--policy-details file:///policyDetails.json
```

The following is an example of the policyDetails.json file.

```json
{
 "PolicyType": "IMAGE_MANAGEMENT",
 "ResourceTypes": [
 "INSTANCE"
 ],
 "TargetTags": [{
 "Key": "purpose",
 "Value": "production"
 }],
}
"Schedules": [{
    "Name": "DailyAMIs",
    "TagsToAdd": [{
        "Key": "type",
        "Value": "myDailyAMI"
    }],
    "CreateRule": {
        "Interval": 24,
        "IntervalUnit": "HOURS",
        "Times": ["01:00"]
    },
    "RetainRule": {
        "Interval": 2,
        "IntervalUnit": "DAYS"
    },
    "DeprecateRule": {
        "Interval": 1,
        "IntervalUnit": "DAYS"
    },
    "CopyTags": true
},
"Parameters": {
    "NoReboot": true
}]
}

If the request succeeds, the command returns the ID of the newly created policy. The following is example output.

```
{
    "PolicyId": "policy-9876543210abcdef0"
}
```

**Example 2: Count-based retention and AMI deprecation with cross-Region copy**

This example creates an AMI lifecycle policy that creates AMIs of all instances that have a tag key of purpose with a value of production and reboots the target instances. The policy includes one schedule that creates an AMI every 6 hours starting at 17:30 UTC. The policy retains 3 AMIs and automatically deprecates the 2 oldest AMIs. It also has a cross-Region copy rule that copies AMIs to us-east-1, retains 2 AMI copies, and automatically deprecates the oldest AMI.

```
aws dlm create-lifecycle-policy --description "My AMI policy" --state ENABLED --execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRoleForAMIManagement --policy-details file://policyDetails.json
```

The following is an example of the policyDetails.json file.

```
{
    "PolicyType": "IMAGE_MANAGEMENT",
    "ResourceTypes": ["INSTANCE"],
    "TargetTags": [[
        "Key": "purpose",
        "Value": "production"
    ]],
}
Considerations for AMI lifecycle policies

The following general considerations apply to creating AMI lifecycle policies:

- AMI lifecycle policies target only instances that are in the same Region as the policy.
- The first AMI creation operation starts within one hour after the specified start time. Subsequent AMI creation operations start within one hour of their scheduled time.
- When Amazon Data Lifecycle Manager deregisters an AMI, it automatically deletes it backing snapshots.
- Target resource tags are case sensitive.
- If you remove the target tags from an instance that is targeted by a policy, Amazon Data Lifecycle Manager no longer manages existing AMIs in the standard; you must manually delete them if they are no longer needed.
- You can create multiple policies to back up an instance. For example, if an instance has two tags, where tag A is the target for policy A to create an AMI every 12 hours, and tag B is the target for policy B to create an AMI every 24 hours, Amazon Data Lifecycle Manager creates AMIs according to the schedules for both policies. Alternatively, you can achieve the same result by creating a single policy that has multiple schedules. For example, you can create a single policy that targets only tag A, and specify two schedules — one for every 12 hours and one for every 24 hours.
- New volumes that are attached to a target instance after the policy has been created are automatically included in the backup at the next policy run. All volumes attached to the instance at the time of the policy run are included.
- If you create a policy with a custom cron-based schedule that is configured to create only one AMI, the policy will not automatically deregister that AMI when the retention threshold is reached. You must manually deregister the AMI if it is no longer needed.
• If you create an age-based policy where the retention period is shorter than the creation frequency, Amazon Data Lifecycle Manager will always retain the last AMI until the next one is created. For example, if an age-based policy creates one AMI every month with a retention period of seven days, Amazon Data Lifecycle Manager will retain each AMI for one month, even though the retention period is seven days.

• For count-based policies, Amazon Data Lifecycle Manager always creates AMIs according to the creation frequency before attempting to deregister the oldest AMI according to the retention policy.

• It can take several hours to successfully deregister an AMI and to delete its associated backing snapshots. If Amazon Data Lifecycle Manager creates the next AMI before the previously created AMI is successfully deregistered, you could temporarily retain a number of AMIs that is greater than your retention count.

The following considerations apply to terminating instances targeted by a policy:

• If you terminate an instance that was targeted by a policy with a count-based retention schedule, the policy no longer manages the AMIs that it previously created from the terminated instance. You must manually deregister those earlier AMIs if they are no longer needed.

• If you terminate an instance that was targeted by a policy with an age-based retention schedule, the policy continues to deregister AMIs that were previously created from the terminated instance on the defined schedule, up to, but not including, the last AMI. You must manually deregister the last AMI if it is no longer needed.

The following considerations apply to AMI policies and AMI deprecation:

• If you increase the AMI deprecation count for a schedule with count-based retention, the change is applied to all AMIs (existing and new) created by the schedule.

• If you increase the AMI deprecation period for a schedule with age-based retention, the change is applied to new AMIs only. Existing AMIs are not affected.

• If you remove the AMI deprecation rule from a schedule, Amazon Data Lifecycle Manager will not cancel deprecation for AMIs that were previously deprecated by that schedule.

• If you decrease the AMI deprecation count or period for a schedule, Amazon Data Lifecycle Manager will not cancel deprecation for AMIs that were previously deprecated by that schedule.

• If you manually deprecate an AMI that was created by an AMI policy, Amazon Data Lifecycle Manager will not override the deprecation.

• If you manually cancel deprecation for an AMI that was previously deprecated by an AMI policy, Amazon Data Lifecycle Manager will not override the cancellation.

• If an AMI is created by multiple conflicting schedules, and one or more of those schedules do not have an AMI deprecation rule, Amazon Data Lifecycle Manager will not deprecate that AMI.

• If an AMI is created by multiple conflicting schedules, and all of those schedules have an AMI deprecation rule, Amazon Data Lifecycle Manager will use the deprecation rule that results in the latest deprecation date.

The following considerations apply to AMI policies and Recycle Bin (p. 2114):

• If Amazon Data Lifecycle Manager deregisters an AMI and sends it to the Recycle Bin when the policy's retention threshold is reached, and you manually restore that AMI from the Recycle Bin, you must manually deregister the AMI when it is no longer needed. Amazon Data Lifecycle Manager will no longer manage the AMI.

• If you manually deregister an AMI that was created by a policy, and that AMI is in the Recycle Bin when the policy's retention threshold is reached, Amazon Data Lifecycle Manager will not deregister the AMI. Amazon Data Lifecycle Manager does not manage AMIs while they are in the Recycle Bin.
If the AMI is restored from the Recycle Bin before the policy's retention threshold is reached, Amazon Data Lifecycle Manager will deregister the AMI when the policy's retention threshold is reached.

If the AMI is restored from the Recycle Bin after the policy's retention threshold is reached, Amazon Data Lifecycle Manager will no longer deregister the AMI. You must manually delete it when it is no longer needed.

The following considerations apply to AMI policies that are in the **error** state:

- For policies with age-based retention schedules, AMIs that are set to expire while the policy is in the **error** state are retained indefinitely. You must deregister the AMIs manually. When you re-enable the policy, Amazon Data Lifecycle Manager resumes deregistering AMIs as their retention periods expire.
- For policies with count-based retention schedules, the policy stops creating and deregistering AMIs while it is in the **error** state. When you re-enable the policy, Amazon Data Lifecycle Manager resumes creating AMIs, and it resumes deregistering AMIs as the retention threshold is met.

**Additional resources**

For more information, see the [Automating Amazon EBS snapshot and AMI management using Amazon Data Lifecycle Manager](https://aws.amazon.com/blogs/storage/automating-amazon-ebs-snapshot-and-ami-management-using-amazon-data-lifecycle-manager) AWS storage blog.

**Automate cross-account snapshot copies**

Automating cross-account snapshot copies enables you to copy your Amazon EBS snapshots to specific Regions in an isolated account and encrypt those snapshots with an encryption key. This enables you to protect yourself against data loss in the event of your account being compromised.

Automating cross-account snapshot copies involves two accounts:

- **Source account**—The source account is the account that creates and shares the snapshots with the target account. In this account, you must create an EBS snapshot policy that creates snapshots at set intervals and then shares them with other AWS accounts.

- **Target account**—The target account is the account with destination account with which the snapshots are shared, and it is the account that creates copies of the shared snapshots. In this account, you must create a cross-account copy event policy that automatically copies snapshots that are shared with it by one or more specified source accounts.

**Topics**

**Create cross-account snapshot copy policies**

To prepare the source and target accounts for cross-account snapshot copying, you need to perform the following steps:

**Topics**

Step 1: Create the EBS snapshot policy (Source account)

In the source account, create an EBS snapshot policy that will create the snapshots and share them with the required target accounts.

When you create the policy, ensure that you enable cross-account sharing and that you specify the target AWS accounts with which to share the snapshots. These are the accounts with which the snapshots are to be shared. If you are sharing encrypted snapshots, then you must give the selected target accounts permission to use the KMS key used to encrypt the source volume. For more information, see Step 2: Share the customer managed key (Source account) (p. 1936).

Note
You can only share snapshots that are unencrypted or that are encrypted using a customer managed key. You can’t share snapshots that are encrypted with the default EBS encryption KMS key. If you share encrypted snapshots, then you must also share the KMS key that was used to encrypt the source volume with the target accounts. For more information, see Allowing users in other accounts to use a KMS key in the AWS Key Management Service Developer Guide.

For more information about creating an EBS snapshot policy, see Automate snapshot lifecycles (p. 1916).

Use one of the following methods to create the EBS snapshot policy.

Step 2: Share the customer managed key (Source account)

If you are sharing encrypted snapshots, you must grant the IAM role and the target AWS accounts (that you selected in the previous step) permissions to use the customer managed key that was used to encrypt the source volume.

Note
Perform this step only if you are sharing encrypted snapshots. If you are sharing unencrypted snapshots, skip this step.

Console

2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose Customer managed key and then select the KMS key that you need to share with the target accounts.
   
   Make note of the KMS key ARN, you’ll need this later.
4. On the Key policy tab, scroll down to the Key users section. Choose Add, enter the name of the IAM role that you selected in the previous step, and then choose Add.
5. On the Key policy tab, scroll down to the Other AWS accounts section. Choose Add other AWS accounts, and then add all of the target AWS accounts that you chose to share the snapshots with in the previous step.
6. Choose Save changes.

Command line

Use the get-key-policy command to retrieve the key policy that is currently attached to the KMS key.

For example, the following command retrieves the key policy for a KMS key with an ID of 9d5e2b3d-e410-4a27-a958-19e220d83a1e and writes it to a file named snapshotKey.json.

```bash
$ aws kms get-key-policy \
```
Open the key policy using your preferred text editor. Add the ARN of the IAM role that you specified when you created the snapshot policy and the ARNs of the target accounts with which to share the KMS key.

For example, in the following policy, we added the ARN of the default IAM role, and the ARN of the root account for target account 222222222222.

Tip
To follow the principle of least privilege, do not allow full access to kms:CreateGrant. Instead, use the kms:GrantIsForAWSResource condition key to allow the user to create grants on the KMS key only when the grant is created on the user’s behalf by an AWS service, as shown in the following example.

```
{
    "Sid": "Allow use of the key",
    "Effect": "Allow",
    "Principal": {
        "AWS": [
            "arn:aws:iam::111111111111:role/service-role/AWSDataLifecycleManagerDefaultRole",
            "arn:aws:iam::222222222222:root"
        ]
    },
    "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:DescribeKey"
    ],
    "Resource": "*"
},
{
    "Sid": "Allow attachment of persistent resources",
    "Effect": "Allow",
    "Principal": {
        "AWS": [
            "arn:aws:iam::111111111111:role/service-role/AWSDataLifecycleManagerDefaultRole",
            "arn:aws:iam::222222222222:root"
        ]
    },
    "Action": [
        "kms:CreateGrant",
        "kms:ListGrants",
        "kms:RevokeGrant"
    ],
    "Resource": "*",
    "Condition": {
        "Bool": {
            "kms:GrantIsForAWSResource": "true"
        }
    }
}
```

Save and close the file. Then use the **put-key-policy** command to attach the updated key policy to the KMS key.
$ aws kms put-key-policy \
   --policy-name default \
   --key-id 9d5e2b3d-e410-4a27-a958-19e220d83a1e \
   --policy file://snapshotKey.json

Step 3: Create cross-account copy event policy (Target account)

In the target account, you must create a cross-account copy event policy that will automatically copy
snapshots that are shared by the required source accounts.

This policy runs in the target account only when one of the specified source accounts shares snapshot
with the account.

Use one of the following methods to create the cross-account copy event policy.

Console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic Block Store, Lifecycle Manager, and then choose Create
   lifecycle policy.
3. On the Select policy type screen, choose Cross-account copy event policy, and then choose Next.
4. For Policy description, enter a brief description for the policy.
5. For Policy tags, add the tags to apply to the lifecycle policy. You can use these tags to identify
   and categorize your policies.
6. In the Event settings section, define the snapshot sharing event that will cause the policy to
   run. Do the following:
   a. For Sharing accounts, specify the source AWS accounts from which you want to copy
      the shared snapshots. Choose Add account, enter the 12-digit AWS account ID, and then
      choose Add.
   b. For Filter by description, enter the required snapshot description using a regular
      expression. Only snapshots that are shared by the specified source accounts and that have
      descriptions that match the specified filter are copied by the policy. For more information,
      see Specify snapshot description filters (p. 1942).
7. For IAM role, choose the IAM role that has permissions to perform snapshot copy actions. To use
   the default role provided by Amazon Data Lifecycle Manager, choose Default role. Alternatively,
   to use a custom IAM role that you previously created, choose Choose another role and then
   select the role to use.

   If you are copying encrypted snapshots, you must grant the selected IAM role permissions to
   use the encryption KMS key used to encrypt the source volume. Similarly, if you are encrypting
   the snapshot in the destination Region using a different KMS key, you must grant the IAM role
   permission to use the destination KMS key. For more information, see Step 4: Allow IAM role to
   use the required KMS keys (Target account) (p. 1940).
8. In the Copy action section, define the snapshot copy actions that the policy should perform
   when it is activated. The policy can copy snapshots to up to three Regions. You must specify a
   separate copy rule for each destination Region. For each rule that you add, do the following:
   a. For Name, enter a descriptive name for the copy action.
   b. For Target Region, select the Region to which to copy the snapshots.
   c. For Expire, specify how long to retain the snapshot copies in the target Region after
      creation.
   d. To encrypt the snapshot copy, for Encryption, select Enable encryption. If the source
      snapshot is encrypted, or if encryption by default is enabled for your account, the snapshot
copy is always encrypted, even if you do not enable encryption here. If the source snapshot is unencrypted and encryption by default is not enabled for your account, you can choose to enable or disable encryption. If you enable encryption, but do not specify a KMS key, the snapshots are encrypted using the default encryption KMS key in each destination Region. If you specify a KMS key for the destination Region, you must have access to the KMS key.

9. To add additional snapshot copy actions, choose Add new Regions.

10. For Policy status after creation, choose Enable policy to start the policy runs at the next scheduled time, or Disable policy to prevent the policy from running. If you do not enable the policy now, it will not start copying snapshots until you manually enable it after creation.

11. Choose Create policy.

Command line

Use the create-lifecycle-policy command to create a policy. To create a cross-account copy event policy, for PolicyType, specify EVENT_BASED_POLICY.

For example, the following command creates a cross-account copy event policy in target account 222222222222. The policy copies snapshots that are shared by source account 111111111111. The policy copies snapshots to sa-east-1 and eu-west-2. Snapshots copied to sa-east-1 are unencrypted and they are retained for 3 days. Snapshots copied to eu-west-2 are encrypted using KMS key 8af79514-350d-4c52-bac8-8985e84171c7 and they are retained for 1 month. The policy uses the default IAM role.

```
$ aws dlm create-lifecycle-policy \
  --description "Copy policy" \
  --state ENABLED \
  --execution-role-arn arn:aws:iam::222222222222:role/service-role/AWSDataLifecycleManagerDefaultRole \
  --policy-details file://policyDetails.json
```

The following shows the contents of the policyDetails.json file.

```
{
  "PolicyType" : "EVENT_BASED_POLICY",
  "EventSource" : {
    "Type" : "MANAGED_CWE",
    "Parameters": {
      "EventType" : "shareSnapshot",
      "SnapshotOwner": ["111111111111"
    }
} ,
  "Actions" : [{
    "Name":"Copy Snapshot to Sao Paulo and London",
    "CrossRegionCopy" : [{
      "Target" : "sa-east-1",
      "EncryptionConfiguration" : {
        "Encrypted" : false
      },
      "RetainRule" : {
        "Interval" : 3,
        "IntervalUnit" : "DAYS"
      }
    },
    { 
      "Target" : "eu-west-2",
      "EncryptionConfiguration" : { 
        "Encrypted" : true,
        "CmkArn" : "arn:aws:kms:eu-west-2:222222222222:key/8af79514-350d-4c52-bac8-8985e84171c7"
    }
  }
```
If the request succeeds, the command returns the ID of the newly created policy. The following is example output.

```
{
  "PolicyId": "policy-9876543210abcdef0"
}
```

**Step 4: Allow IAM role to use the required KMS keys (Target account)**

If you are copying encrypted snapshots, you must grant the IAM role (that you selected in the previous step) permissions to use the customer managed key that was used to encrypt the source volume.

**Note**

Only perform this step if you are copying encrypted snapshots. If you are copying unencrypted snapshots, skip this step.

Use one of the following methods to add the required policies to the IAM role.

**Console**

2. In the navigation pane, select Roles. Search for and select the IAM role that you selected when you created the cross-account copy event policy in the previous step. If you chose to use the default role, the role is named `AWSDataLifecycleManagerDefaultRole`.
3. Choose Add inline policy and then select the JSON tab.
4. Replace the existing policy with the following, and specify the ARN of the KMS key that was used to encrypt the source volumes and that was shared with you by the source account in Step 2.

   **Note**

   If you are copying from multiple source accounts, then you must specify the corresponding KMS key ARN from each source account.

In the following example, the policy grants the IAM role permission to use KMS key 1234abcd-12ab-34cd-56ef-1234567890ab, which was shared by source account 111111111111, and KMS key 4567dcba-23ab-34cd-56ef-0987654321yz, which exists in target account 222222222222.

   **Tip**

   To follow the principle of least privilege, do not allow full access to kms:CreateGrant. Instead, use the kms:GrantIsForAWSResource condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service, as shown in the following example.

   ```json
   {
      "Version": "2012-10-17",
      "Statement": [
      
      ]
   }
   ```
Choose Review policy

6. For Name, enter a descriptive name for the policy, and then choose Create policy.

Command line

Using your preferred text editor, create a new JSON file named policyDetails.json. Add the following policy and specify the ARN of the KMS key that was used to encrypt the source volumes and that was shared with you by the source account in Step 2.

Note
If you are copying from multiple source accounts, then you must specify the corresponding KMS key ARN from each source account.

In the following example, the policy grants the IAM role permission to use KMS key 1234abcd-12ab-34cd-56ef-1234567890ab, which was shared by source account 111111111111, and KMS key 4567dcba-23ab-34cd-56ef-0987654321yz, which exists in target account 222222222222.

Tip
To follow the principle of least privilege, do not allow full access to kms:CreateGrant. Instead, use the kms:GrantIsForAWSResource condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service, as shown in the following example.
"Version": "2012-10-17",
"Statement": [
{
  "Effect": "Allow",
  "Action": [
    "kms:RevokeGrant",
    "kms:CreateGrant",
    "kms:ListGrants"
  ],
  "Resource": [
    "arn:aws:kms:us-east-1:111111111111:key/1234abcd-12ab-34cd-56ef-1234567890ab",
    "arn:aws:kms:us-east-1:222222222222:key/4567dcba-23ab-34cd-56ef-0987654321yz"
  ],
  "Condition": {
    "Bool": {
      "kms:GrantIsForAWSResource": "true"
    }
  }
},
{
  "Effect": "Allow",
  "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey*",
    "kms:DescribeKey"
  ],
  "Resource": [
    "arn:aws:kms:us-east-1:111111111111:key/1234abcd-12ab-34cd-56ef-1234567890ab",
    "arn:aws:kms:us-east-1:222222222222:key/4567dcba-23ab-34cd-56ef-0987654321yz"
  ]
}
]

Save and close the file. Then use the `put-role-policy` command to add the policy to the IAM role.

For example

```
$ aws iam put-role-policy
  --role-name AWSDataLifecycleManagerDefaultRole
  --policy-name CopyPolicy
  --policy-document file://AdminPolicy.json
```

**Specify snapshot description filters**

When you create the snapshot copy policy in the target account, you must specify a snapshot description filter. The snapshot description filter enables you to specify an additional level of filtering that lets you control which snapshots are copied by the policy. This means that a snapshot is only copied by the policy if it is shared by one of the specified source accounts, and it has a snapshot description that matches the specified filter. In other words, if a snapshot is shared by one of the specified source accounts, but it does not have a description that matches the specified filter, it is not copied by the policy.

The snapshot filter description must be specified using a regular expression. It is a mandatory field when creating cross-account copy event policies using the console and the command line. The following are example regular expressions that can be used:
• .*—This filter matches all snapshot descriptions. If you use this expression the policy will copy all snapshots that are shared by one of the specified source accounts.

• Created for policy: policy-0123456789abcdef0.*—This filter matches only snapshots that are created by a policy with an ID of policy-0123456789abcdef0. If you use an expression like this, only snapshots that are shared with your account by one of the specified source accounts, and that have been created by a policy with the specified ID are copied by the policy.

• .*production.*—This filter matches any snapshot that has the word production anywhere in its description. If you use this expression the policy will copy all snapshots that are shared by one of the specified source accounts and that have the specified text in their description.

Considerations for cross-account snapshot copy policies

The following considerations apply to cross-account copy event policies:

• You can only copy snapshots that are unencrypted or that are encrypted using a customer managed key.

• You can create a cross-account copy event policy to copy snapshots that are shared outside of Amazon Data Lifecycle Manager.

• If you want to encrypt snapshots in the target account, then the IAM role selected for the cross-account copy event policy must have permission to use the required KMS key.

Additional resources

For more information, see the Automating copying encrypted Amazon EBS snapshots across AWS accounts AWS storage blog.

View, modify, and delete lifecycle policies

Use the following procedures to view, modify and delete existing lifecycle policies.

Topics

• View lifecycle policies (p. 1943)
• Modify lifecycle policies (p. 1944)
• Delete lifecycle policies (p. 1802)

View lifecycle policies

Use one of the following procedures to view a lifecycle policy.

Console

To view a lifecycle policy

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic Block Store, Lifecycle Manager.
3. Select a lifecycle policy from the list. The Details tab displays information about the policy.

Command line

Use the get-lifecycle-policy command to display information about a lifecycle policy.

aws dlm get-lifecycle-policy --policy-id policy-0123456789abcdef0

1943
The following is example output. It includes the information that you specified, plus metadata inserted by AWS.

```json
{
   "Policy": {
      "Description": "My first policy",
      "DateCreated": "2018-05-15T00:16:21+0000",
      "State": "ENABLED",
      "ExecutionRoleArn": "arn:aws:iam::210774411744:role/AWSDataLifecycleManagerDefaultRole",
      "PolicyId": "policy-0123456789abcdef0",
      "DateModified": "2018-05-15T00:16:22+0000",
      "PolicyDetails": {
         "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
         "ResourceTypes": ["VOLUME"],
         "TargetTags": [
            {
               "Value": "115",
               "Key": "costcenter"
            }
         ],
         "Schedules": [
            {
               "TagsToAdd": [
                  {
                     "Value": "myDailySnapshot",
                     "Key": "type"
                  }
               ],
               "RetainRule": {
                  "Count": 5
               },
               "CopyTags": false,
               "CreateRule": {
                  "Interval": 24,
                  "IntervalUnit": "HOURS",
                  "Times": [
                     "03:00"
                  ],
                  "Name": "DailySnapshots"
               }
            }
         ]
      }
   }
}
```

Modify lifecycle policies

Considerations for modifying policies

- If you modify an AMI or snapshot policy by removing its target tags, the volumes or instances with those tags are no longer managed by the policy.
- If you modify a schedule name, the snapshots or AMIs created under the old schedule name are no longer managed by the policy.
- If you modify an age-based retention schedule to use a new time interval, the new interval is used only for new snapshots or AMIs created after the change. The new schedule does not affect the retention schedule of snapshots or AMIs created before the change.
You cannot change the retention schedule of a policy from count-based to age-based after creation. To make this change, you must create a new policy.

If you disable a policy with an age-based retention schedule, the snapshots or AMIs that are set to expire while the policy is disabled are retained indefinitely. You must delete the snapshots or deregister the AMIs manually. When you re-enable the policy, Amazon Data Lifecycle Manager resumes deleting snapshots or deregistering AMIs as their retention periods expire.

If you disable a policy with a count-based retention schedule, the policy stops creating and deleting snapshots or AMIs. When you re-enable the policy, Amazon Data Lifecycle Manager resumes creating snapshots and AMIs, and it resumes deleting snapshots or AMIs as the retention threshold is met.

If you disable a policy that has a snapshot archiving-enabled policy, snapshots that are in the archive tier at the time of disabling the policy are no longer managed by Amazon Data Lifecycle Manager. You must manually delete the snapshot if they are no longer needed.

If you enable snapshot archiving on a count-based schedule, the archiving rule applies to all new snapshots that are created and archived by the schedule, and also applies to existing snapshots that were previously created and archived.

If you enable snapshot archiving on an age-based schedule, the archiving rule applies only to new snapshots created after enabling snapshot archiving. Existing snapshots created before enabling snapshot archiving continue to be deleted from their respective storage tiers, according to the schedule set when those snapshots were originally created and archived.

If you disable snapshot archiving for a count-based schedule, the schedule immediately stops archiving snapshots. Snapshots that were previously archived by the schedule remain in the archive tier and they will not be deleted by Amazon Data Lifecycle Manager.

If you disable snapshot archiving for an age-based schedule, the snapshots created by the policy and that are scheduled to be archived are permanently deleted at the scheduled archive date and time, as indicated by the \texttt{aws:dlm:expirationTime} system tag.

If you disable snapshot archiving for a schedule, the schedule immediately stops archiving snapshots. Snapshots that were previously archived by the schedule remain in the archive tier and they will not be deleted by Amazon Data Lifecycle Manager.

If you modify the archive retention count for a count-based schedule, the new retention count includes existing snapshots that were previously archived by the schedule.

If you modify the archive retention period for an age-based schedule, the new retention period applies only to snapshots that are archived after modifying the retention rule.

Use one of the following procedures to modify a lifecycle policy.

**Console**

**To modify a lifecycle policy**

1. Open the Amazon EC2 console at \url{https://console.aws.amazon.com/ec2/}.
2. In the navigation pane, choose **Elastic Block Store, Lifecycle Manager**.
3. Select a lifecycle policy from the list.
4. Choose **Actions, Modify Lifecycle Policy**.
5. Modify the policy settings as needed. For example, you can modify the schedule, add or remove tags, or enable or disable the policy.
6. Choose **Update policy**.

**Command line**

Use the `update-lifecycle-policy` command to modify the information in a lifecycle policy. To simplify the syntax, this example references a JSON file, `policyDetailsUpdated.json`, that includes the policy details.
The following is an example of the policyDetailsUpdated.json file.

```json
{
  "ResourceTypes": ["VOLUME"],
  "TargetTags": [
    {
      "Key": "costcenter",
      "Value": "120"
    }
  ],
  "Schedules": [
    {
      "Name": "DailySnapshots",
      "TagsToAdd": [
        {
          "Key": "type",
          "Value": "myDailySnapshot"
        }
      ],
      "CreateRule": {
        "Interval": 12,
        "IntervalUnit": "HOURS",
        "Times": [
          "15:00"
        ]
      },
      "RetainRule": {
        "Count": 5
      },
      "CopyTags": false
    }
  ]
}
```

To view the updated policy, use the `get-lifecycle-policy` command. You can see that the state, the value of the tag, the snapshot interval, and the snapshot start time were changed.

### Delete lifecycle policies

#### Considerations for modifying policies

- If you delete a policy, the snapshots or AMIs created by that policy are not automatically deleted. If you no longer need the snapshots or AMIs, you must delete them manually.
- If you delete a policy that has a snapshot archiving-enabled policy, snapshots that are in the archive tier at the time of deleting the policy are no longer managed by Amazon Data Lifecycle Manager. You must manually delete the snapshot if they are no longer needed.
- If you delete a policy with an archive-enabled, age-based schedule, the snapshots created by the policy and that are scheduled to be archived are permanently deleted at the scheduled archive date and time, as indicated by the `aws:dlm:expirationtime` system tag.

Use one of the following procedures to delete a lifecycle policy.
Console

To delete a lifecycle policy

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic Block Store, Lifecycle Manager.
3. Select a lifecycle policy from the list.
4. Choose Actions, Delete Lifecycle Policy.
5. When prompted for confirmation, choose Delete Lifecycle Policy.

Command line

Use the delete-lifecycle-policy command to delete a lifecycle policy and free up the target tags specified in the policy for reuse.

Note
You can delete snapshots created only by Amazon Data Lifecycle Manager.

```
aws dlm delete-lifecycle-policy --policy-id policy-0123456789abcdef0
```

The Amazon Data Lifecycle Manager API Reference provides descriptions and syntax for each of the actions and data types for the Amazon Data Lifecycle Manager Query API.

Alternatively, you can use one of the AWS SDKs to access the API in a way that's tailored to the programming language or platform that you're using. For more information, see AWS SDKs.

AWS Identity and Access Management

Access to Amazon Data Lifecycle Manager requires credentials. Those credentials must have permissions to access AWS resources, such as instances, volumes, snapshots, and AMIs. The following sections provide details about how you can use AWS Identity and Access Management (IAM), and help secure access to your resources.

Topics
- AWS managed policies (p. 1947)
- IAM service roles (p. 1950)
- Permissions for users (p. 1954)
- Permissions for encryption (p. 1954)

AWS managed policies

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases. AWS managed policies make it more efficient for you to assign appropriate permissions to users, groups, and roles, than if you had to write the policies yourself.

However, you can't change the permissions defined in AWS managed policies. AWS occasionally updates the permissions defined in an AWS managed policy. When this occurs, the update affects all principal entities (users, groups, and roles) that the policy is attached to.

Amazon Data Lifecycle Manager provides two AWS managed policies for common use cases. These policies make it more efficient to define the appropriate permissions and control access to your resources. The AWS managed policies provided by Amazon Data Lifecycle Manager are designed to be attached to roles that you pass to Amazon Data Lifecycle Manager.
The following are the AWS managed policies that Amazon Data Lifecycle Manager provides. You can also find these AWS managed policies in the Policies section of the IAM console.

**AWSDataLifecycleManagerServiceRole**

The **AWSDataLifecycleManagerServiceRole** policy provides appropriate permissions to Amazon Data Lifecycle Manager to create and manage Amazon EBS snapshot policies and cross-account copy event policies.

```json
{
   "Version": "2012-10-17",
   "Statement": [
   {
      "Effect": "Allow",
      "Action": [
         "ec2:CreateSnapshot",
         "ec2:CreateSnapshots",
         "ec2:DeleteSnapshot",
         "ec2:DescribeInstances",
         "ec2:DescribeVolumes",
         "ec2:DescribeSnapshots",
         "ec2:EnableFastSnapshotRestores",
         "ec2:DescribeFastSnapshotRestores",
         "ec2:DisableFastSnapshotRestores",
         "ec2:CopySnapshot",
         "ec2:ModifySnapshotAttribute",
         "ec2:DescribeSnapshotAttribute",
         "ec2:ModifySnapshotTier",
         "ec2:DescribeSnapshotTierStatus"
      ],
      "Resource": "*"
   },
   {
      "Effect": "Allow",
      "Action": [
         "ec2:CreateTags"
      ],
      "Resource": "arn:aws:ec2:*::snapshot/*"
   },
   {
      "Effect": "Allow",
      "Action": [
         "events:PutRule",
         "events:DeleteRule",
         "events:DescribeRule",
         "events:EnableRule",
         "events:DisableRule",
         "events:ListTargetsByRule",
         "events:PutTargets",
         "events:RemoveTargets"
      ],
      "Resource": "arn:aws:events:*::*:rule/AwsDataLifecycleRule.managed-cwe.*"
   }
   ]
}
```

**AWSDataLifecycleManagerServiceRoleForAMIManagement**

The **AWSDataLifecycleManagerServiceRoleForAMIManagement** policy provides appropriate permissions to Amazon Data Lifecycle Manager to create and manage Amazon EBS-backed AMI policies.

```json
{
}
```
AWS managed policy updates

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

The following table provides details about updates to AWS managed policies for Amazon Data Lifecycle Manager since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Document history (p. 2256).
### IAM service roles

An AWS Identity and Access Management (IAM) role is similar to a user, in that it is an AWS identity with permissions policies that determine what the identity can and can't do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. A service role is a role that an AWS service assumes to perform actions on your behalf. As a service that performs backup operations on your behalf, Amazon Data Lifecycle Manager requires that you pass it a role to assume when performing policy operations on your behalf. For more information about IAM roles, see [IAM Roles](#) in the [*IAM User Guide*](#).

The role that you pass to Amazon Data Lifecycle Manager must have an IAM policy with the permissions that enable Amazon Data Lifecycle Manager to perform actions associated with policy operations, such as creating snapshots and AMIs, copying snapshots and AMIs, deleting snapshots, and deregistering AMIs. Different permissions are required for each of the Amazon Data Lifecycle Manager policy types. The role must also have Amazon Data Lifecycle Manager listed as a trusted entity, which enables Amazon Data Lifecycle Manager to assume the role.

**Topics**

- [Default service roles for Amazon Data Lifecycle Manager (p. 1951)](#)
Custom service roles for Amazon Data Lifecycle Manager (p. 1951)

Default service roles for Amazon Data Lifecycle Manager

Amazon Data Lifecycle Manager uses the following default service roles:

- **AWSDataLifecycleManagerDefaultRole**—default role for managing snapshots. It trusts only the dlm.amazonaws.com service to assume the role and it allows Amazon Data Lifecycle Manager to perform the actions required by snapshot and cross-account snapshot copy policies on your behalf. This role uses the AWSDataLifecycleManagerServiceRole AWS managed policy.

  **Note**

  The ARN format of the role differs depending on whether it was created using the console or the AWS CLI. If the role was created using the console, the ARN format is arn:aws:iam::account_id:role/service-role/AWSDataLifecycleManagerDefaultRole. If the role was created using the AWS CLI, the ARN format is arn:aws:iam::account_id:role/AWSDataLifecycleManagerDefaultRole.

- **AWSDataLifecycleManagerDefaultRoleForAMIManagement**—default role for managing AMIs. It trusts only the dlm.amazonaws.com service to assume the role and it allows Amazon Data Lifecycle Manager to perform the actions required by EBS-backed AMI policies on your behalf. This role uses the AWSDataLifecycleManagerServiceRoleForAMIManagement AWS managed policy.

If you are using the Amazon Data Lifecycle Manager console, Amazon Data Lifecycle Manager automatically creates the AWSDataLifecycleManagerDefaultRole service role the first time you create a snapshot or cross-account snapshot copy policy, and it automatically creates the AWSDataLifecycleManagerDefaultRoleForAMIManagement service role the first time you create an EBS-backed AMI policy.

If you are not using the console, you can manually create the service roles using the create-default-role command. For --resource-type, specify snapshot to create AWSDataLifecycleManagerDefaultRole, or image to create AWSDataLifecycleManagerDefaultRoleForAMIManagement.

```
$ aws dlm create-default-role --resource-type snapshot|image
```

If you delete the default service roles, and then need to create them again, you can use the same process to recreate them in your account.

Custom service roles for Amazon Data Lifecycle Manager

As an alternative to using the default service roles, you can create custom IAM roles with the required permissions and then select them when you create a lifecycle policy.

**To create a custom IAM role**

1. Permissions required for managing snapshot lifecycle policies

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CreateSnapshot",
        "ec2:CreateSnapshots",
        "ec2:DeleteSnapshot",
```
Permissions required for managing AMI lifecycle policies

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["ec2:CreateTags"],
            "Resource": ["arn:aws:ec2:::snapshot/*", "arn:aws:ec2:::image/*"]
        },
        {
            "Effect": "Allow",
            "Action": ["ec2:DescribeImages", "ec2:DescribeInstances", "ec2:DescribeImageAttribute", "ec2:DescribeVolumes", "ec2:DescribeSnapshots"]
        },
        {
            "Effect": "Allow",
            "Action": ["ec2:DeleteSnapshot"]
        }
    ]
}
```
For more information, see Creating a Role in the IAM User Guide.

2. Add a trust relationship to the roles.
   a. In the IAM console, choose Roles.
   b. Select the roles that you created, and then choose Trust relationships.
   c. Choose Edit Trust Relationship, add the following policy, and then choose Update Trust Policy.

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Principal": {
            "Service": "dlm.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
    }]
}
```

We recommend that you use the aws:SourceAccount and aws:SourceArn condition keys to protect yourself against the confused deputy problem. For example, you could add the following condition block to the previous trust policy. The aws:SourceAccount is the owner of the lifecycle policy and the aws:SourceArn is the ARN of the lifecycle policy. If you don’t know the lifecycle policy ID, you can replace that portion of the ARN with a wildcard (*) and then update the trust policy after you create the lifecycle policy.

```
"Condition": {
    "StringEquals": {
        "aws:SourceAccount": "account_id"
    },
    "ArnLike": {
        "aws:SourceArn": "arn:partition:dlm:region:account_id:policy/policy_id"
    }
}
```
Permissions for users

A user must have the following permissions to use Amazon Data Lifecycle Manager.

**Note**

- The `ec2:DescribeAvailabilityZones`, `ec2:DescribeRegions`, `kms:ListAliases`, and `kms:DescribeKey` permissions are required for console users only. If console access is not required, you can remove the permissions.
- The ARN format of the `AWSDataLifecycleManagerDefaultRole` role differs depending on whether it was created using the console or the AWS CLI. If the role was created using the console, the ARN format is `arn:aws:iam::account_id:role/service-role/AWSDataLifecycleManagerDefaultRole`. If the role was created using the AWS CLI, the ARN format is `arn:aws:iam::account_id:role/AWSDataLifecycleManagerDefaultRole`. The following policy assumes the role was created using the AWS CLI.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "dlm:*",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": [
                "arn:aws:iam::account_id:role/service-role/AWSDataLifecycleManagerDefaultRole",
                "arn:aws:iam::account_id:role/service-role/AWSDataLifecycleManagerDefaultRoleForAMIManagement"
            ]
        },
        {
            "Effect": "Allow",
            "Action": "iam:ListRoles",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeAvailabilityZones",
                "ec2:DescribeRegions",
                "kms:ListAliases",
                "kms:DescribeKey"
            ],
            "Resource": "*"
        }
    ]
}
```

For more information, see [Changing permissions for a user](https://docs.aws.amazon.com/IAM/latest/userguide/permissions-change.html) in the IAM User Guide.

Permissions for encryption

Consider the following when working with Amazon Data Lifecycle Manager and encrypted resources.

- If the source volume is encrypted, ensure that the Amazon Data Lifecycle Manager default roles (`AWSDataLifecycleManagerDefaultRole` and
**AWSDataLifecycleManagerDefaultRoleForAMIManagement** have permission to use the KMS keys used to encrypt the volume.

- If you enable **Cross Region copy** for unencrypted snapshots or AMIs backed by unencrypted snapshots, and choose to enable encryption in the destination Region, ensure that the default roles have permission to use the KMS key needed to perform the encryption in the destination Region.
- If you enable **Cross Region copy** for encrypted snapshots or AMIs backed by encrypted snapshots, ensure that the default roles have permission to use both the source and destination KMS keys.
- If you enable snapshot archiving for encrypted snapshots, ensure that the Amazon Data Lifecycle Manager default role (**AWSDataLifecycleManagerDefaultRole**) has permission to use the KMS key used to encrypt the snapshot.

For more information, see **Allowing users in other accounts to use a KMS key** in the **AWS Key Management Service Developer Guide**.

**Monitor the lifecycle of snapshots and AMIs**

You can use the following features to monitor the lifecycle of your snapshots and AMIs.

**Features**

- [Console and AWS CLI](#)
- [AWS CloudTrail](#)
- [Monitor your policies using CloudWatch Events](#)
- [Monitor your policies using Amazon CloudWatch](#)

**Console and AWS CLI**

You can view your lifecycle policies using the Amazon EC2 console or the AWS CLI. Each snapshot and AMI created by a policy has a timestamp and policy-related tags. You can filter snapshots and AMIs using these tags to verify that your backups are being created as you intend. For information about viewing lifecycle policies using the console, see **View lifecycle policies**.

**AWS CloudTrail**

With AWS CloudTrail, you can track user activity and API usage to demonstrate compliance with internal policies and regulatory standards. For more information, see the **AWS CloudTrail User Guide**.

**Monitor your policies using CloudWatch Events**

Amazon EBS and Amazon Data Lifecycle Manager emit events related to lifecycle policy actions. You can use AWS Lambda and Amazon CloudWatch Events to handle event notifications programmatically. Events are emitted on a best effort basis. For more information, see the **Amazon CloudWatch Events User Guide**.

The following events are available:

**Note**

No events are emitted for AMI lifecycle policy actions.

- `createSnapshot`—An Amazon EBS event emitted when a `CreateSnapshot` action succeeds or fails. For more information, see **EventBridge for Amazon EBS**.
- `DLM Policy State Change`—An Amazon Data Lifecycle Manager event emitted when a lifecycle policy enters an error state. The event contains a description of what caused the error. The following is an example of an event when the permissions granted by the IAM role are insufficient.
Monitor your policies using Amazon CloudWatch

You can monitor your Amazon Data Lifecycle Manager lifecycle policies using CloudWatch, which collects raw data and processes it into readable, near real-time metrics. You can use these metrics to see exactly how many Amazon EBS snapshots and EBS-backed AMIs are created, deleted, and copied by your policies over time. You can also set alarms that watch for certain thresholds, and send notifications or take actions when those thresholds are met.

Metrics are kept for a period of 15 months, so that you can access historical information and gain a better understanding of how your lifecycle policies perform over an extended period.

For more information about Amazon CloudWatch, see the Amazon CloudWatch User Guide.

Topics
- Supported metrics (p. 1957)
- View CloudWatch metrics for your policies (p. 1960)
- Graph metrics for your policies (p. 1961)
- Create a CloudWatch alarm for a policy (p. 1961)
- Example use cases (p. 208)
• Managing policies that report failed actions (p. 1963)

Supported metrics

The Data Lifecycle Manager namespace includes the following metrics for Amazon Data Lifecycle Manager lifecycle policies. The supported metrics differ by policy type.

All metrics can be measured on the DLMPolicyId dimension. The most useful statistics are sum and average, and the unit of measure is count.

Choose a tab to view the metrics supported by that policy type.

EBS snapshot policies

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourcesTargeted</td>
<td>The number of resources targeted by the tags specified in a snapshot or EBS-backed AMI policy.</td>
</tr>
<tr>
<td>SnapshotsCreateStarted</td>
<td>The number of snapshot create actions initiated by a snapshot policy. Each action is recorded only once, even if there are multiple subsequent retries.</td>
</tr>
<tr>
<td></td>
<td>If a snapshot create action fails, Amazon Data Lifecycle Manager sends a SnapshotsCreateFailed metric.</td>
</tr>
<tr>
<td>SnapshotsCreateCompleted</td>
<td>The number of snapshots created by a snapshot policy. This includes successful retries within 60 minutes of the scheduled time.</td>
</tr>
<tr>
<td>SnapshotsCreateFailed</td>
<td>The number of snapshots that could not be created by a snapshot policy. This includes unsuccessful retries within 60 minutes from the scheduled time.</td>
</tr>
<tr>
<td>SnapshotsSharedCompleted</td>
<td>The number of snapshots shared across accounts by a snapshot policy.</td>
</tr>
<tr>
<td>SnapshotsDeleteCompleted</td>
<td>The number of snapshots deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy. It does not apply to cross-Region snapshot copies created by the policy.</td>
</tr>
<tr>
<td></td>
<td>This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.</td>
</tr>
<tr>
<td>SnapshotsDeleteFailed</td>
<td>The number of snapshots that could not be deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy.</td>
</tr>
<tr>
<td></td>
<td>This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.</td>

EBS-backed AMI policies

The following metrics can be used with EBS-backed AMI policies:

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourcesTargeted</td>
<td>The number of resources targeted by the tags specified in a snapshot or EBS-backed AMI policy.</td>
</tr>
<tr>
<td>SnapshotsDeleteCompleted</td>
<td>The number of snapshots deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy. It does not apply to cross-Region snapshot copies created by the policy. This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.</td>
</tr>
<tr>
<td>SnapshotsDeleteFailed</td>
<td>The number of snapshots that could not be deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy. It does not apply to cross-Region snapshot copies created by the policy. This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegionDelete</td>
<td>The number of cross-Region snapshot copies deleted, as designated by the retention rule, by a snapshot policy.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegionDeleteFailed</td>
<td>The number of cross-Region snapshot copies that could not be deleted, as designated by the retention rule, by a snapshot policy.</td>
</tr>
</tbody>
</table>
### Metric Description

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ImagesCreateStarted</td>
<td>The number of <code>CreateImage</code> actions initiated by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesCreateCompleted</td>
<td>The number of AMIs created by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesCreateFailed</td>
<td>The number of AMIs that could not be created by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesDeregisterCompleted</td>
<td>The number of AMIs deregistered by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesDeregisterFailed</td>
<td>The number of AMIs that could not be deregistered by an EBS-backed AMI policy.</td>

<tr>
<td>ImagesCopiedRegionFailed</td>
<td>The number of cross-Region AMI copies that could not be created by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesCopiedRegionDeregistered</td>
<td>The number of cross-Region AMI copies deregistered, as designated by the retention rule, by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesCopiedRegionDeregisteredFailed</td>
<td>The number of cross-Region AMI copies that could not be deregistered, as designated by the retention rule, by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>EnableImageDeprecationCompleted</td>
<td>The number of AMIs that were marked for deprecation by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>EnableImageDeprecationFailed</td>
<td>The number of AMIs that could not be marked for deprecation by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>EnableCopiedImageDeprecationCompleted</td>
<td>The number of cross-Region AMI copies that were marked for deprecation by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>EnableCopiedImageDeprecationFailed</td>
<td>The number of cross-Region AMI copies that could not be marked for deprecation by an EBS-backed AMI policy.</td>
</tr>
</tbody>
</table>

### Cross-account copy event policies

The following metrics can be used with cross-account copy event policies:

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SnapshotsCopiedAccountStarted</td>
<td>The number of cross-account snapshot copy actions initiated by a cross-account copy event policy.</td>
</tr>
<tr>
<td>SnapshotsCopiedAccountCompleted</td>
<td>The number of snapshots copied from another account by a cross-account copy event policy. This includes successful retries within 24 hours of the scheduled time.</td>
</tr>
<tr>
<td>SnapshotsCopiedAccountFailed</td>
<td>The number of snapshots that could not be copied from another account by a cross-account copy event policy. This includes unsuccessful retries within 24 hours of the scheduled time.</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SnapshotsCopyiedAccountDeleteCompleted</td>
<td>The number of cross-Region snapshot copies deleted, as designated by the retention rule, by a cross-account copy event policy.</td>
</tr>
<tr>
<td>SnapshotsCopyiedAccountDeleteFailed</td>
<td>The number of cross-Region snapshot copies that could not be deleted, as designated by the retention rule, by a cross-account copy event policy.</td>
</tr>
</tbody>
</table>

View CloudWatch metrics for your policies

You can use the AWS Management Console or the command line tools to list the metrics that Amazon Data Lifecycle Manager sends to Amazon CloudWatch.

Amazon EC2 console

**To view metrics using the Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Lifecycle Manager**.
3. Select a policy in the grid and then choose the **Monitoring** tab.

CloudWatch console

**To view metrics using the Amazon CloudWatch console**

2. In the navigation pane, choose **Metrics**.
3. Select the **EBS** namespace and then select **Data Lifecycle Manager metrics**.

AWS CLI

**To list all the available metrics for Amazon Data Lifecycle Manager**

Use the `list-metrics` command.

```bash
$ aws cloudwatch list-metrics \
   --namespace AWS/EBS
```

**To list all the metrics for a specific policy**

Use the `list-metrics` command and specify the `DLMPolicyId` dimension.

```bash
$ aws cloudwatch list-metrics \
   --namespace AWS/EBS \
   --dimensions Name=DLMPolicyId,Value=policy-abcdef01234567890
```

**To list a single metric across all policies**

Use the `list-metrics` command and specify the `--metric-name` option.

```bash
$ aws cloudwatch list-metrics \
   --namespace AWS/EBS \
   --metric-name SnapshotsCreateCompleted
```
Graph metrics for your policies

After you create a policy, you can open the Amazon EC2 console and view the monitoring graphs for the policy on the **Monitoring** tab. Each graph is based on one of the available Amazon EC2 metrics.

The following graphs metrics are available:

- Resources targeted (based on `ResourcesTargeted`)
- Snapshot creation started (based on `SnapshotsCreateStarted`)
- Snapshot creation completed (based on `SnapshotsCreateCompleted`)
- Snapshot creation failed (based on `SnapshotsCreateFailed`)
- Snapshot sharing completed (based on `SnapshotsSharedCompleted`)
- Snapshot deletion completed (based on `SnapshotsDeleteCompleted`)
- Snapshot deletion failed (based on `SnapshotsDeleteFailed`)
- Snapshot cross-Region copy started (based on `SnapshotsCopiedRegionStarted`)
- Snapshot cross-Region copy completed (based on `SnapshotsCopiedRegionCompleted`)
- Snapshot cross-Region copy failed (based on `SnapshotsCopiedRegionFailed`)
- Snapshot cross-Region copy deletion completed (based on `SnapshotsCopiedRegionDeleteCompleted`)
- Snapshot cross-Region copy deletion failed (based on `SnapshotsCopiedRegionDeleteFailed`)
- Snapshot cross-account copy started (based on `SnapshotsCopiedAccountStarted`)
- Snapshot cross-account copy completed (based on `SnapshotsCopiedAccountCompleted`)
- Snapshot cross-account copy failed (based on `SnapshotsCopiedAccountFailed`)
- Snapshot cross-account copy deletion completed (based on `SnapshotsCopiedAccountDeleteCompleted`)
- Snapshot cross-account copy deletion failed (based on `SnapshotsCopiedAccountDeleteFailed`)
- AMI creation started (based on `ImagesCreateStarted`)
- AMI creation completed (based on `ImagesCreateCompleted`)
- AMI creation failed (based on `ImagesCreateFailed`)
- AMI deregistration completed (based on `ImagesDeregisterCompleted`)
- AMI deregistration failed (based on `ImagesDeregisterFailed`)
- AMI cross-Region copy started (based on `ImagesCopiedRegionStarted`)
- AMI cross-Region copy completed (based on `ImagesCopiedRegionCompleted`)
- AMI cross-Region copy failed (based on `ImagesCopiedRegionFailed`)
- AMI cross-Region copy deregistration completed (based on `ImagesCopiedRegionDeregisterCompleted`)
- AMI cross-Region copy deregister failed (based on `ImagesCopiedRegionDeregisteredFailed`)
- AMI enable deprecation completed (based on `EnableImageDeprecationCompleted`)
- AMI enable deprecation failed (based on `EnableImageDeprecationFailed`)
- AMI cross-Region copy enable deprecation completed (based on `EnableCopiedImageDeprecationCompleted`)
- AMI cross-Region copy enable deprecation failed (based on `EnableCopiedImageDeprecationFailed`)

Create a CloudWatch alarm for a policy

You can create a CloudWatch alarm that monitors CloudWatch metrics for your policies. CloudWatch will automatically send you a notification when the metric reaches a threshold that you specify. You can create a CloudWatch alarm using the CloudWatch console.
For more information about creating alarms using the CloudWatch console, see the following topic in the *Amazon CloudWatch User Guide*.

- [Create a CloudWatch Alarm Based on a Static Threshold](#)
- [Create a CloudWatch Alarm Based on Anomaly Detection](#)

### Example use cases

The following are example use cases.

### Topics

- [Example 1: ResourcesTargeted metric (p. 1962)](#)
- [Example 2: SnapshotDeleteFailed metric (p. 1962)](#)
- [Example 3: SnapshotsCopiedRegionFailed metric (p. 1963)](#)

#### Example 1: ResourcesTargeted metric

You can use the `ResourcesTargeted` metric to monitor the total number of resources that are targeted by a specific policy each time it is run. This enables you to trigger an alarm when the number of targeted resources is below or above an expected threshold.

For example, if you expect your daily policy to create backups of no more than 50 volumes, you can create an alarm that sends an email notification when the sum for `ResourcesTargeted` is greater than 50 over a 1 hour period. In this way, you can ensure that no snapshots have been unexpectedly created from volumes that have been incorrectly tagged.

You can use the following command to create this alarm:

```bash
$ aws cloudwatch put-metric-alarm
   --alarm-name resource-targeted-monitor \
   --alarm-description "Alarm when policy targets more than 50 resources" \
   --metric-name ResourcesTargeted \
   --namespace AWS/EBS \
   --statistic Sum \
   --period 3600 \ 
   --threshold 50 \ 
   --comparison-operator GreaterThanThreshold \ 
   --dimensions "Name=DLMPolicyId,Value=policy_id" \
   --evaluation-periods 1 \ 
   --alarm-actions sns_topic_arn
```

#### Example 2: SnapshotDeleteFailed metric

You can use the `SnapshotDeleteFailed` metric to monitor for failures to delete snapshots as per the policy's snapshot retention rule.

For example, if you've created a policy that should automatically delete snapshots every twelve hours, you can create an alarm that notifies your engineering team when the sum of `SnapshotDeletionFailed` is greater than 0 over a 1 hour period. This could help to investigate improper snapshot retention and to ensure that your storage costs are not increased by unnecessary snapshots.

You can use the following command to create this alarm:

```bash
$ aws cloudwatch put-metric-alarm
   --alarm-name snapshot-deletion-failed-monitor \
   --alarm-description "Alarm when snapshot deletions fail" \
   --metric-name SnapshotsDeleteFailed \
```

---

1962
Example 3: SnapshotsCopiedRegionFailed metric

Use the SnapshotsCopiedRegionFailed metric to identify when your policies fail to copy snapshots to other Regions.

For example, if your policy copies snapshots across Regions daily, you can create an alarm that sends an SMS to your engineering team when the sum of SnapshotCrossRegionCopyFailed is greater than 0 over a 1 hour period. This can be useful for verifying whether subsequent snapshots in the lineage were successfully copied by the policy.

You can use the following command to create this alarm:

```bash
$ aws cloudwatch put-metric-alarm
--alarm-name snapshot-copy-region-failed-monitor
--alarm-description "Alarm when snapshot copy fails"
--metric-name SnapshotsCopiedRegionFailed
--namespace AWS/EBS
--statistic Sum
--period 3600
--threshold 0
--comparison-operator GreaterThanThreshold
--dimensions "Name=DLMPolicyId,Value=policy_id"
--evaluation-periods 1
--alarm-actions sns_topic_arn
```

Managing policies that report failed actions

For more information about what to do when one of your policies reports an unexpected non-zero value for a failed action metric, see the What should I do if Amazon Data Lifecycle Manager reports failed actions in CloudWatch metrics? AWS Knowledge Center article.

Amazon EBS data services

Amazon EBS provides the following data services.

Data services
- Amazon EBS Elastic Volumes (p. 1963)
- Amazon EBS encryption (p. 1975)
- Amazon EBS fast snapshot restore (p. 1988)

Amazon EBS Elastic Volumes

With Amazon EBS Elastic Volumes, you can increase the volume size, change the volume type, or adjust the performance of your EBS volumes. If your instance supports Elastic Volumes, you can do so without detaching the volume or restarting the instance. This enables you to continue using your application while the changes take effect.

There is no charge to modify the configuration of a volume. You are charged for the new volume configuration after volume modification starts. For more information, see the Amazon EBS Pricing page.
Contents

- Requirements when modifying volumes (p. 1964)
- Request modifications to your EBS volumes (p. 1965)
- Monitor the progress of volume modifications (p. 1968)
- Extend a Linux file system after resizing a volume (p. 1971)

Requirements when modifying volumes

The following requirements and limitations apply when you modify an Amazon EBS volume. To learn more about the general requirements for EBS volumes, see Constraints on the size and configuration of an EBS volume (p. 1792).

Topics

- Supported instance types (p. 1964)
- Requirements for Linux volumes (p. 1964)
- Limitations (p. 1965)

Supported instance types

Elastic Volumes are supported on the following instances:

- All current-generation instances (p. 275)
- The following previous-generation instances: C1, C3, G2, I2, M1, M3, and R3

If your instance type does not support Elastic Volumes, see Modify an EBS volume if Elastic Volumes is not supported (p. 1968).

Requirements for Linux volumes

Linux AMIs require a GUID partition table (GPT) and GRUB 2 for boot volumes that are 2 TiB (2,048 GiB) or larger. Many Linux AMIs today still use the MBR partitioning scheme, which only supports boot volume sizes up to 2 TiB. If your instance does not boot with a boot volume larger than 2 TiB, the AMI you are using may be limited to a boot volume size of less than 2 TiB. Non-boot volumes do not have this limitation on Linux instances. For requirements affecting Windows volumes, see Requirements for Windows volumes in the Amazon EC2 User Guide for Windows Instances.

Before attempting to resize a boot volume beyond 2 TiB, you can determine whether the volume is using MBR or GPT partitioning by running the following command on your instance:

```
[ec2-user ~]$ sudo gdisk -l /dev/xvda
```

An Amazon Linux instance with GPT partitioning returns the following information:

```
GPT fdisk (gdisk) version 0.8.10
Partition table scan:
  MBR: protective
  BSD: not present
  APM: not present
  GPT: present
Found valid GPT with protective MBR; using GPT.
```

A SUSE instance with MBR partitioning returns the following information:
Limitations

- There are limits to the maximum aggregated storage that can be requested across volume modifications. For more information, see Amazon EBS service quotas in the Amazon Web Services General Reference.
- After modifying a volume, you must wait at least six hours and ensure that the volume is in the in-use or available state before you can modify the same volume. This is sometimes referred to as a cooldown period.
- If the volume was attached before November 3, 2016 23:40 UTC, you must initialize Elastic Volumes support. For more information, see Initializing Elastic Volumes Support (p. 1967).
- If you encounter an error message while attempting to modify an EBS volume, or if you are modifying an EBS volume attached to a previous-generation instance type, take one of the following steps:
  - For a non-root volume, detach the volume from the instance, apply the modifications, and then re-attach the volume.
  - For a root volume, stop the instance, apply the modifications, and then restart the instance.
- Modification time is increased for volumes that are not fully initialized. For more information see Initialize Amazon EBS volumes (p. 2033).
- The new volume size can't exceed the supported capacity of its file system and partitioning scheme. For more information, see Constraints on the size and configuration of an EBS volume (p. 1792).
- If you modify the volume type of a volume, the size and performance must be within the limits of the target volume type. For more information, see Amazon EBS volume types (p. 1775).
- You can't decrease the size of an EBS volume. However, you can create a smaller volume and then migrate your data to it using an application-level tool such as rsync.
- After provisioning over 32,000 IOPS on an existing io1 or io2 volume, you might need to detach and re-attach the volume, or restart the instance to see the full performance improvements.
- For io2 volumes, you can't increase the size beyond 16 TiB or the IOPS beyond 64,000 while the volume is attached to an instance type that does not support io2 Block Express volumes. For more information, see io2 Block Express volumes (p. 1783).
- You can't modify the volume type of Multi-Attach enabled io2 volumes.
- You can't modify the volume type, size, or Provisioned IOPS of Multi-Attach enabled io1 volumes.
- A root volume of type io1, io2, gp2, gp3, or standard can't be modified to an st1 or sc1 volume, even if it is detached from the instance.
- While m3.medium instances fully support volume modification, m3.large, m3.xlarge, and m3.2xlarge instances might not support all volume modification features.

Request modifications to your EBS volumes

With Elastic Volumes, you can dynamically increase the size, increase or decrease the performance, and change the volume type of your Amazon EBS volumes without detaching them.

Use the following process when modifying a volume:

1. (Optional) Before modifying a volume that contains valuable data, it is a best practice to create a snapshot of the volume in case you need to roll back your changes. For more information, see Create Amazon EBS snapshots (p. 1830).
2. Request the volume modification.
3. Monitor the progress of the volume modification. For more information, see Monitor the progress of volume modifications (p. 1968).
4. If the size of the volume was modified, extend the volume's file system to take advantage of the increased storage capacity. For more information, see Extend a Linux file system after resizing a volume (p. 1971).

Contents
- Modify an EBS volume using Elastic Volumes (p. 1966)
- Initialize Elastic Volumes support (if needed) (p. 1967)
- Modify an EBS volume if Elastic Volumes is not supported (p. 1968)

Modify an EBS volume using Elastic Volumes

Considerations
Keep the following in mind when modifying volumes:

- You can't cancel a volume modification request after it has been submitted.
- You can only increase volume size. You can't decrease volume size.
- You can increase or decrease volume performance.
- If you are not changing the volume type, then volume size and performance modifications must be within the limits of the current volume type. If you are changing the volume type, then volume size and performance modifications must be within the limits of the target volume type.
- If you change the volume type from gp2 to gp3, and you do not specify IOPS or throughput performance, Amazon EBS automatically provisions either equivalent performance to that of the source gp2 volume, or the baseline gp3 performance, whichever is higher.

For example, if you modify a 500 GiB gp2 volume with 250 MiB/s throughput and 1500 IOPS to gp3 without specifying IOPS or throughput performance, Amazon EBS automatically provisions the gp3 volume with 3000 IOPS (baseline gp3 IOPS) and 250 MiB/s (to match the source gp2 volume throughput).

To modify an EBS volume, use one of the following methods.

Console

To modify an EBS volume using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Select the volume to modify and choose Actions, Modify volume.
4. The Modify volume screen displays the volume ID and the volume's current configuration, including type, size, IOPS, and throughput. Set new configuration values as follows:

   - To modify the type, choose a value for Volume type.
   - To modify the size, enter a new value for Size.
   - (gp3, io1, and io2 only) To modify the IOPS, enter a new value for IOPS.
   - (gp3 only) To modify the throughput, enter a new value for Throughput.
5. After you have finished changing the volume settings, choose Modify. When prompted for confirmation, choose Modify.
Important
If you've increased the size of your volume, then you must also extend the volume's partition to make use of the additional storage capacity. For more information, see Extend a Linux file system after resizing a volume (p. 1971).

AWS CLI

To modify an EBS volume using the AWS CLI

Use the modify-volume command to modify one or more configuration settings for a volume. For example, if you have a volume of type gp2 with a size of 100 GiB, the following command changes its configuration to a volume of type io1 with 10,000 IOPS and a size of 200 GiB.

```
aws ec2 modify-volume --volume-type io1 --iops 10000 --size 200 --volume-id vol-11111111111111111
```

The following is example output:

```
{
    "VolumeModification": {
        "TargetSize": 200,
        "TargetVolumeType": "io1",
        "ModificationState": "modifying",
        "VolumeId": "vol-11111111111111111",
        "TargetIops": 10000,
        "StartTime": "2017-01-19T22:21:02.959Z",
        "Progress": 0,
        "OriginalVolumeType": "gp2",
        "OriginalIops": 300,
        "OriginalSize": 100
    }
}
```

Important
If you've increased the size of your volume, then you must also extend the volume's partition to make use of the additional storage capacity. For more information, see Extend a Linux file system after resizing a volume (p. 1971).

Initialize Elastic Volumes support (if needed)

Before you can modify a volume that was attached to an instance before November 3, 2016 23:40 UTC, you must initialize volume modification support using one of the following actions:

- Detach and attach the volume
- Stop and start the instance

Use one of the following procedures to determine whether your instances are ready for volume modification.

Console

To determine whether your instances are ready using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the navigation pane, choose Instances.
3. Choose the Show/Hide Columns icon (the gear). Select the Launch time attribute column and then choose Confirm.
4. Sort the list of instances by the **Launch Time** column. For each instance that was started before the cutoff date, choose the **Storage** tab and check the **Attachment time** column to see when its volumes were attached.

**AWS CLI**

**To determine whether your instances are ready using the CLI**

Use the following `describe-instances` command to determine whether the volume was attached before November 3, 2016 23:40 UTC.

```
aws ec2 describe-instances --query "Reservations[\*].Instances[\*].
[InstanceId,LaunchTime<='2016-11-01',BlockDeviceMappings[\*]
[Ebs.AttachTime<='2016-11-01']]" --output text
```

The first line of the output for each instance shows its ID and whether it was started before the cutoff date (True or False). The first line is followed by one or more lines that show whether each EBS volume was attached before the cutoff date (True or False). In the following example output, you must initialize volume modification for the first instance because it was started before the cutoff date and its root volume was attached before the cutoff date. The other instances are ready because they were started after the cutoff date.

<table>
<thead>
<tr>
<th>Instance ID</th>
<th>Attached Before Cutoff</th>
<th>Attached Root Before Cutoff</th>
</tr>
</thead>
<tbody>
<tr>
<td>i-e905622e</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>i-719f99a8</td>
<td>False</td>
<td>True</td>
</tr>
<tr>
<td>i-006b02c1b78381e57</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>i-e3d172ed</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>

**Modify an EBS volume if Elastic Volumes is not supported**

If you are using a supported instance type, you can use Elastic Volumes to dynamically modify the size, performance, and volume type of your Amazon EBS volumes without detaching them.

If you cannot use Elastic Volumes but you need to modify the root (boot) volume, you must stop the instance, modify the volume, and then restart the instance.

After the instance has started, you can check the file system size to see if your instance recognizes the larger volume space. On Linux, use the `df -h` command to check the file system size.

```
[ec2-user ~]$ df -h
Filesystem            Size  Used Avail Use% Mounted on
/dev/xvda1            7.9G  943M  6.9G  12% /
tmpfs                 1.9G     0  1.9G   0% /dev/shm
```

If the size does not reflect your newly expanded volume, you must extend the file system of your device so that your instance can use the new space. For more information, see [Extend a Linux file system after resizing a volume](p. 1971).

**Monitor the progress of volume modifications**

When you modify an EBS volume, it goes through a sequence of states. The volume enters the modifying state, the optimizing state, and finally the completed state. At this point, the volume is ready to be further modified.
Note

Rarely, a transient AWS fault can result in a failed state. This is not an indication of volume health; it merely indicates that the modification to the volume failed. If this occurs, retry the volume modification.

While the volume is in the optimizing state, your volume performance is in between the source and target configuration specifications. Transitional volume performance will be no less than the source volume performance. If you are downgrading IOPS, transitional volume performance is no less than the target volume performance.

Volume modification changes take effect as follows:

- Size changes usually take a few seconds to complete and take effect after the volume has transitioned to the Optimizing state.
- Performance (IOPS) changes can take from a few minutes to a few hours to complete and are dependent on the configuration change being made.
- In some cases, it can take more than 24 hours for a new configuration to take effect, such as when the volume has not been fully initialized. Typically, a fully used 1-TiB volume takes about 6 hours to migrate to a new performance configuration.

To monitor the progress of a volume modification, use one of the following methods.

Console

**To monitor progress of a modification using the Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Volumes**.
3. Select the volume.
4. The **Volume state** column and the **Volume state** field in the **Details** tab contain information in the following format: `volume-state - modification-state (progress%)`.

The possible volume states are creating, available, in-use, deleting, deleted, and error.

The possible modification states are modifying, optimizing, and completed.

After the modification completes, only the volume state (available) is displayed. The modification state and progress are no longer displayed.

AWS CLI

**To monitor progress of a modification using the AWS CLI**

Use the `describe-volumes-modifications` command to view the progress of one or more volume modifications. The following example describes the volume modifications for two volumes.

```bash
aws ec2 describe-volumes-modifications --volume-ids vol-1111111111111111 vol-2222222222222222
```

In the following example output, the volume modifications are still in the modifying state. Progress is reported as a percentage.

```json
{
    "VolumesModifications": [
        {
            "TargetSize": 200,
```
The next example describes all volumes with a modification state of either optimizing or completed, and then filters and formats the results to show only modifications that were initiated on or after February 1, 2017:

```
aws ec2 describe-volumes-modifications --filters Name=modification-state,Values="optimizing","completed" --query "VolumesModifications[?StartTime>='2017-02-01'].{ID:VolumeId,STATE:ModificationState}"
```

The following is example output with information about two volumes:

```
[{
    "STATE": "optimizing",
    "ID": "vol-06397e7a0eEXAMPLE"
},
{
    "STATE": "completed",
    "ID": "vol-ba74e18c2aEXAMPLE"
}]
```

CloudWatch Events console

With CloudWatch Events, you can create a notification rule for volume modification events. You can use your rule to generate a notification message using Amazon SNS or to invoke a Lambda function in response to matching events. Events are emitted on a best effort basis.

**To monitor progress of a modification using CloudWatch Events**

2. Choose Events, Create rule.
3. For **Build event pattern to match events by service**, choose Custom event pattern.
4. For **Build custom event pattern**, replace the contents with the following and choose Save.

```
{  "source": ["aws:ec2"]
```
Extend a Linux file system after resizing a volume

Note

The following topic walks you through the process of extending XFS and Ext4 file systems for Linux. For information about other file systems, see their documentation for instructions.

After you increase the size of an EBS volume (p. 1965), you must use file system–specific commands to extend the file system to the new, larger size. You can do this as soon as the volume enters the optimizing state.

To extend a file system on Linux, you need to:

1. Extend the partition, if your volume has one.
2. Extend the file system.

Before you begin

- Create a snapshot of the volume, in case you need to roll back your changes. For more information, see Create Amazon EBS snapshots (p. 1830).
- Confirm that the volume modification succeeded and that it is in the optimizing or completed state. For more information, see Monitor the progress of volume modifications (p. 1968).
- Ensure that the volume is attached to the instance and that it is formatted and mounted. For more information, see Format and mount an attached volume (p. 1804).
- If you are using logical volumes on the Amazon EBS volume, you must use Logical Volume Manager (LVM) to extend the logical volume. For instructions about how to do this, see the Extend the...
logical volume section in the How do I create an LVM logical volume on an entire EBS volume? AWS Knowledge Center article.

Extend the file system of EBS volumes

Use the following procedure to extend the file system for a resized volume.

Note that device and partition naming differs for Xen instances and Nitro instances (p. 282). To determine whether your instance is Xen-based or Nitro-based, use one of the methods:

- AWS CLI

```bash
[ec2-user ~]$ aws ec2 describe-instance-types --instance-type instance_type --query "InstanceTypes[].Hypervisor"
```

- IMDSv2

```bash
```

nitro indicates that your instance in Nitro-based. xen or xen-on-nitro indicates that you instance in Xen-based.

To extend the file system of EBS volumes

1. Connect to your instance (p. 757).
2. Resize the partition, if needed. To do so:
   a. Check whether the volume has a partition. Use the lsblk command.

Nitro instance example

In the following example output, the root volume (nvme0n1) has two partitions (nvme0n1p1 and nvme0n1p128), while the additional volume (nvme1n1) has no partitions.

```bash
[ec2-user ~]$ sudo lsblk
NAME          MAJ:MIN  RM  SIZE RO TYPE MOUNTPOINT
nvme1n1       259:0    0  30G  0 disk /data
nvme0n1       259:1    0  16G  0 disk
##nvme0n1p1   259:2    0   8G  0 part /
##nvme0n1p128 259:3    0   1M  0 part
```

Xen instance example

In the following example output, the root volume (xvda) has a partition (xvda1), while the additional volume (xvdf) has no partition.

```bash
[ec2-user ~]$ sudo lsblk
NAME   MAJ:MIN  RM  SIZE RO TYPE MOUNTPOINT
xvda   202:0    0  16G  0 disk
##xvda1 202:1    0  8G  0 part /
xvdf   202:80   0  24G  0 disk
```
If the volume has a partition, continue the procedure from the following step (2b). If the volume has no partitions, skip steps 2b, 2c, and 2d, and continue the procedure from step 3.

**Troubleshooting tip**
If you do not see the volume in the command output, ensure that the volume is attached to the instance (p. 1797), and that it is formatted and mounted (p. 1804).

b. Check whether the partition needs to be extended. In the `lsblk` command output from the previous step, compare the partition size and the volume size.

If the partition size is smaller than the volume size, continue to the next step. If the partition size is equal to the volume size, the partition can't be extended.

**Troubleshooting tip**
If the volume still reflects the original size, confirm that the volume modification succeeded (p. 1968).

c. Extend the partition. Use the `growpart` command and specify the partition to extend.

Nitro instance example

For example, to extend a partition named `nvme0n1p1`, use the following command.

```
[ec2-user ~]$ sudo growpart /dev/nvme0n1 1
```

Xen instance example

For example, to extend a partition named `xvda1`, use the following command.

```
[ec2-user ~]$ sudo growpart /dev/xvda 1
```

**Troubleshooting tips**

- `mkdir: cannot create directory ‘/tmp/growpart.31171’: No space left on device FAILED: failed to make temp dir:` Indicates that there is not enough free disk space on the volume for growpart to create the temporary directory it needs to perform the resize. Free up some disk space and then try again.

- `must supply partition-number`: Indicates that you specified an incorrect partition. Use the `lsblk` command to confirm the partition name, and ensure that you enter a space between the device name and the partition number.

- `NOCHANGE: partition 1 is size 16773087. it cannot be grown:` Indicates that the partition already extends the entire volume and can't be extended. Confirm that the volume modification succeeded (p. 1968).

d. Verify that the partition has been extended. Use the `lsblk` command. The partition size should now be equal to the volume size.

Nitro instance example

The following example output shows that both the volume (`nvme0n1`) and the partition (`nvme0n1p1`) are the same size (16 GB).
Xen instance example

The following example output shows that both the volume (xvda) and the partition (xvda1) are the same size (16 GB).

```
[ec2-user ~]$ sudo lsblk
NAME    MAJ:MIN RM SIZE  TYPE MOUNTPOINT
xvda    202:0    0  16G  disk
##xvda1 202:1    0  16G  part /
xvdf    202:80   0  24G  disk
```

3. Extend the file system.

   a. Get the name, size, type, and mount point for the file system that you need to extend. Use the `df -hT` command.

Nitro instance example

The following example output shows that the /dev/nvme0n1p1 file system is 8 GB in size, its type is xfs, and its mount point is /.

```
[ec2-user ~]$ df -hT
Filesystem  Type    Size  Used  Avail  Use%  Mounted on
/dev/nvme0n1p1  xfs   8.0G  1.6G  6.5G  20%  /
/dev/nvme1n1    xfs   8.0G   33M  8.0G   1%   /data
...```

Xen instance example

The following example output shows that the /dev/xvda1 file system is 8 GB in size, its type is ext4, and its mount point is /.

```
[ec2-user ~]$ df -hT
Filesystem  Type  Size  Used  Avail  Use%  Mounted on
/dev/xvda1   ext4  8.0G  1.9G  6.2G  24%   /
/dev/xvdf1    xfs  24.0G  45M  8.0G  1%    /data
...```

   b. The commands to extend the file system differ depending on the file system type. Choose the following correct command based on the file system type that you noted in the previous step.

   • [XFS file system] Use the `xfs_growfs` command and specify the mount point of the file system that you noted in the previous step.

   Nitro and Xen instance example

   For example, to extend a file system mounted on /, use the following command.

   ```
   [ec2-user ~]$ sudo xfs_growfs -d /
   ```
Troubleshooting tips

- `xfs_growfs: /data is not a mounted XFS filesystem`: Indicates that you specified the incorrect mount point, or the file system is not XFS. To verify the mount point and file system type, use the `df -hT` command.

- `data size unchanged, skipping`: Indicates that the file system already extends the entire volume. If the volume has no partitions, confirm that the volume modification succeeded (p. 1968). If the volume has partitions, ensure that the partition was extended as described in step 2.

- [Ext4 file system] Use the `resize2fs` command and specify the name of the file system that you noted in the previous step.

  Nitro instance example

  For example, to extend a file system mounted named `/dev/nvme0n1p1`, use the following command.

  ```bash
  [ec2-user ~] $ sudo resize2fs /dev/nvme0n1p1
  ```

  Xen instance example

  For example, to extend a file system mounted named `/dev/xvda1`, use the following command.

  ```bash
  [ec2-user ~] $ sudo resize2fs /dev/xvda1
  ```

Troubleshooting tips

- `resize2fs: Bad magic number in super-block while trying to open /dev/xvdb1`: Indicates that the file system is not Ext4. To verify the file system type, use the `df -hT` command.

- `open: No such file or directory while opening /dev/xvdb1`: Indicates that you specified an incorrect partition. To verify the partition, use the `df -hT` command.

- The filesystem is already 3932160 blocks long. Nothing to do!: Indicates that the file system already extends the entire volume. If the volume has no partitions, confirm that the volume modification succeeded (p. 1968). If the volume has partitions, ensure that the partition was extended, as described in step 2.

- [Other file system] See the documentation for your file system for instructions.

  c. Verify that the file system has been extended. Use the `df -hT` command and confirm that the file system size is equal to the volume size.

Amazon EBS encryption

Use Amazon EBS encryption as a straight-forward encryption solution for your EBS resources associated with your EC2 instances. With Amazon EBS encryption, you aren’t required to build, maintain, and secure your own key management infrastructure. Amazon EBS encryption uses AWS KMS keys when creating encrypted volumes and snapshots.

Encryption operations occur on the servers that host EC2 instances, ensuring the security of both data-at-rest and data-in-transit between an instance and its attached EBS storage.

You can attach both encrypted and unencrypted volumes to an instance simultaneously.

Contents
How EBS encryption works

You can encrypt both the boot and data volumes of an EC2 instance.

When you create an encrypted EBS volume and attach it to a supported instance type, the following types of data are encrypted:

- Data at rest inside the volume
- All data moving between the volume and the instance
- All snapshots created from the volume
- All volumes created from those snapshots

Amazon EBS encrypts your volume with a data key using industry-standard AES-256 data encryption. The data key is generated by AWS KMS and then encrypted by AWS KMS with your AWS KMS key prior to being stored with your volume information. All snapshots, and any subsequent volumes created from those snapshots using the same AWS KMS key share the same data key. For more information, see Data keys in the AWS Key Management Service Developer Guide.

Amazon EC2 works with AWS KMS to encrypt and decrypt your EBS volumes in slightly different ways depending on whether the snapshot from which you create an encrypted volume is encrypted or unencrypted.

How EBS encryption works when the snapshot is encrypted

When you create an encrypted volume from an encrypted snapshot that you own, Amazon EC2 works with AWS KMS to encrypt and decrypt your EBS volumes as follows:

1. Amazon EC2 sends a GenerateDataKeyWithoutPlaintext request to AWS KMS, specifying the KMS key that you chose for volume encryption.
2. If the volume is encrypted using the same KMS key as the snapshot, AWS KMS uses the same data key as the snapshot and encrypts it under that same KMS key. If the volume is encrypted using a different KMS key, AWS KMS generates a new data key and encrypts it under the KMS key that you specified. The encrypted data key is sent to Amazon EBS to be stored with the volume metadata.
3. When you attach the encrypted volume to an instance, Amazon EC2 sends a CreateGrant request to AWS KMS so that it can decrypt the data key.
4. AWS KMS decrypts the encrypted data key and sends the decrypted data key to Amazon EC2.
5. Amazon EC2 uses the plaintext data key in hypervisor memory to encrypt disk I/O to the volume. The plaintext data key persists in memory as long as the volume is attached to the instance.

How EBS encryption works when the snapshot is unencrypted

When you create an encrypted volume from unencrypted snapshot, Amazon EC2 works with AWS KMS to encrypt and decrypt your EBS volumes as follows:
1. Amazon EC2 sends a `CreateGrant` request to AWS KMS, so that it can encrypt the volume that is created from the snapshot.
2. Amazon EC2 sends a `GenerateDataKeyWithoutPlaintext` request to AWS KMS, specifying the KMS key that you chose for volume encryption.
3. AWS KMS generates a new data key, encrypts it under the KMS key that you chose for volume encryption, and sends the encrypted data key to Amazon EBS to be stored with the volume metadata.
4. Amazon EC2 sends a `Decrypt` request to AWS KMS to get the encryption key to encrypt the volume data.
5. When you attach the encrypted volume to an instance, Amazon EC2 sends a `CreateGrant` request to AWS KMS, so that it can decrypt the data key.
6. When you attach the encrypted volume to an instance, Amazon EC2 sends a `Decrypt` request to AWS KMS, specifying the encrypted data key.
7. AWS KMS decrypts the encrypted data key and sends the decrypted data key to Amazon EC2.
8. Amazon EC2 uses the plaintext data key in hypervisor memory to encrypt disk I/O to the volume. The plaintext data key persists in memory as long as the volume is attached to the instance.

For more information, see [How Amazon Elastic Block Store (Amazon EBS) uses AWS KMS](https://docs.aws.amazon.com/kms/latest/APIReference/developerguide/how-aws-key-management-service-encrypts-data.html) and [Amazon EC2 example two](https://docs.aws.amazon.com/kms/latest/APIReference/developerguide/how-aws-key-management-service-encrypts-data.html) in the [AWS Key Management Service Developer Guide](https://docs.aws.amazon.com/kms/latest/developerguide/).

**Requirements**

Before you begin, verify that the following requirements are met.

**Supported volume types**

Encryption is supported by all EBS volume types. You can expect the same IOPS performance on encrypted volumes as on unencrypted volumes, with a minimal effect on latency. You can access encrypted volumes the same way that you access unencrypted volumes. Encryption and decryption are handled transparently, and they require no additional action from you or your applications.

**Supported instance types**

Amazon EBS encryption is available on all current generation (p. 275) and previous generation (p. 281) instance types.

**Permissions for users**

When you configure a KMS key as the default key for EBS encryption, the default KMS key policy allows any user with access to the required KMS actions to use this KMS key to encrypt or decrypt EBS resources. You must grant users permission to call the following actions in order to use EBS encryption:

- `kms:CreateGrant`
- `kms:Decrypt`
- `kms:DescribeKey`
- `kms:GenerateDataKeyWithoutPlaintext`
- `kms:ReEncrypt`

**Tip**

To follow the principle of least privilege, do not allow full access to `kms:CreateGrant`. Instead, use the `kms:GrantIsForAWSResource` condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service, as shown in the following example.

```
For more information, see [Allows access to the AWS account and enables IAM policies](#) in the [Default key policy section in the AWS Key Management Service Developer Guide](#).

**Permissions for instances**

When an instance attempts to interact with an encrypted AMI, volume, or snapshot, a KMS key grant is issued to the instance's identity-only role. The identity-only role is an IAM role that is used by the instance to interact with encrypted AMIs, volumes, or snapshots on your behalf.

Identity-only roles do not need to be manually created or deleted, and they have no policies associated with them. Additionally, you can’t access the identity-only role credentials.

**Note**

Identity-only roles are not used by applications on your instance to access other AWS KMS encrypted resources, such as Amazon S3 objects or Dynamo DB tables. These operations are done using the credentials of an Amazon EC2 instance role, or other AWS credentials that you have configured on your instance.

Identity-only roles are subject to [service control policies](#) (SCPs), and [KMS key policies](#). If an SCP or KMS key denies the identity-only role access to a KMS key, you may fail to launch EC2 instances with encrypted volumes, or using encrypted AMIs or snapshots.

If you are creating an SCP or key policy that denies access based on network location using the `aws:SourceIp`, `aws:VpcSourceIp`, `aws:SourceVpc`, or `aws:SourceVpce` AWS global condition keys, then you must ensure that these policy statements do not apply to instance-only roles. For example policies, see [Data Perimeter Policy Examples](#).

Identity-only role ARNs use the following format:

```
arn:aws-partition:iam::account_id:role/aws:ec2-infrastructure/instance_id
```

When a key grant is issued to an instance, the key grant is issued to the assumed-role session specific to that instance. The grantee principal ARN uses the following format:

```
arn:aws-partition:sts::account_id:assumed-role/aws:ec2-infrastructure/instance_id
```

**Default KMS key for EBS encryption**

Amazon EBS automatically creates a unique AWS managed key in each Region where you store AWS resources. This KMS key has the alias `alias/aws/ebs`. By default, Amazon EBS uses this KMS key for
encryption. Alternatively, you can specify a symmetric customer managed encryption key that you created as the default KMS key for EBS encryption. Using your own KMS key gives you more flexibility, including the ability to create, rotate, and disable KMS keys.

**Important**
Amazon EBS does not support asymmetric encryption KMS keys. For more information, see Using symmetric and asymmetric encryption KMS keys in the AWS Key Management Service Developer Guide.

**New console**

To configure the default KMS key for EBS encryption for a Region

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region.
3. From the navigation pane, select EC2 Dashboard.
4. In the upper-right corner of the page, choose Account Attributes, EBS encryption.
5. Choose Manage.
6. For Default encryption key, choose a symmetric customer managed encryption key.
7. Choose Update EBS encryption.

**Old console**

To configure the default KMS key for EBS encryption for a Region

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region.
3. From the navigation pane, select EC2 Dashboard.
4. In the upper-right corner of the page, choose Account Attributes, Settings.
5. Choose Change the default key and then choose an available KMS key.
6. Choose Save settings.

**Encryption by default**

You can configure your AWS account to enforce the encryption of the new EBS volumes and snapshot copies that you create. For example, Amazon EBS encrypts the EBS volumes created when you launch an instance and the snapshots that you copy from an unencrypted snapshot. For examples of transitioning from unencrypted to encrypted EBS resources, see Encrypt unencrypted resources (p. 1982).

Encryption by default has no effect on existing EBS volumes or snapshots.

**Considerations**

- Encryption by default is a Region-specific setting. If you enable it for a Region, you cannot disable it for individual volumes or snapshots in that Region.
- Amazon EBS encryption by default is supported on all current generation (p. 275) and previous generation (p. 281) instance types.
- If you copy a snapshot and encrypt it to a new KMS key, a complete (non-incremental) copy is created. This results in additional storage costs.
- When migrating servers using AWS Server Migration Service (SMS), do not turn on encryption by default. If encryption by default is already on and you are experiencing delta replication failures, turn off encryption by default. Instead, enable AMI encryption when you create the replication job.
Amazon EC2 console

To enable encryption by default for a Region
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region.
3. From the navigation pane, select EC2 Dashboard.
4. In the upper-right corner of the page, choose Account Attributes, EBS encryption.
5. Choose Manage.
6. Select Enable. You keep the AWS managed key with the alias alias/aws/ebs created on your behalf as the default encryption key, or choose a symmetric customer managed encryption key.
7. Choose Update EBS encryption.

AWS CLI

To view the encryption by default setting
- For a specific Region
  $ aws ec2 get-ebs-encryption-by-default --region region
- For all Regions in your account
  $ for region in $(aws ec2 describe-regions --region us-east-1 --query "Regions[*].RegionName" --output text); do   default=$(aws ec2 get-ebs-encryption-by-default --region $region --query "{Encryption_By_Default:EbsEncryptionByDefault}" --output text);   kms_key=$(aws ec2 get-ebs-default-kms-key-id --region $region | jq '.KmsKeyId');   echo "$region  --- $default  --- $kms_key"; done

To enable encryption by default
- For a specific Region
  $ aws ec2 enable-ebs-encryption-by-default --region region
- For all Regions in your account
  $ for region in $(aws ec2 describe-regions --region us-east-1 --query "Regions[*].RegionName" --output text); do   default=$(aws ec2 enable-ebs-encryption-by-default --region $region --query "{Encryption_By_Default:EbsEncryptionByDefault}" --output text);   kms_key=$(aws ec2 get-ebs-default-kms-key-id --region $region | jq '.KmsKeyId');   echo "$region  --- $default  --- $kms_key"; done

To disable encryption by default
- For a specific Region
  $ aws ec2 disable-ebs-encryption-by-default --region region
- For all Regions in your account
  $ for region in $(aws ec2 describe-regions --region us-east-1 --query "Regions[*].RegionName" --output text); do   default=$(aws ec2 disable-ebs-encryption-by-default --region $region --query "{Encryption_By_Default:EbsEncryptionByDefault}" --output text);   kms_key=$(aws ec2 get-ebs-default-kms-key-id --region $region | jq '.KmsKeyId');   echo "$region  --- $default  --- $kms_key"; done
To view the encryption by default setting

- For a specific Region

```powershell
PS C:\> Get-EC2EbsEncryptionByDefault -Region region
```

- For all Regions in your account

```powershell
PS C:\> (Get-EC2Region).RegionName | ForEach-Object { [PSCustomObject]@{ Region = $_; EC2EbsEncryptionByDefault = Get-EC2EbsEncryptionByDefault -Region $_; EC2EbsDefaultKmsKeyId = Get-EC2EbsDefaultKmsKeyId -Region $_ } } | Format-Table -AutoSize
```

To enable encryption by default

- For a specific Region

```powershell
PS C:\> Enable-EC2EbsEncryptionByDefault -Region region
```

- For all Regions in your account

```powershell
PS C:\> (Get-EC2Region).RegionName | ForEach-Object { [PSCustomObject]@{ Region = $_; EC2EbsEncryptionByDefault = Enable-EC2EbsEncryptionByDefault -Region $_; EC2EbsDefaultKmsKeyId = Get-EC2EbsDefaultKmsKeyId -Region $_ } } | Format-Table -AutoSize
```

To disable encryption by default

- For a specific Region

```powershell
PS C:\> Disable-EC2EbsEncryptionByDefault -Region region
```

- For all Regions in your account

```powershell
PS C:\> (Get-EC2Region).RegionName | ForEach-Object { [PSCustomObject]@{ Region = $_; EC2EbsEncryptionByDefault = Disable-EC2EbsEncryptionByDefault -Region $_; EC2EbsDefaultKmsKeyId = Get-EC2EbsDefaultKmsKeyId -Region $_ } } | Format-Table -AutoSize
```

You cannot change the KMS key that is associated with an existing snapshot or encrypted volume. However, you can associate a different KMS key during a snapshot copy operation so that the resulting copied snapshot is encrypted by the new KMS key.

Encrypt EBS resources

You encrypt EBS volumes by enabling encryption, either using `encryption by default (p. 1979)` or by enabling encryption when you create a volume that you want to encrypt.
Amazon Elastic Compute Cloud
User Guide for Linux Instances
EBS data services

When you encrypt a volume, you can specify the symmetric encryption KMS key to use to encrypt the volume. If you do not specify a KMS key, the KMS key that is used for encryption depends on the encryption state of the source snapshot and its ownership. For more information, see the encryption outcomes table (p. 1986).

Note
If you are using the API or AWS CLI to specify a KMS key, be aware that AWS authenticates the KMS key asynchronously. If you specify a KMS key ID, an alias, or an ARN that is not valid, the action can appear to complete, but it eventually fails.

You cannot change the KMS key that is associated with an existing snapshot or volume. However, you can associate a different KMS key during a snapshot copy operation so that the resulting copied snapshot is encrypted by the new KMS key.

Encrypt an empty volume on creation

When you create a new, empty EBS volume, you can encrypt it by enabling encryption for the specific volume creation operation. If you enabled EBS encryption by default, the volume is automatically encrypted using your default KMS key for EBS encryption. Alternatively, you can specify a different symmetric encryption KMS key for the specific volume creation operation. The volume is encrypted by the time it is first available, so your data is always secured. For detailed procedures, see Create an Amazon EBS volume (p. 1794).

By default, the KMS key that you selected when creating a volume encrypts the snapshots that you make from the volume and the volumes that you restore from those encrypted snapshots. You cannot remove encryption from an encrypted volume or snapshot, which means that a volume restored from an encrypted snapshot, or a copy of an encrypted snapshot, is always encrypted.

Public snapshots of encrypted volumes are not supported, but you can share an encrypted snapshot with specific accounts. For detailed directions, see Share an Amazon EBS snapshot (p. 1864).

Encrypt unencrypted resources

You cannot directly encrypt existing unencrypted volumes or snapshots. However, you can create encrypted volumes or snapshots from unencrypted volumes or snapshots. If you enable encryption by default, Amazon EBS automatically encrypts new volumes and snapshots using your default KMS key for EBS encryption. Otherwise, you can enable encryption when you create an individual volume or snapshot, using either the default KMS key for Amazon EBS encryption or a symmetric customer managed encryption key. For more information, see Create an Amazon EBS volume (p. 1794) and Copy an Amazon EBS snapshot (p. 1836).

To encrypt the snapshot copy to a customer managed key, you must both enable encryption and specify the KMS key, as shown in Copy an unencrypted snapshot (encryption by default not enabled) (p. 1984).

Important
Amazon EBS does not support asymmetric encryption KMS keys. For more information, see Using Symmetric and Asymmetric encryption KMS keys in the AWS Key Management Service Developer Guide.

You can also apply new encryption states when launching an instance from an EBS-backed AMI. This is because EBS-backed AMIs include snapshots of EBS volumes that can be encrypted as described. For more information, see Use encryption with EBS-backed AMIs (p. 228).

Rotating AWS KMS keys

Cryptographic best practices discourage extensive reuse of encryption keys. To create new cryptographic material for your KMS key, you can create new KMS key, and then change your applications or aliases to use the new KMS key. Or, you can enable automatic key rotation for an existing KMS key.

When you enable automatic key rotation for a KMS key, AWS KMS generates new cryptographic material for the KMS key every year. AWS KMS saves all previous versions of the cryptographic material so you...
can decrypt any data encrypted with that KMS key. AWS KMS does not delete any rotated key material until you delete the KMS key.

When you use a rotated KMS key to encrypt data, AWS KMS uses the current key material. When you use the rotated KMS key to decrypt data, AWS KMS uses the version of the key material that was used to encrypt it. You can safely use a rotated KMS key in applications and AWS services without code changes.

**Note**
Automatic key rotation is supported only for symmetric customer managed keys with key material that AWS KMS creates. AWS KMS automatically rotates AWS managed keys every year. You can't enable or disable key rotation for AWS managed keys.

For more information, see Rotating KMS key in the AWS Key Management Service Developer Guide.

### Encryption scenarios

When you create an encrypted EBS resource, it is encrypted by your account's default KMS key for EBS encryption unless you specify a different customer managed key in the volume creation parameters or the block device mapping for the AMI or instance. For more information, see Default KMS key for EBS encryption (p. 1978).

The following examples illustrate how you can manage the encryption state of your volumes and snapshots. For a full list of encryption cases, see the encryption outcomes table (p. 1986).

**Examples**
- Restore an unencrypted volume (encryption by default not enabled) (p. 1983)
- Restore an unencrypted volume (encryption by default enabled) (p. 1984)
- Copy an unencrypted snapshot (encryption by default not enabled) (p. 1984)
- Copy an unencrypted snapshot (encryption by default enabled) (p. 1984)
- Re-encrypt an encrypted volume (p. 1985)
- Re-encrypt an encrypted snapshot (p. 1985)
- Migrate data between encrypted and unencrypted volumes (p. 1986)
- Encryption outcomes (p. 1986)

**Restore an unencrypted volume (encryption by default not enabled)**

Without encryption by default enabled, a volume restored from an unencrypted snapshot is unencrypted by default. However, you can encrypt the resulting volume by setting the Encrypted parameter and, optionally, the KmsKeyId parameter. The following diagram illustrates the process.

![Diagram illustrating the process of restoring an unencrypted volume](image)

If you leave out the KmsKeyId parameter, the resulting volume is encrypted using your default KMS key for EBS encryption. You must specify a KMS key ID to encrypt the volume to a different KMS key.
For more information, see Create a volume from a snapshot (p. 1796).

**Restore an unencrypted volume (encryption by default enabled)**

When you have enabled encryption by default, encryption is mandatory for volumes restored from unencrypted snapshots, and no encryption parameters are required for your default KMS key to be used. The following diagram shows this simple default case:

![Diagram of default case](image)

If you want to encrypt the restored volume to a symmetric customer managed encryption key, you must supply both the Encrypted and KmsKeyId parameters as shown in Restore an unencrypted volume (encryption by default not enabled) (p. 1983).

**Copy an unencrypted snapshot (encryption by default not enabled)**

Without encryption by default enabled, a copy of an unencrypted snapshot is unencrypted by default. However, you can encrypt the resulting snapshot by setting the Encrypted parameter and, optionally, the KmsKeyId parameter. If you omit KmsKeyId, the resulting snapshot is encrypted by your default KMS key. You must specify a KMS key ID to encrypt the volume to a different symmetric encryption KMS key.

The following diagram illustrates the process:

![Diagram of copy process](image)

You can encrypt an EBS volume by copying an unencrypted snapshot to an encrypted snapshot and then creating a volume from the encrypted snapshot. For more information, see Copy an Amazon EBS snapshot (p. 1836).

**Copy an unencrypted snapshot (encryption by default enabled)**

When you have enabled encryption by default, encryption is mandatory for copies of unencrypted snapshots, and no encryption parameters are required if your default KMS key is used. The following diagram illustrates this default case:
Re-encrypt an encrypted volume

When the CreateVolume action operates on an encrypted snapshot, you have the option of re-encrypting it with a different KMS key. The following diagram illustrates the process. In this example, you own two KMS keys, KMS key A and KMS key B. The source snapshot is encrypted by KMS key A. During volume creation, with the KMS key ID of KMS key B specified as a parameter, the source data is automatically decrypted, then re-encrypted by KMS key B.

For more information, see Create a volume from a snapshot (p. 1796).

Re-encrypt an encrypted snapshot

The ability to encrypt a snapshot during copying allows you to apply a new symmetric encryption KMS key to an already-encrypted snapshot that you own. Volumes restored from the resulting copy are only accessible using the new KMS key. The following diagram illustrates the process. In this example, you own two KMS keys, KMS key A and KMS key B. The source snapshot is encrypted by KMS key A. During copy, with the KMS key ID of KMS key B specified as a parameter, the source data is automatically re-encrypted by KMS key B.
In a related scenario, you can choose to apply new encryption parameters to a copy of a snapshot that has been shared with you. By default, the copy is encrypted with a KMS key shared by the snapshot's owner. However, we recommend that you create a copy of the shared snapshot using a different KMS key that you control. This protects your access to the volume if the original KMS key is compromised, or if the owner revokes the KMS key for any reason. For more information, see Encryption and snapshot copying (p. 1838).

**Migrate data between encrypted and unencrypted volumes**

When you have access to both an encrypted and unencrypted volume, you can freely transfer data between them. EC2 carries out the encryption and decryption operations transparently.

For example, use the `rsync` command to copy the data. In the following command, the source data is located in `/mnt/source` and the destination volume is mounted at `/mnt/destination`.

```
[ec2-user ~]$ sudo rsync -avh --progress /mnt/source/ /mnt/destination/
```

**Encryption outcomes**

The following table describes the encryption outcome for each possible combination of settings.

<table>
<thead>
<tr>

</table>
This is the default customer managed key used for EBS encryption for the AWS account and Region. By default this is a unique AWS managed key for EBS, or you can specify a customer managed key. For more information, see Default KMS key for EBS encryption (p. 1978).

** This is a customer managed key specified for the volume at launch time. This customer managed key is used instead of the default customer managed key for the AWS account and Region.

Set encryption defaults using the API and CLI

You can manage encryption by default and the default KMS key using the following API actions and CLI commands.

<table>
<thead>
<tr>
<th>API action</th>

Amazon EBS fast snapshot restore

Amazon EBS fast snapshot restore (FSR) enables you to create a volume from a snapshot that is fully initialized at creation. This eliminates the latency of I/O operations on a block when it is accessed for the first time. Volumes that are created using fast snapshot restore instantly deliver all of their provisioned performance.

To get started, enable fast snapshot restore for specific snapshots in specific Availability Zones. Each snapshot and Availability Zone pair refers to one fast snapshot restore. When you create a volume from one of these snapshots in one of its enabled Availability Zones, the volume is restored using fast snapshot restore.

Fast snapshot restore must be explicitly enabled on a per-snapshot basis. If you create a new snapshot from a volume that was restored from a fast snapshot restore-enabled snapshot, the new snapshot is not automatically enabled for fast snapshot restore. You must explicitly enable it for the new snapshot.

The number of volumes that you can restore with the full performance benefit of fast snapshot restore is determined by volume creation credits for the snapshot. For more information see Volume creation credits (p. 1989).

You can enable fast snapshot restore for snapshots that you own and for public and private snapshots that are shared with you.
Considerations

- Fast snapshot restore is not supported with AWS Outposts, Local Zones, and Wavelength Zones.
- Fast snapshot restore can be enabled on snapshots with a size of 16 TiB or less.
- Volumes provisioned with performance up to 64,000 IOPS and 1,000 MiB/s throughput receive the full performance benefit of fast snapshot restore. For volumes provisioned with performance greater than 64,000 IOPS or 1,000 MiB/s throughput, we recommend that you initialize the volume to receive its full performance.

Volume creation credits

The number of volumes that receive the full performance benefit of fast snapshot restore is determined by the volume creation credits for the snapshot. There is one credit bucket per snapshot per Availability Zone. Each volume that you create from a snapshot with fast snapshot restore enabled consumes one credit from the credit bucket. You must have at least one credit in the bucket to create an initialized volume from the snapshot. If you create a volume but there is less than one credit in the bucket, the volume is created without benefit of fast snapshot restore.

When you enable fast snapshot restore for a snapshot that is shared with you, you get a separate credit bucket for the shared snapshot in your account. If you create volumes from the shared snapshot, the credits are consumed from your credit bucket; they are not consumed from the snapshot owner’s credit bucket.

The size of a credit bucket and the rate at which it refills depends on the size of the snapshot, not the size of the volumes created from the snapshot.

When you enable fast snapshot restore for a snapshot, the credit bucket starts with zero credits, and it gets filled at a set rate until it reaches its maximum credit capacity. Also, as you consume credits, the credit bucket is refilled over time until it reaches its maximum credit capacity.

The fill rate for a credit bucket is calculated as follows:

\[
\text{MIN} \left( 10, \frac{1024}{\text{snapshot\_size\_gib}} \right)
\]

And the size of the credit bucket is calculated as follows:

\[
\text{MAX} \left( 1, \text{MIN} \left( 10, \frac{1024}{\text{snapshot\_size\_gib}} \right) \right)
\]

For example, if you enable fast snapshot restore for a snapshot with a size of 128 GiB, the fill rate is 0.1333 credits per minute.

\[
\text{MIN} \left( 10, \frac{1024}{128} \right)
= \text{MIN} \left( 10, 8 \right)
= 8 \text{ credits per hour}
= 0.1333 \text{ credits per minute}
\]
And the maximum size of the credit bucket is 8 credits.

\[
\text{MAX } (1, \text{MIN } (10, (1024 ÷ 128))) \\
= \text{MAX } (1, \text{MIN } (10, 8)) \\
= \text{MAX } (1, 8) \\
= 8 \text{ credits}
\]

In this example, when you enable fast snapshot restore, the credit bucket starts with zero credits. After 8 minutes, the credit bucket has enough credits to create one initialized volume (0.1333 credits × 8 minutes = 1.066 credits). When the credit bucket is full, you can create 8 initialized volumes simultaneously (8 credits). When the bucket is below its maximum capacity, it refills with 0.1333 credits per minute.

You can use Cloudwatch metrics to monitor the size of your credit buckets and the number of credits available in each bucket. For more information, see Fast snapshot restore metrics (p. 2047).

After you create a volume from a snapshot with fast snapshot restore enabled, you can describe the volume using describe-volumes and check the fastRestored field in the output to determine whether the volume was created as an initialized volume using fast snapshot restore.

Manage fast snapshot restore

Topics
- Enable or disable fast snapshot restore (p. 1990)
- View the fast snapshot restore state for a snapshot (p. 1991)
- View volumes restored using fast snapshot restore (p. 1992)

Enable or disable fast snapshot restore

Fast snapshot restore is disabled for a snapshot by default. You can enable or disable fast snapshot restore for snapshots that you own and for snapshots that are shared with you. When you enable or disable fast snapshot restore for a snapshot, the changes apply to your account only.

**Note**
When you enable fast snapshot restore for a snapshot, your account is billed for each minute that fast snapshot restore is enabled in a particular Availability Zone. Charges are pro-rated and have a minimum of one hour.

When you delete a snapshot that you own, fast snapshot restore is automatically disabled for that snapshot in your account. If you enabled fast snapshot restore for a snapshot that is shared with you, and the snapshot owner deletes or unshares it, fast snapshot restore is automatically disabled for the shared snapshot in your account.

If you enabled fast snapshot restore for a snapshot that is shared with you, and it has been encrypted using a custom CMK, fast snapshot restore is not automatically disabled for the snapshot when the snapshot owner revokes your access to the custom CMK. You must manually disable fast snapshot restore for that snapshot.

Use one of the following methods to enable or disable fast snapshot restore for a snapshot that you own or for a snapshot that is shared with you.

**Console**

**To enable or disable fast snapshot restore**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Snapshots.
3. Select the snapshot, and choose Actions, Manage fast snapshot restore.
4. The **Fast snapshot restore settings** section lists all of the Availability Zones in which you can enable fast snapshot restore for the selected snapshot. The **Current status** volume indicates whether fast snapshot restore is currently enabled or disabled for each zone.

To enable fast snapshot restore in a zone where it is currently disabled, select the zone, choose **Enable**, and then to confirm, choose **Enable**.

To disable fast snapshot restore in a zone where it is currently enabled, select the zone, and then choose **Disable**.

5. After you have made the required changes, choose **Close**.

**AWS CLI**

**To manage fast snapshot restore using the AWS CLI**

- `enable-fast-snapshot-restores`
- `disable-fast-snapshot-restores`
- `describe-fast-snapshot-restores`

**Note**

After you enable fast snapshot restore for a snapshot, it enters the **optimizing** state. Snapshots that are in the optimizing state provide some performance benefits when using them to restore volumes. They start to provide the full performance benefits of fast snapshot restore only after they enter the enabled state.

**View the fast snapshot restore state for a snapshot**

Fast snapshot restore for a snapshot can be in one of the following states.

- **enabling** — A request was made to enable fast snapshot restore.
- **optimizing** — Fast snapshot restore is being enabled. It takes 60 minutes per TiB to optimize a snapshot. Snapshots in this state offer some performance benefit when restoring volumes.
- **enabled** — Fast snapshot restore is enabled. Snapshots in this state offer the full performance benefit when restoring volumes.
- **disabling** — A request was made to disable fast snapshot restore, or a request to enable fast snapshot restore failed.
- **disabled** — Fast snapshot restore is disabled. You can enable fast snapshot restore again as needed.

Use one of the following methods to view the state of fast snapshot restore for a snapshot that you own or for a snapshot that is shared with you.

**Console**

**To view the state of fast snapshot restore using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Snapshots**.
3. Select the snapshot.
4. On the **Details** tab, **Fast snapshot restore**, indicates the state of fast snapshot restore.

**AWS CLI**

**To view snapshots with fast snapshot restore enabled using the AWS CLI**
Use the `describe-fast-snapshot-restores` command to describe the snapshots that are enabled for fast snapshot restore.

```bash
aws ec2 describe-fast-snapshot-restores --filters Name=state,Values(enabled)
```

The following is example output.

```
{
    "FastSnapshotRestores": [
        {
            "SnapshotId": "snap-0e946653493cb0447",
            "AvailabilityZone": "us-east-2a",
            "State": "enabled",
            "StateTransitionReason": "Client.UserInitiated - Lifecycle state transition",
            "OwnerId": "123456789012",
            "EnablingTime": "2020-01-25T23:57:49.596Z",
            "OptimizingTime": "2020-01-25T23:58:25.573Z",
            "EnabledTime": "2020-01-25T23:59:29.852Z"
        },
        {
            "SnapshotId": "snap-0e946653493cb0447",
            "AvailabilityZone": "us-east-2b",
            "State": "enabled",
            "StateTransitionReason": "Client.UserInitiated - Lifecycle state transition",
            "OwnerId": "123456789012",
            "EnablingTime": "2020-01-25T23:57:49.596Z",
            "OptimizingTime": "2020-01-25T23:58:25.573Z",
            "EnabledTime": "2020-01-25T23:59:29.852Z"
        }
    ]
}
```

View volumes restored using fast snapshot restore

When you create a volume from a snapshot that is enabled for fast snapshot restore in the Availability Zone for the volume, it is restored using fast snapshot restore.

Use the `describe-volumes` command to view volumes that were created from a snapshot that is enabled for fast snapshot restore.

```bash
aws ec2 describe-volumes --filters Name=fast-restored,Values=true
```

The following is example output.

```
{
    "Volumes": [
        {
            "Attachments": [],
            "AvailabilityZone": "us-east-2a",
            "CreateTime": "2020-01-26T00:34:11.093Z",
            "Encrypted": true,
            "KmsKeyId": "arn:aws:kms:us-west-2:123456789012:key/8c5b2c63-b9bc-45a3-a87a-5513e232e843",
            "Size": 20,
            "SnapshotId": "snap-0e946653493cb0447",
            "State": "available",
            "VolumeId": "vol-0d371921d4ca797b0",
```
Monitor fast snapshot restore

Amazon EBS emits Amazon CloudWatch events when the fast snapshot restore state for a snapshot changes. For more information, see EBS fast snapshot restore events (p. 2056).

Fast snapshot restore quotas

You can enable up to 5 snapshots for fast snapshot restore per Region. The quota applies to snapshots that you own and snapshots that are shared with you. If you enable fast snapshot restore for a snapshot that is shared with you, it counts towards your fast snapshot restore quota. It does not count towards the snapshot owner's fast snapshot restore quota.

Pricing and Billing

You are billed for each minute that fast snapshot restore is enabled for a snapshot in a particular Availability Zone. Charges are pro-rated with a minimum of one hour.

For example, if you enable fast snapshot restore for one snapshot in US-East-1a for one month (30 days), you are billed $540 (1 snapshot x 1 AZ x 720 hours x $0.75 per hour). If you enable fast snapshot restore for two snapshots in us-east-1a, us-east-1b, and us-east-1c for the same period, you are billed $3240 (2 snapshots x 3 AZs x 720 hours x $0.75 per hour).

If you enable fast snapshot restore for a public or private snapshot that is shared with you, your account is billed; the snapshot owner is not billed. When a snapshot that is shared with you is deleted or unshared by the snapshot owner, fast snapshot restore is disabled for the snapshot in your account and billing is stopped.

For more information, see Amazon EBS pricing.

Amazon EBS and NVMe on Linux instances

EBS volumes are exposed as NVMe block devices on instances built on the Nitro System (p. 282). The device names are /dev/nvme0n1, /dev/nvme1n1, and so on. The device names that you specify in a block device mapping are renamed using NVMe device names (/dev/nvme[0-26]n1). The block device driver can assign NVMe device names in a different order than you specified for the volumes in the block device mapping.

The EBS performance guarantees stated in Amazon EBS Product Details are valid regardless of the block-device interface.

For information about EBS volumes and NVME on Windows instances, see the User Guide for Windows Instances.

Contents

- Install or upgrade the NVMe driver (p. 1994)
- Identify the EBS device (p. 1995)
- Work with NVMe EBS volumes (p. 1997)
- I/O operation timeout (p. 1997)
Install or upgrade the NVMe driver

To access NVMe volumes, the NVMe drivers must be installed. Instances can support NVMe EBS volumes, NVMe instance store volumes, both types of NVMe volumes, or no NVMe volumes. For more information, see Summary of networking and storage features (p. 284).

The following AMIs include the required NVMe drivers:

- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 or later with linux-aws kernel
  
  **Note** AWS Graviton-based instance types require Ubuntu 18.04 or later with linux-aws kernel
- Red Hat Enterprise Linux 6.5 or later
- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later
- Red Hat Enterprise Linux 6.5 or later
- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later

For more information about NVMe drivers on Windows instances, see Amazon EBS and NVMe on Windows Instances in the Amazon EC2 User Guide for Windows Instances.

To confirm that your instance has the NVMe driver

You can confirm that your instance has the NVMe driver using the following command.

- Amazon Linux, RHEL, CentOS, and SUSE Linux Enterprise Server

  ```
  $ modinfo nvme
  ```

  If the instance has the NVMe driver, the command returns information about the driver.

- Amazon Linux 2 and Ubuntu

  ```
  $ ls /sys/module/ | grep nvme
  ```

  If the instance has the NVMe driver, the command returns the installed drivers.

To update the NVMe driver

If your instance has the NVMe driver, you can update the driver to the latest version using the following procedure.

1. Connect to your instance.
2. Update your package cache to get necessary package updates as follows.

   ```
   [ec2-user ~]$ sudo yum update -y
   ```
For Ubuntu and Debian:

```
[ec2-user ~]$ sudo apt-get update -y
```

3. Ubuntu 16.04 and later include the `linux-aws` package, which contains the NVMe and ENA drivers required by Nitro-based instances. Upgrade the `linux-aws` package to receive the latest version as follows:

```
[ec2-user ~]$ sudo apt-get install --only-upgrade -y linux-aws
```

For Ubuntu 14.04, you can install the latest `linux-aws` package as follows:

```
[ec2-user ~]$ sudo apt-get install linux-aws
```

4. Reboot your instance to load the latest kernel version.

```
sudo reboot
```

5. Reconnect to your instance after it has rebooted.

**Identify the EBS device**

EBS uses single-root I/O virtualization (SR-IOV) to provide volume attachments on Nitro-based instances using the NVMe specification. These devices rely on standard NVMe drivers on the operating system. These drivers typically discover attached devices by scanning the PCI bus during instance boot, and create device nodes based on the order in which the devices respond, not on how the devices are specified in the block device mapping. In Linux, NVMe device names follow the pattern `/dev/nvme<x>n<y>`, where `<x>` is the enumeration order, and, for EBS, `<y>` is 1. Occasionally, devices can respond to discovery in a different order in subsequent instance starts, which causes the device name to change. Additionally, the device name assigned by the block device driver can be different from the name specified in the block device mapping.

We recommend that you use stable identifiers for your EBS volumes within your instance, such as one of the following:

- For Nitro-based instances, the block device mappings that are specified in the Amazon EC2 console when you are attaching an EBS volume or during `AttachVolume` or `RunInstances` API calls are captured in the vendor-specific data field of the NVMe controller identification. With Amazon Linux AMIs later than version 2017.09.01, we provide a `udev` rule that reads this data and creates a symbolic link to the block-device mapping.

- The EBS volume ID and the mount point are stable between instance state changes. The NVMe device name can change depending on the order in which the devices respond during instance boot. We recommend using the EBS volume ID and the mount point for consistent device identification.

- NVMe EBS volumes have the EBS volume ID set as the serial number in the device identification. Use the `lsblk -o +SERIAL` command to list the serial number.

- The NVMe device name format can vary depending on whether the EBS volume was attached during or after the instance launch. NVMe device names for volumes attached after instance launch do not include the `/dev/` prefix, while NVMe device names for volumes attached during instance launch do not include the `/dev/` prefix. If you are using an Amazon Linux or FreeBSD AMI, use the `sudo ebsnvme-id /dev/nvme0n1 -u` command for a consistent NVMe device name. For other distributions, use the `sudo nvme id-ctrl -v /dev/nvme0n1` command to determine the NVMe device name.

- When a device is formatted, a UUID is generated that persists for the life of the filesystem. A device label can be specified at the same time. For more information, see Make an Amazon EBS volume available for use on Linux (p. 1803) and Boot from the wrong volume (p. 2221).
Amazon Linux AMIs

With Amazon Linux AMI 2017.09.01 or later (including Amazon Linux 2), you can run the `ebsnvme-id` command as follows to map the NVMe device name to a volume ID and device name:

The following example shows the command and output for a volume attached during instance launch. Note that the NVMe device name does not include the `/dev/` prefix.

```
[ec2-user ~]$ sudo /sbin/ebsnvme-id /dev/nvme0n1
Volume ID: vol-01324f611e2463981
sda
```

The following example shows the command and output for a volume attached after instance launch. Note that the NVMe device name includes the `/dev/` prefix.

```
[ec2-user ~]$ sudo /sbin/ebsnvme-id /dev/nvme1n1
Volume ID: vol-064784f1011136656
/dev/sdf
```

Amazon Linux also creates a symbolic link from the device name in the block device mapping (for example, `/dev/sdf`), to the NVMe device name.

FreeBSD AMIs

Starting with FreeBSD 12.2-RELEASE, you can run the `ebsnvme-id` command as shown above. Pass either the name of the NVMe device (for example, `nvme0n1`) or the disk device (for example, `nvd0` or `nda0`). FreeBSD also creates symbolic links to the disk devices (for example, `/dev/aws/disk/ebs/volume_id`).

Other Linux AMIs

With a kernel version of 4.2 or later, you can run the `nvme id-ctrl` command as follows to map an NVMe device to a volume ID. First, install the NVMe command line package, `nvme-cli`, using the package management tools for your Linux distribution. For download and installation instructions for other distributions, refer to the documentation specific to your distribution.

The following example gets the volume ID and NVMe device name for a volume that was attached during instance launch. Note that the NVMe device name does not include the `/dev/` prefix. The device name is available through the NVMe controller vendor-specific extension (bytes 384:4095 of the controller identification):

```
[ec2-user ~]$ sudo nvme id-ctrl -v /dev/nvme0n1
NVME Identify Controller:
vid : 0x1d0f
ssvid : 0x1d0f
sn : vol01234567890abcdef
mn : Amazon Elastic Block Store
... 
0000: 2f 64 65 76 2f 73 64 6a 20 20 20 20 20 20 20 20 "sda..."
```

The following example gets the volume ID and NVMe device name for a volume that was attached after instance launch. Note that the NVMe device name includes the `/dev/` prefix.

```
[ec2-user ~]$ sudo nvme id-ctrl -v /dev/nvme1n1
NVME Identify Controller:
vid : 0x1d0f
ssvid : 0x1d0f
sn : volabcdef01234567890
mn : Amazon Elastic Block Store
```
The `lsblk` command lists available devices and their mount points (if applicable). This helps you determine the correct device name to use. In this example, `/dev/nvme0n1p1` is mounted as the root device and `/dev/nvme1n1` is attached but not mounted.

```
[ec2-user ~]$ lsblk
NAME          MAJ:MIN RM SIZE RO TYPE MOUNTPOINT
nvme1n1       259:3   0  100G  0 disk
nvme0n1       259:0   0    8G  0 disk
nvme0n1p1   259:1   0    8G  0 part /
```

**Work with NVMe EBS volumes**

To format and mount an NVMe EBS volume, see [Make an Amazon EBS volume available for use on Linux](p. 1803).

If you are using Linux kernel 4.2 or later, any change you make to the volume size of an NVMe EBS volume is automatically reflected in the instance. For older Linux kernels, you might need to detach and attach the EBS volume or reboot the instance for the size change to be reflected. With Linux kernel 3.19 or later, you can use the `hdparm` command as follows to force a rescan of the NVMe device:

```
[ec2-user ~]$ sudo hdparm -z /dev/nvme
```

When you detach an NVMe EBS volume, the instance does not have an opportunity to flush the file system caches or metadata before detaching the volume. Therefore, before you detach an NVMe EBS volume, you should first sync and unmount it. If the volume fails to detach, you can attempt a `force-detach` command as described in [Detach an Amazon EBS volume from a Linux instance](p. 1821).

**I/O operation timeout**

EBS volumes attached to Nitro-based instances use the default NVMe driver provided by the operating system. Most operating systems specify a timeout for I/O operations submitted to NVMe devices. The default timeout is 30 seconds and can be changed using the `nvme_core.io_timeout` boot parameter. For most Linux kernels earlier than version 4.6, this parameter is `nvme.io_timeout`.

If I/O latency exceeds the value of this timeout parameter, the Linux NVMe driver fails the I/O and returns an error to the filesystem or application. Depending on the I/O operation, your filesystem or application can retry the error. In some cases, your filesystem might be remounted as read-only.

For an experience similar to EBS volumes attached to Xen instances, we recommend setting `nvme_core.io_timeout` to the highest value possible. For current kernels, the maximum is 4294967295, while for earlier kernels the maximum is 255. Depending on the version of Linux, the timeout might already be set to the supported maximum value. For example, the timeout is set to 4294967295 by default for Amazon Linux AMI 2017.09.01 and later.

You can verify the maximum value for your Linux distribution by writing a value higher than the suggested maximum to `/sys/module/nvme_core/parameters/io_timeout` and checking for the Numerical result out of range error when attempting to save the file.

**Abort command**

The `Abort` command is an NVMe Admin command that is issued to abort a specific command that was previously submitted to the controller. This command is typically issued by the device driver to storage devices that have exceeded the I/O operation timeout threshold. Amazon EC2 instance types that
support the **Abort** command by default will abort a specific command that was previously submitted to
the controller of the attached Amazon EBS device to which an **Abort** command is issued.

The following instance types support the **Abort** command for all attached Amazon EBS volumes by
default: R5b, R6i, M6i, M6a, C6gn, C6i, X2gd, X2iezn, Im4gn, Is4gen.

Other instance types take no action when **Abort** commands are issued to attached Amazon EBS
volumes.

Amazon EBS devices with NVMe device version 1.4 or higher support the **Abort** command.

For more information, see section 5.1 **Abort command** of the NVM Express Base Specification.

### Amazon EBS–optimized instances

An Amazon EBS–optimized instance uses an optimized configuration stack and provides additional,
dedicated capacity for Amazon EBS I/O. This optimization provides the best performance for your EBS
volumes by minimizing contention between Amazon EBS I/O and other traffic from your instance.

EBS–optimized instances deliver dedicated bandwidth to Amazon EBS. When attached to an EBS–
optimized instance, General Purpose SSD (gp2 and gp3) volumes are designed to deliver at least 90% of
their provisioned IOPS performance 99% of the time in a given year, and Provisioned IOPS SSD (io1
and io2) volumes are designed to deliver at least 90% of their provisioned IOPS performance 99.9% of
the time in a given year. Both Throughput Optimized HDD (st1) and Cold HDD (sc1) deliver at least 90% of
their expected throughput performance 99% of the time in a given year. Non-compliant periods are
approximately uniformly distributed, targeting 99% of expected total throughput each hour. For more
information, see Amazon EBS volume types (p. 1775).

**Important**

An instance's EBS performance is bounded by the instance's performance limits, or the
aggregated performance of its attached volumes, whichever is smaller. To achieve maximum
EBS performance, an instance must have attached volumes that provide a combined
performance equal to or greater than the maximum instance performance. For example, to
achieve 80,000 IOPS for r6i.16xlarge, the instance must have at least 5 gp3 volumes
provisioned with 16,000 IOPS each (5 volumes x 16,000 IOPS = 80,000 IOPS).

### Supported instance types

The following tables show which instance types support EBS optimization. They include the dedicated
bandwidth to Amazon EBS, the typical maximum aggregate throughput that can be achieved on that
connection with a streaming read workload and 128 KiB I/O size, and the maximum IOPS the instance
can support if you are using a 16 KiB I/O size.

Choose an EBS–optimized instance that provides more dedicated Amazon EBS throughput than your
application needs; otherwise, the connection between Amazon EBS and Amazon EC2 can become a
performance bottleneck.

**Topics**

- EBS optimized by default (p. 1999)
- EBS optimization supported (p. 2023)
EBS optimized by default

The following tables list the instance types that support EBS optimization and EBS optimization is enabled by default. There is no need to enable EBS optimization and no effect if you disable EBS optimization.

**Note**
You can also view this information programatically using the AWS CLI. For more information, see View instances types that support EBS optimization (p. 2025).

**Topics**
- General purpose (p. 1999)
- Compute optimized (p. 2006)
- Memory optimized (p. 2011)
- Storage optimized (p. 2018)
- Accelerated computing (p. 2021)

**General purpose**

**Important**
Instances indicated with an asterisk (*) can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.

Instances not indicated with an asterisk can sustain the maximum performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

### Compute optimized

**Important**

Instances indicated with an asterisk (*) can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.

Instances not indicated with an asterisk can sustain the maximum performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

### Memory optimized

**Important**

Instances indicated with an asterisk (*) can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.
Instances not indicated with an asterisk can sustain the maximum performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

**Storage optimized**

**Important**

Instances indicated with an asterisk (*) can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.

Instances not indicated with an asterisk can sustain the maximum performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

### Accelerated computing

**Important**

Instances indicated with an asterisk (*) can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.

Instances not indicated with an asterisk can sustain the maximum performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

### EBS optimization supported

The following table lists the instance types that support EBS optimization but EBS optimization is not enabled by default. You can enable EBS optimization when you launch these instances or after they are running. Instances must have EBS optimization enabled to achieve the level of performance described. When you enable EBS optimization for an instance that is not EBS-optimized by default, you pay an additional low, hourly fee for the dedicated capacity. For pricing information, see EBS-Optimized Instances on the Amazon EC2 Pricing, On-Demand Pricing page.

**Note**

You can also view this information programatically using the AWS CLI. For more information, see View instances types that support EBS optimization (p. 2025).

<table>
<thead>

</tbody>
</table>

2023
### Instance size | Maximum bandwidth (Mbps) | Maximum throughput (MB/s, 128 KiB I/O) | Maximum IOPS (16 KiB I/O)
---|---|---|---
| c3.xlarge | 500 | 62.5 | 4000
| c3.2xlarge | 1000 | 125.0 | 8000
| c3.4xlarge | 2000 | 250.0 | 16000
| g2.2xlarge | 1000 | 125.0 | 8000
| i2.xlarge | 500 | 62.5 | 4000
| i2.2xlarge | 1000 | 125.0 | 8000
| i2.4xlarge | 2000 | 250.0 | 16000
| m1.large | 500 | 62.5 | 4000
| m1.xlarge | 1000 | 125.0 | 8000
| m2.2xlarge | 500 | 62.5 | 4000
| m2.4xlarge | 1000 | 125.0 | 8000
| m3.xlarge | 500 | 62.5 | 4000
| m3.2xlarge | 1000 | 125.0 | 8000
| r3.xlarge | 500 | 62.5 | 4000
| r3.2xlarge | 1000 | 125.0 | 8000
| r3.4xlarge | 2000 | 250.0 | 16000

The i2.8xlarge, c3.8xlarge, and r3.8xlarge instances do not have dedicated EBS bandwidth and therefore do not offer EBS optimization. On these instances, network traffic and Amazon EBS traffic share the same 10-gigabit network interface.

### Get maximum performance

You can use the EBSI0Balance% and EBSByteBalance% metrics to help you determine whether your instances are sized correctly. You can view these metrics in the CloudWatch console and set an alarm that is triggered based on a threshold you specify. These metrics are expressed as a percentage. Instances with a consistently low balance percentage are candidates to size up. Instances where the balance percentage never drops below 100% are candidates for downsizing. For more information, see Monitor your instances using CloudWatch (p. 1205).

The high memory instances are designed to run large in-memory databases, including production deployments of the SAP HANA in-memory database, in the cloud. To maximize EBS performance, use high memory instances with an even number of io1 or io2 volumes with identical provisioned performance. For example, for IOPS heavy workloads, use four io1 or io2 volumes with 40,000 provisioned IOPS to get the maximum 160,000 instance IOPS. Similarly, for throughput heavy workloads, use six io1 or io2 volumes with 48,000 provisioned IOPS to get the maximum 4,750 MB/s throughput. For additional recommendations, see Storage Configuration for SAP HANA.
Considerations

- G4dn, I3en, Inf1, M5a, M5ad, R5a, R5ad, T3, T3a, and Z1d instances launched after February 26, 2020 provide the maximum performance listed in the table above. To get the maximum performance from an instance launched before February 26, 2020, stop and start it.

- C5, C5d, C5n, M5d, M5n, M5dn, R5, R5d, R5n, R5dn, and P3dn instances launched after December 3, 2019 provide the maximum performance listed in the table above. To get the maximum performance from an instance launched before December 3, 2019, stop and start it.

- u-6tb1.metal, u-9tb1.metal, and u-12tb1.metal instances launched after March 12, 2020 provide the performance in the table above. Instances of these types launched before March 12, 2020 might provide lower performance. To get the maximum performance from an instance launched before March 12, 2020, contact your account team to upgrade the instance at no additional cost.

View instances types that support EBS optimization

You can use the AWS CLI to view the instances types in the current Region that support EBS optimization.

To view the instance types that support EBS optimization and that have it enabled by default

Use the following `describe-instance-types` command.

```bash
```

Example output for `eu-west-1`:

```
+-----------------+--------------------+---------------------+-----------+
| EBSOptimized   | InstanceType       | MaxBandwidth(Mb/s)  | MaxIOPS   | MaxThroughput(MB/s) |
| default        | m5dn.8xlarge       | 6800                | 30000     | 850.0               |
| default        | m6gd.xlarge        | 4750                | 20000     | 593.75              |
| default        | c4.4xlarge         | 2000                | 16000     | 250.0               |
| default        | r4.16xlarge        | 14000               | 75000     | 1750.0              |
| default        | m5ad.large         | 2880                | 16000     | 360.0               |
```

To view the instance types that support EBS optimization but do not have it enabled by default

Use the following `describe-instance-types` command.

```bash
```
Enable EBS optimization at launch

You can enable optimization for an instance by setting its attribute for EBS optimization.

**To enable Amazon EBS optimization when launching an instance using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. Choose **Launch Instance**.
3. In **Step 1: Choose an Amazon Machine Image (AMI)**, select an AMI.
4. In **Step 2: Choose an Instance Type**, select an instance type that is listed as supporting Amazon EBS optimization.
5. In **Step 3: Configure Instance Details**, complete the fields that you need and choose **Launch as EBS-optimized instance**. If the instance type that you selected in the previous step doesn’t support Amazon EBS optimization, this option is not present. If the instance type that you selected is Amazon EBS–optimized by default, this option is selected and you can’t deselect it.
6. Follow the directions to complete the wizard and launch your instance.

**To enable EBS optimization when launching an instance using the command line**

You can use one of the following commands with the corresponding option. For more information about these command line interfaces, see [Access Amazon EC2 (p. 5)](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/).

- run-instances with **--ebs-optimized** (AWS CLI)
- New-EC2Instance with **-EbsOptimized** (AWS Tools for Windows PowerShell)

Enable EBS optimization for an existing instance

You can enable or disable optimization for an existing instance by modifying its Amazon EBS–optimized instance attribute. If the instance is running, you must stop it first.

**Warning**

When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

**To enable EBS optimization for an existing instance using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**, and select the instance.
3. To stop the instance, choose **Actions**, **Instance state**, **Stop instance**. It can take a few minutes for the instance to stop.
4. With the instance still selected, choose **Actions, Instance settings, Change instance type**.

5. For **Change Instance Type**, do one of the following:

   - If the instance type of your instance is Amazon EBS-optimized by default, **EBS-optimized** is selected and you can't change it. You can choose **Cancel**, because Amazon EBS optimization is already enabled for the instance.
   - If the instance type of your instance supports Amazon EBS optimization, choose **EBS-optimized** and then choose **Apply**.
   - If the instance type of your instance does not support Amazon EBS optimization, you can't choose **EBS-optimized**. You can select an instance type from **Instance type** that supports Amazon EBS optimization, choose **EBS-optimized**, and then choose **Apply**.

6. Choose **Instance state, Start instance**.

**To enable EBS optimization for an existing instance using the command line**

1. If the instance is running, use one of the following commands to stop it:
   - `stop-instances` (AWS CLI)
   - `Stop-EC2Instance` (AWS Tools for Windows PowerShell)

2. To enable EBS optimization, use one of the following commands with the corresponding option:
   - `modify-instance-attribute` with `--ebs-optimized` (AWS CLI)
   - `Edit-EC2InstanceAttribute` with `-EbsOptimized` (AWS Tools for Windows PowerShell)

**Amazon EBS volume performance on Linux instances**

Several factors, including I/O characteristics and the configuration of your instances and volumes, can affect the performance of Amazon EBS. Customers who follow the guidance on our Amazon EBS and Amazon EC2 product detail pages typically achieve good performance out of the box. However, there are some cases where you may need to do some tuning in order to achieve peak performance on the platform. This topic discusses general best practices as well as performance tuning that is specific to certain use cases. We recommend that you tune performance with information from your actual workload, in addition to benchmarking, to determine your optimal configuration. After you learn the basics of working with EBS volumes, it's a good idea to look at the I/O performance you require and at your options for increasing Amazon EBS performance to meet those requirements.

AWS updates to the performance of EBS volume types might not immediately take effect on your existing volumes. To see full performance on an older volume, you might first need to perform a `ModifyVolume` action on it. For more information, see [Modifying the Size, IOPS, or Type of an EBS Volume on Linux](https://docs.aws.amazon.com/AmazonEBS/latest/UserGuide/ModifyingInstanceVolume.html).

- Amazon EBS performance tips (p. 2027)
- I/O characteristics and monitoring (p. 2030)
- Initialize Amazon EBS volumes (p. 2033)
- RAID configuration on Linux (p. 2034)
- Benchmark EBS volumes (p. 2038)

**Amazon EBS performance tips**

These tips represent best practices for getting optimal performance from your EBS volumes in a variety of user scenarios.
Use EBS-optimized instances

On instances without support for EBS-optimized throughput, network traffic can contend with traffic between your instance and your EBS volumes; on EBS-optimized instances, the two types of traffic are kept separate. Some EBS-optimized instance configurations incur an extra cost (such as C3, R3, and M3), while others are always EBS-optimized at no extra cost (such as M4, C4, C5, and D2). For more information, see Amazon EBS–optimized instances (p. 1998).

Understand how performance is calculated

When you measure the performance of your EBS volumes, it is important to understand the units of measure involved and how performance is calculated. For more information, see I/O characteristics and monitoring (p. 2030).

Understand your workload

There is a relationship between the maximum performance of your EBS volumes, the size and number of I/O operations, and the time it takes for each action to complete. Each of these factors (performance, I/O, and latency) affects the others, and different applications are more sensitive to one factor or another. For more information, see Benchmark EBS volumes (p. 2038).

Be aware of the performance penalty When initializing volumes from snapshots

There is a significant increase in latency when you first access each block of data on a new EBS volume that was created from a snapshot. You can avoid this performance hit using one of the following options:

- Access each block prior to putting the volume into production. This process is called initialization (formerly known as pre-warming). For more information, see Initialize Amazon EBS volumes (p. 2033).
- Enable fast snapshot restore on a snapshot to ensure that the EBS volumes created from it are fully-initialized at creation and instantly deliver all of their provisioned performance. For more information, see Amazon EBS fast snapshot restore (p. 1988).

Factors that can degrade HDD performance

When you create a snapshot of a Throughput Optimized HDD (st1) or Cold HDD (sc1) volume, performance may drop as far as the volume's baseline value while the snapshot is in progress. This behavior is specific to these volume types. Other factors that can limit performance include driving more throughput than the instance can support, the performance penalty encountered while initializing volumes created from a snapshot, and excessive amounts of small, random I/O on the volume. For more information about calculating throughput for HDD volumes, see Amazon EBS volume types (p. 1775).

Your performance can also be impacted if your application isn't sending enough I/O requests. This can be monitored by looking at your volume's queue length and I/O size. The queue length is the number of pending I/O requests from your application to your volume. For maximum consistency, HDD-backed volumes must maintain a queue length (rounded to the nearest whole number) of 4 or more when performing 1 MiB sequential I/O. For more information about ensuring consistent performance of your volumes, see I/O characteristics and monitoring (p. 2030).

Increase read-ahead for high-throughput, read-heavy workloads on st1 and sc1

Some workloads are read-heavy and access the block device through the operating system page cache (for example, from a file system). In this case, to achieve the maximum throughput, we recommend that you configure the read-ahead setting to 1 MiB. This is a per-block-device setting that should only be applied to your HDD volumes.

To examine the current value of read-ahead for your block devices, use the following command:
Block device information is returned in the following format:

<table>
<thead>
<tr>
<th>RO</th>
<th>RA</th>
<th>SSZ</th>
<th>BSZ</th>
<th>StartSec</th>
<th>Size</th>
<th>Device</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>256</td>
<td>512</td>
<td>4096</td>
<td>4096</td>
<td>8587820544</td>
<td>/dev/&lt;device&gt;</td>
</tr>
</tbody>
</table>

The device shown reports a read-ahead value of 256 (the default). Multiply this number by the sector size (512 bytes) to obtain the size of the read-ahead buffer, which in this case is 128 KiB. To set the buffer value to 1 MiB, use the following command:

```
[ec2-user ~]$ sudo blockdev --setra 2048 /dev/<device>
```

Verify that the read-ahead setting now displays 2,048 by running the first command again.

Only use this setting when your workload consists of large, sequential I/Os. If it consists mostly of small, random I/Os, this setting will actually degrade your performance. In general, if your workload consists mostly of small or random I/Os, you should consider using a General Purpose SSD (gp2 and gp3) volume rather than an st1 or sc1 volume.

**Use a modern Linux kernel**

Use a modern Linux kernel with support for indirect descriptors. Any Linux kernel 3.8 and above has this support, as well as any current-generation EC2 instance. If your average I/O size is at or near 44 KiB, you may be using an instance or kernel without support for indirect descriptors. For information about deriving the average I/O size from Amazon CloudWatch metrics, see I/O characteristics and monitoring (p. 2030).

To achieve maximum throughput on st1 or sc1 volumes, we recommend applying a value of 256 to the xen_blkfront.max parameter (for Linux kernel versions below 4.6) or the xen_blkfront.max_indirect_segments parameter (for Linux kernel version 4.6 and above). The appropriate parameter can be set in your OS boot command line.

For example, in an Amazon Linux AMI with an earlier kernel, you can add it to the end of the kernel line in the GRUB configuration found in /boot/grub/menu.lst:

```
kernel /boot/vmlinuz-4.4.5-15.26.amzn1.x86_64 root=LABEL=/ console=ttyS0 xen_blkfront.max=256
```

For a later kernel, the command would be similar to the following:

```
kernell /boot/vmlinuz-4.9.20-11.31.amzn1.x86_64 root=LABEL=/ console=tty1 console=ttyS0 xen_blkfront.max_indirect_segments=256
```

Reboot your instance for this setting to take effect.

For more information, see Configuring GRUB (p. 262). Other Linux distributions, especially those that do not use the GRUB boot loader, may require a different approach to adjusting the kernel parameters.

For more information about EBS I/O characteristics, see the Amazon EBS: Designing for Performance re:Invent presentation on this topic.

**Use RAID 0 to maximize utilization of instance resources**

Some instance types can drive more I/O throughput than what you can provision for a single EBS volume. You can join multiple volumes together in a RAID 0 configuration to use the available bandwidth for these instances. For more information, see RAID configuration on Linux (p. 2034).
Track performance using Amazon CloudWatch

Amazon Web Services provides performance metrics for Amazon EBS that you can analyze and view with Amazon CloudWatch and status checks that you can use to monitor the health of your volumes. For more information, see Monitor the status of your volumes (p. 1815).

I/O characteristics and monitoring

On a given volume configuration, certain I/O characteristics drive the performance behavior for your EBS volumes. SSD-backed volumes—General Purpose SSD (gp2 and gp3) and Provisioned IOPS SSD (io1 and io2)—deliver consistent performance whether an I/O operation is random or sequential. HDD-backed volumes—Throughput Optimized HDD (st1) and Cold HDD (sc1)—deliver optimal performance only when I/O operations are large and sequential. To understand how SSD and HDD volumes will perform in your application, it is important to know the connection between demand on the volume, the quantity of IOPS available to it, the time it takes for an I/O operation to complete, and the volume's throughput limits.

Topics

- IOPS (p. 2030)
- Volume queue length and latency (p. 2031)
- I/O size and volume throughput limits (p. 2031)
- Monitor I/O characteristics using CloudWatch (p. 2032)
- Related resources (p. 2033)

IOPS

IOPS are a unit of measure representing input/output operations per second. The operations are measured in KiB, and the underlying drive technology determines the maximum amount of data that a volume type counts as a single I/O. I/O size is capped at 256 KiB for SSD volumes and 1,024 KiB for HDD volumes because SSD volumes handle small or random I/O much more efficiently than HDD volumes.

When small I/O operations are physically sequential, Amazon EBS attempts to merge them into a single I/O operation up to the maximum I/O size. Similarly, when I/O operations are larger than the maximum I/O size, Amazon EBS attempts to split them into smaller I/O operations. The following table shows some examples.

<table>
<thead>
<tr>
<th>Volume type</th>
<th>Maximum I/O size</th>
<th>I/O operations from your application</th>
<th>Number of IOPS</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSD</td>
<td>256 KiB</td>
<td>1 x 1024 KiB I/O operation</td>
<td>4 (1,024+256=4)</td>
<td>Amazon EBS splits the 1,024 I/O operation into four smaller 256 KiB operations.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>8 x sequential 32 KiB I/O operations</td>
<td>1 (8x32=256)</td>
<td>Amazon EBS merges the eight sequential 32 KiB I/O operations into a single 256 KiB operation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>8 random 32 KiB I/O operations</td>
<td>8</td>
<td>Amazon EBS counts random</td>
</tr>
</tbody>
</table>
### EBS performance

<table>
<thead>
<tr>
<th>Volume type</th>
<th>Maximum I/O size</th>
<th>I/O operations from your application</th>
<th>Number of IOPS</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>HDD</td>
<td>1,024 KiB</td>
<td>1 x 1024 KiB I/O operation</td>
<td>1</td>
<td>The I/O operation is already equal to the maximum I/O size. It is not merged or split.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>8 x sequential 128 KiB I/O operations</td>
<td>1 (8x128=1,024)</td>
<td>Amazon EBS merges the eight sequential 128 KiB I/O operations into a single 1,024 KiB I/O operation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>8 random 32 KiB I/O operations</td>
<td>8</td>
<td>Amazon EBS counts random I/O operations separately.</td>
</tr>
</tbody>
</table>

Consequently, when you create an SSD-backed volume supporting 3,000 IOPS (either by provisioning a Provisioned IOPS SSD volume at 3,000 IOPS or by sizing a General Purpose SSD volume at 1,000 GiB), and you attach it to an EBS-optimized instance that can provide sufficient bandwidth, you can transfer up to 3,000 I/Os of data per second, with throughput determined by I/O size.

### Volume queue length and latency

The volume queue length is the number of pending I/O requests for a device. Latency is the true end-to-end client time of an I/O operation, in other words, the time elapsed between sending an I/O to EBS and receiving an acknowledgement from EBS that the I/O read or write is complete. Queue length must be correctly calibrated with I/O size and latency to avoid creating bottlenecks either on the guest operating system or on the network link to EBS.

Optimal queue length varies for each workload, depending on your particular application's sensitivity to IOPS and latency. If your workload is not delivering enough I/O requests to fully use the performance available to your EBS volume, then your volume might not deliver the IOPS or throughput that you have provisioned.

Transaction-intensive applications are sensitive to increased I/O latency and are well-suited for SSD-backed volumes. You can maintain high IOPS while keeping latency down by maintaining a low queue length and a high number of IOPS available to the volume. Consistently driving more IOPS to a volume than it has available can cause increased I/O latency.

Throughput-intensive applications are less sensitive to increased I/O latency, and are well-suited for HDD-backed volumes. You can maintain high throughput to HDD-backed volumes by maintaining a high queue length when performing large, sequential I/O.

### I/O size and volume throughput limits

For SSD-backed volumes, if your I/O size is very large, you may experience a smaller number of IOPS than you provisioned because you are hitting the throughput limit of the volume. For example, a gp2 volume under 1,000 GiB with burst credits available has an IOPS limit of 3,000 and a volume throughput limit of 250 MiB/s. If you are using a 256 KiB I/O size, your volume reaches its throughput limit at 1000 IOPS (1000 x 256 KiB = 250 MiB). For smaller I/O sizes (such as 16 KiB), this same volume can sustain...
3,000 IOPS because the throughput is well below 250 MiB/s. (These examples assume that your volume's I/O is not hitting the throughput limits of the instance.) For more information about the throughput limits for each EBS volume type, see Amazon EBS volume types (p. 1775).

For smaller I/O operations, you may see a higher-than-provisioned IOPS value as measured from inside your instance. This happens when the instance operating system merges small I/O operations into a larger operation before passing them to Amazon EBS.

If your workload uses sequential I/Os on HDD-backed st1 and sc1 volumes, you may experience a higher than expected number of IOPS as measured from inside your instance. This happens when the instance operating system merges sequential I/Os and counts them in 1,024 KiB-sized units. If your workload uses small or random I/Os, you may experience a lower throughput than you expect. This is because we count each random, non-sequential I/O toward the total IOPS count, which can cause you to hit the volume's IOPS limit sooner than expected.

**Important**
Whatever your EBS volume type, if you are not experiencing the IOPS or throughput you expect in your configuration, ensure that your EC2 instance bandwidth is not the limiting factor. You should always use a current-generation, EBS-optimized instance (or one that includes 10 Gb/s network connectivity) for optimal performance. For more information, see Amazon EBS-optimized instances (p. 1998). Another possible cause for not experiencing the expected IOPS is that you are not driving enough I/O to the EBS volumes.

**Monitor I/O characteristics using CloudWatch**
You can monitor these I/O characteristics with each volume's CloudWatch volume metrics (p. 2043). Important metrics to consider include the following:

- BurstBalance
- VolumeReadBytes
- VolumeWriteBytes
- VolumeReadOps
- VolumeWriteOps
- VolumeQueueLength

BurstBalance displays the burst bucket balance for gp2, st1, and sc1 volumes as a percentage of the remaining balance. When your burst bucket is depleted, volume I/O (for gp2 volumes) or volume throughput (for st1 and sc1 volumes) is throttled to the baseline. Check the BurstBalance value to determine whether your volume is being throttled for this reason. For a complete list of the available Amazon EBS metrics, see Amazon EBS metrics (p. 2043) and Amazon EBS metrics for Nitro-based instances (p. 1212).

HDD-backed st1 and sc1 volumes are designed to perform best with workloads that take advantage of the 1,024 KiB maximum I/O size. To determine your volume's average I/O size, divide VolumeWriteBytes by VolumeWriteOps. The same calculation applies to read operations. If average I/O size is below 64 KiB, increasing the size of the I/O operations sent to an st1 or sc1 volume should improve performance.

**Note**
If average I/O size is at or near 64 KiB, you might be using an instance or kernel without support for indirect descriptors. Any Linux kernel 3.8 and above has this support, as well as any current-generation instance.

If your I/O latency is higher than you require, check VolumeQueueLength to make sure your application is not trying to drive more IOPS than you have provisioned. If your application requires a greater number of IOPS than your volume can provide, you should consider using one of the following:

- A larger gp2 volume that provides enough baseline IOPS performance
• A gp3, io1, or io2 volume that is provisioned with enough IOPS to achieve the required latency

Related resources

For more information about Amazon EBS I/O characteristics, see the following re:Invent presentation: Amazon EBS: Designing for Performance.

Initialize Amazon EBS volumes

Empty EBS volumes receive their maximum performance the moment that they are created and do not require initialization (formerly known as pre-warming).

For volumes that were created from snapshots, the storage blocks must be pulled down from Amazon S3 and written to the volume before you can access them. This preliminary action takes time and can cause a significant increase in the latency of I/O operations the first time each block is accessed. Volume performance is achieved after all blocks have been downloaded and written to the volume.

Important
While initializing Provisioned IOPS SSD volumes that were created from snapshots, the performance of the volume may drop below 50 percent of its expected level, which causes the volume to display a warning state in the I/O Performance status check. This is expected, and you can ignore the warning state on Provisioned IOPS SSD volumes while you are initializing them. For more information, see EBS volume status checks (p. 1816).

For most applications, amortizing the initialization cost over the lifetime of the volume is acceptable. To avoid this initial performance hit in a production environment, you can use one of the following options:

• Force the immediate initialization of the entire volume. For more information, see Initialize Amazon EBS volumes on Linux (p. 2033).
• Enable fast snapshot restore on a snapshot to ensure that the EBS volumes created from it are fully-initialized at creation and instantly deliver all of their provisioned performance. For more information, see Amazon EBS fast snapshot restore (p. 1988).

Initialize Amazon EBS volumes on Linux

Empty EBS volumes receive their maximum performance the moment that they are available and do not require initialization (formerly known as pre-warming). For volumes that have been created from snapshots, use the `dd` or `fio` utilities to read from all of the blocks on a volume. All existing data on the volume will be preserved.

For information about initializing Amazon EBS volumes on Windows, see Initializing Amazon EBS volumes on Windows.

To initialize a volume created from a snapshot on Linux

1. Attach the newly-restored volume to your Linux instance.
2. Use the `lsblk` command to list the block devices on your instance.

```
[ec2-user ~]$ lsblk
NAME   MAJ:MIN  RM  SIZE RO TYPE MOUNTPOINT
xvdf   202:80  0   30G 0 disk
xvda1  202:1   0   8G 0 disk
```

Here you can see that the new volume, `/dev/xvdf`, is attached, but not mounted (because there is no path listed under the MOUNTPOINT column).
3. Use the `dd` or `fio` utilities to read all of the blocks on the device. The `dd` command is installed by default on Linux systems, but `fio` is considerably faster because it allows multi-threaded reads.
Note
This step may take several minutes up to several hours, depending on your EC2 instance bandwidth, the IOPS provisioned for the volume, and the size of the volume.

**dd** The `if (input file)` parameter should be set to the drive you wish to initialize. The `of (output file)` parameter should be set to the Linux null virtual device, `/dev/null`. The `bs` parameter sets the block size of the read operation; for optimal performance, this should be set to 1 MB.

**Important**
Incorrect use of `dd` can easily destroy a volume's data. Be sure to follow precisely the example command below. Only the `if=/dev/xvdf` parameter will vary depending on the name of the device you are reading.

```
[ec2-user ~]$ sudo dd if=/dev/xvdf of=/dev/null bs=1M
```

**fio** If you have `fio` installed on your system, use the following command to initialize your volume. The `--filename (input file)` parameter should be set to the drive you wish to initialize.

```
[ec2-user ~]$ sudo fio --filename=/dev/xvdf --rw=read --bs=1M --iodepth=32 --ioengine=libaio --direct=1 --name=volume-initialize
```

To install `fio` on Amazon Linux, use the following command:

```
sudo yum install -y fio
```

To install `fio` on Ubuntu, use the following command:

```
sudo apt-get install -y fio
```

When the operation is finished, you will see a report of the read operation. Your volume is now ready for use. For more information, see Make an Amazon EBS volume available for use on Linux (p. 1803).

**RAID configuration on Linux**

With Amazon EBS, you can use any of the standard RAID configurations that you can use with a traditional bare metal server, as long as that particular RAID configuration is supported by the operating system for your instance. This is because all RAID is accomplished at the software level.

Amazon EBS volume data is replicated across multiple servers in an Availability Zone to prevent the loss of data from the failure of any single component. This replication makes Amazon EBS volumes ten times more reliable than typical commodity disk drives. For more information, see Amazon EBS Availability and Durability in the Amazon EBS product detail pages.

**Note**
You should avoid booting from a RAID volume. Grub is typically installed on only one device in a RAID array, and if one of the mirrored devices fails, you may be unable to boot the operating system.

If you need to create a RAID array on a Windows instance, see RAID configuration on Windows in the Amazon EC2 User Guide for Windows Instances.

**Contents**
- RAID configuration options (p. 2035)
- Create a RAID 0 array on Linux (p. 2035)
Create snapshots of volumes in a RAID array (p. 2038)

RAID configuration options

Creating a RAID 0 array allows you to achieve a higher level of performance for a file system than you can provision on a single Amazon EBS volume. Use RAID 0 when I/O performance is of the utmost importance. With RAID 0, I/O is distributed across the volumes in a stripe. If you add a volume, you get the straight addition of throughput and IOPS. However, keep in mind that performance of the stripe is limited to the worst performing volume in the set, and that the loss of a single volume in the set results in a complete data loss for the array.

The resulting size of a RAID 0 array is the sum of the sizes of the volumes within it, and the bandwidth is the sum of the available bandwidth of the volumes within it. For example, two 500 GiB io1 volumes with 4,000 provisioned IOPS each create a 1000 GiB RAID 0 array with an available bandwidth of 8,000 IOPS and 1,000 MiB/s of throughput.

Important
RAID 5 and RAID 6 are not recommended for Amazon EBS because the parity write operations of these RAID modes consume some of the IOPS available to your volumes. Depending on the configuration of your RAID array, these RAID modes provide 20-30% fewer usable IOPS than a RAID 0 configuration. Increased cost is a factor with these RAID modes as well; when using identical volume sizes and speeds, a 2-volume RAID 0 array can outperform a 4-volume RAID 6 array that costs twice as much.
RAID 1 is also not recommended for use with Amazon EBS. RAID 1 requires more Amazon EC2 to Amazon EBS bandwidth than non-RAID configurations because the data is written to multiple volumes simultaneously. In addition, RAID 1 does not provide any write performance improvement.

Create a RAID 0 array on Linux

This documentation provides a basic RAID 0 setup example.

Before you perform this procedure, you need to decide how large your RAID 0 array should be and how many IOPS you want to provision.

Use the following procedure to create a RAID 0 array. Note that you can get directions for Windows instances from Create a RAID 0 array on Windows in the Amazon EC2 User Guide for Windows Instances.

To create a RAID 0 array on Linux

1. Create the Amazon EBS volumes for your array. For more information, see Create an Amazon EBS volume (p. 1794).

   Important
   Create volumes with identical size and IOPS performance values for your array. Make sure you do not create an array that exceeds the available bandwidth of your EC2 instance. For more information, see Amazon EBS–optimized instances (p. 1998).

2. Attach the Amazon EBS volumes to the instance that you want to host the array. For more information, see Attach an Amazon EBS volume to an instance (p. 1797).

3. Use the mdadm command to create a logical RAID device from the newly attached Amazon EBS volumes. Substitute the number of volumes in your array for number_of_volumes and the device names for each volume in the array (such as /dev/xvdf) for device_name. You can also substitute MY_RAID with your own unique name for the array.

   Note
   You can list the devices on your instance with the lsblk command to find the device names.

To create a RAID 0 array, run the following command (note the - -level=0 option to stripe the array):
Tip
If you get the `mdadm: command not found` error, use the following command to install `mdadm`:
```
sudo yum install mdadm
```

4. Allow time for the RAID array to initialize and synchronize. You can track the progress of these operations with the following command:
```
[ec2-user ~]$ sudo cat /proc/mdstat
```
The following is example output:

```
Personalities : [raid0]
md0 : active raid0 xvdc[1] xvdb[0]
    41910272 blocks super 1.2 512k chunks
unused devices: <none>
```

In general, you can display detailed information about your RAID array with the following command:
```
[ec2-user ~]$ sudo mdadm --detail /dev/md0
```
The following is example output:

```
/dev/md0:
    Version : 1.2
    Creation Time : Wed May 19 11:12:56 2021
    Raid Level : raid0
    Array Size : 41910272 (39.97 GiB 42.92 GB)
    Raid Devices : 2
    Total Devices : 2
    Persistence : Superblock is persistent
    Update Time : Wed May 19 11:12:56 2021
    State : clean
    Active Devices : 2
    Working Devices : 2
    Failed Devices : 0
    Spare Devices : 0
    Chunk Size : 512K

Consistency Policy : none

    Name : MY_RAID
    UUID : 646aa723:db31bbbc7:13c43daf:d5c51e0c
    Events : 0

    Number  Major  Minor  RaidDevice State
    0       202     16      0     active sync  /dev/sdb
    1       202     32      1     active sync  /dev/sdc
```

5. Create a file system on your RAID array, and give that file system a label to use when you mount it later. For example, to create an ext4 file system with the label `MY_RAID`, run the following command:
To ensure that the RAID array is reassembled automatically on boot, create a configuration file to contain the RAID information:

```
[ec2-user ~]$ sudo mdadm --detail --scan | sudo tee -a /etc/mdadm.conf
```

**Note**
If you are using a Linux distribution other than Amazon Linux, you might need to modify this command. For example, you might need to place the file in a different location, or you might need to add the `--examine` parameter. For more information, run `man mdadm.conf` on your Linux instance.

7. Create a new ramdisk image to properly preload the block device modules for your new RAID configuration:

```
[ec2-user ~]$ sudo dracut -H -f /boot/initramfs-$(uname -r).img $(uname -r)
```

8. Create a mount point for your RAID array.

```
[ec2-user ~]$ sudo mkdir -p /mnt/raid
```

9. Finally, mount the RAID device on the mount point that you created:

```
[ec2-user ~]$ sudo mount LABEL=MY_RAID /mnt/raid
```

Your RAID device is now ready for use.

10. (Optional) To mount this Amazon EBS volume on every system reboot, add an entry for the device to the `/etc/fstab` file.

   a. Create a backup of your `/etc/fstab` file that you can use if you accidentally destroy or delete this file while you are editing it.

   ```
   [ec2-user ~]$ sudo cp /etc/fstab /etc/fstab.orig
   ```

   b. Open the `/etc/fstab` file using your favorite text editor, such as `nano` or `vim`.

   c. Comment out any lines starting with "UUID=" and, at the end of the file, add a new line for your RAID volume using the following format:

   ```
   device_label mount_point file_system_type fs_mntops fs_freq fs_passno
   ```

   The last three fields on this line are the file system mount options, the dump frequency of the file system, and the order of file system checks done at boot time. If you don't know what these values should be, then use the values in the example below for them (defaults, nofail 0 2). For more information about `/etc/fstab` entries, see the `fstab` manual page (by entering `man fstab` on the command line). For example, to mount the ext4 file system on the device with the label MY_RAID at the mount point /mnt/raid, add the following entry to `/etc/fstab`.

   **Note**
   If you ever intend to boot your instance without this volume attached (for example, so this volume could move back and forth between different instances), you should...
add the nofail mount option that allows the instance to boot even if there are errors in mounting the volume. Debian derivatives, such as Ubuntu, must also add the nobootwait mount option.

| LABEL=MY_RAID | /mnt/raid | ext4 | defaults,nofail | 0  | 2 |

d. After you've added the new entry to /etc/fstab, you need to check that your entry works. Run the `sudo mount -a` command to mount all file systems in /etc/fstab.

```
[ec2-user ~]$ sudo mount -a
```

If the previous command does not produce an error, then your /etc/fstab file is OK and your file system will mount automatically at the next boot. If the command does produce any errors, examine the errors and try to correct your /etc/fstab.

**Warning**

Errors in the /etc/fstab file can render a system unbootable. Do not shut down a system that has errors in the /etc/fstab file.

e. (Optional) If you are unsure how to correct /etc/fstab errors, you can always restore your backup /etc/fstab file with the following command.

```
[ec2-user ~]$ sudo mv /etc/fstab.orig /etc/fstab
```

Create snapshots of volumes in a RAID array

If you want to back up the data on the EBS volumes in a RAID array using snapshots, you must ensure that the snapshots are consistent. This is because the snapshots of these volumes are created independently. To restore EBS volumes in a RAID array from snapshots that are out of sync would degrade the integrity of the array.

To create a consistent set of snapshots for your RAID array, use EBS multi-volume snapshots. Multi-volume snapshots allow you to take point-in-time, data coordinated, and crash-consistent snapshots across multiple EBS volumes attached to an EC2 instance. You do not have to stop your instance to coordinate between volumes to ensure consistency because snapshots are automatically taken across multiple EBS volumes. For more information, see the steps for creating multi-volume snapshots under Creating Amazon EBS snapshots.

Benchmark EBS volumes

You can test the performance of Amazon EBS volumes by simulating I/O workloads. The process is as follows:

1. Launch an EBS-optimized instance.
2. Create new EBS volumes.
3. Attach the volumes to your EBS-optimized instance.
4. Configure and mount the block device.
5. Install a tool to benchmark I/O performance.
7. Delete your volumes and terminate your instance so that you don't continue to incur charges.
Important
Some of the procedures result in the destruction of existing data on the EBS volumes you benchmark. The benchmarking procedures are intended for use on volumes specially created for testing purposes, not production volumes.

Set up your instance

To get optimal performance from EBS volumes, we recommend that you use an EBS-optimized instance. EBS-optimized instances deliver dedicated throughput between Amazon EC2 and Amazon EBS, with instance. EBS-optimized instances deliver dedicated bandwidth between Amazon EC2 and Amazon EBS, with specifications depending on the instance type. For more information, see Amazon EBS–optimized instances (p. 1998).

To create an EBS-optimized instance, choose Launch as an EBS-Optimized instance when launching the instance using the Amazon EC2 console, or specify --ebs-optimized when using the command line. Be sure that you launch a current-generation instance that supports this option. For more information, see Amazon EBS–optimized instances (p. 1998).

Set up Provisioned IOPS SSD or General Purpose SSD volumes

To create Provisioned IOPS SSD (io1 and io2) or General Purpose SSD (gp2 and gp3) volumes using the Amazon EC2 console, for Volume type, choose Provisioned IOPS SSD (io1), Provisioned IOPS SSD (io2), General Purpose SSD (gp2), or General Purpose SSD (gp3). At the command line, specify io1, io2, gp2, or gp3 for the --volume-type parameter. For io1, io2, and gp3 volumes, specify the number of I/O operations per second (IOPS) for the --iops parameter. For more information, see Amazon EBS volume types (p. 1775) and Create an Amazon EBS volume (p. 1794).

For the example tests, we recommend that you create a RAID 0 array with 6 volumes, which offers a high level of performance. Because you are charged by gigabytes provisioned (and the number of provisioned IOPS for io1, io2, and gp3 volumes), not the number of volumes, there is no additional cost for creating multiple, smaller volumes and using them to create a stripe set. If you’re using Oracle Orion to benchmark your volumes, it can simulate striping the same way that Oracle ASM does, so we recommend that you let Orion do the striping. If you are using a different benchmarking tool, you need to stripe the volumes yourself.

For instructions on how to create a RAID 0 array with 6 volumes, see Create a RAID 0 array on Linux (p. 2035).

Set up Throughput Optimized HDD (st1) or Cold HDD (sc1) volumes

To create an st1 volume, choose Throughput Optimized HDD when creating the volume using the Amazon EC2 console, or specify --type st1 when using the command line. To create an sc1 volume, choose Cold HDD when creating the volume using the Amazon EC2 console, or specify --type sc1 when using the command line. For information about creating EBS volumes, see Create an Amazon EBS volume (p. 1794). For information about attaching these volumes to your instance, see Attach an Amazon EBS volume to an instance (p. 1797).

AWS provides a JSON template for use with AWS CloudFormation that simplifies this setup procedure. Access the template and save it as a JSON file. AWS CloudFormation allows you to configure your own SSH keys and offers an easier way to set up a performance test environment to evaluate st1 volumes. The template creates a current-generation instance and a 2 TiB st1 volume, and attaches the volume to the instance at /dev/xvdf.

To create an HDD volume using the template

1. Open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation,
2. Choose Create Stack.
3. Choose Upload a Template to Amazon S3 and select the JSON template you previously obtained.
4. Give your stack a name like "ebs-perf-testing", and select an instance type (the default is r3.8xlarge) and SSH key.

5. Choose Next twice, and then choose Create Stack.

6. After the status for your new stack moves from CREATE_IN_PROGRESS to COMPLETE, choose Outputs to get the public DNS entry for your new instance, which will have a 2 TiB st1 volume attached to it.

7. Connect using SSH to your new stack as user ec2-user, with the hostname obtained from the DNS entry in the previous step.

8. Proceed to Install benchmark tools (p. 2040).

Install benchmark tools

The following table lists some of the possible tools you can use to benchmark the performance of EBS volumes.

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fio</td>
<td>For benchmarking I/O performance. (Note that fio has a dependency on libaio-devel.)</td>
</tr>
<tr>
<td></td>
<td>To install fio on Amazon Linux, run the following command:</td>
</tr>
<tr>
<td></td>
<td>[ec2-user ~]$: sudo yum install -y fio</td>
</tr>
<tr>
<td></td>
<td>To install fio on Ubuntu, run the following command:</td>
</tr>
<tr>
<td></td>
<td>sudo apt-get install -y fio</td>
</tr>
<tr>
<td>Oracle Orion Calibration Tool</td>
<td>For calibrating the I/O performance of storage systems to be used with Oracle databases.</td>
</tr>
</tbody>
</table>

These benchmarking tools support a wide variety of test parameters. You should use commands that approximate the workloads your volumes will support. These commands provided below are intended as examples to help you get started.

Choose the volume queue length

Choosing the best volume queue length based on your workload and volume type.

Queue length on SSD-backed volumes

To determine the optimal queue length for your workload on SSD-backed volumes, we recommend that you target a queue length of 1 for every 1000 IOPS available (baseline for General Purpose SSD volumes and the provisioned amount for Provisioned IOPS SSD volumes). Then you can monitor your application performance and tune that value based on your application requirements.

Increasing the queue length is beneficial until you achieve the provisioned IOPS, throughput or optimal system queue length value, which is currently set to 32. For example, a volume with 3,000 provisioned IOPS should target a queue length of 3. You should experiment with tuning these values up or down to see what performs best for your application.

Queue length on HDD-backed volumes

To determine the optimal queue length for your workload on HDD-backed volumes, we recommend that you target a queue length of at least 4 while performing 1MiB sequential I/Os. Then you can monitor
your application performance and tune that value based on your application requirements. For example, a 2 TiB st1 volume with burst throughput of 500 MiB/s and IOPS of 500 should target a queue length of 4, 8, or 16 while performing 1,024 KiB, 512 KiB, or 256 KiB sequential I/Os respectively. You should experiment with tuning these values up or down to see what performs best for your application.

**Disable C-states**

Before you run benchmarking, you should disable processor C-states. Temporarily idle cores in a supported CPU can enter a C-state to save power. When the core is called on to resume processing, a certain amount of time passes until the core is again fully operational. This latency can interfere with processor benchmarking routines. For more information about C-states and which EC2 instance types support them, see [Processor state control for your EC2 instance](#).

**Disable C-states on Linux**

You can disable C-states on Amazon Linux, RHEL, and CentOS as follows:

1. Get the number of C-states.

   $ cpupower idle-info | grep "Number of idle states:"

2. Disable the C-states from c1 to cN. Ideally, the cores should be in state c0.

   `$ for i in `seq 1 $((N-1))`; do cpupower idle-set -d $i; done`

**Perform benchmarking**

The following procedures describe benchmarking commands for various EBS volume types.

Run the following commands on an EBS-optimized instance with attached EBS volumes. If the EBS volumes were created from snapshots, be sure to initialize them before benchmarking. For more information, see [Initialize Amazon EBS volumes](#). When you are finished testing your volumes, see the following topics for help cleaning up: [Delete an Amazon EBS volume](#) and [Terminate your instance](#).

**Benchmark Provisioned IOPS SSD and General Purpose SSD volumes**

Run `fio` on the RAID 0 array that you created.

The following command performs 16 KB random write operations.

```
[ec2-user ~] $ sudo fio --directory=/mnt/p_iops_vol0 --ioengine=psync --name fio_test_file --direct=1 --rw=randwrite --bs=16k --size=1G --numjobs=16 --time_based --runtime=180 --group_reporting --norandommap
```

The following command performs 16 KB random read operations.

```
[ec2-user ~] $ sudo fio --directory=/mnt/p_iops_vol0 --name fio_test_file --direct=1 --rw=randread --bs=16k --size=1G --numjobs=16 --time_based --runtime=180 --group_reporting --norandommap
```

For more information about interpreting the results, see this tutorial: [Inspecting disk I/O performance with fio](#).

**Benchmark st1 and sc1 volumes**

Run `fio` on your st1 or sc1 volume.
Note
Prior to running these tests, set buffered I/O on your instance as described in Increase read-ahead for high-throughput, read-heavy workloads on st1 and scl (p. 2028).

The following command performs 1 MiB sequential read operations against an attached st1 block device (e.g., /dev/xvdf):

```
[ec2-user ~]$ sudo fio --filename=/dev/<device> --direct=1 --rw=read --randrepeat=0 --ioengine=libaio --bs=1024k --iodepth=8 --time_based=1 --runtime=180 --name=fio_direct_read_test
```

The following command performs 1 MiB sequential write operations against an attached st1 block device:

```
[ec2-user ~]$ sudo fio --filename=/dev/<device> --direct=1 --rw=write --randrepeat=0 --ioengine=libaio --bs=1024k --iodepth=8 --time_based=1 --runtime=180 --name=fio_direct_write_test
```

Some workloads perform a mix of sequential reads and sequential writes to different parts of the block device. To benchmark such a workload, we recommend that you use separate, simultaneous fio jobs for reads and writes, and use the fio offset_increment option to target different block device locations for each job.

Running this workload is a bit more complicated than a sequential-write or sequential-read workload. Use a text editor to create a fio job file, called fio_rw_mix.cfg in this example, that contains the following:

```
[globals]
clocksource=clock_gettime
randrepeat=0
runtime=180

[sequential-write]
bs=1M
ioengine=libaio
direct=1
iodepth=8
filename=/dev/<device>
do_verify=0
rw=write
rwmixread=0
rwmixwrite=100

[sequential-read]
bs=1M
ioengine=libaio
direct=1
iodepth=8
filename=/dev/<device>
do_verify=0
rw=read
rwmixread=100
rwmixwrite=0
offset=100g
```

Then run the following command:

```
[ec2-user ~]$ sudo fio fio_rw_mix.cfg
```
For more information about interpreting the results, see this tutorial: Inspecting disk I/O performance with fio.

Multiple fio jobs for direct I/O, even though using sequential read or write operations, can result in lower than expected throughput for st1 and sc1 volumes. We recommend that you use one direct I/O job and use the iodepth parameter to control the number of concurrent I/O operations.

Amazon CloudWatch metrics for Amazon EBS

Amazon CloudWatch metrics are statistical data that you can use to view, analyze, and set alarms on the operational behavior of your volumes.

Data is available automatically in 1-minute periods at no charge.

When you get data from CloudWatch, you can include a Period request parameter to specify the granularity of the returned data. This is different than the period that we use when we collect the data (1-minute periods). We recommend that you specify a period in your request that is equal to or greater than the collection period to ensure that the returned data is valid.

You can get the data using either the CloudWatch API or the Amazon EC2 console. The console takes the raw data from the CloudWatch API and displays a series of graphs based on the data. Depending on your needs, you might prefer to use either the data from the API or the graphs in the console.

Topics
- Amazon EBS metrics (p. 2043)
- Dimensions for Amazon EBS metrics (p. 2047)
- Graphs in the Amazon EC2 console (p. 2048)

Amazon EBS metrics

Amazon Elastic Block Store (Amazon EBS) sends data points to CloudWatch for several metrics. All Amazon EBS volume types automatically send 1-minute metrics to CloudWatch, but only when the volume is attached to an instance.

Metrics
- Volume metrics for volumes attached to all instance types (p. 2043)
- Volume metrics for volumes attached to Nitro-based instance types (p. 2047)
- Fast snapshot restore metrics (p. 2047)

Volume metrics for volumes attached to all instance types

The AWS/EBS namespace includes the following metrics for EBS volumes that are attached to all instance types. To get information about the available disk space from the operating system on an instance, see View free disk space (p. 1809).

Note
- Some metrics have differences on instances that are built on the Nitro System. For a list of these instance types, see Instances built on the Nitro System (p. 282).
- The AWS/EC2 namespace includes additional Amazon EBS metrics for volumes that are attached to Nitro-based instances that are not bare metal instances. For more information about these metrics see, Amazon EBS metrics for Nitro-based instances (p. 1212).
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VolumeReadBytes</td>
<td>Provides information on the read operations in a specified period of time. The Sum statistic reports the total number of bytes transferred during the period. The Average statistic reports the average size of each read operation during the period, except on volumes attached to a Nitro-based instance, where the average represents the average over the specified period. The SampleCount statistic reports the total number of read operations during the period, except on volumes attached to a Nitro-based instance, where the sample count represents the number of data points used in the statistical calculation. For Xen instances, data is reported only when there is read activity on the volume. The Minimum and Maximum statistics on this metric are supported only by volumes attached to Nitro-based instances. Units: Bytes</td>
</tr>
<tr>
<td>VolumeWriteBytes</td>
<td>Provides information on the write operations in a specified period of time. The Sum statistic reports the total number of bytes transferred during the period. The Average statistic reports the average size of each write operation during the period, except on volumes attached to a Nitro-based instance, where the average represents the average over the specified period. The SampleCount statistic reports the total number of write operations during the period, except on volumes attached to a Nitro-based instance, where the sample count represents the number of data points used in the statistical calculation. For Xen instances, data is reported only when there is write activity on the volume. The Minimum and Maximum statistics on this metric are supported only by volumes attached to Nitro-based instances. Units: Bytes</td>
</tr>
<tr>
<td>VolumeReadOps</td>
<td>The total number of read operations in a specified period of time. Note: read operations are counted on completion. To calculate the average read operations per second (read IOPS) for the period, divide the total read operations in the period by the number of seconds in that period. The Minimum and Maximum statistics on this metric are supported only by volumes attached to Nitro-based instances. Units: Count</td>
</tr>
<tr>
<td>VolumeWriteOps</td>
<td>The total number of write operations in a specified period of time. Note: write operations are counted on completion. To calculate the average write operations per second (write IOPS) for the period, divide the total write operations in the period by the number of seconds in that period.</td>
</tr>
</tbody>
</table>

2044
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
</table>
| VolumeTotalReadTime | **Note**  This metric is not supported with Multi-Attach enabled volumes.  

The total number of seconds spent by all read operations that completed in a specified period of time. If multiple requests are submitted at the same time, this total could be greater than the length of the period. For example, for a period of 1 minute (60 seconds): if 150 operations completed during that period, and each operation took 1 second, the value would be 150 seconds. For Xen instances, data is reported only when there is read activity on the volume.  

The Average statistic on this metric is not relevant for volumes attached to Nitro-based instances.  

The Minimum and Maximum statistics on this metric are supported only by volumes attached to Nitro-based instances.  

Units: Seconds |
| VolumeTotalWriteTime| **Note**  This metric is not supported with Multi-Attach enabled volumes.  

The total number of seconds spent by all write operations that completed in a specified period of time. If multiple requests are submitted at the same time, this total could be greater than the length of the period. For example, for a period of 1 minute (60 seconds): if 150 operations completed during that period, and each operation took 1 second, the value would be 150 seconds. For Xen instances, data is reported only when there is write activity on the volume.  

The Average statistic on this metric is not relevant for volumes attached to Nitro-based instances.  

The Minimum and Maximum statistics on this metric are supported only by volumes attached to Nitro-based instances.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
</table>
| VolumeIdleTime                 | **Note**  
This metric is not supported with Multi-Attach enabled volumes.  
The total number of seconds in a specified period of time when no read or write operations were submitted.  
The Average statistic on this metric is not relevant for volumes attached to Nitro-based instances.  
The Minimum and Maximum statistics on this metric are supported only by volumes attached to Nitro-based instances.  
Units: Seconds                                                                                                                                                                                                                   |
| VolumeQueueLength              | The number of read and write operation requests waiting to be completed in a specified period of time.  
The Sum statistic on this metric is not relevant for volumes attached to Nitro-based instances.  
The Minimum and Maximum statistics on this metric are supported only by volumes attached to Nitro-based instances.  
Units: Count                                                                                                                                                                                                                   |
| VolumeThroughputPercentage     | **Note**  
This metric is not supported with Multi-Attach enabled volumes.  
Used with Provisioned IOPS SSD volumes only. The percentage of I/O operations per second (IOPS) delivered of the total IOPS provisioned for an Amazon EBS volume. Provisioned IOPS SSD volumes deliver their provisioned performance 99.9 percent of the time.  
During a write, if there are no other pending I/O requests in a minute, the metric value will be 100 percent. Also, a volume's I/O performance may become degraded temporarily due to an action you have taken (for example, creating a snapshot of a volume during peak usage, running the volume on a non-EBS-optimized instance, or accessing data on the volume for the first time).  
Units: Percent                                                                                                                                                                                                                    |
| VolumeConsumedReadWriteOps     | Used with Provisioned IOPS SSD volumes only. The total amount of read and write operations (normalized to 256K capacity units) consumed in a specified period of time.  
I/O operations that are smaller than 256K each count as 1 consumed IOPS. I/O operations that are larger than 256K are counted in 256K capacity units. For example, a 1024K I/O would count as 4 consumed IOPS.  
Units: Count                                                                                                                                                                                                                   |
Amazon Elastic Compute Cloud
User Guide for Linux Instances
EBS CloudWatch metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BurstBalance</td>
<td>Used with General Purpose SSD (gp2), Throughput Optimized HDD (st1), and Cold HDD (sc1) volumes only. Provides information about the percentage of I/O credits (for gp2) or throughput credits (for st1 and sc1) remaining in the burst bucket. Data is reported to CloudWatch only when the volume is active. If the volume is not attached, no data is reported. The Sum statistic on this metric is not relevant for volumes attached to instances built on the Nitro System. If the baseline performance of the volume exceeds the maximum burst performance, credits are never spent. If the volume is attached to an instance built on the Nitro System, the burst balance is not reported. For other instances, the reported burst balance is 100%. For more information, see gp2 volume performance (p. 1779). Units: Percent</td>
</tr>
</tbody>
</table>

Volume metrics for volumes attached to Nitro-based instance types

The AWS/EC2 namespace includes additional Amazon EBS metrics for volumes that are attached to Nitro-based instances that are not bare metal instances. For more information about these metrics see, Amazon EBS metrics for Nitro-based instances (p. 1212).

Fast snapshot restore metrics

AWS/EBS namespace includes the following metrics for fast snapshot restore (p. 1988).

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FastSnapshotRestoreCreditsBucketSize</td>
<td>The maximum number of volume create credits that can be accumulated. This metric is reported per snapshot per Availability Zone. The most meaningful statistic is Average. The results for the Minimum and Maximum statistics are the same as for Average and could be used instead.</td>
</tr>
<tr>
<td>FastSnapshotRestoreCreditsBalance</td>
<td>The number of volume create credits available. This metric is reported per snapshot per Availability Zone. The most meaningful statistic is Average. The results for the Minimum and Maximum statistics are the same as for Average and could be used instead.</td>
</tr>
</tbody>
</table>

Dimensions for Amazon EBS metrics

The supported dimension is the volume ID (VolumeId). All available statistics are filtered by volume ID. For the volume metrics (p. 2043), the supported dimension is the volume ID (VolumeId). All available statistics are filtered by volume ID.
For the **fast snapshot restore metrics (p. 2047)**, the supported dimensions are the snapshot ID (SnapshotId) and the Availability Zone (AvailabilityZone).

### Graphs in the Amazon EC2 console

After you create a volume, you can view the volume's monitoring graphs in the Amazon EC2 console. Select a volume on the **Volumes** page in the console and choose **Monitoring**. The following table lists the graphs that are displayed. The column on the right describes how the raw data metrics from the CloudWatch API are used to produce each graph. The period for all the graphs is 5 minutes.

<table>
<thead>
<tr>
<th>Graph</th>
<th>Description using raw metrics</th>

<tr>
<td>Average read latency (ms/op)</td>
<td>( \text{Avg}(\text{VolumeTotalReadTime}) \times 1000 )</td>
</tr>
<tr>
<td></td>
<td>For Nitro-based instances, the following formula derives Average Read Latency using <strong>CloudWatch Metric Math</strong>: ( \frac{\text{Sum}(\text{VolumeTotalReadTime})}{\text{Sum}(\text{VolumeReadOps})} \times 1000 )</td>
</tr>
<tr>
<td></td>
<td>The VolumeTotalReadTime and VolumeReadOps metrics are available in the EBS CloudWatch console.</td>
</tr>
<tr>
<td>Average write latency (ms/op)</td>
<td>( \text{Avg}(\text{VolumeTotalWriteTime}) \times 1000 )</td>
</tr>
</tbody>
</table>
For Nitro-based instances, the following formula derives Average Write Latency using CloudWatch Metric Math:

\[
\frac{\text{Sum(VolumeTotalWriteTime)}}{\text{Sum(VolumeWriteOps)}} \times 1000
\]

The VolumeTotalWriteTime and VolumeWriteOps metrics are available in the EBS CloudWatch console.

For the average latency graphs and average size graphs, the average is calculated over the total number of operations (read or write, whichever is applicable to the graph) that completed during the period.

**EventBridge for Amazon EBS**

Amazon EBS sends events to Amazon EventBridge for actions performed on volumes and snapshots. With EventBridge, you can establish rules that trigger programmatic actions in response to these events. For example, you can create a rule that sends a notification to your email when a snapshot is enabled for fast snapshot restore.

Events in EventBridge are represented as JSON objects. The fields that are unique to the event are contained in the "detail" section of the JSON object. The "event" field contains the event name. The "result" field contains the completed status of the action that triggered the event. For more information, see Amazon EventBridge event patterns in the Amazon EventBridge User Guide.

For more information, see What Is Amazon EventBridge? in the Amazon EventBridge User Guide.

**Events**

- **EBS volume events** (p. 2049)
- **EBS volume modification events** (p. 2052)
- **EBS snapshot events** (p. 2052)
- **EBS Snapshots Archive events** (p. 2056)
- **EBS fast snapshot restore events** (p. 2056)
- **Using AWS Lambda to handle EventBridge events** (p. 2057)

**EBS volume events**

Amazon EBS sends events to EventBridge when the following volume events occur.

**Events**

- **Create volume (createVolume)** (p. 2049)
- **Delete volume (deleteVolume)** (p. 2051)
- **Volume attach or reattach (attachVolume, reattachVolume)** (p. 2051)

**Create volume (createVolume)**

The createVolume event is sent to your AWS account when an action to create a volume completes. However it is not saved, logged, or archived. This event can have a result of either available or failed. Creation will fail if an invalid AWS KMS key was provided, as shown in the examples below.
Event data

The listing below is an example of a JSON object emitted by EBS for a successful createVolume event.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Volume Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:012345678901:volume/vol-01234567"
    ],
    "detail": {
        "result": "available",
        "cause": "",
        "event": "createVolume",
        "request-id": "01234567-0123-0123-0123-012345678901"
    }
}
```

The listing below is an example of a JSON object emitted by EBS after a failed createVolume event. The cause for the failure was a disabled KMS key.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-0123456789ab",
    "detail-type": "EBS Volume Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "sa-east-1",
    "resources": [
    ],
    "detail": {
        "event": "createVolume",
        "result": "failed",
        "cause": "arn:aws:kms:sa-east-1:0123456789ab:key/01234567-0123-0123-0123-0123456789ab is disabled.",
        "request-id": "01234567-0123-0123-0123-0123456789ab"
    }
}
```

The following is an example of a JSON object that is emitted by EBS after a failed createVolume event. The cause for the failure was a KMS key pending import.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-0123456789ab",
    "detail-type": "EBS Volume Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "sa-east-1",
    "resources": [
    ],
    "detail": {
        "event": "createVolume",
        "result": "failed",
        "cause": "arn:aws:kms:sa-east-1:0123456789ab:key/01234567-0123-0123-0123-0123456789ab is pending import.",
        "request-id": "01234567-0123-0123-0123-0123456789ab"
    }
}
```
Delete volume (deleteVolume)

The deleteVolume event is sent to your AWS account when an action to delete a volume completes. However it is not saved, logged, or archived. This event has the result deleted. If the deletion does not complete, the event is never sent.

Event data

The listing below is an example of a JSON object emitted by EBS for a successful deleteVolume event.

```
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Volume Notification",
  "source": "aws.ec2",
  "account": "012345678901",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-1",
  "resources": [
    "arn:aws:kms:sa-east-1:0123456789ab:key/01234567-0123-0123-0123456789ab"
  ],
  "detail": {
    "result": "deleted",
    "cause": "",
    "event": "deleteVolume",
    "request-id": "01234567-0123-0123-0123-0123456789ab"
  }
}
```

Volume attach or reattach (attachVolume, reattachVolume)

The attachVolume or reattachVolume event is sent to your AWS account if a volume fails to attach or reattach to an instance. However it is not saved, logged, or archived. If you use a KMS key to encrypt an EBS volume and the KMS key becomes invalid, EBS will emit an event if that KMS key is later used to attach or reattach to an instance, as shown in the examples below.

Event data

The listing below is an example of a JSON object emitted by EBS after a failed attachVolume event. The cause for the failure was a KMS key pending deletion.

```
Note
AWS may attempt to reattach to a volume following routine server maintenance.
```

```
{
  "version": "0",
  "id": "01234567-0123-0123-0123-0123456789ab",
  "detail-type": "EBS Volume Notification",
  "source": "aws.ec2",
  "account": "012345678901",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-1",
  "resources": [
    "arn:aws:kms:us-east-1:0123456789ab:key/01234567-0123-0123-0123456789ab"
  ],
  "detail": {
    "result": "failed",
    "cause": "arn:aws:kms:sa-east-1:0123456789ab:key/01234567-0123-0123-0123456789ab is pending import."
  }
}
```
The listing below is an example of a JSON object emitted by EBS after a failed reattachVolume event. The cause for the failure was a KMS key pending deletion.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-0123456789ab",
    "detail-type": "EBS Volume Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:kms:us-east-1:0123456789ab:key/01234567-0123-0123-0123456789ab"
    ],
    "detail": {
        "event": "reattachVolume",
        "result": "failed",
        "cause": "arn:aws:kms:us-east-1:0123456789ab:key/01234567-0123-0123-0123456789ab is pending deletion.",
        "request-id": ""
    }
}
```

**EBS volume modification events**

Amazon EBS sends modifyVolume events to EventBridge when a volume is modified. However it is not saved, logged, or archived.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-0123456789ab",
    "detail-type": "EBS Volume Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:0123456789ab:volume/vol-03a55cf56513fa1b6"
    ],
    "detail": {
        "result": "optimizing",
        "cause": "",
        "event": "modifyVolume",
        "request-id": "01234567-0123-0123-0123456789ab"
    }
}
```

**EBS snapshot events**

Amazon EBS sends events to EventBridge when the following volume events occur.
Events

- Create snapshot (createSnapshot) (p. 2053)
- Create snapshots (createSnapshots) (p. 2053)
- Copy snapshot (copySnapshot) (p. 2055)
- Share snapshot (shareSnapshot) (p. 2056)

Create snapshot (createSnapshot)

The createSnapshot event is sent to your AWS account when an action to create a snapshot completes. However it is not saved, logged, or archived. This event can have a result of either succeeded or failed.

Event data

The listing below is an example of a JSON object emitted by EBS for a successful createSnapshot event. In the detail section, the source field contains the ARN of the source volume. The startTime and endTime fields indicate when creation of the snapshot started and completed.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2::us-west-2:volume/vol-01234567",
        "arn:aws:ec2::us-west-2:volume/vol-01234567",
        "arn:aws:ec2::us-west-2:volume/vol-01234567",
        "arn:aws:ec2::us-west-2:volume/vol-01234567"
    ],
    "detail": {
        "event": "createSnapshot",
        "result": "succeeded",
        "cause": "",
        "request-id": "",
        "snapshot_id": "arn:aws:ec2::us-west-2:volume/snap-01234567",
        "source": "arn:aws:ec2::us-west-2:volume/vol-01234567",
        "startTime": "yyyy-mm-ddThh:mm:ssZ",
        "endTime": "yyyy-mm-ddThh:mm:ssZ"
    }
}
```

Create snapshots (createSnapshots)

The createSnapshots event is sent to your AWS account when an action to create a multi-volume snapshot completes. This event can have a result of either succeeded or failed.

Event data

The listing below is an example of a JSON object emitted by EBS for a successful createSnapshots event. In the detail section, the source field contains the ARNs of the source volumes of the multi-volume snapshot set. The startTime and endTime fields indicate when creation of the snapshot started and completed.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Multi-Volume Snapshots Completion Status",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2::us-west-2:volume/vol-01234567",
        "arn:aws:ec2::us-west-2:volume/vol-01234567",
        "arn:aws:ec2::us-west-2:volume/vol-01234567",
        "arn:aws:ec2::us-west-2:volume/vol-01234567"
    ],
    "detail": {
        "event": "createSnapshots",
        "result": "succeeded",
        "cause": "",
        "request-id": "",
        "snapshot-ids": [
            "arn:aws:ec2::us-west-2:volume/snap-01234567",
            "arn:aws:ec2::us-west-2:volume/snap-01234567",
            "arn:aws:ec2::us-west-2:volume/snap-01234567",
            "arn:aws:ec2::us-west-2:volume/snap-01234567"
        ],
        "source": "arn:aws:ec2::us-west-2:volume/vol-01234567",
        "startTime": "yyyy-mm-ddThh:mm:ssZ",
        "endTime": "yyyy-mm-ddThh:mm:ssZ"
    }
}
```
The listing below is an example of a JSON object emitted by EBS after a failed `createSnapshots` event. The cause for the failure was one or more snapshots for the multi-volume snapshot set failed to complete. The values of `snapshot_id` are the ARNs of the failed snapshots. `startTime` and `endTime` represent when the `create-snapshots` action started and ended.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Multi-Volume Snapshots Completion Status",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2::us-east-1:snapshot/snap-01234567",
        "arn:aws:ec2::us-east-1:snapshot/snap-012345678"
    ],
    "detail": {
        "event": "createSnapshots",
        "result": "failed",
        "cause": "Snapshot snap-01234567 is in status error",
        "request-id": "",
        "startTime": "yyyy-mm-ddThh:mm:ssZ",
        "endTime": "yyyy-mm-ddThh:mm:ssZ",
        "snapshots": [
            {
                "snapshot_id": "arn:aws:ec2::us-east-1:snapshot/snap-01234567",
                "source": "arn:aws:ec2::us-east-1:volume/vol-01234567",
                "status": "error"
            },
            {
                "snapshot_id": "arn:aws:ec2::us-east-1:snapshot/snap-012345678",
                "source": "arn:aws:ec2::us-east-1:volume/vol-012345678",
                "status": "error"
            }
        ]
    }
}
```
Copy snapshot (copySnapshot)

The copySnapshot event is sent to your AWS account when an action to copy a snapshot completes. However it is not saved, logged, or archived. This event can have a result of either succeeded or failed.

Event data

The listing below is an example of a JSON object emitted by EBS after a successful copySnapshot event. The value of snapshot_id is the ARN of the newly created snapshot. In the detail section, the value of source is the ARN of the source snapshot. startTime and endTime represent when the copy-snapshot action started and ended.

```json
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Snapshot Notification",
  "source": "aws.ec2",
  "account": "123456789012",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-1",
  "resources": ["arn:aws:ec2::us-west-2:snapshot/snap-01234567"],
  "detail": {
    "event": "copySnapshot",
    "result": "succeeded",
    "cause": "",
    "request-id": "",
    "snapshot_id": "arn:aws:ec2::us-west-2:snapshot/snap-01234567",
    "source": "arn:aws:ec2::eu-west-1:snapshot/snap-76543210",
    "startTime": "yyyy-mm-ddThh:mm:ssZ",
    "endTime": "yyyy-mm-ddThh:mm:ssZ",
    "Incremental": "true"
  }
}
```

The listing below is an example of a JSON object emitted by EBS after a failed copySnapshot event. The cause for the failure was an invalid source snapshot ID. The value of snapshot_id is the ARN of the failed snapshot. In the detail section, the value of source is the ARN of the source snapshot. startTime and endTime represent when the copy-snapshot action started and ended.

```json
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Snapshot Notification",
  "source": "aws.ec2",
  "account": "123456789012",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-1",
  "resources": ["arn:aws:ec2::us-west-2:snapshot/snap-01234567"],
  "detail": {
    "event": "copySnapshot",
    "result": "failed",
    "cause": "Source snapshot ID is not valid",
```
EBS EventBridge events

Share snapshot (shareSnapshot)

The shareSnapshot event is sent to your AWS account when another account shares a snapshot with it. However, it is not saved, logged, or archived. The result is always succeeded.

Event data

The following is an example of a JSON object emitted by EBS after a completed shareSnapshot event. In the detail section, the value of source is the AWS account number of the user that shared the snapshot with you. startTime and endTime represent when the share-snapshot action started and ended. The shareSnapshot event is emitted only when a private snapshot is shared with another user. Sharing a public snapshot does not trigger the event.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2::us-west-2:snapshot/snap-01234567"
    ],
    "detail": {
        "event": "shareSnapshot",
        "result": "succeeded",
        "cause": "",
        "request-id": "",
        "snapshot_id": "arn:aws:ec2::us-west-2:snapshot/snap-01234567",
        "source": "012345678901",
        "startTime": "yyyy-mm-ddThh:mm:ssZ",
        "endTime": "yyyy-mm-ddThh:mm:ssZ"
    }
}
```

EBS Snapshots Archive events

Amazon EBS emits events related to snapshot archiving actions. For more information, see Monitor snapshot archiving (p. 1860).

EBS fast snapshot restore events

Amazon EBS sends events to EventBridge when the state of fast snapshot restore for a snapshot changes. Events are emitted on a best effort basis.

The following is example data for this event.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Restoration Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2::us-west-2:snapshot/snap-01234567"
    ],
    "detail": {
        "event": "fastSnapshotRestore",
        "result": "succeeded",
        "cause": "",
        "request-id": "",
        "snapshot_id": "arn:aws:ec2::us-west-2:snapshot/snap-01234567",
        "source": "012345678901",
        "startTime": "yyyy-mm-ddThh:mm:ssZ",
        "endTime": "yyyy-mm-ddThh:mm:ssZ"
    }
}
```
The possible values for state are enabling, optimizing, enabled, disabling, and disabled.

The possible values for message are as follows:

**Client.InvalidSnapshot.InvalidState** - The requested snapshot transitioned to an invalid state (Error)

A request to enable fast snapshot restore failed and the state transitioned to disabling or disabled. Fast snapshot restore cannot be enabled for this snapshot.

**Client.UserInitiated**

The state successfully transitioned to enabling or disabling.

**Client.UserInitiated - Lifecycle state transition**

The state successfully transitioned to optimizing, enabled, or disabled.

**Server.InsufficientCapacity** - There was insufficient capacity available to satisfy the request

A request to enable fast snapshot restore failed due to insufficient capacity, and the state transitioned to disabling or disabled. Wait and then try again.

**Server.InternalError** - An internal error caused the operation to fail

A request to enable fast snapshot restore failed due to an internal error, and the state transitioned to disabling or disabled. Wait and then try again.

**Client.InvalidSnapshot.InvalidState** - The requested snapshot was deleted or access permissions were revoked

The fast snapshot restore state for the snapshot has transitioned to disabling or disabled because the snapshot was deleted or unshared by the snapshot owner. Fast snapshot restore cannot be enabled for a snapshot that has been deleted or is no longer shared with you.

### Using AWS Lambda to handle EventBridge events

You can use Amazon EBS and Amazon EventBridge to automate your data-backup workflow. This requires you to create an IAM policy, a AWS Lambda function to handle the event, and an EventBridge rule that matches incoming events and routes them to the Lambda function.

The following procedure uses the `createSnapshot` event to automatically copy a completed snapshot to another Region for disaster recovery.
To copy a completed snapshot to another Region

1. Create an IAM policy, such as the one shown in the following example, to provide permissions to use the CopySnapshot action and write to the EventBridge log. Assign the policy to the user that will handle the EventBridge event.

```
{

```

2. Define a function in Lambda that will be available from the EventBridge console. The sample Lambda function below, written in Node.js, is invoked by EventBridge when a matching createSnapshot event is emitted by Amazon EBS (signifying that a snapshot was completed). When invoked, the function copies the snapshot from us-east-2 to us-east-1.

```
// Sample Lambda function to copy an EBS snapshot to a different Region
var AWS = require('aws-sdk');
var ec2 = new AWS.EC2();

// define variables
var destinationRegion = 'us-east-1';
var sourceRegion = 'us-east-2';
console.log ('Loading function');

//main function
exports.handler = (event, context, callback) => {
    // Get the EBS snapshot ID from the event details
    var snapshotArn = event.detail.snapshot_id.split('/');
    const snapshotId = snapshotArn[1];
    const description = `Snapshot copy from ${snapshotId} in ${sourceRegion}.`;
    console.log ('snapshotId:', snapshotId);

    // Load EC2 class and update the configuration to use destination Region to initiate the snapshot.
    AWS.config.update({region: destinationRegion});
    var ec2 = new AWS.EC2();

    // Prepare variables for ec2.modifySnapshotAttribute call
    const copySnapshotParams = {
        Description: description,
        DestinationRegion: destinationRegion,
        SourceRegion: sourceRegion,
        SourceSnapshotId: snapshotId
    }
```

2058
To ensure that your Lambda function is available from the EventBridge console, create it in the Region where the EventBridge event will occur. For more information, see the AWS Lambda Developer Guide.

3. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.

4. In the navigation pane, choose Rules, and then choose Create rule.

5. For Step 1: Define rule detail, do the following:
   a. Enter values for Name and Description.
   b. For Event bus, keep default.
   c. Ensure that Enable the rule on the selected event bus is toggled on.
   d. For Event type, select Rule with an event pattern.
   e. Choose Next.

6. For Step 2: Build event pattern, do the following:
   a. For Event source, select AWS events or EventBridge partner events.
   b. In the Event pattern section, for Event source, ensure that AWS service is selected, and for AWS service, select EC2.
   c. For Event type, select EBS Snapshot Notification, select Specific event(s), and then choose createSnapshot.
   d. Select Specific result(s) and then choose succeeded.
   e. Choose Next.

7. For Step 3: Select targets, do the following:
   a. For Target types, choose AWS service.
   b. For Select target, choose Lambda function, and for Function select the function that you created earlier.
   c. Choose Next

8. For Step 4: Configure tags, specify tags for the rule if needed, and then choose Next.

9. For Step 5: Review and create, review the rule and then choose Create rule.

Your rule should now appear on the Rules tab. In the example shown, the event that you configured should be emitted by EBS the next time you copy a snapshot.
Amazon EBS quotas

To view the quotas for your Amazon EBS resources, open the Service Quotas console at https://console.aws.amazon.com/servicequotas/. In the navigation pane, choose AWS services, and select Amazon Elastic Block Store (Amazon EBS).

For a list of Amazon EBS service quotas, see Amazon Elastic Block Store service quotas in the AWS General Reference.

Amazon EC2 instance store

An instance store provides temporary block-level storage for your instance. This storage is located on disks that are physically attached to the host computer. Instance store is ideal for temporary storage of information that changes frequently, such as buffers, caches, scratch data, and other temporary content. It can also be used to store temporary data that you replicate across a fleet of instances, such as a load-balanced pool of web servers.

An instance store consists of one or more instance store volumes exposed as block devices. The size of an instance store as well as the number of devices available varies by instance type and instance size. For more information, see Instance store volumes (p. 2062).

The virtual devices for instance store volumes are ephemeral[0-23]. Instance types that support one instance store volume have ephemeral0. Instance types that support two or more instance store volumes have ephemeral0, ephemeral1, and so on.

Instance store pricing

Instance store volumes are included as part of the instance's usage cost.
Instance store volume and data lifetime

The number, size, and type of instance store volumes are determined by the instance type and instance size. For more information, see Instance store volumes (p. 2062).

Instance store volumes are attached only at instance launch. You can't attach instance store volumes after launch. You can't detach an instance store volume from one instance and attach it to a different instance.

An instance store volume exists only during the lifetime of the instance to which it is attached. You can't configure an instance store volume to persist beyond the lifetime of its associated instance.

The data on an instance store volume persists even if the instance is rebooted. However, the data does not persist if the instance is stopped, hibernated, or terminated. When the instance is stopped, hibernated, or terminated, every block of the instance store volume is cryptographically erased.

Therefore, do not rely on instance store volumes for valuable, long-term data. If you need to retain the data stored on an instance store volume beyond the lifetime of the instance, you need to manually copy that data to more persistent storage, such as an Amazon EBS volume, an Amazon S3 bucket, or an Amazon EFS file system.

There are some events that can result in your data not persisting throughout the lifetime of the instance. The following table indicates whether data on instance store volumes is persisted during specific events, for both virtualized and bare metal instances.

<table>
<thead>
<tr>
<th>Event</th>
<th>What happens to your data?</th>
</tr>

</tbody>
</table>

* If the new instance type supports instance store, the instance gets the number of instance store volumes supported by the new instance type, but the data does not transfer to the new instance. If the new instance type does not support instance store, the instance does not get the instance store volumes.

** The data is not included in the EBS-backed AMI, and it is not included on instance store volumes attached to instances launched from that AMI.

*** The data is included in the AMI bundle that is uploaded to Amazon S3. When you launch an instance from that AMI, the instance gets the instance store volumes bundled in the AMI with the data they contained at the time the AMI was created.

† Termination protection and stop protection do not protect instances against instance stops or terminations as a result of shutdowns initiated through the operating system on the instance. Data stored on instance store volumes does not persist in both instance stop and termination events.

## Instance store volumes

The number, size, and type of instance store volumes are determined by the instance type and instance size. Some instance types, such as M6, C6, and R6, do not support instance store volumes, while other instance types, such as M5d, C6gd, and R6gd, do support instance store volumes. You can't attach more instance store volumes to an instance than is supported by its instance type. For the instance types that do support instance store volumes, the number and size of the instance store volumes vary by instance size. For example, m5d.1.large supports 1 x 75 GB instance store volume, while m5d.24xlarge supports 4 x 900 GB instance store volumes.

For instance types with **NVMe instance store volumes**, all of the supported instance store volumes are automatically attached to the instance at launch. For instance types with **non-NVMe instance store volumes**, such as C1, C3, M1, M2, M3, R3, D2, H1, I2, G2, X1, and X1e, you must manually specify the block device mappings for the instance store volumes that you want to attach at launch. Then, after the instance has launched, you must **format and mount the attached instance store volumes (p. 2077)** before you can use them. You can't attach an instance store volume after you launch the instance.

Some instance types use NVMe or SATA-based solid state drives (SSD), while others use SATA-based hard disk drives (HDD). SSDs deliver high random I/O performance with very low latency, but you don't need the data to persist when the instance terminates or you can take advantage of fault-tolerant architectures. For more information, see **SSD instance store volumes (p. 2078).**
The data on NVMe instance store volumes and some HDD instance store volumes is encrypted at rest. For more information, see Data protection in Amazon EC2 (p. 1656).

Available instance store volumes

The following table provides the quantity, size, type, and performance optimizations of instance store volumes available on each supported instance type.

* Volumes attached to certain instances suffer a first-write penalty unless initialized. For more information, see Optimize disk performance for instance store volumes (p. 2082).

** For more information, see Instance store volume TRIM support (p. 2079).
† The c1.medium and m1.small instance types also include a 900 MB instance store swap volume, which may not be automatically enabled at boot time. For more information, see Instance store swap volumes (p. 2080).

Instance store volume performance

The following documentation describes the I/O performance of the instance store volumes.

- General purpose instances (p. 309)
- Compute optimized instances (p. 362)
- Memory optimized instances (p. 386)
- Storage optimized instances (p. 399)
- Accelerated computing instances (p. 414)

To query instance store volume information using the AWS CLI

You can use the describe-instance-types AWS CLI command to display information about an instance type, such as its instance store volumes. The following example displays the total size of instance storage for all R5 instances with instance store volumes.

```
aws ec2 describe-instance-types \
  --filters "Name=instance-type,Values=r5*" "Name=instance-storage-supported,Values=true" \
  --query "InstanceTypes[].InstanceStorageInfo.TotalSizeInGB" \
  --output table
```

Example output

```
<table>
<thead>
<tr>
<th>DescribeInstanceTypes</th>
<th>+----------------+--------+</th>
</tr>
</thead>
<tbody>
<tr>
<td>r5ad.24xlarge</td>
<td>3600</td>
</tr>
<tr>
<td>r5ad.12xlarge</td>
<td>1800</td>
</tr>
<tr>
<td>r5dn.8xlarge</td>
<td>1200</td>
</tr>
<tr>
<td>r5ad.8xlarge</td>
<td>1200</td>
</tr>
<tr>
<td>r5ad.large</td>
<td>75</td>
</tr>
<tr>
<td>r5d.4xlarge</td>
<td>600</td>
</tr>
<tr>
<td>r5d.2xlarge</td>
<td>300</td>
</tr>
<tr>
<td>r5d.12xlarge</td>
<td>1800</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------</td>
</tr>
</tbody>
</table>
```

The following example displays the complete instance storage details for the specified instance type.

```
aws ec2 describe-instance-types \
  --filters "Name=instance-type,Values=r5d.4xlarge" \
  --query "InstanceTypes[].InstanceStorageInfo"
```

The example output shows that this instance type has two 300 GB NVMe SSD volumes, for a total of 600 GB of instance storage.

```
[ 
  { 
    "TotalSizeInGB": 600, 
    "Disks": [ 
      { 
        "SizeInGB": 300, 
        "Count": 2, 
      } 
    ] 
  } 
] 
```
Add instance store volumes to your EC2 instance

For instance types with **NVMe instance store volumes**, all of the supported instance store volumes are automatically attached to the instance at launch. They are automatically enumerated and assigned a device name on instance launch.

For instance types with **non-NVMe instance store volumes**, such as C1, C3, M1, M2, M3, R3, D2, H1, I2, G2, X1, and X1e, you must manually specify the block device mappings for the instance store volumes that you want to attach at launch. Block device mappings can be specified in the instance launch request or in the AMI used to launch the instance. The block device mapping includes a device name and the volume that it maps to. For more information, see [Block device mappings](p. 2101).

**Important**

Instance store volumes can be attached to an instance only when you launch it. You can't attach instance store volumes to an instance after you've launched it.

After you launch an instance, you must ensure that the instance store volumes for your instance are formatted and mounted before you can use them. The root volume of an instance store-backed instance is mounted automatically.

**Consideration for root volumes**

A block device mapping always specifies the root volume for the instance. The root volume is either an Amazon EBS volume or an instance store volume. The root volume is mounted automatically. For instances with an instance store volume for the root volume, the size of this volume varies by AMI, but the maximum size is 10 GB. For more information, see [Storage for the root device](p. 111).

**Contents**

- Add instance store volumes to an AMI (p. 2075)
- Add non-NVME instance store volumes to an instance (p. 2076)
- Make instance store volumes available on your instance (p. 2077)

Add instance store volumes to an AMI

You can create an AMI with a block device mapping that includes instance store volumes.

If you launch an instance that supports **non-NVMe instance store volumes** using an AMI that specifies instance store volume block device mappings, the instance includes the instance store volumes. If the number of instance store volume block device mappings in the AMI exceeds the number of instance store volumes available to the instance, the additional instance store volume block device mappings are ignored.

If you launch an instance that supports **NVMe instance store volumes** using an AMI that specifies instance store volume block device mappings, the instance store volume block device mappings are ignored. Instances that support NVMe instance store volumes get all of their supported instance store volumes, regardless of the block device mappings specified in the instance launch request and the AMI.

**Considerations**

- For M3 instances, specify instance store volumes in the block device mapping of the instance, not the AMI. Amazon EC2 might ignore instance store volume block device mappings in the AMI.
When you launch an instance, you can omit non-NVMe instance store volumes specified in the AMI block device mapping or add instance store volumes.

**New console**

**To add instance store volumes to an Amazon EBS-backed AMI using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances** and select the instance.
3. Choose **Actions, Image and templates, Create image**.
4. On the **Create image** page, enter a meaningful name and description for your image.
5. For each instance store volume to add, choose **Add volume**, from **Volume type** select an instance store volume, and from **Device** select a device name. (For more information, see **Device names on Linux instances** (p. 2099).) The number of available instance store volumes depends on the instance type. For instances with NVMe instance store volumes, the device mapping of these volumes depends on the order in which the operating system enumerates the volumes.
6. Choose **Create image**.

**AWS CLI**

**To add instance store volumes to an AMI using the command line**

You can use one of the following commands. For more information about these command line interfaces, see **Access Amazon EC2** (p. 5).

- **create-image** or **register-image** (AWS CLI)
- **New-EC2Image** and **Register-EC2Image** (AWS Tools for Windows PowerShell)

**Add non-NVME instance store volumes to an instance**

When you launch an instance that supports **non-NVMe instance store volumes** you must specify block device mappings for the instance store volumes to attach. The block device mappings must be specified in the instance launch request or in the AMI used to launch the instance.

If the AMI includes block device mappings for the instance store volumes, you do not need to specify block device mappings in the instance launch request, unless you need more instance store volumes than is included in the AMI.

If the AMI does not include block device mappings for instance store volumes, then you must specify the block device mappings in the instance launch request.

**Considerations**

- For M3 instances, you might receive instance store volumes even if you do not specify them in the block device mapping for the instance.

To specify block device mappings in the instance launch request, use one of the following methods.

**Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. From the dashboard, choose **Launch instance**.
3. In the **Application and OS Images** section, select the AMI to use.

4. In the **Configure storage** section, the **Instance store volumes** section lists the instance store volumes that can be attached to the instance. The number of available instance store volumes depends on the instance type.

5. For each instance store volume to attach, for **Device name**, select the device name to use.

6. Configure the remaining instance settings as needed, and then choose **Launch instance**.

**Command line**

You can use one of the following options commands with the corresponding option.

- `--block-device-mappings` with `run-instances` (AWS CLI)
- `-BlockDeviceMapping` with `New-EC2Instance` (AWS Tools for Windows PowerShell)

**Make instance store volumes available on your instance**

After you launch an instance with attached instance store volumes, you must mount the volumes before you can access them.

For Linux instances, many instance store volumes are pre-formatted with the ext3 file system. SSD-based instance store volumes that support TRIM instruction are not pre-formatted with any file system. However, you can format volumes with the file system of your choice after you launch your instance. For more information, see **Instance store volume TRIM support** (p. 2079). For Windows instances, we reformat the instance store volumes with the NTFS file system.

You can confirm that the instance store devices are available from within the instance itself using instance metadata. For more information, see **View the instance block device mapping for instance store volumes** (p. 2109).

For Linux instances, you can view and mount the instance store volumes as described in the following procedure.

**To make an instance store volume available on Linux**

1. Connect to the instance using an SSH client. For more information, see **Connect to your Linux instance** (p. 757).

2. Use the `df -h` command to view the volumes that are formatted and mounted.

   ```
   [ec2-user ~]$ df -h
   Filesystem  Size  Used Avail Use% Mounted on
   devtmpfs  3.8G   72K  3.8G   1% /dev
   tmpfs     3.8G     0  3.8G   0% /dev/shm
   /dev/nvme0n1p1  7.9G  1.2G  6.6G  15% /
   ```

3. Use the `lsblk` to view any volumes that were mapped at launch but not formatted and mounted.

   ```
   [ec2-user ~]$ lsblk
   NAME   MAJ:MIN  RM  SIZE RO TYPE MOUNTPOINT
   nvme0n1 259:1    0   8G 0  disk
   ##nvme0n1p1 259:2    0   8G 0  part /
   ##nvme0n1p128 259:3    0  1M 0  part
   nvme1n1 259:0    0 69.9G 0  disk
   ```

4. To format and mount an instance store volume that was mapped only, do the following:

   a. Create a file system on the device using the `mkfs` command.
To ensure the best IOPS performance from your SSD instance store volumes on Linux, we recommend that you use the most recent version of Amazon Linux, or another Linux AMI with a kernel version of 3.8 or later. If you do not use a Linux AMI with a kernel version of 3.8 or later, your instance won’t achieve the maximum IOPS performance available for these instance types.

Like other instance store volumes, you must map the SSD instance store volumes for your instance when you launch it. The data on an SSD instance volume persists only for the life of its associated instance. For more information, see Add instance store volumes to your EC2 instance (p. 2075).

NVMe SSD volumes

Some instances offer non-volatile memory express (NVMe) solid state drives (SSD) instance store volumes. For more information about the type of instance store volume supported by each instance type, see Instance store volumes (p. 2062).

To access NVMe volumes, the NVMe drivers (p. 1994) must be installed. The following AMIs meet this requirement:

- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 or later with linux-aws kernel

Note

AWS Graviton-based instance types require Ubuntu 18.04 or later with linux-aws kernel

- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later
- Bottlerocket

After you connect to your instance, you can list the NVMe devices using the lspci command. The following is example output for an i3.8xlarge instance, which supports four NVMe devices.

[ec2-user ~]$ lspci
If you are using a supported operating system but you do not see the NVMe devices, verify that the NVMe module is loaded using the following command.

- Amazon Linux, Amazon Linux 2, Ubuntu 14/16, Red Hat Enterprise Linux, SUSE Linux Enterprise Server, CentOS 7
  
  ```
  $ lsmod | grep nvme
  nvme          48813  0
  ```

- Ubuntu 18
  
  ```
  $ cat /lib/modules/$(uname -r)/modules.builtin | grep nvme
  s/nvme/host/nvme-core.ko
  kernel/drivers/nvme/host/nvme.ko
  kernel/drivers/nvmem/nvmem_core.ko
  ```

The NVMe volumes are compliant with the NVMe 1.0e specification. You can use the NVMe commands with your NVMe volumes. With Amazon Linux, you can install the `nvme-cli` package from the repo using the `yum install` command. With other supported versions of Linux, you can download the `nvme-cli` package if it's not available in the image.

The data on NVMe instance storage is encrypted using an XTS-AES-256 block cipher implemented in a hardware module on the instance. The encryption keys are generated using the hardware module and are unique to each NVMe instance storage device. All encryption keys are destroyed when the instance is stopped or terminated and cannot be recovered. You cannot disable this encryption and you cannot provide your own encryption key.

**Non-NVMe SSD volumes**

The following instances support instance store volumes that use non-NVMe SSDs to deliver high random I/O performance: C3, G2, I2, M3, R3, and X1. For more information about the instance store volumes supported by each instance type, see [Instance store volumes](p. 2062).

**Instance store volume TRIM support**

Some instance types support SSD volumes with TRIM. For more information, see [Instance store volumes](p. 2062).

Instance store volumes that support TRIM are fully trimmed before they are allocated to your instance. These volumes are not formatted with a file system when an instance launches, so you must format them before they can be mounted and used. For faster access to these volumes, you should skip the TRIM operation when you format them.

With instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller when you no longer need data that you've written. This provides the controller with more...
free space, which can reduce write amplification and increase performance. On Linux, use the fstrim
command to enable periodic TRIM.

**Instance store swap volumes**

Swap space in Linux can be used when a system requires more memory than it has been physically
allocated. When swap space is enabled, Linux systems can swap infrequently used memory pages from
physical memory to swap space (either a dedicated partition or a swap file in an existing file system) and
free up that space for memory pages that require high-speed access.

**Note**
Using swap space for memory paging is not as fast or efficient as using RAM. If your workload
is regularly paging memory into swap space, you should consider migrating to a larger instance
type with more RAM. For more information, see Change the instance type (p. 449).

The c1.medium and m1.small instance types have a limited amount of physical memory to work with,
and they are given a 900 MiB swap volume at launch time to act as virtual memory for Linux AMIs.
Although the Linux kernel sees this swap space as a partition on the root device, it is actually a separate
instance store volume, regardless of your root device type.

Amazon Linux automatically enables and uses this swap space, but your AMI may require some
additional steps to recognize and use this swap space. To see if your instance is using swap space, you
can use the `swapon -s` command.

```
[ec2-user ~]$ swapon -s
Filename                                Type            Size    Used    Priority
/dev/xvda3                              partition       917500  0       -1
```

The above instance has a 900 MiB swap volume attached and enabled. If you don’t see a swap volume
listed with this command, you may need to enable swap space for the device. Check your available disks
using the `lsblk` command.

```
[ec2-user ~]$ lsblk
NAME  MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvda1 202:1    0    8G  0 disk /
xvda3 202:3    0  896M  0 disk
```

Here, the swap volume xvda3 is available to the instance, but it is not enabled (notice that the
MOUNTPOINT field is empty). You can enable the swap volume with the `swapon` command.

**Note**
You must prepend `/dev/` to the device name listed by `lsblk`. Your device may be named
differently, such as sda3, sde3, or xvde3. Use the device name for your system in the command
below.

```
[ec2-user ~]$ sudo swapon /dev/xvda3
```

Now the swap space should show up in `lsblk` and `swapon -s` output.

```
[ec2-user ~]$ lsblk
NAME  MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvda1 202:1    0    8G  0 disk /
xvda3 202:3    0  896M  0 disk [SWAP]
```

```
[ec2-user ~]$ swapon -s
Filename                                Type            Size    Used    Priority
/dev/xvda3                              partition       917500  0       -1
```
You also need to edit your /etc/fstab file so that this swap space is automatically enabled at every system boot.

```
[ec2-user ~]$ sudo vim /etc/fstab
```

Append the following line to your /etc/fstab file (using the swap device name for your system):

```
/dev/xvda3 none swap sw 0 0
```

To use an instance store volume as swap space

Any instance store volume can be used as swap space. For example, the m3.medium instance type includes a 4 GB SSD instance store volume that is appropriate for swap space. If your instance store volume is much larger (for example, 350 GB), you may consider partitioning the volume with a smaller swap partition of 4-8 GB and the rest for a data volume.

**Note**

This procedure applies only to instance types that support instance storage. For a list of supported instance types, see Instance store volumes (p. 2062).

1. List the block devices attached to your instance to get the device name for your instance store volume.

```
[ec2-user ~]$ lsblk -p
NAME       MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
/dev/xvdb  202:16   0   4G  0 disk /media/ephemeral0
/dev/xvda1 202:1    0   8G  0 disk /
```

In this example, the instance store volume is /dev/xvdb. Because this is an Amazon Linux instance, the instance store volume is formatted and mounted at /media/ephemeral0; not all Linux operating systems do this automatically.

2. (Optional) If your instance store volume is mounted (it lists a MOUNTPOINT in the lsblk command output), unmount it with the following command.

```
[ec2-user ~]$ sudo umount /dev/xvdb
```

3. Set up a Linux swap area on the device with the mkswap command.

```
[ec2-user ~]$ sudo mkswap /dev/xvdb
```

```
mkswap: /dev/xvdb: warning: wiping old ext3 signature.
Setting up swapspace version 1, size = 4188668 KiB
no label, UUID=b4f63d28-67ed-46f0-b5e5-6928319e620b
```

4. Enable the new swap space.

```
[ec2-user ~]$ sudo swapon /dev/xvdb
```

5. Verify that the new swap space is being used.

```
[ec2-user ~]$ swapon -s
Filename   Type  Size Used Priority
/dev/xvdb          4188668 0 -1
```

6. Edit your /etc/fstab file so that this swap space is automatically enabled at every system boot.

```
[ec2-user ~]$ sudo vim /etc/fstab
```
If your /etc/fstab file has an entry for /dev/xvdb (or /dev/sdb) change it to match the line below; if it does not have an entry for this device, append the following line to your /etc/fstab file (using the swap device name for your system):

<table>
<thead>
<tr>
<th>Mount Point</th>
<th>Type</th>
<th>Options</th>
<th>Freq</th>
<th>Dev</th>
</tr>
</thead>
<tbody>
<tr>
<td>/dev/xvdb</td>
<td>none</td>
<td>swap</td>
<td>sw</td>
<td>0</td>
</tr>
</tbody>
</table>

**Important**

Instance store volume data is lost when an instance is stopped or hibernated; this includes the instance store swap space formatting created in Step 3 (p. 2081). If you stop and restart an instance that has been configured to use instance store swap space, you must repeat Step 1 (p. 2081) through Step 5 (p. 2081) on the new instance store volume.

### Optimize disk performance for instance store volumes

Because of the way that Amazon EC2 virtualizes disks, the first write to any location on some instance store volumes performs more slowly than subsequent writes. For most applications, amortizing this cost over the lifetime of the instance is acceptable. However, if you require high disk performance, we recommend that you initialize your drives by writing once to every drive location before production use.

**Note**

Some instance types with direct-attached solid state drives (SSD) and TRIM support provide maximum performance at launch time, without initialization. For information about the instance store for each instance type, see Instance store volumes (p. 2062).

If you require greater flexibility in latency or throughput, we recommend using Amazon EBS. To initialize the instance store volumes, use the following dd commands, depending on the store to initialize (for example, /dev/sdb or /dev/nvme1n1).

**Note**

Make sure to unmount the drive before performing this command. Initialization can take a long time (about 8 hours for an extra large instance).

To initialize the instance store volumes, use the following commands on the m1.large, m1.xlarge, c1.xlarge, m2.xlarge, m2.2xlarge, and m2.4xlarge instance types:

```
dd if=/dev/zero of=/dev/sdb bs=1M
dd if=/dev/zero of=/dev/sdc bs=1M
dd if=/dev/zero of=/dev/sdd bs=1M
dd if=/dev/zero of=/dev/sde bs=1M
```

To perform initialization on all instance store volumes at the same time, use the following command:

```
dd if=/dev/zero bs=1M|tee /dev/sdb|tee /dev/sdc|tee /dev/sde > /dev/sdd
```

Configuring drives for RAID initializes them by writing to every drive location. When configuring software-based RAID, make sure to change the minimum reconstruction speed:

```
echo $(30*1024) > /proc/sys/dev/raid/speed_limit_min
```
File storage

Cloud file storage is a method for storing data in the cloud that provides servers and applications access to data through shared file systems. This compatibility makes cloud file storage ideal for workloads that rely on shared file systems and provides simple integration without code changes.

There are many file storage solutions that exist, ranging from a single node file server on a compute instance using block storage as the underpinnings with no scalability or few redundancies to protect the data, to a do-it-yourself clustered solution, to a fully-managed solution. The following content introduces some of the storage services provided by AWS for use with Linux.

Contents

- Use Amazon S3 with Amazon EC2 (p. 2083)
- Use Amazon EFS with Amazon EC2 (p. 2085)
- Use Amazon FSx with Amazon EC2 (p. 2088)

Use Amazon S3 with Amazon EC2

Amazon S3 is a repository for internet data. Amazon S3 provides access to reliable, fast, and inexpensive data storage infrastructure. It is designed to make web-scale computing easier by enabling you to store and retrieve any amount of data, at any time, from within Amazon EC2 or anywhere on the web. Amazon S3 stores data objects redundantly on multiple devices across multiple facilities and allows concurrent read or write access to these data objects by many separate clients or application threads. You can use the redundant data stored in Amazon S3 to recover quickly and reliably from instance or application failures.

Amazon EC2 uses Amazon S3 for storing Amazon Machine Images (AMIs). You use AMIs for launching EC2 instances. In case of instance failure, you can use the stored AMI to immediately launch another instance, thereby allowing for fast recovery and business continuity.

Amazon EC2 also uses Amazon S3 to store snapshots (backup copies) of the data volumes. You can use snapshots for recovering data quickly and reliably in case of application or system failures. You can also use snapshots as a baseline to create multiple new data volumes, expand the size of an existing data volume, or move data volumes across multiple Availability Zones, thereby making your data usage highly scalable. For more information about using data volumes and snapshots, see Amazon Elastic Block Store (p. 1770).

Objects are the fundamental entities stored in Amazon S3. Every object stored in Amazon S3 is contained in a bucket. Buckets organize the Amazon S3 namespace at the highest level and identify the account responsible for that storage. Amazon S3 buckets are similar to internet domain names. Objects stored in the buckets have a unique key value and are retrieved using a URL. For example, if an object with a key value /photos/mygarden.jpg is stored in the DOC-EXAMPLE-BUCKET1 bucket, then it is addressable using the URL https://DOC-EXAMPLE-BUCKET1.s3.amazonaws.com/photos/mygarden.jpg.

For more information about the features of Amazon S3, see the Amazon S3 product page.

Usage examples

Note

We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints.

Given the benefits of Amazon S3 for storage, you might decide to use this service to store files and data sets for use with EC2 instances. There are several ways to move data to and from Amazon S3 to your
instances. In addition to the examples discussed below, there are a variety of tools that people have written that you can use to access your data in Amazon S3 from your computer or your instance. Some of the common ones are discussed in the AWS forums.

If you have permission, you can copy a file to or from Amazon S3 and your instance using one of the following methods.

**GET or wget**

*Note*

This method works for public objects only. If the object is not public, you receive an ERROR 403: Forbidden message. If you receive this error, you must use either the Amazon S3 console, AWS CLI, AWS API, AWS SDK, or AWS Tools for Windows PowerShell, and you must have the required permissions. For more information, see Identity and access management in Amazon S3 and Downloading an object in the Amazon S3 User Guide.

The `wget` utility is an HTTP and FTP client that allows you to download public objects from Amazon S3. It is installed by default in Amazon Linux and most other distributions, and available for download on Windows. To download an Amazon S3 object, use the following command, substituting the URL of the object to download.

```
[ec2-user ~]$ wget https://my_bucket.s3.amazonaws.com/path-to-file
```

**AWS Command Line Interface**

The AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services. The AWS CLI enables users to authenticate themselves and download restricted items from Amazon S3 and also to upload items. For more information, such as how to install and configure the tools, see the AWS Command Line Interface detail page.

The `aws s3 cp` command is similar to the Unix `cp` command. You can copy files from Amazon S3 to your instance, copy files from your instance to Amazon S3, and copy files from one Amazon S3 location to another.

Use the following command to copy an object from Amazon S3 to your instance.

```
[ec2-user ~]$ aws s3 cp s3://my_bucket/my_folder/my_file.ext my_copied_file.ext
```

Use the following command to copy an object from your instance back into Amazon S3.

```
[ec2-user ~]$ aws s3 cp my_copied_file.ext s3://my_bucket/my_folder/my_file.ext
```

The `aws s3 sync` command can synchronize an entire Amazon S3 bucket to a local directory location. This can be helpful for downloading a data set and keeping the local copy up-to-date with the remote set. If you have the proper permissions on the Amazon S3 bucket, you can push your local directory back up to the cloud when you are finished by reversing the source and destination locations in the command.

Use the following command to download an entire Amazon S3 bucket to a local directory on your instance.

```
[ec2-user ~]$ aws s3 sync s3://remote_S3_bucket local_directory
```

**Amazon S3 API**

If you are a developer, you can use an API to access data in Amazon S3. For more information, see the Amazon Simple Storage Service User Guide. You can use this API and its examples to help develop your application and integrate it with other APIs and SDKs, such as the boto Python interface.
Use Amazon EFS with Amazon EC2

Amazon EFS provides scalable file storage for use with Amazon EC2. You can use an EFS file system as a common data source for workloads and applications running on multiple instances. For more information, see the Amazon Elastic File System product page.

For a tutorial on how to create a file system using the Amazon EFS console, see Getting started with Amazon Elastic File System in the Amazon Elastic File System User Guide.

**Important**
Amazon EFS is not supported on Windows instances.

**Topics**
- Create an EFS file system using Amazon EFS Quick Create (p. 2085)
- Test the EFS file system (p. 2087)
- Delete the EFS file system (p. 2088)

Create an EFS file system using Amazon EFS Quick Create

You can create an EFS file system and mount it to your instance when you launch your instance using the Amazon EFS Quick Create feature of the Amazon EC2 launch instance wizard (p. 676).

When you create an EFS file system using EFS Quick Create, the file system is created with the following service recommended settings:

- Automatic backups turned on. For more information, see Using AWS Backup to back up and restore Amazon EFS file systems in the Amazon Elastic File System User Guide.
- Mount targets in each default subnet in the selected VPC, using the VPC's default security group. For more information, see Managing file system network accessibility in the Amazon Elastic File System User Guide.
- General Purpose performance mode. For more information, see Performance modes in the Amazon Elastic File System User Guide.
- Bursting throughput mode. For more information, see Throughput modes in the Amazon Elastic File System User Guide.
- Encryption of data at rest enabled using your default key for Amazon EFS (aws/elasticfilesystem). For more information, see Encrypting data at rest in the Amazon Elastic File System User Guide.
- Amazon EFS lifecycle management enabled with a 30-day policy. For more information, see Amazon EFS lifecycle management in the Amazon Elastic File System User Guide.

**New console**

**To create an EFS file system using Amazon EFS Quick Create**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. Choose **Launch instance**.
3. (Optional) Under **Name and tags**, for **Name**, enter a name to identify your instance.
4. Under **Application and OS Images (Amazon Machine Image)**, choose a Linux operating system, and then for **Amazon Machine Image (AMI)**, select a Linux AMI.
5. Under **Instance type**, for **Instance type**, select an instance type or keep the default.
6. Under **Key pair (login)**, for **Key pair name**, choose an existing key pair or create a new one.
7. Under **Network settings**, choose **Edit** (at right), and then for **Subnet**, select a subnet.
Note
You must select a subnet before you can add an EFS file system.

8. Under Configure storage, choose Edit (at bottom right), and then do the following:
   a. Make sure that EFS is selected.
   b. Choose Add shared file system.

   Troubleshooting tip
   If Add shared file system is not visible, you must first select a subnet.
   c. For File system, select an existing file system, or choose Create new shared file system and create a file system using Amazon EFS Quick Create.
   d. For Mount point, specify a mount point or keep the default.
   e. To enable access to the file system, select Automatically create and attach security groups. By selecting this check box, the necessary security groups will automatically be created and attached to the instance and the mount targets of the file system, as follows:
      • Instance security group – Includes an outbound rule that allows traffic over the NFS 2049 port, but includes no inbound rules.
      • File system mount targets security group – Includes an inbound rule that allows traffic over the NFS 2049 port from the instance security group (described above), and an outbound rule that allows traffic over the NFS 2049 port.

   You can choose to manually create and attach the security groups. If you want to manually create and attach the security groups, clear Automatically create and attach the required security groups.
   f. To automatically mount the shared file system when the instance launches, select Automatically mount shared file system by attaching required user data script. To view the user data that is automatically generated, expand Advanced details, and scroll down to User data.

   Note
   If you added user data before selecting this check box, the original user data is overwritten by the user data that is automatically generated.

9. Configure any other instance configuration settings as needed.
10. In the Summary panel, review your instance configuration, and then choose Launch instance.
    For more information, see Launch an instance using the new launch instance wizard (p. 676)

Old console

To create an EFS file system using Amazon EFS Quick Create
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance.
3. On the Choose an AMI page, choose a Linux AMI.
4. On the Choose an Instance Type page, select an instance type and then choose Next: Configure Instance Details.
5. On the Configure Instance Details page, for File systems, choose Create new file system, enter a name for the new file system, and then choose Create.

To enable access to the file system, the following security groups are automatically created and attached to the instance and the mount targets of the file system.
   • Instance security group—Includes no inbound rules and an outbound rule that allows traffic over the NFS 2049 port.
- File system mount targets security group—Includes an inbound rule that allows traffic over the NFS 2049 port from the instance security group (described above), and an outbound rule that allows traffic over the NFS 2049 port.

You can also choose to manually create and attach the security groups. To do this, clear Automatically create and attach the required security groups.

Configure the remaining settings as needed and choose Next: Add Storage.

6. On the Add Storage page, make any necessary changes, and then choose Next: Add Tags.
7. On the Add Tags page, specify any tags if necessary, and then choose Next: Configure Security Group.
8. On the Configure Security Group page, review the security groups and then choose Review and Launch.
9. On the Review Instance Launch page, review the settings, and then choose Launch to choose a key pair and to launch your instance.

Test the EFS file system

You can connect to your instance and verify that the file system is mounted to the directory that you specified (for example, /mnt/efs).

To verify that the file system is mounted

1. Connect to your instance. For more information, see Connect to your Linux instance (p. 757).
2. From the terminal window for the instance, run the df -T command to verify that the EFS file system is mounted.

```
$ df -T
Filesystem     Type               1K-blocks   Used       Available   Use% Mounted on
/dev/xvda1     ext4            8123812 1949800       6073764   25% /
devtmpfs       devtmpfs         4078468    56      4078412   1% /dev
tmpfs          tmpfs            4089312       0      4089312   0% /dev/shm
efs-dns        nfs4          9007199254740992 0 9007199254740992 0% /mnt/efs
```

Note that the name of the file system, shown in the example output as efs-dns, has the following form.

```
file-system-id.efs.aws-region.amazonaws.com/
```

3. (Optional) Create a file in the file system from the instance, and then verify that you can view the file from another instance.
   a. From the instance, run the following command to create the file.
      
      ```
      $ sudo touch /mnt/efs/test-file.txt
      ```
   b. From the other instance, run the following command to view the file.
      
      ```
      $ ls /mnt/efs
      test-file.txt
      ```
Delete the EFS file system

If you no longer need your file system, you can delete it.

To delete the file system

2. Select the file system to delete.
3. Choose Actions, Delete file system.
4. When prompted for confirmation, enter the file system ID and choose Delete file system.

Use Amazon FSx with Amazon EC2

The Amazon FSx family of services makes it easy to launch, run, and scale shared storage powered by popular commercial and open-source file systems. You can use the new launch instance wizard to automatically attach the following types of Amazon FSx file systems to your Amazon EC2 instances at launch:

- Amazon FSx for NetApp ONTAP provides fully managed shared storage in the AWS Cloud with the popular data access and management capabilities of NetApp ONTAP.
- Amazon FSx for OpenZFS provides fully managed cost-effective shared storage powered by the popular OpenZFS file system.

**Note**

- This functionality is available in the new launch instance wizard only. For more information, see Launch an instance using the new launch instance wizard (p. 676)
- Amazon FSx for Windows File Server and Amazon FSx for Lustre file systems can't be mounted at launch. You must mount these file systems manually after launch.

You can choose to mount an existing file system that you created previously, or you can create a new file system to mount to an instance at launch.

**Topics**

- Security groups and user data script (p. 2088)
- Mount an Amazon FSx file system at launch (p. 2090)

Security groups and user data script

When you mount an Amazon FSx file system to an instance using the launch instance wizard, you can choose whether to automatically create and attach the security groups needed to enable access to the file system, and whether to automatically include the user data scripts needed to mount the file system and make it available for use.

**Topics**

- Security groups (p. 2089)
- User data script (p. 2090)
Security groups

If you choose to automatically create the security groups that are needed to enable access to the file system, the launch instance wizard creates and attaches two security groups - one security group is attached to the instance, and the other is attached to the file system. For more information about the security group requirements, see FSx for ONTAP file system access control with Amazon VPC and FSx for OpenZFS file system access control with Amazon VPC.

We add the tag Name=instance-sg-1 to the security group that is created and attached to the instance. The value in the tag is automatically incremented each time the launch instance wizard creates a security group for Amazon FSx file systems.

The security group includes the following output rules, but no inbound rules.

### Outbound rules

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Port number</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>UDP</td>
<td>111</td>
<td>file system security group</td>
</tr>
<tr>
<td>UDP</td>
<td>20001 - 20003</td>
<td>file system security group</td>
</tr>
<tr>
<td>UDP</td>
<td>4049</td>
<td>file system security group</td>
</tr>
<tr>
<td>UDP</td>
<td>2049</td>
<td>file system security group</td>
</tr>
<tr>
<td>UDP</td>
<td>635</td>
<td>file system security group</td>
</tr>
<tr>
<td>UDP</td>
<td>4045 - 4046</td>
<td>file system security group</td>
</tr>
<tr>
<td>TCP</td>
<td>4049</td>
<td>file system security group</td>
</tr>
<tr>
<td>TCP</td>
<td>635</td>
<td>file system security group</td>
</tr>
<tr>
<td>TCP</td>
<td>2049</td>
<td>file system security group</td>
</tr>
<tr>
<td>TCP</td>
<td>111</td>
<td>file system security group</td>
</tr>
<tr>
<td>TCP</td>
<td>4045 - 4046</td>
<td>file system security group</td>
</tr>
<tr>
<td>TCP</td>
<td>20001 - 20003</td>
<td>file system security group</td>
</tr>
<tr>
<td>All</td>
<td>All</td>
<td>file system security group</td>
</tr>
</tbody>
</table>

The security group that is created and attached to the file system is tagged with Name=fsx-sg-1. The value in the tag is automatically incremented each time the launch instance wizard creates a security group for Amazon FSx file systems.

The security group includes the following rules.

### Inbound rules

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Port number</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>UDP</td>
<td>2049</td>
<td>instance security group</td>
</tr>
<tr>
<td>UDP</td>
<td>20001 - 20003</td>
<td>instance security group</td>
</tr>
<tr>
<td>UDP</td>
<td>4049</td>
<td>instance security group</td>
</tr>
<tr>
<td>UDP</td>
<td>111</td>
<td>instance security group</td>
</tr>
</tbody>
</table>
### Protocol type | Port number | Source
---|---|---
UDP | 635 | instance security group
UDP | 4045 - 4046 | instance security group
TCP | 4045 - 4046 | instance security group
TCP | 635 | instance security group
TCP | 2049 | instance security group
TCP | 4049 | instance security group
TCP | 20001 - 20003 | instance security group
TCP | 111 | instance security group

### Outbound rules

| Protocol type | Port number | Destination |
---|---|---|
All | All | 0.0.0.0/0

### User data script

If you choose to automatically attach user data scripts, the launch instance wizard adds the following user data to the instance. This script installs the necessary packages, mounts the file system, and updates your instance settings so that the file system will automatically re-mount whenever the instance restarts.

```
#cloud-config
package_update: true
package_upgrade: true
runcmd:
  - yum install -y nfs-utils
  - apt-get -y install nfs-common
  - svm_id_1=${svm_id}
  - file_system_id_1=${file_system_id}
  - vol_path_1=${vol1}
  - fsx_mount_point_1=/mnt/fsx/fs1
  - mkdir -p "${fsx_mount_point_1}"
  - if [ -z "${svm_id_1}" ]; then printf "\n${file_system_id_1}.fsx.eu-north-1.amazonaws.com:/$vol_path_1 nfs4 nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport,_netdev 0 0\n" >> /etc/fstab; else printf "\n${svm_id_1}.${file_system_id_1}.fsx.eu-north-1.amazonaws.com:/$vol_path_1 nfs4 nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport,_netdev 0 0\n" >> /etc/fstab; fi
  - retryCnt=15; waitTime=30; while true; do mount -a -t nfs4 defaults; if [ $? = 0 ] || [ $retryCnt -lt 1 ]; then echo File system mounted successfully; break; fi; echo File system not available, retrying to mount.; ((retryCnt--)); sleep $waitTime; done;
```

### Mount an Amazon FSx file system at launch

**To mount a new or existing Amazon FSx file system at launch**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances** and then choose **Launch instance** to open the launch instance wizard.

3. In the **Application and OS Images** section, select the AMI to use.

4. In the **Instance type** section, select the instance type.

5. In the **Key pair** section, select an existing key pair or create a new one.

6. In the **Network settings** section, do the following:
   a. Choose **Edit**.
   b. If you want to **mount an existing file system**, for **Subnet**, choose the file system's preferred subnet. We recommend that you launch the instance into the same Availability Zone as the file system's preferred subnet to optimize performance.

   If you want to **create a new file system** to mount to an instance, for **Subnet**, choose the subnet into which to launch the instance.

   **Important**
   You must select a subnet to enable the Amazon FSx functionality in the new launch instance wizard. If you do not select a subnet, you will not be able to mount an existing file system or create a new one.

7. In the **Storage** section, do the following:
   a. Configure the volumes as needed.
   b. Expand the **File systems** section and select **FSx**.
   c. Choose **Add shared file system**.
   d. For **File system**, select the file system to mount.

   **Note**
   The list displays all Amazon FSx for NetApp ONTAP and Amazon FSx for OpenZFS file systems in your account in the selected Region.

   e. To automatically create and attach the security groups needed to enable access to the file system, select **Automatically create and attach security groups**. If you prefer to create the security groups manually, clear the check box. For more information, see **Security groups** (p. 2089).

   f. To automatically attach the user data scripts needed to mount the file system, select **Automatically mount shared file system by attaching required user data script**. If you prefer to provide the user data scripts manually, clear the check box. For more information, see **User data script** (p. 2090).

8. In the **Advanced** section, configure the additional instance settings as needed.

9. Choose **Launch**.

---

**Instance volume limits**

The maximum number of volumes that your instance can have depends on the operating system and instance type. When considering how many volumes to add to your instance, you should consider whether you need increased I/O bandwidth or increased storage capacity.

**Contents**

- Nitro System volume limits (p. 2092)
- Linux-specific volume limits (p. 2092)
- Bandwidth versus capacity (p. 2092)
Nitro System volume limits

Instances built on the Nitro System (p. 282) support a maximum number of attachments, which are shared between network interfaces, EBS volumes, and NVMe instance store volumes. Every instance has at least one network interface attachment. NVMe instance store volumes are automatically attached. For more information, see Elastic network interfaces (p. 1321) and Instance store volumes (p. 2062).

Most of these instances support a maximum of 28 attachments. For example, if you have no additional network interface attachments on an EBS-only instance, you can attach up to 27 EBS volumes to it. If you have one additional network interface on an instance with 2 NVMe instance store volumes, you can attach 24 EBS volumes to it.

For other instances, the following limits apply:

- Most bare metal instances support a maximum of 31 EBS volumes.
- High memory virtualized instances support a maximum of 27 EBS volumes.
- High memory bare metal instances support a maximum of 19 EBS volumes.
- inf1.xlarge and inf1.2xlarge instances support a maximum of 26 EBS volumes.
- inf1.6xlarge instances support a maximum of 23 EBS volumes.
- mac1.metal instances support a maximum of 16 EBS volumes.
- inf1.24xlarge instances support a maximum of 11 EBS volumes.
- g5.48xlarge instances support a maximum of 9 EBS volumes.
- d3.8xlarge and d3en.12xlarge instances support a maximum of 3 EBS volumes.

Linux-specific volume limits

Attaching more than 40 volumes can cause boot failures. This number includes the root volume, plus any attached instance store volumes and EBS volumes. If you experience boot problems on an instance with a large number of volumes, stop the instance, detach any volumes that are not essential to the boot process, and then reattach the volumes after the instance is running.

Important
Attaching more than 40 volumes to a Linux instance is supported on a best effort basis only and is not guaranteed.

Bandwidth versus capacity

For consistent and predictable bandwidth use cases, use EBS-optimized or 10 Gigabit network connectivity instances and General Purpose SSD or Provisioned IOPS SSD volumes. Follow the guidance in Amazon EBS–optimized instances (p. 1998) to match the IOPS you have provisioned for your volumes to the bandwidth available from your instances for maximum performance. For RAID configurations, many administrators find that arrays larger than 8 volumes have diminished performance returns due to increased I/O overhead. Test your individual application performance and tune it as required.

Amazon EC2 instance root device volume

When you launch an instance, the root device volume contains the image used to boot the instance. When we introduced Amazon EC2, all AMIs were backed by Amazon EC2 instance store, which means the root device for an instance launched from the AMI is an instance store volume created from a template stored in Amazon S3. After we introduced Amazon EBS, we introduced AMIs that are backed by Amazon EBS. This means that the root device for an instance launched from the AMI is an Amazon EBS volume created from an Amazon EBS snapshot.
You can choose between AMIs backed by Amazon EC2 instance store and AMIs backed by Amazon EBS. We recommend that you use AMIs backed by Amazon EBS, because they launch faster and use persistent storage.

Important

- Only the following instance types support an instance store volume as the root device: C3, D2, G2, I2, M3, and R3.
- st1 and sc1 volumes can't be used as root volumes.

For more information about the device names Amazon EC2 uses for your root volumes, see Device names on Linux instances (p. 2099).

Contents

- Root device storage concepts (p. 2093)
- Choose an AMI by root device type (p. 2094)
- Determine the root device type of your instance (p. 2095)
- Change the root volume to persist (p. 2096)
- Change the initial size of the root volume (p. 2098)

Root device storage concepts

You can launch an instance from either an instance store-backed AMI or an Amazon EBS-backed AMI. The description of an AMI includes which type of AMI it is; you'll see the root device referred to in some places as either ebs (for Amazon EBS-backed) or instance store (for instance store-backed). This is important because there are significant differences between what you can do with each type of AMI. For more information about these differences, see Storage for the root device (p. 111).

Instance store-backed instances

Instances that use instance stores for the root device automatically have one or more instance store volumes available, with one volume serving as the root device volume. When an instance is launched, the image that is used to boot the instance is copied to the root volume. Note that you can optionally use additional instance store volumes, depending on the instance type.

Any data on the instance store volumes persists as long as the instance is running, but this data is deleted when the instance is terminated (instance store-backed instances do not support the Stop action) or if it fails (such as if an underlying drive has issues).
After an instance store-backed instance fails or terminates, it cannot be restored. If you plan to use Amazon EC2 instance store-backed instances, we highly recommend that you distribute the data on your instance stores across multiple Availability Zones. You should also back up critical data from your instance store volumes to persistent storage on a regular basis.

For more information, see Amazon EC2 instance store (p. 2060).

**Amazon EBS-backed instances**

Instances that use Amazon EBS for the root device automatically have an Amazon EBS volume attached. When you launch an Amazon EBS-backed instance, we create an Amazon EBS volume for each Amazon EBS snapshot referenced by the AMI you use. You can optionally use other Amazon EBS volumes or instance store volumes, depending on the instance type.

An Amazon EBS-backed instance can be stopped and later restarted without affecting data stored in the attached volumes. There are various instance- and volume-related tasks you can do when an Amazon EBS-backed instance is in a stopped state. For example, you can modify the properties of the instance, change its size, or update the kernel it is using, or you can attach your root volume to a different running instance for debugging or any other purpose.

If an Amazon EBS-backed instance fails, you can restore your session by following one of these methods:

- Stop and then start again (try this method first).
- Automatically snapshot all relevant volumes and create a new AMI. For more information, see Create an Amazon EBS-backed Linux AMI (p. 164).
- Attach the volume to the new instance by following these steps:
  1. Create a snapshot of the root volume.
  2. Register a new AMI using the snapshot.
  3. Launch a new instance from the new AMI.
  4. Detach the remaining Amazon EBS volumes from the old instance.
  5. Reattach the Amazon EBS volumes to the new instance.

For more information, see Amazon EBS volumes (p. 1772).

**Choose an AMI by root device type**

The AMI that you specify when you launch your instance determines the type of root device volume that your instance has. You can view AMIs by root device type using one of the following methods.
To choose an Amazon EBS-backed AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose AMIs.
3. From the filter lists, select the image type (such as Public images). In the search bar choose Platform to select the operating system (such as Amazon Linux), and Root Device Type to select EBS images.
4. (Optional) To get additional information to help you make your choice, choose the Show/Hide Columns icon, update the columns to display, and choose Close.
5. Choose an AMI and write down its AMI ID.

To choose an instance store-backed AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose AMIs.
3. From the filter lists, select the image type (such as Public images). In the search bar, choose Platform to select the operating system (such as Amazon Linux), and Root Device Type to select Instance store.
4. (Optional) To get additional information to help you make your choice, choose the Show/Hide Columns icon, update the columns to display, and choose Close.
5. Choose an AMI and write down its AMI ID.

AWS CLI

To verify the type of the root device volume of an AMI using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- `describe-images` (AWS CLI)
- `Get-EC2Image` (AWS Tools for Windows PowerShell)

Determine the root device type of your instance

Console

To determine the root device type of an instance using the console

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose Instances, and select the instance.
3. On the Storage tab, under Root device details, check the value of Root device type as follows:
   - If the value is EBS, this is an Amazon EBS-backed instance.
   - If the value is INSTANCE-STORE, this is an instance store-backed instance.

AWS CLI

To determine the root device type of an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).
Change the root volume to persist

By default, the root volume for an AMI backed by Amazon EBS is deleted when the instance terminates. You can change the default behavior to ensure that the volume persists after the instance terminates. To change the default behavior, set the `DeleteOnTermination` attribute to `false` using a block device mapping.

**Tasks**
- Configure the root volume to persist during instance launch (p. 2096)
- Configure the root volume to persist for an existing instance (p. 2097)
- Confirm that a root volume is configured to persist (p. 2098)

**Configure the root volume to persist during instance launch**

You can configure the root volume to persist when you launch an instance using the Amazon EC2 console or the command line tools.

**Console**

To configure the root volume to persist when you launch an instance using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances** and then choose **Launch instances**.
3. On the **Choose an Amazon Machine Image (AMI)** page, select the AMI to use and choose **Select**.
4. Follow the wizard to complete the **Choose an Instance Type** and **Configure Instance Details** pages.
5. On the **Add Storage** page, deselect **Delete On Termination** for the root volume.
6. Complete the remaining wizard pages, and then choose **Launch**.

**AWS CLI**

To configure the root volume to persist when you launch an instance using the AWS CLI

Use the `run-instances` command and include a block device mapping that sets the `DeleteOnTermination` attribute to `false`.

```bash
$ aws ec2 run-instances --block-device-mappings file://mapping.json ...other parameters...
```

Specify the following in `mapping.json`.

```json
[
  {
    "DeviceName": "/dev/sda1",
    "Ebs": {
      "DeleteOnTermination": false
    }
  }
]
```
Tools for Windows PowerShell

To configure the root volume to persist when you launch an instance using the Tools for Windows PowerShell

Use the `New-EC2Instance` command and include a block device mapping that sets the `DeleteOnTermination` attribute to `false`.

```powershell
C:\> $ebs = New-Object Amazon.EC2.Model.EbsBlockDevice
C:\> $ebs.DeleteOnTermination = $false
C:\> $bdm = New-Object Amazon.EC2.Model.BlockDeviceMapping
C:\> $bdm.DeviceName = "dev/xvda"
C:\> $bdm.Ebs = $ebs
C:\> New-EC2Instance -ImageId ami-0abcdef1234567890 -BlockDeviceMapping $bdm ...other parameters...
```

Configure the root volume to persist for an existing instance

You can configure the root volume to persist for a running instance using the command line tools only.

AWS CLI

To configure the root volume to persist for an existing instance using the AWS CLI

Use the `modify-instance-attribute` command with a block device mapping that sets the `DeleteOnTermination` attribute to `false`.

```bash
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --block-device-mappings file://mapping.json
```

Specify the following in `mapping.json`.

```json
[
  {
    "DeviceName": "/dev/xvda",
    "Ebs": {
      "DeleteOnTermination": false
    }
  }
]
```

Tools for Windows PowerShell

To configure the root volume to persist for an existing instance using the AWS Tools for Windows PowerShell

Use the `Edit-EC2InstanceAttribute` command with a block device mapping that sets the `DeleteOnTermination` attribute to `false`.

```powershell
C:\> $ebs = New-Object Amazon.EC2.Model.EbsInstanceBlockDeviceSpecification
C:\> $ebs.DeleteOnTermination = $false
C:\> $bdm = New-Object Amazon.EC2.Model.InstanceBlockDeviceMappingSpecification
C:\> $bdm.DeviceName = "/dev/xvda"
C:\> $bdm.Ebs = $ebs
C:\> Edit-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -BlockDeviceMapping $bdm ...
```
Confirm that a root volume is configured to persist

You can confirm that a root volume is configured to persist using the Amazon EC2 console or the command line tools.

**Console**

**To confirm that a root volume is configured to persist using the Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances** and then select the instance.
3. In the **Storage** tab, under **Block devices**, locate the entry for the root volume. If **Delete on termination** is **No**, the volume is configured to persist.

**AWS CLI**

**To confirm that a root volume is configured to persist using the AWS CLI**

Use the `describe-instances` command and verify that the `DeleteOnTermination` attribute in the `BlockDeviceMappings` response element is set to `false`.

```
$ aws ec2 describe-instances --instance-id i-1234567890abcdef0
```

```
...
  "BlockDeviceMappings": [
    {
      "DeviceName": "/dev/sda1",
      "Ebs": {
        "Status": "attached",
        "DeleteOnTermination": false,
        "VolumeId": "vol-1234567890abcdef0",
        "AttachTime": "2013-07-19T02:42:39.000Z"
      }
    }
  ...
```

**Tools for Windows PowerShell**

**To confirm that a root volume is configured to persist using the AWS Tools for Windows PowerShell**

Use the `Get-EC2Instance` and verify that the `DeleteOnTermination` attribute in the `BlockDeviceMappings` response element is set to `false`.

```
C:\> (Get-EC2Instance -InstanceId i-i-1234567890abcdef0).Instances.BlockDeviceMappings.Ebs
```

Change the initial size of the root volume

By default, the size of the root volume is determined by the size of the snapshot. You can increase the initial size of the root volume using the block device mapping of the instance as follows.

1. Determine the device name of the root volume specified in the AMI, as described in [View the EBS volumes in an AMI block device mapping](p. 2105).
2. Confirm the size of the snapshot specified in the AMI block device mapping, as described in View Amazon EBS snapshot information (p. 1863).

3. Override the size of the root volume using the instance block device mapping, as described in Update the block device mapping when launching an instance (p. 2106), specifying a volume size that is larger than the snapshot size.

For example, the following entry for the instance block device mapping increases the size of the root volume, /dev/xvda, to 100 GiB. You can omit the snapshot ID in the instance block device mapping because the snapshot ID is already specified in the AMI block device mapping.

```
{
  "DeviceName": "/dev/xvda",
  "Ebs": {
    "VolumeSize": 100
  }
}
```

For more information, see Block device mappings (p. 2101).

Device names on Linux instances

When you attach a volume to your instance, you include a device name for the volume. This device name is used by Amazon EC2. The block device driver for the instance assigns the actual volume name when mounting the volume, and the name assigned can be different from the name that Amazon EC2 uses.

The number of volumes that your instance can support is determined by the operating system. For more information, see Instance volume limits (p. 2091).

Contents
- Available device names (p. 2099)
- Device name considerations (p. 2100)

For information about device names on Windows instances, see Device naming on Windows instances in the Amazon EC2 User Guide for Windows Instances.

Available device names

There are two types of virtualization available for Linux instances: paravirtual (PV) and hardware virtual machine (HVM). The virtualization type of an instance is determined by the AMI used to launch the instance. All instance types support HVM AMIs. Some previous generation instance types support PV AMIs. Be sure to note the virtualization type of your AMI because the recommended and available device names that you can use depend on the virtualization type of your instance. For more information, see Linux AMI virtualization types (p. 113).

The following table lists the available device names that you can specify in a block device mapping or when attaching an EBS volume.

<table>
<thead>
<tr>
<th>Virtualization type</th>
<th>Available</th>
<th>Reserved for root volume</th>
<th>Recommended for EBS volumes</th>
<th>Instance store volumes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Paravirtual</td>
<td>/dev/sd[a-z]</td>
<td>/dev/sda1</td>
<td>/dev/sdf-p</td>
<td>/dev/sd[b-e]</td>
</tr>
<tr>
<td></td>
<td>/dev/sd[a-z][1-15]</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Device name considerations

Keep the following in mind when selecting a device name:

- Although you can attach your EBS volumes using the device names used to attach instance store volumes, we strongly recommend that you don’t because the behavior can be unpredictable.

- The number of NVMe instance store volumes for an instance depends on the size of the instance. NVMe instance store volumes are automatically enumerated and assigned an NVMe device name (/dev/nvme[0-26]n1).

- Depending on the block device driver of the kernel, the device could be attached with a different name than you specified. For example, if you specify a device name of /dev/sdh, your device could be renamed /dev/xvdh or /dev/hdh. In most cases, the trailing letter remains the same. In some versions of Red Hat Enterprise Linux (and its variants, such as CentOS), the trailing letter could change (/dev/sda could become /dev/xvde). In these cases, the trailing letter of each device name is incremented the same number of times. For example, if /dev/sdb is renamed /dev/xvdf, then /dev/sdc is renamed /dev/xvdf. Amazon Linux creates a symbolic link for the name you specified to the renamed device. Other operating systems could behave differently.

- HVM AMIs do not support the use of trailing numbers on device names, except for /dev/sda1, which is reserved for the root device, and /dev/sda2. While using /dev/sda2 is possible, we do not recommend using this device mapping with HVM instances.

- When using PV AMIs, you cannot attach volumes that share the same device letters both with and without trailing digits. For example, if you attach a volume as /dev/sdc and another volume as /dev/sdc1, only /dev/sdc is visible to the instance. To use trailing digits in device names, you must use trailing digits on all device names that share the same base letters (such as /dev/sdc1, /dev/sdc2, /dev/sdc3).
Some custom kernels might have restrictions that limit use to /dev/sd[f-p] or /dev/sd[f-p][1-6]. If you're having trouble using /dev/sd[q-z] or /dev/sd[q-z][1-6], try switching to /dev/sd[f-p] or /dev/sd[f-p][1-6].

Block device mappings

Each instance that you launch has an associated root device volume, which is either an Amazon EBS volume or an instance store volume. You can use block device mapping to specify additional EBS volumes or instance store volumes to attach to an instance when it's launched. You can also attach additional EBS volumes to a running instance; see Attach an Amazon EBS volume to an instance (p. 1797). However, the only way to attach instance store volumes to an instance is to use block device mapping to attach the volumes as the instance is launched.

For more information about root device volumes, see Change the root volume to persist (p. 2096).

Contents

- Block device mapping concepts (p. 2101)
- AMI block device mapping (p. 2104)
- Instance block device mapping (p. 2106)

Block device mapping concepts

A block device is a storage device that moves data in sequences of bytes or bits (blocks). These devices support random access and generally use buffered I/O. Examples include hard disks, CD-ROM drives, and flash drives. A block device can be physically attached to a computer or accessed remotely as if it were physically attached to the computer.

Amazon EC2 supports two types of block devices:

- Instance store volumes (virtual devices whose underlying hardware is physically attached to the host computer for the instance)
- EBS volumes (remote storage devices)

A block device mapping defines the block devices (instance store volumes and EBS volumes) to attach to an instance. You can specify a block device mapping as part of creating an AMI so that the mapping is used by all instances launched from the AMI. Alternatively, you can specify a block device mapping when you launch an instance, so this mapping overrides the one specified in the AMI from which you launched the instance. Note that all NVMe instance store volumes supported by an instance type are automatically enumerated and assigned a device name on instance launch; including them in your block device mapping has no effect.

Contents

- Block device mapping entries (p. 2101)
- Block device mapping instance store caveats (p. 2102)
- Example block device mapping (p. 2103)
- How devices are made available in the operating system (p. 2103)

Block device mapping entries

When you create a block device mapping, you specify the following information for each block device that you need to attach to the instance:
• The device name used within Amazon EC2. The block device driver for the instance assigns the actual volume name when mounting the volume. The name assigned can be different from the name that Amazon EC2 recommends. For more information, see Device names on Linux instances (p. 2099).

For Instance store volumes, you also specify the following information:

• The virtual device: ephemeral[0-23]. Note that the number and size of available instance store volumes for your instance varies by instance type.

For NVMe instance store volumes, the following information also applies:

• These volumes are automatically enumerated and assigned a device name; including them in your block device mapping has no effect.

For EBS volumes, you also specify the following information:

• The ID of the snapshot to use to create the block device (snap-xxxxxxxx). This value is optional as long as you specify a volume size.
• The size of the volume, in GiB. The specified size must be greater than or equal to the size of the specified snapshot.
• Whether to delete the volume on instance termination (true or false). The default value is true for the root device volume and false for attached volumes. When you create an AMI, its block device mapping inherits this setting from the instance. When you launch an instance, it inherits this setting from the AMI.
• The volume type, which can be gp2 and gp3 for General Purpose SSD, io1 and io2 for Provisioned IOPS SSD, st1 for Throughput Optimized HDD, sc1 for Cold HDD, or standard for Magnetic. The default value is gp2.
• The number of input/output operations per second (IOPS) that the volume supports. (Used only with io1 and io2 volumes.)

Block device mapping instance store caveats

There are several caveats to consider when launching instances with AMIs that have instance store volumes in their block device mappings.

• Some instance types include more instance store volumes than others, and some instance types contain no instance store volumes at all. If your instance type supports one instance store volume, and your AMI has mappings for two instance store volumes, then the instance launches with one instance store volume.
• Instance store volumes can only be mapped at launch time. You cannot stop an instance without instance store volumes (such as the t2.micro), change the instance to a type that supports instance store volumes, and then restart the instance with instance store volumes. However, you can create an AMI from the instance and launch it on an instance type that supports instance store volumes, and map those instance store volumes to the instance.
• If you launch an instance with instance store volumes mapped, and then stop the instance and change it to an instance type with fewer instance store volumes and restart it, the instance store volume mappings from the initial launch still show up in the instance metadata. However, only the maximum number of supported instance store volumes for that instance type are available to the instance.

Note
When an instance is stopped, all data on the instance store volumes is lost.

• Depending on instance store capacity at launch time, M3 instances may ignore AMI instance store block device mappings at launch unless they are specified at launch. You should specify instance
store block device mappings at launch time, even if the AMI you are launching has the instance store volumes mapped in the AMI, to ensure that the instance store volumes are available when the instance launches.

**Example block device mapping**

This figure shows an example block device mapping for an EBS-backed instance. It maps /dev/sdb to ephemeral0 and maps two EBS volumes, one to /dev/sdh and the other to /dev/sdj. It also shows the EBS volume that is the root device volume, /dev/sda1.

![Block device mapping diagram](image)

Note that this example block device mapping is used in the example commands and APIs in this topic. You can find example commands and APIs that create block device mappings in [Specify a block device mapping for an AMI](p. 2104) and [Update the block device mapping when launching an instance](p. 2106).

**How devices are made available in the operating system**

Device names like /dev/sdh and xvdh are used by Amazon EC2 to describe block devices. The block device mapping is used by Amazon EC2 to specify the block devices to attach to an EC2 instance. After a block device is attached to an instance, it must be mounted by the operating system before you can access the storage device. When a block device is detached from an instance, it is unmounted by the operating system and you can no longer access the storage device.

With a Linux instance, the device names specified in the block device mapping are mapped to their corresponding block devices when the instance first boots. The instance type determines which instance store volumes are formatted and mounted by default. You can mount additional instance store volumes at launch, as long as you don’t exceed the number of instance store volumes available for your instance type. For more information, see [Amazon EC2 instance store](p. 2060). The block device driver for the
instance determines which devices are used when the volumes are formatted and mounted. For more information, see [Attach an Amazon EBS volume to an instance](p. 1797).

## AMI block device mapping

Each AMI has a block device mapping that specifies the block devices to attach to an instance when it is launched from the AMI. An AMI that Amazon provides includes a root device only. To add more block devices to an AMI, you must create your own AMI.

### Specify a block device mapping for an AMI

There are two ways to specify volumes in addition to the root volume when you create an AMI. If you've already attached volumes to a running instance before you create an AMI from the instance, the block device mapping for the AMI includes those same volumes. For EBS volumes, the existing data is saved to a new snapshot, and it's this new snapshot that's specified in the block device mapping. For instance store volumes, the data is not preserved.

For an EBS-backed AMI, you can add EBS volumes and instance store volumes using a block device mapping. For an instance store-backed AMI, you can add instance store volumes only by modifying the block device mapping entries in the image manifest file when registering the image.

**Note**

For M3 instances, you must specify instance store volumes in the block device mapping for the instance when you launch it. When you launch an M3 instance, instance store volumes specified in the block device mapping for the AMI may be ignored if they are not specified as part of the instance block device mapping.

### To add volumes to an AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **Instances**.
3. Select an instance and choose **Actions, Image and templates, Create image**.
4. Enter a name and a description for the image.
5. The instance volumes appear under **Instance volumes**. To add another volume, choose **Add volume**.
6. For **Volume type**, choose the volume type. For **Device** choose the device name. For an EBS volume, you can specify additional details, such as a snapshot, volume size, volume type, IOPS, and encryption state.
7. Choose **Create image**.

### To add volumes to an AMI using the command line

Use the `create-image` AWS CLI command to specify a block device mapping for an EBS-backed AMI. Use the `register-image` AWS CLI command to specify a block device mapping for an instance store-backed AMI.

Specify the block device mapping using the `--block-device-mappings` parameter. Arguments encoded in JSON can be supplied either directly on the command line or by reference to a file:

```
--block-device-mappings [mapping, ...]
```
--block-device-mappings [file://mapping.json]

To add an instance store volume, use the following mapping.

```json
{
    "DeviceName": "/dev/sdf",
    "VirtualName": "ephemeral0"
}
```

To add an empty 100 GiB gp2 volume, use the following mapping.

```json
{
    "DeviceName": "/dev/sdg",
    "Ebs": {
        "VolumeSize": 100
    }
}
```

To add an EBS volume based on a snapshot, use the following mapping.

```json
{
    "DeviceName": "/dev/sdh",
    "Ebs": {
        "SnapshotId": "snap-xxxxxxxx"
    }
}
```

To omit a mapping for a device, use the following mapping.

```json
{
    "DeviceName": "/dev/sdj",
    "NoDevice": ""
}
```

Alternatively, you can use the -BlockDeviceMapping parameter with the following commands (AWS Tools for Windows PowerShell):

- `New-EC2Image`
- `Register-EC2Image`

**View the EBS volumes in an AMI block device mapping**

You can easily enumerate the EBS volumes in the block device mapping for an AMI.

**To view the EBS volumes for an AMI using the console**

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **AMIs**.
3. Choose **EBS images** from the **Filter** list to get a list of EBS-backed AMIs.
4. Select the desired AMI, and look at the **Details** tab. At a minimum, the following information is available for the root device:
   - **Root Device Type** (ebs)
   - **Root Device Name** (for example, /dev/sda1)
   - **Block Devices** (for example, /dev/sda1=snap-1234567890abcdef0:8:true)
If the AMI was created with additional EBS volumes using a block device mapping, the **Block Devices** field displays the mapping for those additional volumes as well. (This screen doesn't display instance store volumes.)

**To view the EBS volumes for an AMI using the command line**

Use the `describe-images` (AWS CLI) command or `Get-EC2Image` (AWS Tools for Windows PowerShell) command to enumerate the EBS volumes in the block device mapping for an AMI.

**Instance block device mapping**

By default, an instance that you launch includes any storage devices specified in the block device mapping of the AMI from which you launched the instance. You can specify changes to the block device mapping for an instance when you launch it, and these updates overwrite or merge with the block device mapping of the AMI.

**Limitations**

- For the root volume, you can only modify the following: volume size, volume type, and the **Delete on Termination** flag.
- When you modify an EBS volume, you can't decrease its size. Therefore, you must specify a snapshot whose size is equal to or greater than the size of the snapshot specified in the block device mapping of the AMI.

**Contents**

- Update the block device mapping when launching an instance (p. 2106)
- Update the block device mapping of a running instance (p. 2108)
- View the EBS volumes in an instance block device mapping (p. 2108)
- View the instance block device mapping for instance store volumes (p. 2109)

**Update the block device mapping when launching an instance**

You can add EBS volumes and instance store volumes to an instance when you launch it. Note that updating the block device mapping for an instance doesn't make a permanent change to the block device mapping of the AMI from which it was launched.

**To add volumes to an instance using the console**

1. Open the Amazon EC2 console.
2. From the dashboard, choose **Launch Instance**.
3. On the **Choose an Amazon Machine Image (AMI)** page, select the AMI to use and choose **Select**.
4. Follow the wizard to complete the **Choose an Instance Type** and **Configure Instance Details** pages.
5. On the **Add Storage** page, you can modify the root volume, EBS volumes, and instance store volumes as follows:
   - To change the size of the root volume, locate the **Root** volume under the **Type** column, and change its **Size** field.
   - To suppress an EBS volume specified by the block device mapping of the AMI used to launch the instance, locate the volume and click its **Delete** icon.
   - To add an EBS volume, choose **Add New Volume**, choose **EBS** from the **Type** list, and fill in the fields (**Device**, **Snapshot**, and so on).
To suppress an instance store volume specified by the block device mapping of the AMI used to launch the instance, locate the volume, and choose its Delete icon.

To add an instance store volume, choose Add New Volume, select Instance Store from the Type list, and select a device name from Device.

6. Complete the remaining wizard pages, and choose Launch.

To add volumes to an instance using the AWS CLI

Use the run-instances AWS CLI command with the --block-device-mappings option to specify a block device mapping for an instance at launch.

For example, suppose that an EBS-backed AMI specifies the following block device mapping:

- /dev/sdb=ephemeral0
- /dev/sdh=snap-1234567890abcdef0
- /dev/sdj=:100

To prevent /dev/sdj from attaching to an instance launched from this AMI, use the following mapping.

```
{
  "DeviceName": "/dev/sdj",
  "NoDevice": ""
}
```

To increase the size of /dev/sdh to 300 GiB, specify the following mapping. Notice that you don’t need to specify the snapshot ID for /dev/sdh, because specifying the device name is enough to identify the volume.

```
{
  "DeviceName": "/dev/sdh",
  "Ebs": {
    "VolumeSize": 300
  }
}
```

To increase the size of the root volume at instance launch, first call describe-images with the ID of the AMI to verify the device name of the root volume. For example, "RootDeviceName": "/dev/xvda".

To override the size of the root volume, specify the device name of the root device used by the AMI and the new volume size.

```
{
  "DeviceName": "/dev/xvda",
  "Ebs": {
    "VolumeSize": 100
  }
}
```

To attach an additional instance store volume, /dev/sdc, specify the following mapping. If the instance type doesn’t support multiple instance store volumes, this mapping has no effect. If the instance supports NVMe instance store volumes, they are automatically enumerated and assigned an NVMe device name.

```
{
  "DeviceName": "/dev/sdc",
  "VirtualName": "ephemeral1"
}
```
To add volumes to an instance using the AWS Tools for Windows PowerShell

Use the -BlockDeviceMapping parameter with the New-EC2Instance command (AWS Tools for Windows PowerShell).

Update the block device mapping of a running instance

You can use the modify-instance-attribute AWS CLI command to update the block device mapping of a running instance. You do not need to stop the instance before changing this attribute.

```bash
aws ec2 modify-instance-attribute --instance-id i-1a2b3c4d --block-device-mappings file://mapping.json
```

For example, to preserve the root volume at instance termination, specify the following in mapping.json.

```json
[
  {
    "DeviceName": "/dev/sda1",
    "Ebs": {
      "DeleteOnTermination": false
    }
  }
]
```

Alternatively, you can use the -BlockDeviceMapping parameter with the Edit-EC2InstanceAttribute command (AWS Tools for Windows PowerShell).

View the EBS volumes in an instance block device mapping

You can easily enumerate the EBS volumes mapped to an instance.

**Note**

For instances launched before the release of the 2009-10-31 API, AWS can't display the block device mapping. You must detach and reattach the volumes so that AWS can display the block device mapping.

To view the EBS volumes for an instance using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose Instances.
3. In the search box, enter Root device type, and then choose EBS. This displays a list of EBS-backed instances.
4. Select the desired instance and look at the details displayed in the Storage tab. At a minimum, the following information is available for the root device:
   - Root device type (for example, EBS)
   - Root device name (for example, /dev/xvda)
   - Block devices (for example, /dev/xvda, /dev/sdf, and /dev/sdj)

If the instance was launched with additional EBS volumes using a block device mapping, they appear under Block devices. Any instance store volumes do not appear on this tab.

5. To display additional information about an EBS volume, choose its volume ID to go to the volume page. For more information, see View information about an Amazon EBS volume (p. 1807).
To view the EBS volumes for an instance using the command line

Use the `describe-instances` (AWS CLI) command or `Get-EC2Instance` (AWS Tools for Windows PowerShell) command to enumerate the EBS volumes in the block device mapping for an instance.

**View the instance block device mapping for instance store volumes**

When you view the block device mapping for your instance, you can see only the EBS volumes, not the instance store volumes. The method you use to view the instance store volumes for your instance depends on the volume type.

**NVMe instance store volumes**

You can use the NVMe command line package, `nvme-cli`, to query the NVMe instance store volumes in the block device mapping. Download and install the package on your instance, and then run the following command.

```
[ec2-user ~]$ sudo nvme list
```

The following is example output for an instance. The text in the Model column indicates whether the volume is an EBS volume or an instance store volume. In this example, both `/dev/nvme1n1` and `/dev/nvme2n1` are instance store volumes.

<table>
<thead>
<tr>
<th>Node</th>
<th>SN</th>
<th>Model</th>
<th>Namespace</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/dev/nvme0n1</code></td>
<td><code>vol06afc3f8715b7a597</code></td>
<td>Amazon Elastic Block Store</td>
<td>1</td>
</tr>
<tr>
<td><code>/dev/nvme1n1</code></td>
<td><code>AWS2C1436FS159EB6614</code></td>
<td>Amazon EC2 NVMe Instance Storage</td>
<td>1</td>
</tr>
<tr>
<td><code>/dev/nvme2n1</code></td>
<td><code>AWSB1F4FF00A6C281EA</code></td>
<td>Amazon EC2 NVMe Instance Storage</td>
<td>1</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**HDD or SSD instance store volumes**

You can use instance metadata to query the HDD or SSD instance store volumes in the block device mapping. NVMe instance store volumes are not included.

The base URI for all requests for instance metadata is `http://169.254.169.254/latest/`. For more information, see [Instance metadata and user data](p. 929).

First, connect to your running instance. From the instance, use this query to get its block device mapping.

**IMDSv2**

```
[ec2-user ~]$
```

```
```

**IMDSv1**

```
[ec2-user ~]$
```

```
```

The response includes the names of the block devices for the instance. For example, the output for an instance store–backed `m1.small` instance looks like this.

```
ami
```
Amazon Elastic Compute Cloud
User Guide for Linux Instances

| root        
| swap        

The ami device is the root device as seen by the instance. The instance store volumes are named ephemeral0–23. The swap device is for the page file. If you've also mapped EBS volumes, they appear as ebs1, ebs2, and so on.

To get details about an individual block device in the block device mapping, append its name to the previous query, as shown here.

IMDSv2

```
```

IMDSv1

```
```

The instance type determines the number of instance store volumes that are available to the instance. If the number of instance store volumes in a block device mapping exceeds the number of instance store volumes available to an instance, the additional volumes are ignored. To view the instance store volumes for your instance, run the `lsblk` command. To learn how many instance store volumes are supported by each instance type, see Instance store volumes (p. 2062).

## Torn write prevention

Torn write prevention is a block storage feature designed by AWS to improve the performance of your I/O-intensive relational database workloads and reduce latency without negatively impacting data resiliency. Relational databases that use InnoDB or XtraDB as the database engine, such as MySQL and MariaDB, will benefit from torn write prevention.

Typically, relational databases that use pages larger than the power fail atomicity of the storage device use data logging mechanisms to protect against torn writes. MariaDB and MySQL use a doublewrite buffer file to log data before writing it to data tables. In the event of incomplete or torn writes, as a result of operating system crashes or power loss during write transactions, the database can recover the data from the doublewrite buffer. The additional I/O overhead associated with writing to the doublewrite buffer impacts database performance and application latency, and it reduces the number transactions that can be processed per second. For more information about doublewrite buffer, see the MariaDB and MySQL documentation.

With torn write prevention, data is written to storage in all-or-nothing write transactions, which eliminates the need for using the doublewrite buffer. This prevents partial, or torn, data from being written to storage in the event of operating system crashes or power loss during write transactions. The number of transactions processed per second can be increased by up to 30 percent, and write latency can be decreased by up to 50 percent, without compromising the resiliency of your workloads.

### Pricing

There are no additional costs for using torn write prevention.
Supported block sizes and block boundary alignments

Torn write prevention supports write operations for 4 KiB, 8 KiB, and 16 KiB blocks of data. The data block start logical block address (LBA) must be aligned to the respective block boundary size of 4 KiB, 8 KiB, or 16 KiB. For example, for 16 KiB write operations, the data block start LBA must be aligned to a block boundary size of 16 KiB.

The following table shows support across storage and instance types.

<table>
<thead>
<tr>
<th></th>
<th>4 KiB blocks</th>
<th>8 KiB blocks</th>
<th>16 KiB blocks</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Instance store volumes</strong></td>
<td>All NVMe instance store volumes attached to <strong>current generation I-family instances (p. 275)</strong>.</td>
<td>I4i, Im4gn, and Is4gen instances supported by AWS Nitro SSD.</td>
<td></td>
</tr>
<tr>
<td><strong>Amazon EBS volumes</strong></td>
<td>All Amazon EBS volumes attached to <strong>nitro-based instances (p. 282)</strong>.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

To confirm whether your instance and volume support torn write prevention, query to check if the instance supports torn write prevention and other details, like supported block and boundary sizes. For more information, see **Check torn write prevention support and configuration (p. 2111)**.

Requirements

For torn write prevention to work properly, an I/O operation must meet size, alignment, and boundary requirements, as specified in the NTWPU, NTWGU, NTWBU fields. You must configure your operating system to ensure that the specific storage subsystem (file system, LVM, RAID, etc) does not modify I/O properties down the storage stack, including block merges, splits, or block address relocation, before being submitted to the device.

Torn write prevent has been tested with the following configuration:

- An instance type and storage type that supports the required block size.
- Amazon Linux 2 with kernel version 5.10 or later.
- ext4 with bigalloc enabled and a cluster size of 16 KiB, and the most recent ext4 utilities (e2fsprogs 1.46.5 or later).
- O_DIRECT file access mode to bypass Linux kernel buffer cache.

**Note**

You do not need to disable I/O merging for MySQL and MariaDB workloads.

Check torn write prevention support and configuration

To confirm whether your instance and volume supports torn write prevention, and to view the NVMe namespace vendor specific data that contains torn write prevention information, use the following command.

$ sudo nvme id-ns -v device_name
Configure your software stack for torn write prevention

Torn write prevention is enabled by default on supported instance types with supported volumes (p. 2111). You do not need to enabled any additional settings to enable your volume or instance for torn write prevention.
Configure your software stack for torn write prevention

Note
There is no performance impact on workloads that do not support torn write prevention. You do not need to make any changes for these workloads. Workloads that do support torn write prevention, but are not configured to use it, continue to use the doublewrite buffer and do not receive any performance benefits.

To configure your MySQL or MariaDB software stack to disable the doublewrite buffer and use torn write prevention, complete the following steps:

1. Configure your volume to use ext4 file system with the BigAlloc option and set the cluster size to 4 KiB, 8 KiB, or 16 KiB. Using BigAlloc with a cluster size of 4 KiB, 8 KiB, or 16 KiB ensures that the file system allocates files that align with the respective boundary.

   $ mkfs.ext4 -O bigalloc -C 4096|8192|16384 device_name

   Note
   For MySQL and MariaDB, you must use -C 16384 to match the database page size. Setting allocation granularity to a value other than a multiple of the page size can result in allocations that might be mismatched with torn write prevention boundaries of the storage device.

   For example:

   $ mkfs.ext4 -O bigalloc -C 16384 /dev/nvme1n1

2. Configure InnoDB to use the 0_DIRECT flushing method and turn off InnoDB doublewrite. Use your preferred text editor to open /etc/my.cnf, and update the innodb_flush_method and innodb_doublewrite parameters as follows:

   innodb_flush_method=0_DIRECT
   innodb_doublewrite=0

   Important
   If you are using Logical Volume Manager (LVM) or other storage virtualization layer, make sure that the starting offsets of the volumes are aligned on 16 KiB multiples. This is relative to the underlying NVMe storage to account for the metadata headers and superblocks used by the storage virtualization layer. If you add an offset to the LVM physical volume, it can cause misalignment between the file system allocations and the NVMe device's offsets, which would invalidate torn write prevention. For more information, see --dataalignmentoffset in the Linux manual page.
Resources and tags

Amazon EC2 provides different resources that you can create and use. Some of these resources include images, instances, volumes, and snapshots. When you create a resource, we assign the resource a unique resource ID.

Some resources can be tagged with values that you define, to help you organize and identify them.

The following topics describe resources and tags, and how you can work with them.

Contents

- Recycle Bin (p. 2114)
- Resource locations (p. 2144)
- Resource IDs (p. 2145)
- List and filter your resources (p. 2146)
- Tag your Amazon EC2 resources (p. 2154)
- Amazon EC2 service quotas (p. 2169)
- Amazon EC2 usage reports (p. 2171)

Recycle Bin

Recycle Bin is a data recovery feature that enables you to restore accidentally deleted Amazon EBS snapshots and EBS-backed AMIs. When using Recycle Bin, if your resources are deleted, they are retained in the Recycle Bin for a time period that you specify before being permanently deleted.

You can restore a resource from the Recycle Bin at any time before its retention period expires. After you restore a resource from the Recycle Bin, the resource is removed from the Recycle Bin and you can use it in the same way that you use any other resource of that type in your account. If the retention period expires and the resource is not restored, the resource is permanently deleted from the Recycle Bin and it is no longer available for recovery.

Using Recycle Bin helps to ensure business continuity by protecting your business-critical data against accidental deletion.

Topics

- How does it work? (p. 2114)
- Supported resources (p. 2115)
- Considerations (p. 2115)
- Quotas (p. 2117)
- Related services (p. 2118)
- Pricing (p. 2118)
- Required IAM permissions (p. 2118)
- Work with retention rules (p. 2122)
- Work with resources in the Recycle Bin (p. 2131)
- Monitor Recycle Bin (p. 2132)

How does it work?

To enable and use Recycle Bin, you must create retention rules in the AWS Regions in which you want to protect your resources. Retention rules specify the following:
• The resource type that you want to protect.
• The resources that you want to retain in the Recycle Bin when they are deleted.
• The retention period for which to retain resources in the Recycle Bin before they are permanently deleted.

With Recycle Bin, you can create two types of retention rules:

• **Tag-level retention rules** — A tag-level retention rule uses resource tags to identify the resources that are to be retained in the Recycle Bin. For each retention rule, you specify one or more tag key and value pairs. Resources of the specified type that are tagged with at least one of the tag key and value pairs that are specified in the retention rule are automatically retained in the Recycle Bin upon deletion. Use this type of retention rule if you want to protect specific resources in your account based on their tags.

• **Region-level retention rules** — A Region-level retention rule does not have any resource tags specified. It applies to all of the resources of the specified type in the Region in which the rule is created, even if the resources are not tagged. Use this type of retention rule if you want to protect all resources of a specific type in a specific Region.

While a resource is in the Recycle Bin, you have the ability to restore it for use at any time.

The resource remains in the Recycle Bin until one of the following happens:

• You manually restore it for use. When you restore a resource from the Recycle Bin, the resource is removed from the Recycle Bin and it immediately becomes available for use. You can use restored resources in the same way as any other resource of that type in your account.

• The retention period expires. If the retention period expires, and the resource has not been restored from the Recycle Bin, the resource is permanently deleted from the Recycle Bin and it can no longer be viewed or restored.

**Supported resources**

Recycle Bin supports the following resource types:

• Amazon EBS snapshots
  
  **Important**

  Recycle Bin retention rules also apply to archived snapshots in the archive storage tier. If you delete an archived snapshot that matches a retention rule, that snapshot is retained in the Recycle Bin for the period defined in the retention rule. Archived snapshots are billed at the rate for archived snapshots while they are in the Recycle Bin.

• Amazon EBS-backed Amazon Machine Images (AMIs)

**Considerations**

The following considerations apply when working with Recycle Bin and retention rules.

**General considerations**

• **Important**

  When you create your first retention rule, it can take up to 30 minutes for the rule to become active and for it to start retaining resources. After you create the first retention rule, subsequent retention rules become active and start retaining resources almost immediately.
• If a resource matches more than one retention rule upon deletion, then the retention rule with the longest retention period takes precedence.

• You can't manually delete a resource from the Recycle Bin. The resource will be automatically deleted when its retention period expires.

• While a resource is in the Recycle Bin, you can only view it, restore it, or modify its tags. To use the resource in any other way, you must first restore it.

• If any AWS service, such as AWS Backup or Amazon Data Lifecycle Manager, deletes a resource that matches a retention rule, that resource is automatically retained by Recycle Bin.

• When a resource is sent to the Recycle Bin, the following system-generate tag is assigned to the resource:
  • Tag key — aws:recycle-bin:resource-in-bin
  • Tag value — true

  You can't manually edit or delete this tag. When the resource is restored from the Recycle Bin, the tag is automatically removed.

Considerations for snapshots

• **Important**
  If you have retention rules for AMIs and for their associated snapshots, make the retention period for the snapshots the same or longer than the retention period for the AMIs. This ensures that Recycle Bin does not delete the snapshots associated with an AMI before deleting the AMI itself, as this would make the AMI unrecoverable.

• If a snapshot is enabled for fast snapshot restore when it is deleted, fast snapshot restore is automatically disabled shortly after the snapshot is sent to the Recycle Bin.

• If you restore the snapshot before fast snapshot restore is disabled for the snapshot, it remains enabled.

• If you restore the snapshot, after fast snapshot restore has been disabled, it remains disabled. If needed, you must manually re-enable fast snapshot restore.

• If a snapshot is shared when it is deleted, it is automatically unshared when it is sent to the Recycle Bin. If you restore the snapshot, all of the previous sharing permissions are automatically restored.

• If a snapshot that was created by another AWS service, such as AWS Backup, is sent to the Recycle Bin and you later restore that snapshot from the Recycle Bin, it is no longer managed by the AWS service that created it. You must manually delete the snapshot if it is no longer needed.

Considerations for AMIs

• Only Amazon EBS-backed AMIs are supported.

• **Important**
  If you have retention rules for AMIs and for their associated snapshots, make the retention period for the snapshots the same or longer than the retention period for the AMIs. This ensures that Recycle Bin does not delete the snapshots associated with an AMI before deleting the AMI itself, as this would make the AMI unrecoverable.

• If an AMI is shared when it is deleted, it is automatically unshared when it is sent to the Recycle Bin. If you restore the AMI, all of the previous sharing permissions are automatically restored.

• Before you can restore an AMI from the Recycle Bin, you must first restore all of its associated snapshots from the Recycle Bin and ensure that they are in the available state.

• If the snapshots that are associated with the AMI are deleted from the Recycle Bin, the AMI is no longer recoverable. The AMI will be deleted when the retention period expires.

• If an AMI that was created by another AWS service, such as AWS Backup, is sent to the Recycle Bin and you later restore that AMI from the Recycle Bin, it is no longer managed by the AWS service that created it. You must manually delete the AMI if it is no longer needed.
Considerations for Amazon Data Lifecycle Manager snapshot policies

- If Amazon Data Lifecycle Manager deletes a snapshot that matches a retention rule, that snapshot is automatically retained by Recycle Bin.

- If Amazon Data Lifecycle Manager deletes a snapshot and sends it to the Recycle Bin when the policy's retention threshold is reached, and you manually restore the snapshot from the Recycle Bin, you must manually delete that snapshot when it is no longer needed. Amazon Data Lifecycle Manager will no longer manage the snapshot.

- If you manually delete a snapshot that was created by a policy, and that snapshot is in the Recycle Bin when the policy's retention threshold is reached, Amazon Data Lifecycle Manager does not manage the snapshots while they are stored in the Recycle Bin.

If the snapshot is restored from the Recycle Bin before the policy's retention threshold is reached, Amazon Data Lifecycle Manager will delete the snapshot when the policy's retention threshold is reached.

If the snapshot is restored from the Recycle Bin after the policy's retention threshold is reached, Amazon Data Lifecycle Manager will no longer delete the snapshot. You must manually delete the snapshot when it is no longer needed.

Considerations for AWS Backup

- If AWS Backup deletes a snapshot that matches a retention rule, that snapshot is automatically retained by Recycle Bin.

Considerations for archived snapshots

- Recycle Bin retention rules also apply to archived snapshots in the archive storage tier. If you delete an archived snapshot that matches a retention rule, that snapshot is retained in the Recycle Bin for the period defined in the retention rule.

Archived snapshots are billed at the rate for archived snapshots while they are in the Recycle Bin.

If a retention rule deletes an archived snapshot from the Recycle Bin before the minimum archive period of 90 days, you are billed for the remaining days. For more information, see Pricing and billing (p. 1842).

To use an archived snapshot that is in the Recycle Bin, you must first recover the snapshot from the Recycle Bin and then restore it from the archive tier to the standard tier.

Quotas

The following quotas apply to Recycle Bin.

<table>
<thead>
<tr>
<th>Quota</th>
<th>Default quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Retention rules per Region</td>
<td>250</td>
</tr>
<tr>
<td>Tag key and value pairs per retention rule</td>
<td>50</td>
</tr>
</tbody>
</table>
Related services

Recycle Bin works with the following services:

- **AWS CloudTrail** — Enables you to record events that occur in Recycle Bin. For more information, see [Monitor Recycle Bin using AWS CloudTrail](#).

Pricing

Resources in the Recycle Bin are billed at their standard rates. There are no additional charges for using Recycle Bin and retention rules. For more information, see [Amazon EBS pricing](#).

**Note**

Some resources might still appear in the Recycle Bin console or in the AWS CLI and API output for a short period after their retention periods have expired and they have been permanently deleted. You are not billed for these resources. Billing stops as soon as the retention period expires.

You can use the following AWS generated cost allocation tags for cost tracking and allocation purposes when using AWS Billing and Cost Management.

- **Key:** `aws:recycle-bin:resource-in-bin`
- **Value:** `true`

For more information, see [AWS-generated cost allocation tags](#) in the [AWS Billing and Cost Management User Guide](#).

Required IAM permissions

By default, users don’t have permission to work with Recycle Bin, retention rules, or with resources that are in the Recycle Bin. To allow users to work with these resources, you must create IAM policies that grant permission to use specific resources and API actions. Once the policies are created, you must add permissions to your users, groups, or roles.

**Topics**

- [Permissions for working with Recycle Bin and retention rules](#)
- [Permissions for working with resources in the Recycle Bin](#)
- [Condition keys for Recycle Bin](#)

Permissions for working with Recycle Bin and retention rules

To work with Recycle Bin and retention rules, users need the following permissions.

- `rbin:CreateRule`
- `rbin:UpdateRule`
- `rbin:GetRule`
- `rbin:ListRules`
- `rbin:DeleteRule`
- `rbin:TagResource`
- `rbin:UntagResource`
• rbin:ListTagsForResource
• rbin:LockRule
• rbin:UnlockRule

To use the Recycle Bin console, users need the tag:GetResources permission.

The following is an example IAM policy that includes the tag:GetResources permission for console users. If some permissions are not needed, you can remove them from the policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "rbin:CreateRule",
        "rbin:UpdateRule",
        "rbin:GetRule",
        "rbin:ListRules",
        "rbin:DeleteRule",
        "rbin:TagResource",
        "rbin:UntagResource",
        "rbin:ListTagsForResource",
        "rbin:LockRule",
        "rbin:UnlockRule",
        "tag:GetResources"
      ],
      "Resource": "*"
    }
  ]
}
```

To provide access, add permissions to your users, groups, or roles:

• Users and groups in AWS IAM Identity Center (successor to AWS Single Sign-On):
  
  Create a permission set. Follow the instructions in [Create a permission set](#) in the [AWS IAM Identity Center (successor to AWS Single Sign-On) User Guide](#).

• Users managed in IAM through an identity provider:
  
  Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider (federation)](#) in the [IAM User Guide](#).

• IAM users:
  
  • Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the [IAM User Guide](#).
  
  • (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user (console)](#) in the [IAM User Guide](#).

Permissions for working with resources in the Recycle Bin

For more information about the IAM permissions needed to work with resources in the Recycle Bin, see the following:

• [Permissions for working with snapshots in the Recycle Bin (p. 1868)](#)
• [Permissions for working with AMIs in the Recycle Bin (p. 225)](#)
Condition keys for Recycle Bin

Recycle Bin defines the following condition keys that you can use in the Condition element of an IAM policy to control the conditions under which the policy statement applies. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

Topics
- rbin:Request/ResourceType condition key (p. 2120)
- rbin:Attribute/ResourceType condition key (p. 2121)

rbin:Request/ResourceType condition key

The rbin:Request/ResourceType condition key can be used to filter access on CreateRule and ListRules requests based on the value specified for the ResourceType request parameter.

Example 1 - CreateRule

The following sample IAM policy allows IAM principals to make CreateRule requests only if the value specified for the ResourceType request parameter is EBS_SNAPSHOT or EC2_IMAGE. This allows the principal to create new retention rules for snapshots and AMIs only.

```json
{  
  "Version" : "2012-10-17",
  "Statement" : [  
    {  
      "Effect" : "Allow",
      "Action" : [
        "rbin:CreateRule"
      ],
      "Resource" : "*",
      "Condition" : {  
        "StringEquals" : {
          "rbin:Request/ResourceType" : ["EBS_SNAPSHOT", "EC2_IMAGE"]
        }
      }
    }
  ]
}
```

Example 2 - ListRules

The following sample IAM policy allows IAM principals to make ListRules requests only if the value specified for the ResourceType request parameter is EBS_SNAPSHOT. This allows the principal to list retention rules for snapshots only, and it prevents them from listing retention rules for any other resource type.

```json
{  
  "Version" : "2012-10-17",
  "Statement" : [  
    {  
      "Effect" : "Allow",
      "Action" : [
        "rbin:ListRules"
      ],
      "Resource" : "*",
      "Condition" : {  
        "StringEquals" : {
          "rbin:Request/ResourceType" : "EBS_SNAPSHOT"
        }
      }
    }
  ]
}
```
The `rbin:Attribute/ResourceType` condition key can be used to filter access on `DeleteRule`, `GetRule`, `UpdateRule`, `LockRule`, `UnlockRule`, `TagResource`, `UntagResource`, and `ListTagsForResource` requests based on the value of the retention rule's `ResourceType` attribute.

**Example 1 - UpdateRule**

The following sample IAM policy allows IAM principals to make `UpdateRule` requests only if the `ResourceType` attribute of the requested retention rule is `EBS_SNAPSHOT` or `EC2_IMAGE`. This allows the principal to update retention rules for snapshots and AMIs only.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["rbin:UpdateRule"],
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "rbin:Attribute/ResourceType": ["EBS_SNAPSHOT", "EC2_IMAGE"]
            }
         }
      }
   ]
}
```

**Example 2 - DeleteRule**

The following sample IAM policy allows IAM principals to make `DeleteRule` requests only if the `ResourceType` attribute of the requested retention rule is `EBS_SNAPSHOT`. This allows the principal to delete retention rules for snapshots only.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["rbin:DeleteRule"],
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "rbin:Attribute/ResourceType": "EBS_SNAPSHOT"
            }
         }
      }
   ]
}
```
Work with retention rules

To enable and use Recycle Bin, you must create retention rules in the AWS Regions in which you want to protect your resources. Retention rules specify the following:

- The resource type that you want to protect.
- The resources that you want to retain in the Recycle Bin when they are deleted.
- The retention period for which to retain resources in the Recycle Bin before they are permanently deleted.

With Recycle Bin, you can create two types of retention rules:

- **Tag-level retention rules** — A tag-level retention rule uses resource tags to identify the resources that are to be retained in the Recycle Bin. For each retention rule, you specify one or more tag key and value pairs. Resources of the specified type that are tagged with at least one of the tag key and value pairs that are specified in the retention rule are automatically retained in the Recycle Bin upon deletion. Use this type of retention rule if you want to protect specific resources in your account based on their tags.

- **Region-level retention rules** — A Region-level retention rule does not have any resource tags specified. It applies to all of the resources of the specified type in the Region in which the rule is created, even if the resources are not tagged. Use this type of retention rule if you want to protect all resources of a specific type in a specific Region.

After you create a retention rule, resources that match its criteria are automatically retained in the Recycle Bin for the specified retention period after they are deleted.

Topics

- [Create a retention rule](#)
- [View Recycle Bin retention rules](#)
- [Update retention rules](#)
- [Lock retention rules](#)
- [Unlock retention rules](#)
- [Tag retention rules](#)
- [View retention rule tags](#)
- [Remove tags from retention rules](#)
- [Delete Recycle Bin retention rules](#)

Create a retention rule

When you create a retention rule, you must specify the following required parameters:

- The resource type that is to be protected by the retention rule.
- The resources that are to be protected by the retention rule. You can create retention rules at the tag level and the Region level.
  - To create a tag-level retention rule, specify the resource tags that identify the resources to protect. You can specify up to 50 tags for each rule, and add the same tag key and value pair to a maximum of five retention rules.
  - To create a Region-level retention rule, do not specify any tag key and value pairs. In this case, all resources of the specified type are protected.
- The period to retain the resources in the Recycle Bin after they are deleted. The period can be up to 1 year (365 days).
You can also specify the following optional parameters:

- An optional name for the retention rule. The name can be up to 255 characters long.
- An optional description for the retention rule. The description can be up to 255 characters long.

**Note**

We recommend that you do not include personally identifying, confidential, or sensitive information in the retention rule description.

- Optional retention rule tags to help identify and organize your retention rules. You can assign up to 50 tags to each rule.

You can also optionally lock retention rules on creation. If you lock a retention rule on creation, you must also specify the unlock delay period, which can be 7 to 30 days. Retention rules remain unlocked by default unless you explicitly lock them.

Retention rules function only in the Regions in which they are created. If you intend to use Recycle Bin in other Regions, you must create additional retention rules in those Regions.

You can create a Recycle Bin retention rule using one of the following methods.

**Recycle Bin console**

**To create a retention rule**

1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation pane, choose **Retention rules**, and then choose **Create retention rule**.
3. In the **Rule details** section, do the following:
   a. *(Optional)* For **Retention rule name**, enter a descriptive name for the retention rule.
   b. *(Optional)* For **Retention rule description**, enter a brief description for the retention rule.
4. In the **Rule settings** section, do the following:
   a. For **Resource type**, select choose the type of resource for the retention rule to protect. The retention rule will retain only resources of this type in the Recycle Bin.
   b. Do one of the following:
      - To create a Region-level retention rule that matches all deleted resources of the specified type in the Region, select **Apply to all resources**. The retention rule will retain all deleted resources of the specified in the Recycle Bin upon deletion, even if the resources do not have any tags.
      - To create a tag-level retention rule, for **Resource tags to match**, enter the tag key and value pairs to use to identify resource of the specified type that are to be retained in the Recycle Bin. Only resources of the specified type that have at least one of the specified tag key and value pairs will be retained by the retention rule.
   c. For **Retention period**, enter the number of days for which the retention rule is to retain resources in the Recycle Bin.
5. *(Optional)* To lock the retention rule, for **Rule lock settings**, select **Lock**, and then for **Unlock delay period**, specify the unlock delay period in days. A locked retention rule can't be modified or deleted. To modify or delete the rule, you must first unlock it and then wait for the unlock delay period to expire. For more information, see **Lock retention rules** (p. 2126)

To leave the retention rule unlocked, for **Rule lock settings**, keep **Unlock** selected. An unlocked retention rule can be modified or deleted at any time. For more information, see **Unlock retention rules** (p. 2128).
6. *(Optional)* In the **Tags** section, do the following:
To tag the rule with custom tags, choose **Add tag** and then enter the tag key and value pair.

7. Choose **Create retention rule**.

**AWS CLI**

**To create a retention rule**

Use the **create-rule** AWS CLI command. For **--retention-period**, specify the number of days to retain deleted snapshots in the Recycle Bin. For **--resource-type**, specify `EBS_SNAPSHOT` for snapshots or `EC2_IMAGE` for AMIs. To create a tag-level retention rule, for **--resource-tags**, specify the tags to use to identify the snapshots that are to be retained. To create a Region-level retention rule, omit **--resource-tags**. To lock a retention rule, include **--lock-configuration**, and specify the unlock delay period in days.

```
$ aws rbin create-rule \
  --retention-period RetentionPeriodValue=number_of_days,RetentionPeriodUnit=DAYS \
  --resource-type EBS_SNAPSHOT|EC2_IMAGE \
  --description "rule_description" \
  --lock-configuration 'UnlockDelay={UnlockDelayUnit=DAYS,UnlockDelayValue=unlock_delay_in_days}' \
  --resource-tags ResourceTagKey=tag_key,ResourceTagValue=tag_value
```

**Example 1**

The following example command creates an unlocked Region-level retention rule that retains all deleted snapshots for a period of 7 days.

```
$ aws rbin create-rule \
  --retention-period RetentionPeriodValue=7,RetentionPeriodUnit=DAYS \
  --resource-type EBS_SNAPSHOT \
  --description "Match all snapshots"
```

**Example 2**

The following example command creates a tag-level rule that retains deleted snapshots that are tagged with `purpose=production` for a period of 7 days.

```
$ aws rbin create-rule \
  --retention-period RetentionPeriodValue=7,RetentionPeriodUnit=DAYS \
  --resource-type EBS_SNAPSHOT \
  --description "Match snapshots with a specific tag" \
  --resource-tags ResourceTagKey=purpose,ResourceTagValue=production
```

**Example 3**

The following example command creates a locked Region-level retention rule that retains all deleted snapshots for a period of 7 days. The retention rule is locked with an unlock delay period of 7 days.

```
$ aws rbin create-rule \
  --retention-period RetentionPeriodValue=7,RetentionPeriodUnit=DAYS \
  --resource-type EBS_SNAPSHOT \
  --description "Match all snapshots" \
  --lock-configuration 'UnlockDelay={UnlockDelayUnit=DAYS,UnlockDelayValue=7}'
```
View Recycle Bin retention rules

You can view Recycle Bin retention rules using one of the following methods.

Recycle Bin console

To view retention rules

1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation pane, choose Retention rules.
3. The grid lists all of the retention rules for the selected Region. To view more information about a specific retention rule, select it in the grid.

AWS CLI

To view all of your retention rules

Use the list-rules AWS CLI command, and for --resource-type, specify EBS_SNAPSHOT for snapshots or EC2_IMAGE for AMIs.

```
$ aws rbin list-rules --resource-type EBS_SNAPSHOT|EC2_IMAGE
```

Example

The following example command provides lists all retention rules that retain snapshots.

```
$ aws rbin list-rules --resource-type EBS_SNAPSHOT
```

To view information for a specific retention rule

Use the get-rule AWS CLI command.

```
$ aws rbin get-rule --identifier rule_ID
```

Example

The following example command provides information about retention rule pwxIkFcvge4.

```
$ aws rbin get-rule --identifier pwxIkFcvge4
```

Update retention rules

You can update an unlocked retention rule's description, resource tags, and retention period at any time after creation. You can’t update a retention rule’s resource type or unlock delay period, even if the retention rule is unlocked.

You can’t update a locked retention rule in any way. If you need to modify a locked retention rule, you must first unlock it and wait for the unlock delay period to expire.

If you need to modify the unlock delay period for a locked retention rule, you must unlock the retention rule (p. 2128), and wait for the current unlock delay period to expire. When the unlock delay period is expired, you must relock the retention rule (p. 2126) and specify the new unlock delay period.

Note

We recommend that you do not include personally identifying, confidential, or sensitive information in the retention rule description.
After you update a retention rule, the changes only apply to new resources that it retains. The changes do not affect resources that it previously sent to the Recycle Bin. For example, if you update a retention rule's retention period, only snapshots that are deleted after the update are retained for the new retention period. Snapshots that it sent to the Recycle Bin before the update are still retained for the previous (old) retention period.

You can update a retention rule using one of the following methods.

Recycle Bin console

To update a retention rule

1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation pane, choose Retention rules.
3. In the grid, select the retention rule to update, and choose Actions, Edit retention rule.
4. In the Rule details section, update Retention rule name and Retention rule description as needed.
5. In the Rule settings section, update the Resource type, Resource tags to match, and Retention period as needed.
6. In the Tags section, add or remove retention rule tags as needed.
7. Choose Save retention rule.

AWS CLI

To update a retention rule

Use the update-rule AWS CLI command. For --identifier, specify the ID of the retention rule to update. For --resource-types, specify EBS_SNAPSHOT for snapshots or EC2_IMAGE for AMIs.

```
$ aws rbin update-rule \
--identifier rule_ID \
--retention-period RetentionPeriodValue=number_of_days,RetentionPeriodUnit=DAYS \
--resource-type EBS_SNAPSHOT|EC2_IMAGE \
--description "rule_description"
```

Example

The following example command updates retention rule 6lsJ2Fa9nh9 to retain all snapshots for 7 days and updates its description.

```
$ aws rbin update-rule \
--identifier 6lsJ2Fa9nh9 \
--retention-period RetentionPeriodValue=7,RetentionPeriodUnit=DAYS \
--resource-type EBS_SNAPSHOT \
--description "Retain for three weeks"
```

Lock retention rules

Recycle Bin lets you lock Region-level retention rules at any time.

Note
You can't lock tag-level retention rules.

A locked retention rule can't be modified or deleted, even by users who have the required IAM permissions. Lock your retention rules to help protect them against accidental or malicious modifications and deletions.
When you lock a retention rule, you must specify an unlock delay period. This is the period of time that you must wait after unlocking the retention rule before you can modify or delete it. You cannot modify or delete the retention rule during the unlock delay period. You can modify or delete the retention rule only after the unlock delay period has expired.

You can't change the unlock delay period after the retention rule has been locked. If your account permissions have been compromised, the unlock delay period gives you additional time to detect and respond to security threats. The length of this period should be longer than the time it takes for you to identify and respond to security breaches. To set the right duration, you can review previous security incidents and the time needed to identify and remediate an account breach.

We recommend that you use Amazon EventBridge rules to notify you of retention rule lock state changes. For more information, see Monitor Recycle Bin using Amazon EventBridge (p. 2132).

**Considerations**

- You can lock Region-level retention rules only.
- You can lock an unlocked retention rule at any time.
- The unlock delay period must be 7 to 30 days.
- You can re-lock a retention rule during the unlock delay period. Relocking the retention rule resets the unlock delay period.

You can lock a Region-level retention rule using one of the following methods.

**Recycle Bin console**

**To lock a retention rule**

2. In the navigation panel, choose Retention rules.
3. In the grid, select the unlocked retention rule to lock, and choose Actions, Edit retention rule lock.
4. In the Edit retention rule lock screen, choose Lock, and then for Unlock delay period, specify the unlock delay period in days.
5. Select the I acknowledge that locking the retention rule will prevent it from being modified or deleted check box, and then choose Save.

**AWS CLI**

**To lock an unlocked retention rule**

Use the lock-rule AWS CLI command. For --identifier, specify the ID of the retention rule to lock. For --lock-configuration, specify the unlock delay period in days.

```
$ aws rbin lock-rule
--identifier rule_ID
--lock-configuration
'UnlockDelay={UnlockDelayUnit=DAYS,UnlockDelayValue=number_of_days}"
```

**Example**

The following example command locks retention rule 61sJ2Fa9nh9 and sets the unlock delay period to 15 days.

```
$ aws rbin lock-rule
```
Unlock retention rules

You can't modify or delete a locked retention rule. If you need to modify a locked retention rule, you must first unlock it. After you have unlocked the retention rule, you must wait for the unlock delay period to expire before you modify or delete it. You can't modify or delete a retention rule during the unlock delay period.

An unlocked retention rule can be modified and deleted at any time by a user who has the required IAM permissions. Leaving your retention rules unlocked could expose them to accidental or malicious modifications and deletions.

Considerations

• You can re-lock a retention rule during the unlock delay period.
• You can re-lock a retention rule after the unlock delay period has expired.
• You can't bypass the unlock delay period.
• You can't change the unlock delay period after the initial lock.

We recommend that you use Amazon EventBridge rules to notify you of retention rule lock state changes. For more information, see Monitor Recycle Bin using Amazon EventBridge (p. 2132).

You can unlock a locked Region-level retention rule using one of the following methods.

Recycle Bin console

To unlock a retention rule

1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation panel, choose Retention rules.
3. In the grid, select the locked retention rule to unlock, and choose Actions, Edit retention rule lock.
4. On the Edit retention rule lock screen, choose Unlock, and then choose Save.

AWS CLI

To unlock a locked retention rule

Use the unlock-rule AWS CLI command. For --identifier, specify the ID of the retention rule to unlock.

```
$ aws rbin unlock-rule \
   --identifier rule_ID
```

Example

The following example command unlocks retention rule 6lsJ2Fa9nh9

```
$ aws rbin unlock-rule \
   --identifier 6lsJ2Fa9nh9
```
Tag retention rules

You can assign custom tags to your retention rules to categorize them in different ways, for example, by purpose, owner, or environment. This helps you to efficiently find a specific retention rule based on the custom tags that you assigned.

You can assign a tag to a retention rule using one of the following methods.

Recycle Bin console

To tag a retention rule

1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation pane, choose Retention rules.
3. Select the retention rule to tag, choose the Tags tab, and then choose Manage tags.
4. Choose Add tag. For Key, enter the tag key. For Value, enter the tag value.
5. Choose Save.

AWS CLI

To tag a retention rule

Use the tag-resource AWS CLI command. For --resource-arn, specify the Amazon Resource Name (ARN) of the retention rule to tag, and for --tags, specify the tag key and value pair.

```
$ aws rbin tag-resource \
--resource-arn retention_rule_arn \
--tags key=tag_key,value=tag_value
```

Example

The following example command tags retention rule arn:aws:rbin:us-east-1:123456789012:rule/n0oSBBtItF3 with tag purpose=production.

```
$ aws rbin tag-resource \
--resource-arn arn:aws:rbin:us-east-1:123456789012:rule/n0oSBBtItF3 \
--tags key=purpose,value=production
```

View retention rule tags

You can view the tags assigned to a retention rule using one of the following methods.

Recycle Bin console

To view tags for a retention rule

1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation pane, choose Retention rules.
3. Select the retention rule for which to view the tags, and choose the Tags tab.

AWS CLI

To view the tags assigned to a retention rule
Use the `list-tags-for-resource` AWS CLI command. For `--resource-arn`, specify the ARN of the retention rule.

```
$ aws rbin list-tags-for-resource \
--resource-arn retention_rule_arn
```

**Example**

The following example command lists the tags for retention rule `arn:aws:rbin:us-east-1:123456789012:rule/nOoSBBtItF3`.

```
$ aws rbin list-tags-for-resource \
--resource-arn arn:aws:rbin:us-east-1:123456789012:rule/nOoSBBtItF3
```

**Remove tags from retention rules**

You can remove tags from a retention rule using one of the following methods.

**Recycle Bin console**

*To remove a tag from a retention rule*

2. In the navigation pane, choose **Retention rules**.
3. Select the retention rule from which to remove the tag, choose the **Tags** tab, and then choose **Manage tags**.
4. Choose **Remove** next to the tag to remove.
5. Choose **Save**.

**AWS CLI**

*To remove a tag from a retention rule*

Use the `untag-resource` AWS CLI command. For `--resource-arn`, specify the ARN of the retention rule. For `--tagkeys`, specify the tags keys of the tags to remove.

```
$ aws rbin untag-resource \
--resource-arn retention_rule_arn \
--tagkeys tag_key
```

**Example**

The following example command removes tags that have a tag key of `purpose` from retention rule `arn:aws:rbin:us-east-1:123456789012:rule/nOoSBBtItF3`.

```
$ aws rbin untag-resource \
--resource-arn arn:aws:rbin:us-east-1:123456789012:rule/nOoSBBtItF3 \
--tagkeys purpose
```

**Delete Recycle Bin retention rules**

You can delete a retention rule at any time. When you delete a retention rule, it no longer retains new resources in the Recycle Bin after they have been deleted. Resources that were sent to the Recycle...
Work with resources in the Recycle Bin

Recycle Bin supports the following resource types:

- Amazon EBS snapshots
- Amazon EBS-backed Amazon Machine Images (AMIs)

Topics

- Work with snapshots in the Recycle Bin (p. 2131)
- Work with AMIs in the Recycle Bin (p. 2131)

This section includes links to the topics that explain how to work with the supported resource types.

Work with snapshots in the Recycle Bin

For more information about working with snapshots in the Recycle Bin, see Recover snapshots from the Recycle Bin (p. 1868).

Work with AMIs in the Recycle Bin

For more information about working with AMIs in the Recycle Bin, see Recover AMIs from the Recycle Bin (p. 224).
Monitor Recycle Bin

You can use the following features to monitor the Recycle Bin.

Topics

- Monitor Recycle Bin using Amazon EventBridge (p. 2132)
- Monitor Recycle Bin using AWS CloudTrail (p. 2134)

Monitor Recycle Bin using Amazon EventBridge

Recycle Bin sends events to Amazon EventBridge for actions performed on retention rules. With EventBridge, you can establish rules that initiate programmatic actions in response to these events. For example, you can create a EventBridge rule that sends a notification to your email when a retention rule is unlocked and it enters its unlock delay period. For more information, see Creating Amazon EventBridge rules that react to events.

Events in EventBridge are represented as JSON objects. The fields that are unique to the event are contained in the detail section of the JSON object. The event field contains the event name. The result field contains the completed status of the action that initiated the event. For more information, see Amazon EventBridge event patterns in the Amazon EventBridge User Guide.

For more information about Amazon EventBridge, see What Is Amazon EventBridge? in the Amazon EventBridge User Guide.

Events

- RuleLocked (p. 2132)
- RuleChangeAttempted (p. 2133)
- RuleUnlockScheduled (p. 2133)
- RuleUnlockingNotice (p. 2133)
- RuleUnlocked (p. 2134)

RuleLocked

The following is an example of an event that Recycle Bin generates when a retention rule is successfully locked. This event can be generated by CreateRule and LockRule requests. The API that generated the event is noted in the api-name field.

```
{
    "version": "0",
    "id": "exampleb-b491-4cf7-a9f1-bf370example",
    "detail-type": "Recycle Bin Rule Locked",
    "source": "aws.rbin",
    "account": "123456789012",
    "time": "2022-08-10T16:37:50Z",
    "region": "us-west-2",
    "resources": [
        "arn:aws:rbin:us-west-2:123456789012:rule/a12345abcdef"
    ],
    "detail": {
        "detail-version": "1.0.0",
        "rule-id": "a12345abcdef",
        "rule-description": "locked account level rule",
        "unlock-delay-period": "30 days",
        "api-name": "CreateRule"
    }
}
```
RuleChangeAttempted

The following is an example of an event that Recycle Bin generates for unsuccessful attempts to modify or delete a locked rule. This event can be generated by `DeleteRule` and `UpdateRule` requests. The API that generated the event is noted in the `api-name` field.

```json
{
  "version": "0",
  "id": "exampleb-b491-4cf7-a9f1-bf370example",
  "detail-type": "Recycle Bin Rule Change Attempted",
  "source": "aws.rbin",
  "account": "123456789012",
  "time": "2022-08-10T16:37:50Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:rbin:us-west-2:123456789012:rule/a12345abcde"
  ],
  "detail": {
    "detail-version": "1.0.0",
    "rule-id": "a12345abcde",
    "rule-description": "locked account level rule",
    "unlock-delay-period": "30 days",
    "api-name": "DeleteRule"
  }
}
```

RuleUnlockScheduled

The following is an example of an event that Recycle Bin generates when a retention rule is unlocked and it starts its unlock delay period.

```json
{
  "version": "0",
  "id": "exampleb-b491-4cf7-a9f1-bf370example",
  "detail-type": "Recycle Bin Rule Unlock Scheduled",
  "source": "aws.rbin",
  "account": "123456789012",
  "time": "2022-08-10T16:37:50Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:rbin:us-west-2:123456789012:rule/a12345abcde"
  ],
  "detail": {
    "detail-version": "1.0.0",
    "rule-id": "a12345abcde",
    "rule-description": "locked account level rule",
    "unlock-delay-period": "30 days",
    "scheduled-unlock-time": "2022-09-10T16:37:50Z"
  }
}
```

RuleUnlockingNotice

The following is an example of an event that Recycle Bin generates daily while a retention rule is in its unlock delay period, until the day before the unlock delay period expires.

```json
{
  "version": "0",
  "id": "exampleb-b491-4cf7-a9f1-bf370example",
  "detail-type": "Recycle Bin Rule Unlocking Notice",
  "source": "aws.rbin",
  "account": "123456789012",
  "time": "2022-08-10T16:37:50Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:rbin:us-west-2:123456789012:rule/a12345abcde"
  ],
  "detail": {
    "detail-version": "1.0.0",
    "rule-id": "a12345abcde",
    "rule-description": "locked account level rule",
    "unlock-delay-period": "30 days",
    "scheduled-unlock-time": "2022-09-10T16:37:50Z"
  }
}
```
RuleUnlocked

The following is an example of an event that Recycle Bin generates when the unlock delay period for a retention rule expires and the retention rule can be modified or deleted.

```
{
  "version": "0",
  "id": "exampleb-b491-4cf7-a9f1-bf370example",
  "detail-type": "Recycle Bin Rule Unlocked",
  "source": "aws.rbin",
  "account": "123456789012",
  "time": "2022-08-10T16:37:50Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:rbin:us-west-2:123456789012:rule/a12345abcde"
  ],
  "detail":
  {
    "detail-version": " 1.0.0",
    "rule-id": "a12345abcde",
    "rule-description": "locked account level rule",
    "unlock-delay-period": "30 days",
    "scheduled-unlock-time": "2022-09-10T16:37:50Z"
  }
}
```

Monitor Recycle Bin using AWS CloudTrail

The Recycle Bin service is integrated with AWS CloudTrail. CloudTrail is a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls performed in Recycle Bin as events. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon Simple Storage Service (Amazon S3) bucket. If you don't configure a trail, you can still view the most recent management events in the CloudTrail console in Event history. You can use the information collected by CloudTrail to determine the request that was made to Recycle Bin, the IP address from which the request was made, who made the request, when it was made, and additional details.

For more information about CloudTrail, see the AWS CloudTrail User Guide.

Recycle Bin information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When supported event activity occurs in Recycle Bin, that activity is recorded in a CloudTrail event along with other AWS service events.
in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for Recycle Bin, create a trail. A trail enables CloudTrail to deliver log files to an S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see Overview for creating a trail in the AWS CloudTrail User Guide.

Supported API actions

For Recycle Bin, you can use CloudTrail to log the following API actions as management events.

- CreateRule
- UpdateRule
- GetRules
- ListRule
- DeleteRule
- TagResource
- UntagResource
- ListTagsForResource
- LockRule
- UnlockRule

For more information about logging management events, see Logging management events for trails in the CloudTrail User Guide.

Identity information

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentityElement.

Understand Recycle Bin log file entries

A trail is a configuration that enables delivery of events as log files to an S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following are example CloudTrail log entries.

CreateRule

{

Resource locations

Amazon EC2 resources are specific to the AWS Region or Availability Zone in which they reside.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon EC2 resource identifiers</td>
<td>Regional</td>
<td>Each resource identifier, such as an AMI ID, instance ID, EBS volume ID, or EBS snapshot ID, is tied to its Region and can be used only in the Region where you created the resource.</td>
</tr>
<tr>
<td>User-supplied resource names</td>
<td>Regional</td>
<td>Each resource name, such as a security group name or key pair name, is tied to its Region and can be used only in the Region where you created the resource. Although you can create resources with the same name in multiple Regions, they aren't related to each other.</td>
</tr>
<tr>
<td>Resource</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>AMIs</td>
<td>Regional</td>
<td>An AMI is tied to the Region where its files are located within Amazon S3. You can copy an AMI from one Region to another. For more information, see Copy an AMI (p. 201).</td>
</tr>
<tr>
<td>EBS snapshots</td>
<td>Regional</td>
<td>An EBS snapshot is tied to its Region and can only be used to create volumes in the same Region. You can copy a snapshot from one Region to another. For more information, see Copy an Amazon EBS snapshot (p. 1836).</td>
</tr>
<tr>
<td>EBS volumes</td>
<td>Availability Zone</td>
<td>An Amazon EBS volume is tied to its Availability Zone and can be attached only to instances in the same Availability Zone.</td>
</tr>
<tr>
<td>Elastic IP addresses</td>
<td>Regional</td>
<td>An Elastic IP address is tied to a Region and can be associated only with an instance in the same Region.</td>
</tr>
<tr>
<td>Instances</td>
<td>Availability Zone</td>
<td>An instance is tied to the Availability Zones in which you launched it. However, its instance ID is tied to the Region.</td>
</tr>
<tr>
<td>Key pairs</td>
<td>Global or Regional</td>
<td>The key pairs that you create using Amazon EC2 are tied to the Region where you created them. You can create your own RSA key pair and upload it to the Region in which you want to use it; therefore, you can make your key pair globally available by uploading it to each Region. For more information, see Amazon EC2 key pairs and Linux instances (p. 1730).</td>
</tr>
<tr>
<td>Security groups</td>
<td>Regional</td>
<td>A security group is tied to a Region and can be assigned only to instances in the same Region. You can't enable an instance to communicate with an instance outside its Region using security group rules. Traffic from an instance in another Region is seen as WAN bandwidth.</td>
</tr>
</tbody>
</table>

**Resource IDs**

When resources are created, we assign each resource a unique resource ID. A resource ID takes the form of a resource identifier (such as snap for a snapshot) followed by a hyphen and a unique combination of letters and numbers.

Each resource identifier, such as an AMI ID, instance ID, EBS volume ID, or EBS snapshot ID, is tied to its Region and can be used only in the Region where you created the resource.

You can use resource IDs to find your resources in the Amazon EC2 console. If you are using a command line tool or the Amazon EC2 API to work with Amazon EC2, resource IDs are required for certain commands. For example, if you are using the `stop-instances` AWS CLI command to stop an instance, you must specify the instance ID in the command.

**Resource ID length**
Prior to January 2016, the IDs assigned to newly created resources of certain resource types used 8 characters after the hyphen (for example, i-1a2b3c4d). From January 2016 to June 2018, we changed the IDs of these resource types to use 17 characters after the hyphen (for example, i-1234567890abcdef0). Depending on when your account was created, you might have some existing resources with short IDs, however, any new resources will receive the longer IDs.

List and filter your resources

You can get a list of some types of resources using the Amazon EC2 console. You can get a list of each type of resource using its corresponding command or API action. If you have many resources, you can filter the results to include, or exclude, only the resources that match certain criteria.

Contents

- List and filter resources using the console (p. 2146)
- List and filter using the CLI and API (p. 2150)
- List and filter resources across Regions using Amazon EC2 Global View (p. 2152)

List and filter resources using the console

Contents

- List resources using the console (p. 2146)
- Filter resources using the console (p. 2146)

List resources using the console

You can view the most common Amazon EC2 resource types using the console. To view additional resources, use the command line interface or the API actions.

To list EC2 resources using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose the option that corresponds to the resource type. For example, to list your instances, choose Instances.

   The page displays all resources of the selected resource type.

Filter resources using the console

To filter a list of resources

1. In the navigation pane, select a resource type (for example, Instances).
2. Choose the search field.
3. Select the filter from the list.
4. Select an operator, for example, = (Equals). Some attributes have more available operators to select. Note that not all screens support selecting an operator.
5. Select a filter value.
6. To edit a selected filter, choose the filter token (blue box), make the required edits, and then choose Apply. Note that not all screens support editing the selected filter.
7. When you are finished, remove the filter.

The search and filter functionality differs slightly between the *old* and *new* Amazon EC2 console.

**New console**

The new console supports two types of filtering.

- **API filtering** happens on the server side. The filtering is applied on the API call, which reduces the number of resources returned by the server. It allows for quick filtering across large sets of resources, and it can reduce data transfer time and cost between the server and the browser. API filtering supports `=` (equals) and `:` (contains) operators, and is always case sensitive.

- **Client filtering** happens on the client side. It enables you to filter down on data that is already available in the browser (in other words, data that has already been returned by the API). Client filtering works well in conjunction with an API filter to filter down to smaller data sets in the browser. In addition to `=` (equals) and `:` (contains) operators, client filtering can also support range operators, such as `=>` (greater than or equal), and negation (inverse) operators, such as `!=` (does not equal).

The new Amazon EC2 console supports the following types of searches:

**Search by keyword**

Searching by keyword is a free text search that lets you search for a value across all of your resources' attributes or tags, without specifying an attribute or tag key to search.

**Note**

All keyword searches use *client filtering*.

To search by keyword, enter or paste what you’re looking for in the search field, and then choose Enter. For example, searching for 123 matches all instances that have 123 in any of their attributes, such as an IP address, instance ID, VPC ID, or AMI ID, or in any of their tags, such as the Name. If your free text search returns unexpected matches, apply additional filters.

**Search by attribute**

Searching by an attribute lets you search a specific attribute across all of your resources.

**Note**

Attribute searches use either *API filtering* or *client filtering*, depending on the selected attribute. When performing an attribute search, the attributes are grouped accordingly.

For example, you can search the **Instance state** attribute for all of your instances to return only instances that are in the **stopped** state. To do this:

1. In the search field on the **Instances** screen, start entering **Instance state**. As you enter the characters, the two types of filters appear for **Instance state: API filters** and **Client filters**.
2. To search on the server side, choose **Instance state** under **API filters**. To search on the client side, choose **Instance state (client)** under **Client filters**.

A list of possible operators for the selected attribute appears.

3. Choose the \( \text{=} \) (Equals) operator.

A list of possible values for the selected attribute and operator appears.

4. Choose **stopped** from the list.

**Search by tag**

Searching by a tag lets you filter the resources in the currently displayed table by a tag key or a tag value.

Tag searches use either **API filtering** or **client filtering**, depending on the settings in the Preferences window.

**To ensure API filtering for tags**

1. Open the **Preferences** window.
2. Clear the **Use regular expression matching** check box. If this check box is selected, client filtering is performed.
3. Select the **Use case sensitive matching** check box. If this check box is cleared, client filtering is performed.
4. Choose **Confirm**.

When searching by tag, you can use the following values:

- **(empty)** – Find all resources with the specified tag key, but there must be no tag value.
- **All values** – Find all resources with the specified tag key and any tag value.
- **Not tagged** – Find all resources that do not have the specified tag key.
- **The displayed value** – Find all resources with the specified tag key and the specified tag value.

You can use the following techniques to enhance or refine your searches:

**Inverse search**

Inverse searches let you search for resources that do **not** match a specified value. In the **Instances** and **AMIs** screens, inverse searches are performed by selecting the \( \neq \) (Does not equal) or \( \\not{=} \) (Does not contain) operator and then selecting a value. In other screens, inverse searches are performed by prefixing the search keyword with the exclamation mark (!) character.

**Note**

Inverse search is supported with keyword searches and attribute searches on **client filters** only. It is not supported with attribute searches on **API filters**.

For example, you can search the **Instance state** attribute for all of your instances to exclude all instances that are in the `terminated` state. To do this:

1. In the search field on the **Instances** screen, start entering **Instance state**. As you enter the characters, the two types of filters appear for **Instance state: API filters** and **Client filters**.
2. Under **Client filters**, choose **Instance state (client)**. Inverse search is only supported on **client filters**.
3. A list of possible operators for the selected attribute appears.
4. Choose \( \neq \) (Does not equal), and then choose **terminated**.
To filter instances based on an instance state attribute, you can also use the search icons ( ) in the Instance state column. The search icon with a plus sign ( + ) displays all the instances that match that attribute. The search icon with a minus sign ( - ) excludes all instances that match that attribute.

Here is another example of using the inverse search: To list all instances that are not assigned the security group named launch-wizard-1, under Client filters, search by the Security group name attribute, choose !=, and in the search bar, enter launch-wizard-1.

Partial search

With partial searches, you can search for partial string values. To perform a partial search, enter only a part of the keyword that you want to search for. On the Instances and AMIs screens, partial searches can only be performed with the : (Contains) operator. On other screens, you can select the client filter attribute and immediately enter only a part of the keyword that you want to search for. For example, on the Instance type screen, to search for all t2.micro, t2.small, and t2.medium instances, search by the Instance Type attribute, and for the keyword, enter t2.

Regular expression search

To use regular expression searches, you must select the Use regular expression matching check box in the Preferences window.

Regular expressions are useful when you need to match the values in a field with a specific pattern. For example, to search for a value that starts with s, search for ^s. To search for a value that ends with xyz, search for xyz$. Or to search for a value that starts with a number that is followed by one or more characters, search for [0-9]*.

**Note**

Regular expression search is supported with keyword searches and attribute searches on client filters only. It is not supported with attribute searches on API filters.

Case-sensitive search

To use case-sensitive searches, you must select the Use case sensitive matching check box in the Preferences window. The case-sensitive preference only applies to client and tag filters.

**Note**

API filters are always case-sensitive.

Wildcard search

Use the * wildcard to match zero or more characters. Use the ? wildcard to match zero or one character. For example, if you have a data set with the values prod, prods, and production, a search of prod* matches all values, whereas prod? matches only prod and prods. To use the literal values, escape them with a backslash (\). For example, "prod\" would match prod*.

**Note**

Wildcard search is supported with attribute and tag searches on API filters only. It is not supported with keyword searches, and with attribute and tag searches on client filters.

Combining searches

In general, multiple filters with the same attribute are automatically joined with OR. For example, searching for Instance State : Running and Instance State : Stopped returns all instances that are either running OR stopped. To join search with AND, search across different attributes. For example, searching for Instance State : Running and Instance Type : c4.large returns only instances that are of type c4.large AND that are in the running state.

Old console

The old Amazon EC2 console supports the following types of searches:
Search by keyword

Searching by keyword is a free text search that lets you search for a value across all of your resources' attributes. To search by keyword, enter or paste what you're looking for in the search field, and then choose Enter. For example, searching for 123 matches all instances that have 123 in any of their attributes, such as an IP address, instance ID, VPC ID, or AMI ID. If your free text search returns unexpected matches, apply additional filters.

Search by attributes

Searching by an attribute lets you search a specific attribute across all of your resources. For example, you can search the State attribute for all of your instances to return only instances that are in the stopped state. To do this:

1. In the search field on the Instances screen, start entering Instance State. As you enter characters, a list of matching attributes appears.
2. Select Instance State from the list. A list of possible values for the selected attribute appears.
3. Select Stopped from the list.

You can use the following techniques to enhance or refine your searches:

Inverse search

Inverse searches let you search for resources that do not match a specified value. Inverse searches are performed by prefixing the search keyword with the exclamation mark (!) character. For example, to list all instances that are not terminated, search by the Instance State attribute, and for the keyword, enter !Terminated.

Partial search

With partial searches, you can search for partial string values. To perform a partial search, enter only a part of the keyword you want to search for. For example, to search for all t2.micro, t2.small, and t2.medium instances, search by the Instance Type attribute, and for the keyword, enter t2.

Regular expression search

Regular expressions are useful when you need to match the values in a field with a specific pattern. For example, to search for all instances that have an attribute value that starts with s, search for ^s. Or to search for all instances that have an attribute value that ends with xyz, search for xyz$. Regular expression searches are not case-sensitive.

Combining searches

In general, multiple filters with the same attribute are automatically joined with OR. For example, searching for Instance State: Running and Instance State: Stopped returns all instances that are either running OR stopped. To join search with AND, search across different attributes. For example, searching for Instance State: Running and Instance Type: c4.large returns only instances that are of type c4.large AND that are in the stopped state.

List and filter using the CLI and API

Each resource type has a corresponding CLI command and API action that you use to list resources of that type. The resulting lists of resources can be long, so it can be faster and more useful to filter the results to include only the resources that match specific criteria.

Filtering considerations

- You can specify multiple filters and multiple filter values in a single request.
- You can use wildcards with the filter values. An asterisk (*) matches zero or more characters, and a question mark (?) matches zero or one character.
• Filter values are case sensitive.
• Your search can include the literal values of the wildcard characters; you just need to escape them with a backslash before the character. For example, a value of "*amazon?\" searches for the literal string "*amazon?\".

Supported filters
To see the supported filters for each Amazon EC2 resource, see the following documentation:
• AWS CLI: The describe commands in the AWS CLI Command Reference-Amazon EC2.
• Query API: The Describe API actions in the Amazon EC2 API Reference.

Example Example: Specify a single filter
You can list your Amazon EC2 instances using describe-instances. Without filters, the response contains information for all of your resources. You can use the following command to include only the running instances in your output.

```bash
aws ec2 describe-instances --filters Name=instance-state-name,Values=running
```

To list only the instance IDs for your running instances, add the --query parameter as follows.

```bash
aws ec2 describe-instances --filters Name=instance-state-name,Values=running --query "Reservations[*].Instances[*].InstanceId" --output text
```

The following is example output.

```
i-0ef1f57f78d4775a4
i-0626d4edd54f1286d
i-04a63ed18e83cfacb
```

Example Example: Specify multiple filters or filter values
If you specify multiple filters or multiple filter values, the resource must match all filters to be included in the results.

You can use the following command to list all instances whose type is either m5.large or m5d.large.

```bash
aws ec2 describe-instances --filters Name=instance-type,Values=m5.large,m5d.large
```

You can use the following command to list all stopped instances whose type is t2.micro.

```bash
aws ec2 describe-instances --filters Name=instance-state-name,Values=stopped Name=instance-type,Values=t2.micro
```

Example Example: Use wildcards in a filter value
If you specify database as the filter value for the description filter when describing EBS snapshots using describe-snapshots, the command returns only the snapshots whose description is "database".

```bash
aws ec2 describe-snapshots --filters Name=description,Values=database
```
The * wildcard matches zero or more characters. If you specify *database* as the filter value, the command returns only snapshots whose description includes the word database.

```bash
aws ec2 describe-snapshots --filters Name=description,Values=*database*
```

The ? wildcard matches exactly 1 character. If you specify database? as the filter value, the command returns only snapshots whose description is "database" or "database" followed by one character.

```bash
aws ec2 describe-snapshots --filters Name=description,Values=database?
```

If you specify database????, the command returns only snapshots whose description is "database" followed by up to four characters. It excludes descriptions with "database" followed by five or more characters.

```bash
aws ec2 describe-snapshots --filters Name=description,Values=database????
```

**Example Example: Filter based on date**

With the AWS CLI, you can use JMESPath to filter results using expressions. For example, the following `describe-snapshots` command displays the IDs of all snapshots created by your AWS account (represented by `123456789012`) before the specified date (represented by `2020-03-31`). If you do not specify the owner, the results include all public snapshots.

```bash
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[? (StartTime<='2020-03-31')].[SnapshotId]" --output text
```

The following command displays the IDs of all snapshots created in the specified date range.

```bash
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[? (StartTime>='2019-01-01') && (StartTime<='2019-12-31')].[SnapshotId]" --output text
```

**Filter based on tags**

For examples of how to filter a list of resources according to their tags, see [Work with tags using the command line](p. 2163).

**List and filter resources across Regions using Amazon EC2 Global View**

Amazon EC2 Global View enables you to view some of your Amazon EC2 and Amazon VPC resources across a single AWS Region, or across multiple Regions in a single console. Amazon EC2 Global View also provides global search functionality that lets you search for specific resources or specific resource types across multiple Regions simultaneously.

Amazon EC2 Global View does not let you modify resources in any way.

**Supported resources**

Using Amazon EC2 Global View, you can view a global summary of the following resources across all of the Regions for which your AWS account is enabled.

- VPCs
- Subnets
Required permissions

A user must have the following permissions to use Amazon EC2 Global View.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ec2:DescribeInstances",
            "ec2:DescribeVpcs",
            "ec2:DescribeRegions",
            "ec2:DescribeVolumes",
            "ec2:DescribeSubnets",
            "ec2:DescribeSecurityGroups",
            "ec2:DescribeRouteTables",
            "ec2:DescribeVpcEndpoints",
            "ec2:DescribeNatGateways",
            "ec2:DescribeInternetGateways",
            "ec2:DescribeEgressOnlyInternetGateways",
            "autoscaling:DescribeAutoScalingGroups"
         ],
         "Resource": "*"
      }
   ]
}
```

To use Amazon EC2 Global View

Open the Amazon EC2 Global View console at [https://console.aws.amazon.com/ec2globalview/home](https://console.aws.amazon.com/ec2globalview/home).

**Important**
You cannot use a private window in Firefox to access Amazon EC2 Global View.

The console consists of two tabs:

- **Region explorer**—This tab includes the following sections:
  - **Resource summary**—Provides a high-level overview of your resources across all Regions.

  **Enabled Regions** indicates the number of Regions for which your AWS account is enabled. The remaining fields indicate the number of resources that you currently have in those Regions. Choose any of the links to view the resources of that type across all Regions. For example, if the link below the **Instances** label is 29 in 10 Regions, it indicates that you currently have 29 instances across 10 Regions. Choose the link to view a list of all 29 instances.

  - **Resource counts per Region**—Lists all of the AWS Regions (including those for which your account is not enabled) and provides totals for each resource type for each Region.

    Choose a Region name to view all resources of all types for that specific Region. For example, choose **Africa (Cape Town) af-south-1** to view all VPCs, subnets, instances, security groups, volumes, and...
Auto Scaling groups in that Region. Alternatively, select a Region and choose View resources for selected Region.

Choose the value for a specific resource type in a specific Region to view only resources of that type in that Region. For example, choose the value for Instances for Africa (Cape Town) af-south-1 to view only the instances in that Region.

- **Global search**—This tab enables you to search for specific resources or specific resource types across a single Region or across multiple Regions. It also enables you to view details for a specific resource.

  To search for resources, enter the search criteria in the field preceding the grid. You can search by Region, by resource type, and by the tags assigned to resources.

  To view the details for a specific resource, select it in the grid. You can also choose the resource ID of a resource to open it in its respective console. For example, choose an instance ID to open the instance in the Amazon EC2 console, or choose a subnet ID to open the subnet in the Amazon VPC console.

---

**Tag your Amazon EC2 resources**

To help you manage your instances, images, and other Amazon EC2 resources, you can assign your own metadata to each resource in the form of tags. Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. This is useful when you have many resources of the same type—you can quickly identify a specific resource based on the tags that you've assigned to it. This topic describes tags and shows you how to create them.

**Warning**

Tag keys and their values are returned by many different API calls. Denying access to DescribeTags doesn't automatically deny access to tags returned by other APIs. As a best practice, we recommend that you do not include sensitive data in your tags.

**Contents**

- **Tag basics** (p. 2154)

- **Add tags to a resource using CloudFormation** (p. 2168)

---

**Tag basics**

A tag is a label that you assign to an AWS resource. Each tag consists of a key and an optional value, both of which you define.

Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. For example, you could define a set of tags for your account's Amazon EC2 instances that helps you track each instance's owner and stack level.

The following diagram illustrates how tagging works. In this example, you've assigned two tags to each of your instances—one tag with the key Owner and another with the key Stack. Each tag also has an associated value.
We recommend that you devise a set of tag keys that meets your needs for each resource type. Using a consistent set of tag keys makes it easier for you to manage your resources. You can search and filter the resources based on the tags you add. For more information about how to implement an effective resource tagging strategy, see the Tagging Best Practices AWS Whitepaper.

Tags don't have any semantic meaning to Amazon EC2 and are interpreted strictly as a string of characters. Also, tags are not automatically assigned to your resources. You can edit tag keys and values, and you can remove tags from a resource at any time. You can set the value of a tag to an empty string, but you can't set the value of a tag to null. If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value. If you delete a resource, any tags for the resource are also deleted.

**Note**  
After you delete a resource, its tags might remain visible in the console, API, and CLI output for a short period. These tags will be gradually disassociated from the resource and be permanently deleted.

**Tag your resources**

You can tag most Amazon EC2 resources that already exist in your account. The following table lists the resources that support tagging.

If you're using the Amazon EC2 console, you can apply tags to resources by using the Tags tab on the relevant resource screen, or you can use the Tags Editor in the AWS Resource Groups console. Some resource screens enable you to specify tags for a resource when you create the resource; for example, a tag with a key of Name and a value that you specify. In most cases, the console applies the tags immediately after the resource is created (rather than during resource creation). The console might organize resources according to the Name tag, but this tag doesn't have any semantic meaning to the Amazon EC2 service.
If you’re using the Amazon EC2 API, the AWS CLI, or an AWS SDK, you can use the `CreateTags` EC2 API action to apply tags to existing resources. Additionally, some resource-creating actions enable you to specify tags for a resource when the resource is created. If tags cannot be applied during resource creation, we roll back the resource creation process. This ensures that resources are either created with tags or not created at all, and that no resources are left untagged at any time. By tagging resources at the time of creation, you can eliminate the need to run custom tagging scripts after resource creation. For more information about enabling users to tag resources on creation, see [Grant permission to tag resources during creation](p. 1667).

The following table describes the Amazon EC2 resources that can be tagged, and the resources that can be tagged on creation using the Amazon EC2 API, the AWS CLI, or an AWS SDK.

Tag restrictions

You can tag instances, volumes, elastic graphics, network interfaces, and Spot Instance requests on creation using the Amazon EC2 launch instance wizard (p. 679) in the Amazon EC2 console. You can tag your EBS volumes on creation using the Volumes screen, or EBS snapshots using the Snapshots screen. Alternatively, use the resource-creating Amazon EC2 APIs (for example, RunInstances) to apply tags when creating your resource.

You can apply tag-based resource-level permissions in your IAM policies to the Amazon EC2 API actions that support tagging on creation to implement granular control over the users and groups that can tag resources on creation. Your resources are properly secured from creation—tags are applied immediately to your resources, therefore any tag-based resource-level permissions controlling the use of resources are immediately effective. Your resources can be tracked and reported on more accurately. You can enforce the use of tagging on new resources, and control which tag keys and values are set on your resources.

You can also apply resource-level permissions to the CreateTags and DeleteTags Amazon EC2 API actions in your IAM policies to control which tag keys and values are set on your existing resources. For more information, see Example: Tag resources (p. 1699).

For more information about tagging your resources for billing, see Using cost allocation tags in the AWS Billing User Guide.

The following basic restrictions apply to tags:

- Maximum number of tags per resource – 50
- For each resource, each tag key must be unique, and each tag key can have only one value.
- Maximum key length – 128 Unicode characters in UTF-8
- Maximum value length – 256 Unicode characters in UTF-8
- Allowed characters
  - Although EC2 allows for any character in its tags, other services are more restrictive. The allowed characters across services are: letters (a-z, A-Z), numbers (0-9), and spaces representable in UTF-8, and the following characters: + = . _ : / @.
  - If you enable instance tags in instance metadata, instance tag keys can only use letters (a-z, A-Z), numbers (0-9), and the following characters: + = . _ : @. Instance tag keys can’t contain spaces or /, and can’t comprise only . (one period), . . (two periods), or _index. For more information, see Work with instance tags in instance metadata (p. 2166).
- Tag keys and values are case-sensitive.
- The aws: prefix is reserved for AWS use. If a tag has a tag key with this prefix, then you can’t edit or delete the tag’s key or value. Tags with the aws: prefix do not count against your tags per resource limit.
Tags and access management

You can't terminate, stop, or delete a resource based solely on its tags; you must specify the resource identifier. For example, to delete snapshots that you tagged with a tag key called DeleteMe, you must use the DeleteSnapshots action with the resource identifiers of the snapshots, such as snap-1234567890abcdef0.

When you tag public or shared resources, the tags you assign are available only to your AWS account; no other AWS account will have access to those tags. For tag-based access control to shared resources, each AWS account must assign its own set of tags to control access to the resource.

You can't tag all resources. For more information, see Tagging support for Amazon EC2 resources (p. 2156).

Tag your resources for billing

You can use tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. For more information about setting up a cost allocation report with tags, see Monthly cost allocation report in the AWS Billing User Guide. To see the cost of your combined resources, you can organize your billing information based on resources that have the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information, see Using cost allocation tags in the AWS Billing User Guide.

Note
If you've just enabled reporting, data for the current month is available for viewing after 24 hours.

Cost allocation tags can indicate which resources are contributing to costs, but deleting or deactivating resources doesn't always reduce costs. For example, snapshot data that is referenced by another snapshot is preserved, even if the snapshot that contains the original data is deleted. For more information, see Amazon Elastic Block Store volumes and snapshots in the AWS Billing User Guide.

Note
Elastic IP addresses that are tagged do not appear on your cost allocation report.

Work with tags using the console

You can use the Amazon EC2 console to display the tags of an individual resource, and to apply or remove tags from one resource at a time.

You can use the Tag Editor in the AWS Resource Groups console to display the tags of all of your Amazon EC2 resources across all Regions. You can view tags by resource and by resource type, and you can see which resource types are associated with a specified tag. You can apply or remove tags from multiple resources and multiple resource types at a time. The Tag Editor provides a central, unified way to create and manage your tags. For more information, see the Tagging AWS Resources User Guide.

Tasks
Display tags

You can display the tags of an individual resource in the Amazon EC2 console. To display the tags of all your resources, use the Tag Editor in the AWS Resource Groups console.

Display tags of an individual resource

When you select a resource-specific page in the Amazon EC2 console, it displays a list of those resources. For example, if you select Instances from the navigation pane, the console displays your Amazon EC2 instances. When you select a resource from one of these lists (for example, an instance), if the resource supports tags, you can view and manage its tags. On most resource pages, you can view the tags by choosing the Tags tab.

You can add a column to the resource list to display all values for tags with the same key. You can use this column to sort and filter the resource list by the tag.

New console

To add a column to the resource list to display your tags

1. In the EC2 console, choose the Preferences gear-shaped icon in the top right corner of the screen.
2. In the Preferences dialog box, for Tag columns (at bottom left), select one or more tag keys, and then choose Confirm.

Old console

There are two ways to add a new column to the resource list to display your tags:

- On the Tags tab, select Show Column. A new column is added to the console.
- Choose the Show/Hide Columns gear-shaped icon, and in the Show/Hide Columns dialog box, select the tag key under Your Tag Keys.

Display tags for multiple resources

You can display tags across multiple resources by using the Tag Editor in the AWS Resource Groups console. For more information, see the Tagging AWS Resources User Guide.

Add and delete tags on an individual resource

You can manage tags for an individual resource directly from the resource's page.

To add a tag to an individual resource

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region where the resource to tag is located. For more information, see Resource locations (p. 2144).
3. In the navigation pane, select a resource type (for example, **Instances**).
4. Select the resource from the resource list and choose the **Tags** tab.
5. Choose **Manage tags**, and then choose **Add new tag**. Enter the key and value for the tag. Choose **Add new tag** again for each additional tag to add. When you are finished adding tags, choose **Save**.

**To delete a tag from an individual resource**
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region where the resource to untag is located. For more information, see Resource locations (p. 2144).
3. In the navigation pane, choose a resource type (for example, **Instances**).
4. Select the resource from the resource list and choose the **Tags** tab.
5. Choose **Manage tags**. For each tag to remove, choose **Remove**. When you are finished removing tags, choose **Save**.

**Add and delete tags for multiple resources**

**To add a tag to multiple resources**
2. For **Regions**, select one or more Regions where the resources to tag are located.
3. For **Resource types**, select the type of resources to tag (for example, **AWS::EC2::Instance**).
4. Choose **Search resources**.
5. Under **Resource search results**, select the check box next to each resource to tag.
6. Choose **Manage tags of selected resources**.
7. Under **Edit tags of all selected resources**, choose **Add tag**, and then enter the new tag key and value. Choose **Add tag** again for each additional tag to add.
   
   **Note**
   If you add a new tag with the same tag key as an existing tag, the new tag overwrites the existing tag.
8. Choose **Review and apply tag changes**.
9. Choose **Apply changes to all selected**.

**To remove a tag from multiple resources**
2. For **Regions**, select the Regions where the resources to untag are located.
3. For **Resource types**, select the type of resources to untag (for example, **AWS::EC2::Instance**).
4. Choose **Search resources**.
5. Under **Resource search results**, select the check box next to each resource to untag.
6. Choose **Manage tags of selected resources**.
7. Under **Edit tags of all selected resources**, next to the tag to remove, choose **Remove tag**.
8. Choose **Review and apply tag changes**.
9. Choose **Apply changes to all selected**.
Add a tag when you launch an instance

New console

**To add a tag using the launch instance wizard**

1. From the navigation bar, select the Region for the instance. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. Select the Region that meets your needs. For more information, see Resource locations (p. 2144).
2. Choose Launch instance.
3. Under **Name and tags**, you can enter a descriptive name for your instance and specify tags.
   
   The instance name is a tag, where the key is Name, and the value is the name that you specify. You can tag the instance, volumes, elastic graphics, and network interfaces. For Spot Instances, you can tag the Spot Instance request only.
   
   Specifying an instance name and additional tags is optional.

   • For Name, enter a descriptive name for the instance. If you don't specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.

   • To add additional tags, choose Add additional tags. Choose Add tag, and then enter a key and value, and select the resource type to tag. Choose Add tag again for each additional tag to add.

4. Under Application and OS Images (Amazon Machine Image), choose the operating system (OS) for your instance and an AMI. For more information, see Application and OS Images (Amazon Machine Image) (p. 679).
5. Under Key pair (login), for Key pair name, choose an existing key pair or create a new one.
6. Either keep all the other fields at their default values or choose specific values for your desired instance configuration. For information about the fields, see Launch an instance using defined parameters (p. 678).
7. In the Summary panel, review your settings, and then choose Launch instance.

Old console

**To add a tag using the launch instance wizard**

1. From the navigation bar, select the Region for the instance. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. Select the Region that meets your needs. For more information, see Resource locations (p. 2144).
2. Choose Launch Instance.
3. The Choose an Amazon Machine Image (AMI) page displays a list of basic configurations called Amazon Machine Images (AMIs). Select the AMI to use and choose Select. For more information, see Find a Linux AMI (p. 135).
4. On the Configure Instance Details page, configure the instance settings as necessary, and then choose Next: Add Storage.
5. On the Add Storage page, you can specify additional storage volumes for your instance. Choose Next: Add Tags when done.
6. On the Add Tags page, specify tags for the instance, the volumes, or both. Choose Add another tag to add more than one tag to your instance. Choose Next: Configure Security Group when you are done.
7. On the Configure Security Group page, you can choose from an existing security group that you own, or let the wizard create a new security group for you. Choose Review and Launch when you are done.
8. Review your settings. When you're satisfied with your selections, choose Launch. Select an existing key pair or create a new one, select the acknowledgment check box, and then choose Launch Instances.

Filter a list of resources by tag

You can filter your list of resources based on one or more tag keys and tag values.

To filter a list of resources by tag in the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, select a resource type (for example, Instances).
3. Choose the search field.
4. In the list, under Tags, choose the tag key.
5. Choose the corresponding tag value from the list.
6. When you are finished, remove the filter.

For more information about using filters in the Amazon EC2 console, see List and filter your resources (p. 2146).

To filter multiple resources across multiple Regions by tag using the Tag Editor

You can use the Tag Editor in the AWS Resource Groups console to filter multiple resources across multiple Regions by tag. For more information, see Finding resources to tag in the Tagging AWS Resources User Guide.

Work with tags using the command line

You can add tags to many EC2 resources when you create them, using the tag specifications parameter for the create command. You can view the tags for a resource using the describe command for the resource. You can also add, update, or delete tags for your existing resources using the following commands.

<table>
<thead>
<tr>
<th>Task</th>
<th>AWS CLI</th>
<th>AWS Tools for Windows PowerShell</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add or overwrite one or more tags</td>
<td>create-tags</td>
<td>New-EC2Tag</td>
</tr>
<tr>
<td>Delete one or more tags</td>
<td>delete-tags</td>
<td>Remove-EC2Tag</td>
</tr>
<tr>
<td>Describe one or more tags</td>
<td>describe-tags</td>
<td>Get-EC2Tag</td>
</tr>
</tbody>
</table>

Tasks

- Add tags on resource creation (p. 2163)
- Add tags to an existing resource (p. 2164)
- Describe tagged resources (p. 2165)

Add tags on resource creation

The following examples demonstrate how to apply tags when you create resources.
Note
The way you enter JSON-formatted parameters on the command line differs depending on your operating system.

- Linux, macOS, or Unix and Windows PowerShell – Use single quotes (') to enclose the JSON data structure.
- Windows – Omit the single quotes when using the commands with the Windows command line.

For more information, see Specifying parameter values for the AWS CLI.

Example Example: Launch an instance and apply tags to the instance and volume

The following run-instances command launches an instance and applies a tag with the key `webserver` and the value `production` to the instance. The command also applies a tag with the key `cost-center` and the value `cc123` to any EBS volume that's created (in this case, the root volume).

```
aws ec2 run-instances \
  --image-id ami-abc12345 \
  --count 1 \
  --instance-type t2.micro \
  --key-name MyKeyPair \
  --subnet-id subnet-6e7f829e \
  --tag-specifications 'ResourceType=instance,Tags=[{Key=webserver,Value=production}]' 'ResourceType=volume,Tags=[{Key=cost-center,Value=cc123}]'
```

You can apply the same tag keys and values to both instances and volumes during launch. The following command launches an instance and applies a tag with a key of `cost-center` and a value of `cc123` to both the instance and any EBS volume that's created.

```
aws ec2 run-instances \
  --image-id ami-abc12345 \
  --count 1 \
  --instance-type t2.micro \
  --key-name MyKeyPair \
  --subnet-id subnet-6e7f829e \
  --tag-specifications 'ResourceType=instance,Tags=[{Key=cost-center,Value=cc123}]' 'ResourceType=volume,Tags=[{Key=cost-center,Value=cc123}]'
```

Example Example: Create a volume and apply a tag

The following create-volume command creates a volume and applies two tags: `purpose=production` and `cost-center=cc123`.

```
aws ec2 create-volume \
  --availability-zone us-east-1a \
  --volume-type gp2 \
  --size 80 \
  --tag-specifications 'ResourceType=volume,Tags=[[Key=purpose,Value=production], [Key=cost-center,Value=cc123]]'
```

Add tags to an existing resource

The following examples demonstrate how to add tags to an existing resource using the create-tags command.
Example Example: Add a tag to a resource

The following command adds the tag **Stack=production** to the specified image, or overwrites an existing tag for the AMI where the tag key is **Stack**. If the command succeeds, no output is returned.

```
aws ec2 create-tags \
  --resources ami-78a54011 \
  --tags Key=Stack,Value=production
```

Example Example: Add tags to multiple resources

This example adds (or overwrites) two tags for an AMI and an instance. One of the tags contains just a key (**webserver**), with no value (we set the value to an empty string). The other tag consists of a key (**stack** and value (**Production**). If the command succeeds, no output is returned.

```
aws ec2 create-tags \
  --resources ami-1a2b3c4d i-1234567890abcdef0 \
  --tags Key=webserver,Value=  Key=stack,Value=Production
```

Example Example: Add tags with special characters

This example adds the tag **[Group]=test** to an instance. The square brackets ([ and ]) are special characters, which must be escaped.

If you are using Linux or OS X, to escape the special characters, enclose the element with the special character with double quotes ("), and then enclose the entire key and value structure with single quotes (').

```
aws ec2 create-tags \
  --resources i-1234567890abcdef0 \ 
  --tags 'Key="[Group]",Value=test'
```

If you are using Windows, to escape the special characters, enclose the element that has special characters with double quotes ("), and then precede each double quote character with a backslash (\) as follows:

```
aws ec2 create-tags ^ \
  --resources i-1234567890abcdef0 ^ \
  --tags [Group],Value=test
```

If you are using Windows PowerShell, to escape the special characters, enclose the value that has special characters with double quotes ("), precede each double quote character with a backslash (\), and then enclose the entire key and value structure with single quotes (') as follows:

```
aws ec2 create-tags ` \
  --resources i-1234567890abcdef0 ` \
  --tags ['[Group]','Value=test'
```

Describe tagged resources

The following examples show you how to use filters with the **describe-instances** to view instances with specific tags. All EC2 describe commands use this syntax to filter by tag across a single resource type. Alternatively, you can use the **describe-tags** command to filter by tag across EC2 resource types.

Example Example: Describe instances with the specified tag key

The following command describes the instances with a **Stack** tag, regardless of the value of the tag.
Work with instance tags in instance metadata

You can access an instance’s tags from the instance metadata. By accessing tags from the instance metadata, you no longer need to use the DescribeInstances or DescribeTags API calls to retrieve tag information, which reduces your API transactions per second, and lets your tag retrievals scale with the number of instances that you control. Furthermore, local processes that are running on an instance can view the instance’s tag information directly from the instance metadata.

By default, tags are not available from the instance metadata; you must explicitly allow access. You can allow access at instance launch, or after launch on a running or stopped instance. You can also allow access to tags by specifying this in a launch template. Instances that are launched by using the template allow access to tags in the instance metadata.

If you add or remove an instance tag, the instance metadata is updated while the instance is running, without needing to stop and then start the instance.

Topics
- Allow access to tags in instance metadata (p. 2166)
- Turn off access to tags in instance metadata (p. 2167)
- View if access to tags in instance metadata is allowed (p. 2167)
- Retrieve tags from instance metadata (p. 2168)

Allow access to tags in instance metadata

By default, there is no access to instance tags in the instance metadata. For each instance, you must explicitly allow access by using one of the following methods.
To allow access to tags in instance metadata using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select an instance, and then choose Actions, Instance settings, Allow tags in instance metadata.
4. To allow access to tags in instance metadata, select the Allow check box.
5. Choose Save.

To allow access to tags in instance metadata at launch using the AWS CLI

Use the `run-instances` command and set `InstanceMetadataTags` to enabled.

```bash
aws ec2 run-instances \
    --image-id ami-0abcdef1234567890 \
    --instance-type c3.large \
    ... \
    --metadata-options "InstanceMetadataTags=enabled"
```

To allow access to tags in instance metadata on a running or stopped instance using the AWS CLI

Use the `modify-instance-metadata-options` command and set `--instance-metadata-tags` to enabled.

```bash
aws ec2 modify-instance-metadata-options \
    --instance-id i-123456789example \
    --instance-metadata-tags enabled
```

Turn off access to tags in instance metadata

To turn off access to instance tags in the instance metadata, use one of the following methods. You don't need to turn off access to instance tags on instance metadata at launch because it's turned off by default.

To turn off access to tags in instance metadata using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select an instance, and then choose Actions, Instance settings, Allow tags in instance metadata.
4. To turn off access to tags in instance metadata, clear the Allow check box.
5. Choose Save.

To turn off access to tags in instance metadata using the AWS CLI

Use the `modify-instance-metadata-options` command and set `--instance-metadata-tags` to disabled.

```bash
aws ec2 modify-instance-metadata-options \
    --instance-id i-123456789example \
    --instance-metadata-tags disabled
```

View if access to tags in instance metadata is allowed

For each instance, you can use the Amazon EC2 console or AWS CLI to view whether access to instance tags from the instance metadata is allowed.
To view if access to tags in instance metadata is allowed using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select an instance.
3. On the Details tab, check the Allow tags in instance metadata field. If the value is Enabled, tags in instance metadata is allowed. If the value is Disabled, tags in instance metadata is not allowed.

To view if access to tags in instance metadata is allowed using the AWS CLI

Use the describe-instances command and specify the instance ID.

```bash
aws ec2 describe-instances
  --instance-ids i-1234567890abcdef0
```

The following example output is truncated for space. The "InstanceMetadataTags" parameter indicates whether tags in instance metadata is allowed. If the value is enabled, tags in instance metadata is allowed. If the value is disabled, tags in instance metadata is not allowed.

```
{
  "Reservations": [
    {
      "Groups": [],
      "Instances": [
        {
          "AmiLaunchIndex": 0,
          "ImageId": "ami-0abcdef1234567890",
          "InstanceId": "i-1234567890abcdef0",

          "MetadataOptions": {
            "State": "applied",
            "HttpTokens": "optional",
            "HttpPutResponseHopLimit": 1,
            "HttpEndpoint": "enabled",
            "HttpProtocolIpv6": "disabled",
            "InstanceMetadataTags": "enabled"
          }
        }
      ]
    }
  ]
}
```

Retrieval tags from instance metadata

If instance tags are allowed in the instance metadata, the tags/instance category is accessible from the instance metadata. For examples on how to retrieve tags from the instance metadata, see Get the instance tags for an instance (p. 949).

Add tags to a resource using CloudFormation

With Amazon EC2 resource types, you specify tags using either a Tags or TagSpecifications property.

The following examples add the tag Stack=Production to AWS::EC2::Instance using its Tags property.

**Example Example: Tags in YAML**

```
Tags:
  - Key: "Stack"
```
Amazon Elastic Compute Cloud
User Guide for Linux Instances
Service quotas

Value: "Production"

Example Example: Tags in JSON

"Tags": [  
  {  
    "Key": "Stack",  
    "Value": "Production"  
  }  
]

The following examples add the tag Stack=Production to AWS::EC2::LaunchTemplate LaunchTemplateData using its TagSpecifications property.

Example Example: TagSpecifications in YAML

TagSpecifications:
- ResourceType: "instance"
  Tags:
  - Key: "Stack"
    Value: "Production"

Example Example: TagSpecifications in JSON

"TagSpecifications": [  
  {  
    "ResourceType": "instance",  
    "Tags": [  
      {  
        "Key": "Stack",  
        "Value": "Production"  
      }  
    ]  
  }  
]

Amazon EC2 service quotas

Amazon EC2 provides different resources that you can use. These resources include images, instances, volumes, and snapshots. When you create your AWS account, we set default quotas (also referred to as limits) on these resources on a per-Region basis. For example, there is a maximum number of instances that you can launch in a Region. So if you were to launch an instance in the US West (Oregon) Region, for example, the request must not cause your usage to exceed your maximum number of instances in that Region.

The Service Quotas console is a central location where you can view and manage your quotas for AWS services, and request a quota increase for many of the resources that you use. Use the quota information that we provide to manage your AWS infrastructure. Plan to request any quota increases in advance of the time that you'll need them.

For more information, see Amazon EC2 endpoints and quotas in the Amazon Web Services General Reference. For information about Amazon EBS quotas, see Amazon EBS quotas (p. 2060).

View your current quotas

You can view your quotas for each Region using the Service Quotas console.
To view your current quotas using the Service Quotas console

2. From the navigation bar (at the top of the screen), select a Region.

3. Use the filter field to filter the list by resource name. For example, enter On-Demand to locate the quotas for On-Demand Instances.
4. To view more information, choose the quota name to open the details page for the quota.

Request an increase

You can request a quota increase for each Region.

To request an increase using the Service Quotas console

2. From the navigation bar (at the top of the screen), select a Region.
3. Use the filter field to filter the list by resource name. For example, enter On-Demand to locate the quotas for On-Demand Instances.
4. If the quota is adjustable, choose the quota and then choose Request quota increase.
5. For Change quota value, enter the new quota value.
6. Choose Request.
7. To view any pending or recently resolved requests in the console, choose Dashboard from the navigation pane. For pending requests, choose the status of the request to open the request receipt. The initial status of a request is Pending. After the status changes to Quota requested, you’ll see the case number with AWS Support. Choose the case number to open the ticket for your request.
For more information, including how to use the AWS CLI or SDKs to request a quota increase, see Requesting a quota increase in the Service Quotas User Guide.

Restriction on email sent using port 25

On all instances, Amazon EC2 restricts outbound traffic to public IP addresses over port 25 by default. You can request that this restriction be removed. For more information, see How do I remove the restriction on port 25 from my Amazon EC2 instance or AWS Lambda function? in the AWS Knowledge Center.

Note
This restriction does not apply to outbound traffic sent over port 25 to:

- IP addresses in the primary CIDR block of the VPC in which the originating network interface exists.
- IP addresses in the CIDRs defined in RFC 1918, RFC 6598, and RFC 4193.

Amazon EC2 usage reports

AWS provides a free reporting tool called AWS Cost Explorer that enables you to analyze the cost and usage of your EC2 instances and the usage of your Reserved Instances. You can view data up to the last 12 months, and forecast how much you are likely to spend for the next three months. You can use Cost Explorer to see patterns in how much you spend on AWS resources over time, identify areas that need further inquiry, and see trends that you can use to understand your costs. You also can specify time ranges for the data, and view time data by day or by month.

Here’s an example of some of the questions that you can answer when using Cost Explorer:

- How much am I spending on instances of each instance type?
- How many instance hours are being used by a particular department?
- How is my instance usage distributed across Availability Zones?
- How is my instance usage distributed across AWS accounts?
- How well am I using my Reserved Instances?
- Are my Reserved Instances helping me save money?

For more information about working with reports in Cost Explorer, including saving reports, see Analyzing your costs with AWS Cost Explorer in the AWS Cost Management User Guide.
Troubleshoot EC2 instances

The following documentation can help you troubleshoot problems that you might have with your instance.

Contents

- Troubleshoot instance launch issues (p. 2172)
- Troubleshoot connecting to your instance (p. 2175)
- Troubleshoot stopping your instance (p. 2193)
- Troubleshoot instance termination (shutting down) (p. 2196)
- Troubleshoot instances with failed status checks (p. 2197)
- Troubleshoot an unreachable instance (p. 2218)
- Boot from the wrong volume (p. 2221)
- Use EC2Rescue for Linux (p. 2222)
- EC2 Serial Console for Linux instances (p. 2232)
- Send a diagnostic interrupt (for advanced users) (p. 2250)

For additional help with Windows instances, see Troubleshoot Windows instances in the Amazon EC2 User Guide for Windows Instances.

Troubleshoot instance launch issues

The following issues prevent you from launching an instance.

Launch Issues

- Invalid device name (p. 2172)
- Instance limit exceeded (p. 2173)
- Insufficient instance capacity (p. 2173)
- The requested configuration is currently not supported. Please check the documentation for supported configurations. (p. 2174)
- Instance terminates immediately (p. 2174)

Invalid device name

Description

You get the Invalid device name device_name error when you try to launch a new instance.

Cause

If you get this error when you try to launch an instance, the device name specified for one or more volumes in the request has an invalid device name. Possible causes include:

- The device name might be in use by the selected AMI.
- The device name might be reserved for root volumes.
- The device name might be used for another volume in the request.
Instance limit exceeded

Description
You get the InstanceLimitExceeded error when you try to launch a new instance or restart a stopped instance.

Cause
If you get an InstanceLimitExceeded error when you try to launch a new instance or restart a stopped instance, you have reached the limit on the number of instances that you can launch in a Region. When you create your AWS account, we set default limits on the number of instances you can run on a per-Region basis.

Solution
You can request an instance limit increase on a per-region basis. For more information, see Amazon EC2 service quotas (p. 2169).

Insufficient instance capacity

Description
You get the InsufficientInstanceCapacity error when you try to launch a new instance or restart a stopped instance.

Cause
If you get this error when you try to launch an instance or restart a stopped instance, AWS does not currently have enough available On-Demand capacity to fulfill your request.

Solution
To resolve the issue, try the following:
The requested configuration is currently not supported. Please check the documentation for supported configurations.

Description
You get the Unsupported error when you try to launch a new instance because the instance configuration is not supported.

Cause
The error message provides additional details. For example, an instance type or instance purchasing option might not be supported in the specified Region or Availability Zone.

Solution
Try a different instance configuration. To search for an instance type that meets your requirements, see Find an Amazon EC2 instance type (p. 445).

Instance terminates immediately

Description
Your instance goes from the pending state to the terminated state.

Cause
The following are a few reasons why an instance might immediately terminate:

• You've exceeded your EBS volume limits. For more information, see Instance volume limits (p. 2091).
• An EBS snapshot is corrupted.
• The root EBS volume is encrypted and you do not have permissions to access the KMS key for decryption.
• A snapshot specified in the block device mapping for the AMI is encrypted and you do not have permissions to access the KMS key for decryption or you do not have access to the KMS key to encrypt the restored volumes.
• The instance store-backed AMI that you used to launch the instance is missing a required part (an image.part.xx file).

For more information, get the termination reason using one of the following methods.
To get the termination reason using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and select the instance.
3. On the first tab, find the reason next to **State transition reason**.

To get the termination reason using the AWS Command Line Interface

1. Use the `describe-instances` command and specify the instance ID.
   ```bash
   aws ec2 describe-instances --instance-id instance_id
   ```
2. Review the JSON response returned by the command and note the values in the `StateReason` response element.

   The following code block shows an example of a `StateReason` response element.

   ```json
   "StateReason": {
     "Code": "Server.InternalError"
   },
   ```

To get the termination reason using AWS CloudTrail

For more information, see **Viewing events with CloudTrail event history** in the **AWS CloudTrail User Guide**.

**Solution**

Depending on the termination reason, take one of the following actions:

- **Client.VolumeLimitExceeded: Volume limit exceeded** — Delete unused volumes. You can submit a request to increase your volume limit.
- **Client.InternalError: Client error on launch** — Ensure that you have the permissions required to access the AWS KMS keys used to decrypt and encrypt volumes. For more information, see **Using key policies in AWS KMS** in the **AWS Key Management Service Developer Guide**.

**Troubleshoot connecting to your instance**

The following information and common errors can help you troubleshoot connecting to your Linux instance.

To troubleshoot connecting to Windows instances, see **Troubleshoot Windows instances** in the **Amazon EC2 User Guide for Windows Instances**.

**Connection problems and errors**

- **Common causes for connection issues** *(p. 2176)*
- **Error connecting to your instance: Connection timed out** *(p. 2177)*
- **Error: unable to load key ... Expecting: ANY PRIVATE KEY** *(p. 2180)*
- **Error: User key not recognized by server** *(p. 2181)*
- **Error: Permission denied or connection closed by [instance] port 22** *(p. 2182)*
- **Error: Unprotected private key file** *(p. 2184)*
• **Error: Private key must begin with "-----BEGIN RSA PRIVATE KEY-----" and end with "-----END RSA PRIVATE KEY-----"** (p. 2185)
• **Error: Server refused our key or No supported authentication methods available** (p. 2185)
• **Cannot ping instance** (p. 2186)
• **Error: Server unexpectedly closed network connection** (p. 2186)
• **Error: Host key validation failed for EC2 Instance Connect** (p. 2187)
• **Can't connect to Ubuntu instance using EC2 Instance Connect** (p. 2188)
• **I've lost my private key. How can I connect to my Linux instance?** (p. 2188)

### Common causes for connection issues

We recommend that you start to troubleshoot instance connection problems by verifying that you have accurately performed the following tasks.

#### Verify the username for your instance

You can connect to your instance using the username for your user account or the default username for the AMI that you used to launch your instance.

- **Get the username for your user account.**
  
  For more information about how to create a user account, see [Manage users on your Linux instance](p. 846).

- **Get the default username for the AMI that you used to launch your instance:**

<table>
<thead>
<tr>
<th>AMI used to launch instance</th>
<th>Default username</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Linux 2023</td>
<td>ec2-user</td>
</tr>
<tr>
<td>Amazon Linux 2</td>
<td></td>
</tr>
<tr>

</table>

#### Verify that your security group rules allow traffic

Ensure that the security group associated with your instance allows incoming SSH traffic from your IP address. The default security group for the VPC does not allow incoming SSH traffic by default. The security group created by the launch instance wizard enables SSH traffic by default. For steps to add a rule for inbound SSH traffic to your Linux instance, see [Authorize inbound traffic for your Linux](p. 2176)
instances (p. 1727). For steps to verify, see Error connecting to your instance: Connection timed out (p. 2177).

Verify that your instance is ready

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check your instance to make sure it is running and has passed its status checks.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select your instance.
3. Verify the following:
   a. In the Instance state column, verify that your instance is in the running state.
   b. In the Status check column, verify that your instance has passed the two status checks.

Verify that you have performed the setup tasks and prerequisites to connect to your instance

For general setup tasks, see Set up to connect to your instance (p. 758).

For prerequisites specific to connection types, such as SSH, EC2 Instance Connect, OpenSSH, PuTTY, and more, see the following options.

Linux or macOS X

If your local computer operating system is Linux or macOS X, check the specific prerequisites for the following connection options:
- SSH client (p. 763)
- EC2 Instance Connect (p. 767)
- AWS Systems Manager Session Manager

Windows

If your local computer operating system is Windows, check the specific prerequisites for the following connection options:
- OpenSSH (p. 777)
- PuTTY (p. 779)
- AWS Systems Manager Session Manager
- Windows Subsystem for Linux (p. 785)

Error connecting to your instance: Connection timed out

If you try to connect to your instance and get the error message Network error: Connection timed out or Error connecting to [instance], reason: -> Connection timed out: connect, try the following:

Check your security group rules.

You need a security group rule that allows inbound traffic from your local computer’s public IPv4 address on the proper port.

New console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and then select your instance.

3. On the **Security** tab at the bottom of the console page, under **Inbound rules**, check the list of rules that are in effect for the selected instance.
   - For Linux instances: Verify that there is a rule that allows traffic from your local computer to port 22 (SSH).
   - For Windows instances: Verify that there is a rule that allows traffic from your local computer to port 3389 (RDP).

   If your security group does not have a rule that allows inbound traffic from your local computer, add a rule to your security group. For more information, see **Authorize inbound traffic for your Linux instances** (p. 1727).

4. For the rule that allows inbound traffic, check the **Source** field. If the value is a single IP address, and if the IP address is not static, a new IP address will be assigned each time you restart your computer. This will result in the rule not including your computer's IP address traffic. The IP address might not be static if your computer is on a corporate network, or you're connecting through an internet service provider (ISP), or your computer IP address is dynamic and changes each time you restart your computer. To ensure that your security group rule allows inbound traffic from your local computer, instead of specifying a single IP address for **Source**, rather specify the range of IP addresses used by your client computers.

   For more information about security group rules, see **Security group rules** in the **Amazon VPC User Guide**.

---

**Old console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

2. In the navigation pane, choose **Instances**, and then select your instance.

3. In the **Description** tab at the bottom of the console page, next to **Security groups**, select **view inbound rules** to display the list of rules that are in effect for the selected instance.
   - For Linux instances: When you select **view inbound rules**, a window will appear that displays the port(s) to which traffic is allowed. Verify that there is a rule that allows traffic from your computer to port 22 (SSH).
   - For Windows instances: When you select **view inbound rules**, a window will appear that displays the port(s) to which traffic is allowed. Verify that there is a rule that allows traffic from your computer to port 3389 (RDP).

   If your security group does not have a rule that allows inbound traffic, add a rule to your security group. For more information, see **Authorize inbound traffic for your Linux instances** (p. 1727).

4. Each time you restart your local computer, a new IP address (and host name) can be assigned. If your security group has a rule that allows inbound traffic from a single IP address, this address might not be static if your computer is on a corporate network or if you are connecting through an internet service provider (ISP). Instead, specify the range of IP addresses used by client computers.

   For more information about security group rules, see **Security group rules** in the **Amazon VPC User Guide**.

**Check the route table for the subnet.**

You need a route that sends all traffic destined outside the VPC to the internet gateway for the VPC.
Amazon Elastic Compute Cloud
User Guide for Linux Instances

Error connecting to your instance: Connection timed out

New console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select your instance.
3. On the Networking tab, make note of the values for VPC ID and Subnet ID.
4. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
5. In the navigation pane, choose Internet Gateways. Verify that there is an internet gateway attached to your VPC. Otherwise, choose Create internet gateway, enter a name for the internet gateway, and choose Create internet gateway. Then, for the internet gateway you created, choose Actions, Attach to VPC, select your VPC, and then choose Attach internet gateway to attach it to your VPC.
6. In the navigation pane, choose Subnets, and then select your subnet.
7. On the Route table tab, verify that there is a route with 0.0.0.0/0 as the destination and the internet gateway for your VPC as the target. If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (::/0) that points to the internet gateway. Otherwise, do the following:
   a. Choose the ID of the route table (rtb-xxxxxxxx) to navigate to the route table.
   b. On the Routes tab, choose Edit routes. Choose Add route, use 0.0.0.0/0 as the destination and the internet gateway as the target. For IPv6, choose Add route, use ::/0 as the destination and the internet gateway as the target.
   c. Choose Save routes.

Old console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select your instance.
3. In the Description tab, write down the values of VPC ID and Subnet ID.
4. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
5. In the navigation pane, choose Internet Gateways. Verify that there is an internet gateway attached to your VPC. Otherwise, choose Create Internet Gateway to create an internet gateway. Select the internet gateway, and then choose Attach to VPC and follow the directions to attach it to your VPC.
6. In the navigation pane, choose Subnets, and then select your subnet.
7. On the Route Table tab, verify that there is a route with 0.0.0.0/0 as the destination and the internet gateway for your VPC as the target. If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (::/0) that points to the internet gateway. Otherwise, do the following:
   a. Choose the ID of the route table (rtb-xxxxxxxx) to navigate to the route table.
   b. On the Routes tab, choose Edit routes. Choose Add route, use 0.0.0.0/0 as the destination and the internet gateway as the target. For IPv6, choose Add route, use ::/0 as the destination and the internet gateway as the target.
   c. Choose Save routes.

Check the network access control list (ACL) for the subnet.

The network ACLs must allow inbound traffic from your local IP address on port 22 (for Linux instances) or port 3389 (for Windows instances). It must also allow outbound traffic to the ephemeral ports (1024-65535).

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. In the navigation pane, choose Subnets.
3. Select your subnet.
4. On the Network ACL tab, for Inbound rules, verify that the rules allow inbound traffic from your computer on the required port. Otherwise, delete or modify the rule that is blocking the traffic.
5. For Outbound rules, verify that the rules allow outbound traffic to your computer on the ephemeral ports. Otherwise, delete or modify the rule that is blocking the traffic.

If your computer is on a corporate network

Ask your network administrator whether the internal firewall allows inbound and outbound traffic from your computer on port 22 (for Linux instances) or port 3389 (for Windows instances).

If you have a firewall on your computer, verify that it allows inbound and outbound traffic from your computer on port 22 (for Linux instances) or port 3389 (for Windows instances).

Check that your instance has a public IPv4 address.

If not, you can associate an Elastic IP address with your instance. For more information, see Elastic IP addresses (p. 1309).

Check the CPU load on your instance; the server may be overloaded.

AWS automatically provides data such as Amazon CloudWatch metrics and instance status, which you can use to see how much CPU load is on your instance and, if necessary, adjust how your loads are handled. For more information, see Monitor your instances using CloudWatch (p. 1205).

- If your load is variable, you can automatically scale your instances up or down using Auto Scaling and Elastic Load Balancing.
- If your load is steadily growing, you can move to a larger instance type. For more information, see Change the instance type (p. 449).

To connect to your instance using an IPv6 address, check the following:

- Your subnet must be associated with a route table that has a route for IPv6 traffic (: /0) to an internet gateway.
- Your security group rules must allow inbound traffic from your local IPv6 address on the proper port (22 for Linux and 3389 for Windows).
- Your network ACL rules must allow inbound and outbound IPv6 traffic.
- If you launched your instance from an older AMI, it might not be configured for DHCPv6 (IPv6 addresses are not automatically recognized on the network interface). For more information, see Configure IPv6 on your instances in the Amazon VPC User Guide.
- Your local computer must have an IPv6 address, and must be configured to use IPv6.

Error: unable to load key ... Expecting: ANY PRIVATE KEY

If you try to connect to your instance and get the error message, unable to load key ... Expecting: ANY PRIVATE KEY, the file in which the private key is stored is incorrectly configured. If the private key file ends in .pem, it might still be incorrectly configured. A possible cause for an incorrectly configured private key file is a missing certificate.

If the private key file is incorrectly configured, follow these steps to resolve the error

1. Create a new key pair. For more information, see Create a key pair using Amazon EC2 (p. 1731).
Note
Alternatively, you can create a new key pair using a third-party tool. For more information, see Create a key pair using a third-party tool and import the public key to Amazon EC2 (p. 1734).

2. Add the new key pair to your instance. For more information, see I've lost my private key. How can I connect to my Linux instance? (p. 2188).

3. Connect to your instance using the new key pair.

Error: User key not recognized by server

If you use SSH to connect to your instance

- Use ssh -vvv to get triple verbose debugging information while connecting:

```
ssh -vvv -i path/key-pair-name.pem instance-user-name@ec2-203-0-113-25.compute-1.amazonaws.com
```

The following sample output demonstrates what you might see if you were trying to connect to your instance with a key that was not recognized by the server:

```
debug2: bits set: 504/1024
dbg1: ssh_rsa_verify: signature correct
dbg2: kex_derive_keys
dbg2: set_newkeys: mode 1
dbg1: SSH2_MSG_NEWKEYS sent
dbg1: expecting SSH2_MSG_NEWKEYS
dbg2: set_newkeys: mode 0
dbg1: SSH2_MSG_NEWKEYS received
dbg1: Roaming not allowed by server
dbg1: SSH2_MSG_SERVICE_REQUEST sent
dbg2: service_accept: ssh-userauth
dbg1: SSH2_MSG_SERVICE_ACCEPT received
dbg1: Authentication that can continue: publickey
dbg3: start over, passed a different list publickey
dbg3: preferred gssapi-keyex,gssapi-with-mic,publickey,keyboard-interactive,password
dbg3: authmethod_lookup publickey
dbg3: remaining preferred: keyboard-interactive,password
dbg3: authmethod_is_enabled publickey
dbg1: Next authentication method: publickey
dbg1: Trying private key: bogus.pem
```

If you use PuTTY to connect to your instance

- Verify that your private key (.pem) file has been converted to the format recognized by PuTTY (.ppk). For more information about converting your private key, see Connect to your Linux instance from Windows using PuTTY (p. 779).
Note
In PuTTYgen, load your private key file and select Save Private Key rather than Generate.

- Verify that you are connecting with the appropriate user name for your AMI. Enter the user name in the Host name box in the PuTTY Configuration window.

<table>
<thead>
<tr>
<th>AMI used to launch instance</th>
<th>Default username</th>
</tr>
</thead>
<tbody>
<tr>

</table>

- Verify that you have an inbound security group rule to allow inbound traffic to the appropriate port. For more information, see Authorizing Network Access to Your Instances (p. 1727).

Error: Permission denied or connection closed by [instance] port 22

If you connect to your instance using SSH and get any of the following errors, Host key not found in [directory], Permission denied (publickey), Authentication failed, permission denied, or Connection closed by [instance] port 22, verify that you are connecting with the appropriate user name for your AMI and that you have specified the proper private key (.pem) file for your instance.

The appropriate user names are as follows:

<table>
<thead>
<tr>
<th>AMI used to launch instance</th>
<th>Default username</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Linux 2023</td>
<td>ec2-user</td>
</tr>
<tr>
<td>Amazon Linux 2</td>
<td></td>
</tr>
<tr>
<td>Amazon Linux</td>
<td></td>
</tr>
<tr>
<td>CentOS</td>
<td>centos or ec2-user</td>
</tr>
<tr>
<td>Debian</td>
<td>admin</td>
</tr>
</tbody>
</table>
Amazon Elastic Compute Cloud
User Guide for Linux Instances

Error: Permission denied or connection closed by [instance] port 22

<table>
<thead>
<tr>
<th>AMI used to launch instance</th>
<th>Default username</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fedora</td>
<td>fedora or ec2-user</td>
</tr>
<tr>
<td>RHEL</td>
<td>ec2-user or root</td>
</tr>
<tr>
<td>SUSE</td>
<td>ec2-user or root</td>
</tr>
<tr>
<td>Ubuntu</td>
<td>ubuntu</td>
</tr>
<tr>
<td>Oracle</td>
<td>ec2-user</td>
</tr>
<tr>

<td>Check with the AMI provider</td>
</tr>
</tbody>
</table>

For example, to use an SSH client to connect to an Amazon Linux instance, use the following command:

```
ssh -i /path/key-pair-name.pem instance-user-name@ec2-203-0-113-25.compute-1.amazonaws.com
```

Confirm that you are using the private key file that corresponds to the key pair that you selected when you launched the instance.

New console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances** and then select your instance.
3. On the **Details** tab, under **Instance details**, verify the value of **Key pair name**.
4. If you did not specify a key pair when you launched the instance, you can terminate the instance and launch a new instance, ensuring that you specify a key pair. If this is an instance that you have been using but you no longer have the .pem file for your key pair, you can replace the key pair with a new one. For more information, see [I've lost my private key. How can I connect to my Linux instance?](p. 2188).

Old console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances** and then select your instance.
3. In the **Description** tab, verify the value of **Key pair name**.
4. If you did not specify a key pair when you launched the instance, you can terminate the instance and launch a new instance, ensuring that you specify a key pair. If this is an instance that you have been using but you no longer have the .pem file for your key pair, you can replace the key pair with a new one. For more information, see [I've lost my private key. How can I connect to my Linux instance?](p. 2188).

If you generated your own key pair, ensure that your key generator is set up to create RSA keys. DSA keys are not accepted.

If you get a `Permission denied (publickey)` error and none of the above applies (for example, you were able to connect previously), the permissions on the home directory of your instance may have been changed. Permissions for `/home/instance-user-name/.ssh/authorized_keys` must be limited to the owner only.
To verify the permissions on your instance

1. Stop your instance and detach the root volume. For more information, see Stop and start your instance (p. 718) and Detach an Amazon EBS volume from a Linux instance (p. 1821).

2. Launch a temporary instance in the same Availability Zone as your current instance (use a similar or the same AMI as you used for your current instance), and attach the root volume to the temporary instance. For more information, see Attach an Amazon EBS volume to an instance (p. 1797).

3. Connect to the temporary instance, create a mount point, and mount the volume that you attached. For more information, see Make an Amazon EBS volume available for use on Linux (p. 1803).

4. From the temporary instance, check the permissions of the /home/instance-user-name/ directory of the attached volume. If necessary, adjust the permissions as follows:

   ```bash
   [ec2-user ~]$ chmod 600 mount_point/home/instance-user-name/.ssh/authorized_keys
   [ec2-user ~]$ chmod 700 mount_point/home/instance-user-name/.ssh
   [ec2-user ~]$ chmod 700 mount_point/home/instance-user-name
   ```

5. Unmount the volume, detach it from the temporary instance, and re-attach it to the original instance. Ensure that you specify the correct device name for the root volume; for example, /dev/xvda.

6. Start your instance. If you no longer require the temporary instance, you can terminate it.

Error: Unprotected private key file

Your private key file must be protected from read and write operations from any other users. If your private key can be read or written to by anyone but you, then SSH ignores your key and you see the following warning message below.

```
@ WARNING: UNPROTECTED PRIVATE KEY FILE!
Permissions 0777 for '../.ssh/my_private_key.pem' are too open.
It is required that your private key files are NOT accessible by others. This private key will be ignored.
bad permissions: ignore key: ../.ssh/my_private_key.pem
Permission denied (publickey).
```

If you see a similar message when you try to log in to your instance, examine the first line of the error message to verify that you are using the correct public key for your instance. The above example uses the private key .ssh/my_private_key.pem with file permissions of 0777, which allow anyone to read or write to this file. This permission level is very insecure, and so SSH ignores this key.

If you are connecting from MacOS or Linux, run the following command to fix this error, substituting the path for your private key file.

```
[ec2-user ~]$ chmod 0400 .ssh/my_private_key.pem
```

If you are connecting from Windows, perform the following steps on your local computer.

1. Navigate to your .pem file.
2. Right-click on the .pem file and select Properties.
3. Choose the **Security** tab.

4. Select **Advanced**.

5. Verify that you are the owner of the file. If not, change the owner to your username.

6. Select **Disable inheritance** and **Remove all inherited permissions from this object**.

7. Select **Add**, **Select a principal**, enter your username, and select **OK**.

8. From the **Permission Entry** window, grant **Read** permissions and select **OK**.

9. Click **Apply** to ensure all settings are saved.

10. Select **OK** to close the **Advanced Security Settings** window.

11. Select **OK** to close the **Properties** window.

12. You should be able to connect to your Linux instance from Windows via SSH.

From a Windows command prompt, run the following commands:

1. From the command prompt, navigate to the file path location of your .pem file.

2. Run the following command to reset and remove explicit permissions:

   ```
   icacls.exe $path /reset
   ```

3. Run the following command to grant Read permissions to the current user:

   ```
   icacls.exe $path /GRANT:R "($env:USERNAME):(R)"
   ```

4. Run the following command to disable inheritance and remove inherited permissions.

   ```
   icacls.exe $path /inheritance:r
   ```

5. You should be able to connect to your Linux instance from Windows via SSH.

**Error: Private key must begin with "-----BEGIN RSA PRIVATE KEY-----" and end with "-----END RSA PRIVATE KEY-----"**

If you use a third-party tool, such as `ssh-keygen`, to create an RSA key pair, it generates the private key in the OpenSSH key format. When you connect to your instance, if you use the private key in the OpenSSH format to decrypt the password, you'll get the error **Private key must begin with "-----BEGIN RSA PRIVATE KEY-----" and end with "-----END RSA PRIVATE KEY-----"**.

To resolve the error, the private key must be in the PEM format. Use the following command to create the private key in the PEM format:

```
ssh-keygen -m PEM
```

**Error: Server refused our key or No supported authentication methods available**

If you use PuTTY to connect to your instance and get either of the following errors, **Error: Server refused our key** or **Error: No supported authentication methods available**, verify that you are connecting with
the appropriate user name for your AMI. Type the user name in **User name** in the **PuTTY Configuration**
window.

The appropriate user names are as follows:

<table>
<thead>
<tr>
<th>AMI used to launch instance</th>
<th>Default username</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Linux 2023</td>
<td>ec2-user</td>
</tr>
<tr>
<td>Amazon Linux 2</td>
<td></td>
</tr>
<tr>
<td>Amazon Linux</td>
<td></td>
</tr>
<tr>
<td>CentOS</td>
<td>centos or ec2-user</td>
</tr>
<tr>
<td>Debian</td>
<td>admin</td>
</tr>
<tr>
<td>Fedora</td>
<td>fedora or ec2-user</td>
</tr>
<tr>
<td>RHEL</td>
<td>ec2-user or root</td>
</tr>
<tr>
<td>SUSE</td>
<td>ec2-user or root</td>
</tr>
<tr>
<td>Ubuntu</td>
<td>ubuntu</td>
</tr>
<tr>
<td>Oracle</td>
<td>ec2-user</td>
</tr>
<tr>
<td>Bitnami</td>
<td>bitnami</td>
</tr>
<tr>
<td>Other</td>
<td>Check with the AMI provider</td>
</tr>
</tbody>
</table>

You should also verify that:

- You are using the latest version of PuTTY. For more information, see the [PuTTY web page](https://putty.org).
- Your private key (.pem) file has been correctly converted to the format recognized by PuTTY (.ppk). For more information about converting your private key, see [Connect to your Linux instance from Windows using PuTTY](p. 779).

### Cannot ping instance

The ping command is a type of ICMP traffic — if you are unable to ping your instance, ensure that your inbound security group rules allow ICMP traffic for the Echo Request message from all sources, or from the computer or instance from which you are issuing the command.

If you are unable to issue a ping command from your instance, ensure that your outbound security group rules allow ICMP traffic for the Echo Request message to all destinations, or to the host that you are attempting to ping.

Ping commands can also be blocked by a firewall or time out due to network latency or hardware issues. You should consult your local network or system administrator for help with further troubleshooting.

### Error: Server unexpectedly closed network connection

If you are connecting to your instance with PuTTY and you receive the error "Server unexpectedly closed network connection," verify that you have enabled keepalives on the Connection page of the PuTTY
Configuration to avoid being disconnected. Some servers disconnect clients when they do not receive any data within a specified period of time. Set the Seconds between keepalives to 59 seconds.

If you still experience issues after enabling keepalives, try to disable Nagle's algorithm on the Connection page of the PuTTY Configuration.

**Error: Host key validation failed for EC2 Instance Connect**

If you rotate your instance host keys, the new host keys are not automatically uploaded to the AWS trusted host keys database. This causes host key validation to fail when you try to connect to your instance using the EC2 Instance Connect browser-based client, and you're unable to connect to your instance.

To resolve the error, you must run the `eic_harvest_hostkeys` script on your instance, which uploads your new host key to EC2 Instance Connect. The script is located at `/opt/aws/bin/` on Amazon Linux 2 instances, and at `/usr/share/ec2-instance-connect/` on Ubuntu instances.

**Amazon Linux 2**

**To resolve the host key validation failed error on an Amazon Linux 2 instance**

1. Connect to your instance using SSH.

   You can connect by using the EC2 Instance Connect CLI or by using the SSH key pair that was assigned to your instance when you launched it and the default user name of the AMI that you used to launch your instance. For Amazon Linux 2, the default user name is `ec2-user`.

   For example, if your instance was launched using Amazon Linux 2, your instance's public DNS name is `ec2-a-b-c-d.us-west-2.compute.amazonaws.com`, and the key pair is `my_ec2_private_key.pem`, use the following command to SSH into your instance:

   ```bash
   $ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
   ```

   For more information about connecting to your instance, see [Connect to your Linux instance using SSH](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/using-ssh.html) (p. 763).

2. Navigate to the following folder.

   ```bash
   [ec2-user ~]$ cd /opt/aws/bin/
   ```

3. Run the following command on your instance.

   ```bash
   [ec2-user ~]$ ./eic_harvest_hostkeys
   ```

   Note that a successful call results in no output.

   You can now use the EC2 Instance Connect browser-based client to connect to your instance.

**Ubuntu**

**To resolve the host key validation failed error on an Ubuntu instance**

1. Connect to your instance using SSH.

   ```bash
   $ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
   ```
You can connect by using the EC2 Instance Connect CLI or by using the SSH key pair that was assigned to your instance when you launched it and the default user name of the AMI that you used to launch your instance. For Ubuntu, the default user name is ubuntu.

For example, if your instance was launched using Ubuntu, your instance's public DNS name is ec2-a-b-c-d.us-west-2.compute.amazonaws.com, and the key pair is my_ec2_private_key.pem, use the following command to SSH into your instance:

```
$ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see Connect to your Linux instance using SSH (p. 763).

2. Navigate to the following folder.

```
[ec2-user ~]$ cd /usr/share/ec2-instance-connect/
```

3. Run the following command on your instance.

```
[ec2-user ~]$ ./eic_harvest_hostkeys
```

Note that a successful call results in no output.

You can now use the EC2 Instance Connect browser-based client to connect to your instance.

**Can't connect to Ubuntu instance using EC2 Instance Connect**

If you use EC2 Instance Connect to connect to your Ubuntu instance and you get an error when attempting to connect, you can use the following information to try to fix the issue.

**Possible cause**

The ec2-instance-connect package on the instance is not the latest version.

**Solution**

Update the ec2-instance-connect package on the instance to the latest version, as follows:

1. **Connect (p. 757)** to your instance using a method other than EC2 Instance Connect.
2. Run the following command on your instance to update the ec2-instance-connect package to the latest version.

```
apt update && apt upgrade
```

**I've lost my private key. How can I connect to my Linux instance?**

If you lose the private key for an EBS-backed instance, you can regain access to your instance. You must stop the instance, detach its root volume and attach it to another instance as a data volume, modify the authorized_keys file with a new public key, move the volume back to the original instance, and
I've lost my private key. How can I connect to my Linux instance?

This procedure is only supported for instances with EBS root volumes. If the root device is an instance store volume, you cannot use this procedure to regain access to your instance; you must have the private key to connect to the instance. To determine the root device type of your instance, open the Amazon EC2 console, choose Instances, select the instance, choose the Storage tab, and in the Root device details section, check the value of Root device type.

The value is either EBS or INSTANCE-STORE.

In addition to the following steps, there are other ways to connect to your Linux instance if you lose your private key. For more information, see How can I connect to my Amazon EC2 instance if I lost my SSH key pair after its initial launch?

Steps for connecting to an EBS-backed instance with a different key pair

- **Step 1:** Create a new key pair (p. 2189)
- **Step 2:** Get information about the original instance and its root volume (p. 2189)
- **Step 3:** Stop the original instance (p. 2190)
- **Step 4:** Launch a temporary instance (p. 2190)
- **Step 5:** Detach the root volume from the original instance and attach it to the temporary instance (p. 2190)
- **Step 6:** Add the new public key to authorized_keys on the original volume mounted to the temporary instance (p. 2191)
- **Step 7:** Unmount and detach the original volume from the temporary instance, and reattach it to the original instance (p. 2192)
- **Step 8:** Connect to the original instance using the new key pair (p. 2193)
- **Step 9:** Clean up (p. 2193)

**Step 1: Create a new key pair**

Create a new key pair using either the Amazon EC2 console or a third-party tool. If you want to name your new key pair exactly the same as the lost private key, you must first delete the existing key pair. For information about creating a new key pair, see Create a key pair using Amazon EC2 (p. 1731) or Create a key pair using a third-party tool and import the public key to Amazon EC2 (p. 1734).

**Step 2: Get information about the original instance and its root volume**

Make note of the following information because you'll need it to complete this procedure.

**To get information about your original instance**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Instances in the navigation pane, and then select the instance that you'd like to connect to. (We'll refer to this as the original instance.)
3. On the Details tab, make note of the instance ID and AMI ID.
4. On the Networking tab, make note of the Availability Zone.
5. On the Storage tab, under Root device name, make note of the device name for the root volume (for example, /dev/xvda). Then, under Block devices, find this device name and make note of the volume ID (for example, vol-0a1234b5678c910de).
Step 3: Stop the original instance

Choose **Instance state, Stop instance**. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.

**Warning**
When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

Step 4: Launch a temporary instance

New console

To launch a temporary instance

1. In the navigation pane, choose **Instances**, and then choose **Launch instances**.
2. In the **Name and tags** section, for Name, enter **Temporary**.
3. In the **Application and OS Images** section, select the same AMI that you used to launch the original instance. If this AMI is unavailable, you can create an AMI that you can use from the stopped instance. For more information, see [Create an Amazon EBS-backed Linux AMI](p. 164).
4. In the **Instance type** section, keep the default instance type.
5. In the **Key pair** section, for **Key pair name**, select the existing key pair to use or create a new one.
6. In the **Network settings** section, choose **Edit**, and then for **Subnet**, select a subnet in the same **Availability Zone** as the original instance.
7. In the **Summary** panel, choose **Launch**.

Old console

Choose **Launch instances**, and then use the launch wizard to launch a temporary instance with the following options:

- On the **Choose an AMI** page, select the same AMI that you used to launch the original instance. If this AMI is unavailable, you can create an AMI that you can use from the stopped instance. For more information, see [Create an Amazon EBS-backed Linux AMI](p. 164).
- On the **Choose an Instance Type** page, leave the default instance type that the wizard selects for you.
- On the **Configure Instance Details** page, specify the same **Availability Zone** as the original instance. If you're launching an instance in a VPC, select a subnet in this **Availability Zone**.
- On the **Add Tags** page, add the tag **Name=Temporary** to the instance to indicate that this is a temporary instance.
- On the **Review** page, choose **Launch**. Choose the key pair that you created in Step 1, then choose **Launch Instances**.

Step 5: Detach the root volume from the original instance and attach it to the temporary instance

1. In the navigation pane, choose **Volumes** and select the root device volume for the original instance (you made note of its volume ID in a previous step). Choose **Actions, Detach volume**, and then choose **Detach**. Wait for the state of the volume to become available. (You might need to choose the Refresh icon.)
I've lost my private key. How can I connect to my Linux instance?

2. With the volume still selected, choose Actions, and then choose Attach volume. Select the instance ID of the temporary instance, make note of the device name specified under Device name (for example, /dev/sdf), and then choose Attach volume.

Note
If you launched your original instance from an AWS Marketplace AMI and your volume contains AWS Marketplace codes, you must first stop the temporary instance before you can attach the volume.

Step 6: Add the new public key to authorized_keys on the original volume mounted to the temporary instance

1. Connect to the temporary instance.
2. From the temporary instance, mount the volume that you attached to the instance so that you can access its file system. For example, if the device name is /dev/sdf, use the following commands to mount the volume as /mnt/tempvol.

Note
The device name might appear differently on your instance. For example, devices mounted as /dev/sdf might show up as /dev/xvdf on the instance. Some versions of Red Hat (or its variants, such as CentOS) might even increment the trailing letter by 4 characters, where /dev/sdf becomes /dev/xvdk.

a. Use the lsblk command to determine if the volume is partitioned.

```
[ec2-user ~]$ lsblk
NAME  MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
xvda  202:0   0   8G  0 disk
##xvda1 202:1   0   8G  0 part /
xvdf  202:80   0  101G  0 disk
##xvdf1 202:81   0  101G  0 part
xvdg  202:96   0  300G  0 disk
```

In the preceding example, /dev/xvda and /dev/xvdf are partitioned volumes, and /dev/xvdg is not. If your volume is partitioned, you mount the partition (/dev/xvdf1) instead of the raw device (/dev/xvdf) in the next steps.

b. Create a temporary directory to mount the volume.

```
[ec2-user ~]$ sudo mkdir /mnt/tempvol
```

c. Mount the volume (or partition) at the temporary mount point, using the volume name or device name that you identified earlier. The required command depends on your operating system's file system. Note that the device name might appear differently on your instance. See the note in Step 6 for more information.

- Amazon Linux, Ubuntu, and Debian

```
[ec2-user ~]$ sudo mount /dev/xvdf1 /mnt/tempvol
```

- Amazon Linux 2, CentOS, SUSE Linux 12, and RHEL 7.x

```
[ec2-user ~]$ sudo mount -o nouuid /dev/xvdf1 /mnt/tempvol
```
Note
If you get an error stating that the file system is corrupt, run the following command to use the `fsck` utility to check the file system and repair any issues:

```bash
[ec2-user ~]$ sudo fsck /dev/xvdf1
```

3. From the temporary instance, use the following command to update `authorized_keys` on the mounted volume with the new public key from the `authorized_keys` for the temporary instance.

   **Important**
   The following examples use the Amazon Linux user name `ec2-user`. You might need to substitute a different user name, such as `ubuntu` for Ubuntu instances.

   ```bash
   [ec2-user ~]$ cp .ssh/authorized_keys /mnt/tempvol/home/ec2-user/.ssh
   ``

   If this copy succeeded, you can go to the next step.

   (Optional) Otherwise, if you don't have permission to edit files in `/mnt/tempvol`, you must update the file using `sudo` and then check the permissions on the file to verify that you are able to log into the original instance. Use the following command to check the permissions on the file.

   ```bash
   [ec2-user ~]$ sudo ls -l /mnt/tempvol/home/ec2-user/.ssh
   total 4
   -rw------- 1 222 500 398 Sep 13 22:54 authorized_keys
   ```

   In this example output, `222` is the user ID and `500` is the group ID. Next, use `sudo` to re-run the copy command that failed.

   ```bash
   [ec2-user ~]$ sudo cp .ssh/authorized_keys /mnt/tempvol/home/ec2-user/.ssh/authorized_keys
   ``

   Run the following command again to determine whether the permissions changed.

   ```bash
   [ec2-user ~]$ sudo ls -l /mnt/tempvol/home/ec2-user/.ssh
   ``

   If the user ID and group ID have changed, use the following command to restore them.

   ```bash
   [ec2-user ~]$ sudo chown 222:500 /mnt/tempvol/home/ec2-user/.ssh/authorized_keys
   ``

Step 7: Unmount and detach the original volume from the temporary instance, and reattach it to the original instance

1. From the temporary instance, unmount the volume that you attached so that you can reattach it to the original instance. For example, use the following command to unmount the volume at `/mnt/tempvol`.

   ```bash
   [ec2-user ~]$ sudo umount /mnt/tempvol
   ```

2. Detach the volume from the temporary instance (you unmounted it in the previous step): From the Amazon EC2 console, choose Volumes in the navigation pane, select the root device volume for the original instance (you made note of the volume ID in a previous step), choose Actions, Detach.
volume, and then choose Detach. Wait for the state of the volume to become available. (You might need to choose the Refresh icon.)

3. Reattach the volume to the original instance: With the volume still selected, choose Actions, Attach volume. Select the instance ID of the original instance, specify the device name that you noted earlier in Step 2 (p. 2189) for the original root device attachment (/dev/sda1 or /dev/xvda), and then choose Attach volume.

Important
If you don't specify the same device name as the original attachment, you cannot start the original instance. Amazon EC2 expects the root device volume at sda1 or /dev/xvda.

Step 8: Connect to the original instance using the new key pair

Select the original instance, choose Instance state, Start instance. After the instance enters the running state, you can connect to it using the private key file for your new key pair.

Note
If the name of your new key pair and corresponding private key file is different from the name of the original key pair, ensure that you specify the name of the new private key file when you connect to your instance.

Step 9: Clean up

(Optional) You can terminate the temporary instance if you have no further use for it. Select the temporary instance, and choose Instance state, Terminate instance.

Troubleshoot stopping your instance

If you have stopped your Amazon EBS-backed instance and it appears stuck in the stopping state, there may be an issue with the underlying host computer.

There is no cost for instance usage while an instance is in the stopping state or in any other state except running. You are only charged for instance usage when an instance is in the running state.

Force stop the instance

Force the instance to stop using either the console or the AWS CLI.

Note
You can force an instance to stop using the console only while the instance is in the stopping state. You can force an instance to stop using the AWS CLI while the instance is in any state, except shutting-down and terminated.

New console

To force stop the instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and select the stuck instance.
3. Choose Instance state, Force stop instance, Stop.

Note that Force stop instance is only available in the console if your instance is in the stopping state. If your instance is in another state (except shutting-down and terminated) you can use the AWS CLI to force stop your instance.
Old console

**To force stop the instance using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances** and select the stuck instance.
3. Choose **Instance State, Stop, Yes, Forcefully Stop**.

AWS CLI

**To force stop the instance using the AWS CLI**

Use the `stop-instances` command and the `--force` option as follows:

```
aws ec2 stop-instances --instance-ids i-0123ab456c789d01e --force
```

If, after 10 minutes, the instance has not stopped, post a request for help on AWS re:Post. To help expedite a resolution, include the instance ID, and describe the steps that you’ve already taken. Alternatively, if you have a support plan, create a technical support case in the [Support Center](https://aws.amazon.com/support/).

Create a replacement instance

To attempt to resolve the problem while you are waiting for assistance from AWS re:Post or the Support Center, create a replacement instance. Create an AMI of the stuck instance, and launch a new instance using the new AMI.

**Important**

Creating a replacement instance is recommended if it’s registering system status checks (p. 1175) only, as instance status checks will result in the AMI copying over an exact replica of the broken OS. Once you’ve confirmed the status message, create the AMI and launch a new instance using the new AMI.

New console

**To create a replacement instance using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances** and select the stuck instance.
3. Choose **Actions, Image and templates, Create image**.
4. On the **Create image** page, do the following:
   a. Enter a name and description for the AMI.
   b. Choose **No reboot**.
   c. Choose **Create image**.

   For more information, see [Create a Linux AMI from an instance](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/creating-an-ami-instances.html) (p. 166).

5. Launch a new instance from the AMI and verify that the new instance is working.
6. Select the stuck instance, and choose **Actions, Instance state, Terminate instance**. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.
Old console

To create a replacement instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and select the stuck instance.
4. In the Create Image dialog box, fill in the following fields, and then choose Create Image:
   a. Specify a name and description for the AMI.
   b. Choose No reboot.

For more information, see Create a Linux AMI from an instance (p. 166).
5. Launch a new instance from the AMI and verify that the new instance is working.
6. Select the stuck instance, and choose Actions, Instance State, Terminate. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

AWS CLI

To create a replacement instance using the CLI

1. Create an AMI from the stuck instance using the create-image (AWS CLI) command and the --no-reboot option as follows:

   ```bash
   aws ec2 create-image --instance-id i-0123ab456c789d01e --name "AMI" --description "AMI for replacement instance" --no-reboot
   ```

2. Launch a new instance from the AMI using the run-instances (AWS CLI) command as follows:

   ```bash
   aws ec2 run-instances --image-id ami-1a2b3c4d --count 1 --instance-type c3.large --key-name MyKeyPair --security-groups MySecurityGroup
   ```

3. Verify that the new instance is working.
4. Terminate the stuck instance using the terminate-instances (AWS CLI) command as follows:

   ```bash
   aws ec2 terminate-instances --instance-ids i-1234567890abcdef0
   ```

If you are unable to create an AMI from the instance as described in the previous procedure, you can set up a replacement instance as follows:

(Alternate) To create a replacement instance using the console

1. Select the instance and choose Description, Block devices. Select each volume and make note of its volume ID. Be sure to note which volume is the root volume.
2. In the navigation pane, choose Volumes. Select each volume for the instance, and choose Actions, Create Snapshot.
3. In the navigation pane, choose Snapshots. Select the snapshot that you just created, and choose Actions, Create Volume.
4. Launch an instance with the same operating system as the stuck instance. Note the volume ID and device name of its root volume.
5. In the navigation pane, choose Instances, select the instance that you just launched, and choose Instance state, Stop instance.
6. In the navigation pane, choose **Volumes**, select the root volume of the stopped instance, and choose **Actions, Detach Volume**.

7. Select the root volume that you created from the stuck instance, choose **Actions, Attach Volume**, and attach it to the new instance as its root volume (using the device name that you made note of). Attach any additional non-root volumes to the instance.

8. In the navigation pane, choose **Instances** and select the replacement instance. Choose **Instance state, Start instance**. Verify that the instance is working.

9. Select the stuck instance, choose **Instance state, Terminate instance**. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

---

**Troubleshoot instance termination (shutting down)**

You are not billed for any instance usage while an instance is not in the **running** state. In other words, when you terminate an instance, you stop incurring charges for that instance as soon as its state changes to **shutting-down**.

### Instance terminates immediately

Several issues can cause your instance to terminate immediately on start-up. See [Instance terminates immediately (p. 2174)](#) for more information.

### Delayed instance termination

If your instance remains in the **shutting-down** state longer than a few minutes, it might be delayed due to shutdown scripts being run by the instance.

Another possible cause is a problem with the underlying host computer. If your instance remains in the **shutting-down** state for several hours, Amazon EC2 treats it as a stuck instance and forcibly terminates it.

If it appears that your instance is stuck terminating and it has been longer than several hours, post a request for help to [AWS re:Post](https://aws.amazon.com/support). To help expedite a resolution, include the instance ID and describe the steps that you’ve already taken. Alternatively, if you have a support plan, create a technical support case in the [Support Center](https://aws.amazon.com/support).

### Terminated instance still displayed

After you terminate an instance, it remains visible for a short while before being deleted. The state shows as **terminated**. If the entry is not deleted after several hours, contact Support.

### Error: The instance may not be terminated. Modify its 'disableApiTermination' instance attribute

If you try to terminate an instance and get the **The instance instance_id may not be terminated. Modify its 'disableApiTermination' instance attribute** error message, it indicates that the instance has been enabled for termination protection. Termination protection prevents the instance from being accidentally terminated. For more information, see [Enable termination protection (p. 748)](https://aws.amazon.com/support).

You must disable termination protection before you can terminate the instance.
To disable termination protection using the Amazon EC2 console, select the instance and then choose **Actions, Instance Settings, Change Termination Protection**.

To disable termination protection using the AWS CLI, use the following command.

```
$ aws ec2 modify-instance-attribute --instance-id instance_id --no-disable-api-termination
```

**Instances automatically launched or terminated**

Generally, the following behaviors mean that you've used Amazon EC2 Auto Scaling, EC2 Fleet, or Spot Fleet to scale your computing resources automatically based on criteria that you've defined:

- You terminate an instance and a new instance launches automatically.
- You launch an instance and one of your instances terminates automatically.
- You stop an instance and it terminates and a new instance launches automatically.

To stop automatic scaling, see the [Amazon EC2 Auto Scaling User Guide](https://docs.aws.amazon.com/autoscaling/ec2/userguide/), EC2 Fleet (p. 999), or Create a [Spot Fleet request](https://docs.aws.amazon.com/autoscaling/ec2/userguide/spot-fleet-creation.html) (p. 1095).

**Troubleshoot instances with failed status checks**

The following information can help you troubleshoot issues if your instance fails a status check. First determine whether your applications are exhibiting any problems. If you verify that the instance is not running your applications as expected, review the status check information and the system logs.

For examples of problems that can cause status checks to fail, see [Status checks for your instances](https://docs.aws.amazon.com/autoscaling/ec2/userguide/autoscaling-status-checks.html) (p. 1175).

**Contents**

- Review status check information (p. 2198)
- Retrieve the system logs (p. 2198)
- Troubleshoot system log errors for Linux-based instances (p. 2199)
- Out of memory: kill process (p. 2200)
- ERROR: mmu_update failed (Memory management update failed) (p. 2200)
- I/O error (block device failure) (p. 2201)
- I/O ERROR: neither local nor remote disk (Broken distributed block device) (p. 2202)
- request_module: runaway loop modprobe (Looping legacy kernel modprobe on older Linux versions) (p. 2203)
- "FATAL: kernel too old" and "fsck: No such file or directory while trying to open /dev" (Kernel and AMI mismatch) (p. 2204)
- "FATAL: Could not load /lib/modules" or "BusyBox" (Missing kernel modules) (p. 2204)
- ERROR Invalid kernel (EC2 incompatible kernel) (p. 2206)
- fsck: No such file or directory while trying to open... (File system not found) (p. 2207)
- General error mounting filesystems (failed mount) (p. 2208)
- VFS: Unable to mount root fs on unknown-block (Root filesystem mismatch) (p. 2209)
- Error: Unable to determine major/minor number of root device... (Root file system/device mismatch) (p. 2210)
Review status check information

To investigate impaired instances using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select your instance.
3. In the details pane, choose Status Checks to see the individual results for all System Status Checks
   and Instance Status Checks.

If a system status check has failed, you can try one of the following options:

- Create an instance recovery alarm. For more information, see Create alarms that stop, terminate,
  reboot, or recover an instance (p. 1229).
- If you changed the instance type to an instance built on the Nitro System (p. 282), status checks fail
  if you migrated from an instance that does not have the required ENA and NVMe drivers. For more
  information, see Compatibility for changing the instance type (p. 452).
- For an instance using an Amazon EBS-backed AMI, stop and restart the instance.
- For an instance using an instance-store backed AMI, terminate the instance and launch a replacement.
- Wait for Amazon EC2 to resolve the issue.
- Post your issue to AWS re:Post.
- If your instance is in an Auto Scaling group, the Amazon EC2 Auto Scaling service automatically
  launches a replacement instance. For more information, see Health Checks for Auto Scaling Instances
  in the Amazon EC2 Auto Scaling User Guide.
- Retrieve the system log and look for errors.

Retrieve the system logs

If an instance status check fails, you can reboot the instance and retrieve the system logs. The logs may
reveal an error that can help you troubleshoot the issue. Rebooting clears unnecessary information from
the logs.

To reboot an instance and retrieve the system log

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and select your instance.
3. Choose Instance state, Reboot instance. It might take a few minutes for your instance to reboot.
4. Verify that the problem still exists; in some cases, rebooting may resolve the problem.
5. When the instance is in the running state, choose Actions, Monitor and troubleshoot, Get system log.
6. Review the log that appears on the screen, and use the list of known system log error statements below to troubleshoot your issue.
7. If your experience differs from our check results, or if you are having an issue with your instance that our checks did not detect, choose Submit feedback on the Status Checks tab to help us improve our detection tests.
8. If your issue is not resolved, you can post your issue to AWS re:Post.

Troubleshoot system log errors for Linux-based instances

For Linux-based instances that have failed an instance status check, such as the instance reachability check, verify that you followed the steps above to retrieve the system log. The following list contains some common system log errors and suggested actions you can take to resolve the issue for each error.

Memory Errors

- Out of memory: kill process (p. 2200)
- ERROR: mmu_update failed (Memory management update failed) (p. 2200)

Device Errors

- I/O error (block device failure) (p. 2201)
- I/O ERROR: neither local nor remote disk (Broken distributed block device) (p. 2202)

Kernel Errors

- request_module: runaway loop modprobe (Looping legacy kernel modprobe on older Linux versions) (p. 2203)
- "FATAL: kernel too old" and "fsck: No such file or directory while trying to open /dev" (Kernel and AMI mismatch) (p. 2204)
- "FATAL: Could not load /lib/modules" or "BusyBox" (Missing kernel modules) (p. 2204)
- ERROR Invalid kernel (EC2 incompatible kernel) (p. 2206)

File System Errors

- fsck: No such file or directory while trying to open... (File system not found) (p. 2207)
- General error mounting filesystems (failed mount) (p. 2208)
- VFS: Unable to mount root fs on unknown-block (Root filesystem mismatch) (p. 2209)
- Error: Unable to determine major/minor number of root device... (Root file system/device mismatch) (p. 2210)
- XENBUS: Device with no driver... (p. 2211)
- ... days without being checked, check forced (File system check required) (p. 2212)
- fsck died with exit status... (Missing device) (p. 2213)

Operating System Errors
• GRUB prompt (grubdom>) (p. 2213)
• Bringing up interface eth0: Device eth0 has different MAC address than expected, ignoring. (Hard-coded MAC address) (p. 2215)
• Unable to load SELinux Policy. Machine is in enforcing mode. Halting now. (SELinux misconfiguration) (p. 2216)
• XENBUS: Timeout connecting to devices (Xenbus timeout) (p. 2217)

Out of memory: kill process

An out-of-memory error is indicated by a system log entry similar to the one shown below.

```
[115879.769795] Out of memory: kill process 20273 (httpd) score 1285879
or a child
```

Potential cause

Exhausted memory

</tbody>
</table>

I/O ERROR: neither local nor remote disk (Broken distributed block device)

An input/output error on the device is indicated by a system log entry similar to the following example:

```
...
block drbd1: Local I/O failed in request_timer_fn. Detaching...
Aborting journal on device drbd1-8.
block drbd1: **I/O ERROR: neither local nor remote disk**
Buffer I/O error on device drbd1, logical block 557056
lost page write due to I/O error on drbd1
JBD2: I/O error detected when updating journal superblock for drbd1-8.
```

Potential causes

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Potential cause</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon EBS-backed</td>
<td>A failed Amazon EBS volume</td>
</tr>
</tbody>
</table>
Suggested action

Terminate the instance and launch a new instance.

For an Amazon EBS-backed instance you can recover data from a recent snapshot by creating an image from it. Any data added after the snapshot cannot be recovered.

request_module: runaway loop modprobe (Looping legacy kernel modprobe on older Linux versions)

This condition is indicated by a system log similar to the one shown below. Using an unstable or old Linux kernel (for example, 2.6.16-xenU) can cause an interminable loop condition at startup.

```
Linux version 2.6.16-xenU (builder@xenbat.amazonsa) (gcc version 4.0.1 20050727 (Red Hat 4.0.1-5)) #1 SMP Mon May 28 03:41:49 SAST 2007
BIOS-provided physical RAM map:
  Xen: 0000000000000000 - 0000000026700000 (usable)
0MB HIGHMEM available.
...
request_module: runaway loop modprobe binfmt-464c
request_module: runaway loop modprobe binfmt-464c
request_module: runaway loop modprobe binfmt-464c
request_module: runaway loop modprobe binfmt-464c
request_module: runaway loop modprobe binfmt-464c
```

<td>Use the following procedure: 1. Stop the instance. 2. Modify the configuration to use a newer kernel. 3. Start the instance.</td>
</tr>
<tr>
<td>Instance store-backed</td>
<td>Use the following procedure: 1. Create an AMI that uses a newer kernel. 2. Terminate the instance. 3. Start a new instance from the AMI you created.</td>
</tr>
</tbody>
</table>
Potential causes

One or more of the following conditions can cause this problem:

- Missing ramdisk
- Missing correct modules from ramdisk
- Amazon EBS root volume not correctly attached as /dev/sda1

Suggested actions

For this instance type | Do this
---|---
Amazon EBS-backed | Use the following procedure:
1. Select corrected ramdisk for the Amazon EBS volume.
2. Stop the instance.
3. Detach the volume and repair it.
4. Attach the volume to the instance.
5. Start the instance.
6. Modify the AMI to use the corrected ramdisk.

Instance store-backed | Use the following procedure:
1. Terminate the instance and launch a new instance with the correct ramdisk.
2. Create a new AMI with the correct ramdisk.
ERROR Invalid kernel (EC2 incompatible kernel)

This condition is indicated by a system log similar to the one shown below.

```
... root (hd0)
  Filesystem type is ext2fs, using whole disk
  kernel /vmlinuz root=/dev/sda1 ro
  initrd /initrd.img
  ERROR Invalid kernel: elf_xen_note_check: ERROR: Will only load images
  built for the generic loader or Linux images
  xc_dom_parse_image returned -1
  Error 9: Unknown boot failure
  Booting 'Fallback'
  root (hd0)
  Filesystem type is ext2fs, using whole disk
  kernel /vmlinuz.old root=/dev/sda1 ro
  Error 15: File not found
```

Potential causes

One or both of the following conditions can cause this problem:

- Supplied kernel is not supported by GRUB
- Fallback kernel does not exist

Suggested actions

<table>
<thead>
<tr>
<th>For this instance type</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon EBS-backed</td>
<td>Use the following procedure:</td>
</tr>
<tr>
<td></td>
<td>1. Stop the instance.</td>

### Potential causes

- A bug exists in ramdisk filesystem definitions /etc/fstab
- Misconfigured filesystem definitions in /etc/fstab
- Missing/failed drive

### Suggested actions

<table>
<thead>
<tr>
<th>For this instance type</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon EBS-backed</td>
<td>Use the following procedure:</td>
</tr>
<tr>
<td></td>
<td>1. Stop the instance, detach the root volume, repair/modify /etc/fstab the volume, attach the volume to the instance, and start the instance.</td>
</tr>
<tr>
<td>For this instance type</td>
<td>Do this</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
|                       | 2. Fix ramdisk to include modified /etc/fstab (if applicable).  
|                       | 3. Modify the AMI to use a newer ramdisk. |

The sixth field in the fstab defines availability requirements of the mount – a nonzero value implies that an fsck will be done on that volume and must succeed. Using this field can be problematic in Amazon EC2 because a failure typically results in an interactive console prompt that is not currently available in Amazon EC2. Use care with this feature and read the Linux man page for fstab.

<table>

**Troubleshoot an unreachable instance**

You can use the following methods to troubleshoot an unreachable Linux instance. For information about troubleshooting an unreachable Windows instance, see Troubleshoot an unreachable instance.

**Contents**

- Instance reboot (p. 2218)
- Instance console output (p. 2218)
- Capture a screenshot of an unreachable instance (p. 2219)
- Instance recovery when a host computer fails (p. 2220)

**Instance reboot**

The ability to reboot instances that are otherwise unreachable is valuable for both troubleshooting and general instance management.

Just as you can reset a computer by pressing the reset button, you can reset EC2 instances using the Amazon EC2 console, CLI, or API. For more information, see Reboot your instance (p. 742)

**Instance console output**

Console output is a valuable tool for problem diagnosis. It is especially useful for troubleshooting kernel problems and service configuration issues that could cause an instance to terminate or become unreachable before its SSH daemon can be started.

For Linux/Unix, the instance console output displays the exact console output that would normally be displayed on a physical monitor attached to a computer. The console output returns buffered information that was posted shortly after an instance transition state (start, stop, reboot, and terminate). The posted output is not continuously updated; only when it is likely to be of the most value.

For Windows instances, the instance console output includes the last three system event log errors.
You can optionally retrieve the latest serial console output at any time during the instance lifecycle. This option is only supported on Instances built on the Nitro System (p. 282). It is not supported through the Amazon EC2 console.

**Note**
Only the most recent 64 KB of posted output is stored, which is available for at least 1 hour after the last posting.

Only the instance owner can access the console output. You can retrieve the console output for your instances using the console or the command line.

Use one of the following methods to get console output.

**New console**

**To get console output**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances**, and select the instance.
3. Choose **Actions, Monitor and troubleshoot, Get system log**.

**Old console**

**To get console output**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose **Instances**, and select the instance.
3. Choose **Actions, Instance Settings, Get System Log**.

**Command line**

**To get console output**

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

For more information about common system log errors, see Troubleshoot system log errors for Linux-based instances (p. 2199).

**Capture a screenshot of an unreachable instance**

If you are unable to reach your instance via SSH or RDP, you can capture a screenshot of your instance and view it as an image. The image can provide visibility as to the status of the instance, and allows for quicker troubleshooting. You can generate screenshots while the instance is running or after it has crashed. There is no data transfer cost for this screenshot. The image is generated in JPG format and is no larger than 100 kb. This feature is not supported when the instance is using an NVIDIA GRID driver, is on bare metal instances (instances of type *.metal*), or is powered by Arm-based Graviton or Graviton 2 processors. This feature is available in the following Regions:

- US East (N. Virginia) Region
- US East (Ohio) Region
- US West (Oregon) Region
- US West (N. California) Region
To access the instance console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose Instances.
3. Select the instance to capture.
4. Choose Actions, Monitor and troubleshoot.
5. Choose Get instance screenshot.

Right-click the image to download and save it.

To capture a screenshot using the command line

You can use one of the following commands. The returned content is base64-encoded. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- get-console-screenshot (AWS CLI)
- GetConsoleScreenshot (Amazon EC2 Query API)

Instance recovery when a host computer fails

If there is an unrecoverable issue with the hardware of an underlying host computer, AWS may schedule an instance stop event. You are notified of such an event ahead of time by email.

To recover an Amazon EBS-backed instance running on a host computer that failed

1. Back up any important data on your instance store volumes to Amazon EBS or Amazon S3.
2. Stop the instance.
3. Start the instance.
4. Restore any important data.

For more information, see Stop and start your instance (p. 718).

To recover an instance store-backed instance running on a host computer that failed

1. Create an AMI from the instance.
2. Upload the image to Amazon S3.
3. Back up important data to Amazon EBS or Amazon S3.
4. Terminate the instance.
5. Launch a new instance from the AMI.
6. Restore any important data to the new instance.

For more information, see Create an instance store-backed Linux AMI (p. 169).

Boot from the wrong volume

In some situations, you may find that a volume other than the volume attached to /dev/xvda or /dev/sda has become the root volume of your instance. This can happen when you have attached the root volume of another instance, or a volume created from the snapshot of a root volume, to an instance with an existing root volume.

This is due to how the initial ramdisk in Linux works. It chooses the volume defined as / in the /etc/fstab, and in some distributions, this is determined by the label attached to the volume partition. Specifically, you find that your /etc/fstab looks something like the following:

<table>
<thead>
<tr>
<th>LABEL=/</th>
<th>/</th>
<th>ext4 defaults,noatime 1 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>tmpfs /dev/shm tmpfs defaults 0 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>devpts /dev/pts devpts gid=5,mode=620 0 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>sysfs /sys sysfs defaults 0 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>proc /proc proc defaults 0 0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If you check the label of both volumes, you see that they both contain the / label:

```
[ec2-user ~]$ sudo e2label /dev/xvda1 /  
[ec2-user ~]$ sudo e2label /dev/xvdf1 /  
```

In this example, you could end up having /dev/xvdf1 become the root device that your instance boots to after the initial ramdisk runs, instead of the /dev/xvda1 volume from which you had intended to boot. To solve this, use the same e2label command to change the label of the attached volume that you do not want to boot from.

In some cases, specifying a UUID in /etc/fstab can resolve this. However, if both volumes come from the same snapshot, or the secondary is created from a snapshot of the primary volume, they share a UUID.

```
[ec2-user ~]$ sudo blkid  
/dev/xvda1: LABEL="/" UUID=73947a77-ddbe-4dc7-bd8f-3fe0bc840778 TYPE="ext4"  
PARTLABEL="Linux" PARTUUID=d55925ee-72c8-41e7-b514-7084e28f7334  
/dev/xvdf1: LABEL="/old/" UUID=73947a77-ddbe-4dc7-bd8f-3fe0bc840778 TYPE="ext4"  
PARTLABEL="Linux" PARTUUID=d55925ee-72c8-41e7-b514-7084e28f7334  
```

To change the label of an attached ext4 volume

1. Use the e2label command to change the label of the volume to something other than /.

```
[ec2-user ~]$ sudo e2label /dev/xvdf1 old/  
```

2. Verify that the volume has the new label.

```
[ec2-user ~]$ sudo e2label /dev/xvdf1 old/  
```
To change the label of an attached xfs volume

- Use the `xfs_admin` command to change the label of the volume to something other than `/`.

```bash
[ec2-user ~]$ sudo xfs_admin -L old/ /dev/xvdf1
writing all SBs
new label = "old/"
```

After changing the volume label as shown, you should be able to reboot the instance and have the proper volume selected by the initial ramdisk when the instance boots.

**Important**

If you intend to detach the volume with the new label and return it to another instance to use as the root volume, you must perform the above procedure again and change the volume label back to its original value. Otherwise, the other instance does not boot because the ramdisk is unable to find the volume with the label `/`.

---

**Use EC2Rescue for Linux**

EC2Rescue for Linux is an easy-to-use, open-source tool that can be run on an Amazon EC2 Linux instance to diagnose and troubleshoot common issues using its library of over 100 modules. A few generalized use cases for EC2Rescue for Linux include gathering syslog and package manager logs, collecting resource utilization data, and diagnosing/remediating known problematic kernel parameters and common OpenSSS issues.

The AWS Support - TroubleshootSSH runbook installs EC2Rescue for Linux and then uses the tool to check or attempt to fix common issues that prevent a remote connection to a Linux machine via SSH. For more information, and to run this automation, see [AWS Support - TroubleshootSSH](https://aws-support.github.io/tutorials/troubleshootssh).

If you are using a Windows instance, see [EC2Rescue for Windows Server](https://aws-support.github.io/tutorials/EC2RescueForWindowsServer).

### Contents

- [Install EC2Rescue for Linux (p. 2222)](#)
- [Work with EC2Rescue for Linux (p. 2226)](#)
- [Develop EC2Rescue modules (p. 2228)](#)

---

**Install EC2Rescue for Linux**

**Note**

We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see [TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints](https://aws-support.github.io/tutorials/EC2RescueForLinux).

The EC2Rescue for Linux tool can be installed on an Amazon EC2 Linux instance that meets the following prerequisites.

**Prerequisites**

- Supported operating systems:
  - Amazon Linux 2
  - Amazon Linux 2016.09+
  - SUSE Linux Enterprise Server 12+
  - RHEL 7+
• Ubuntu 16.04+
• Software requirements:
  • Python 2.7.9+ or 3.2+

The AWSSupport-TroubleshootSSH runbook installs EC2Rescue for Linux and then uses the tool to check or attempt to fix common issues that prevent a remote connection to a Linux machine via SSH. For more information, and to run this automation, see AWS Support-TroubleshootSSH.

If your system has the required Python version, you can install the standard build. Otherwise, you can install the bundled build, which includes a minimal copy of Python.

**To install the standard build**

1. From a working Linux instance, download the EC2Rescue for Linux tool:
   ```bash
curl -O https://s3.amazonaws.com/ec2rescuelinux/ec2rl.tgz
   ```
2. (Optional) Before proceeding, you can optionally verify the signature of the EC2Rescue for Linux installation file. For more information, see (Optional) Verify the signature of EC2Rescue for Linux (p. 2223).
3. Download the sha256 hash file:
   ```bash
curl -O https://s3.amazonaws.com/ec2rescuelinux/ec2rl.tgz.sha256
   ```
4. Verify the integrity of the tarball:
   ```bash
sha256sum -c ec2rl.tgz.sha256
   ```
5. Unpack the tarball:
   ```bash
tar -xzvf ec2rl.tgz
   ```
6. Verify the installation by listing out the help file:
   ```bash
cd ec2rl-Version_number>/ec2rl help
   ```

**To install the bundled build**

For a link to the download and a list of limitations, see EC2Rescue for Linux on github.

**(Optional) Verify the signature of EC2Rescue for Linux**

The following is the recommended process of verifying the validity of the EC2Rescue for Linux package for Linux-based operating systems.

When you download an application from the internet, we recommend that you authenticate the identity of the software publisher and check that the application has not been altered or corrupted after it was published. This protects you from installing a version of the application that contains a virus or other malicious code.

If, after running the steps in this topic, you determine that the software for EC2Rescue for Linux is altered or corrupted, do not run the installation file. Instead, contact Amazon Web Services.
EC2Rescue for Linux files for Linux-based operating systems are signed using GnuPG, an open-source implementation of the Pretty Good Privacy (OpenPGP) standard for secure digital signatures. GnuPG (also known as GPG) provides authentication and integrity checking through a digital signature. AWS publishes a public key and signatures that you can use to verify the downloaded EC2Rescue for Linux package. For more information about PGP and GnuPG (GPG), see http://www.gnupg.org.

The first step is to establish trust with the software publisher. Download the public key of the software publisher, check that the owner of the public key is who they claim to be, and then add the public key to your keyring. Your keyring is a collection of known public keys. After you establish the authenticity of the public key, you can use it to verify the signature of the application.

Tasks
- Install the GPG tools (p. 2224)
- Authenticate and import the public key (p. 2224)
- Verify the signature of the package (p. 2225)

Install the GPG tools

If your operating system is Linux or Unix, the GPG tools may already be installed. To test whether the tools are installed on your system, enter gpg2 at a command prompt. If the GPG tools are installed, you see a GPG command prompt. If the GPG tools are not installed, you see an error stating that the command cannot be found. You can install the GnuPG package from a repository.

To install GPG tools on Debian-based Linux

- From a terminal, run the following command:
  
  ```bash
  apt-get install gnupg2
  ```

To install GPG tools on Red Hat-based Linux

- From a terminal, run the following command:
  
  ```bash
  yum install gnupg2
  ```

Authenticate and import the public key

The next step in the process is to authenticate the EC2Rescue for Linux public key and add it as a trusted key in your GPG keyring.

To authenticate and import the EC2Rescue for Linux public key

1. At a command prompt, use the following command to obtain a copy of our public GPG build key:

   ```bash
   curl -O https://s3.amazonaws.com/ec2rescuelinux/ec2rl.key
   ```

2. At a command prompt in the directory where you saved ec2rl.key, use the following command to import the EC2Rescue for Linux public key into your keyring:

   ```bash
   gpg2 --import ec2rl.key
   ```

   The command returns results similar to the following:
Verify the signature of the package

After you've installed the GPG tools, authenticated and imported the EC2Rescue for Linux public key, and verified that the EC2Rescue for Linux public key is trusted, you are ready to verify the signature of the EC2Rescue for Linux installation script.

To verify the EC2Rescue for Linux installation script signature

1. At a command prompt, run the following command to download the signature file for the installation script:

   curl -O https://s3.amazonaws.com/ec2rescuelinux/ec2rl.tgz.sig

2. Verify the signature by running the following command at a command prompt in the directory where you saved ec2rl.tgz.sig and the EC2Rescue for Linux installation file. Both files must be present.

   gpg2 --verify ./ec2rl.tgz.sig

The output should look something like the following:

   gpg: Signature made Thu 12 Jul 2018 01:57:51 AM UTC using RSA key ID 6991ED45
   gpg: Good signature from "ec2autodiag@amazon.com <EC2 Rescue for Linux>"
   gpg: WARNING: This key is not certified with a trusted signature!
   Primary key fingerprint: E528 BCC9 0DBF 0F6C C36A F780 4843 2FAE 2A1C
   Subkey fingerprint: 966B 0D27 85E9 AEEC 1146 7A9D 8851 1153 6991 ED45

If the output contains the phrase Good signature from "ec2autodiag@amazon.com <EC2 Rescue for Linux>", it means that the signature has successfully been verified, and you can proceed to run the EC2Rescue for Linux installation script.

If the output includes the phrase BAD signature, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services and do not run the installation file that you downloaded previously.

The following are details about the warnings that you might see:

- **WARNING: This key is not certified with a trusted signature! There is no indication that the signature belongs to the owner.** This refers to your personal level of trust in your belief that you possess an authentic public key for EC2Rescue for Linux. In an ideal world, you would visit an Amazon Web Services office and receive the key in person. However, more often you download it from a website. In this case, the website is an Amazon Web Services website.

- **gpg2: no ultimately trusted keys found.** This means that the specific key is not "ultimately trusted" by you (or by other people whom you trust).

For more information, see [http://www.gnupg.org](http://www.gnupg.org).
Work with EC2Rescue for Linux

The following are common tasks you can perform to get started using this tool.

Tasks

- Run EC2Rescue for Linux (p. 2226)
- Upload the results (p. 2226)
- Create backups (p. 2227)
- Get help (p. 2227)

Run EC2Rescue for Linux

You can run EC2Rescue for Linux as shown in the following examples.

Example Example: Run all modules

To run all modules, run EC2Rescue for Linux with no options:

```
./ec2rl run
```

Some modules require root access. If you are not a root user, use `sudo` to run these modules as follows:

```
sudo ./ec2rl run
```

Example Example: Run a specific module

To run only specific modules, use the `--only-modules` parameter:

```
./ec2rl run --only-modules=module_name --arguments
```

For example, this command runs the `dig` module to query the `amazon.com` domain:

```
./ec2rl run --only-modules=dig --domain=amazon.com
```

Example Example: View the results

You can view the results in `/var/tmp/ec2rl`:

```
cat /var/tmp/ec2rl/logfile_location
```

For example, view the log file for the `dig` module:

```
cat /var/tmp/ec2rl/2017-05-11T15_39_21.893145/mod_out/run/dig.log
```

Upload the results

If AWS Support has requested the results or to share the results from an S3 bucket, upload them using the EC2Rescue for Linux CLI tool. The output of the EC2Rescue for Linux commands should provide the commands that you need to use.
Example Example: Upload results to AWS Support

```
./ec2rl upload --upload-directory=/var/tmp/ec2rl/2017-05-11T15_39_21.893145 --support-url="URLProvidedByAWSSupport"
```

Example Example: Upload results to an S3 bucket

```
./ec2rl upload --upload-directory=/var/tmp/ec2rl/2017-05-11T15_39_21.893145 --presigned-url="YourPresignedS3URL"
```

For more information about generating pre-signed URLs for Amazon S3, see *Uploading Objects Using Pre-Signed URLs*.

**Create backups**

Create a backup for your instance, one or more volumes, or a specific device ID using the following commands.

**Example Example: Back up an instance using an Amazon Machine Image (AMI)**

```
./ec2rl run --backup=ami
```

**Example Example: Back up all volumes associated with the instance**

```
./ec2rl run --backup=allvolumes
```

**Example Example: Back up a specific volume**

```
./ec2rl run --backup=volumeID
```

**Get help**

EC2Rescue for Linux includes a help file that gives you information and syntax for each available command.

**Example Example: Display the general help**

```
./ec2rl help
```

**Example Example: List the available modules**

```
./ec2rl list
```

**Example Example: Display the help for a specific module**

```
./ec2rl help module_name
```

For example, use the following command to show the help file for the *dig* module:

```
./ec2rl help dig
```
Develop EC2Rescue modules

Modules are written in YAML, a data serialization standard. A module's YAML file consists of a single document, representing the module and its attributes.

Add module attributes

The following table lists the available module attributes.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the module. The name should be less than or equal to 18 characters in length.</td>
</tr>
<tr>
<td>version</td>
<td>The version number of the module.</td>
</tr>
<tr>
<td>title</td>
<td>A short, descriptive title for the module. This value should be less than or equal to 50 characters in length.</td>
</tr>
<tr>
<td>helptext</td>
<td>The extended description of the module. Each line should be less than or equal to 75 characters in length. If the module consumes arguments, required or optional, include them in the helptext value. For example:</td>
</tr>
</tbody>
</table>
|           | ```
|           |  helptext: !!str |
|           | Collect output from ps for system analysis
|           | Consumes --times= for number of times to repeat
<p>|           | Consumes --period= for time period between repetition |
| placement | The stage in which the module should be run. Supported values: |
|           | • prediagnostic |
|           | • run |
|           | • postdiagnostic |
| language  | The language that the module code is written in. Supported values: |
|           | • bash |
|           | • python |
|           | <strong>Note</strong> |
|           | Python code must be compatible with both Python 2.7.9+ and Python 3.2+. |
| remediation | Indicates whether the module supports remediation. Supported values are True or False. |</p>
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>content</td>
<td>The entirety of the script code.</td>
</tr>
<tr>
<td>constraint</td>
<td>The name of the object containing the constraint values.</td>
</tr>
</tbody>
</table>
| domain    | A descriptor of how the module is grouped or classified. The set of included modules uses the following domains:  
  - application  
  - net  
  - os  
  - performance |
| class     | A descriptor of the type of task performed by the module. The set of included modules uses the following classes:  
  - collect (collects output from programs)  
  - diagnose (pass/fail based on a set of criteria)  
  - gather (copies files and writes to specific file) |
| distro    | The list of Linux distributions that this module supports. The set of included modules uses the following distributions:  
  - alami (Amazon Linux)  
  - rhel  
  - ubuntu  
  - suse |
| required  | The required arguments that the module is consuming from the CLI options. |
| optional  | The optional arguments that the module can use. |
| software  | The software executables used in the module. This attribute is intended to specify software that is not installed by default. The EC2Rescue for Linux logic ensures that these programs are present and executable before running the module. |
| package   | The source software package for an executable. This attribute is intended to provide extended details on the package with the software, including a URL for downloading or getting further information. |
### Develop EC2Rescue modules

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sudo</td>
<td>Indicates whether root access is required to run the module. You do not need to implement sudo checks in the module script. If the value is true, then the EC2Rescue for Linux logic only runs the module when the executing user has root access.</td>
</tr>
<tr>
<td>perfimpact</td>
<td>Indicates whether the module can have significant performance impact upon the environment in which it is run. If the value is true and the --perfimpact=true argument is not present, then the module is skipped.</td>
</tr>
<tr>
<td>parallelexclusive</td>
<td>Specifies a program that requires mutual exclusivity. For example, all modules specifying &quot;bpf&quot; run in a serial manner.</td>
</tr>
</tbody>
</table>

### Add environment variables

The following table lists the available environment variables.

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EC2RL_CALLPATH</td>
<td>The path to ec2rl.py. This path can be used to locate the lib directory and use vendored Python modules.</td>
</tr>
<tr>
<td>EC2RL_WORKDIR</td>
<td>The main tmp directory for the diagnostic tool. Default value: /var/tmp/ec2rl.</td>
</tr>
<tr>
<td>EC2RL_RUNDIR</td>
<td>The directory where all output is stored. Default value: /var/tmp/ec2rl/&lt;date&amp;timestamp&gt;.</td>
</tr>
<tr>
<td>EC2RL_GATHEREDDIR</td>
<td>The root directory for placing gathered module data. Default value: /var/tmp/ec2rl/&lt;date&amp;timestamp&gt;/mod_out/gathered/.</td>
</tr>
<tr>
<td>EC2RL_NET_DRIVER</td>
<td>The driver in use for the first, alphabetically ordered, non-virtual network interface on the instance. Examples: xen_netfront, ixgbevf, ena</td>
</tr>
<tr>
<td>EC2RL_SUDO</td>
<td>True if EC2Rescue for Linux is running as root; otherwise, false.</td>
</tr>
<tr>
<td>Environment Variable</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>EC2RL_VIRT_TYPE</td>
<td>The virtualization type as provided by the instance metadata.</td>
</tr>
<tr>
<td></td>
<td>Examples:</td>
</tr>
<tr>
<td></td>
<td>• default-hvm</td>
</tr>
<tr>
<td></td>
<td>• default-paravirtual</td>
</tr>
<tr>
<td>EC2RL_INTERFACES</td>
<td>An enumerated list of interfaces on the system. The value is a string containing names, such as eth0, eth1, etc. This is generated via the functions.bash and is only available for modules that have sourced it.</td>
</tr>
</tbody>
</table>

Use YAML syntax

The following should be noted when constructing your module YAML files:

- The triple hyphen (---) denotes the explicit start of a document.
- The !ec2rlcore.module.Module tag tells the YAML parser which constructor to call when creating the object from the data stream. You can find the constructor inside the module.py file.
- The !!str tag tells the YAML parser to not attempt to determine the type of data, and instead interpret the content as a string literal.
- The pipe character (|) tells the YAML parser that the value is a literal-style scalar. In this case, the parser includes all whitespace. This is important for modules because indentation and newline characters are kept.
- The YAML standard indent is two spaces, which can be seen in the following examples. Ensure that you maintain standard indentation (for example, four spaces for Python) for your script and then indent the entire content two spaces inside the module file.

Example modules

Example one (mod.d/ps.yaml):

```yaml
--- !ec2rlcore.module.Module
# Module document. Translates directly into an almost-complete Module object
name: !!str ps
path: !!str
version: !!str 1.0
title: !!str Collect output from ps for system analysis
helptext: !!str |
   Collect output from ps for system analysis
   Requires --times= for number of times to repeat
   Requires --period= for time period between repetition
placement: !!str run
package:
   - !!str
language: !!str bash
content: !!str |
   #!/bin/bash
error_trap()
{
   printf "%0.s=" {1..80}
   echo -e "\nERROR: "$BASH_COMMAND" exited with an error on line "$BASH_LINENO[0]"\n"```
EC2 Serial Console for Linux instances

With the EC2 serial console, you have access to your Amazon EC2 instance's serial port, which you can use to troubleshoot boot, network configuration, and other issues. The serial console does not require your instance to have any networking capabilities. With the serial console, you can enter commands to an instance as if your keyboard and monitor are directly attached to the instance's serial port. The serial console session lasts during instance reboot and stop. During reboot, you can view all of the boot messages from the start.

Access to the serial console is not available by default. Your organization must grant account access to the serial console and configure IAM policies to grant your users access to the serial console. Serial console access can be controlled at a granular level by using instance IDs, resource tags, and other IAM levers. For more information, see Configure access to the EC2 Serial Console (p. 2234).

The serial console can be accessed by using the EC2 console or the AWS CLI.

The serial console is available at no additional cost.

If you are using a Windows instance, see EC2 Serial Console for Windows instances in the Amazon EC2 User Guide for Windows Instances.

Topics

- Prerequisites (p. 2232)
- Configure access to the EC2 Serial Console (p. 2234)
- Connect to the EC2 Serial Console (p. 2240)
- Terminate an EC2 Serial Console session (p. 2244)
- Troubleshoot your Linux instance using the EC2 Serial Console (p. 2245)

Prerequisites

To connect to the EC2 Serial Console, the following prerequisites must be in place:

```bash
exit 0
}
trap error_trap ERR

# read-in shared function
source functions.bash

echo "I will collect `ps auxww` from this $EC2RL_DISTRO box for $times times every $period seconds."

for i in $(seq 1 $times); do
  `ps auxww`
  sleep $period
done

constraint:
  requires_ec2: !!str False
  domain: !!str performance
  class: !!str collect
  distro: !!str alami ubuntu rhel suse
  required: !!str period times
  optional: !!str
  software: !!str
  sudo: !!str False
  perfimpact: !!str False
  parallelexclusive: !!str
```
AWS Regions

Supported in the following AWS Regions:

- US East (N. Virginia), US East (Ohio), US West (N. California), US West (Oregon)
- Asia Pacific (Mumbai), Asia Pacific (Seoul), Asia Pacific (Singapore), Asia Pacific (Sydney), Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt), Europe (Ireland), Europe (London), Europe (Paris), Europe (Stockholm)
- South America (São Paulo)
- AWS GovCloud (US-East), AWS GovCloud (US-West)

Wavelength Zones and AWS Outposts

Not supported.

Local Zones

Supported in the following Local Zones:

- Dallas, US
  
  Local Zone name: us-east-1-dfw-1a
  
  Parent Region: US East (N. Virginia)
- Los Angeles, US
  
  Local Zone names: us-west-2-lax-1a, us-west-2-lax-1b
  
  Parent Region: US West (Oregon)

Instance types

Supported instance types:

- All virtualized instances built on the Nitro System (p. 283).
- All bare metal instances except:
  
  - General purpose: a1.metal, mac1.metal, mac2.metal
  
  - Accelerated computing: g5g.metal
• Memory optimized: u-6tb1.metal, u-9tb1.metal, u-12tb1.metal, u-18tb1.metal, u-24tb1.metal

Grant access

You must complete the configuration tasks to grant access to the EC2 Serial Console. For more information, see Configure access to the EC2 Serial Console (p. 2234).

Support for browser-based client

To connect to the serial console using the browser-based client (p. 2240), your browser must support WebSocket. If your browser does not support WebSocket, connect to the serial console using your own key and an SSH client. (p. 2241)

Instance state

Must be running.

You can't connect to the serial console if the instance is in the pending, stopping, stopped, shutting-down, or terminated state.

For more information about the instance states, see Instance lifecycle (p. 670).

Amazon EC2 Systems Manager

If the instance uses Amazon EC2 Systems Manager, then SSM Agent version 3.0.854.0 or later must be installed on the instance. For information about SSM Agent, see Working with SSM Agent in the AWS Systems Manager User Guide.

sshd server

You do not need an sshd server installed or running on your instance.

Configure access to the EC2 Serial Console

To configure access to the serial console, you must grant serial console access at the account level and then configure IAM policies to grant access to your users. You must also configure a password-based user on every instance so that your users can use the serial console for troubleshooting.

Topics

• Levels of access to the EC2 Serial Console (p. 2234)
• Manage account access to the EC2 Serial Console (p. 2235)
• Configure IAM policies for EC2 Serial Console access (p. 2237)
• Set an OS user password (p. 2239)

Levels of access to the EC2 Serial Console

By default, there is no access to the serial console at the account level. You need to explicitly grant access to the serial console at the account level. For more information, see Manage account access to the EC2 Serial Console (p. 2235).
You can use a service control policy (SCP) to allow access to the serial console within your organization. You can then have granular access control at the user level by using an IAM policy to control access. By using a combination of SCP and IAM policies, you have different levels of access control to the serial console.

**Organization level**

You can use a service control policy (SCP) to allow access to the serial console for member accounts within your organization. For more information about SCPs, see [Service control policies](https://docs.aws.amazon.com/organizations/latest/userguide/orgs跚control_policies.html) in the AWS Organizations User Guide.

**Instance level**

You can configure the serial console access policies by using IAM PrincipalTag and ResourceTag constructions and by specifying instances by their ID. For more information, see [Configure IAM policies for EC2 Serial Console access](https://docs.aws.amazon.com/autoscaling/ec2/userguide/configure-iam-policies-for-ec2-serial-console-access.html).

**User level**

You can configure access at the user level by configuring an IAM policy to allow or deny a specified user the permission to push the SSH public key to the serial console service of a particular instance. For more information, see [Configure IAM policies for EC2 Serial Console access](https://docs.aws.amazon.com/autoscaling/ec2/userguide/configure-iam-policies-for-ec2-serial-console-access.html).

**OS level**

You can set a user password at the guest OS level. This provides access to the serial console for some use cases. However, to monitor the logs, you don't need a password-based user. For more information, see [Set an OS user password](https://docs.aws.amazon.com/autoscaling/ec2/userguide/set-ec2-instance-user-password.html).

### Manage account access to the EC2 Serial Console

By default, there is no access to the serial console at the account level. You need to explicitly grant access to the serial console at the account level.

**Topics**

- [Grant permission to users to manage account access](https://docs.aws.amazon.com/autoscaling/ec2/userguide/enable-manage-account-access.html) (p. 2235)
- [View account access status to the serial console](https://docs.aws.amazon.com/autoscaling/ec2/userguide/enable-manage-account-access.html) (p. 2236)
- [Grant account access to the serial console](https://docs.aws.amazon.com/autoscaling/ec2/userguide/enable-manage-account-access.html) (p. 2236)
- [Deny account access to the serial console](https://docs.aws.amazon.com/autoscaling/ec2/userguide/enable-manage-account-access.html) (p. 2237)

**Grant permission to users to manage account access**

To allow your users to manage account access to the EC2 serial console, you need to grant them the required IAM permissions.

The following policy grants permissions to view the account status, and to allow and prevent account access to the EC2 serial console.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ec2:GetSerialConsoleAccessStatus",
            "ec2:EnableSerialConsoleAccess",
            "ec2:DisableSerialConsoleAccess"
         ]
      }
   ]
}
```
Configure access to the EC2 Serial Console

For more information, see Creating IAM policies in the IAM User Guide.

View account access status to the serial console

To view account access status to the serial console (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the left navigation pane, choose EC2 Dashboard.
3. From Account attributes, choose EC2 Serial Console.

The EC2 Serial Console access field indicates whether account access is Allowed or Prevented.

The following screenshot shows that the account is prevented from using the EC2 serial console.

To view account access status to the serial console (AWS CLI)

Use the get-serial-console-access-status command to view account access status to the serial console.

aws ec2 get-serial-console-access-status --region us-east-1

In the following output, true indicates that the account is allowed access to the serial console.

```
{  
  "SerialConsoleAccessEnabled": true
}
```

Grant account access to the serial console

To grant account access to the serial console (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the left navigation pane, choose EC2 Dashboard.
3. From Account attributes, choose EC2 Serial Console.
4. Choose Manage.
5. To allow access to the EC2 serial console of all instances in the account, select the Allow check box.
6. Choose Update.
To grant account access to the serial console (AWS CLI)

Use the `enable-serial-console-access` command to allow account access to the serial console.

```
aws ec2 enable-serial-console-access --region us-east-1
```

In the following output, `true` indicates that the account is allowed access to the serial console.

```
{
  "SerialConsoleAccessEnabled": true
}
```

Deny account access to the serial console

To deny account access to the serial console (console)

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. On the left navigation pane, choose `EC2 Dashboard`.
3. From `Account attributes`, choose `EC2 Serial Console`.
4. Choose `Manage`.
5. To prevent access to the EC2 serial console of all instances in the account, clear the `Allow` check box.
6. Choose `Update`.

To deny account access to the serial console (AWS CLI)

Use the `disable-serial-console-access` command to prevent account access to the serial console.

```
aws ec2 disable-serial-console-access --region us-east-1
```

In the following output, `false` indicates that the account is denied access to the serial console.

```
{
  "SerialConsoleAccessEnabled": false
}
```

Configure IAM policies for EC2 Serial Console access

By default, your users do not have access to the serial console. Your organization must configure IAM policies to grant your users the required access. For more information, see [Creating IAM policies](https://docs.aws.amazon.com/IAM/latest/userguide/creating-iam-policies.html) in the [IAM User Guide](https://docs.aws.amazon.com/IAM/latest/userguide/creating-iam-policies.html).

For serial console access, create a JSON policy document that includes the `ec2-instance-connect:SendSerialConsoleSSHPublicKey` action. This action grants a user permission to push the public key to the serial console service, which starts a serial console session. We recommend restricting access to specific EC2 instances. Otherwise, all users with this permission can connect to the serial console of all EC2 instances.

**Example IAM policies**

- [Explicitly allow access to the serial console (p. 2238)](https://docs.aws.amazon.com/IAM/latest/userguide/creating-iam-policies.html)
- [Explicitly deny access to the serial console (p. 2238)](https://docs.aws.amazon.com/IAM/latest/userguide/creating-iam-policies.html)
- [Use resource tags to control access to the serial console (p. 2239)](https://docs.aws.amazon.com/IAM/latest/userguide/creating-iam-policies.html)
Explicitly allow access to the serial console

By default, no one has access to the serial console. To grant access to the serial console, you need to configure a policy to explicitly allow access. We recommend configuring a policy that restricts access to specific instances.

The following policy allows access to the serial console of a specific instance, identified by its instance ID.

Note that the `DescribeInstances`, `DescribeInstanceTypes`, and `GetSerialConsoleAccessStatus` actions do not support resource-level permissions, and therefore all resources, indicated by the `*` (asterisk), must be specified for these actions.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowDescribeInstances",
            "Effect": "Allow",
            "Action": [ 
                "ec2:DescribeInstances",
                "ec2:DescribeInstanceTypes",
                "ec2:GetSerialConsoleAccessStatus"
            ],
            "Resource": "*"
        },
        {
            "Sid": "AllowinstanceBasedSerialConsoleAccess",
            "Effect": "Allow",
            "Action": [ 
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey"
            ],
            "Resource": "arn:aws:ec2:region:account-id:instance/i-0598c7d356eba48d7"
        }
    ]
}
```

Explicitly deny access to the serial console

The following IAM policy allows access to the serial console of all instances, denoted by the `*` (asterisk), and explicitly denies access to the serial console of a specific instance, identified by its ID.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowSerialConsoleAccess",
            "Effect": "Allow",
            "Action": [ 
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey",
                "ec2:DescribeInstances",
                "ec2:DescribeInstanceTypes",
                "ec2:GetSerialConsoleAccessStatus"
            ],
            "Resource": "*"
        },
        {
            "Sid": "DenySerialConsoleAccess",
            "Effect": "Deny",
            "Action": [ 
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey"
            ],
        }
    ]
}
```
Use resource tags to control access to the serial console

You can use resource tags to control access to the serial console of an instance.

Attribute-based access control is an authorization strategy that defines permissions based on tags that can be attached to users and AWS resources. For example, the following policy allows a user to initiate a serial console connection for an instance only if that instance's resource tag and the principal's tag have the same SerialConsole value for the tag key.

For more information about using tags to control access to your AWS resources, see Controlling access to AWS resources in the IAM User Guide.

Note that the DescribeInstances, DescribeInstanceTypes, and GetSerialConsoleAccessStatus actions do not support resource-level permissions, and therefore all resources, indicated by the * (asterisk), must be specified for these actions.

```json
{
    "Version": "2012-10-17",
    "Statement": [  
        {
            "Sid": "AllowDescribeInstances",
            "Effect": "Allow",
            "Action": [  
                "ec2:DescribeInstances",
                "ec2:DescribeInstanceTypes",
                "ec2:GetSerialConsoleAccessStatus"
            ],
            "Resource": "*
        },
        {
            "Sid": "AllowTagBasedSerialConsoleAccess",
            "Effect": "Allow",
            "Action": [  
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey"
            ],
            "Condition": {  
                "StringEquals": {  
                    "aws:ResourceTag/SerialConsole": "${aws:PrincipalTag/SerialConsole}"
                }
            }
        }
    ]
}
```

Set an OS user password

You can connect to the serial console without a password. However, to use the serial console for troubleshooting an instance, the instance must have a password-based OS user.

You can set the password for any OS user, including the root user. Note that the root user can modify all files, while each OS user might have limited permissions.

You must set a user password for every instance for which you will use the serial console. This is a one-time requirement for each instance.
Note
The following instructions are applicable only if you launched your instance using an AMI provided by AWS because, by default, AMIs provided by AWS are not configured with a password-based user. If you launched your instance using an AMI that already has the root user password configured, you can skip these instructions.

To set an OS user password

1. Connect (p. 757) to your instance. You can use any method for connecting to your instance, except the EC2 Serial Console connection method.
2. To set the password for a user, use the passwd command. In the following example, the user is root.

```
[ec2-user ~]$ sudo passwd root
```

The following is example output.

```
Changing password for user root.
New password:
```

3. At the New password prompt, enter the new password.
4. At the prompt, re-enter the password.

Connect to the EC2 Serial Console

You can connect to the serial console of your EC2 instance by using the Amazon EC2 console or via SSH. After connecting to the serial console, you can use it for troubleshooting boot, network configuration, and other issues. For more information about troubleshooting, see Troubleshoot your Linux instance using the EC2 Serial Console (p. 2245).

Considerations

- Only 1 active serial console connection is supported per instance.
- The serial console connection typically lasts for 1 hour unless you terminate it. However, during system maintenance, Amazon EC2 will terminate the serial console session.
- It takes 30 seconds to tear down a session after you've disconnected from the serial console in order to allow a new session.
- Supported serial console port for Linux: ttyS0
- When you connect to the serial console, you might observe a slight drop in your instance's throughput.

Topics

- Connect using the browser-based client (p. 2240)
- Connect using your own key and SSH client (p. 2241)
- EC2 Serial Console fingerprints (p. 2243)

Connect using the browser-based client

You can connect to your EC2 instance's serial console by using the browser-based client. You do this by selecting the instance in the Amazon EC2 console and choosing to connect to the serial console. The browser-based client handles the permissions and provides a successful connection.
EC2 serial console works from most browsers, and supports keyboard and mouse input.

Before connecting, make sure you have completed the prerequisites (p. 2232).

**To connect to your instance's serial port using the browser-based client (Amazon EC2 console)**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**.
3. Select the instance and choose **Actions, Monitor and troubleshoot, EC2 Serial Console, Connect**.

   Alternatively, select the instance and choose **Connect, EC2 Serial Console, Connect**.

   An in-browser terminal window opens.

4. Press **Enter**. If a login prompt returns, you are connected to the serial console.

   If the screen remains black, you can use the following information to help resolve issues with connecting to the serial console:

   • **Check that you have configured access to the serial console.** For more information, see Configure access to the EC2 Serial Console (p. 2234).
   • **Use SysRq to connect to the serial console.** SysRq does not require that you connect via the browser-based client. For more information, see Troubleshoot your Linux instance using SysRq (p. 2248).
   • **Restart getty.** If you have SSH access to your instance, then connect to your instance using SSH, and restart getty using the following command.

     ```
     [ec2-user ~]$ sudo systemctl restart serial-getty@ttyS0
     ```

   • **Reboot your instance.** You can reboot your instance by using SysRq, the EC2 console, or the AWS CLI. For more information, see Troubleshoot your Linux instance using SysRq (p. 2248) or Reboot your instance (p. 742).

5. At the login prompt, enter the user name of the password-based user that you set up previously (p. 2239), and then press **Enter**.
6. At the Password prompt, enter the password, and then press **Enter**.

   You are now logged onto the instance and can use the serial console for troubleshooting.

**Connect using your own key and SSH client**

You can use your own SSH key and connect to your instance from the SSH client of your choice while using the serial console API. This enables you to benefit from the serial console capability to push a public key to the instance.

Before connecting, make sure you have completed the prerequisites (p. 2232).

**To connect to an instance's serial console using SSH**

1. **Push your SSH public key to the instance to start a serial console session**

   Use the `send-serial-console-ssh-public-key` command to push your SSH public key to the instance. This starts a serial console session.

   If a serial console session has already been started for this instance, the command fails because you can only have one session open at a time. It takes 30 seconds to tear down a session after you've disconnected from the serial console in order to allow a new session.
Connect to the EC2 Serial Console

2. Connect to the serial console using your private key

Use the `ssh` command to connect to the serial console before the public key is removed from the serial console service. You have 60 seconds before it is removed.

Use the private key that corresponds to the public key.

The user name format is `instance-id.port0`, which comprises the instance ID and port 0. In the following example, the user name is `i-001234a4bf70dec41EXAMPLE.port0`.

For all supported AWS Regions, except AWS GovCloud (US) Regions:

The format of the public DNS name of the serial console service is `serial-console.ec2-instance-connect.region.aws`. In the following example, the serial console service is in the `us-east-1` Region.

```
$ ssh -i my_key i-001234a4bf70dec41EXAMPLE.port0@serial-console.ec2-instance-connect.us-east-1.amazonaws.com
```

For AWS GovCloud (US) Regions only:

The format of the public DNS name of the serial console service in the AWS GovCloud (US) Regions is `serial-console.ec2-instance-connect.GovCloud-region.amazonaws.com`. In the following example, the serial console service is in the `us-gov-east-1` Region.

```
$ ssh -i my_key i-001234a4bf70dec41EXAMPLE.port0@serial-console.ec2-instance-connect.us-gov-east-1.amazonaws.com
```

3. (Optional) Verify the fingerprint

When you connect for the first time to the serial console, you are prompted to verify the fingerprint. You can compare the serial console fingerprint with the fingerprint that's displayed for verification. If these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, you can confidently connect to the serial console.

The following fingerprint is for the serial console service in the `us-east-1` Region. For the fingerprints for each Region, see EC2 Serial Console fingerprints (p. 2243).

```
SHA256:dXwn5ma/xadVMebZGEnru512gx+yISLDi3aLUcz0FMmw
```

Note

The fingerprint only appears the first time you connect to the serial console.

4. Press **Enter**. If a prompt returns, you are connected to the serial console.

If the screen remains black, you can use the following information to help resolve issues with connecting to the serial console:

- **Check that you have configured access to the serial console.** For more information, see Configure access to the EC2 Serial Console (p. 2234).
- **Use SysRq to connect to the serial console.** SysRq does not require that you connect via SSH. For more information, see Troubleshoot your Linux instance using SysRq (p. 2248).
• **Restart getty.** If you have SSH access to your instance, then connect to your instance using SSH, and restart getty using the following command.

```
[ec2-user ~]$ sudo systemctl restart serial-getty@ttyS0
```

• **Reboot your instance.** You can reboot your instance by using SysRq, the EC2 console, or the AWS CLI. For more information, see [Troubleshoot your Linux instance using SysRq](p. 2248) or [Reboot your instance](p. 742).

5. At the `login` prompt, enter the user name of the password-based user that you set up previously (p. 2239), and then press `Enter`.

6. At the `Password` prompt, enter the password, and then press `Enter`.

You are now logged onto the instance and can use the serial console for troubleshooting.

**EC2 Serial Console fingerprints**

The EC2 Serial Console fingerprint is unique for each AWS Region.

- **us-east-1** – US East (N. Virginia)
  
  SHA256: dXwn5ma/xadVMeBZGEru5l2gx+yI5LD1JaULcz0FMmw

- **us-east-2** – US East (Ohio)
  
  SHA256: EhwpKzTz87TRZzz26XbB0/HvVjRM7mCZN0xw/d/0

- **us-west-1** – US West (N. California)
  
  SHA256: OHldlcMET8u7QLXS3jRTRAPFHvtqbyolZBMUCqiH3Y

- **us-west-2** – US West (Oregon)
  
  SHA256: EMCIe23TqKaB16yGHaq9ZCm7qNhAVHa102JxVuc

- **ap-south-1** – Asia Pacific (Mumbai)
  
  SHA256: oBLXcYmklqHHEbliARxEgH8lS051rezTPIS5BsaU40

- **ap-northeast-2** – Asia Pacific (Seoul)
  
  SHA256: FoqWXNX+dZ++GuNTztg9PK49WYMQ8X+Frc2z2dSqrI

- **ap-southeast-1** – Asia Pacific (Singapore)
  
  SHA256: PFLN7wCQ0Hx3qtmwLu16y/08TUX7LQgZuaC6L45CoY

- **ap-southeast-2** – Asia Pacific (Sydney)
  
  SHA256: yFvMwUK91EUQjQTRoXXzuN+cW9/VSe9W984Cf5Tgzo4

- **ap-northeast-1** – Asia Pacific (Tokyo)
  
  SHA256: RQfsDCZT0FQawewTRDVT19Em/HmzFQe+CRI1T5um4k

- **ca-central-1** – Canada (Central)
Terminate an EC2 Serial Console session

The way to terminate a serial console session depends on the client.

**Browser-based client**

To terminate the serial console session, close the serial console in-browser terminal window.

**Standard OpenSSH client**

To terminate the serial console session, use the following command to close the SSH connection. This command must be run immediately following a new line.

```
$ ~.
```

**Note**

The command that you use for closing an SSH connection might be different depending on the SSH client that you're using.
Troubleshoot your Linux instance using the EC2 Serial Console

By using EC2 Serial Console, you can troubleshoot boot, network configuration, and other issues by connecting to your instance's serial port.

Topics

- Troubleshoot your Linux instance using GRUB (p. 2245)
- Troubleshoot your Linux instance using SysRq (p. 2248)

For information about troubleshooting your Windows instance, see Troubleshoot your Windows instance using the EC2 Serial Console in the Amazon EC2 User Guide for Windows Instances.

Troubleshoot your Linux instance using GRUB

GNU GRUB (short for GNU GRand Unified Bootloader, commonly referred to as GRUB) is the default boot loader for most Linux operating systems. From the GRUB menu, you can select which kernel to boot into, or modify menu entries to change how the kernel will boot. This can be useful when troubleshooting a failing instance.

The GRUB menu is displayed during the boot process. The menu is not accessible via normal SSH, but you can access it via the EC2 Serial Console.

Topics

- Prerequisites (p. 2245)
- Configure GRUB (p. 2245)
- Use GRUB (p. 2247)

Prerequisites

Before you can configure and use GRUB, you must grant access to the serial console. For more information, see Configure access to the EC2 Serial Console (p. 2234).

Configure GRUB

Before you can use GRUB via the serial console, you must configure your instance to use GRUB via the serial console.

To configure GRUB, choose one of the following procedures based on the AMI that was used to launch the instance.

Amazon Linux 2

To configure GRUB on an Amazon Linux 2 instance

1. Connect (p. 757) to your instance.
2. Add or change the following options in /etc/default/grub:
   - Set GRUB_TIMEOUT=1.
   - Add GRUB_TERMINAL="console serial".
   - Add GRUB_SERIAL_COMMAND="serial --speed=115200".
The following is an example of `/etc/default/grub`. You might need to change the configuration based on your system setup.

```
GRUB_CMDLINE_LINUX_DEFAULT="console=tty0 console=ttyS0,115200n8 net.ifnames=0
  biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff rd.shell=0"
GRUB_TIMEOUT=1
GRUB_DISABLE_RECOVERY="true"
GRUB_TERMINAL="console serial"
GRUB_SERIAL_COMMAND="serial --speed=115200"
```

3. Apply the updated configuration by running the following command.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

Ubuntu

To configure GRUB on an Ubuntu instance

1. [Connect](p. 757) to your instance.
2. Add or change the following options in `/etc/default/grub.d/50-cloudimg-settings.cfg`:
   - Set `GRUB_TIMEOUT=1`.
   - Add `GRUB_TIMEOUT_STYLE=menu`.
   - Add `GRUB_TERMINAL="console serial"`.
   - Remove `GRUB_HIDDEN_TIMEOUT`.
   - Add `GRUB_SERIAL_COMMAND="serial --speed=115200"`.

The following is an example of `/etc/default/grub.d/50-cloudimg-settings.cfg`. You might need to change the configuration based on your system setup.

```
# Cloud Image specific Grub settings for Generic Cloud Images
# CLOUD_IMG: This file was created/modified by the Cloud Image build process

# Set the recordfail timeout
GRUB_RECORDFAIL_TIMEOUT=0

# Do not wait on grub prompt
GRUB_TIMEOUT=1
GRUB_TIMEOUT_STYLE=menu

# Set the default commandline
GRUB_CMDLINE_LINUX_DEFAULT="console=tty1 console=ttyS0
  nvme_core.io_timeout=4294967295"

# Set the grub console type
GRUB_TERMINAL="console serial"
GRUB_SERIAL_COMMAND="serial --speed=115200"
```

3. Apply the updated configuration by running the following command.

```
[ec2-user ~]$ sudo update-grub
```
RHEL

To configure GRUB on a RHEL instance

1. Connect (p. 757) to your instance.
2. Add or change the following options in /etc/default/grub:
   - Remove GRUB_TERMINAL_OUTPUT.
   - Add GRUB_TERMINAL="console serial".
   - Add GRUB_SERIAL_COMMAND="serial --speed=115200".

   The following is an example of /etc/default/grub. You might need to change the configuration based on your system setup.

   ```
   GRUB_TIMEOUT=1
   GRUB_DISTRIBUTOR="$(sed 's, release .*$,,g' /etc/system-release)"
   GRUB_DEFAULT=saved
   GRUB_DISABLE_SUBMENU=true
   GRUB_CMDLINE_LINUX="console=tty0 console=ttyS0,115200n8 net.ifnames=0 rd.blacklist=nouveau nvme_core.io_timeout=4294967295 crashkernel=auto"
   GRUB_DISABLE_RECOVERY="true"
   GRUB_ENABLE_BLSCFG=true
   GRUB_TERMINAL="serial console"
   GRUB_SERIAL_COMMAND="serial --speed=115200"
   ```

   3. Apply the updated configuration by running the following command.

   ```
   [ec2-user ~]$
   sudo grub2-mkconfig -o /boot/grub2/grub.cfg
   ```

CentOS

For instances that are launched using a CentOS AMI, GRUB is configured for the serial console by default.

The following is an example of /etc/default/grub. Your configuration might be different based on your system setup.

```
GRUB_TIMEOUT=1
GRUB_DISTRIBUTOR="$(sed 's, release .*$,,g' /etc/system-release)"
GRUB_DEFAULT=saved
GRUB_DISABLE_SUBMENU=true
GRUB_TERMINAL="serial console"
GRUB_SERIAL_COMMAND="serial --speed=115200"
GRUB_CMDLINE_LINUX="console=tty0 crashkernel=auto console=ttyS0,115200"
GRUB_DISABLE_RECOVERY="true"
```

Use GRUB

After GRUB is configured, connect to the serial console and reboot the instance with the reboot command. During reboot, you see the GRUB menu. Press any key when the GRUB menu appears to stop the boot process, allowing you to interact with the GRUB menu.

Topics

- Single user mode (p. 2248)
- Emergency mode (p. 2248)
Single user mode

Single user mode will boot the kernel at a lower runlevel. For example, it might mount the filesystem but not activate the network, giving you the opportunity to perform the maintenance necessary to fix the instance.

To boot into single user mode

1. Connect (p. 2240) to the instance's serial console.
2. Reboot the instance using the following command.

   ```
   [ec2-user ~]$ sudo reboot
   ```
3. During reboot, when the GRUB menu appears, press any key to stop the boot process.
4. In the GRUB menu, use the arrow keys to select the kernel to boot into, and press e on your keyboard.
5. Use the arrow keys to locate your cursor on the line containing the kernel. The line begins with either `linux` or `linux16` depending on the AMI that was used to launch the instance. For Ubuntu, two lines begin with `linux`, which must both be modified in the next step.
6. At the end of the line, add the word `single`.

   The following is an example for Amazon Linux 2.

   ```
   linux /boot/vmlinuz-4.14.193-149.317.amzn2.aarch64 root=UUID=d33f9c9a-
   dadd-4499-958d-ebbf42c3e499 ro console=tty0 console=ttyS0,115200n8 net.ifname s=0 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff rd.shel
   l=0 single
   ```
7. Press Ctrl+X to boot into single user mode.
8. At the login prompt, enter the user name of the password-based user that you set up previously (p. 2239), and then press Enter.
9. At the Password prompt, enter the password, and then press Enter.

Emergency mode

Emergency mode is similar to single user mode except that the kernel runs at the lowest runlevel possible.

To boot into emergency mode, follow the steps in Single user mode (p. 2248) in the preceding section, but at step 6 add the word `emergency` instead of `single`.

Troubleshoot your Linux instance using SysRq

The System Request (SysRq) key, which is sometimes referred to as "magic SysRq", can be used to directly send the kernel a command, outside of a shell, and the kernel will respond, regardless of what the kernel is doing. For example, if the instance has stopped responding, you can use the SysRq key to tell the kernel to crash or reboot. For more information, see Magic SysRq key in Wikipedia.

Topics

- Prerequisites (p. 2249)
- Configure SysRq (p. 2249)
- Use SysRq (p. 2249)
Prerequisites

Before you can configure and use SysRq, you must grant access to the serial console. For more information, see Configure access to the EC2 Serial Console (p. 2234).

Configure SysRq

To configure SysRq, you enable the SysRq commands for the current boot cycle. To make the configuration persistent, you can also enable the SysRq commands for subsequent boots.

To enable all SysRq commands for the current boot cycle

1. Connect (p. 757) to your instance.
2. Run the following command.

   ```
   [ec2-user ~]$ sudo sysctl -w kernel.sysrq=1
   ```

   **Note**
   This setting will clear on the next reboot.

To enable all SysRq commands for subsequent boots

1. Create the file `/etc/sysctl.d/99-sysrq.conf` and open it in your favorite editor.

   ```
   [ec2-user ~]$ sudo vi /etc/sysctl.d/99-sysrq.conf
   ```

2. Add the following line.

   ```
   kernel.sysrq=1
   ```

3. Reboot the instance to apply the changes.

   ```
   [ec2-user ~]$ sudo reboot
   ```

4. At the login prompt, enter the user name of the password-based user that you set up previously (p. 2239), and then press Enter.
5. At the Password prompt, enter the password, and then press Enter.

Use SysRq

You can use SysRq commands in the EC2 Serial Console browser-based client or in an SSH client. The command to send a break request is different for each client.

To use SysRq, choose one of the following procedures based on the client that you are using.

Browser-based client

**To use SysRq in the serial console browser-based client**

1. Connect (p. 2240) to the instance’s serial console.
2. To send a break request, press CTRL+0 (zero). If your keyboard supports it, you can also send a break request using the Pause or Break key.

   ```
   [ec2-user ~]$ CTRL+0
   ```
3. To issue a SysRq command, press the key on your keyboard that corresponds to the required command. For example, to display a list of SysRq commands, press `h`.

```
[ec2-user ~]$ h
```

The `h` command outputs something similar to the following.

```
[ 1169.389495] sysrq: HELP : loglevel(0-9) reboot(b) crash(c) terminate-all-tasks(e) memory-full-oom-kill(f) kill-all-tasks(i) thaw-filesystems(j) sak(k) show-backtrace-all-active-cpus(l) show-memory-usage(m) nice-all-RT-tasks(n) poweroff(o) show-registers(p) show-all-timers(q) unraw(r) sync(s) show-task-states(t) unmount(u) show-blocked-tasks(w) dump-ftrace-buffer(z)
```

SSH client

**To use SysRq in an SSH client**

1. Connect (p. 2240) to the instance's serial console.
2. To send a break request, press `~B` (tilde, followed by uppercase B).

```
[ec2-user ~]$ ~B
```

3. To issue a SysRq command, press the key on your keyboard that corresponds to the required command. For example, to display a list of SysRq commands, press `h`.

```
[ec2-user ~]$ h
```

The `h` command outputs something similar to the following.

```
[ 1169.389495] sysrq: HELP : loglevel(0-9) reboot(b) crash(c) terminate-all-tasks(e) memory-full-oom-kill(f) kill-all-tasks(i) thaw-filesystems(j) sak(k) show-backtrace-all-active-cpus(l) show-memory-usage(m) nice-all-RT-tasks(n) poweroff(o) show-registers(p) show-all-timers(q) unraw(r) sync(s) show-task-states(t) unmount(u) show-blocked-tasks(w) dump-ftrace-buffer(z)
```

**Note**
The command that you use for sending a break request might be different depending on the SSH client that you're using.

Send a diagnostic interrupt (for advanced users)

**Warning**
Diagnostic interrupts are intended for use by advanced users. Incorrect usage could negatively impact your instance. Sending a diagnostic interrupt to an instance could trigger an instance to crash and reboot, which could lead to the loss of data.

You can send a diagnostic interrupt to an unreachable or unresponsive Linux instance to manually trigger a **kernel panic**.

Linux operating systems typically crash and reboot when a kernel panic occurs. The specific behavior of the operating system depends on its configuration. A kernel panic can also be used to cause the
instance's operating system kernel to perform tasks, such as generating a crash dump file. You can then use the information in the crash dump file to conduct root cause analysis and debug the instance.

The crash dump data is generated locally by the operating system on the instance itself.

Before sending a diagnostic interrupt to your instance, we recommend that you consult the documentation for your operating system and then make the necessary configuration changes.

Contents
- Supported instance types (p. 2251)
- Prerequisites (p. 2251)
- Send a diagnostic interrupt (p. 2253)

Supported instance types

Diagnostic interrupt is supported on all Nitro-based instance types, except those powered by AWS Graviton processors. For more information, see Instances built on the Nitro System (p. 282) and AWS Graviton.

Prerequisites

Before using a diagnostic interrupt, you must configure your instance's operating system. This ensures that it performs the actions that you need when a kernel panic occurs.

To configure Amazon Linux 2 to generate a crash dump when a kernel panic occurs

1. Connect to your instance.
2. Install kexec and kdump.
   
   ```bash
   [ec2-user ~]$ sudo yum install kexec-tools -y
   ```
3. Configure the kernel to reserve an appropriate amount of memory for the secondary kernel. The amount of memory to reserve depends on the total available memory of your instance. Open the /etc/default/grub file using your preferred text editor, locate the line that starts with GRUB_CMDLINE_LINUX_DEFAULT, and then add the crashkernel parameter in the following format: crashkernel=memory_to_reserve. For example, to reserve 160MB, modify the grub file as follows:
   
   ```text
   GRUB_CMDLINE_LINUX_DEFAULT="crashkernel=160M console=tty0 console=ttyS0,115200n8
   net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff
   rd.shell=0"
   GRUB_TIMEOUT=0
   GRUB_DISABLE_RECOVERY="true"
   ```
4. Save the changes and close the grub file.
5. Rebuild the GRUB2 configuration file.
   
   ```bash
   [ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
   ```
6. On instances based on Intel and AMD processors, the send-diagnostic-interrupt command sends an unknown non-maskable interrupt (NMI) to the instance. You must configure the kernel to crash when it receives the unknown NMI. Open the /etc/sysctl.conf file using your preferred text editor and add the following.
   
   ```text
   kernel.unknown_nmi_panic=1
   ```
7. Reboot and reconnect to your instance.
8. Verify that the kernel has been booted with the correct `crashkernel` parameter.

```
$ grep crashkernel /proc/cmdline
```

The following example output indicates successful configuration.

```
BOOT_IMAGE=/boot/vmlinuz-4.14.128-112.105.amzn2.x86_64 root=UUID=a1e1011e-e38f-408e-878b-fed395b47ad6 ro crashkernel=160M console=tty0 console=ttyS0,115200n8 net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff rd.shell=0
```

9. Verify that the `kdump` service is running.

```
[ec2-user ~]$ systemctl status kdump.service
```

The following example output shows the result if the `kdump` service is running.

```
kdump.service - Crash recovery kernel arming
   Loaded: loaded (/usr/lib/systemd/system/kdump.service; enabled; vendor preset: enabled)
   Active: active (exited) since Fri 2019-05-24 23:29:13 UTC; 22s ago
     Process: 2503 ExecStart=/usr/bin/kdumpctl start (code=exited, status=0/SUCCESS)
     Main PID: 2503 (code=exited, status=0/SUCCESS)
```

**Note**

By default, the crash dump file is saved to `/var/crash/`. To change the location, modify the `/etc/kdump.conf` file using your preferred text editor.

**To configure Amazon Linux to generate a crash dump when a kernel panic occurs**

1. Connect to your instance.
2. Install `kexec` and `kdump`.

```
[ec2-user ~]$ sudo yum install kexec-tools -y
```

3. Configure the kernel to reserve an appropriate amount of memory for the secondary kernel. The amount of memory to reserve depends on the total available memory of your instance.

```
$ sudo grubby --args="crashkernel=memory_to_reserve" --update-kernel=ALL
```

For example, to reserve 160MB for the crash kernel, use the following command.

```
$ sudo grubby --args="crashkernel=160M" --update-kernel=ALL
```

4. On instances based on Intel and AMD processors, the `send-diagnostic-interrupt` command sends an unknown non-maskable interrupt (NMI) to the instance. You must configure the kernel to crash when it receives the unknown NMI. Open the `/etc/sysctl.conf` file using your preferred text editor and add the following.

```
kernal.unknown_nmi_panic=1
```

5. Reboot and reconnect to your instance.
6. Verify that the kernel has been booted with the correct `crashkernel` parameter.
Send a diagnostic interrupt

After you have completed the necessary configuration changes, you can send a diagnostic interrupt to your instance using the AWS CLI or Amazon EC2 API.

To send a diagnostic interrupt to your instance (AWS CLI)

Use the `send-diagnostic-interrupt` command and specify the instance ID.

```bash
aws ec2 send-diagnostic-interrupt --instance-id i-1234567890abcdef0
```

</table>
M6i instances (p. 2256)  | New general purpose instances featuring third generation Intel Xeon Scalable processors (Ice Lake).  | August 16, 2021

CloudWatch metrics for Amazon Data Lifecycle Manager  | You can monitor your Amazon Data Lifecycle Manager policies using Amazon CloudWatch.  | July 28, 2021

New Local Zone added  | Add Local Zone in Denver.  | July 27, 2021

CloudTrail data events for EBS direct APIs  | The ListSnapshotBlocks, ListChangedBlocks, GetSnapshotBlock, and PutSnapshotBlock APIs can be logged data events in CloudTrail.  | July 27, 2021

Prefixes for network interfaces  | You can assign a private IPv4 or IPv6 CIDR range, either automatically or manually, to your network interfaces.  | July 22, 2021

io2 Block Express volumes  | io2 Block Express volumes are now generally available in all Regions and Availability Zones that support R5b instances.  | July 19, 2021

Event windows  | You can define custom, weekly-recurring event windows for scheduled events that reboot, stop, or terminate your Amazon EC2 instances.  | July 15, 2021

Resource IDs and tagging support for security group rules (p. 2256)  | You can refer to security group rules by resource ID. You can also add tags to your security group rules.  | July 7, 2021

New Local Zones added  | Add Local Zones in Dallas and Philadelphia.  | July 7, 2021

Deprecate an AMI  | You can now specify when an AMI is deprecated.  | June 11, 2021

Windows per-second billing (p. 2256)  | Amazon EC2 charges for Windows- and SQL Server-based usage by the second, with a one-minute minimum charge.  | June 10, 2021

Capacity Reservations on AWS Outposts  | You can now use Capacity Reservations on AWS Outposts.  | May 24, 2021

Capacity Reservation sharing  | You can now share Capacity Reservations created in Local Zones and Wavelength Zones.  | May 24, 2021

### History for previous years

The following table describes important additions to the Amazon EC2 documentation in 2018 and earlier years.

<table>
<thead>
<tr>
<th>Feature</th>
<th>API version</th>
<th>Description</th>
<th>Release date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Partition placement groups</td>
<td>2016-11-15</td>
<td>Partition placement groups spread instances across logical partitions, ensuring that instances in one partition do not share underlying hardware with instances in other partitions. For more information, see Partition placement groups (p. 1451).</td>
<td>20 December 2018</td>
</tr>
<tr>
<td>p3dn.24xlarge instances</td>
<td>2016-11-15</td>
<td>New p3dn.24xlarge instances provide 100 Gbps of network bandwidth.</td>
<td>7 December 2018</td>
</tr>
<tr>
<td>Hibernate EC2 Linux instances</td>
<td>2016-11-15</td>
<td>You can hibernate a Linux instance if it's enabled for hibernation and it meets the hibernation prerequisites. For more information, see Hibernate your On-Demand Linux instance (p. 726).</td>
<td>28 November 2018</td>
</tr>
<tr>
<td>Amazon Elastic Inference Accelerators</td>
<td>2016-11-15</td>
<td>You can attach an Amazon EI accelerator to your instances to add GPU-powered acceleration to reduce the cost of running deep learning</td>
<td>28 November 2018</td>
</tr>
<tr>
<td>Feature</td>
<td>API version</td>
<td>Description</td>
<td>Release date</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Instances featuring 100 Gbps of network bandwidth</td>
<td>2016-11-15</td>
<td>New C5n instances can utilize up to 100 Gbps of network bandwidth.</td>
<td>26 November 2018</td>
</tr>
<tr>
<td>Instances featuring Arm-based Processors</td>
<td>2016-11-15</td>
<td>New A1 instances deliver significant cost savings and are ideally suited for scale-out and Arm-based workloads.</td>
<td>26 November 2018</td>
</tr>
<tr>
<td>Spot console recommends a fleet of instances</td>
<td>2016-11-15</td>
<td>The Spot console recommends a fleet of instances based on Spot best practice (instance diversification) to meet the minimum hardware specifications (vCPUs, memory, and storage) for your application need. For more information, see Create a Spot Fleet request (p. 1095).</td>
<td>20 November 2018</td>
</tr>
<tr>
<td>New EC2 Fleet request type: instant</td>
<td>2016-11-15</td>
<td>EC2 Fleet now supports a new request type, instant, that you can use to synchronously provision capacity across instance types and purchase models. The instant request returns the launched instances in the API response, and takes no further action, enabling you to control if and when instances are launched. For more information, see EC2 Fleet request types (p. 1001).</td>
<td>14 November 2018</td>
</tr>
<tr>
<td>Instances featuring AMD EPYC processors</td>
<td>2016-11-15</td>
<td>New general purpose (M5a) and memory optimized instances (R5a) offer lower-priced options for microservices, small to medium databases, virtual desktops, development and test environments, business applications, and more.</td>
<td>6 November 2018</td>
</tr>
<tr>
<td>Spot savings information</td>
<td>2016-11-15</td>
<td>You can view the savings made from using Spot Instances for a single Spot Fleet or for all Spot Instances. For more information, see Savings from purchasing Spot Instances (p. 526).</td>
<td>5 November 2018</td>
</tr>
<tr>
<td>Console support for optimizing CPU options</td>
<td>2016-11-15</td>
<td>When you launch an instance, you can optimize the CPU options to suit specific workloads or business needs using the Amazon EC2 console. For more information, see Optimize CPU options (p. 863).</td>
<td>31 October 2018</td>
</tr>
<tr>
<td>Console support for creating a launch template from an instance</td>
<td>2016-11-15</td>
<td>You can create a launch template using an instance as the basis for a new launch template using the Amazon EC2 console. For more information, see Create a launch template (p. 694).</td>
<td>30 October 2018</td>
</tr>
<tr>
<td>Feature</td>

</tr>
<tr>
<td>----------------------------------------------</td>
<td>----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>On-Demand Capacity Reservations</td>
<td>2016-11-15</td>
<td>You can reserve capacity for your Amazon EC2 instances in a specific Availability Zone for any duration. This allows you to create and manage capacity reservations independently from the billing discounts offered by Reserved Instances (RI). For more information, see On-Demand Capacity Reservations (p. 628).</td>
<td>25 October 2018</td>
</tr>
<tr>
<td>Bring Your Own IP Addresses (BYOIP)</td>
<td>2016-11-15</td>
<td>You can bring part or all of your public IPv4 address range from your on-premises network to your AWS account. After you bring the address range to AWS, it appears in your account as an address pool. You can create an Elastic IP address from your address pool and use it with your AWS resources. For more information, see Bring your own IP addresses (BYOIP) in Amazon EC2 (p. 1284).</td>
<td>23 October 2018</td>
</tr>
<tr>
<td>g3s.xlarge instances</td>
<td>2016-11-15</td>
<td>Expands the range of the accelerated-computing G3 instance family with the introduction of g3s.xlarge instances.</td>
<td>11 October 2018</td>
</tr>
<tr>
<td>Dedicated Host tag on create and console support</td>
<td>2016-11-15</td>
<td>You can tag your Dedicated Hosts on creation, and you can manage your Dedicated Host tags using the Amazon EC2 console. For more information, see Allocate Dedicated Hosts (p. 589).</td>
<td>08 October 2018</td>
</tr>
<tr>
<td>High memory instances</td>
<td>2016-11-15</td>
<td>These instances are purpose-built to run large in-memory databases. They offer bare metal performance with direct access to host hardware. For more information, see Memory optimized instances (p. 365).</td>
<td>27 September 2018</td>
</tr>
<tr>
<td>f1.4xlarge instances</td>
<td>2016-11-15</td>
<td>Expands the range of the accelerated-computing F1 instance family with the introduction of f1.4xlarge instances.</td>
<td>25 September 2018</td>
</tr>
<tr>
<td>Console support for scheduled scaling for Spot Fleet</td>
<td>2016-11-15</td>
<td>Increase or decrease the current capacity of the fleet based on the date and time. For more information, see Scale Spot Fleet using scheduled scaling (p. 1115).</td>
<td>20 September 2018</td>
</tr>
<tr>
<td>T3 instances</td>
<td>2016-11-15</td>
<td>T3 instances are burstable general-purpose instance type that provide a baseline level of CPU performance with the ability to burst CPU usage at any time for as long as required. For more information, see Burstable performance instances (p. 313).</td>
<td>21 August 2018</td>
</tr>
<tr>
<td>Allocation strategies for EC2 Fleets</td>
<td>2016-11-15</td>
<td>You can specify whether On-Demand capacity is fulfilled by price (lowest price first) or priority (highest priority first). You can specify the number of Spot pools across which to allocate your target Spot capacity. For more information, see Allocation strategies for Spot Instances (p. 1020).</td>
<td>26 July 2018</td>
</tr>
<tr>

<tr>
<td>Allocation strategies for Spot Fleets</td>
<td>2016-11-15</td>
<td>You can specify whether On-Demand capacity is fulfilled by price (lowest price first) or priority (highest priority first). You can specify the number of Spot pools across which to allocate your target Spot capacity. For more information, see Allocation strategies for Spot Instances (p. 1064).</td>
<td>26 July 2018</td>
</tr>
<tr>
<td>RS and R5d instances</td>
<td>2016-11-15</td>
<td>RS and R5d instances are ideally suited for high-performance databases, distributed in-memory caches, and in-memory analytics. R5d instances come with NVMe instance store volumes. For more information, see Memory optimized instances (p. 365).</td>
<td>25 July 2018</td>
</tr>
<tr>
<td>z1d instances</td>
<td>2016-11-15</td>
<td>These instances are designed for applications that require high per-core performance with a large amount of memory, such as electronic design automation (EDA) and relational databases. These instances come with NVME instance store volumes. For more information, see Memory optimized instances (p. 365).</td>
<td>25 July 2018</td>
</tr>
<tr>
<td>Automate snapshot lifecycle</td>
<td>2016-11-15</td>
<td>You can use Amazon Data Lifecycle Manager to automate creation and deletion of snapshots for your EBS volumes. For more information, see Amazon Data Lifecycle Manager (p. 1913).</td>
<td>12 July 2018</td>
</tr>
<tr>
<td>Launch template CPU options</td>
<td>2016-11-15</td>
<td>When you create a launch template using the command line tools, you can optimize the CPU options to suit specific workloads or business needs. For more information, see Create a launch template (p. 694).</td>
<td>11 July 2018</td>
</tr>
<tr>
<td>Tag Dedicated Hosts</td>
<td>2016-11-15</td>
<td>You can tag your Dedicated Hosts. For more information, see Tag Dedicated Hosts (p. 599).</td>
<td>3 July 2018</td>
</tr>
<tr>
<td>i3.metal instances</td>
<td>2016-11-15</td>
<td>i3.metal instances provide your applications with direct access to the physical resources of the host server, such as processors and memory. For more information, see Storage optimized instances (p. 391).</td>
<td>17 May 2018</td>
</tr>
<tr>
<td>Get latest console output</td>
<td>2016-11-15</td>
<td>You can retrieve the latest console output for some instance types when you use the get-console-output AWS CLI command.</td>
<td>9 May 2018</td>
</tr>
<tr>
<td>Optimize CPU options</td>
<td>2016-11-15</td>
<td>When you launch an instance, you can optimize the CPU options to suit specific workloads or business needs. For more information, see Optimize CPU options (p. 863).</td>
<td>8 May 2018</td>
</tr>
</tbody>
</table>
## Feature

<table>
<thead>
<tr>
<th>Feature</th>
<th>API version</th>
<th>Description</th>
<th>Release date</th>
</tr>
</thead>
<tbody>
<tr>
<td>EC2 Fleet</td>
<td>2016-11-15</td>
<td>You can use EC2 Fleet to launch a group of instances across different EC2 instance types and Availability Zones, and across On-Demand Instance, Reserved Instance, and Spot Instance purchasing models. For more information, see [EC2 Fleet](p. 999).</td>
<td>2 May 2018</td>
</tr>
<tr>
<td>On-Demand Instances in Spot Fleets</td>
<td>2016-11-15</td>
<td>You can include a request for On-Demand capacity in your Spot Fleet request to ensure that you always have instance capacity. For more information, see [Spot Fleet](p. 1062).</td>
<td>2 May 2018</td>
</tr>
<tr>
<td>Tag EBS snapshots on creation</td>
<td>2016-11-15</td>
<td>You can apply tags to snapshots during creation. For more information, see [Create Amazon EBS snapshots](p. 1830).</td>
<td>2 April 2018</td>
</tr>
<tr>
<td>Change placement groups</td>
<td>2016-11-15</td>
<td>You can move an instance in or out of a placement group, or change its placement group. For more information, see [Change the placement group for an instance](p. 1461).</td>
<td>1 March 2018</td>
</tr>
<tr>
<td>Longer resource IDs</td>
<td>2016-11-15</td>
<td>You can enable the longer ID format for more resource types. For more information, see [Resource IDs](p. 2145).</td>
<td>9 February 2018</td>
</tr>
<tr>
<td>Network performance improvements</td>
<td>2016-11-15</td>
<td>Instances outside of a cluster placement group can now benefit from increased bandwidth when sending or receiving network traffic between other instances or Amazon S3.</td>
<td>24 January 2018</td>
</tr>
<tr>
<td>Tag Elastic IP addresses</td>
<td>2016-11-15</td>
<td>You can tag your Elastic IP addresses. For more information, see [Tag an Elastic IP address](p. 1312).</td>
<td>21 December 2017</td>
</tr>
<tr>
<td>Amazon Linux 2</td>
<td>2016-11-15</td>
<td>Amazon Linux 2 is a new version of Amazon Linux. It provides a high performance, stable, and secure foundation for your applications. For more information, see [Amazon Linux](p. 240).</td>
<td>13 December 2017</td>
</tr>
<tr>
<td>Amazon Time Sync Service</td>
<td>2016-11-15</td>
<td>You can use the Amazon Time Sync Service to keep accurate time on your instance. For more information, see [Set the time for your Linux instance](p. 856).</td>
<td>29 November 2017</td>
</tr>
<tr>
<td>T2 Unlimited</td>
<td>2016-11-15</td>
<td>T2 Unlimited instances can burst above the baseline for as long as required. For more information, see [Burstable performance instances](p. 313).</td>
<td>29 November 2017</td>
</tr>
<tr>
<td>Launch templates</td>
<td>2016-11-15</td>
<td>A launch template can contain all or some of the parameters to launch an instance, so that you don’t have to specify them every time you launch an instance. For more information, see [Launch an instance from a launch template](p. 691).</td>
<td>29 November 2017</td>
</tr>
</tbody>
</table>
### Feature | API version | Description | Release date
---|---|---|---
Spread placement | 2016-11-15 | Spread placement groups are recommended for applications that have a small number of critical instances that should be kept separate from each other. For more information, see Spread placement groups (p. 1452). | 29 November 2017
H1 instances | 2016-11-15 | H1 instances are designed for high-performance big data workloads. For more information, see Storage optimized instances (p. 391). | 28 November 2017
M5 instances | 2016-11-15 | M5 instances are general purpose compute instances. They provide a balance of compute, memory, storage, and network resources. | 28 November 2017
Spot Instance hibernation | 2016-11-15 | The Spot service can hibernate Spot Instances in the event of an interruption. For more information, see Hibernate interrupted Spot Instances (p. 559). | 28 November 2017
Spot Fleet target tracking | 2016-11-15 | You can set up target tracking scaling policies for your Spot Fleet. For more information, see Scale Spot Fleet using a target tracking policy (p. 1112). | 17 November 2017
Spot Fleet integrates with Elastic Load Balancing | 2016-11-15 | You can attach one or more load balancers to a Spot Fleet. | 10 November 2017
X1e instances | 2016-11-15 | X1e instances are ideally suited for high-performance databases, in-memory databases, and other memory-intensive enterprise applications. For more information, see Memory optimized instances (p. 365). | 28 November 2017
C5 instances | 2016-11-15 | C5 instances are designed for compute-heavy applications. For more information, see Compute optimized instances (p. 347). | 6 November 2017
Merge and splitConvertible Reserved Instances | 2016-11-15 | You can exchange (merge) two or more Convertible Reserved Instances for a new Convertible Reserved Instance. You can also use the modification process to split a Convertible Reserved Instance into smaller reservations. For more information, see Exchange Convertible Reserved Instances (p. 510). | 6 November 2017
P3 instances | 2016-11-15 | P3 instances are compute-optimized GPU instances. For more information, see Linux accelerated computing instances (p. 404). | 25 October 2017
Modify VPC tenancy | 2016-11-15 | You can change the instance tenancy attribute of a VPC from dedicated to default. For more information, see Change the tenancy of a VPC (p. 628). | 16 October 2017
Per second billing | 2016-11-15 | Amazon EC2 charges for Linux-based usage by the second, with a one-minute minimum charge. | 2 October 2017

<tr>
<td>Dedicated Spot Instances</td>
<td>2016-11-15</td>
<td>You can run Spot Instances on single-tenant hardware in a virtual private cloud (VPC). For more information, see Specify a tenancy for your Spot Instances (p. 530).</td>
<td>19 January 2017</td>
</tr>
<tr>
<td>IPv6 support</td>
<td>2016-11-15</td>
<td>You can associate an IPv6 CIDR with your VPC and subnets, and assign IPv6 addresses to instances in your VPC. For more information, see Amazon EC2 instance IP addressing (p. 1264).</td>
<td>1 December 2016</td>
</tr>
<tr>
<td>R4 instances</td>
<td>2016-09-15</td>
<td>R4 instances are memory optimized instances. R4 instances are well-suited for memory-intensive, latency-sensitive workloads such as business intelligence (BI), data mining and analysis, in-memory databases, distributed web scale in-memory caching, and applications performance real-time processing of unstructured big data. For more information, see Memory optimized instances (p. 365).</td>
<td>30 November 2016</td>
</tr>
<tr>
<td>New t2.xlarge and t2.2xlarge instance types</td>
<td>2016-09-15</td>
<td>T2 instances are designed to provide moderate base performance and the capability to burst to significantly higher performance as required by your workload. They are intended for applications that need responsiveness, high performance for limited periods of time, and a low cost. For more information, see Burstable performance instances (p. 313).</td>
<td>30 November 2016</td>
</tr>
<tr>
<td>P2 instances</td>
<td>2016-09-15</td>
<td>P2 instances use NVIDIA Tesla K80 GPUs and are designed for general purpose GPU computing using the CUDA or OpenCL programming models. For more information, see Linux accelerated computing instances (p. 404).</td>
<td>29 September 2016</td>
</tr>
<tr>
<td>m4.16xlarge instances</td>
<td>2016-04-01</td>
<td>Expands the range of the general-purpose M4 family with the introduction of m4.16xlarge instances, with 64 vCPUs and 256 GiB of RAM.</td>
<td>6 September 2016</td>
</tr>
<tr>
<td>Automatic scaling for Spot Fleet</td>
<td>2016-04-01</td>
<td>You can now set up scaling policies for your Spot Fleet. For more information, see Automatic scaling for Spot Fleet (p. 1110).</td>
<td>1 September 2016</td>
</tr>
<tr>
<td>Elastic Network Adapter (ENA)</td>
<td>2016-04-01</td>
<td>You can now use ENA for enhanced networking. For more information, see Enhanced networking support (p. 1361).</td>
<td>28 June 2016</td>
</tr>
<tr>
<td>Enhanced support for viewing and modifying longer IDs</td>
<td>2016-04-01</td>
<td>You can now view and modify longer ID settings for other IAM users, IAM roles, or the root user. For more information, see Resource IDs (p. 2145).</td>
<td>23 June 2016</td>
</tr>
<tr>
<td>Copy encrypted Amazon EBS snapshots between AWS accounts</td>
<td>2016-04-01</td>
<td>You can now copy encrypted EBS snapshots between AWS accounts. For more information, see Copy an Amazon EBS snapshot (p. 1836).</td>
<td>21 June 2016</td>

<tr>
<td>Capture a screenshot of an instance console</td>
<td>2015-10-01</td>
<td>You can now obtain additional information when debugging instances that are unreachable. For more information, see [Capture a screenshot of an unreachable instance](p. 2219).</td>
<td>24 May 2016</td>
</tr>
<tr>
<td>X1 instances</td>
<td>2015-10-01</td>
<td>Memory-optimized instances designed for running in-memory databases, big data processing engines, and high performance computing (HPC) applications. For more information, see [Memory optimized instances](p. 365).</td>
<td>18 May 2016</td>
</tr>
<tr>
<td>Two new EBS volume types</td>
<td>2015-10-01</td>
<td>You can now create Throughput Optimized HDD (st1) and Cold HDD (sc1) volumes. For more information, see [Amazon EBS volume types](p. 1775).</td>
<td>19 April 2016</td>
</tr>
<tr>
<td>Added new NetworkPacketsIn and NetworkPacketsOut metrics for Amazon EC2</td>
<td>2015-10-01</td>
<td>Added new NetworkPacketsIn and NetworkPacketsOut metrics for Amazon EC2. For more information, see [Instance metrics](p. 1208).</td>
<td>23 March 2016</td>
</tr>
<tr>
<td>CloudWatch metrics for Spot Fleet</td>
<td>2015-10-01</td>
<td>You can now get CloudWatch metrics for your Spot Fleet. For more information, see [CloudWatch metrics for Spot Fleet](p. 1108).</td>
<td>21 March 2016</td>
</tr>
<tr>
<td>Scheduled Instances</td>
<td>2015-10-01</td>
<td>Scheduled Reserved Instances (Scheduled Instances) enable you to purchase capacity reservations that recur on a daily, weekly, or monthly basis, with a specified start time and duration.</td>
<td>13 January 2016</td>
</tr>
<tr>
<td>Longer resource IDs</td>
<td>2015-10-01</td>
<td>We’re gradually introducing longer length IDs for some Amazon EC2 and Amazon EBS resource types. During the opt-in period, you can enable the longer ID format for supported resource types. For more information, see [Resource IDs](p. 2145).</td>
<td>13 January 2016</td>
</tr>
<tr>
<td>ClassicLink DNS support</td>
<td>2015-10-01</td>
<td>You can enable ClassicLink DNS support for your VPC so that DNS hostnames that are addressed between linked EC2-Classic instances and instances in the VPC resolve to private IP addresses and not public IP addresses. For more information, see [Enable ClassicLink DNS support](p. 1483).</td>
<td>11 January 2016</td>
</tr>
<tr>
<td>New t2.nano instance type</td>
<td>2015-10-01</td>
<td>T2 instances are designed to provide moderate base performance and the capability to burst to significantly higher performance as required by your workload. They are intended for applications that need responsiveness, high performance for limited periods of time, and a low cost. For more information, see [Burstable performance instances](p. 313).</td>

<tr>
<td>Dedicated hosts</td>
<td>2015-10-01</td>
<td>An Amazon EC2 Dedicated host is a physical server with instance capacity dedicated for your use. For more information, see Dedicated Hosts (p. 582).</td>
<td>23 November 2015</td>
</tr>
<tr>
<td>Spot Instance duration</td>
<td>2015-10-01</td>
<td>You can now specify a duration for your Spot Instances. Spot blocks is not supported (January 2023).</td>
<td>6 October 2015</td>
</tr>
<tr>
<td>Spot Fleet modify request</td>
<td>2015-10-01</td>
<td>You can now modify the target capacity of your Spot Fleet request. For more information, see Modify a Spot Fleet request (p. 1106).</td>
<td>29 September 2015</td>
</tr>
<tr>
<td>Spot Fleet diversified allocation strategy</td>
<td>2015-04-15</td>
<td>You can now allocate Spot Instances in multiple Spot pools using a single Spot Fleet request. For more information, see Allocation strategies for Spot Instances (p. 1064).</td>
<td>15 September 2015</td>
</tr>
<tr>
<td>Spot Fleet instance weighting</td>
<td>2015-04-15</td>
<td>You can now define the capacity units that each instance type contributes to your application's performance, and adjust the amount you are willing to pay for Spot Instances for each Spot pool accordingly. For more information, see Spot Fleet instance weighting (p. 1085).</td>
<td>31 August 2015</td>
</tr>
<tr>
<td>New reboot alarm action and new IAM role for use with alarm actions</td>
<td></td>
<td>Added the reboot alarm action and new IAM role for use with alarm actions. For more information, see Create alarms that stop, terminate, reboot, or recover an instance (p. 1229).</td>
<td>23 July 2015</td>
</tr>
<tr>
<td>New t2.large instance type</td>
<td></td>
<td>T2 instances are designed to provide moderate base performance and the capability to burst to significantly higher performance as required by your workload. They are intended for applications that need responsiveness, high performance for limited periods of time, and a low cost. For more information, see Burstable performance instances (p. 313).</td>
<td>16 June 2015</td>
</tr>
<tr>
<td>M4 instances</td>
<td></td>
<td>General-purpose instances that provide a balance of compute, memory, and network resources. M4 instances are powered by a custom Intel 2.4 GHz Intel® Xeon® E5 2676v3 (Haswell) processor with AVX2.</td>
<td>11 June 2015</td>
</tr>
<tr>
<td>Spot Fleets</td>
<td>2015-04-15</td>
<td>You can manage a collection, or fleet, of Spot Instances instead of managing separate Spot Instance requests. For more information, see Spot Fleet (p. 1062).</td>
<td>18 May 2015</td>
</tr>
<tr>
<td>Migrate Elastic IP addresses to EC2-Classic</td>
<td>2015-04-15</td>
<td>You can migrate an Elastic IP address that you’ve allocated for use in EC2-Classic to be used in a VPC. For more information, see the section called “Elastic IP addresses” (p. 1490).</td>
<td>15 May 2015</td>

<tr>
<td>Importing VMs with multiple disks as AMIs</td>
<td>2015-03-01</td>
<td>The VM Import process now supports importing VMs with multiple disks as AMIs. For more information, see Importing a VM as an Image Using VM Import/Export in the VM Import/Export User Guide.</td>
<td>23 April 2015</td>
</tr>
<tr>
<td>New g2.8xlarge instance type</td>
<td></td>
<td>The new g2.8xlarge instance is backed by four high-performance NVIDIA GPUs, making it well suited for GPU compute workloads including large scale rendering, transcoding, machine learning, and other server-side workloads that require massive parallel processing power.</td>
<td>7 April 2015</td>
</tr>
<tr>
<td>D2 instances</td>
<td></td>
<td>Dense-storage instances that are optimized for applications requiring sequential access to large amount of data on direct attached instance storage. D2 instances are designed to offer best price/performance in the dense-storage family. Powered by 2.4 GHz Intel® Xeon® E5 2676v3 (Haswell) processors, D2 instances improve on HS1 instances by providing additional compute power, more memory, and Enhanced Networking. In addition, D2 instances are available in four instance sizes with 6TB, 12TB, 24TB, and 48TB storage options. For more information, see Storage optimized instances (p. 391).</td>
<td>24 March 2015</td>
</tr>
<tr>
<td>Automatic recovery for EC2 instances</td>
<td></td>
<td>You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically recovers the instance if it becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair. A recovered instance is identical to the original instance, including the instance ID, IP addresses, and all instance metadata. For more information, see Recover your instance (p. 753).</td>

<tr>
<td>C4 instances</td>
<td></td>
<td>Next-generation compute-optimized instances that provide very high CPU performance at an economical price. C4 instances are based on custom 2.9 GHz Intel® Xeon® E5-2666 v3 (Haswell) processors. With additional Turbo boost, the processor clock speed in C4 instances can reach as high as 3.5Ghz with 1 or 2 core turbo. Expanding on the capabilities of C3 compute-optimized instances, C4 instances offer customers the highest processor performance among EC2 instances. These instances are ideally suited for high-traffic web applications, ad serving, batch processing, video encoding, distributed analytics, high-energy physics, genome analysis, and computational fluid dynamics. For more information, see [Compute optimized instances](p. 347).</td>
<td>11 January 2015</td>
</tr>
<tr>
<td>ClassicLink</td>
<td>2014-10-01</td>
<td>ClassicLink enables you to link your EC2-Classic instance to a VPC in your account. You can associate VPC security groups with the EC2-Classic instance, enabling communication between your EC2-Classic instance and instances in your VPC using private IP addresses. For more information, see [ClassicLink](p. 1478).</td>
<td>7 January 2015</td>
</tr>
<tr>
<td>Spot Instance termination notices</td>
<td></td>
<td>The best way to protect against Spot Instance interruption is to architect your application to be fault tolerant. In addition, you can take advantage of Spot Instance termination notices, which provide a two-minute warning before Amazon EC2 must terminate your Spot Instance. For more information, see [Spot Instance interruption notices](p. 564).</td>
<td>5 January 2015</td>
</tr>
<tr>
<td>DescribeVolumes pagination support</td>
<td>2014-09-01</td>
<td>The DescribeVolumes API call now supports the pagination of results with the MaxResults and NextToken parameters. For more information, see [DescribeVolumes](p. 313) in the Amazon EC2 API Reference.</td>
<td>23 October 2014</td>
</tr>
<tr>
<td>T2 instances</td>
<td>2014-06-15</td>
<td>T2 instances are designed to provide moderate base performance and the capability to burst to significantly higher performance as required by your workload. They are intended for applications that need responsiveness, high performance for limited periods of time, and a low cost. For more information, see [Burstable performance instances](p. 313).</td>

<td>19 June 2014</td>
</tr>
<tr>
<td>Amazon EBS General Purpose SSD Volumes</td>
<td>2014-05-01</td>
<td>General Purpose SSD volumes offer cost-effective storage that is ideal for a broad range of workloads. These volumes deliver single-digit millisecond latencies, the ability to burst to 3,000 IOPS for extended periods of time, and a base performance of 3 IOPS/GiB. General Purpose SSD volumes can range in size from 1 GiB to 1 TiB. For more information, see [General Purpose SSD (gp2) volumes](p. 1779).</td>
<td>16 June 2014</td>
</tr>
<tr>
<td>Amazon EBS encryption</td>
<td>2014-05-01</td>
<td>Amazon EBS encryption offers seamless encryption of EBS data volumes and snapshots, eliminating the need to build and maintain a secure key management infrastructure. EBS encryption enables data at rest security by encrypting your data using AWS managed keys. The encryption occurs on the servers that host EC2 instances, providing encryption of data as it moves between EC2 instances and EBS storage. For more information, see [Amazon EBS encryption](p. 1975).</td>
<td>21 May 2014</td>
</tr>
<tr>
<td>R3 instances</td>
<td>2014-02-01</td>
<td>Memory-optimized instances with the best price point per GiB of RAM and high performance. These instances are ideally suited for relational and NoSQL databases, in-memory analytics solutions, scientific computing, and other memory-intensive applications that can benefit from the high memory per vCPU, high compute performance, and enhanced networking capabilities of R3 instances. For more information, see [Amazon EC2 Instance Types](p. 1975).</td>
<td>9 April 2014</td>

<tr>
<td>Provisioned IOPS SSD for Amazon EBS</td>
<td>2012-07-20</td>
<td>Provisioned IOPS SSD volumes deliver predictable, high performance for I/O intensive workloads, such as database applications, that rely on consistent and fast response times. For more information, see Amazon EBS volume types (p. 1775).</td>
<td>31 July 2012</td>
</tr>
<tr>
<td>High I/O instances for Amazon EC2</td>
<td>2012-06-15</td>
<td>High I/O instances provides very high, low latency, disk I/O performance using SSD-based local instance storage.</td>
<td>18 July 2012</td>
</tr>
</tbody>
</table>
| IAM roles on Amazon EC2 instances | 2012-06-01 | IAM roles for Amazon EC2 provide:  
  • AWS access keys for applications running on Amazon EC2 instances.  
  • Automatic rotation of the AWS access keys on the Amazon EC2 instance.  
  • Granular permissions for applications running on Amazon EC2 instances that make requests to your AWS services. | 11 June 2012 |
| Spot Instance features that make it easier to get started and handle the potential of interruption. | | You can now manage your Spot Instances as follows:  
  • Specify the amount you are willing to pay for Spot Instances using Auto Scaling launch configurations, and set up a schedule for specifying the amount you are willing to pay for Spot Instances. For more information, see Launching Spot Instances in Your Auto Scaling Group in the Amazon EC2 Auto Scaling User Guide.  
  • Get notifications when instances are launched or terminated.  
  • Use AWS CloudFormation templates to launch Spot Instances in a stack with AWS resources. | 7 June 2012 |
| EC2 instance export and timestamps for status checks for Amazon EC2 | 2012-05-01 | Added support for timestamps on instance status and system status to indicate the date and time that a status check failed. | 25 May 2012 |
| EC2 instance export, and timestamps in instance and system status checks for Amazon VPC | 2012-05-01 | Added support for EC2 instance export to Citrix Xen, Microsoft Hyper-V, and VMware vSphere.  
  Added support for timestamps in instance and system status checks. | 25 May 2012 |
<p>| Cluster Compute Eight Extra Large instances | 2012-04-01 | Added support for cc2.8xlarge instances in a VPC. | 26 April 2012 |
| AWS Marketplace AMIs | 2012-04-01 | Added support for AWS Marketplace AMIs. | 19 April 2012 |
| New Linux AMI release | | Amazon Linux AMI 2012.03 is released. | 28 March 2012 |</p>

<tbody>
<tr>
<td>New AKI version</td>
<td></td>
<td>We've released AKI version 1.03 and AKIs for the AWS GovCloud (US) region.</td>
<td>28 March 2012</td>
</tr>
<tr>
<td>Medium instances, support for 64-bit on all AMIs, and a Java-based SSH Client</td>
<td>2011-12-15</td>
<td>Added support for a new instance type and 64-bit information. Added procedures for using the Java-based SSH client to connect to Linux instances.</td>
<td>7 March 2012</td>
</tr>
<tr>
<td>Reserved Instance pricing tiers</td>
<td>2011-12-15</td>
<td>Added a new section discussing how to take advantage of the discount pricing that is built into the Reserved Instance pricing tiers.</td>
<td>5 March 2012</td>
</tr>
<tr>
<td>Elastic Network Interfaces (ENIs) for EC2 instances in Amazon Virtual Private Cloud</td>
<td>2011-12-01</td>
<td>Added new section about elastic network interfaces (ENIs) for EC2 instances in a VPC. For more information, see Elastic network interfaces (p. 1321).</td>
<td>21 December 2011</td>
</tr>
<tr>
<td>New GRU Region and AKIs</td>
<td></td>
<td>Added information about the release of new AKIs for the SA-East-1 Region. This release deprecates the AKI version 1.01. AKI version 1.02 will continue to be backward compatible.</td>
<td>14 December 2011</td>
</tr>
<tr>
<td>New offering types for Amazon EC2 Reserved Instances</td>
<td>2011-11-01</td>
<td>You can choose from a variety of Reserved Instance offerings that address your projected use of the instance.</td>
<td>01 December 2011</td>
</tr>
<tr>
<td>Amazon EC2 instance status</td>
<td>2011-11-01</td>
<td>You can view additional details about the status of your instances, including scheduled events planned by AWS that might have an impact on your instances. These operational activities include instance reboots required to apply software updates or security patches, or instance retirements required where there are hardware issues. For more information, see Monitor the status of your instances (p. 1175).</td>
<td>16 November 2011</td>
</tr>
<tr>
<td>Amazon EC2 Cluster Compute Instance Type</td>
<td></td>
<td>Added support for Cluster Compute Eight Extra Large (cc2.8xlarge) to Amazon EC2.</td>
<td>14 November 2011</td>
</tr>
<tr>
<td>New PDX Region and AKIs</td>
<td></td>
<td>Added information about the release of new AKIs for the new US-West 2 Region.</td>
<td>8 November 2011</td>
</tr>
<tr>
<td>Spot Instances in Amazon VPC</td>
<td>2011-07-15</td>
<td>Added information about the support for Spot Instances in Amazon VPC. With this update, users can launch Spot Instances a virtual private cloud (VPC). By launching Spot Instances in a VPC, users of Spot Instances can enjoy the benefits of Amazon VPC.</td>
<td>11 October 2011</td>
</tr>
<tr>
<td>Feature</td>
<td>API version</td>
<td>Description</td>
<td>Release date</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>New Linux AMI release</td>
<td></td>
<td>Added information about the release of Amazon Linux AMI 2011.09. This update removes the beta tag from the Amazon Linux AMI, supports the ability to lock the repositories to a specific version, and provides for notification when updates are available to installed packages including security updates.</td>
<td>26 September 2011</td>
</tr>
<tr>
<td>Simplified VM import process for users of the CLI tools</td>
<td>2011-07-15</td>
<td>The VM Import process is simplified with the enhanced functionality of ImportInstance and ImportVolume, which now will perform the upload of the images into Amazon EC2 after creating the import task. In addition, with the introduction of ResumeImport, users can restart an incomplete upload at the point the task stopped.</td>
<td>15 September 2011</td>
</tr>
<tr>
<td>Support for importing in VHD file format</td>
<td></td>
<td>VM Import can now import virtual machine image files in VHD format. The VHD file format is compatible with the Citrix Xen and Microsoft Hyper-V virtualization platforms. With this release, VM Import now supports RAW, VHD and VMDK (VMware ESX-compatible) image formats. For more information, see the VM Import/Export User Guide.</td>
<td>24 August 2011</td>
</tr>
<tr>
<td>Update to the Amazon EC2 VM Import Connector for VMware vCenter</td>
<td></td>
<td>Added information about the 1.1 version of the Amazon EC2 VM Import Connector for VMware vCenter virtual appliance (Connector). This update includes proxy support for Internet access, better error handling, improved task progress bar accuracy, and several bug fixes.</td>
<td>27 June 2011</td>
</tr>
<tr>
<td>Enabling Linux AMI to run user-provided kernels</td>
<td></td>
<td>Added information about the AKI version change from 1.01 to 1.02. This version updates the PVGRUB to address launch failures associated with t1.micro Linux instances. For more information, see User provided kernels (p. 261).</td>
<td>20 June 2011</td>
</tr>
<tr>
<td>Spot Instances Availability Zone pricing changes</td>
<td>2011-05-15</td>
<td>Added information about the Spot Instances Availability Zone pricing feature. In this release, we've added new Availability Zone pricing options as part of the information returned when you query for Spot Instance requests and Spot price history. These additions make it easier to determine the price required to launch a Spot Instance into a particular Availability Zone.</td>
<td>26 May 2011</td>
</tr>
<tr>
<td>AWS Identity and Access Management</td>
<td></td>
<td>Added information about AWS Identity and Access Management (IAM), which enables users to specify which Amazon EC2 actions a user can use with Amazon EC2 resources in general. For more information, see Identity and access management for Amazon EC2 (p. 1658).</td>
<td>26 April 2011</td>
</tr>
<tr>
<td>Feature</td>
<td>API version</td>
<td>Description</td>
<td>Release date</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Enabling Linux AMI to run user-provided kernels</td>
<td></td>
<td>Added information about enabling a Linux AMI to use PVGRUB Amazon Kernel Image (AKI) to run a user-provided kernel. For more information, see User provided kernels (p. 261).</td>
<td>26 April 2011</td>
</tr>
<tr>
<td>Dedicated instances</td>
<td></td>
<td>Launched within your Amazon Virtual Private Cloud (Amazon VPC), Dedicated Instances are instances that are physically isolated at the host hardware level. Dedicated Instances let you take advantage of Amazon VPC and the AWS cloud, with benefits including on-demand elastic provisioning and pay only for what you use, while isolating your Amazon EC2 compute instances at the hardware level. For more information, see Dedicated Instances (p. 623).</td>
<td>27 March 2011</td>
</tr>
<tr>
<td>Reserved Instances updates to the AWS Management Console</td>
<td></td>
<td>Updates to the AWS Management Console make it easier for users to view their Reserved Instances and purchase additional Reserved Instances, including Dedicated Reserved Instances. For more information, see Reserved Instances (p. 472).</td>
<td>27 March 2011</td>
</tr>
<tr>
<td>New Amazon Linux reference AMI</td>
<td></td>
<td>The new Amazon Linux reference AMI replaces the CentOS reference AMI. Removed information about the CentOS reference AMI, including the section named Correcting Clock Drift for Cluster Instances on CentOS 5.4 AMI.</td>
<td>15 March 2011</td>
</tr>
<tr>
<td>Metadata information</td>
<td>2011-01-01</td>
<td>Added information about metadata to reflect changes in the 2011-01-01 release. For more information, see Instance metadata and user data (p. 929) and Instance metadata categories (p. 953).</td>
<td>11 March 2011</td>
</tr>
<tr>
<td>Amazon EC2 VM Import Connector for VMware vCenter</td>
<td></td>
<td>Added information about the Amazon EC2 VM Import Connector for VMware vCenter virtual appliance (Connector). The Connector is a plug-in for VMware vCenter that integrates with VMware vSphere Client and provides a graphical user interface that you can use to import your VMware virtual machines to Amazon EC2.</td>
<td>3 March 2011</td>
</tr>
<tr>
<td>Force volume detachment</td>
<td></td>
<td>You can now use the AWS Management Console to force the detachment of an Amazon EBS volume from an instance. For more information, see Detach an Amazon EBS volume from a Linux instance (p. 1821).</td>
<td>23 February 2011</td>
</tr>
<tr>
<td>Instance termination protection</td>
<td></td>
<td>You can now use the AWS Management Console to prevent an instance from being terminated. For more information, see Enable termination protection (p. 748).</td>
<td>23 February 2011</td>
</tr>
<tr>
<td>Feature</td>
<td>API version</td>
<td>Description</td>
<td>Release date</td>
</tr>
<tr>
<td>---------</td>

<td>-------------</td>
<td>--------------</td>
</tr>
<tr>
<td>Correcting Clock Drift for Cluster Instances on CentOS 5.4 AMI</td>
<td></td>
<td>Added information about how to correct clock drift for cluster instances running on Amazon's CentOS 5.4 AMI.</td>
<td>25 January 2011</td>
</tr>
<tr>
<td>VM Import</td>
<td>2010-11-15</td>
<td>Added information about VM Import, which allows you to import a virtual machine or volume into Amazon EC2. For more information, see the VM Import/Export User Guide.</td>
<td>15 December 2010</td>
</tr>
<tr>
<td>Basic monitoring for instances</td>
<td>2010-08-31</td>
<td>Added information about basic monitoring for EC2 instances.</td>
<td>12 December 2010</td>
</tr>
<tr>
<td>Filters and Tags</td>
<td>2010-08-31</td>
<td>Added information about listing, filtering, and tagging resources. For more information, see List and filter your resources (p. 2146) and Tag your Amazon EC2 resources (p. 2154).</td>
<td>19 September 2010</td>
</tr>
<tr>
<td>Idempotent Instance Launch</td>
<td>2010-08-31</td>
<td>Added information about ensuring idempotency when running instances. For more information, see Ensure idempotency in the Amazon EC2 API Reference.</td>
<td>19 September 2010</td>
</tr>
<tr>
<td>Micro instances</td>
<td>2010-06-15</td>
<td>Amazon EC2 offers the t1.micro instance type for certain types of applications. For more information, see Burstable performance instances (p. 313).</td>
<td>8 September 2010</td>
</tr>
<tr>
<td>AWS Identity and Access Management for Amazon EC2</td>
<td></td>
<td>Amazon EC2 now integrates with AWS Identity and Access Management (IAM). For more information, see Identity and access management for Amazon EC2 (p. 1658).</td>
<td>2 September 2010</td>
</tr>
<tr>
<td>Cluster instances</td>
<td>2010-06-15</td>
<td>Amazon EC2 offers cluster compute instances for high-performance computing (HPC) applications. For more information, see Amazon EC2 Instance Types.</td>
<td>12 July 2010</td>
</tr>
<tr>
<td>Amazon VPC IP Address Designation</td>
<td>2010-06-15</td>
<td>Amazon VPC users can now specify the IP address to assign an instance launched in a VPC.</td>
<td>12 July 2010</td>
</tr>
<tr>
<td>Amazon CloudWatch monitoring for Amazon EBS Volumes</td>
<td></td>
<td>Amazon CloudWatch monitoring is now automatically available for Amazon EBS volumes. For more information, see Amazon CloudWatch metrics for Amazon EBS (p. 2043).</td>
<td>14 June 2010</td>
</tr>
<tr>
<td>High-memory extra large instances</td>
<td>2009-11-30</td>
<td>Amazon EC2 now supports a High-Memory Extra Large (m2.xlarge) instance type. For more information, see Amazon EC2 Instance Types.</td>
<td>22 February 2010</td>
</tr>
</tbody>
</table>
