For a complete list of AWS SDK developer guides and code examples, see Using Amazon EC2 with an AWS SDK (p. 22). This topic also includes information about getting started and details about previous SDK versions.

Get started with Amazon EC2 instances using an AWS SDK

The following code examples show how to:

- Create a key pair and security group.
- Select an Amazon Machine Image (AMI) and compatible instance type, then create an instance.
- Stop and restart the instance.
- Associate an Elastic IP address with your instance.
- Connect to your instance with SSH, then clean up resources.

.NET

AWS SDK for .NET

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

Run a scenario at a command prompt.

/// <summary>
/// Show Amazon Elastic Compute Cloud (Amazon EC2) Basics actions.

Java

SDK for Java 2.x

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

```java
/**
 * Before running this Java (v2) code example, set up your development environment, including your credentials.
 * For more information, see the following documentation topic:
 * https://docs.aws.amazon.com/sdk-for-java/latest/developer-guide/get-started.html
 * This Java example performs the following tasks:
 * 1. Creates an RSA key pair and saves the private key data as a .pem file.
 * 2. Lists key pairs.
 * 3. Creates a security group for the default VPC.
 * 4. Displays security group information.
 * 5. Gets a list of Amazon Linux 2 AMIs and selects one.
 * 6. Gets more information about the image.
 * 7. Gets a list of instance types that are compatible with the selected AMI’s architecture.
 * 8. Creates an instance with the key pair, security group, AMI, and an instance type.
 * 10. Stops the instance and waits for it to stop.
 * 11. Starts the instance and waits for it to start.
 * 12. Allocates an Elastic IP address and associates it with the instance.
 * 13. Displays SSH connection info for the instance.
 * 14. Disassociates and deletes the Elastic IP address.
 * 15. Terminates the instance and waits for it to terminate.
 * 16. Deletes the security group.
 * 17. Deletes the key pair.
 */

Kotlin

SDK for Kotlin

Note
There's more on GitHub. Find the complete example and learn how to set up and run in the AWS Code Examples Repository.

/**
   * Before running this Kotlin code example, set up your development environment, including your credentials.

   * For more information, see the following documentation topic: https://docs.aws.amazon.com/sdk-for-kotlin/latest/developer-guide/setup.html

   * This Kotlin example performs the following tasks:

   * 1. Creates an RSA key pair and saves the private key data as a .pem file.
   * 2. Lists key pairs.
   * 3. Creates a security group for the default VPC.
   * 4. Displays security group information.
   * 5. Gets a list of Amazon Linux 2 AMIs and selects one.
   * 6. Gets more information about the image.
   * 7. Gets a list of instance types that are compatible with the selected AMI’s architecture.
   * 8. Creates an instance with the key pair, security group, AMI, and an instance type.
   * 10. Stops the instance and waits for it to stop.
   * 11. Starts the instance and waits for it to start.
   * 12. Allocates an Elastic IP address and associates it with the instance.
   * 13. Displays SSH connection info for the instance.
   * 14. Disassociates and deletes the Elastic IP address.
   * 15. Terminates the instance.
   * 16. Deletes the security group.
   * 17. Deletes the key pair.
   */

Security in Amazon EC2

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that are built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS Compliance Programs. To learn about the compliance programs that apply to Amazon EC2, see AWS Services in Scope by Compliance Program.
- **Security in the cloud** – Your responsibility includes the following areas:
  - Controlling network access to your instances, for example, through configuring your VPC and security groups. For more information, see Controlling network traffic (p. 1931).
  - Managing the credentials used to connect to your instances.
  - Managing the guest operating system and software deployed to the guest operating system, including updates and security patches. For more information, see Update management in Amazon EC2 (p. 2043).
  - Configuring the IAM roles that are attached to the instance and the permissions associated with those roles. For more information, see IAM roles for Amazon EC2 (p. 1995).

This documentation helps you understand how to apply the shared responsibility model when using Amazon EC2. It shows you how to configure Amazon EC2 to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Amazon EC2 resources.

Infrastructure security in Amazon EC2

As a managed service, Amazon Elastic Compute Cloud is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see AWS Cloud Security.
To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in Security Pillar AWS Well-Architected Framework.

You use AWS published API calls to access Amazon EC2 through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

For more information, see Infrastructure Protection in the Security Pillar – AWS Well-Architected Framework.

**Network isolation**

A virtual private cloud (VPC) is a virtual network in your own logically isolated area in the AWS Cloud. Use separate VPCs to isolate infrastructure by workload or organizational entity.

A subnet is a range of IP addresses in a VPC. When you launch an instance, you launch it into a subnet in your VPC. Use subnets to isolate the tiers of your application (for example, web, application, and database) within a single VPC. Use private subnets for your instances if they should not be accessed directly from the internet.

To call the Amazon EC2 API from your VPC using private IP addresses, use AWS PrivateLink. For more information, see Access Amazon EC2 using an interface VPC endpoint (p. 2041).

**Isolation on physical hosts**

Different EC2 instances on the same physical host are isolated from each other as though they are on separate physical hosts. The hypervisor isolates CPU and memory, and the instances are provided virtualized disks instead of access to the raw disk devices.

When you stop or terminate an instance, the memory allocated to it is scrubbed (set to zero) by the hypervisor before it is allocated to a new instance, and every block of storage is reset. This ensures that your data is not unintentionally exposed to another instance.

Network MAC addresses are dynamically assigned to instances by the AWS network infrastructure. IP addresses are either dynamically assigned to instances by the AWS network infrastructure, or assigned by an EC2 administrator through authenticated API requests. The AWS network allows instances to send traffic only from the MAC and IP addresses assigned to them. Otherwise, the traffic is dropped.

By default, an instance cannot receive traffic that is not specifically addressed to it. If you need to run network address translation (NAT), routing, or firewall services on your instance, you can disable source/destination checking for the network interface.

**Controlling network traffic**

Consider the following options for controlling network traffic to your EC2 instances:

- Restrict access to your instances using security groups (p. 2023). For example, you can allow traffic only from the address ranges for your corporate network.
• Use private subnets for your instances if they should not be accessed directly from the internet. Use a bastion host or NAT gateway for internet access from an instance in a private subnet.

• Use AWS Virtual Private Network or AWS Direct Connect to establish private connections from your remote networks to your VPCs. For more information, see Network-to-Amazon VPC Connectivity Options.

• Use VPC Flow Logs to monitor the traffic that reaches your instances.

• Use AWS Security Hub to check for unintended network accessibility from your instances.

• Use EC2 Instance Connect (p. 831) to connect to your instances using Secure Shell (SSH) without the need to share and manage SSH keys.

• Use AWS Systems Manager Session Manager to access your instances remotely instead of opening inbound SSH ports and managing SSH keys.

• Use AWS Systems Manager Run Command to automate common administrative tasks instead of opening inbound SSH ports and managing SSH keys.

In addition to restricting network access to each Amazon EC2 instance, Amazon VPC supports implementing additional network security controls like in-line gateways, proxy servers, and various network monitoring options.

Resilience in Amazon EC2

The AWS global infrastructure is built around AWS Regions and Availability Zones. Regions provide multiple physically separated and isolated Availability Zones, which are connected through low-latency, high-throughput, and highly redundant networking. With Availability Zones, you can design and operate applications and databases that automatically fail over between zones without interruption. Availability Zones are more highly available, fault tolerant, and scalable than traditional single or multiple data center infrastructures.

If you need to replicate your data or applications over greater geographic distances, use AWS Local Zones. An AWS Local Zone is an extension of an AWS Region in geographic proximity to your users. Local Zones have their own connections to the internet and support AWS Direct Connect. Like all AWS Regions, AWS Local Zones are completely isolated from other AWS Zones.

If you need to replicate your data or applications in an AWS Local Zone, AWS recommends that you use one of the following zones as the failover zone:

• Another Local Zone
• An Availability Zone in the Region that is not the parent zone. You can use the describe-availability-zones command to view the parent zone.

For more information about AWS Regions and Availability Zones, see AWS Global Infrastructure.

In addition to the AWS global infrastructure, Amazon EC2 offers the following features to support your data resiliency:

• Copying AMIs across Regions
• Copying EBS snapshots across Regions
• Automating EBS-backed AMIs using Amazon Data Lifecycle Manager
• Automating EBS snapshots using Amazon Data Lifecycle Manager
• Maintaining the health and availability of your fleet using Amazon EC2 Auto Scaling
• Distributing incoming traffic across multiple instances in a single Availability Zone or multiple Availability Zones using Elastic Load Balancing.
Data protection in Amazon EC2

The AWS shared responsibility model applies to data protection in Amazon Elastic Compute Cloud. As described in this model, AWS is responsible for protecting the global infrastructure that runs all of the AWS Cloud. You are responsible for maintaining control over your content that is hosted on this infrastructure. You are also responsible for the security configuration and management tasks for the AWS services that you use. For more information about data privacy, see the Data Privacy FAQ. For information about data protection in Europe, see the AWS Shared Responsibility Model and GDPR blog post on the AWS Security Blog.

For data protection purposes, we recommend that you protect AWS account credentials and set up individual users with AWS IAM Identity Center or AWS Identity and Access Management (IAM). That way, each user is given only the permissions necessary to fulfill their job duties. We also recommend that you secure your data in the following ways:

- Use multi-factor authentication (MFA) with each account.
- Use SSL/TLS to communicate with AWS resources. We require TLS 1.2 and recommend TLS 1.3.
- Set up API and user activity logging with AWS CloudTrail.
- Use AWS encryption solutions, along with all default security controls within AWS services.
- Use advanced managed security services such as Amazon Macie, which assists in discovering and securing sensitive data that is stored in Amazon S3.
- If you require FIPS 140-2 validated cryptographic modules when accessing AWS through a command line interface or an API, use a FIPS endpoint. For more information about the available FIPS endpoints, see Federal Information Processing Standard (FIPS) 140-2.

We strongly recommend that you never put confidential or sensitive information, such as your customers' email addresses, into tags or free-form text fields such as a Name field. This includes when you work with Amazon EC2 or other AWS services using the console, API, AWS CLI, or AWS SDKs. Any data that you enter into tags or free-form text fields used for names may be used for billing or diagnostic logs. If you provide a URL to an external server, we strongly recommend that you do not include credentials information in the URL to validate your request to that server.

Topics
- Amazon EBS data security (p. 1933)
- Encryption at rest (p. 1933)
- Encryption in transit (p. 1934)

Amazon EBS data security

Amazon EBS volumes are presented to you as raw, unformatted block devices. These devices are logical devices that are created on the EBS infrastructure and the Amazon EBS service ensures that the devices are logically empty (that is, the raw blocks are zeroed or they contain cryptographically pseudorandom data) prior to any use or re-use by a customer.

If you have procedures that require that all data be erased using a specific method, either after or before use (or both), such as those detailed in DoD 5220.22-M (National Industrial Security Program Operating Manual) or NIST 800-88 (Guidelines for Media Sanitization), you have the ability to do so on Amazon EBS. That block-level activity will be reflected down to the underlying storage media within the Amazon EBS service.

Encryption at rest

EBS volumes
Amazon EBS encryption is an encryption solution for your EBS volumes and snapshots. It uses AWS KMS keys. For more information, see Amazon EBS encryption (p. 2316).

**Instance store volumes**

The data on NVMe instance store volumes is encrypted using an XTS-AES-256 cipher, implemented on a hardware module on the instance. The keys used to encrypt data that's written to locally-attached NVMe storage devices are per-customer, and per volume. The keys are generated by, and only reside within, the hardware module, which is inaccessible to AWS personnel. The encryption keys are destroyed when the instance is stopped or terminated and cannot be recovered. You cannot disable this encryption and you cannot provide your own encryption key.

The data on HDD instance store volumes on H1, D3, and D3en instances is encrypted using XTS-AES-256 and one-time keys.

When you stop, hibernate, or terminate an instance, every block of storage in the instance store volume is reset. Therefore, your data cannot be accessed through the instance store of another instance.

**Memory**

Memory encryption is enabled on the following instances:

- Instances with AWS Graviton processors. AWS Graviton2, AWS Graviton3, and AWS Graviton3E support always-on memory encryption. The encryption keys are securely generated within the host system, do not leave the host system, and are destroyed when the host is rebooted or powered down. For more information, see AWS Graviton Processors.
- Instances with 3rd generation Intel Xeon Scalable processors (Ice Lake), such as M6i instances, and 4th generation Intel Xeon Scalable processors (Sapphire Rapids), such as M7i instances. These processors support always-on memory encryption using Intel Total Memory Encryption (TME).
- Instances with 3rd generation AMD EPYC processors (Milan), such as M6a instances, and 4th generation AMD EPYC processors (Genoa), such as M7a instances. These processors support always-on memory encryption using AMD Secure Memory Encryption (SME). Instances with 3rd generation AMD EPYC processors (Milan) also support AMD Secure Encrypted Virtualization-Secure Nested Paging (SEV-SNP).

**Encryption in transit**

**Encryption at the physical layer**

All data flowing across AWS Regions over the AWS global network is automatically encrypted at the physical layer before it leaves AWS secured facilities. All traffic between AZs is encrypted. Additional layers of encryption, including those listed in this section, may provide additional protections.

**Encryption provided by Amazon VPC and Transit Gateway cross-Region peering**

All cross-Region traffic that uses Amazon VPC and Transit Gateway peering is automatically bulk-encrypted when it exits a Region. An additional layer of encryption is automatically provided at the physical layer for all cross-Region traffic, as previously noted in this section.

**Encryption between instances**

AWS provides secure and private connectivity between EC2 instances of all types. In addition, some instance types use the offload capabilities of the underlying Nitro System hardware to automatically encrypt in-transit traffic between instances. This encryption uses Authenticated Encryption with Associated Data (AEAD) algorithms, with 256-bit encryption. There is no impact on network performance. To support this additional in-transit traffic encryption between instances, the following requirements must be met:

- The instances use the following instance types:
• **General purpose**: M5dn, M5n, M5zn, M6a, M6i, M6id, M6idn, M6in, M7a, M7g, M7gd, M7i, and M7i-flex
• **Compute optimized**: C5a, C5ad, C5n, C6a, C6gn, C6i, C6id, C6in, C7a, C7g, C7gd, C7gn, C7i, Hpc6a, Hpc7g, and Hpc7a
• **Memory optimized**: Hpc6id, R5dn, R5n, R6a, R6i, R6idn, R6in, R6id, R7a, R7g, R7gd, R7i, R7iz, U-3tb1, U-6tb1, U-9tb1, U-12tb1, U-18tb1, U-24tb1, X2idn, X2iedn, and X2iezn
• **Storage optimized**: D3, D3en, I3en, I4g, I4i, Im4gn, and Is4gen
• **Accelerated computing**: DL1, DL2q, G4ad, G4dn, G5, Inf1, Inf2, P3dn, P4d, P4de, P5, Trn1, Trn1n, and VT1

The instances are in the same Region.

The instances are in the same VPC or peered VPCs, and the traffic does not pass through a virtual network device or service, such as a load balancer or a transit gateway.

An additional layer of encryption is automatically provided at the physical layer for all traffic before it leaves AWS secured facilities, as previously noted in this section.

**To view the instance types that encrypt in-transit traffic between instances using the AWS CLI**

Use the following `describe-instance-types` command.

```
aws ec2 describe-instance-types \
  --filters Name=network-info.encryption-in-transit-supported,Values=true \
  --query "InstanceTypes[0].InstanceType" \
  --output text | sort
```

**Encryption to and from AWS Outposts**

An Outpost creates special network connections called *service links* to its AWS home Region and, optionally, private connectivity to a VPC subnet that you specify. All traffic over those connection is fully encrypted. For more information, see *Connectivity through service links* and *Encryption in transit* in the *AWS Outposts User Guide*.

**Remote access encryption**

SSH provides a secure communications channel for remote access to your Linux instances, whether directly or through EC2 Instance Connect. Remote access to your instances using AWS Systems Manager Session Manager or the Run Command is encrypted using TLS 1.2, and requests to create a connection are signed using *SigV4* and authenticated and authorized by *AWS Identity and Access Management*.

It is your responsibility to use an encryption protocol, such as Transport Layer Security (TLS), to encrypt sensitive data in transit between clients and your Amazon EC2 instances.

**Identity and access management for Amazon EC2**

Your security credentials identify you to services in AWS and grant you unlimited use of your AWS resources, such as your Amazon EC2 resources. You can use features of Amazon EC2 and AWS Identity and Access Management (IAM) to allow other users, services, and applications to use your Amazon EC2 resources without sharing your security credentials. You can use IAM to control how other users use resources in your AWS account, and you can use security groups to control access to your Amazon EC2 instances. You can choose to allow full use or limited use of your Amazon EC2 resources.

For best practices for securing your AWS resources using IAM, see *Security best practices in IAM*.

**Contents**
Network access to your instance

A security group acts as a firewall that controls the traffic allowed to reach one or more instances. When you launch an instance, you assign it one or more security groups. You add rules to each security group that control traffic for the instance. You can modify the rules for a security group at any time; the new rules are automatically applied to all instances to which the security group is assigned.

For more information, see Authorize inbound traffic for your Linux instances (p. 2005).

Amazon EC2 permission attributes

Your organization might have multiple AWS accounts. Amazon EC2 enables you to specify additional AWS accounts that can use your Amazon Machine Images (AMIs) and Amazon EBS snapshots. These permissions work at the AWS account level only; you can't restrict permissions for specific users within the specified AWS account. All users in the AWS account that you've specified can use the AMI or snapshot.

Each AMI has a LaunchPermission attribute that controls which AWS accounts can access the AMI. For more information, see Make an AMI public (p. 149).

Each Amazon EBS snapshot has a createVolumePermission attribute that controls which AWS accounts can use the snapshot. For more information, see Share an Amazon EBS snapshot (p. 2156).

IAM and Amazon EC2

IAM enables you to do the following:

• Create users and groups under your AWS account
• Assign unique security credentials to each user under your AWS account
• Control each user’s permissions to perform tasks using AWS resources
• Allow the users in another AWS account to share your AWS resources
• Create roles for your AWS account and define the users or services that can assume them
• Use existing identities for your enterprise to grant permissions to perform tasks using AWS resources

By using IAM with Amazon EC2, you can control whether users in your organization can perform a task using specific Amazon EC2 API actions and whether they can use specific AWS resources.

This topic helps you answer the following questions:

• How do I create groups and users in IAM?
• How do I create a policy?
• What IAM policies do I need to carry out tasks in Amazon EC2?
• How do I grant permissions to perform actions in Amazon EC2?
• How do I grant permissions to perform actions on specific resources in Amazon EC2?
Create users, groups, and roles

You can create users and groups for your AWS account and then assign them the permissions they require. As a best practice, users should acquire the permissions by assuming IAM roles. For more information on how to set up users and groups for your AWS account, see Set up to use Amazon EC2.

An IAM role is an IAM identity that you can create in your account that has specific permissions. An IAM role is similar to an IAM user in that it is an AWS identity with permissions policies that determine what the identity can and cannot do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. Also, a role does not have standard long-term credentials such as a password or access keys associated with it. Instead, when you assume a role, it provides you with temporary security credentials for your role session. For more information on how to create IAM roles and grant permissions with them, see IAM roles for Amazon EC2.

Related topics

For more information about IAM, see the following:

- IAM policies for Amazon EC2 (p. 1937)
- IAM roles for Amazon EC2 (p. 1995)

IAM policies for Amazon EC2

By default, users don't have permission to create or modify Amazon EC2 resources, or perform tasks using the Amazon EC2 API, Amazon EC2 console, or CLI. To allow users to create or modify resources and perform tasks, you must create IAM policies that grant users permission to use the specific resources and API actions they'll need, and then attach those policies to the users, groups, or IAM roles that require those permissions.

When you attach a policy to a user, group of users, or role it allows or denies the users permission to perform the specified tasks on the specified resources. For more general information about IAM policies, see Policies and permissions in IAM in the IAM User Guide. For more information about managing and creating custom IAM policies, see Managing IAM policies.

Getting Started

An IAM policy must grant or deny permissions to use one or more Amazon EC2 actions. It must also specify the resources that can be used with the action, which can be all resources, or in some cases, specific resources. The policy can also include conditions that you apply to the resource.

Amazon EC2 partially supports resource-level permissions. This means that for some EC2 API actions, you cannot specify which resource a user is allowed to work with for that action. Instead, you have to allow users to work with all resources for that action.

**Grant permissions to users, groups, and roles**

The following are examples of some AWS managed policies that are available to utilize if they meet your needs:

- **PowerUserAccess**
- **ReadOnlyAccess**
- **AmazonEC2FullAccess**
- **AmazonEC2ReadOnlyAccess**

For more information on the AWS managed policies available to work with Amazon EC2, see [AWS managed policies for Amazon Elastic Compute Cloud](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-user-managed-policies.html).

To provide access, add permissions to your users, groups, or roles:

- **Users and groups in AWS IAM Identity Center**:
  
  Create a permission set. Follow the instructions in [Create a permission set](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_credentials_permissionsets.html) in the *AWS IAM Identity Center User Guide*.

- **Users managed in IAM through an identity provider**:
  
  Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider (federation)](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users_federate.html) in the *IAM User Guide*.

- **IAM users**:
  
  - Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users_create-role.html) in the *IAM User Guide*.
  
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user (console)](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_users_assign-policy-console.html) in the *IAM User Guide*.

**Policy structure**

The following topics explain the structure of an IAM policy.

**Contents**

- **Policy syntax (p. 1939)**
- **Actions for Amazon EC2 (p. 1939)**
- **Supported resource-level permissions for Amazon EC2 API actions (p. 1940)**
Policy syntax

An IAM policy is a JSON document that consists of one or more statements. Each statement is structured as follows.

```json
{
  "Statement": [{
    "Effect": "effect",
    "Action": "action",
    "Resource": "arn",
    "Condition": {
      "condition": {
        "key": "value"
      }
    }
  }]
}
```

There are various elements that make up a statement:

- **Effect**: The effect can be Allow or Deny. By default, users don't have permission to use resources and API actions, so all requests are denied. An explicit allow overrides the default. An explicit deny overrides any allows.
- **Action**: The action is the specific API action for which you are granting or denying permission. To learn about specifying action, see [Actions for Amazon EC2](p. 1939).
- **Resource**: The resource that's affected by the action. Some Amazon EC2 API actions allow you to include specific resources in your policy that can be created or modified by the action. You specify a resource using an Amazon Resource Name (ARN) or using the wildcard (*) to indicate that the statement applies to all resources. For more information, see [Supported resource-level permissions for Amazon EC2 API actions](p. 1940).
- **Condition**: Conditions are optional. They can be used to control when your policy is in effect. For more information about specifying conditions for Amazon EC2, see [Condition keys for Amazon EC2](p. 1941).

For more information about policy requirements, see the [IAM JSON policy reference](in the IAM User Guide). For example IAM policy statements for Amazon EC2, see [Example policies for working with the AWS CLI or an AWS SDK](p. 1947).

**Actions for Amazon EC2**

In an IAM policy statement, you can specify any API action from any service that supports IAM. For Amazon EC2, use the following prefix with the name of the API action: `ec2:`. For example: `ec2:RunInstances` and `ec2:CreateImage`.

To specify multiple actions in a single statement, separate them with commas as follows:

```
"Action": ["ec2:action1", "ec2:action2"]
```

You can also specify multiple actions using wildcards. For example, you can specify all actions whose name begins with the word "Describe" as follows:
"Action": "ec2:Describe*"

**Note**
Currently, the Amazon EC2 Describe* API actions do not support resource-level permissions. For more information about resource-level permissions for Amazon EC2, see IAM policies for Amazon EC2 (p. 1937).

To specify all Amazon EC2 API actions, use the * wildcard as follows:

"Action": "ec2:*"

For a list of Amazon EC2 actions, see Actions defined by Amazon EC2 in the Service Authorization Reference.

**Supported resource-level permissions for Amazon EC2 API actions**

*Resource-level permissions* refers to the ability to specify which resources users are allowed to perform actions on. Amazon EC2 has partial support for resource-level permissions. This means that for certain Amazon EC2 actions, you can control when users are allowed to use those actions based on conditions that have to be fulfilled, or specific resources that users are allowed to use. For example, you can grant users permissions to launch instances, but only of a specific type, and only using a specific AMI.

To specify a resource in an IAM policy statement, use its Amazon Resource Name (ARN). For more information about specifying the ARN value, see Amazon Resource Names (ARNs) for Amazon EC2 (p. 1940). If an API action does not support individual ARNs, you must use a wildcard (*) to specify that all resources can be affected by the action.

To see tables that identify which Amazon EC2 API actions support resource-level permissions, and the ARNs and condition keys that you can use in a policy, see Actions, resources, and condition keys for Amazon EC2.

Keep in mind that you can apply tag-based resource-level permissions in the IAM policies you use for Amazon EC2 API actions. This gives you better control over which resources a user can create, modify, or use. For more information, see Grant permission to tag resources during creation (p. 1945).

**Amazon Resource Names (ARNs) for Amazon EC2**

Each IAM policy statement applies to the resources that you specify using their ARNs.

An ARN has the following general syntax:

```
arn:aws:[service]:[region]:[account-id]:resourceType/resourcePath
```

- **service**
  - The service (for example, ec2).
- **region**
  - The Region for the resource (for example, us-east-1).
- **account-id**
  - The AWS account ID, with no hyphens (for example, 123456789012).
- **resourceType**
  - The type of resource (for example, instance).
- **resourcePath**
  - A path that identifies the resource. You can use the * wildcard in your paths.
For example, you can indicate a specific instance (i-1234567890abcdef0) in your statement using its ARN as follows.

```
"Resource": "arn:aws:ec2:us-east-1:123456789012:instance/i-1234567890abcdef0"
```

You can specify all instances that belong to a specific account by using the * wildcard as follows.

```
"Resource": "arn:aws:ec2:us-east-1:123456789012:instance/*"
```

You can also specify all Amazon EC2 resources that belong to a specific account by using the * wildcard as follows.

```
"Resource": "arn:aws:ec2:us-east-1:123456789012:*"
```

To specify all resources, or if a specific API action does not support ARNs, use the * wildcard in the Resource element as follows.

```
"Resource": ".*
```

Many Amazon EC2 API actions involve multiple resources. For example, AttachVolume attaches an Amazon EBS volume to an instance, so a user must have permissions to use the volume and the instance. To specify multiple resources in a single statement, separate their ARNs with commas, as follows.

```
"Resource": ["arn1", "arn2"]
```

For a list of ARNs for Amazon EC2 resources, see Resource types defined by Amazon EC2.

**Condition keys for Amazon EC2**

In a policy statement, you can optionally specify conditions that control when it is in effect. Each condition contains one or more key-value pairs. Condition keys are not case-sensitive. We've defined AWS global condition keys, plus additional service-specific condition keys.

For a list of service-specific condition keys for Amazon EC2, see Condition keys for Amazon EC2. Amazon EC2 also implements the AWS global condition keys. For more information, see Information available in all requests in the IAM User Guide.

To use a condition key in your IAM policy, use the Condition statement. For example, the following policy grants users permission to add and remove inbound and outbound rules for any security group. It uses the ec2:Vpc condition key to specify that these actions can only be performed on security groups in a specific VPC.

```
{
  "Version": "2012-10-17",
  "Statement": [ {
    "Effect": "Allow",
    "Condition": { "StringEquals": { "ec2:Vpc": "arn:aws:ec2:region:account:vpc/vpc-1234567890" } }
  }
}
```
If you specify multiple conditions, or multiple keys in a single condition, we evaluate them using a logical AND operation. If you specify a single condition with multiple values for one key, we evaluate the condition using a logical OR operation. For permissions to be granted, all conditions must be met.

You can also use placeholders when you specify conditions. For more information, see IAM policy elements: Variables and tags in the IAM User Guide.

**Important**

Many condition keys are specific to a resource, and some API actions use multiple resources. If you write a policy with a condition key, use the Resource element of the statement to specify the resource to which the condition key applies. If not, the policy may prevent users from performing the action at all, because the condition check fails for the resources to which the condition key does not apply. If you do not want to specify a resource, or if you've written the Action element of your policy to include multiple API actions, then you must use the ...IfExists condition type to ensure that the condition key is ignored for resources that do not use it. For more information, see ...IfExists Conditions in the IAM User Guide.

All Amazon EC2 actions support the aws:RequestedRegion and ec2:Region condition keys. For more information, see Example: Restrict access to a specific Region (p. 1948).

**ec2:SourceInstanceARN condition key**

The ec2:SourceInstanceARN condition key can be used for conditions that specify the ARN of the instance from which a request is made. This is an AWS global condition key and is not service-specific. For policy examples, see Amazon EC2: Attach or detach volumes to an EC2 instance and Example: Allow a specific instance to view resources in other AWS services (p. 1980). The ec2:SourceInstanceARN key cannot be used as a variable to populate the ARN for the Resource element in a statement.

For example policy statements for Amazon EC2, see Example policies for working with the AWS CLI or an AWS SDK (p. 1947).

**ec2:Attribute condition key**

The ec2:Attribute condition key can be used for conditions that filter access by an attribute of a resource. The condition key supports only properties that are of a primitive data type (such as a string or integer), or complex AttributeValue objects that have only a Value property (such as the Description or ImdsSupport objects of the ModifyImageAttribute API action).

**Important**

The condition key can't be used with complex objects that have multiple properties, such as the LaunchPermission object of the ModifyImageAttribute API action.

For example, the following policy uses the ec2:Attribute/Description condition key to filter access by the complex Description object of the ModifyImageAttribute API action. The condition key allows only requests that modify an image's description to either Production or Development.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2:ModifyImageAttribute",
            "Resource": "arn:aws:ec2:us-east-1::image/ami-*",
            "Condition": {
                "StringEquals": {
                    "ec2:Attribute/Description": ["Production", "Development"]
                }
            }
        }
    ]
}
```
The following example policy uses the `ec2:Attribute` condition key to filter access by the primitive `Attribute` property of the `ModifyImageAttribute` API action. The condition key denies all requests that attempt to modify an image's description.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "ec2:ModifyImageAttribute",
      "Resource": "arn:aws:ec2:us-east-1::image/ami-*",
      "Condition": {
        "StringEquals": {
          "ec2:Attribute": "Description"
        }
      }
    }
  ]
}
```

**`ec2:ResourceId` condition keys**

When using the following `ec2:ResourceId` condition keys with the specified API actions, the condition key value is used to specify the resulting resource that is created by the API action. `ec2:ResourceId` condition keys can't be used to specify a source resource that is specified in the API request. If you use one of the following `ec2:ResourceId` condition keys with a specified API, then you must always specify the wildcard (`*`). If you specify a different value, the condition always resolves to `*` during runtime. For example, to use the `ec2:ImageId` condition key with the `CopyImage` API, then you must specify the condition key as follows:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:CopyImage",
      "Resource": "arn:aws:ec2:us-east-1::image/ami-*",
      "Condition": {
        "StringEquals": {
          "ec2:ImageId": "*"
        }
      }
    }
  ]
}
```

<table>

<td>CreateVpcPeeringConnection</td>
</tr>
</tbody>
</table>

We recommend that you avoid using `ec2:`Resource ID condition keys with these API actions. Instead, if you need to filter access based on specific resource IDs, we recommend that you do so using the Resource policy element, as follows:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:CopyImage",
      "Resource": "arn:aws:ec2:us-east-1:image/ami-01234567890abcdef"
    }
  ]
}
```

Check that users have the required permissions

After you've created an IAM policy, we recommend that you check whether it grants users the permissions to use the particular API actions and resources they need before you put the policy into production.

First, create a user for testing purposes, and then attach the IAM policy that you created to the test user. Then, make a request as the test user.
If the Amazon EC2 action that you are testing creates or modifies a resource, you should make the request using the DryRun parameter (or run the AWS CLI command with the --dry-run option). In this case, the call completes the authorization check, but does not complete the operation. For example, you can check whether the user can terminate a particular instance without actually terminating it. If the test user has the required permissions, the request returns DryRunOperation; otherwise, it returns UnauthorizedOperation.

If the policy doesn't grant the user the permissions that you expected, or is overly permissive, you can adjust the policy as needed and retest until you get the desired results.

**Important**

It can take several minutes for policy changes to propagate before they take effect. Therefore, we recommend that you allow five minutes to pass before you test your policy updates.

If an authorization check fails, the request returns an encoded message with diagnostic information. You can decode the message using the DecodeAuthorizationMessage action. For more information, see DecodeAuthorizationMessage in the AWS Security Token Service API Reference, and decode-authorization-message in the AWS CLI Command Reference.

### Grant permission to tag resources during creation

Some resource-creating Amazon EC2 API actions enable you to specify tags when you create the resource. You can use resource tags to implement attribute-based control (ABAC). For more information, see [Tag your resources (p. 2509)](http://example.com/tag-your-resources) and [Control access to EC2 resources using resource tags (p. 1947)](http://example.com/control-access-to-ec2-resources-using-resource-tags).

To enable users to tag resources on creation, they must have permissions to use the action that creates the resource, such as ec2:RunInstances or ec2:CreateVolume. If tags are specified in the resource-creating action, Amazon performs additional authorization on the ec2:CreateTags action to verify if users have permissions to create tags. Therefore, users must also have explicit permissions to use the ec2:CreateTags action.

In the IAM policy definition for the ec2:CreateTags action, use the Condition element with the ec2:CreateAction condition key to give tagging permissions to the action that creates the resource.

The following example demonstrates a policy that allows users to launch instances and apply any tags to instances and volumes during launch. Users are not permitted to tag any existing resources (they cannot call the ec2:CreateTags action directly).

```json
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:RunInstances"
      ],
      "Resource": "*
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CreateTags"
      ],
      "Resource": "arn:aws:ec2:region:account:*/*",
      "Condition": {
        "StringEquals": {
          "ec2:CreateAction": "RunInstances"
        }
      }
    }
  ]
}
```
Similarly, the following policy allows users to create volumes and apply any tags to the volumes during volume creation. Users are not permitted to tag any existing resources (they cannot call the `ec2:CreateTags` action directly).

```json
{
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateVolume"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateTags"
            ],
            "Resource": "arn:aws:ec2:region:account:*/*",
            "Condition": {
                "StringEquals": {
                    "ec2:CreateAction": "CreateVolume"
                }
            }
        }
    ]
}
```

The `ec2:CreateTags` action is only evaluated if tags are applied during the resource-creating action. Therefore, a user that has permissions to create a resource (assuming there are no tagging conditions) does not require permissions to use the `ec2:CreateTags` action if no tags are specified in the request. However, if the user attempts to create a resource with tags, the request fails if the user does not have permissions to use the `ec2:CreateTags` action.

The `ec2:CreateTags` action is also evaluated if tags are provided in a launch template. For an example policy, see Tags in a launch template (p. 1968).

**Control access to specific tags**

You can use additional conditions in the Condition element of your IAM policies to control the tag keys and values that can be applied to resources.

The following condition keys can be used with the examples in the preceding section:

- **aws:RequestTag**: To indicate that a particular tag key or tag key and value must be present in a request. Other tags can also be specified in the request.
  - Use with the `StringEquals` condition operator to enforce a specific tag key and value combination, for example, to enforce the tag `cost-center=cc123`:

  ```json
  "StringEquals": { "aws:RequestTag/cost-center": "cc123" }
  ```

- **aws:TagKeys**: To enforce the tag keys that are used in the request.
  - Use with the `ForAllValues` modifier to enforce specific tag keys if they are provided in the request (if tags are specified in the request, only specific tag keys are allowed; no other tags are allowed). For example, the tag keys `environment` or `cost-center` are allowed:
• Use with the ForAnyValue modifier to enforce the presence of at least one of the specified tag keys in the request. For example, at least one of the tag keys environment or webserver must be present in the request:

"ForAnyValue:StringEquals": { "aws:TagKeys": ["environment","webserver"] }

These condition keys can be applied to resource-creating actions that support tagging, as well as the ec2:CreateTags and ec2:DeleteTags actions. To learn whether an Amazon EC2 API action supports tagging, see Actions, resources, and condition keys for Amazon EC2.

To force users to specify tags when they create a resource, you must use the aws:RequestTag condition key or the aws:TagKeys condition key with the ForAnyValue modifier on the resource-creating action. The ec2:CreateTags action is not evaluated if a user does not specify tags for the resource-creating action.

For conditions, the condition key is not case-sensitive and the condition value is case-sensitive. Therefore, to enforce the case-sensitivity of a tag key, use the aws:TagKeys condition key, where the tag key is specified as a value in the condition.

For example IAM policies, see Example policies for working with the AWS CLI or an AWS SDK (p. 1947). For more information about multi-value conditions, see Creating a Condition That Tests Multiple Key Values in the IAM User Guide.

Control access to EC2 resources using resource tags

When you create an IAM policy that grants users permission to use EC2 resources, you can include tag information in the Condition element of the policy to control access based on tags. This is known as attribute-based access control (ABAC). ABAC provides better control over which resources a user can modify, use, or delete. For more information, see What is ABAC for AWS?

For example, you can create a policy that allows users to terminate an instance, but denies the action if the instance has the tag environment=production. To do this, you use the aws:ResourceTag condition key to allow or deny access to the resource based on the tags that are attached to the resource.

"StringEquals": { "aws:ResourceTag/environment": "production" }

To learn whether an Amazon EC2 API action supports controlling access using the aws:ResourceTag condition key, see Actions, resources, and condition keys for Amazon EC2. Note that the Describe actions do not support resource-level permissions, so you must specify them in a separate statement without conditions.

For example IAM policies, see Example policies for working with the AWS CLI or an AWS SDK (p. 1947).

If you allow or deny users access to resources based on tags, you must consider explicitly denying users the ability to add those tags to or remove them from the same resources. Otherwise, it's possible for a user to circumvent your restrictions and gain access to a resource by modifying its tags.

Example policies for working with the AWS CLI or an AWS SDK

You must grant users the permissions they require for Amazon EC2 using IAM policies. The following examples show policy statements that you could use to control the permissions that users have to Amazon EC2. These policies are designed for requests that are made with the AWS CLI or an AWS SDK.
For more information, see Creating IAM policies in the IAM User Guide. For example policies for working in the Amazon EC2 console, see Example policies for working in the Amazon EC2 console (p. 1985). For examples of IAM policies specific to Amazon VPC, see Identity and Access Management for Amazon VPC.

In the following examples, replace each user input placeholder with your own information.

Examples

- Example: Read-only access (p. 1948)
- Example: Restrict access to a specific Region (p. 1948)
- Work with instances (p. 1949)
- Work with volumes (p. 1951)
- Work with snapshots (p. 1953)
- Launch instances (RunInstances) (p. 1960)
- Work with Spot Instances (p. 1972)
- Example: Work with Reserved Instances (p. 1976)
- Example: Tag resources (p. 1977)
- Example: Work with IAM roles (p. 1979)
- Example: Work with route tables (p. 1980)
- Example: Allow a specific instance to view resources in other AWS services (p. 1980)
- Example: Work with launch templates (p. 1981)
- Work with instance metadata (p. 1981)

Example: Read-only access

The following policy grants users permissions to use all Amazon EC2 API actions whose names begin with Describe. The Resource element uses a wildcard to indicate that users can specify all resources with these API actions. The * wildcard is also necessary in cases where the API action does not support resource-level permissions. For more information about which ARNs you can use with which Amazon EC2 API actions, see Actions, resources, and condition keys for Amazon EC2.

Users don't have permission to perform any actions on the resources (unless another statement grants them permission to do so) because they're denied permission to use API actions by default.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:Describe*",
      "Resource": "*"
    }
  ]
}
```

Example: Restrict access to a specific Region

The following policy denies users permission to use all Amazon EC2 API actions unless the Region is Europe (Frankfurt). It uses the global condition key aws:RequestedRegion, which is supported by all Amazon EC2 API actions.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "ec2:*",
      "Resource": "*",
      "Condition": {
        "aws:RequestedRegion": {
          "NotEquals": "eu-central-1"
        }
      }
    }
  ]
}
```
IAM policies

```
{
  "Effect": "Deny",
  "Action": "ec2:*",
  "Resource": "*",
  "Condition": {
    "StringNotEquals": {
      "aws:RequestedRegion": "eu-central-1"
    }
  }
}
```

Alternatively, you can use the condition key `ec2:Region`, which is specific to Amazon EC2 and is supported by all Amazon EC2 API actions.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "ec2:*",
      "Resource": "*",
      "Condition": {
        "StringNotEquals": {
          "ec2:Region": "eu-central-1"
        }
      }
    }
  ]
}
```

Work with instances

Examples

- Example: Describe, launch, stop, start, and terminate all instances (p. 1949)
- Example: Describe all instances, and stop, start, and terminate only particular instances (p. 1950)

Example: Describe, launch, stop, start, and terminate all instances

The following policy grants users permissions to use the API actions specified in the Action element. The Resource element uses a * wildcard to indicate that users can specify all resources with these API actions. The * wildcard is also necessary in cases where the API action does not support resource-level permissions. For more information about which ARNs you can use with which Amazon EC2 API actions, see Actions, resources, and condition keys for Amazon EC2.

The users don't have permission to use any other API actions (unless another statement grants them permission to do so) because users are denied permission to use API actions by default.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeInstances",
        "ec2:DescribeImages",
        "ec2:DescribeKeyPairs",
```

1949
IAM policies

```json
"ec2:DescribeAvailabilityZones",
"ec2:RunInstances",
"ec2:TerminateInstances",
"ec2:StopInstances",
"ec2:StartInstances"
],
"Resource": "*"
}]

Example: Describe all instances, and stop, start, and terminate only particular instances

The following policy allows users to describe all instances, to start and stop only instances
i-1234567890abcdef0 and i-0598c7d356eba48d7, and to terminate only instances in the US East (N.
Virginia) Region (us-east-1) with the resource tag "purpose=test".

The first statement uses a * wildcard for the Resource element to indicate that users can
specify all resources with the action; in this case, they can list all instances. The * wildcard is also
necessary in cases where the API action does not support resource-level permissions (in this case,
ec2:DescribeInstances). For more information about which ARNs you can use with which Amazon
EC2 API actions, see Actions, resources, and condition keys for Amazon EC2.

The second statement uses resource-level permissions for the StopInstances and StartInstances
actions. The specific instances are indicated by their ARNs in the Resource element.

The third statement allows users to terminate all instances in the US East (N. Virginia) Region
(us-east-1) that belong to the specified AWS account, but only where the instance has the tag
"purpose=test". The Condition element qualifies when the policy statement is in effect.

```
Work with volumes

Examples

- Example: Attach and detach volumes (p. 1951)
- Example: Create a volume (p. 1951)
- Example: Create a volume with tags (p. 1952)

Example: Attach and detach volumes

When an API action requires a caller to specify multiple resources, you must create a policy statement that allows users to access all required resources. If you need to use a Condition element with one or more of these resources, you must create multiple statements as shown in this example.

The following policy allows users to attach volumes with the tag "volume_user=iام-user-name" to instances with the tag "department=dev", and to detach those volumes from those instances. If you attach this policy to an IAM group, the aws:username policy variable gives each user in the group permission to attach or detach volumes from the instances with a tag named volume_user that has their username as a value.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["ec2:AttachVolume", "ec2:DetachVolume" ],
      "Resource": "arn:aws:ec2:us-east-1:account-id:instance/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/department": "dev"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": ["ec2:AttachVolume", "ec2:DetachVolume" ],
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/volume_user": "${aws:username}"
        }
      }
    }
  ]
}
```

Example: Create a volume

The following policy allows users to use the CreateVolume API action. The user is allowed to create a volume only if the volume is encrypted and only if the volume size is less than 20 GiB.

```
{
  "Version": "2012-10-17",
  "Statement": [
```
Example: Create a volume with tags

The following policy includes the aws:RequestTag condition key that requires users to tag any volumes they create with the tags costcenter=115 and stack=prod. If users don’t pass these specific tags, or if they don’t specify tags at all, the request fails.

For resource-creating actions that apply tags, users must also have permissions to use the CreateTags action. The second statement uses the ec2:CreateAction condition key to allow users to create tags only in the context of CreateVolume. Users cannot tag existing volumes or any other resources. For more information, see Grant permission to tag resources during creation (p. 1945).

The following policy allows users to create a volume without having to specify tags. The CreateTags action is only evaluated if tags are specified in the CreateVolume request. If users do specify tags, the tag must be purpose=test. No other tags are allowed in the request.
Work with snapshots

The following are example policies for both CreateSnapshot (point-in-time snapshot of an EBS volume) and CreateSnapshots (multi-volume snapshots).

Examples

- Example: Create a snapshot (p. 1953)
- Example: Create snapshots (p. 1954)
- Example: Create a snapshot with tags (p. 1954)
- Example: Create multi-volume snapshots with tags (p. 1955)
- Example: Copying snapshots (p. 1959)
- Example: Modify permission settings for snapshots (p. 1960)

Example: Create a snapshot

The following policy allows customers to use the CreateSnapshot API action. The customer can create snapshots only if the volume is encrypted and only if the volume size is less than 20 GiB.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": "ec2:CreateSnapshot",
         "Resource": "arn:aws:ec2:us-east-1::snapshot/*"
      },
      {
         "Effect": "Allow",
         "Action": ["ec2:CreateSnapshot"],
         "Condition": {
            "StringEquals": {
               "aws:RequestTag/purpose": "test",
               "ec2:CreateAction": "CreateSnapshot"
            },
            "ForAllValues:StringEquals": {
               "aws:TagKeys": "purpose"
            }
         }
      }
   ]
}
```
Example: Create snapshots

The following policy allows customers to use the CreateSnapshots API action. The customer can create snapshots only if all of the volumes on the instance are type GP2.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect":"Allow",
            "Action":"ec2:CreateSnapshots",
            "Resource": ["arn:aws:ec2:us-east-1::snapshot/**",
                          "arn:aws:ec2:*:*:instance/*"
                      ],
            "Condition": {
                "StringLikeIfExists": {
                    "ec2:VolumeType": "gp2"
                }
            }
        },
        {
            "Effect":"Allow",
            "Action":"ec2:CreateSnapshots",
            "Resource": "arn:aws:ec2:us-east-1:*:volume/*",
            "Condition": {
                "StringLikeIfExists": {
                    "ec2:VolumeType": "gp2"
                }
            }
        }
    ]
}
```

Example: Create a snapshot with tags

The following policy includes the aws:RequestTag condition key that requires the customer to apply the tags costcenter=115 and stack=prod to any new snapshot. If users don't pass these specific tags, or if they don't specify tags at all, the request fails.

For resource-creating actions that apply tags, customers must also have permissions to use the CreateTags action. The third statement uses the ec2:CreateAction condition key to allow customers to create tags only in the context of CreateSnapshot. Customers cannot tag existing volumes or any other resources. For more information, see [Grant permission to tag resources during creation](p. 1945).

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect":" Allow",
            "Action": "ec2:CreateSnapshot",
        }
    ]
}
```
Example: Create multi-volume snapshots with tags

The following policy includes the `aws:RequestTag` condition key that requires the customer to apply the tags `costcenter=115` and `stack=prod` when creating a multi-volume snapshot set. If users don’t pass these specific tags, or if they don’t specify tags at all, the request fails.
The following policy allows customers to create a snapshot without having to specify tags. The CreateTags action is evaluated only if tags are specified in the CreateSnapshot or CreateSnapshots request. Tags can be omitted in the request. If a tag is specified, the tag must be purpose=test. No other tags are allowed in the request.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect":"Allow",
            "Action":"ec2:CreateSnapshot",
            "Resource":"*"
        },
        {
            "Effect":"Allow",
            "Action":"ec2:CreateTags",
            "Resource":"arn:aws:ec2:us-east-1::snapshot/*",
            "Condition":{
                "StringEquals":{
                    "aws:RequestTag/purpose":"test",
                    "ec2:CreateAction":"CreateSnapshot"
                },
                "ForAllValues:StringEquals":{
                    "aws:TagKeys":"purpose"
                }
            }
        }
    ]
}
```

The following policy allows customers to create multi-volume snapshot sets without having to specify tags. The CreateTags action is evaluated only if tags are specified in the CreateSnapshot or CreateSnapshots request. Tags can be omitted in the request. If a tag is specified, the tag must be purpose=test. No other tags are allowed in the request.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect":"Allow",
            "Action":"ec2:CreateSnapshots",
            "Resource":"*"
        },
        {
            "Effect":"Allow",
            "Action":"ec2:CreateTags",
            "Resource":"arn:aws:ec2:us-east-1::snapshot/*",
            "Condition":{
                "StringEquals":{
                    "aws:RequestTag/purpose":"test",
                    "ec2:CreateAction":"CreateSnapshots"
                },
                "ForAllValues:StringEquals":{
                    "aws:TagKeys":"purpose"
                }
            }
        }
    ]
}
```
The following policy allows snapshots to be created only if the source volume is tagged with
User:username for the customer, and the snapshot itself is tagged with Environment:Dev and
User:username. The customer can add additional tags to the snapshot.

```
{
  "Version":"2012-10-17",
  "Statement": [
    
    {
      "Effect":"Allow",
      "Action":"ec2:CreateSnapshot",
      "Resource":"arn:aws:ec2:us-east-1:account-id:volume/*",
      "Condition":{
        "StringEquals":{
          "aws:ResourceTag/User":"${aws:username}"}
      }
    },
    
    {
      "Effect":"Allow",
      "Action":"ec2:CreateSnapshot",
      "Resource":"arn:aws:ec2:us-east-1::snapshot/*",
      "Condition":{
        "StringEquals":{
          "aws:RequestTag/Environment":"Dev",
          "aws:RequestTag/User":"${aws:username}"}
      }
    },
    
    {
      "Effect":"Allow",
      "Action":"ec2:CreateTags",
      "Resource":"arn:aws:ec2:us-east-1::snapshot/*"
    }
  ]
}
```

The following policy for CreateSnapshots allows snapshots to be created only if the source
volume is tagged with User:username for the customer, and the snapshot itself is tagged with
Environment:Dev and User:username.

```
{
  "Version":"2012-10-17",
  "Statement": [
    
    {
      "Effect":"Allow",
      "Action":"ec2:CreateSnapshots",
      "Resource":"arn:aws:ec2:us-east-1:*:instance/*",
    },
    
    {
      "Effect":"Allow",
      "Action":"ec2:CreateSnapshots",
      "Resource":"arn:aws:ec2:us-east-1:account-id:volume/*",
      "Condition":{
        "StringEquals":{
          "aws:ResourceTag/User":"${aws:username}"}
      }
    },
    
    {
      "Effect":"Allow",
      "Action":null,
      "Resource":null
    }
  ]
}
```
The following policy allows deletion of a snapshot only if the snapshot is tagged with User:username for the customer.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect":"Allow",
            "Action":"ec2:DeleteSnapshot",
            "Resource":"arn:aws:ec2:us-east-1::snapshot/*",
            "Condition":{
                "StringEquals":{
                    "aws:ResourceTag/User":"${aws:username}"}
            }
        }
    ]
}
```

The following policy allows a customer to create a snapshot but denies the action if the snapshot being created has a tag key value=stack.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect":"Allow",
            "Action": [ "ec2:CreateSnapshot", "ec2:CreateTags" ],
            "Resource": "*"
        },
        {
            "Effect":"Deny",
            "Action": "ec2:CreateSnapshot",
            "Resource": "arn:aws:ec2:us-east-1::snapshot/*",
            "Condition":{
                "ForAnyValue:StringEquals":{
                    "aws:TagKeys":"stack"
                }
            }
        }
    ]
}
```
The following policy allows a customer to create snapshots but denies the action if the snapshots being created have a tag key value=stack.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateSnapshots",
                "ec2:CreateTags"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Deny",
            "Action": "ec2:CreateSnapshots",
            "Resource": "arn:aws:ec2:us-east-1::snapshot/*",
            "Condition": {
                "ForAnyValue:StringEquals": {
                    "aws:TagKeys": "stack"
                }
            }
        }
    ]
}
```

The following policy allows you to combine multiple actions into a single policy. You can only create a snapshot (in the context of CreateSnapshots) when the snapshot is created in Region us-east-1. You can only create snapshots (in the context of CreateSnapshots) when the snapshots are being created in the Region us-east-1 and when the instance type is t2*.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateSnapshots",
                "ec2:CreateSnapshot",
                "ec2:CreateTags"
            ],
            "Resource": [
                "arn:aws:ec2:*:*:instance/*",
                "arn:aws:ec2:*:*:snapshot/*",
                "arn:aws:ec2:*:*:volume/*"
            ],
            "Condition": {
                "StringEqualsIgnoreCase": {
                    "ec2:Region": "us-east-1"
                },
                "StringLikeIfExists": {
                    "ec2:InstanceType": ["t2.*"]
                }
            }
        }
    ]
}
```

**Example: Copying snapshots**

Resource-level permissions specified for the CopySnapshot action apply to the new snapshot only. They cannot be specified for the source snapshot.
The following example policy allows principals to copy snapshots only if the new snapshot is created with tag key of `purpose` and a tag value of `production` (`purpose=production`).

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowCopySnapshotWithTags",
      "Effect": "Allow",
      "Action": "ec2:CopySnapshot",
      "Resource": "arn:aws:ec2:*:account-id:snapshot/*",
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/purpose": "production"
        }
      }
    }
  ]
}
```

**Example: Modify permission settings for snapshots**

The following policy allows modification of a snapshot only if the snapshot is tagged with `User:USERNAME`, where `USERNAME` is the customer's AWS account user name. The request fails if this condition is not met.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:ModifySnapshotAttribute",
      "Resource": "arn:aws:ec2:us-east-1::snapshot/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/user-name": "${aws:username}"}
      }
    }
  ]
}
```

**Launch instances (RunInstances)**

The `RunInstances` API action launches one or more On-Demand Instances or one or more Spot Instances. `RunInstances` requires an AMI and creates an instance. Users can specify a key pair and security group in the request. Launching into a VPC requires a subnet, and creates a network interface. Launching from an Amazon EBS-backed AMI creates a volume. Therefore, the user must have permissions to use these Amazon EC2 resources. You can create a policy statement that requires users to specify an optional parameter on `RunInstances`, or restricts users to particular values for a parameter.

For more information about the resource-level permissions that are required to launch an instance, see Actions, resources, and condition keys for Amazon EC2.

By default, users don't have permissions to describe, start, stop, or terminate the resulting instances. One way to grant the users permission to manage the resulting instances is to create a specific tag for each instance, and then create a statement that enables them to manage instances with that tag. For more information, see Work with instances (p. 1949).

**Resources**
AMIs (p. 1961)
Instance types (p. 1962)
Subnets (p. 1963)
EBS volumes (p. 1964)
Tags (p. 1964)
Tags in a launch template (p. 1968)
Elastic GPUs (p. 1969)
Launch templates (p. 1970)

AMIs

The following policy allows users to launch instances using only the specified AMIs, ami-9e1670f7 and ami-45cf5c3c. The users can't launch an instance using other AMIs (unless another statement grants the users permission to do so).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws:ec2::region:image/ami-9e1670f7",
        "arn:aws:ec2::region:image/ami-45cf5c3c",
        "arn:aws:ec2:region:account-id:instance/*",
        "arn:aws:ec2:region:account-id:key-pair/*",
        "arn:aws:ec2:region:account-id:subnet/*",
      ]
    }
  ]
}
```

Alternatively, the following policy allows users to launch instances from all AMIs owned by Amazon, or certain trusted and verified partners. The Condition element of the first statement tests whether ec2:Owner is amazon. The users can't launch an instance using other AMIs (unless another statement grants the users permission to do so).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws:ec2:region:image/ami-*"
      ],
      "Condition": {
        "StringEquals": {
          "ec2:Owner": "amazon"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws:ec2:region:image/ami-*"
      ]
    }
  ]
}
```
Instance types

The following policy allows users to launch instances using only the t2.micro or t2.small instance type, which you might do to control costs. The users can't launch larger instances because the Condition element of the first statement tests whether ec2:InstanceType is either t2.micro or t2.small.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": [
                "arn:aws:ec2::instance/*"
            ],
            "Condition": {
                "StringEquals": {
                    "ec2:InstanceType": ["t2.micro", "t2.small"]
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": [
                "arn:aws:ec2::image/ami-**",
                "arn:aws:ec2::region:account-id:subnet/**",
                "arn:aws:ec2::region:account-id:network-interface/**",
                "arn:aws:ec2::region:account-id:volume/**",
                "arn:aws:ec2::region:account-id:security-group/**",
                "arn:aws:ec2::region:account-id:key-pair/**"
            ]
        }
    ]
}
```

Alternatively, you can create a policy that denies users permissions to launch any instances except t2.micro and t2.small instance types.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": "ec2:RunInstances",
            "Resource": [
                "arn:aws:ec2::region:account-id:instance/**"
            ],
            "Condition": {
                "StringNotEquals": {
                    "ec2:InstanceType": ["t2.micro", "t2.small"]
                }
            }
        }
    ]
}
```
Subnets

The following policy allows users to launch instances using only the specified subnet, subnet-12345678. The group can't launch instances into any another subnet (unless another statement grants the users permission to do so).

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": [
        "arn:aws:ec2:region::account-id:subnet/subnet-12345678",
        "arn:aws:ec2:region:account-id:instance/**",
        "arn:aws:ec2:region:account-id:volume/**",
        "arn:aws:ec2:region:account-id:key-pair/**",
      ]
    }
  ]
}
```

Alternatively, you could create a policy that denies users permissions to launch an instance into any other subnet. The statement does this by denying permission to create a network interface, except where subnet subnet-12345678 is specified. This denial overrides any other policies that are created to allow launching instances into other subnets.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "ec2:RunInstances",
      "Resource": [
      ],
      "Condition": {
        "ArnNotEquals": {
        }
      }
    }
  ]
}
```
IAM policies

EBS volumes

The following policy allows users to launch instances only if the EBS volumes for the instance are encrypted. The user must launch an instance from an AMI that was created with encrypted snapshots, to ensure that the root volume is encrypted. Any additional volume that the user attaches to the instance during launch must also be encrypted.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": [
                "arn:aws:ec2:*:*:volume/*"
            ],
            "Condition": {
                "Bool": {
                    "ec2:Encrypted": "true"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": [
                "arn:aws:ec2:*:*:image/ami-*",
                "arn:aws:ec2:*:*:network-interface/*",
                "arn:aws:ec2:*:*:instance/*",
                "arn:aws:ec2:*:*:subnet/*",
                "arn:aws:ec2:*:*:volume/*",
                "arn:aws:ec2:*:*:key-pair/*",
                "arn:aws:ec2:*:*:security-group/*"
            ]
        }
    ]
}
```

Tags

Tag instances on creation

The following policy allows users to launch instances and tag the instances during creation. For resource-creating actions that apply tags, users must have permissions to use the CreateTags action. The second statement uses the ec2:CreateAction condition key to allow users to create tags only in the context of RunInstances, and only for instances. Users cannot tag existing resources, and users cannot tag volumes using the RunInstances request.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
            "Resource": [
                "arn:aws:ec2:*:*:image/ami-*",
                "arn:aws:ec2:*:*:network-interface/*",
                "arn:aws:ec2:*:*:instance/*",
                "arn:aws:ec2:*:*:subnet/*",
                "arn:aws:ec2:*:*:key-pair/*",
                "arn:aws:ec2:*:*:security-group/*"
            ]
        }
    ]
}
```
For more information, see Grant permission to tag resources during creation (p. 1945).

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [ "ec2:RunInstances"
        ],
        "Resource": "*"
    },
    {
        "Effect": "Allow",
        "Action": [ "ec2:CreateTags"
        ],
        "Resource": "arn:aws:ec2:us-east-1:account-id:instance/*",
        "Condition": {
            "StringEquals": {
                "ec2:CreateAction": "RunInstances"
            }
        }
    }
}
```

**Tag instances and volumes on creation with specific tags**

The following policy includes the `aws:RequestTag` condition key that requires users to tag any instances and volumes that are created by `RunInstances` with the tags `environment=production` and `purpose=webserver`. If users don't pass these specific tags, or if they don't specify tags at all, the request fails.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [ "ec2:RunInstances"
        ],
        "Resource": [
            "arn:aws:ec2:region:image/*",
            "arn:aws:ec2:region:account-id:subnet/*",
            "arn:aws:ec2:region:account-id:key-pair/*"
        ]
    },
    {
        "Effect": "Allow",
        "Action": [ "ec2:RunInstances"
        ],
        "Resource": [
            "arn:aws:ec2:region:account-id:instance/*"
        ],
        "Condition": {
            "StringEquals": {
                "aws:RequestTag/environment": "production",
                "aws:RequestTag/purpose": "webserver"
            }
        }
    }
}
```
Tag instances and volumes on creation with at least one specific tag

The following policy uses the ForAnyValue modifier on the aws:TagKeys condition to indicate that at least one tag must be specified in the request, and it must contain the key environment or webserver. The tag must be applied to both instances and volumes. Any tag values can be specified in the request.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["ec2:RunInstances"],
      "Resource": ["arn:aws:ec2:region::image/**",
                    "arn:aws:ec2:region:account-id:subnet/**",
                    "arn:aws:ec2:region:account-id:key-pair/**"
                  ],
      "Condition": {
        "ForAnyValue:StringEquals": {
          "aws:TagKeys": ["environment","webserver"]
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": ["ec2:RunInstances"],
                    "arn:aws:ec2:region:account-id:instance/**
                  ],
      "Condition": {
        "ForAnyValue:StringEquals": {
          "aws:TagKeys": ["environment","webserver"]
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": ["ec2:CreateTags"],
      "Resource": "arn:aws:ec2:region:account-id:/**",
      "Condition": {
        "StringEquals": {
          "ec2:CreateAction": "RunInstances"
        }
      }
    }
  ]
}
```
If instances are tagged on creation, they must be tagged with a specific tag

In the following policy, users do not have to specify tags in the request, but if they do, the tag must be purpose=test. No other tags are allowed. Users can apply the tags to any taggable resource in the RunInstances request.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:RunInstances"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CreateTags"
      ],
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/purpose": "test",
          "ec2:CreateAction": "RunInstances"
        },
        "ForAllValues:StringEquals": {
          "aws:TagKeys": "purpose"
        }
      }
    }
  ]
]
```

To disallow anyone called tag on create for RunInstances

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowRun",
      "Effect": "Allow",
      "Action": [
        "ec2:RunInstances"
      ],
      "Resource": [
        "arn:aws:ec2:us-east-1::image/*",
        "arn:aws:ec2:us-east-1::subnet/*",
        "arn:aws:ec2:us-east-1::network-interface/*",
        "arn:aws:ec2:us-east-1::security-group/*",
        "arn:aws:ec2:us-east-1::key-pair/*",
        "arn:aws:ec2:us-east-1::volume/*",
        "arn:aws:ec2:us-east-1::instance/*",
        "arn:aws:ec2:us-east-1::spot-instances-request/*"
      ]
    }
  ]
}
```
Only allow specific tags for spot-instances-request. Surprise inconsistency number 2 comes into play here. Under normal circumstances, specifying no tags will result in Unauthenticated. In the case of spot-instances-request, this policy will not be evaluated if there are no spot-instances-request tags, so a non-tag Spot on Run request will succeed.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Deny",
      "Action": "ec2:CreateTags",
      "Resource": "*"
    }
  ]
}
```

Tags in a launch template

In the following example, users can launch instances, but only if they use a specific launch template (lt-09477bcd97b0d310e). The ec2:IsLaunchTemplateResource condition key prevents users from overriding any of the resources specified in the launch template. The second part of the statement allows users to tag instances on creation—this part of the statement is necessary if tags are specified for the instance in the launch template.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowRun",
      "Effect": "Allow",
      "Action": ["ec2:RunInstances"],
      "Resource": [
        "arn:aws:ec2:us-east-1::image/*",
        "arn:aws:ec2:us-east-1::subnet/*",
        "arn:aws:ec2:us-east-1::network-interface/*",
        "arn:aws:ec2:us-east-1::security-group/*",
        "arn:aws:ec2:us-east-1::key-pair/*",
        "arn:aws:ec2:us-east-1::volume/*",
        "arn:aws:ec2:us-east-1::instance/*",
        "arn:aws:ec2:us-east-1:*:spot-instances-request/*",
        "arn:aws:ec2:us-east-1:*:volume/*",
        "arn:aws:ec2:us-east-1:*:instance/*",
      ],
      "Condition": {
        "StringEquals": {
          "aws:RequestTag/environment": "production"
        }
      }
    }
  ]
}
```
Elastic GPUs

In the following policy, users can launch an instance and specify an elastic GPU to attach to the instance. Users can launch instances in any Region, but they can only attach an elastic GPU during a launch in the us-east-2 Region.

The ec2:ElasticGpuType condition key ensures that instances use either the eg1.medium or eg1.large elastic GPU type.
Launch templates

In the following example, users can launch instances, but only if they use a specific launch template (lt-09477bcd97b0d310e). Users can override any parameters in the launch template by specifying the parameters in the RunInstances action.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": "*",
      "Condition": {
        "ArnLike": {
          "ec2:LaunchTemplate": "arn:aws:ec2:region:account-id:launch-template/lt-09477bcd97b0d310e"
        }
      }
    }
  ]
}
```

In this example, users can launch instances only if they use a launch template. The policy uses the `ec2:IsLaunchTemplateResource` condition key to prevent users from overriding any pre-existing ARNs in the launch template.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:RunInstances",
      "Resource": "*",
      "Condition": {
        "ArnLike": {
        },
        "Bool": {
          "ec2:IsLaunchTemplateResource": "true"
        }
      }
    }
  ]
}
```

The following example policy allows user to launch instances, but only if they use a launch template. Users cannot override the subnet and network interface parameters in the request; these parameters can only be specified in the launch template. The first part of the statement uses the `NotResource` element to allow all other resources except subnets and network interfaces. The second part of the statement allows the subnet and network interface resources, but only if they are sourced from the launch template.
The following example allows users to launch instances only if they use a launch template, and only if the launch template has the tag `Purpose=Webservers`. Users cannot override any of the launch template parameters in the `RunInstances` action.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
                            "arn:aws:ec2:region:account-id:network-interface/**" ],
            "Condition": {
                "ArnLike": {
                    "ec2:LaunchTemplate": "arn:aws:ec2:region:account-id:launch-template/**"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": "ec2:RunInstances",
                          "arn:aws:ec2:region:account-id:network-interface/**" ],
            "Condition": {
                "ArnLike": {
                    "ec2:LaunchTemplate": "arn:aws:ec2:region:account-id:launch-template/**"
                },
                "Bool": {
                    "ec2:IsLaunchTemplateResource": "true"
                }
            }
        }
    ]
}
```
Work with Spot Instances

You can use the RunInstances action to create Spot Instance requests, and tag the Spot Instance requests on create. The resource to specify for RunInstances is `spot-instances-request`.

The `spot-instances-request` resource is evaluated in the IAM policy as follows:

- If you don't tag a Spot Instance request on create, Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement.
- If you tag a Spot Instance request on create, Amazon EC2 evaluates the `spot-instances-request` resource in the RunInstances statement.

Therefore, for the `spot-instances-request` resource, the following rules apply to the IAM policy:

- If you use RunInstances to create a Spot Instance request and you don't intend to tag the Spot Instance request on create, you don't need to explicitly allow the `spot-instances-request` resource; the call will succeed.
- If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must include the `spot-instances-request` resource in the RunInstances allow statement, otherwise the call will fail.
- If you use RunInstances to create a Spot Instance request and intend to tag the Spot Instance request on create, you must specify the `spot-instances-request` resource or * wildcard in the CreateTags allow statement, otherwise the call will fail.

You can request Spot Instances using RunInstances or RequestSpotInstances. The following example IAM policies apply only when requesting Spot Instances using RunInstances.

Example: Request Spot Instances using RunInstances

The following policy allows users to request Spot Instances by using the RunInstances action. The `spot-instances-request` resource, which is created by RunInstances, requests Spot Instances.

**Note**

To use RunInstances to create Spot Instance requests, you can omit `spot-instances-request` from the Resource list if you do not intend to tag the Spot Instance requests on create. This is because Amazon EC2 does not evaluate the `spot-instances-request` resource in the RunInstances statement if the Spot Instance request is not tagged on create.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowRun",
         "Effect": "Allow",
         "Action": [
            "ec2:RunInstances"
         ],
         "Resource": [
            "arn:aws:ec2:us-east-1::image/*",
            "arn:aws:ec2:us-east-1:*:subnet/*",
            "arn:aws:ec2:us-east-1:*:network-interface/*",
            "arn:aws:ec2:us-east-1:*:security-group/*",
            "arn:aws:ec2:us-east-1:*:key-pair/*",
            "arn:aws:ec2:us-east-1:*:volume/*",
            "arn:aws:ec2:us-east-1:*:instance/*",
            "arn:aws:ec2:us-east-1:*:spot-instances-request/*"
         ]
      }
   ]
}
```
Warning

NOT SUPPORTED – Example: Deny users permission to request Spot Instances using RunInstances

The following policy is not supported for the spot-instances-request resource. The following policy is meant to give users the permission to launch On-Demand Instances, but deny users the permission to request Spot Instances. The spot-instances-request resource, which is created by RunInstances, is the resource that requests Spot Instances. The second statement is meant to deny the RunInstances action for the spot-instances-request resource. However, this condition is not supported because Amazon EC2 does not evaluate the spot-instances-request resource in the RunInstances statement if the Spot Instance request is not tagged on create.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": ["ec2:RunInstances"
            ],
            "Resource": ["arn:aws:ec2:us-east-1::image/*",
                        "arn:aws:ec2:us-east-1:*:subnet/*",
                        "arn:aws:ec2:us-east-1:*:network-interface/*",
                        "arn:aws:ec2:us-east-1:*:security-group/*",
                        "arn:aws:ec2:us-east-1:*:key-pair/*",
                        "arn:aws:ec2:us-east-1:*:volume/*",
                        "arn:aws:ec2:us-east-1:*:instance/*"
                        ]
        },
        {
            "Sid": "DenySpotInstancesRequests - NOT SUPPORTED - DO NOT USE!",
            "Effect": "Deny",
            "Action": ["ec2:RunInstances",
                        "Resource": "arn:aws:ec2:us-east-1:*:spot-instances-request/*"
            ]
        }
    ]
}
```

Example: Tag Spot Instance requests on create

The following policy allows users to tag all resources that are created during instance launch. The first statement allows RunInstances to create the listed resources. The spot-instances-request resource, which is created by RunInstances, is the resource that requests Spot Instances. The second statement provides a * wildcard to allow all resources to be tagged when they are created at instance launch.

**Note**

If you tag a Spot Instance request on create, Amazon EC2 evaluates the spot-instances-request resource in the RunInstances statement. Therefore, you must explicitly allow the spot-instances-request resource for the RunInstances action, otherwise the call will fail.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowRun",
            "Effect": "Allow",
            "Action": ["ec2:RunInstances",
                        "Resource": "arn:aws:ec2:us-east-1:*:spot-instances-request/*"
            ]
        }
    ]
}
```
Example: Deny tag on create for Spot Instance requests

The following policy denies users the permission to tag the resources that are created during instance
launch.

The first statement allows RunInstances to create the listed resources. The spot-instances-request
resource, which is created by RunInstances, is the resource that requests Spot Instances. The second
statement provides a * wildcard to deny all resources being tagged when they are created at instance
launch. If spot-instances-request or any other resource is tagged on create, the RunInstances call
will fail.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowRun",
      "Effect": "Allow",
      "Action": [ "ec2:RunInstances"
    },
    "Resource": [ "arn:aws:ec2:us-east-1::image/*",
                   "arn:aws:ec2:us-east-1::subnet/*",
                   "arn:aws:ec2:us-east-1::network-interface/*",
                   "arn:aws:ec2:us-east-1::security-group/*",
                   "arn:aws:ec2:us-east-1::key-pair/*",
                   "arn:aws:ec2:us-east-1::volume/*",
                   "arn:aws:ec2:us-east-1::instance/*",
                   "arn:aws:ec2:us-east-1::spot-instances-request/*"
    }
  ],
  "Sid": "DenyTagResources",
  "Effect": "Deny",
  "Action": [ "ec2:CreateTags",
              "ec2:ModifyTags"
  ],
  "Resource": "*"
}
```
Warning

NOT SUPPORTED – Example: Allow creating a Spot Instance request only if it is assigned a specific tag

The following policy is not supported for the spot-instances-request resource.
The following policy is meant to grant RunInstances the permission to create a Spot Instance request only if the request is tagged with a specific tag.
The first statement allows RunInstances to create the listed resources.
The second statement is meant to grant users the permission to create a Spot Instance request only if the request has the tag environment=production. If this condition is applied to other resources created by RunInstances, specifying no tags results in an Unauthenticated error.
However, if no tags are specified for the Spot Instance request, Amazon EC2 does not evaluate the spot-instances-request resource in the RunInstances statement, which results in non-tagged Spot Instance requests being created by RunInstances.
Note that specifying another tag other than environment=production results in an Unauthenticated error, because if a user tags a Spot Instance request, Amazon EC2 evaluates the spot-instances-request resource in the RunInstances statement.

```
{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "AllowRun",
        "Effect": "Allow",
        "Action": ["ec2:RunInstances"],
        "Resource": [
          "arn:aws:ec2:us-east-1::image/**",
          "arn:aws:ec2:us-east-1::subnet/**",
          "arn:aws:ec2:us-east-1::*:network-interface/**",
          "arn:aws:ec2:us-east-1::*:security-group/**",
          "arn:aws:ec2:us-east-1::*:key-pair/**",
          "arn:aws:ec2:us-east-1::*:volume/**",
          "arn:aws:ec2:us-east-1::*:instance/**"
        ]
      },
      {
        "Sid": "RequestSpotInstancesOnlyIfTagIs_environment=production - NOT SUPPORTED - DO NOT USE!",
        "Effect": "Allow",
        "Action": "ec2:RunInstances",
        "Resource": "arn:aws:ec2:us-east-1::*:spot-instances-request/**",
        "Condition": {
          "StringEquals": {
            "aws:RequestTag/environment": "production"
          }
        }
      },
      {
        "Sid": "TagResources",
        "Effect": "Allow",
        "Action": "ec2:CreateTags",
        "Resource": "*"
      }
    ]
}
```

Example: Deny creating a Spot Instance request if it is assigned a specific tag

The following policy denies RunInstances the permission to create a Spot Instance request if the request is tagged with environment=production.
The first statement allows RunInstances to create the listed resources.

The second statement denies users the permission to create a Spot Instance request if the request has the tag `environment=production`. Specifying `environment=production` as a tag results in an Unauthenticated error. Specifying other tags or specifying no tags will result in the creation of a Spot Instance request.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowRun",
         "Effect": "Allow",
         "Action": ["ec2:RunInstances"],
         "Resource": [
            "arn:aws:ec2:us-east-1::image/*",
            "arn:aws:ec2:us-east-1:*:subnet/*",
            "arn:aws:ec2:us-east-1:*:network-interface/*",
            "arn:aws:ec2:us-east-1:*:security-group/*",
            "arn:aws:ec2:us-east-1:*:key-pair/*",
            "arn:aws:ec2:us-east-1:*:volume/*",
            "arn:aws:ec2:us-east-1:*:instance/*",
            "arn:aws:ec2:us-east-1:*:spot-instances-request/*"
         ]
      },
      {
         "Sid": "DenySpotInstancesRequests",
         "Effect": "Deny",
         "Action": "ec2:RunInstances",
         "Resource": "arn:aws:ec2:us-east-1:*:spot-instances-request/*",
         "Condition": {
            "StringEquals": {
               "aws:RequestTag/environment": "production"
            }
         }
      },
      {
         "Sid": "TagResources",
         "Effect": "Allow",
         "Action": "ec2:CreateTags",
         "Resource": "*"
      }
   ]
}
```

Example: Work with Reserved Instances

The following policy gives users permission to view, modify, and purchase Reserved Instances in your account.

It is not possible to set resource-level permissions for individual Reserved Instances. This policy means that users have access to all the Reserved Instances in the account.

The Resource element uses a * wildcard to indicate that users can specify all resources with the action; in this case, they can list and modify all Reserved Instances in the account. They can also purchase Reserved Instances using the account credentials. The * wildcard is also necessary in cases where the API action does not support resource-level permissions.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "AllowCreate",
         "Effect": "Allow",
         "Action": ["ec2:CreateReservedInstances"],
         "Resource": "*"
      },
      {
         "Sid": "DenyCreateReservedInstances",
         "Effect": "Deny",
         "Action": "ec2:CreateReservedInstances",
         "Resource": "*"
      },
      {
         "Sid": "AllowModify",
         "Effect": "Allow",
         "Action": ["ec2:ModifyReservedInstances"],
         "Resource": "*"
      },
      {
         "Sid": "DenyModifyReservedInstances",
         "Effect": "Deny",
         "Action": "ec2:ModifyReservedInstances",
         "Resource": "*"
      },
      {
         "Sid": "AllowPurchase",
         "Effect": "Allow",
         "Action": ["ec2:CreateReservedInstances"],
         "Resource": "*"
      },
      {
         "Sid": "DenyPurchaseReservedInstances",
         "Effect": "Deny",
         "Action": "ec2:CreateReservedInstances",
         "Resource": "*"
      }
   ]
}
```
"Statement": [
    {
        "Effect": "Allow",
        "Action": [
            "ec2:DescribeReservedInstances",
            "ec2:ModifyReservedInstances",
            "ec2:PurchaseReservedInstancesOffering",
            "ec2:DescribeAvailabilityZones",
            "ec2:DescribeReservedInstancesOfferings"
        ],
        "Resource": "*"
    }
]
}

To allow users to view and modify the Reserved Instances in your account, but not purchase new Reserved Instances.

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeReservedInstances",
                "ec2:ModifyReservedInstances",
                "ec2:DescribeAvailabilityZones"
            ],
            "Resource": "*"
        }
    ]
}

Example: Tag resources

The following policy allows users to use the CreateTags action to apply tags to an instance only if the tag contains the key environment and the value production. No other tags are allowed and the user cannot tag any other resource types.

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:CreateTags"
            ],
            "Condition": {
                "StringEquals": {
                    "aws:RequestTag/environment": "production"
                }
            }
        }
    ]
}

The following policy allows users to tag any taggable resource that already has a tag with a key of owner and a value of the username. In addition, users must specify a tag with a key of anycompany:environment-type and a value of either test or prod in the request. Users can specify additional tags in the request.
You can create an IAM policy that allows users to delete specific tags for a resource. For example, the following policy allows users to delete tags for a volume if the tag keys specified in the request are environment or cost-center. Any value can be specified for the tag but the tag key must match either of the specified keys.

**Note**

If you delete a resource, all tags associated with the resource are also deleted. Users do not need permissions to use the `ec2:DeleteTags` action to delete a resource that has tags; they only need permissions to perform the deleting action.

This policy allows users to delete only the `environment=prod` tag on any resource, and only if the resource is already tagged with a key of owner and a value of the username. Users can't delete any other tags for a resource.
Example: Work with IAM roles

The following policy allows users to attach, replace, and detach an IAM role to instances that have the tag department=test. Replacing or detaching an IAM role requires an association ID, therefore the policy also grants users permission to use the ec2:DescribeIamInstanceProfileAssociations action.

Users must have permission to use the iam:PassRole action in order to pass the role to the instance.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:AssociateIamInstanceProfile",
        "ec2:ReplaceIamInstanceProfileAssociation",
        "ec2:DisassociateIamInstanceProfile"
      ],
      "Resource": "arn:aws:ec2:us-east-1:account-id:instance/*",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/department": "test"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": "ec2:DescribeIamInstanceProfileAssociations",
      "Resource": "+"  
    },
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::account-id:role/DevTeam*"
    }
  ]
}
```

The following policy allows users to attach or replace an IAM role for any instance. Users can only attach or replace IAM roles with names that begin with TestRole-. For the iam:PassRole action, ensure that you specify the name of the IAM role and not the instance profile (if the names are different). For more information, see Instance profiles (p. 1996).

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:AssociateIamInstanceProfile",
        "ec2:ReplaceIamInstanceProfileAssociation"
      ],
      "Resource": "arn:aws:ec2:us-east-1:account-id:instance/*",
      "Condition": {
        "StringEquals": {
          "aws:TagKeys": ["environment"]
        }
      }
    }
  ]
}
```
IAM policies

Example: Work with route tables

The following policy allows users to add, remove, and replace routes for route tables that are associated with VPC `vpc-ec43eb89` only. To specify a VPC for the `ec2:Vpc` condition key, you must specify the full ARN of the VPC.

```
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Action": ["ec2:DeleteRoute", "ec2:CreateRoute", "ec2:ReplaceRoute"],
    "Condition": {
      "StringEquals": {
        "ec2:Vpc": "arn:aws:ec2:region:account-id:vpc/vpc-ec43eb89"
      }
    }
  }
]
```

Example: Allow a specific instance to view resources in other AWS services

The following is an example of a policy that you might attach to an IAM role. The policy allows an instance to view resources in various AWS services. It uses the `ec2:SourceInstanceARN` condition key to specify that the instance from which the request is made must be instance `i-093452212644b0dd6`. If the same IAM role is associated with another instance, the other instance cannot perform any of these actions.

The `ec2:SourceInstanceARN` key is an AWS global condition key, therefore it can be used for other service actions, not just Amazon EC2.

```
"Version": "2012-10-17",
"Statement": [
  {
    "Effect": "Allow",
    "Action": ["ec2:DescribeVolumes", "s3:ListAllMyBuckets"],
    "Condition": {
      "StringEquals": {
        "ec2:SourceInstanceARN": "i-093452212644b0dd6"
      }
    }
  }
]
```
IAM policies

Example: Work with launch templates

The following policy allows users to create a launch template version and modify a launch template, but only for a specific launch template (lt-09477bcd97b0d3abc). Users cannot work with other launch templates.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ec2:CreateLaunchTemplateVersion",
        "ec2:ModifyLaunchTemplate"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:ec2:region:account-id:launch-template/lt-09477bcd97b0d3abc"
    }
  ]
}
```

The following policy allows users to delete any launch template and launch template version, provided that the launch template has the tag Purpose=Testing.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ec2:DeleteLaunchTemplate",
        "ec2:DeleteLaunchTemplateVersions"
      ],
      "Effect": "Allow",
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/Purpose": "Testing"
        }
      }
    }
  ]
}
```

Work with instance metadata

The following policies ensure that users can only retrieve instance metadata (p. 1004) using Instance Metadata Service Version 2 (IMDSv2). You can combine the following four policies into one policy with
four statements. When combined as one policy, you can use the policy as a service control policy (SCP). It can work equally well as a *deny* policy that you apply to an existing IAM policy (taking away and limiting existing permission), or as an SCP that is applied globally across an account, an organizational unit (OU), or an entire organization.

**Note**
The following RunInstances metadata options policies must be used in conjunction with a policy that gives the principal permissions to launch an instance with RunInstances. If the principal does not also have RunInstances permissions, it will not be able to launch an instance. For more information, see the policies in [Work with instances](#) and [Launch instances](#).

**Important**
If you use Auto Scaling groups and you need to require the use of IMDSv2 on all new instances, your Auto Scaling groups must use *launch templates*.

When an Auto Scaling group uses a launch template, the `ec2:RunInstances` permissions of the IAM principal are checked when a new Auto Scaling group is created. They are also checked when an existing Auto Scaling group is updated to use a new launch template or a new version of a launch template.

Restrictions on the use of IMDSv1 on IAM principals for RunInstances are only checked when an Auto Scaling group that is using a launch template, is created or updated. For an Auto Scaling group that is configured to use the *Latest* or *Default* launch template, the permissions are not checked when a new version of the launch template is created. For permissions to be checked, you must configure the Auto Scaling group to use a *specific version* of the launch template.

To enforce the use of IMDSv2 on instances launched by Auto Scaling groups, the following additional steps are required:

1. Disable the use of launch configurations for all accounts in your organization by using either service control policies (SCPs) or IAM permissions boundaries for new principals that are created. For existing IAM principals with Auto Scaling group permissions, update their associated policies with this condition key. To disable the use of launch configurations, create or modify the relevant SCP, permissions boundary, or IAM policy with the "autoscaling:LaunchConfigurationName" condition key with the value specified as null.

2. For new launch templates, configure the instance metadata options in the launch template. For existing launch templates, create a new version of the launch template and configure the instance metadata options in the new version.

3. In the policy that gives any principal the permission to use a launch template, restrict association of $latest and $default by specifying "autoscaling:LaunchTemplateVersionSpecified": "true". By restricting the use to a specific version of a launch template, you can ensure that new instances will be launched using the version in which the instance metadata options are configured. For more information, see [LaunchTemplateSpecification](#) in the Amazon EC2 Auto Scaling API Reference, specifically the Version parameter.

4. For an Auto Scaling group that uses a launch configuration, replace the launch configuration with a launch template. For more information, see [Replacing a Launch Configuration with a Launch Template](#) in the Amazon EC2 Auto Scaling User Guide.

5. For an Auto Scaling group that uses a launch template, make sure that it uses a new launch template with the instance metadata options configured, or uses a new version of the current launch template with the instance metadata options configured. For more information, see [update-auto-scaling-group](#) in the AWS CLI Command Reference.

**Examples**
- [Require the use of IMDSv2](#)
• Deny opt-out of IMDSv2 (p. 1983)
• Specify maximum hop limit (p. 1983)
• Limit who can modify the instance metadata options (p. 1984)
• Require role credentials to be retrieved from IMDSv2 (p. 1984)

Require the use of IMDSv2

The following policy specifies that you can't call the RunInstances API unless the instance is also opted in to require the use of IMDSv2 (indicated by "ec2:MetadataHttpTokens": "required"). If you do not specify that the instance requires IMDSv2, you get an UnauthorizedOperation error when you call the RunInstances API.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RequireImdsV2",
            "Effect": "Deny",
            "Action": "ec2:RunInstances",
            "Resource": "arn:aws:ec2:*::*:instance/*",
            "Condition": {
                "StringNotEquals": {
                    "ec2:MetadataHttpTokens": "required"
                }
            }
        }
    ]
}
```

Deny opt-out of IMDSv2

The following policy specifies that you cannot call the ModifyInstanceMetadataOptions API and allow the option of IMDSv1 or IMDSv2. If you call the ModifyInstanceMetadataOptions API, the HttpTokens attribute must be set to required.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "DenyIMDSv1HttpTokensModification",
            "Effect": "Deny",
            "Action": "ec2:ModifyInstanceMetadataOptions",
            "Resource": "arn:aws:ec2:*::*:instance/*",
            "Condition": {
                "StringNotEquals": {
                    "ec2:Attribute/HttpTokens": "required"
                },
                "Null": {
                    "ec2:Attribute/HttpTokens": false
                }
            }
        }
    ]
}
```

Specify maximum hop limit

The following policy specifies that you can't call the RunInstances API unless you also specify a hop limit, and the hop limit can't be more than 3. If you fail to do that, you get an UnauthorizedOperation error when you call the RunInstances API.

```
```
IAM policies

Limit who can modify the instance metadata options

The following policy permits only users with the role `ec2-imds-admins` to make changes to the instance metadata options. If any principal other than the `ec2-imds-admins` role tries to call the `ModifyInstanceMetadataOptions` API, it will get an `UnauthorizedOperation` error. This statement could be used to control the use of the `ModifyInstanceMetadataOptions` API; there are currently no fine-grained access controls (conditions) for the `ModifyInstanceMetadataOptions` API.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowOnlyImdsAdminsToModifySettings",
            "Effect": "Deny",
            "Action": "ec2:ModifyInstanceMetadataOptions",
            "Resource": "*",
            "Condition": {
                "StringNotLike": {
                    "aws:PrincipalARN": "arn:aws:iam::*:role/ec2-imds-admins"
                }
            }
        }
    ]
}
```

Require role credentials to be retrieved from IMDSv2

The following policy specifies that if this policy is applied to a role, and the role is assumed by the EC2 service and the resulting credentials are used to sign a request, then the request must be signed by EC2 role credentials retrieved from IMDSv2. Otherwise, all of its API calls will get an UnauthorizedOperation error. This statement/policy can be applied generally because, if the request is not signed by EC2 role credentials, it has no effect.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RequireAllEc2RolesToUseV2",
            "Effect": "Deny",
            "Action": "*",
            "Resource": "*",
            "Condition": {
                "NumericLessThan": {
                    "ec2:RoleDelivery": "2.0"
                }
            }
        }
    ]
}
```
Example policies for working in the Amazon EC2 console

You must grant users the permissions they require for Amazon EC2 using IAM policies. You can use IAM policies to grant users permissions to view and work with specific resources in the Amazon EC2 console. You can use the example policies in the previous section; however, they are designed for requests that are made with the AWS CLI or an AWS SDK. For more information, see Example policies for working with the AWS CLI or an AWS SDK (p. 1947) and Creating IAM policies in the IAM User Guide.

The console uses additional API actions for its features, so these policies may not work as expected. For example, a user that has permission to use only the DescribeVolumes API action will encounter errors when trying to view volumes in the console. This section demonstrates policies that enable users to work with specific parts of the console. For additional information about creating policies for the Amazon EC2 console, see the following AWS Security Blog post:Granting Users Permission to Work in the Amazon EC2 Console.

Tip
To help you work out which API actions are required to perform tasks in the console, you can use a service such as AWS CloudTrail. For more information, see the AWS CloudTrail User Guide.

If your policy does not grant permission to create or modify a specific resource, the console displays an encoded message with diagnostic information. You can decode the message using the DecodeAuthorizationMessage API action for AWS STS, or the decode-authorization-message command in the AWS CLI.

Examples
- Example: Read-only access (p. 1985)
- Example: Use the EC2 launch instance wizard (p. 1986)
- Example: Work with volumes (p. 1989)
- Example: Work with security groups (p. 1990)
- Example: Work with Elastic IP addresses (p. 1992)
- Example: Work with Reserved Instances (p. 1993)

Example: Read-only access

To allow users to view all resources in the Amazon EC2 console, you can use the same policy as the following example: Example: Read-only access (p. 1948). Users cannot perform any actions on those resources or create new resources, unless another statement grants them permission to do so.

View instances, AMIs, and snapshots

Alternatively, you can provide read-only access to a subset of resources. To do this, replace the * wildcard in the ec2:Describe API action with specific ec2:Describe actions for each resource. The following policy allows users to view all instances, AMIs, and snapshots in the Amazon EC2 console. The ec2:DescribeTags action allows users to view public AMIs. The console requires the tagging information to display public AMIs; however, you can remove this action to allow users to view only private AMIs.

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [
```
Note
The Amazon EC2 ec2:Describe* API actions do not support resource-level permissions, so you cannot control which individual resources users can view in the console. Therefore, the * wildcard is necessary in the Resource element of the above statement. For more information about which ARNs you can use with which Amazon EC2 API actions, see Actions, resources, and condition keys for Amazon EC2.

View instances and CloudWatch metrics

The following policy allows users to view instances in the Amazon EC2 console, as well as CloudWatch alarms and metrics in the Monitoring tab of the Instances page. The Amazon EC2 console uses the CloudWatch API to display the alarms and metrics, so you must grant users permission to use the cloudwatch:DescribeAlarms, cloudwatch:DescribeAlarmsForMetric, cloudwatch:ListMetrics, cloudwatch:GetMetricStatistics, and cloudwatch:GetMetricData actions.

Example: Use the EC2 launch instance wizard

The Amazon EC2 launch instance wizard is a screen with options to configure and launch an instance. Your policy must include permission to use the API actions that allow users to work with the wizard's options. If your policy does not include permission to use those actions, some items in the wizard cannot load properly, and users cannot complete a launch.

Basic launch instance wizard access

To complete a launch successfully, users must be given permission to use the ec2:RunInstances API action, and at least the following API actions:

- ec2:DescribeImages: To view and select an AMI.
- ec2:DescribeInstanceTypes: To view and select an instance type.
- ec2:DescribeVpcs: To view the available network options.
- ec2:DescribeSubnets: To view all available subnets for the chosen VPC.
IAM policies

- ec2:DescribeSecurityGroups or ec2:CreateSecurityGroup: To view and select an existing security group, or to create a new one.
- ec2:DescribeKeyPairs or ec2:CreateKeyPair: To select an existing key pair, or to create a new one.
- ec2:AuthorizeSecurityGroupIngress: To add inbound rules.

```
{
"Version": "2012-10-17",
"Statement": [
{
"Effect": "Allow",
"Action": [
"ec2:DescribeInstances",
"ec2:DescribeImages",
"ec2:DescribeInstanceTypes",
"ec2:DescribeKeyPairs",
"ec2:DescribeVpcs",
"ec2:DescribeSubnets",
"ec2:DescribeSecurityGroups",
"ec2:CreateSecurityGroup",
"ec2:AuthorizeSecurityGroupIngress",
"ec2:CreateKeyPair"
],
"Resource": "*"
},
{
"Effect": "Allow",
"Action": "ec2:RunInstances",
"Resource": "*"
}
]
}
```

You can add API actions to your policy to provide more options for users, for example:

- ec2:DescribeAvailabilityZones: To view and select a specific Availability Zone.
- ec2:DescribeNetworkInterfaces: To view and select existing network interfaces for the selected subnet.
- To add outbound rules to VPC security groups, users must be granted permission to use the ec2:AuthorizeSecurityGroupEgress API action. To modify or delete existing rules, users must be granted permission to use the relevant ec2:RevokeSecurityGroup* API action.
- ec2:CreateTags: To tag the resources that are created by RunInstances. For more information, see Grant permission to tag resources during creation (p. 1945). If users do not have permission to use this action and they attempt to apply tags on the tagging page of the launch instance wizard, the launch fails.

Important

Specifying a Name while launching an instance creates a tag and requires the ec2:CreateTags action. Be careful about granting users permission to use the ec2:CreateTags action, because doing so limits your ability to use the aws:ResourceTag condition key to restrict their use of other resources. If you grant users permission to use the ec2:CreateTags action, they can change a resource's tag in order to bypass those restrictions. For more information, see Control access to EC2 resources using resource tags (p. 1947).

- To use Systems Manager parameters when selecting an AMI, you must add ssm:DescribeParameters and ssm:GetParameters to your policy. ssm:DescribeParameters grants your users the permission to view and select Systems Manager parameters. ssm:GetParameters grants your users the permission to get the values of the Systems Manager
parameters. You can also restrict access to specific Systems Manager parameters. For more information, see **Restrict access to specific Systems Manager parameters** later in this section.

Currently, the Amazon EC2 Describe* API actions do not support resource-level permissions, so you cannot restrict which individual resources users can view in the launch instance wizard. However, you can apply resource-level permissions on the ec2:RunInstances API action to restrict which resources users can use to launch an instance. The launch fails if users select options that they are not authorized to use.

**Restrict access to a specific instance type, subnet, and Region**

The following policy allows users to launch t2.micro instances using AMIs owned by Amazon, and only into a specific subnet (subnet-1a2b3c4d). Users can only launch in the sa-east-1 Region. If users select a different Region, or select a different instance type, AMI, or subnet in the launch instance wizard, the launch fails.

The first statement grants users permission to view the options in the launch instance wizard or to create new ones, as explained in the example above. The second statement grants users permission to use the network interface, volume, key pair, security group, and subnet resources for the ec2:RunInstances action, which are required to launch an instance into a VPC. For more information about using the ec2:RunInstances action, see [Launch instances (RunInstances)](p.1960). The third and fourth statements grant users permission to use the instance and AMI resources respectively, but only if the instance is a t2.micro instance, and only if the AMI is owned by Amazon, or certain trusted and verified partners.

```json
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": [
      "ec2:DescribeInstances",
      "ec2:DescribeImages",
      "ec2:DescribeInstanceTypes",
      "ec2:DescribeKeyPairs",
      "ec2:CreateKeyPair",
      "ec2:DescribeVpcs",
      "ec2:DescribeSubnets",
      "ec2:DescribeSecurityGroups",
      "ec2:CreateSecurityGroup",
      "ec2:AuthorizeSecurityGroupIngress"
    ],
    "Resource": "*"
  },
  {
    "Effect": "Allow",
    "Action": "ec2:RunInstances",
    "Resource": [
      "arn:aws:ec2:sa-east-1:111122223333:key-pair/**",
      "arn:aws:ec2:sa-east-1:111122223333:subnet/subnet-1a2b3c4d"
    ]
  },
  {
    "Effect": "Allow",
    "Action": "ec2:RunInstances",
    "Resource": [
    ],
    "Condition": {
      "StringEquals": {
        "ec2:InstanceType": "t2.micro"
      }
    }
  }
}
```
Restrict access to specific Systems Manager parameters

The following policy grants access to use Systems Manager parameters with a specific name.

The first statement grants users the permission to view Systems Manager parameters when selecting an AMI in the launch instance wizard. The second statement grants users the permission to only use parameters that are named `prod-`.*

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": ["ssm:DescribeParameters"],
    "Resource": "*"
  },
  {
    "Effect": "Allow",
    "Action": ["ssm:GetParameters"],
  }
}
```

Example: Work with volumes

The following policy grants users permission to view and create volumes, and attach and detach volumes to specific instances.

Users can attach any volume to instances that have the tag "purpose=test", and also detach volumes from those instances. To attach a volume using the Amazon EC2 console, it is helpful for users to have permission to use the `ec2:DescribeInstances` action, as this allows them to select an instance from a pre-populated list in the **Attach Volume** dialog box. However, this also allows users to view all instances on the **Instances** page in the console, so you can omit this action.

In the first statement, the `ec2:DescribeAvailabilityZones` action is necessary to ensure that a user can select an Availability Zone when creating a volume.

Users cannot tag the volumes that they create (either during or after volume creation).

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Effect": "Allow",
    "Action": ["ec2:RunInstances"],
    "Resource": ["arn:aws:ec2:sa-east-1:image/ami-*"],
    "Condition": {
      "StringEquals": {
        "ec2:Owner": "amazon"
      }
    }
  },
  {
    "Effect": "Allow",
    "Action": ["ec2:GetAtt"],
    "Condition": {
      "StringEquals": {
        "ec2:InstanceId": "$aws:cdk:ref:MyInstance"
      }
    }
  }
}
```

1989
Example: Work with security groups

View security groups and add and remove rules

The following policy grants users permission to view security groups in the Amazon EC2 console, to add and remove inbound and outbound rules, and to list and modify rule descriptions for existing security groups that have the tag Department=Test.

In the first statement, the `ec2:DescribeTags` action allows users to view tags in the console, which makes it easier for users to identify the security groups that they are allowed to modify.

```json
[  
  "Version": "2012-10-17",  
  "Statement": [{  
    "Effect": "Allow",  
    "Action": [  
      "ec2:DescribeSecurityGroups",  
      "ec2:DescribeSecurityGroupRules",  
      "ec2:DescribeTags"  
    ],  
    "Resource": "*"  
  },  
  {  
    "Effect": "Allow",  
    "Action": [  
      "ec2:AuthorizeSecurityGroupIngress",  
      "ec2:RevokeSecurityGroupIngress",  
      "ec2:AuthorizeSecurityGroupEgress",  
      "ec2:RevokeSecurityGroupEgress",  
      "ec2:ModifySecurityGroupRules",  
      "ec2:AttachVolume",  
      "ec2:DetachVolume"  
    ],  
    "Condition": {  
      "StringEquals": {  
        "aws:ResourceTag/purpose": "test"  
      }  
    }  
  },  
  {  
    "Effect": "Allow",  
    "Action": [  
      "ec2:AttachVolume",  
      "ec2:DetachVolume"  
    ],  
  }  
]  
]
Work with the Create Security Group dialog box

You can create a policy that allows users to work with the Create Security Group dialog box in the Amazon EC2 console. To use this dialog box, users must be granted permission to use at least the following API actions:

- `ec2:CreateSecurityGroup`: To create a new security group.
- `ec2:DescribeVpcs`: To view a list of existing VPCs in the VPC list.

With these permissions, users can create a new security group successfully, but they cannot add any rules to it. To work with rules in the Create Security Group dialog box, you can add the following API actions to your policy:

- `ec2:AuthorizeSecurityGroupIngress`: To add inbound rules.
- `ec2:AuthorizeSecurityGroupEgress`: To add outbound rules to VPC security groups.
- `ec2:RevokeSecurityGroupIngress`: To modify or delete existing inbound rules. This is useful to allow users to use the Copy to new feature in the console. This feature opens the Create Security Group dialog box and populates it with the same rules as the security group that was selected.
- `ec2:RevokeSecurityGroupEgress`: To modify or delete outbound rules for VPC security groups. This is useful to allow users to modify or delete the default outbound rule that allows all outbound traffic.
- `ec2:DeleteSecurityGroup`: To cater for when invalid rules cannot be saved. The console first creates the security group, and then adds the specified rules. If the rules are invalid, the action fails, and the console attempts to delete the security group. The user remains in the Create Security Group dialog box so that they can correct the invalid rule and try to create the security group again. This API action is not required, but if a user is not granted permission to use it and attempts to create a security group with invalid rules, the security group is created without any rules, and the user must add them afterward.
- `ec2:UpdateSecurityGroupRuleDescriptionsIngress`: To add or update descriptions of ingress (inbound) security group rules.
- `ec2:UpdateSecurityGroupRuleDescriptionsEgress`: To add or update descriptions of egress (outbound) security group rules.
- `ec2:ModifySecurityGroupRules`: To modify security group rules.
- `ec2:DescribeSecurityGroupRules`: To list security group rules.
The following policy grants users permission to use the **Create Security Group** dialog box, and to create inbound and outbound rules for security groups that are associated with a specific VPC (`vpc-1a2b3c4d`). Users can create security groups for a VPC, but they cannot add any rules to them. Similarly, users cannot add any rules to any existing security group that's not associated with VPC `vpc-1a2b3c4d`. Users are also granted permission to view all security groups in the console. This makes it easier for users to identify the security groups to which they can add inbound rules. This policy also grants users permission to delete security groups that are associated with VPC `vpc-1a2b3c4d`.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeSecurityGroups",
                "ec2:CreateSecurityGroup",
                "ec2:DescribeVpcs"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DeleteSecurityGroup",
                "ec2:AuthorizeSecurityGroupIngress",
                "ec2:AuthorizeSecurityGroupEgress"
            ],
            "Condition": {
                "ArnEquals": {
                    "ec2:Vpc": "arn:aws:ec2:region:111122223333:vpc/vpc-1a2b3c4d"
                }
            }
        }
    ]
}
```

**Example: Work with Elastic IP addresses**

To allow users to view Elastic IP addresses in the Amazon EC2 console, you must grant users permission to use the `ec2:DescribeAddresses` action.

To allow users to work with Elastic IP addresses, you can add the following actions to your policy.

- `ec2:AllocateAddress`: To allocate an Elastic IP address.
- `ec2:ReleaseAddress`: To release an Elastic IP address.
- `ec2:AssociateAddress`: To associate an Elastic IP address with an instance or a network interface.
- `ec2:DescribeNetworkInterfaces` and `ec2:DescribeInstances`: To work with the **Associate address** screen. The screen displays the available instances or network interfaces to which you can associate an Elastic IP address.
- `ec2:DisassociateAddress`: To disassociate an Elastic IP address from an instance or a network interface.

The following policy allows users to view, allocate, and associate Elastic IP addresses with instances. Users cannot associate Elastic IP addresses with network interfaces, disassociate Elastic IP addresses, or release them.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeAddresses",
                "ec2:AllocateAddress",
                "ec2:ReleaseAddress",
                "ec2:AssociateAddress",
                "ec2:DescribeNetworkInterfaces",
                "ec2:DescribeInstances"
            ],
            "Resource": "*"
        }
    ]
}
```
Example: Work with Reserved Instances

The following policy allows users to view and modify Reserved Instances in your account, as well as purchase new Reserved Instances in the AWS Management Console.

This policy allows users to view all the Reserved Instances, as well as On-Demand Instances, in the account. It's not possible to set resource-level permissions for individual Reserved Instances.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeReservedInstances",
        "ec2:ModifyReservedInstances",
        "ec2:PurchaseReservedInstancesOffering",
        "ec2:DescribeInstances",
        "ec2:DescribeInstanceTypes",
        "ec2:DescribeAvailabilityTypes",
        "ec2:DescribeAvailabilityZones",
        "ec2:DescribeReservedInstancesOfferings"
      ],
      "Resource": "*"
    }
  ]
}
```

The `ec2:DescribeAvailabilityZones` action is necessary to ensure that the Amazon EC2 console can display information about the Availability Zones in which you can purchase Reserved Instances. The `ec2:DescribeInstances` action is not required, but ensures that the user can view the instances in the account and purchase reservations to match the correct specifications.

You can adjust the API actions to limit user access, for example removing `ec2:DescribeInstances` and `ec2:DescribeAvailabilityZones` means the user has read-only access.

AWS managed policies for Amazon Elastic Compute Cloud

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to
support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won’t break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the **ReadOnlyAccess** AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see [AWS managed policies for job functions](#) in the IAM User Guide.

### AWS managed policy: AmazonEC2FullAccess

You can attach the AmazonEC2FullAccess policy to your IAM identities. This policy grants permissions that allow full access to Amazon EC2.

To view the permissions for this policy, see [AmazonEC2FullAccess](#) in the AWS Managed Policy Reference.

### AWS managed policy: AmazonEC2ReadOnlyAccess

You can attach the AmazonEC2ReadOnlyAccess policy to your IAM identities. This policy grants permissions that allow read-only access to Amazon EC2.

To view the permissions for this policy, see [AmazonEC2ReadOnlyAccess](#) in the AWS Managed Policy Reference.

### AWS managed policy: AWSEC2CapacityReservationFleetRolePolicy

This policy is attached to the service-linked role named AWSServiceRoleForEC2CapacityReservationFleet to allow Capacity Reservations to create, modify, and cancel Capacity Reservations on your behalf. For more information, see Service-linked role for Capacity Reservation Fleet (p. 694).

### AWS managed policy: AWSEC2FleetServiceRolePolicy

This policy is attached to the service-linked role named AWSServiceRoleForEC2Fleet to allow EC2 Fleet to request, launch, terminate, and tag instances on your behalf. For more information, see Service-linked role for EC2 Fleet (p. 1135).

### AWS managed policy: AWSEC2SpotFleetServiceRolePolicy

This policy is attached to the service-linked role named AWSServiceRoleForEC2SpotFleet to allow Spot Fleet to launch and manage instances on your behalf. For more information, see Service-linked role for Spot Fleet (p. 1181).

### AWS managed policy: AWSEC2SpotServiceRolePolicy

This policy is attached to the service-linked role named AWSServiceRoleForEC2Spot to allow Amazon EC2 to launch and manage Spot Instances on your behalf. For more information, see Service-linked role for Spot Instance requests (p. 560).

### Amazon EC2 updates to AWS managed policies

View details about updates to AWS managed policies for Amazon EC2 since this service began tracking these changes.
IAM roles for Amazon EC2

Applications must sign their API requests with AWS credentials. Therefore, if you are an application developer, you need a strategy for managing credentials for your applications that run on EC2 instances. For example, you can securely distribute your AWS credentials to the instances, enabling the applications on those instances to use your credentials to sign requests, while protecting your credentials from other users. However, it's challenging to securely distribute credentials to each instance, especially those that AWS creates on your behalf, such as Spot Instances or instances in Auto Scaling groups. You must also be able to update the credentials on each instance when you rotate your AWS credentials.

**Note**
For your Amazon EC2 workloads, we recommend that you retrieve session credentials using the method described below. These credentials should enable your workload to make AWS API requests, without needing to use `sts:AssumeRole` to assume the same role that is already associated with the instance. Unless you need to pass session tags for attribute-based access control (ABAC) or pass a session policy to further restrict permissions of the role, such role assumption calls are unnecessary as they create a new set of the same temporary role session credentials.

If your workload uses a role to assume itself, you must create a trust policy that explicitly allows that role to assume itself. If you do not create the trust policy, you get the `AccessDenied` error. For more information, see [Modifying a role trust policy](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles wielder-manage.html) in the *IAM User Guide*.

We designed IAM roles so that your applications can securely make API requests from your instances, without requiring you to manage the security credentials that the applications use. Instead of creating and distributing your AWS credentials, you can delegate permission to make API requests using IAM roles as follows:

1. Create an IAM role.
2. Define which accounts or AWS services can assume the role.
3. Define which API actions and resources the application can use after assuming the role.
4. Specify the role when you launch your instance, or attach the role to an existing instance.
5. Have the application retrieve a set of temporary credentials and use them.

For example, you can use IAM roles to grant permissions to applications running on your instances that need to use a bucket in Amazon S3. You can specify permissions for IAM roles by creating a policy in JSON format. These are similar to the policies that you create for users. If you change a role, the change is propagated to all instances.

When creating IAM roles, associate least privilege IAM policies that restrict access to the specific API calls the application requires.

You can only attach one IAM role to an instance, but you can attach the same role to many instances. For more information about creating and using IAM roles, see [Roles](https://docs.aws.amazon.com/IAM/latest/UserGuide/r_iam-creating-new-role.html) in the *IAM User Guide*.

You can apply resource-level permissions to your IAM policies to control the users' ability to attach, replace, or detach IAM roles for an instance. For more information, see [Supported resource-level permissions for Amazon EC2 API actions](https://docs.aws.amazon.com/AWSEC2/latest/APIReference/ResourceLevelPermissions.html) and the following example: [Example: Work with IAM roles](https://docs.aws.amazon.com/AWSEC2/latest/APIReference/Example_create_iam_role.html).
**Instance profiles**

Amazon EC2 uses an *instance profile* as a container for an IAM role. When you create an IAM role using the IAM console, the console creates an instance profile automatically and gives it the same name as the role to which it corresponds. If you use the Amazon EC2 console to launch an instance with an IAM role or to attach an IAM role to an instance, you choose the role based on a list of instance profile names.

If you use the AWS CLI, API, or an AWS SDK to create a role, you create the role and instance profile as separate actions, with potentially different names. If you then use the AWS CLI, API, or an AWS SDK to launch an instance with an IAM role or to attach an IAM role to an instance, specify the instance profile name.

An instance profile can contain only one IAM role. This limit cannot be increased.

For more information, see *Instance Profiles* in the *IAM User Guide*.

**Retrieve security credentials from instance metadata**

An application on the instance retrieves the security credentials provided by the role from the instance metadata item `iam/security-credentials/role-name`. The application is granted the permissions for the actions and resources that you've defined for the role through the security credentials associated with the role. These security credentials are temporary and we rotate them automatically. We make new credentials available at least five minutes before the expiration of the old credentials.

**Warning**

If you use services that use instance metadata with IAM roles, ensure that you don't expose your credentials when the services make HTTP calls on your behalf. The types of services that could expose your credentials include HTTP proxies, HTML/CSS validator services, and XML processors that support XML inclusion.

The following command retrieves the security credentials for an IAM role named *s3access*.

**IMDSv2**

```
```

**IMDSv1**

```
```

The following is example output.

```
{
    "Code" : "Success",
```
For applications, AWS CLI, and Tools for Windows PowerShell commands that run on the instance, you do not have to explicitly get the temporary security credentials—the AWS SDKs, AWS CLI, and Tools for Windows PowerShell automatically get the credentials from the EC2 instance metadata service and use them. To make a call outside of the instance using temporary security credentials (for example, to test IAM policies), you must provide the access key, secret key, and the session token. For more information, see Using Temporary Security Credentials to Request Access to AWS Resources in the IAM User Guide.

For more information about instance metadata, see Instance metadata and user data (p. 1004). For information about the instance metadata IP address, see Retrieve instance metadata (p. 1021).

### Grant a user permission to pass an IAM role to an instance

To enable a user to launch an instance with an IAM role or to attach or replace an IAM role for an existing instance, you must grant the user permission to use the following API actions:

- `iam:PassRole`
- `ec2:AssociateIamInstanceProfile`
- `ec2:ReplaceIamInstanceProfileAssociation`

For example, the following IAM policy grants users permission to launch instances with an IAM role, or to attach or replace an IAM role for an existing instance using the AWS CLI.

**Note**
If you want the policy to grant users access to all of your roles, specify the resource as `*` in the policy. However, please consider the principle of least privilege as a best-practice.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:RunInstances",
        "ec2:AssociateIamInstanceProfile",
        "ec2:ReplaceIamInstanceProfileAssociation"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::123456789012:role/DevTeam*"
    }
  ]
}
```

To grant users permission to launch instances with an IAM role, or to attach or replace an IAM role for an existing instance using the Amazon EC2 console, you must grant them permission to use `iam:ListInstanceProfiles`, `iam:PassRole`, `ec2:AssociateIamInstanceProfile`, and `ec2:ReplaceIamInstanceProfileAssociation` in addition to any other permissions they might need. For example policies, see Example policies for working in the Amazon EC2 console (p. 1985).
Work with IAM roles

You can create an IAM role and attach it to an instance during or after launch. You can also replace or detach an IAM role for an instance.

Contents

- Create an IAM role (p. 1998)
- Launch an instance with an IAM role (p. 2000)
- Attach an IAM role to an instance (p. 2002)
- Replace an IAM role (p. 2003)
- Detach an IAM role (p. 2004)
- Generate a policy for your IAM role based on access activity (p. 2005)

Create an IAM role

You must create an IAM role before you can launch an instance with that role or attach it to an instance.

Console

To create an IAM role using the IAM console

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles then choose Create role.
3. On the Select trusted entity page, choose AWS service, and then select the EC2 use case. Choose Next.
4. On the Add permissions page, select the policies that grants your instances access to the resources that they need. Choose Next.
5. On the Name, review, and create page, enter a name and description for the role. Optionally, add tags to the role. Choose Create role.

Command line

The following example creates an IAM role with a policy that allows the role to use an Amazon S3 bucket.

To create an IAM role and instance profile (AWS CLI)

1. Create the following trust policy and save it in a text file named ec2-role-trust-policy.json.

   ```json
   {
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Principal": { "Service": "ec2.amazonaws.com"},
   "Action": "sts:AssumeRole"
   }
   ]
   }
   ```

2. Create the s3access role and specify the trust policy that you created using the create-role command.

   ```bash
   aws iam create-role
   ```
--role-name s3access \
--assume-role-policy-document file://ec2-role-trust-policy.json

Example response

```json
{
   "Role": {
      "AssumeRolePolicyDocument": {
         "Version": "2012-10-17",
         "Statement": [
            {
               "Action": "sts:AssumeRole",
               "Effect": "Allow",
               "Principal": {
                  "Service": "ec2.amazonaws.com"
               }
            }
         ],
         "RoleId": "AROAIIZKPBKS2LEXAMPLE",
         "CreateDate": "2013-12-12T23:46:37.247Z",
         "RoleName": "s3access",
         "Path": "/",
         "Arn": "arn:aws:iam::123456789012:role/s3access"
      }
   }
}
```

3. Create an access policy and save it in a text file named `ec2-role-access-policy.json`. For example, this policy grants administrative permissions for Amazon S3 to applications running on the instance.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["s3:*"],
         "Resource": ["*"]
      }
   ]
}
```

4. Attach the access policy to the role using the `put-role-policy` command.

```bash
aws iam put-role-policy \
   --role-name s3access \
   --policy-name S3-Permissions \
   --policy-document file://ec2-role-access-policy.json
```

5. Create an instance profile named `s3access-profile` using the `create-instance-profile` command.

```bash
aws iam create-instance-profile --instance-profile-name s3access-profile
```

Example response

```json
{
   "InstanceProfile": {
      "InstanceProfileId": "AIPAJTLBPJLEGEXAMPLE",
      "Roles": [],
      "CreateDate": "2013-12-12T23:53:34.093Z"
   }
}
```
6. Add the s3access role to the s3access-profile instance profile.

```bash
aws iam add-role-to-instance-profile --instance-profile-name s3access-profile --role-name s3access
```

Alternatively, you can use the following AWS Tools for Windows PowerShell commands:

- New-IAMRole
- Register-IAMRolePolicy
- New-IAMInstanceProfile

Launch an instance with an IAM role

After you’ve created an IAM role, you can launch an instance, and associate that role with the instance during launch.

**Important**

After you create an IAM role, it might take several seconds for the permissions to propagate. If your first attempt to launch an instance with a role fails, wait a few seconds before trying again. For more information, see Troubleshooting IAM roles in the IAM User Guide.

**New console**

**To launch an instance with an IAM role (console)**

1. Follow the procedure to launch an instance (p. 722).
2. Expand **Advanced details**, and for **IAM instance profile**, select the IAM role that you created.

   **Note**
   The **IAM instance profile** list displays the name of the instance profile that you created when you created your IAM role. If you created your IAM role using the console, the instance profile was created for you and given the same name as the role. If you created your IAM role using the AWS CLI, API, or an AWS SDK, you may have named your instance profile differently.
3. Configure any other details that you require for your instance or accept the defaults, and select a key pair. For information about the fields in the launch instance wizard, see Launch an instance using defined parameters (p. 722).
4. In the **Summary** panel, review your instance configuration, and then choose **Launch instance**.
5. If you are using the Amazon EC2 API actions in your application, retrieve the AWS security credentials made available on the instance and use them to sign the requests. The AWS SDK does this for you.

**IMDSv2**

```bash
```
Old console

To launch an instance with an IAM role (console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the dashboard, choose Launch instance.
3. Select an AMI and instance type and then choose Next: Configure Instance Details.
4. On the Configure Instance Details page, for IAM role, select the IAM role that you created.
   
   **Note**
   The IAM role list displays the name of the instance profile that you created when you created your IAM role. If you created your IAM role using the console, the instance profile was created for you and given the same name as the role. If you created your IAM role using the AWS CLI, API, or an AWS SDK, you may have named your instance profile differently.

5. Configure any other details, then follow the instructions through the rest of the wizard, or choose Review and Launch to accept default settings and go directly to the Review Instance Launch page.
6. Review your settings, then choose Launch to choose a key pair and launch your instance.
7. If you are using the Amazon EC2 API actions in your application, retrieve the AWS security credentials made available on the instance and use them to sign the requests. The AWS SDK does this for you.

Command line

You can use the AWS CLI to associate a role with an instance during launch. You must specify the instance profile in the command.

To launch an instance with an IAM role (AWS CLI)

1. Use the run-instances command to launch an instance using the instance profile. The following example shows how to launch an instance with the instance profile.

```
aws ec2 run-instances
   --image-id ami-11aa22bb
   --iam-instance-profile Name="s3access-profile"
```
Attach an IAM role to an instance

To attach an IAM role to an instance that has no role, the instance can be in the stopped or running state.

Console

To attach an IAM role to an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, choose Actions, Security, Modify IAM role.
4. Select the IAM role to attach to your instance, and choose Save.

Command line

To attach an IAM role to an instance (AWS CLI)

1. If required, describe your instances to get the ID of the instance to which to attach the role.

aws ec2 describe-instances

2. Use the associate-iam-instance-profile command to attach the IAM role to the instance by specifying the instance profile. You can use the Amazon Resource Name (ARN) of the instance profile, or you can use its name.

aws ec2 associate-iam-instance-profile \
--instance-id i-1234567890abcdef0 \
--iam-instance-profile Name="TestRole-1"

Example response

```json
{
    "IamInstanceProfileAssociation": {
        "InstanceId": "i-1234567890abcdef0",
        "State": "associating",
        "AssociationId": "iip-assoc-0dbd8529a48294120",
        "IamInstanceProfile": {
            "Id": "AIPAJLNLDX3AMYZNYYAY",
            "Arn": "arn:aws:iam::123456789012:instance-profile/TestRole-1"
        }
    }
}
```
Alternatively, use the following Tools for Windows PowerShell commands:

- Get-EC2Instance
- Register-EC2IamInstanceProfile

Replace an IAM role

To replace the IAM role on an instance that already has an attached IAM role, the instance must be in the running state. You can do this if you want to change the IAM role for an instance without detaching the existing one first. For example, you can do this to ensure that API actions performed by applications running on the instance are not interrupted.

Console

To replace an IAM role for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance, choose Actions, Security, Modify IAM role.
4. Select the IAM role to attach to your instance, and choose Save.

Command line

To replace an IAM role for an instance (AWS CLI)

1. If required, describe your IAM instance profile associations to get the association ID for the IAM instance profile to replace.

   ```bash
   aws ec2 describe-iam-instance-profile-associations
   ```

2. Use the `replace-iam-instance-profile-association` command to replace the IAM instance profile by specifying the association ID for the existing instance profile and the ARN or name of the instance profile that should replace it.

   ```bash
   aws ec2 replace-iam-instance-profile-association
   --association-id iip-assoc-0044d817db6c0a4ba
   --iam-instance-profile Name="TestRole-2"
   ```

Example response

```json
{
   "IamInstanceProfileAssociation": {
   "InstanceId": "i-087711ddaf98f9489",
   "State": "associating",
   "AssociationId": "iip-assoc-09654be48e33b9e0",
   "IamInstanceProfile": {
   "Id": "AIPAJCJEDKX7QYHMK76S",
   "Arn": "arn:aws:iam::123456789012:instance-profile/TestRole-2"
   }"n
   }
}
```

Alternatively, use the following Tools for Windows PowerShell commands:

- Get-EC2IamInstanceProfileAssociation
• **Set-EC2IamInstanceProfileAssociation**

**Detach an IAM role**

You can detach an IAM role from a running or stopped instance.

**Console**

**To detach an IAM role from an instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance, choose **Actions, Security, Modify IAM role**.
4. For **IAM role**, choose **No IAM Role**. Choose **Save**.
5. In the confirmation dialog box, enter **Detach**, and then choose **Detach**.

**Command line**

**To detach an IAM role from an instance (AWS CLI)**

1. If required, use **describe-iam-instance-profile-associations** to describe your IAM instance profile associations and get the association ID for the IAM instance profile to detach.

   ```bash
   aws ec2 describe-iam-instance-profile-associations
   ```

   **Example response**

   ```json
   {
   "IamInstanceProfileAssociations": [
   {
   "InstanceId": "i-088ce778fbfeb4361",
   "State": "associated",
   "AssociationId": "iip-assoc-0044d817db6c0a4ba",
   "IamInstanceProfile": {
   "Id": "AIPAJEDNCAA64SSD265D6",
   "Arn": "arn:aws:iam::123456789012:instance-profile/TestRole-2"
   }
   }]
   }
   ```

2. Use the **disassociate-iam-instance-profile** command to detach the IAM instance profile using its association ID.

   ```bash
   aws ec2 disassociate-iam-instance-profile --association-id iip-assoc-0044d817db6c0a4ba
   ```

   **Example response**

   ```json
   {
   "IamInstanceProfileAssociation": {
   "InstanceId": "i-087711ddaf98f9489",
   "State": "disassociating",
   "AssociationId": "iip-assoc-0044d817db6c0a4ba",
   "IamInstanceProfile": {
   "Id": "AIPAJEDNCAA64SSD265D6",
   }"};
   ```

---

2004
Generate a policy for your IAM role based on access activity

When you first create an IAM role for your applications, you might sometimes grant permissions beyond what is required. Before launching your application in your production environment, you can generate an IAM policy that is based on the access activity for an IAM role. IAM Access Analyzer reviews your AWS CloudTrail logs and generates a policy template that contains the permissions that have been used by the role in your specified date range. You can use the template to create a managed policy with fine-grained permissions and then attach it to the IAM role. That way, you grant only the permissions that the role needs to interact with AWS resources for your specific use case. This helps you adhere to the best practice of granting least privilege. To learn more, see Generate policies based on access activity in the IAM User Guide.

Authorize inbound traffic for your Linux instances

Security groups enable you to control traffic to your instance, including the kind of traffic that can reach your instance. For example, you can allow computers from only your home network to access your instance using SSH. If your instance is a web server, you can allow all IP addresses to access your instance using HTTP or HTTPS, so that external users can browse the content on your web server.

Your default security groups and newly created security groups include default rules that do not enable you to access your instance from the internet. For more information, see Default security groups (p. 2029) and Custom security groups (p. 2030). To enable network access to your instance, you must allow inbound traffic to your instance. To open a port for inbound traffic, add a rule to a security group that you associated with your instance when you launched it.

To connect to your instance, you must set up a rule to authorize SSH traffic from your computer’s public IPv4 address. To allow SSH traffic from additional IP address ranges, add another rule for each range you need to authorize.

If you’ve enabled your VPC for IPv6 and launched your instance with an IPv6 address, you can connect to your instance using its IPv6 address instead of a public IPv4 address. Your local computer must have an IPv6 address and must be configured to use IPv6.

If you need to enable network access to a Windows instance, see Authorizing inbound traffic for your Windows instances in the Amazon EC2 User Guide for Windows Instances.

Before you start

Decide who requires access to your instance; for example, a single host or a specific network that you trust such as your local computer’s public IPv4 address. The security group editor in the Amazon EC2 console can automatically detect the public IPv4 address of your local computer for you. Alternatively, you can use the search phrase "what is my IP address" in an internet browser, or use the following service: Check IP. If you are connecting through an ISP or from behind your firewall without a static IP address, you need to find out the range of IP addresses used by client computers.
Warning
If you use 0.0.0.0/0, you enable all IPv4 addresses to access your instance using SSH. If you use ::/0, you enable all IPv6 addresses to access your instance. You should authorize only a specific IP address or range of addresses to access your instance.

Decide whether you’ll support SSH access to your instances using EC2 Instance Connect. If you will not use EC2 Instance Connect, consider uninstalling it or denying the following action in your IAM policies: ec2-instance-connect:SendSSHPublicKey. For more information, see Uninstall EC2 Instance Connect (p. 846) and Configure IAM Permissions for EC2 Instance Connect (p. 833).

Add a rule for inbound SSH traffic to a Linux instance

Security groups act as a firewall for associated instances, controlling both inbound and outbound traffic at the instance level. You must add rules to a security group to enable you to connect to your Linux instance from your IP address using SSH.

To add a rule to a security group for inbound SSH traffic over IPv4 (console)
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the top navigation bar, select a Region for the security group. Security groups are specific to a Region, so you should select the same Region in which you created your instance.
3. In the navigation pane, choose Instances.
4. Select your instance and, in bottom half of the screen, choose the Security tab. Security groups lists the security groups that are associated with the instance. Inbound rules displays a list of the inbound rules that are in effect for the instance.
5. For the security group to which you’ll add the new rule, choose the security group ID link to open the security group.
7. On the Edit inbound rules page, do the following:
   a. Choose Add rule.
   b. For Type, choose SSH.
   c. For Source, choose My IP to automatically populate the field with the public IPv4 address of your local computer. Alternatively, for Source, choose Custom and enter the public IPv4 address of your computer or network in CIDR notation. For example, if your IPv4 address is 203.0.113.25, enter 203.0.113.25/32 to list this single IPv4 address in CIDR notation. If your company allocates addresses from a range, enter the entire range, such as 203.0.113.0/24.
   d. Choose Save rules.

If you launched an instance with an IPv6 address and want to connect to your instance using its IPv6 address, you must add rules that allow inbound IPv6 traffic over SSH.

To add a rule to a security group for inbound SSH traffic over IPv6 (console)
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the top navigation bar, select a Region for the security group. Security groups are specific to a Region, so you should select the same Region in which you created your instance.
3. In the navigation pane, choose Instances.
4. Select your instance and, in bottom half of the screen, choose the Security tab. Security groups lists the security groups that are associated with the instance. Inbound rules displays a list of the inbound rules that are in effect for the instance.
5. For the security group to which you'll add the new rule, choose the security group ID link to open the security group.

7. On the Edit inbound rules page, do the following:
   a. Choose Add rule.
   b. For Type, choose SSH.
   c. For Source, choose Custom and enter the IPv6 address of your computer in CIDR notation. For example, if your IPv6 address is 2001:db8:1234:1a00:9691:9503:25ad:1761, enter 2001:db8:1234:1a00:9691:9503:25ad:1761/128 to list the single IP address in CIDR notation. If your company allocates addresses from a range, enter the entire range, such as 2001:db8:1234:1a00::/64.
   d. Choose Save rules.

**Note**

Be sure to run the following commands on your local system, not on the instance itself. For more information about these command line interfaces, see *Access Amazon EC2 (p. 5)*.

**To add a rule to a security group using the command line**

1. Find the security group that is associated with your instance using one of the following commands:

   **describe-instance-attribute** (AWS CLI)

   ```bash
   aws ec2 describe-instance-attribute --region region --instance-id instance_id --attribute groupSet
   ```

   **Get-EC2InstanceAttribute** (AWS Tools for Windows PowerShell)

   ```powershell
   PS C:\> (Get-EC2InstanceAttribute -Region region -InstanceId instance_id -Attribute groupSet).Groups
   ```

   Both commands return a security group ID, which you use in the next step.

2. Add the rule to the security group using one of the following commands:

   **authorize-security-group-ingress** (AWS CLI)

   ```bash
   aws ec2 authorize-security-group-ingress --region region --group-id security_group_id --protocol tcp --port 22 --cidr cidr_ip_range
   ```

   **Grant-EC2SecurityGroupIngress** (AWS Tools for Windows PowerShell)

   The Grant-EC2SecurityGroupIngress command needs an IpPermission parameter, which describes the protocol, port range, and IP address range to be used for the security group rule. The following command creates the IpPermission parameter:

   ```powershell
   PS C:\> $ip1 = @([PSCustomObject]@{ IpProtocol="tcp"; FromPort=22; ToPort=22; IpRanges="cidr_ip_range" })
   ```

   ```powershell
   PS C:\> Grant-EC2SecurityGroupIngress -Region region -GroupId security_group_id -IpPermission @{$ip1}
   ```
Assign a security group to an instance

You can assign a security group to an instance when you launch the instance. When you add or remove rules, those changes are automatically applied to all instances to which you've assigned the security group.

After you launch an instance, you can change its security groups. For more information, see the section called "Change an instance's security group" (p. 2036).

Amazon EC2 key pairs and Linux instances

A key pair, consisting of a public key and a private key, is a set of security credentials that you use to prove your identity when connecting to an Amazon EC2 instance. Amazon EC2 stores the public key on your instance, and you store the private key. For Linux instances, the private key allows you to securely SSH into your instance. As an alternative to key pairs, you can use AWS Systems Manager Session Manager to connect to your instance with an interactive one-click browser-based shell or the AWS Command Line Interface (AWS CLI).

Anyone who possesses your private key can connect to your instances, so it's important that you store your private key in a secure place.

When you launch an instance, you can specify a key pair (p. 724). If you plan to connect to the instance using SSH, you must specify a key pair. You can choose an existing key pair or create a new one. Depending on how you manage your security, you can specify the same key pair for all your instances or you can specify different key pairs. When your instance boots for the first time, the public key that you specified at launch is placed on your Linux instance in an entry within ~/.ssh/authorized_keys. When you connect to your Linux instance using SSH, to log in you must specify the private key that corresponds to the public key. For more information about connecting to your instance, see Connect to your Linux instance (p. 811). For more information about key pairs and Windows instances, see Amazon EC2 key pairs and Windows instances in the Amazon EC2 User Guide for Windows Instances.

Because Amazon EC2 doesn't keep a copy of your private key, there is no way to recover a private key if you lose it. However, there can still be a way to connect to instances for which you've lost the private key. For more information, see I've lost my private key. How can I connect to my Linux instance? (p. 2545)

You can use Amazon EC2 to create your key pairs. You can also use a third-party tool to create your key pairs, and then import the public keys to Amazon EC2.

Amazon EC2 supports ED25519 and 2048-bit SSH-2 RSA keys for Linux instances.

You can have up to 5,000 key pairs per Region.

Contents

- Create key pairs (p. 2008)
- Tag a public key (p. 2013)
- Describe public keys (p. 2015)
- Delete your public key on Amazon EC2 (p. 2019)
- Add or remove a public key on your instance (p. 2020)
- Verify the fingerprint of your key pair (p. 2021)

Create key pairs

You can use Amazon EC2 to create an RSA or ED25519 key pair, or you can use a third-party tool to create a key pair and then import the public key to Amazon EC2.
Create a key pair using Amazon EC2

When you create a key pair using Amazon EC2, the public key is stored in Amazon EC2, and you store the private key.

You can use Amazon EC2 to create a key pair using one of the following methods.

Console

To create a key pair using Amazon EC2

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, under Network & Security, choose Key Pairs.
3. Choose Create key pair.
4. For Name, enter a descriptive name for the key pair. Amazon EC2 associates the public key with the name that you specify as the key name. A key name can include up to 255 ASCII characters. It can’t include leading or trailing spaces.
5. For Key pair type, choose either RSA or ED25519.
6. For Private key file format, choose the format in which to save the private key. To save the private key in a format that can be used with OpenSSH, choose pem. To save the private key in a format that can be used with PuTTY, choose ppk.
7. To add a tag to the public key, choose Add tag, and enter the key and value for the tag. Repeat for each tag.
8. Choose Create key pair.
9. The private key file is automatically downloaded by your browser. The base file name is the name that you specified as the name of your key pair, and the file name extension is determined by the file format that you chose. Save the private key file in a safe place.
10. If you plan to use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

   chmod 400 key-pair-name.pem

   If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see Error: Unprotected private key file (p. 2541).

AWS CLI

To create a key pair using Amazon EC2

1. Use the create-key-pair command as follows to generate the key pair and to save the private key to a .pem file.
Create key pairs

For **--key-name**, specify a name for the public key. The name can be up to 255 ASCII characters.

For **--key-type**, specify either rsa or ed25519. If you do not include the **--key-type** parameter, an rsa key is created by default. Note that ED25519 keys are not supported for Windows instances.

For **--key-format**, specify either pem or ppk. If you do not include the **--key-format** parameter, a pem file is created by default.

**--query** "KeyMaterial" prints the private key material to the output.

**--output** text > *my-key-pair.pem* saves the private key material in a file with the specified extension. The extension can be either .pem or .ppk. The private key can have a name that's different from the public key name, but for ease of use, use the same name.

```shell
code
aws ec2 create-key-pair \
  --key-name *my-key-pair* \
  --key-type rsa \
  --key-format pem \
  --query "KeyMaterial" \
  --output text > *my-key-pair.pem*
```

2. If you plan to use an SSH client on a macOS or Linux computer to connect to your Linux instance, use the following command to set the permissions of your private key file so that only you can read it.

```
code
chmod 400 *key-pair-name*.pem
```

If you do not set these permissions, then you cannot connect to your instance using this key pair. For more information, see Error: Unprotected private key file (p. 2541).

PowerShell

**To create a key pair using Amazon EC2**

Use the *New-EC2KeyPair* AWS Tools for Windows PowerShell command as follows to generate the key and save it to a .pem or .ppk file.

For **-KeyName**, specify a name for the public key. The name can be up to 255 ASCII characters.

For **-KeyType**, specify either rsa or ed25519. If you do not include the **-KeyType** parameter, an rsa key is created by default. Note that ED25519 keys are not supported for Windows instances.

For **-KeyFormat**, specify either pem or ppk. If you do not include the **-KeyFormat** parameter, a pem file is created by default.

**KeyMaterial** prints the private key material to the output.

```
code
Out-File -Encoding ascii -FilePath C:\path\my-key-pair.pem saves the private key material in a file with the specified extension. The extension can be .pem or .ppk. The private key can have a name that's different from the public key name, but for ease of use, use the same name.

```
Create a key pair using AWS CloudFormation

When you create a new key pair using AWS CloudFormation, the private key is saved to AWS Systems Manager Parameter Store. The parameter name has the following format:

```
/ec2/keypair/key_pair_id
```

For more information, see AWS Systems Manager Parameter Store in the AWS Systems Manager User Guide.

To create a key pair using AWS CloudFormation

1. Specify the `AWS::EC2::KeyPair` resource in your template.

   ```
   Resources:
     NewKeyPair:
       Type: 'AWS::EC2::KeyPair'
       Properties:
         KeyName: new-key-pair
   ```

2. Use the `describe-key-pairs` command as follows to get the ID of the key pair.

   ```
   aws ec2 describe-key-pairs --filters Name=key-name,Values=new-key-pair --query KeyPairs[*].KeyPairId --output text
   ```

   The following is example output.

   ```
   key-05abb699beEXAMPLE
   ```

3. Use the `get-parameter` command as follows to get the parameter for your key and save the key material in a `.pem` file.

   ```
   aws ssm get-parameter --name /ec2/keypair/key-05abb699beEXAMPLE --with-decryption --query Parameter.Value --output text > new-key-pair.pem
   ```

Required IAM permissions

To enable AWS CloudFormation to manage Parameter Store parameters on your behalf, the IAM role assumed by AWS CloudFormation or your user must have the following permissions:

- `ssm:PutParameter` – Grants permission to create a parameter for the private key material.
- `ssm:DeleteParameter` – Grants permission to delete the parameter that stored the private key material. This permission is required whether the key pair was imported or created by AWS CloudFormation.

When AWS CloudFormation deletes a key pair that was created or imported by a stack, it performs a permissions check to determine whether you have permission to delete parameters, even though AWS CloudFormation creates a parameter only when it creates a key pair, not when it imports a key pair. AWS CloudFormation tests for the required permission using a fabricated parameter name that does not match any parameter in your account. Therefore, you might see a fabricated parameter name in the `AccessDeniedException` error message.
Create a key pair using a third-party tool and import the public key to Amazon EC2

Instead of using Amazon EC2 to create a key pair, you can create an RSA or ED25519 key pair by using a third-party tool, and then import the public key to Amazon EC2.

Requirements for key pairs

- Supported types: RSA and ED25519. Amazon EC2 does not accept DSA keys.
  
  **Note**
  ED25519 keys are not supported for Windows instances.

- Supported formats:
  - OpenSSH public key format (the format in `~/.ssh/authorized_keys`). If you connect using SSH while using the EC2 Instance Connect API, the SSH2 format is also supported.
  - SSH private key file format must be PEM or PPK
  - (RSA only) Base64 encoded DER format
  - (RSA only) SSH public key file format as specified in RFC 4716

- Supported lengths: 1024, 2048, and 4096. If you connect using SSH while using the EC2 Instance Connect API, the supported lengths are 2048 and 4096.

To create a key pair using a third-party tool

1. Generate a key pair with a third-party tool of your choice. For example, you can use `ssh-keygen` (a tool provided with the standard OpenSSH installation). Alternatively, Java, Ruby, Python, and many other programming languages provide standard libraries that you can use to create an RSA or ED25519 key pair.

   **Important**
   The private key must be in the PEM or PPK format. For example, use `ssh-keygen -m PEM` to generate the OpenSSH key in the PEM format.

2. Save the public key to a local file. For example, `~/.ssh/my-key-pair.pub`. The file name extension for this file is not important.

3. Save the private key to a local file that has the .pem or .ppk extension. For example, `~/.ssh/my-key-pair.pem` or `~/.ssh/my-key-pair.ppk`.

   **Important**
   Save the private key file in a safe place. You'll need to provide the name of your public key when you launch an instance, and the corresponding private key each time you connect to the instance.

After you have created the key pair, use one of the following methods to import your public key to Amazon EC2.

Console

To import the public key to Amazon EC2

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Key Pairs**.
3. Choose **Import key pair**.
4. For **Name**, enter a descriptive name for the public key. The name can include up to 255 ASCII characters. It can't include leading or trailing spaces.
Note
When you connect to your instance from the EC2 console, the console suggests this name for the name of your private key file.

5. Either choose Browse to navigate to and select your public key, or paste the contents of your public key into the Public key contents field.

6. Choose Import key pair.

7. Verify that the public key that you imported appears in the list of key pairs.

AWS CLI

To import the public key to Amazon EC2
Use the `import-key-pair` AWS CLI command.

To verify that the key pair was imported successfully
Use the `describe-key-pairs` AWS CLI command.

PowerShell

To import the public key to Amazon EC2
Use the `Import-EC2KeyPair` AWS Tools for Windows PowerShell command.

To verify that the key pair was imported successfully
Use the `Get-EC2KeyPair` AWS Tools for Windows PowerShell command.

Tag a public key

To help categorize and manage the public keys that you've either created using Amazon EC2 or imported to Amazon EC2, you can tag them with custom metadata. For more information about how tags work, see Tag your Amazon EC2 resources (p. 2507).

You can view, add, and delete tags using one of the following methods.

Console

To view, add, or delete a tag for a public key

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Key Pairs.
3. Select a public key, and then choose Actions, Manage tags.
4. The Manage tags page displays any tags that are assigned to the public key.
   - To add a tag, choose Add tag, and then enter the tag key and value. You can add up to 50 tags per key. For more information, see Tag restrictions (p. 2512).
   - To delete a tag, choose Remove next to the tag to delete.
5. Choose Save.

AWS CLI

To view public key tags
Use the `describe-tags` AWS CLI command. In the following example, you describe the tags for all of your public keys.

```bash
$ aws ec2 describe-tags --filters "Name=resource-type,Values=key-pair"
```

```
{
  "Tags": [
    {
      "Key": "Environment",
      "ResourceId": "key-0123456789EXAMPLE",
      "ResourceType": "key-pair",
      "Value": "Production"
    },
    {
      "Key": "Environment",
      "ResourceId": "key-9876543210EXAMPLE",
      "ResourceType": "key-pair",
      "Value": "Production"
    }
  ]
}
```

**To describe the tags for a specific public key**

Use the `describe-key-pairs` AWS CLI command.

```bash
$ aws ec2 describe-key-pairs --key-pair-ids key-0123456789EXAMPLE
```

```
{
  "KeyPairs": [
    {
      "KeyName": "MyKeyPair",
      "KeyPairId": "key-0123456789EXAMPLE",
      "Tags": [
        {
          "Key": "Environment",
          "Value": "Production"
        }
      ]
    }
  ]
}
```

**To tag a public key**

Use the `create-tags` AWS CLI command. In the following example, the public key is tagged with Key=Cost-Center and Value=CC-123.

```bash
$ aws ec2 create-tags --resources key-0123456789EXAMPLE --tags Key=Cost-Center,Value=CC-123
```

**To delete a tag from a public key**

Use the `delete-tags` AWS CLI command. For examples, see [Examples](#) in the [AWS CLI Command Reference](#).

**PowerShell**

**To view public key tags**
Use the Get-EC2Tag command.

To describe the tags for a specific public key
Use the Get-EC2KeyPair command.

To tag a public key
Use the New-EC2Tag command.

To delete a tag from a public key
Use the Remove-EC2Tag command.

Describe public keys

You can describe the public keys that are stored in Amazon EC2. You can also retrieve the public key material and identify the public key that was specified at launch.

Topics

- Describe public keys (p. 2015)
- Retrieve the public key material (p. 2016)
- Identify the public key specified at launch (p. 2019)

Describe public keys

You can view the following information about your public keys that are stored in Amazon EC2: public key name, ID, key type, fingerprint, public key material, the date and time (in the UTC time zone) the key was created by Amazon EC2 (if the key was created by a third-party tool, then it's the date and time the key was imported to Amazon EC2), and any tags that are associated with the public key.

You can use the Amazon EC2 console or AWS CLI to view information about your public keys.

Console

To view information about your public keys

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigator, choose Key Pairs.
3. You can view the information about each public key in the Key pairs table.

   Key pairs (23)  Info

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Created</th>
<th>Fingerprint</th>
<th>ID</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>2021/08/05 10:06 GMT+2</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>2020/05/13 17:16 GMT+2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

4. To view a public key's tags, select the check box next to the key, and then choose Actions, Manage tags.

AWS CLI

To describe a public key
Use the `describe-key-pairs` command and specify the `--key-names` parameter.

```bash
aws ec2 describe-key-pairs --key-names key-pair-name
```

Example output

```
{
    "KeyPairs": [
        {
            "KeyPairId": "key-0123456789example",
            "KeyName": "key-pair-name",
            "KeyType": "rsa",
            "Tags": [],
            "CreateTime": "2022-04-28T11:37:26.000Z"
        }
    ]
}
```

Alternatively, instead of `--key-names`, you can specify the `--key-pair-ids` parameter to identify the public key.

```bash
aws ec2 describe-key-pairs --key-pair-ids key-0123456789example
```

To view the public key material in the output, you must specify the `--include-public-key` parameter.

```bash
aws ec2 describe-key-pairs --key-names key-pair-name --include-public-key
```

Example output – In the output, the `PublicKey` field contains the public key material.

```
{
    "KeyPairs": [
        {
            "KeyPairId": "key-0123456789example",
            "KeyName": "key-pair-name",
            "KeyType": "rsa",
            "Tags": [],
            "PublicKey": "ssh-ed25519 AAAAC3NzaC1lZDI1NTE5AAAAIj7azlDjVHAsSxgcpCRZ3oWnTm0nAFM64y9jd22ioI/ my-key-pair",
            "CreateTime": "2022-04-28T11:37:26.000Z"
        }
    ]
}
```

**Retrieve the public key material**

You can use various methods to get access to the public key material. You can retrieve the public key material from the matching private key on your local computer, or from the instance metadata or the `authorized_keys` file on the instance that was launched with the public key, or by using the `describe-key-pairs` AWS CLI command.

Use one of the following methods to retrieve the public key material.
Describe public keys

To retrieve the public key material from the private key

On your local Linux or macOS computer, you can use the `ssh-keygen` command to retrieve the public key for your key pair. Specify the path where you downloaded your private key (the `.pem` file).

```
ssh-keygen -y -f /path_to_key_pair/my-key-pair.pem
```

The command returns the public key, as shown in the following example.

```
ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eYhcE53pcjqP3maAhDFcvBS706Vhz2ltxCihi+PnDSUaw+WNQm/zpHtk/a/gUBjEzo0WbkM6yymb/w896xbiFve5FUq/p/d6RJhJQ10IBXr1sLnbItnctkiJ7FbtXjMLvWjvJryDU1BMTjYWb+BQyXYMIZcse5Pjiz5/iBseEtjnV31AoG/cQk+0FzZqaeJAHco+CY/SzUBkrHm3r6HcxvJdWPYQ5SxqC0+Fmu2Ozflz221BCt5IMucXxPkJ4zrWi+7wB3RbBQoQd8v7ye7B07z1PnWoyN0qFU0XA246RA8QFYiCNywI3f05p6KLxEXAMPLE
```

If the command fails, run the following command to ensure that you've changed the permissions on your private key pair file so that only you can view it.

```
chmod 400 key-pair-name.pem
```

From the instance metadata

You can use Instance Metadata Service Version 2 or Instance Metadata Service Version 1 to retrieve the public key from the instance metadata.

**Note**

If you change the key pair that you use to connect to the instance, Amazon EC2 does not update the instance metadata to show the new public key. The instance metadata continues to show the public key for the key pair that you specified when you launched the instance.

To retrieve the public key material from the instance metadata

Use one of the following commands from your instance.

**IMDSv2**

```
```

**IMDSv1**

```
```

Example output

```
ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eYhcE53pcjqP3maAhDFcvBS706Vhz2ltxCihi+PnDSUaw+WNQm/zpHtk/a/gUBjEzo0WbkM6yymb/w896xbiFve5FUq/p/d6RJhJQ10IBXr1sLnbItnctkiJ7FbtXjMLvWjvJryDU1BMTjYWb+BQyXYMIZcse5Pjiz5/iBseEtjnV31AoG/cQk+0FzZqaeJAHco+CY/SzUBkrHm3r6HcxvJdWPYQ5SxqC0+Fmu2Ozflz221BCt5IMucXxPkJ4zrWi+7wB3RbBQoQd8v7ye7B07z1PnWoyN0qFU0XA246RA8QFYiCNywI3f05p6KLxEXAMPLE key-pair-name
```

For more information about instance metadata, see [Retrieve instance metadata](p. 1021).
Amazon Elastic Compute Cloud
User Guide for Linux Instances
Describe public keys

From the instance

If you specify a key pair when launching a Linux instance, when the instance boots for the first time, the content of the public key is placed on the instance in an entry within ~/.ssh/authorized_keys.

To retrieve the public key material from an instance

1. Connect to your instance (p. 811).
2. In the terminal window, open the authorized_keys file using your favorite text editor (such as vim or nano).

```
[ec2-user ~]$ nano ~/.ssh/authorized_keys
```

The authorized_keys file opens, displaying the public key followed by the name of the key pair. The following is an example entry for the key pair named key-pair-name.

```
ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eyHceS3pcjqP3maAhDFcvBS70GVh21txCih+phDSUawWwQn/mzphTk/a/gU8jezo0wWkbM4xyyb/wB9ExbiFveSFJUoP/d6RJhJ0l0iBXs
lsLnBItntcii7FbtxJMXLvvwJzyDUi1BMTjYtwB+QhXYXUMOzce5Pjz5/i8SeJtjVn3iAoG/cQk+0FzZqa3AAHco+CY/5wCktrHmFjZ6hCkCkvJdwpKYQ5xqC0+FmUZOfz221C8tSIMucxxPkkX4riWi+z7wB3Rb
BQqQzd8v7yeb70z1PnW0YNqF0Xc246RA8QFYiCNYwI3f05p6KLxEXAMPLE key-pair-name
```

From describe-key-pairs

To retrieve the public key material from the describe-key-pairs AWS CLI command

Use the describe-key-pairs command and specify the --key-names parameter to identify the public key. To include the public key material in the output, specify the --include-public-key parameter.

```
aws ec2 describe-key-pairs --key-names key-pair-name --include-public-key
```

Example output – In the output, the PublicKey field contains the public key material.

```
{
    "KeyPairs": [
        {
            "KeyPairId": "key-0123456789example",
            "KeyName": "key-pair-name",
            "KeyType": "rsa",
            "Tags": [],
            "PublicKey": "ssh-ed25519 AAAAC3NzaC1lZDI1NTE5AAAAAIIj7a2i1jVHAs5xgcpCRZ3oWnTm0nAFM64y9jd2210I/ my-key-pair",
            "CreateTime": "2022-04-28T11:37:26.000Z"
        }
    ]
}
```

Alternatively, instead of --key-names, you can specify the --key-pair-ids parameter to identify the public key.

```
aws ec2 describe-key-pairs --key-pair-ids key-0123456789example --include-public-key
```
Identify the public key specified at launch

If you specify a public key when you launch an instance, the public key name is recorded by the instance.

To identify the public key that was specified at launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select your instance.
3. On the Details tab, under Instance details, the Key pair assigned at launch field displays the name of the public key that you specified when you launched the instance.

   Note
   The value of the Key pair assigned at launch field does not change even if you change the public key on the instance, or add public keys.

Delete your public key on Amazon EC2

You can delete public keys that are stored in Amazon EC2. Deleting a public key does not delete the matching private key.

When you delete a public key using the following methods, you're only deleting the public key that you stored in Amazon EC2 when you created (p. 2009) or imported (p. 2012) the key pair. Deleting a public key doesn't remove the public key from any instances to which you've added it, either when you launched the instance or later. It also doesn't delete the private key on your local computer. You can continue to connect to instances that you launched using a public key that you've deleted from Amazon EC2 as long as you still have the private key (.pem) file.

   Note
   To remove a public key from an instance, see Add or remove a public key on your instance (p. 2020).

   Important
   If you're using an Auto Scaling group (for example, in an Elastic Beanstalk environment), ensure that the public key you're deleting is not specified in an associated launch template or launch configuration. If Amazon EC2 Auto Scaling detects an unhealthy instance, it launches a replacement instance. However, the instance launch fails if the public key cannot be found. For more information, see Launch templates in the Amazon EC2 Auto Scaling User Guide.

You can delete a public key on Amazon EC2 using the following methods.

Console

To delete your public key on Amazon EC2

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Key Pairs.
3. Select the key pair to delete and choose Actions, Delete.
4. In the confirmation field, enter Delete and then choose Delete.

AWS CLI

To delete your public key on Amazon EC2

Use the delete-key-pair AWS CLI command.
Add or remove a public key on your instance

When you launch an instance, you can specify a key pair (p. 724). If you specify a key pair at launch, when your instance boots for the first time, the public key material is placed on your Linux instance in an entry within ~/.ssh/authorized_keys.

You can change the key pair that is used to access the default system account of your instance by adding a new public key on the instance, or by replacing the public key (deleting the existing public key and adding a new one) on the instance. You can also remove all public keys from an instance. You might take these actions for the following reasons:

- If a user in your organization requires access to the system user using a separate key pair, you can add the public key to your instance.
- If someone has a copy of the private key (.pem file) and you want to prevent them from connecting to your instance (for example, if they've left your organization), you can delete the public key on the instance and replace it with a new one.
- If you create a Linux AMI from an instance, the public key material is copied from the instance to the AMI. If you launch an instance from the AMI, the new instance includes the public key from the original instance. To prevent someone who has the private key from connecting to the new instance, you can remove the public key from the original instance before creating the AMI.

The public keys are located in the .ssh/authorized_keys file on the instance.

To add or replace a key pair, you must be able to connect to your instance. If you've lost your existing private key or you launched your instance without a key pair, you won't be able to connect to your instance and therefore won't be able to add or replace a key pair. If you've lost your private key, you might be able to retrieve it. For more information, see I've lost my private key. How can I connect to my Linux instance? (p. 2545) If you launched your instance without a key pair, you won't be able to connect to the instance unless you chose an AMI that is configured to allow users another way to log in.

Note
These procedures are for modifying the key pair for the default user, such as ec2-user. For information about adding users to your instance, see Manage users on your Linux instance (p. 907).

To add or replace a key pair

1. Create a new key pair using the Amazon EC2 console (p. 2009) or a third-party tool (p. 2012).
2. Retrieve the public key from your new key pair. For more information, see Retrieve the public key material (p. 2016).
3. Connect to your instance (p. 811) using your existing private key.
4. Using a text editor of your choice, open the .ssh/authorized_keys file on the instance. Paste the public key information from your new key pair underneath the existing public key information. Save the file.
5. Disconnect from your instance, and test that you can connect to your instance using the new private key file.
6. (Optional) If you're replacing an existing key pair, connect to your instance and delete the public key information for the original key pair from the .ssh/authorized_keys file.
Important
If you're using an Auto Scaling group, ensure that the key pair you're replacing is not specified in your launch template or launch configuration. If Amazon EC2 Auto Scaling detects an unhealthy instance, it launches a replacement instance. However, the instance launch fails if the key pair cannot be found. For more information, see Launch templates in the Amazon EC2 Auto Scaling User Guide.

To remove a public key from an instance

1. Connect to your instance (p. 811).
2. Using a text editor of your choice, open the .ssh/authorized_keys file on the instance. Delete the public key information, and then save the file.

Warning
After you remove all the public keys from an instance and disconnect from the instance, you can't connect to it again unless the AMI provides another way of logging in.

Verify the fingerprint of your key pair

To verify the fingerprint of your key pair, compare the fingerprint displayed on the Key pairs page in the Amazon EC2 console, or returned by the describe-key-pairs command, with the fingerprint that you generate using the private key on your local computer. These fingerprints should match.

When Amazon EC2 calculates a fingerprint, Amazon EC2 might append padding to the fingerprint with = characters. Other tools, such as ssh-keygen, might omit this padding.

If you're trying to verify the fingerprint of your EC2 instance, not the fingerprint of your key pair, see Get the instance fingerprint (p. 815).

How the fingerprints are calculated

Amazon EC2 uses different hash functions to calculate the fingerprints for RSA and ED25519 key pairs. Furthermore, for RSA key pairs, Amazon EC2 calculates the fingerprints differently using different hash functions depending on whether the key pair was created by Amazon EC2 or imported to Amazon EC2.

The following table lists the hash functions that are used to calculate the fingerprints for RSA and ED25519 key pairs that are created by Amazon EC2 and imported to Amazon EC2.

<table>
<thead>
<tr>
<th>Hash functions used to calculate fingerprints</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key pair source</td>
</tr>
<tr>
<td>-----------------</td>
</tr>
<tr>
<td>Created by Amazon EC2</td>
</tr>
<tr>
<td>Imported to Amazon EC2</td>
</tr>
</tbody>
</table>

¹ If you import a public RSA key to Amazon EC2, the fingerprint is calculated using an MD5 hash function. This is true regardless of how you created the key pair, for example, by using a third-party tool or by generating a new public key from an existing private key created using Amazon EC2.

When using the same key pair in different Regions

If you plan to use the same key pair to connect to instances in different AWS Regions, you must import the public key to all of the Regions in which you’ll use it. If you use Amazon EC2 to create the key pair,
you can Retrieve the public key material (p. 2016) so that you can import the public key to the other Regions.

**Note**
If you create an RSA key pair using Amazon EC2, and then you generate a public key from the Amazon EC2 private key, the imported public keys will have a different fingerprint than the original public key. This is because the fingerprint of the original RSA key created using Amazon EC2 is calculated using a SHA-1 hash function, while the fingerprint of the imported RSA keys is calculated using an MD5 hash function.

For ED25519 key pairs, the fingerprints will be same regardless of whether they’re created by Amazon EC2 or imported to Amazon EC2, because the same SHA-256 hash function is used to calculate the fingerprint.

### Generate a fingerprint from the private key

Use one of the following commands to generate a fingerprint from the private key on your local machine.

If you're using a Windows local machine, you can run the following commands using the Windows Subsystem for Linux (WSL). Install the WSL and a Linux distribution using the instructions in the Windows 10 Installation Guide. The example in the instructions installs the Ubuntu distribution of Linux, but you can install any distribution. You are prompted to restart your computer for the changes to take effect.

- **If you created the key pair using Amazon EC2**
  
  Use the OpenSSL tools to generate a fingerprint as shown in the following examples.

  For RSA key pairs:

  ```
  openssl pkcs8 -in path_to_private_key -inform PEM -outform DER -topk8 -nocrypt | openssl sha1 -c
  ```

  For ED25519 key pairs:

  ```
  ssh-keygen -l -f path_to_private_key
  ```

- **(RSA key pairs only) If you imported the public key to Amazon EC2**
  
  You can follow this procedure regardless of how you created the key pair, for example, by using a third-party tool or by generating a new public key from an existing private key created using Amazon EC2

  Use the OpenSSL tools to generate the fingerprint as shown in the following example.

  ```
  openssl rsa -in path_to_private_key -pubout -outform DER | openssl md5 -c
  ```

- **If you created an OpenSSH key pair using OpenSSH 7.8 or later and imported the public key to Amazon EC2**

  Use **ssh-keygen** to generate the fingerprint as shown in the following examples.

  For RSA key pairs:

  ```
  ssh-keygen -ef path_to_private_key -m PEM | openssl rsa -RSAPublicKey_in -outform DER | openssl md5 -c
  ```
For ED25519 key pairs:

```
ssh-keygen -l -f path_to_private_key
```

## Amazon EC2 security groups for Linux instances

A security group acts as a virtual firewall for your EC2 instances to control incoming and outgoing traffic. Inbound rules control the incoming traffic to your instance, and outbound rules control the outgoing traffic from your instance. When you launch an instance, you can specify one or more security groups. If you don’t specify a security group, Amazon EC2 uses the default security group for the VPC. You can add rules to each security group that allow traffic to or from its associated instances. You can modify the rules for a security group at any time. New and modified rules are automatically applied to all instances that are associated with the security group. When Amazon EC2 decides whether to allow traffic to reach an instance, it evaluates all of the rules from all of the security groups that are associated with the instance.

When you launch an instance in a VPC, you must specify a security group that's created for that VPC. After you launch an instance, you can change its security groups. Security groups are associated with network interfaces. Changing an instance's security groups changes the security groups associated with the primary network interface (eth0). For more information, see Change an instance's security group (p. 2036). You can also change the security groups associated with any other network interface. For more information, see Modify network interface attributes (p. 1440).

Security is a shared responsibility between AWS and you. For more information, see Security in Amazon EC2 (p. 1930). AWS provides security groups as one of the tools for securing your instances, and you need to configure them to meet your security needs. If you have requirements that aren't fully met by security groups, you can maintain your own firewall on any of your instances in addition to using security groups.

To allow traffic to a Windows instance, see Amazon EC2 security groups for Windows instances in the Amazon EC2 User Guide for Windows Instances.

There is no additional charge for using security groups.

  - Add rules to a security group (p. 2032)
Security group rules

The rules of a security group control the inbound traffic that's allowed to reach the instances that are associated with the security group. The rules also control the outbound traffic that's allowed to leave them.

The following are the characteristics of security group rules:

• By default, security groups contain outbound rules that allow all outbound traffic. You can delete these rules. Note that Amazon EC2 blocks traffic on port 25 by default. For more information, see Restriction on email sent using port 25 (p. 2524).
• Security group rules are always permissive; you can’t create rules that deny access.
• Security group rules enable you to filter traffic based on protocols and port numbers.
• Security groups are stateful—if you send a request from your instance, the response traffic for that request is allowed to flow in regardless of inbound security group rules. For VPC security groups, this also means that responses to allowed inbound traffic are allowed to flow out, regardless of outbound rules. For more information, see Security group connection tracking (p. 2026).
• You can add and remove rules at any time. Your changes are automatically applied to the instances that are associated with the security group.

The effect of some rule changes can depend on how the traffic is tracked. For more information, see Security group connection tracking (p. 2026).

• When you associate multiple security groups with an instance, the rules from each security group are effectively aggregated to create one set of rules. Amazon EC2 uses this set of rules to determine whether to allow access.

You can assign multiple security groups to an instance. Therefore, an instance can have hundreds of rules that apply. This might cause problems when you access the instance. We recommend that you condense your rules as much as possible.

Note
Security groups cannot block DNS requests to or from the Route 53 Resolver, sometimes referred to as the 'VPC+2 IP address' (see What is Amazon Route 53 Resolver? in the Amazon Route 53 Developer Guide), or the 'AmazonProvidedDNS' (see Work with DHCP option sets in the
Security group rules

If you wish to filter DNS requests through the Route 53 Resolver, you can enable Route 53 Resolver DNS Firewall (see Route 53 Resolver DNS Firewall in the Amazon Route 53 Developer Guide).

For each rule, you specify the following:

- **Name**: The name for the security group (for example, "my-security-group").
  
  A name can be up to 255 characters in length. Allowed characters are a-z, A-Z, 0-9, spaces, and _-:/@\+=!$*. When the name contains trailing spaces, we trim the spaces when we save the name. For example, if you enter "Test Security Group " for the name, we store it as "Test Security Group".

- **Protocol**: The protocol to allow. The most common protocols are 6 (TCP), 17 (UDP), and 1 (ICMP).

- **Port range**: For TCP, UDP, or a custom protocol, the range of ports to allow. You can specify a single port number (for example, 22), or range of port numbers (for example, 7000-8000).

- **ICMP type and code**: For ICMP, the ICMP type and code. For example, use type 8 for ICMP Echo Request or type 128 for ICMPv6 Echo Request.

- **Source or destination**: The source (inbound rules) or destination (outbound rules) for the traffic to allow. Specify one of the following:
  
  - A single IPv4 address. You must use the /32 prefix length. For example, 203.0.113.1/32.
  
  - A single IPv6 address. You must use the /128 prefix length. For example, 2001:db8:1234:1a00::123/128.
  
  - A range of IPv4 addresses, in CIDR block notation. For example, 203.0.113.0/24.
  
  - A range of IPv6 addresses, in CIDR block notation. For example, 2001:db8:1234:1a00::/64.
  
  - The ID of a prefix list. For example, p1-1234abc1234abc123. For more information, see Prefix lists in the Amazon VPC User Guide.
  
  - The ID of a security group (referred to here as the specified security group). For example, the current security group, a security group from the same VPC, or a security group for a peered VPC. This allows traffic based on the private IP addresses of the resources associated with the specified security group. This does not add rules from the specified security group to the current security group.

- **(Optional) Description**: You can add a description for the rule, which can help you identify it later. A description can be up to 255 characters in length. Allowed characters are a-z, A-Z, 0-9, spaces, and _-:/@\+=!$*.

When you create a security group rule, AWS assigns a unique ID to the rule. You can use the ID of a rule when you use the API or CLI to modify or delete the rule.

When you specify a security group as the source or destination for a rule, the rule affects all instances that are associated with the security group. Incoming traffic is allowed based on the private IP addresses of the instances that are associated with the source security group (and not the public IP or Elastic IP addresses). For more information about IP addresses, see Amazon EC2 instance IP addressing (p. 1358).

If your security group rule references a deleted security group, the rule affects all instances that are associated with the deleted security group. For more information about deleted security groups, see Working with Stale Security Group Rules in the Amazon VPC Peering Guide.

If there is more than one rule for a specific port, Amazon EC2 applies the most permissive rule. For example, if you have a rule that allows access to TCP port 22 (SSH) from IP address 203.0.113.1, and another rule that allows access to TCP port 22 from everyone, everyone has access to TCP port 22.

When you add, update, or remove rules, the changes are automatically applied to all instances associated with the security group.
Security group connection tracking

Your security groups use connection tracking to track information about traffic to and from the instance. Rules are applied based on the connection state of the traffic to determine if the traffic is allowed or denied. With this approach, security groups are stateful. This means that responses to inbound traffic are allowed to flow out of the instance regardless of outbound security group rules, and vice versa.

As an example, suppose that you initiate a command such as netcat or similar to your instances from your home computer, and your inbound security group rules allow ICMP traffic. Information about the connection (including the port information) is tracked. Response traffic from the instance for the command is not tracked as a new request, but rather as an established connection, and is allowed to flow out of the instance, even if your outbound security group rules restrict outbound ICMP traffic.

For protocols other than TCP, UDP, or ICMP, only the IP address and protocol number is tracked. If your instance sends traffic to another host, and the host sends the same type of traffic to your instance within 600 seconds, the security group for your instance accepts it regardless of inbound security group rules. The security group accepts it because it’s regarded as response traffic for the original traffic.

When you change a security group rule, its tracked connections are not immediately interrupted. The security group continues to allow packets until existing connections time out. To ensure that traffic is immediately interrupted, or that all traffic is subject to firewall rules regardless of the tracking state, you can use a network ACL for your subnet. Network ACLs are stateless and therefore do not automatically allow response traffic. Adding a network ACL that blocks traffic in either direction breaks existing connections. For more information, see Network ACLs in the Amazon VPC User Guide.

Note
Security groups have no effect on DNS traffic to or from the Route 53 Resolver, sometimes referred to as the ‘VPC+2 IP address’ (see What is Amazon Route 53 Resolver? in the Amazon Route 53 Developer Guide), or the ‘AmazonProvidedDNS’ (see Work with DHCP option sets in the Amazon Virtual Private Cloud User Guide). If you wish to filter DNS requests through the Route 53 Resolver, you can enable Route 53 Resolver DNS Firewall (see Route 53 Resolver DNS Firewall in the Amazon Route 53 Developer Guide).

Untracked connections

Not all flows of traffic are tracked. If a security group rule permits TCP or UDP flows for all traffic (0.0.0.0/0 or ::/0) and there is a corresponding rule in the other direction that permits all response traffic (0.0.0.0/0 or ::/0) for all ports (0-65535), then that flow of traffic is not tracked, unless it is part of an automatically tracked connection (p. 2026). The response traffic for an untracked flow is allowed based on the inbound or outbound rule that permits the response traffic, not based on tracking information.

An untracked flow of traffic is immediately interrupted if the rule that enables the flow is removed or modified. For example, if you have an open (0.0.0.0/0) outbound rule, and you remove a rule that allows all (0.0.0.0/0) inbound SSH (TCP port 22) traffic to the instance (or modify it such that the connection would no longer be permitted), your existing SSH connections to the instance are immediately dropped. The connection was not previously being tracked, so the change will break the connection. On the other hand, if you have a narrower inbound rule that initially allows an SSH connection (meaning that the connection was tracked), but change that rule to no longer allow new connections from the address of the current SSH client, the existing SSH connection is not interrupted because it is tracked.

Automatically tracked connections

Connections made through the following are automatically tracked, even if the security group configuration does not otherwise require tracking. These connections must be tracked to ensure symmetric routing, as there could be multiple valid reply paths.

- Egress-only internet gateways
Connection tracking

- Gateway Load Balancers
- Global Accelerator accelerators
- NAT gateways
- Network Firewall firewall endpoints
- Network Load Balancers
- AWS PrivateLink (interface VPC endpoints)
- Transit gateway attachments
- AWS Lambda (Hyperplane elastic network interfaces)

Throttling

Amazon EC2 defines the maximum number of connections that can be tracked per instance. After the maximum is reached, any packets that are sent or received are dropped because a new connection cannot be established. When this happens, applications that send and receive packets cannot communicate properly. Use the `conntrack_allowance_available` network performance metric to determine the number of tracked connections still available for that instance type.

To determine whether packets were dropped because the network traffic for your instance exceeded the maximum number of connections that can be tracked, use the `conntrack_allowance_exceeded` network performance metric. For more information, see Monitor network performance for your EC2 instance (p. 1491).

With Elastic Load Balancing, if you exceed the maximum number of connections that can be tracked per instance, we recommend that you scale either the number of instances registered with the load balancer or the size of the instances registered with the load balancer.

Idle connection tracking timeout

The security group tracks each connection established to ensure that return packets are delivered as expected. There is a maximum number of connections that can be tracked per instance. Connections that remain idle can lead to connection tracking exhaustion and cause connections not to be tracked and packets to be dropped. You can set the timeout for idle connection tracking on an Elastic network interface.

**Note**
This feature is only available for Nitro-based EC2 instances (p. 295).

There are three configurable timeouts:

- **TCP established timeout**: Timeout (in seconds) for idle TCP connections in an established state. Min: 60 seconds. Max: 432000 seconds (5 days). Default: 432000 seconds. Recommended: Less than 432000 seconds.
- **UDP timeout**: Timeout (in seconds) for idle UDP flows that have seen traffic only in a single direction or a single request-response transaction. Min: 30 seconds. Max: 60 seconds. Default: 30 seconds.
- **UDP stream timeout**: Timeout (in seconds) for idle UDP flows classified as streams which have seen more than one request-response transaction. Min: 60 seconds. Max: 180 seconds (3 minutes). Default: 180 seconds.

You may want to modify the default timeouts for any of the following cases:

- If you are monitoring tracked connections using Amazon EC2 network performance metrics (p. 1491), the `conntrack_allowance_exceeded` and `conntrack_allowance_available` metrics enable you to monitor dropped packets and tracked connection utilization to proactively manage EC2 instance capacity with
scale up or out actions to help meet network connections demand before dropping packets. If you are observing `conntrack_allowance_exceeded` drops on your EC2 instances, you may benefit from setting a lower TCP established timeout to account for stale TCP/UDP sessions resulting from improper clients or network middle boxes.

- Typically, load balancers or firewalls have TCP Established idle timeout in the range of 60 to 90 minutes. If you are running workloads that are expected to handle a very high number of connections (greater than 100k) from appliances like network firewalls, configuring a similar timeout on an EC2 network interface is advised.

- If you are running workloads with high numbers of connections like DNS, SIP, SNMP, Syslog, Radius and other services that primarily use UDP to serve requests, setting the ‘UDP-stream’ timeout to 60s provides higher scale/performance for existing capacity and to prevent gray failures.

- For TCP/UDP connections through network load balancers (NLBs) and elastic load balancers (ELB), all connections are tracked. Idle timeout value for TCP flows is 350secs and UDP flows is 120 secs, and varies from interface level timeout values. You may want to configure timeouts at the network interface level to allow for more flexibility for timeout than the defaults for ELB/NLB.

You have the option to configure the connection tracking timeouts when you do the following:

- [Create a network interface](p. 1435)
- [Modify network interface attributes](p. 1440)
- [Launch an EC2 instance](p. 724)
- [Create an EC2 instance launch template](p. 746)

### Example

In the following example, the security group has inbound rules that allow TCP and ICMP traffic, and outbound rules that allow all outbound traffic.

#### Inbound

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Port number</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>22 (SSH)</td>
<td>203.0.113.1/32</td>
</tr>
<tr>
<td>TCP</td>
<td>80 (HTTP)</td>
<td>0.0.0.0/0</td>
</tr>
<tr>
<td>TCP</td>
<td>80 (HTTP)</td>
<td>::/0</td>
</tr>
<tr>
<td>ICMP</td>
<td>All</td>
<td>0.0.0.0/0</td>
</tr>
</tbody>
</table>

#### Outbound

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Port number</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>All</td>
<td>All</td>
<td>0.0.0.0/0</td>
</tr>
<tr>
<td>All</td>
<td>All</td>
<td>::/0</td>
</tr>
</tbody>
</table>

With a direct network connection to the instance or network interface, the tracking behavior is as follows:

- Inbound and outbound TCP traffic on port 22 (SSH) is tracked, because the inbound rule allows traffic from 203.0.113.1/32 only, and not all IP addresses (0.0.0.0/0).
• Inbound and outbound TCP traffic on port 80 (HTTP) is not tracked, because the inbound and outbound rules allow traffic from all IP addresses.
• ICMP traffic is always tracked.

If you remove the outbound rule for IPv4 traffic, all inbound and outbound IPv4 traffic is tracked, including traffic on port 80 (HTTP). The same applies for IPv6 traffic if you remove the outbound rule for IPv6 traffic.

Default and custom security groups

Your AWS account automatically has a default security group for the default VPC in each Region. If you don't specify a security group when you launch an instance, the instance is automatically associated with the default security group for the VPC. If you don't want your instances to use the default security group, you can create your own custom security groups and specify them when you launch your instances.

Contents
• Default security groups (p. 2029)
• Custom security groups (p. 2030)

Default security groups

Each VPC comes with a default security group. We recommend that you create security groups for specific instances or groups of instances instead of using the default security group. However, if you don't specify a security group when you launch an instance, we associate the instance with the default security group for the VPC.

The name of a default security group is "default". The following are the default rules for a default security group.

Inbound

<table>
<thead>
<tr>
<th>Source</th>
<th>Protocol</th>
<th>Port range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sg-1234567890abcdef0</td>
<td>All</td>
<td>All</td>
<td>Allows inbound traffic from all resources that are assigned to this security group. The source is the ID of this security group.</td>
</tr>
</tbody>
</table>

Outbound

<table>
<thead>
<tr>
<th>Destination</th>
<th>Protocol</th>
<th>Port range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0.0/0</td>
<td>All</td>
<td>All</td>
<td>Allows all outbound IPv4 traffic.</td>
</tr>
<tr>
<td>::/0</td>
<td>All</td>
<td>All</td>
<td>Allows all outbound IPv6 traffic. This rule is added only if your VPC has an associated IPv6 CIDR block.</td>
</tr>
</tbody>
</table>

Default security group basics

• You can change the rules for a default security group.
• You can't delete a default security group. If you try to delete a default security group, we return the following error code: Client.CannotDelete.
Custom security groups

You can create multiple security groups to reflect the different roles that your instances play; for example, web servers or database servers.

When you create a security group, you must provide it with a name and a description. Security group names and descriptions can be up to 255 characters in length, and are limited to the following characters:

a-z, A-Z, 0-9, spaces, and _-/:@[]+=&;{}!*#'

A security group name cannot start with the following: sg-. A security group name must be unique for the VPC.

The following are the default rules for a security group that you create:

- Allows no inbound traffic
- Allows all outbound traffic

After you've created a security group, you can change its inbound rules to reflect the type of inbound traffic that you want to reach the associated instances. You can also change its outbound rules.

For more information about the rules you can add to a security group, see Security group rules for different use cases (p. 2037).

Work with security groups

You can assign a security group to an instance when you launch the instance. When you add or remove rules, those changes are automatically applied to all instances to which you've assigned the security group. For more information, see Assign a security group to an instance (p. 2036).

After you launch an instance, you can change its security groups. For more information, see Change an instance's security group (p. 2036).

You can create, view, update, and delete security groups and security group rules using the Amazon EC2 console and the command line tools.

Tasks

- Create a security group (p. 2030)
- Copy a security group (p. 2031)
- View your security groups (p. 2032)
- Add rules to a security group (p. 2032)
- Update security group rules (p. 2034)
- Delete rules from a security group (p. 2035)
- Delete a security group (p. 2036)
- Assign a security group to an instance (p. 2036)
- Change an instance's security group (p. 2036)

Create a security group

Although you can use the default security group for your instances, you might want to create your own groups to reflect the different roles that instances play in your system.
By default, new security groups start with only an outbound rule that allows all traffic to leave the instances. You must add rules to enable any inbound traffic or to restrict the outbound traffic.

A security group can be used only in the VPC for which it is created.

**Console**

**To create a security group**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Security Groups**.
3. Choose **Create security group**.
4. In the **Basic details** section, do the following.
   a. Enter a descriptive name and brief description for the security group. They can't be edited after the security group is created. The name and description can be up to 255 characters long. The valid characters are a-z, A-Z, 0-9, spaces, and _-:/()#,@\[\]+=&;{}!$*.
   b. For **VPC**, choose the VPC.
5. You can add security group rules now, or you can add them later. For more information, see Add rules to a security group (p. 2032).
6. You can add tags now, or you can add them later. To add a tag, choose **Add new tag** and enter the tag key and value.
7. Choose **Create security group**.

**Command line**

**To create a security group**

Use one of the following commands:

- `create-security-group` (AWS CLI)

**Copy a security group**

You can create a new security group by creating a copy of an existing one. When you copy a security group, the copy is created with the same inbound and outbound rules as the original security group. If the original security group is in a VPC, the copy is created in the same VPC unless you specify a different one.

The copy receives a new unique security group ID and you must give it a name. You can also add a description.

You can't copy a security group from one Region to another Region.

You can create a copy of a security group using the Amazon EC2 console.

**To copy a security group**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Security Groups**.
3. Select the security group to copy and choose **Actions, Copy to new security group**.
4. Specify a name and optional description, and change the VPC and security group rules if needed.
5. Choose **Create**.

**View your security groups**

You can view information about your security groups using one of the following methods.

**Console**

**To view your security groups**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Security Groups**.
3. Your security groups are listed. To view the details for a specific security group, including its inbound and outbound rules, choose its ID in the **Security group ID** column.

**Command line**

**To view your security groups**

Use one of the following commands.

- `describe-security-groups` (AWS CLI)
- `describe-security-group-rules` (AWS CLI)

**Amazon EC2 Global View**

You can use Amazon EC2 Global View to view your security groups across all Regions for which your AWS account is enabled. For more information, see [Amazon EC2 Global View (p. 2505)](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/).
b. For **Source**, do one of the following to allow traffic.
   - Choose **Custom** and then enter an IP address in CIDR notation, a CIDR block, another security group, or a prefix list.
   - Choose **Anywhere** to allow all traffic for the specified protocol to reach your instance. This option automatically adds the 0.0.0.0/0 IPv4 CIDR block as the source. If your security group is in a VPC that's enabled for IPv6, this option automatically adds a rule for the ::/0 IPv6 CIDR block.

   **Warning**
   If you choose **Anywhere**, you enable all IPv4 and IPv6 addresses to access your instance the specified protocol. If you are adding rules for ports 22 (SSH) or 3389 (RDP), you should authorize only a specific IP address or range of addresses to access your instance.

   - Choose **My IP** to allow inbound traffic from only your local computer's public IPv4 address.

c. For **Description**, optionally specify a brief description for the rule.

5. Choose **Preview changes**, **Save rules**.

### To add an outbound rule to a security group

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Security Groups**.
3. Select the security group, and choose **Actions**, **Edit outbound rules**.
4. For each rule, choose **Add rule** and do the following.
   a. For **Type**, choose the type of protocol to allow.
      - For custom TCP or UDP, you must enter the port range to allow.
      - For custom ICMP, you must choose the ICMP type from **Protocol**, and, if applicable, the code from **Port range**.
      - For any other type, the protocol and port range are configured automatically.
   b. For **Destination**, do one of the following.
      - Choose **Custom** and then enter an IP address in CIDR notation, a CIDR block, another security group, or a prefix list for which to allow outbound traffic.
      - Choose **Anywhere** to allow outbound traffic to all IP addresses. This option automatically adds the 0.0.0.0/0 IPv4 CIDR block as the destination.

   If your security group is in a VPC that's enabled for IPv6, this option automatically adds a rule for the ::/0 IPv6 CIDR block.

   - Choose **My IP** to allow outbound traffic only to your local computer's public IPv4 address.

c. (Optional) For **Description**, specify a brief description for the rule.

5. Choose **Preview changes**, **Confirm**.

### Command line

#### To add rules to a security group

Use one of the following commands.

- [authorize-security-group-ingress](https://docs.aws.amazon.com/cli/latest/reference/ec2authorize-security-group-ingress.html) (AWS CLI)
To add one or more egress rules to a security group

Use one of the following commands.

- `authorize-security-group-egress` (AWS CLI)
- `Grant-EC2SecurityGroupEgress` (AWS Tools for Windows PowerShell)

Update security group rules

You can update a security group rule using one of the following methods. The updated rule is automatically applied to any instances that are associated with the security group.

Console

When you modify the protocol, port range, or source or destination of an existing security group rule using the console, the console deletes the existing rule and adds a new one for you.

To update a security group rule

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
3. Select the security group.
4. Choose Actions, Edit inbound rules to update a rule for inbound traffic or Actions, Edit outbound rules to update a rule for outbound traffic.
5. Update the rule as required.
6. Choose Preview changes, Confirm.

To tag a security group rule

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
3. Select the security group.
4. On the Inbound rules or Outbound rules tab, select the check box for the rule and then choose Manage tags.
5. The Manage tags page displays any tags that are assigned to the rule. To add a tag, choose Add tag and enter the tag key and value. To delete a tag, choose Remove next to the tag that you want to delete.
6. Choose Save changes.

Command line

You cannot modify the protocol, port range, or source or destination of an existing rule using the Amazon EC2 API or a command line tools. Instead, you must delete the existing rule and add a new rule. You can, however, update the description of an existing rule.

To update a rule

Use one of the following command.

- `modify-security-group-rules` (AWS CLI)

To update the description for an existing inbound rule

Use one of the following commands.
Work with security groups

• update-security-group-rule-descriptions-ingress (AWS CLI)
  Update-EC2SecurityGroupRuleIngressDescription (AWS Tools for Windows PowerShell)

To update the description for an existing outbound rule

Use one of the following commands.

• update-security-group-rule-descriptions-egress (AWS CLI)
  Update-EC2SecurityGroupRuleEgressDescription (AWS Tools for Windows PowerShell)

To tag a security group rule

Use one of the following commands.

• create-tags (AWS CLI)
  New-EC2Tag (AWS Tools for Windows PowerShell)

Delete rules from a security group

When you delete a rule from a security group, the change is automatically applied to any instances associated with the security group.

You can delete rules from a security group using one of the following methods.

Console

To delete a security group rule

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
3. Select the security group to update, choose Actions, and then choose Edit inbound rules to remove an inbound rule or Edit outbound rules to remove an outbound rule.
4. Choose the Delete button to the right of the rule to delete.
5. Choose Save rules. Alternatively, choose Preview changes, review your changes, and choose Confirm.

Command line

To remove one or more ingress rules from a security group

Use one of the following commands.

• revoke-security-group-ingress (AWS CLI)
  Revoke-EC2SecurityGroupIngress (AWS Tools for Windows PowerShell)

To remove one or more egress rules from a security group

Use one of the following commands.

• revoke-security-group-egress (AWS CLI)
  Revoke-EC2SecurityGroupEgress (AWS Tools for Windows PowerShell)
Delete a security group

You can't delete a security group that is associated with an instance. You can't delete the default security group. You can't delete a security group that is referenced by a rule in another security group in the same VPC. If your security group is referenced by one of its own rules, you must delete the rule before you can delete the security group.

Console

To delete a security group

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Security Groups.
3. Select the security group and choose Actions, Delete security groups.
4. When prompted for confirmation, choose Delete.

Command line

To delete a security group

Use one of the following commands.

- delete-security-group (AWS CLI)
- Remove-EC2SecurityGroup (AWS Tools for Windows PowerShell)

Assign a security group to an instance

You can assign one or more security groups to an instance when you launch the instance. You can also specify one or more security groups in a launch template. The security groups are assigned to all instances that are launched using the launch template.

- To assign a security group to an instance when you launch the instance, see Network settings (p. 724) of Launch an instance using defined parameters (p. 722) (new console) or Step 6: Configure Security Group (p. 735) (old console).
- To specify a security group in a launch template, see Network settings (p. 746) of Create a new launch template using parameters you define (p. 743).

Change an instance's security group

After you launch an instance, you can change its security groups by adding or removing security groups.

Requirements

- The instance must be in the running or stopped state.
- A security group is specific to a VPC. You can assign a security group to one or more instances launched in the VPC for which you created the security group.

Console

To change the security groups for an instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select your instance, and then choose **Actions, Security, Change security groups.**

4. For **Associated security groups**, select a security group from the list and choose **Add security group.**

   To remove an already associated security group, choose **Remove** for that security group.

5. Choose **Save.**

Command line

**To change the security groups for an instance**

Use one of the following commands.

- `modify-instance-attribute` (AWS CLI)
- `Edit-EC2InstanceAttribute` (AWS Tools for Windows PowerShell)

Security group rules for different use cases

You can create a security group and add rules that reflect the role of the instance that's associated with the security group. For example, an instance that's configured as a web server needs security group rules that allow inbound HTTP and HTTPS access. Likewise, a database instance needs rules that allow access for the type of database, such as access over port 3306 for MySQL.

The following are examples of the kinds of rules that you can add to security groups for specific kinds of access.

**Examples**

- [Web server rules](#)
- [Database server rules](#)
- [Rules to connect to instances from your computer](#)
- [Rules to connect to instances from an instance with the same security group](#)
- [Rules for ping/ICMP](#)
- [DNS server rules](#)
- [Amazon EFS rules](#)
- [Elastic Load Balancing rules](#)
- [VPC peering rules](#)

**Web server rules**

The following inbound rules allow HTTP and HTTPS access from any IP address. If your VPC is enabled for IPv6, you can add rules to control inbound HTTP and HTTPS traffic from IPv6 addresses.

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Port</th>
<th>Source IP</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>80 (HTTP)</td>
<td>0.0.0.0/0</td>
<td>Allows inbound HTTP access from any IPv4 address</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>443 (HTTPS)</td>
<td>0.0.0.0/0</td>
<td>Allows inbound HTTPS access from any IPv4 address</td>
</tr>
</tbody>
</table>

2037
### Protocol type | Protocol number | Port | Source IP | Notes |
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>80 (HTTP)</td>
<td>::/0</td>
<td>Allows inbound HTTP access from any IPv6 address</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>443 (HTTPS)</td>
<td>::/0</td>
<td>Allows inbound HTTPS access from any IPv6 address</td>
</tr>
</tbody>
</table>

### Database server rules

The following inbound rules are examples of rules you might add for database access, depending on what type of database you’re running on your instance. For more information about Amazon RDS instances, see the [Amazon RDS User Guide](#).

For the source IP, specify one of the following:

- A specific IP address or range of IP addresses (in CIDR block notation) in your local network
- A security group ID for a group of instances that access the database

### Protocol type | Protocol number | Port | Notes |
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>1433 (MS SQL)</td>
<td>The default port to access a Microsoft SQL Server database, for example, on an Amazon RDS instance</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>3306 (MYSQL/Aurora)</td>
<td>The default port to access a MySQL or Aurora database, for example, on an Amazon RDS instance</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>5439 (Redshift)</td>
<td>The default port to access an Amazon Redshift cluster database.</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>5432 (PostgreSQL)</td>
<td>The default port to access a PostgreSQL database, for example, on an Amazon RDS instance</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>1521 (Oracle)</td>
<td>The default port to access an Oracle database, for example, on an Amazon RDS instance</td>
</tr>
</tbody>
</table>

You can optionally restrict outbound traffic from your database servers. For example, you might want to allow access to the internet for software updates, but restrict all other kinds of traffic. You must first remove the default outbound rule that allows all outbound traffic.

### Protocol type | Protocol number | Port | Destination IP | Notes |
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>80 (HTTP)</td>
<td>0.0.0.0/0</td>
<td>Allows outbound HTTP access to any IPv4 address</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>443 (HTTPS)</td>
<td>0.0.0.0/0</td>
<td>Allows outbound HTTPS access to any IPv4 address</td>
</tr>
</tbody>
</table>
Security group rules for different use cases

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Port</th>
<th>Destination IP</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>80 (HTTP)</td>
<td>::/0</td>
<td>(IPv6-enabled VPC only) Allows outbound HTTP access to any IPv6 address</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>443 (HTTPS)</td>
<td>::/0</td>
<td>(IPv6-enabled VPC only) Allows outbound HTTPS access to any IPv6 address</td>
</tr>
</tbody>
</table>

Rules to connect to instances from your computer

To connect to your instance, your security group must have inbound rules that allow SSH access (for Linux instances) or RDP access (for Windows instances).

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Port</th>
<th>Source IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>22 (SSH)</td>
<td>The public IPv4 address of your computer, or a range of IP addresses in your local network. If your VPC is enabled for IPv6 and your instance has an IPv6 address, you can enter an IPv6 address or range.</td>
</tr>
<tr>
<td>TCP</td>
<td>6</td>
<td>3389 (RDP)</td>
<td>The public IPv4 address of your computer, or a range of IP addresses in your local network. If your VPC is enabled for IPv6 and your instance has an IPv6 address, you can enter an IPv6 address or range.</td>
</tr>
</tbody>
</table>

Rules to connect to instances from an instance with the same security group

To allow instances that are associated with the same security group to communicate with each other, you must explicitly add rules for this.

**Note**
If you configure routes to forward the traffic between two instances in different subnets through a middlebox appliance, you must ensure that the security groups for both instances allow traffic to flow between the instances. The security group for each instance must reference the private IP address of the other instance, or the CIDR range of the subnet that contains the other instance, as the source. If you reference the security group of the other instance as the source, this does not allow traffic to flow between the instances.

The following table describes the inbound rule for a security group that enables associated instances to communicate with each other. The rule allows all types of traffic.

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Ports</th>
<th>Source IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1 (All)</td>
<td>-1 (All)</td>
<td>-1 (All)</td>
<td>The ID of the security group, or the CIDR range of the subnet that contains the other instance (see note).</td>
</tr>
</tbody>
</table>
Rules for ping/ICMP

The ping command is a type of ICMP traffic. To ping your instance, you must add one of the following inbound ICMP rules.

<table>
<thead>
<tr>
<th>Type</th>
<th>Protocol</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>Custom ICMP - IPv4</td>
<td>Echo request</td>
<td>The public IPv4 address of your computer, a specific IPv4 address, or an IPv4 or IPv6 address from anywhere.</td>
</tr>
<tr>
<td>All ICMP - IPv4</td>
<td>IPv4 ICMP (1)</td>
<td>The public IPv4 address of your computer, a specific IPv4 address, or an IPv4 or IPv6 address from anywhere.</td>
</tr>
</tbody>
</table>

To use the ping6 command to ping the IPv6 address for your instance, you must add the following inbound ICMPv6 rule.

<table>
<thead>
<tr>
<th>Type</th>
<th>Protocol</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>All ICMP - IPv6</td>
<td>IPv6 ICMP (58)</td>
<td>The IPv6 address of your computer, a specific IPv4 address, or an IPv4 or IPv6 address from anywhere.</td>
</tr>
</tbody>
</table>

DNS server rules

If you've set up your EC2 instance as a DNS server, you must ensure that TCP and UDP traffic can reach your DNS server over port 53.

For the source IP, specify one of the following:

- An IP address or range of IP addresses (in CIDR block notation) in a network
- The ID of a security group for the set of instances in your network that require access to the DNS server

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>53</td>
</tr>
<tr>
<td>UDP</td>
<td>17</td>
<td>53</td>
</tr>
</tbody>
</table>
Amazon EFS rules

If you're using an Amazon EFS file system with your Amazon EC2 instances, the security group that you associate with your Amazon EFS mount targets must allow traffic over the NFS protocol.

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Ports</th>
<th>Source IP</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>2049 (NFS)</td>
<td>The ID of the security group</td>
<td>Allows inbound NFS access from resources (including the mount target) associated with this security group</td>
</tr>
</tbody>
</table>

To mount an Amazon EFS file system on your Amazon EC2 instance, you must connect to your instance. Therefore, the security group associated with your instance must have rules that allow inbound SSH from your local computer or local network.

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Protocol number</th>
<th>Ports</th>
<th>Source IP</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6</td>
<td>22 (SSH)</td>
<td>The IP address range of your local computer, or the range of IP addresses (in CIDR block notation) for your network.</td>
<td>Allows inbound SSH access from your local computer.</td>
</tr>
</tbody>
</table>

Elastic Load Balancing rules

If you're using a load balancer, the security group associated with your load balancer must have rules that allow communication with your instances or targets. For more information, see Configure security groups for your Classic Load Balancer in the User Guide for Classic Load Balancers, and Security groups for your Application Load Balancer in the User Guide for Application Load Balancers.

VPC peering rules

You can update the inbound or outbound rules for your VPC security groups to reference security groups in the peered VPC. Doing so allows traffic to flow to and from instances that are associated with the referenced security group in the peered VPC. For more information about how to configure security groups for VPC peering, see Updating your security groups to reference peer VPC groups.

Access Amazon EC2 using an interface VPC endpoint

You can improve the security posture of your VPC by creating a private connection between your VPC and Amazon EC2. You can access Amazon EC2 as if it were in your VPC, without the use of an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC don’t need public IP addresses to access Amazon EC2.

For more information, see Access AWS services through AWS PrivateLink in the AWS PrivateLink Guide.
Create an interface VPC endpoint

Create an interface endpoint for Amazon EC2 using the following service name:

- `com.amazonaws.region.ec2` — Creates an endpoint for the Amazon EC2 API actions.

For more information, see Access an AWS service using an interface VPC endpoint in the AWS PrivateLink Guide.

Create an endpoint policy

An endpoint policy is an IAM resource that you can attach to your interface endpoint. The default endpoint policy allows full access to the Amazon EC2 API through the interface endpoint. To control the access allowed to the Amazon EC2 API from your VPC, attach a custom endpoint policy to the interface endpoint.

An endpoint policy specifies the following information:

- The principals that can perform actions.
- The actions that can be performed.
- The resource on which the actions can be performed.

**Important**

When a non-default policy is applied to an interface VPC endpoint for Amazon EC2, certain failed API requests, such as those failing from RequestLimitExceeded, might not be logged to AWS CloudTrail or Amazon CloudWatch.

For more information, see Control access to services using endpoint policies in the AWS PrivateLink Guide.

The following example shows a VPC endpoint policy that denies permission to create unencrypted volumes or to launch instances with unencrypted volumes. The example policy also grants permission to perform all other Amazon EC2 actions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": "ec2:*",
            "Effect": "Allow",
            "Resource": "*",
            "Principal": "*"
        },
        {
            "Action": [
                "ec2:CreateVolume"
            ],
            "Effect": "Deny",
            "Resource": "*",
            "Principal": "*",
            "Condition": {
                "Bool": {
```
Update management in Amazon EC2

We recommend that you regularly patch, update, and secure the operating system and applications on your EC2 instances. You can use AWS Systems Manager Patch Manager to automate the process of installing security-related updates for both the operating system and applications.

For EC2 instances in an Auto Scaling group, you can use the AWS-PatchAsgInstance runbook to help avoid instances that are undergoing patching from being replaced. Alternatively, you can use any automatic update services or recommended processes for installing updates that are provided by the application vendor.

For a list of the latest Amazon EC2 AMIs running Windows Server, see Details About AWS Windows AMI Versions.

Compliance validation for Amazon EC2

To learn whether an AWS service is within the scope of specific compliance programs, see AWS services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company’s compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.
- **Architecting for HIPAA Security and Compliance on Amazon Web Services** – This whitepaper describes how companies can use AWS to create HIPAA-eligible applications.

  **Note**
  Not all AWS services are HIPAA eligible. For more information, see the HIPAA Eligible Services Reference.
- **AWS Compliance Resources** – This collection of workbooks and guides might apply to your industry and location.
NitroTPM

Nitro Trusted Platform Module (NitroTPM) is a virtual device that is provided by the AWS Nitro System and conforms to the TPM 2.0 specification. It securely stores artifacts (such as passwords, certificates, or encryption keys) that are used to authenticate the instance. NitroTPM can generate keys and use them for cryptographic functions (such as hashing, signing, encryption, and decryption).

NitroTPM provides measured boot, a process where the bootloader and operating system create cryptographic hashes of every boot binary and combine them with the previous values in NitroTPM internal Platform Configuration Registers (PCRs). With measured boot, you can obtain signed PCR values from NitroTPM and use them to prove to remote entities the integrity of the instance's boot software. This is known as remote attestation.

With NitroTPM, keys and secrets can be tagged with a specific PCR value so that they can never be accessed if the value of the PCR, and thus the instance integrity, changes. This special form of conditional access is referred to as sealing and unsealing. Operating system technologies, like BitLocker, can use NitroTPM to seal a drive decryption key so that the drive can only be decrypted when the operating system has booted correctly and is in a known good state.

To use NitroTPM, you must select an Amazon Machine Image (AMI) that has been configured for NitroTPM support, and then use the AMI to launch a Nitro-based instance. You can select one of Amazon's prebuilt AMIs or create one yourself.

Costs

There is no additional cost for using NitroTPM. You pay only for the underlying resources that you use.

Topics

- Considerations (p. 2044)
- Prerequisites for launching Linux instances (p. 2045)
- Create a Linux AMI for NitroTPM support (p. 2045)
- Verify whether an AMI is enabled for NitroTPM (p. 2046)
- Enable or stop using NitroTPM on an instance (p. 2047)

Considerations

The following considerations apply when using NitroTPM:
Prerequisites

• BitLocker volumes that are encrypted with NitroTPM-based keys can only be used on the original instance.
• The NitroTPM state is not included in Amazon EBS snapshots (p. 2107).
• The NitroTPM state is not included in VM Import/Export images.
• NitroTPM support is enabled by specifying a value of v2.0 for the tpm-support parameter when creating an AMI. After you launch an instance with the AMI, you can't modify the attributes on the instance. Instances with NitroTPM do not support the ModifyInstanceAttribute API.
• You can only create an AMI with NitroTPM configured by using the RegisterImage API by using the AWS CLI and not with the Amazon EC2 console.
• NitroTPM is not supported on Outposts.
• NitroTPM is not supported in Local Zones or Wavelength Zones.

Prerequisites for launching Linux instances

To launch a Linux instance with NitroTPM enabled, the following prerequisites must be in place. For the prerequisites for launching a Windows instance, see Prerequisites for launching Windows instances in the Amazon EC2 User Guide for Windows Instances.

AMI

Requires an AMI with NitroTPM enabled.

Currently, there are no NitroTPM-enabled Amazon Linux AMIs. To use a supported AMI, you must perform a number of configuration steps on your own Linux AMI. For more information, see Create a Linux AMI for NitroTPM support (p. 2045).

Operating system

The AMI must include an operating system with a TPM 2.0 Command Response Buffer (CRB) driver. Most current operating systems, such as Amazon Linux 2, contain a TPM 2.0 CRB driver.

Instance type

Supported virtualized instance types:
• General purpose: M5, M5a, M5ad, M5d, M5dn, M5n, M5zn, M6a, M6i, M6id, M6idn, M6in, T3, and T3a
• Compute optimized: C5, C5a, C5ad, C5d, C5n, C6a, C6i, C6id, C6in, and Hpc6a
• Memory optimized: Hpc6id, R5, R5a, R5ad, R5b, R5d, R5dn, R5n, R6a, R6i, R6idn, R6in, R6id, and z1d
• Storage optimized: D3, D3en, I3en, and I4i
• Accelerated computing: G4dn, G5, Inf1, and Inf2

Not supported: Graviton-based instances, Xen instances, Mac instances, and bare metal instances

UEFI boot mode

NitroTPM requires that an instance runs in UEFI boot mode, which requires that the AMI must be configured for UEFI boot mode. For more information, see UEFI Secure Boot (p. 132).

Create a Linux AMI for NitroTPM support

You configure your Linux AMI for NitroTPM support when you register the AMI. You can't configure NitroTPM support later.

For the list of Windows AMIs that are preconfigured for NitroTPM support, see Prerequisites for launching Windows instances in the Amazon EC2 User Guide for Windows Instances.
To configure a Linux AMI for NitroTPM support

Use the `register-image` command and set the `tpm-support` parameter to `v2.0` and the `boot-mode` parameter to `uefi`.

```bash
aws ec2 register-image \
   --region us-east-1 \
   --name my-image \
   --boot-mode uefi \
   --architecture x86_64 \
   --root-device-name /dev/xvda \
   --block-device-mappings DeviceName=/dev/xvda,Ebs={SnapshotId=snap-0123456789example} DeviceName=/dev/xvdf,Ebs={VolumeSize=10} \
   --tpm-support v2.0
```

Expected output

```json
{
   "ImageId": "ami-0123456789example"
}
```

Verify whether an AMI is enabled for NitroTPM

You can use either `describe-images` or `describe-image-attributes` to verify whether an AMI is enabled for NitroTPM.

To verify whether an AMI is enabled for NitroTPM using `describe-images`

Use the `describe-images` command and specify the AMI ID.

```bash
aws ec2 describe-images --image-ids ami-0123456789example
```

If NitroTPM is enabled for the AMI, "TpmSupport": "v2.0" appears in the output.

```json
{
   "Images": [
      {
         ...
         "BootMode": "uefi",
         ...
         "TpmSupport": "v2.0"
      }
   ]
}
```

To verify whether an AMI is enabled for NitroTPM using `describe-image-attribute`

Use the `describe-image-attribute` command and specify the attribute parameter with the `tpmSupport` value.

**Note**
You must be the AMI owner to call `describe-image-attribute`.

```bash
aws ec2 describe-image-attribute \
   --region us-east-1 \
   --image-id ami-0123456789example \
   --attribute tpmSupport
```
Enable or stop using NitroTPM on an instance

When you launch an instance from an AMI that has NitroTPM support enabled, the instance launches with NitroTPM enabled. You can configure the instance to stop using NitroTPM. You can verify whether an instance is enabled for NitroTPM.

Topics

- Launch an instance with NitroTPM enabled (p. 2047)
- Stop using NitroTPM on an instance (p. 2047)
- Verify whether NitroTPM is accessible inside the instance (p. 2047)

Launch an instance with NitroTPM enabled

When you launch an instance with the prerequisites (p. 2045), NitroTPM is automatically enabled on the instance. You can only enable NitroTPM on an instance at launch. For information about launching an instance, see Launch your instance (p. 719).

Stop using NitroTPM on an instance

After launching an instance with NitroTPM enabled, you can’t disable NitroTPM for the instance. However, you can configure the operating system to stop using NitroTPM by disabling the TPM 2.0 device driver on the instance by using the following tools:

- For Linux, use tpm-tools.

For more information about disabling the device driver, see the documentation for your operating system.

Verify whether NitroTPM is accessible inside the instance

To verify whether an instance is enabled for NitroTPM support using the AWS CLI

Use the describe-instances AWS CLI command and specify the instance ID. Currently, the Amazon EC2 console does not display the TpmSupport field.

```bash
aws ec2 describe-instances --instance-ids i-0123456789example
```

If NitroTPM support is enabled on the instance, "TpmSupport": "v2.0" appears in the output.

```json
"Instances": {
    "InstanceId": "0123456789example",
    "TpmSupport": {
        "Value": "v2.0"
    }
}
```
Enable or stop using NitroTPM on an instance

```json

"TpmSupport": "v2.0"

```
Storage options for your Amazon EC2 instances

Amazon EC2 provides you with flexible, cost effective, and easy-to-use data storage options for your instances. Each option has a unique combination of performance and durability. These storage options can be used independently or in combination to suit your requirements.

Amazon Elastic Block Store (p. 2050)

Amazon EBS provides durable, block-level storage volumes that you can attach and detach from your instances. You can attach multiple EBS volumes to an instance. An EBS volume persists independently from the life of its associated instance. You can encrypt your EBS volumes. To keep a backup copy of your data, you can create snapshots from your EBS volumes. Snapshots are stored in Amazon S3. You can create an EBS volume from a snapshot.

Instance store (p. 2411)

Instance store provides temporary block-level storage for instances. The number, size, and type of instance store volumes are determined by the instance type and instance size. The data on an instance store volume persists only during the life of the associated instance; if you stop, hibernate, or terminate an instance, any data on instance store volumes is lost.

Amazon EFS (p. 2437)

Amazon EFS provides scalable file storage for use with Amazon EC2. You can create an EFS file system and configure your instances to mount the file system. You can use an EFS file system as a common data source for workloads and applications running on multiple instances.

Amazon S3 (p. 2435)

Amazon S3 provides access to reliable and inexpensive data storage infrastructure. It is designed to make web-scale computing easier by enabling you to store and retrieve any amount of data, at any time, from within Amazon EC2 or anywhere on the web. For example, you can use Amazon S3 to store backup copies of your data and applications. Amazon EC2 uses Amazon S3 to store EBS snapshots and instance store-backed AMIs.

Amazon FSx (p. 2440)

With Amazon FSx, you can launch, run, and scale feature-rich, high-performance file systems in the cloud. Amazon FSx is a fully-managed service that supports a wide range of workloads. You can choose between these widely-used file systems: Lustre, NetApp ONTAP, OpenZFS, and Windows File Server.

The following figure shows the relationship between these storage options and your instance.
Amazon Elastic Block Store (Amazon EBS)

Amazon Elastic Block Store (Amazon EBS) provides block level storage volumes for use with EC2 instances. EBS volumes behave like raw, unformatted block devices. You can mount these volumes as devices on your instances. EBS volumes that are attached to an instance are exposed as storage volumes that persist independently from the life of the instance. You can create a file system on top of these volumes, or use them in any way you would use a block device (such as a hard drive). You can dynamically change the configuration of a volume attached to an instance.

We recommend Amazon EBS for data that must be quickly accessible and requires long-term persistence. EBS volumes are particularly well-suited for use as the primary storage for file systems, databases, or for any applications that require fine granular updates and access to raw, unformatted, block-level storage. Amazon EBS is well suited to both database-style applications that rely on random reads and writes, and to throughput-intensive applications that perform long, continuous reads and writes.
With Amazon EBS, you pay only for what you provision. For more information about Amazon EBS pricing, see [http://aws.amazon.com/ebs/pricing/](http://aws.amazon.com/ebs/pricing/).

**Contents**
- Features of Amazon EBS (p. 2051)

**Features of Amazon EBS**

- You create an EBS volume in a specific Availability Zone, and then attach it to an instance in that same Availability Zone. To make a volume available outside of the Availability Zone, you can create a snapshot and restore that snapshot to a new volume anywhere in that Region. You can copy snapshots to other Regions and then restore them to new volumes there, making it easier to leverage multiple AWS Regions for geographical expansion, data center migration, and disaster recovery.

- Amazon EBS provides the following volume types: General Purpose SSD, Provisioned IOPS SSD, Throughput Optimized HDD, and Cold HDD. For more information, see [EBS volume types (p. 2055)](http://aws.amazon.com/ebs/pricing/).

The following is a summary of performance and use cases for each volume type.

- **General Purpose SSD volumes** (gp2 and gp3) balance price and performance for a wide variety of transactional workloads. These volumes are ideal for use cases such as boot volumes, medium-size single instance databases, and development and test environments.

- **Provisioned IOPS SSD volumes** (io1 and io2) are designed to meet the needs of I/O-intensive workloads that are sensitive to storage performance and consistency. They provide a consistent IOPS rate that you specify when you create the volume. This enables you to predictably scale to tens of thousands of IOPS per instance. Additionally, io2 volumes provide the highest levels of volume durability.

- **Throughput Optimized HDD volumes** (st1) provide low-cost magnetic storage that defines performance in terms of throughput rather than IOPS. These volumes are ideal for large, sequential workloads such as Amazon EMR, ETL, data warehouses, and log processing.

- **Cold HDD volumes** (sc1) provide low-cost magnetic storage that defines performance in terms of throughput rather than IOPS. These volumes are ideal for large, sequential, cold-data workloads. If you require infrequent access to your data and are looking to save costs, these volumes provide inexpensive block storage.

- You can create your EBS volumes as encrypted volumes, in order to meet a wide range of data-at-rest encryption requirements for regulated/audited data and applications. When you create an encrypted EBS volume and attach it to a supported instance type, data stored at rest on the volume, disk I/O, and snapshots created from the volume are all encrypted. The encryption occurs on the servers that host EC2 instances, providing encryption of data-in-transit from EC2 instances to EBS storage. For more information, see [Amazon EBS encryption (p. 2316)](http://aws.amazon.com/ebs/pricing/).

- You can create point-in-time snapshots of EBS volumes, which are persisted to Amazon S3. Snapshots protect data for long-term durability, and they can be used as the starting point for new EBS volumes.
The same snapshot can be used to create as many volumes as needed. These snapshots can be copied across AWS Regions. For more information, see Amazon EBS snapshots (p. 2107).

- Performance metrics, such as bandwidth, throughput, latency, and average queue length, are available through the AWS Management Console. These metrics, provided by Amazon CloudWatch, allow you to monitor the performance of your volumes to make sure that you are providing enough performance for your applications without paying for resources you don’t need. For more information, see Amazon EBS volume performance on Linux instances (p. 2373).

Amazon EBS volumes

An Amazon EBS volume is a durable, block-level storage device that you can attach to your instances. After you attach a volume to an instance, you can use it as you would use a physical hard drive. EBS volumes are flexible. For current-generation volumes attached to current-generation instance types, you can dynamically increase size, modify the provisioned IOPS capacity, and change volume type on live production volumes.

You can use EBS volumes as primary storage for data that requires frequent updates, such as the system drive for an instance or storage for a database application. You can also use them for throughput-intensive applications that perform continuous disk scans. EBS volumes persist independently from the running life of an EC2 instance.

You can attach multiple EBS volumes to a single instance. The volume and instance must be in the same Availability Zone. Depending on the volume and instance types, you can use Multi-Attach (p. 2077) to mount a volume to multiple instances at the same time.

Amazon EBS provides the following volume types: General Purpose SSD (gp2 and gp3), Provisioned IOPS SSD (io1 and io2), Throughput Optimized HDD (st1), Cold HDD (sc1), and Magnetic (standard). They differ in performance characteristics and price, allowing you to tailor your storage performance and cost to the needs of your applications. For more information, see Amazon EBS volume types (p. 2055).

Your account has a limit on the total storage available to you. For more information about these limits, and how to request an increase in your limits, see Amazon EBS endpoints and quotas.

For more information about pricing, see Amazon EBS Pricing.

Benefits of using EBS volumes

EBS volumes provide benefits that are not provided by instance store volumes.

Topics

- Data availability (p. 2053)
- Data persistence (p. 2053)
- Data encryption (p. 2054)
- Data security (p. 2054)
- Snapshots (p. 2054)
- Flexibility (p. 2055)

Data availability

When you create an EBS volume, it is automatically replicated within its Availability Zone to prevent data loss due to failure of any single hardware component. You can attach an EBS volume to any EC2 instance in the same Availability Zone. After you attach a volume, it appears as a native block device similar to a hard drive or other physical device. At that point, the instance can interact with the volume just as it would with a local drive. You can connect to the instance and format the EBS volume with a file system, such as ext3, and then install applications.

If you attach multiple volumes to a device that you have named, you can stripe data across the volumes for increased I/O and throughput performance.

You can attach io1 and io2 EBS volumes to up to 16 Nitro-based instances. For more information, see Attach a volume to multiple instances with Amazon EBS Multi-Attach. Otherwise, you can attach an EBS volume to a single instance.

You can get monitoring data for your EBS volumes, including root device volumes for EBS-backed instances, at no additional charge. For more information about monitoring metrics, see Amazon CloudWatch metrics for Amazon EBS. For information about tracking the status of your volumes, see EventBridge for Amazon EBS.

Data persistence

An EBS volume is off-instance storage that can persist independently from the life of an instance. You continue to pay for the volume usage as long as the data persists.

EBS volumes that are attached to a running instance can automatically detach from the instance with their data intact when the instance is terminated if you uncheck the Delete on Termination check box when you configure EBS volumes for your instance on the EC2 console. The volume can then be reattached to a new instance, enabling quick recovery. If the check box for Delete on Termination is checked, the volume(s) will delete upon termination of the EC2 instance. If you are using an EBS-backed instance, you can stop and restart that instance without affecting the data stored in the attached volume. The volume remains attached throughout the stop-start cycle. This enables you to process and store the data on your volume indefinitely, only using the processing and storage resources when required. The data persists on the volume until the volume is deleted explicitly. The physical block storage used by deleted EBS volumes is overwritten with zeroes before it is allocated to a new volume. If you are dealing with sensitive data, you should consider encrypting your data manually or storing the data on a volume protected by Amazon EBS encryption. For more information, see Amazon EBS encryption.

By default, the root EBS volume that is created and attached to an instance at launch is deleted when that instance is terminated. You can modify this behavior by changing the value of the flag DeleteOnTermination to false when you launch the instance. This modified value causes the...
volume to persist even after the instance is terminated, and enables you to attach the volume to another instance.

By default, additional EBS volumes that are created and attached to an instance at launch are not deleted when that instance is terminated. You can modify this behavior by changing the value of the flag DeleteOnTermination to true when you launch the instance. This modified value causes the volumes to be deleted when the instance is terminated.

**Data encryption**

For simplified data encryption, you can create encrypted EBS volumes with the Amazon EBS encryption feature. All EBS volume types support encryption. You can use encrypted EBS volumes to meet a wide range of data-at-rest encryption requirements for regulated/audited data and applications. Amazon EBS encryption uses 256-bit Advanced Encryption Standard algorithms (AES-256) and an Amazon-managed key infrastructure. The encryption occurs on the server that hosts the EC2 instance, providing encryption of data-in-transit from the EC2 instance to Amazon EBS storage. For more information, see Amazon EBS encryption (p. 2316).

Amazon EBS encryption uses AWS Key Management Service (AWS KMS) master keys when creating encrypted volumes and any snapshots created from your encrypted volumes. The first time you create an encrypted EBS volume in a region, a default master key is created for you automatically. This key is used for Amazon EBS encryption unless you select a customer master key (CMK) that you created separately using AWS KMS. Creating your own CMK gives you more flexibility, including the ability to create, rotate, disable, define access controls, and audit the encryption keys used to protect your data. For more information, see the AWS Key Management Service Developer Guide.

**Data security**

Amazon EBS volumes are presented to you as raw, unformatted block devices. These devices are logical devices that are created on the EBS infrastructure and the Amazon EBS service ensures that the devices are logically empty (that is, the raw blocks are zeroed or they contain cryptographically pseudorandom data) prior to any use or re-use by a customer.

If you have procedures that require that all data be erased using a specific method, either after or before use (or both), such as those detailed in DoD 5220.22-M (National Industrial Security Program Operating Manual) or NIST 800-88 (Guidelines for Media Sanitization), you have the ability to do so on Amazon EBS. That block-level activity will be reflected down to the underlying storage media within the Amazon EBS service.

**Snapshots**

Amazon EBS provides the ability to create snapshots (backups) of any EBS volume and write a copy of the data in the volume to Amazon S3, where it is stored redundantly in multiple Availability Zones. The volume does not need to be attached to a running instance in order to take a snapshot. As you continue to write data to a volume, you can periodically create a snapshot of the volume to use as a baseline for new volumes. These snapshots can be used to create multiple new EBS volumes or move volumes across Availability Zones. Snapshots of encrypted EBS volumes are automatically encrypted.

When you create a new volume from a snapshot, it's an exact copy of the original volume at the time the snapshot was taken. EBS volumes that are created from encrypted snapshots are automatically encrypted. By optionally specifying a different Availability Zone, you can use this functionality to create a duplicate volume in that zone. The snapshots can be shared with specific AWS accounts or made public. When you create snapshots, you incur charges in Amazon S3 based on the volume's total size. For a successive snapshot of the volume, you are only charged for any additional data beyond the volume's original size.

Snapshots are incremental backups, meaning that only the blocks on the volume that have changed after your most recent snapshot are saved. If you have a volume with 100 GiB of data, but only 5 GiB of data have changed since your last snapshot, only the 5 GiB of modified data is written to Amazon S3.
Even though snapshots are saved incrementally, the snapshot deletion process is designed so that you need to retain only the most recent snapshot.

To help categorize and manage your volumes and snapshots, you can tag them with metadata of your choice. For more information, see Tag your Amazon EC2 resources (p. 2507).

To back up your volumes automatically, you can use Amazon Data Lifecycle Manager (p. 2211) or AWS Backup.

Flexibility

EBS volumes support live configuration changes while in production. You can modify volume type, volume size, and IOPS capacity without service interruptions. For more information, see Amazon EBS Elastic Volumes (p. 2304).

Amazon EBS volume types

Amazon EBS provides the following volume types, which differ in performance characteristics and price, so that you can tailor your storage performance and cost to the needs of your applications.

Important

There are several factors that can affect the performance of EBS volumes, such as instance configuration, I/O characteristics, and workload demand. To fully use the IOPS provisioned on an EBS volume, use EBS-optimized instances (p. 2339). For more information about getting the most out of your EBS volumes, see Amazon EBS volume performance on Linux instances (p. 2373).

For more information about pricing, see Amazon EBS Pricing.

Volume types

- Solid state drive (SSD) volumes (p. 2055)
- Hard disk drive (HDD) volumes (p. 2057)
- Previous generation volumes (p. 2057)

Solid state drive (SSD) volumes

SSD-backed volumes are optimized for transactional workloads involving frequent read/write operations with small I/O size, where the dominant performance attribute is IOPS. SSD-backed volume types include General Purpose SSD and Provisioned IOPS SSD. The following is a summary of the use cases and characteristics of SSD-backed volumes.

1. The throughput limit is between 128 MiB/s and 250 MiB/s, depending on the volume size. For more information, see [gp2 volume performance](p. 2059). Volumes created before December 3, 2018 that have not been modified since creation might not reach full performance unless you [modify the volume](p. 2304).

2. To achieve maximum throughput of 1,000 MiB/s, the volume must be provisioned with 64,000 IOPS and it must be attached to an [instance built on the Nitro System](p. 295). Volumes created before December 6, 2017 that have not been modified since creation might not reach full performance unless you [modify the volume](p. 2304).

3. All io2 volumes created after November 21, 2023 are io2 Block Express volumes. io2 volumes created before November 21, 2023 can be converted to io2 Block Express volumes by [modifying the IOPS or size of the volume](p. 2304).

4. Instances built on the Nitro System ([p. 295](p. 295)) can be attached to volumes up to 64 TiB in size. Other instance types can be attached to volumes up to 16 TiB in size.

5. Instances built on the Nitro System ([p. 295](p. 295)) can be attached to volumes provisioned with up to 256,000 IOPS. Other instance types can be attached to volumes provisioned with up to 64,000 IOPS, but can achieve up to 32,000 IOPS.

For more information about the SSD-backed volume types, see the following:

- [General Purpose SSD volumes](p. 2058)
- [Provisioned IOPS SSD volumes](p. 2061)
Hard disk drive (HDD) volumes

HDD-backed volumes are optimized for large streaming workloads where the dominant performance attribute is throughput. HDD volume types include Throughput Optimized HDD and Cold HDD. The following is a summary of the use cases and characteristics of HDD-backed volumes.

<table>
<thead>
<tr>

For more information about the Hard disk drives (HDD) volumes, see Throughput Optimized HDD and Cold HDD volumes (p. 2063).

Previous generation volumes

Magnetic (standard) volumes are previous generation volumes that are backed by magnetic drives. They are suited for workloads with small datasets where data is accessed infrequently and performance is not of primary importance. These volumes deliver approximately 100 IOPS on average, with burst capability of up to hundreds of IOPS, and they can range in size from 1 GiB to 1 TiB.

**Tip**

Magnetic is a previous generation volume type. If you need higher performance or performance consistency than previous-generation volumes can provide, we recommend using one of the newer volume types.

The following table describes previous-generation EBS volume types.

For more information, see Previous Generation Volumes.

General Purpose SSD volumes

General Purpose SSD (gp2 and gp3) volumes are backed by solid-state drives (SSDs). They balance price and performance for a wide variety of transactional workloads. These include virtual desktops, medium-sized single instance databases, latency sensitive interactive applications, development and test environments, and boot volumes. We recommend these volumes for most workloads.

Amazon EBS offers the following types of General Purpose SSD volumes:

Types
- General Purpose SSD (gp3) volumes
- General Purpose SSD (gp2) volumes

General Purpose SSD (gp3) volumes

General Purpose SSD (gp3) volumes are the latest generation of General Purpose SSD volumes, and the lowest cost SSD volume offered by Amazon EBS. This volume type helps to provide the right balance of price and performance for most applications. It also helps you to scale volume performance independently of volume size. This means that you can provision the required performance without needing to provision additional block storage capacity. Additionally, gp3 volumes offer a 20 percent lower price per GiB than General Purpose SSD (gp2) volumes.

gp3 volumes provide single-digit millisecond latency and 99.8 percent to 99.9 percent volume durability with an annual failure rate (AFR) no higher than 0.2 percent, which translates to a maximum of two volume failures per 1,000 running volumes over a one-year period. AWS designs gp3 volumes to deliver their provisioned performance 99 percent of the time.

Contents
- gp3 volume performance
- gp3 volume size
- Migrate to gp3 from gp2

gp3 volume performance

Tip

gp3 volumes do not use burst performance. They can indefinitely sustain their full provisioned IOPS and throughput performance.

IOPS performance

gp3 volumes deliver a consistent baseline IOPS performance of 3,000 IOPS, which is included with the price of storage. You can provision additional IOPS (up to a maximum of 16,000) for an additional cost at a ratio of 500 IOPS per GiB of volume size. Maximum IOPS can be provisioned for volumes 32 GiB or larger (500 IOPS per GiB × 32 GiB = 16,000 IOPS).

Throughput performance
gp3 volumes deliver a consistent baseline throughput performance of 125 MiB/s, which is included with the price of storage. You can provision additional throughput (up to a maximum of 1,000 MiB/s) for an additional cost at a ratio of 0.25 MiB/s per provisioned IOPS. Maximum throughput can be provisioned at 4,000 IOPS or higher and 8 GiB or larger (4,000 IOPS × 0.25 MiB/s per IOPS = 1,000 MiB/s).

gp3 volume size

A gp3 volume can range in size from 1 GiB to 16 TiB.

Migrate to gp3 from gp2

If you are currently using gp2 volumes, you can migrate your volumes to gp3 using Amazon EBS Elastic Volumes operations. You can use Amazon EBS Elastic Volumes operations to modify the volume type, IOPS, and throughput of your existing volumes without interrupting your Amazon EC2 instances. When using the console to create a volume or to create an AMI from a snapshot, General Purpose SSD gp3 is the default selection for volume type. In other cases, gp2 is the default selection. In these cases, you can select gp3 as the volume type instead of using gp2.

To find out how much you can save by migrating your gp2 volumes to gp3, use the Amazon EBS gp2 to gp3 migration cost savings calculator.

General Purpose SSD (gp2) volumes

They offer cost-effective storage that is ideal for a broad range of transactional workloads. With gp2 volumes, performance scales with volume size.

Tip

gp3 volumes are the latest generation of General Purpose SSD volumes. They offer more predictable performance scaling and prices that are up to 20 percent lower than gp2 volumes. For more information, see General Purpose SSD (gp3) volumes (p. 2058).

To find out how much you can save by migrating your gp2 volumes to gp3, use the Amazon EBS gp2 to gp3 migration cost savings calculator.

gp2 volumes provide single-digit millisecond latency and 99.8 percent to 99.9 percent volume durability with an annual failure rate (AFR) no higher than 0.2 percent, which translates to a maximum of two volume failures per 1,000 running volumes over a one-year period. AWS designs gp2 volumes to deliver their provisioned performance 99 percent of the time.

Contents

- gp2 volume performance (p. 2059)
- gp2 volume size (p. 2061)

gp2 volume performance

IOPS performance

Baseline IOPS performance scales linearly between a minimum of 100 and a maximum of 16,000 at a rate of 3 IOPS per GiB of volume size. IOPS performance is provisioned as follows:

- Volumes 33.33 GiB and smaller are provisioned with the minimum of 100 IOPS.
- Volumes larger than 33.33 GiB are provisioned with 3 IOPS per GiB of volume size up to the maximum of 16,000 IOPS, which is reached at 5,334 GiB (3 × 5,334).
- Volumes 5,334 GiB and larger are provisioned with 16,000 IOPS.

gp2 volumes smaller than 1 TiB (and that are provisioned with less than 3,000 IOPS) can burst to 3,000 IOPS when needed for an extended period of time. A volume's ability to burst is governed by I/O credits. When I/O demand is greater than baseline performance, the volume spends I/O credits to burst to the
required performance level (up to 3,000 IOPS). While bursting, I/O credits are not accumulated and they are spent at the rate of IOPS that is being used above baseline IOPS (spend rate = burst IOPS - baseline IOPS). The more I/O credits a volume has accrued, the longer it can sustain its burst performance. You can calculate Burst duration as follows:

$$\text{Burst duration} = \frac{\text{(I/O credit balance)}}{(\text{Burst IOPS}) - (\text{Baseline IOPS})}$$

When I/O demand drops to baseline performance level or lower, the volume starts to earn I/O credits at a rate of 3 I/O credits per GiB of volume size per second. Volumes have an I/O credit accrual limit of 5.4 million I/O credits, which is enough to sustain the maximum burst performance of 3,000 IOPS for at least 30 minutes.

**Note**

Each volume receives an initial I/O credit balance of 5.4 million I/O credits, which provides a fast initial boot cycle for boot volumes and a good bootstrapping experience for other applications.

The following table lists example volume sizes and the associated baseline performance of the volume, the burst duration (when starting with 5.4 million I/O credits), and the time needed to refill an empty I/O credits balance.

<table>
<thead>
<tr>

</tbody>
</table>

* The baseline performance of the volume exceeds the maximum burst performance.

You can monitor the I/O credit balance for a volume using the Amazon EBS BurstBalance metric in Amazon CloudWatch. This metric shows the percentage of I/O credits for gp2 remaining. For more information, see I/O characteristics and monitoring (p. 2376). You can set an alarm that notifies you when the BurstBalance value falls to a certain level. For more information, see Creating CloudWatch Alarms.

**Throughput performance**

gp2 volumes deliver throughput between 128 MiB/s and 250 MiB/s, depending on the volume size. Throughput performance is provisioned as follows:

- Volumes that are 170 GiB and smaller deliver a maximum throughput of 128 MiB/s.
- Volumes larger than 170 GiB but smaller than 334 GiB can burst to a maximum throughput of 250 MiB/s.
- Volumes that are 334 GiB and larger deliver 250 MiB/s.
Throughput for a gp2 volume can be calculated using the following formula, up to the throughput limit of 250 MiB/s:

Throughput in MiB/s = IOPS performance \times I/O size in KiB / 1,024

**gp2 volume size**

A gp2 volume can range in size from 1 GiB to 16 TiB. Keep in mind that volume performance scales linearly with the volume size.

**Provisioned IOPS SSD volumes**

Provisioned IOPS SSD volumes are backed by solid-state drives (SSDs). They are the highest performance Amazon EBS storage volumes designed for critical, IOPS-intensive, and throughput-intensive workloads that require low latency. Provisioned IOPS SSD volumes deliver their provisioned IOPS performance 99.9 percent of the time.

Amazon EBS offers two types of Provisioned IOPS SSD volumes:

- **Provisioned IOPS SSD (io2) Block Express volumes** (p. 2061)
- **Provisioned IOPS SSD (io1) volumes** (p. 2062)

**Provisioned IOPS SSD (io2) Block Express volumes**

io2 Block Express volumes are built on the next generation of Amazon EBS storage server architecture. It has been built for the purpose of meeting the performance requirements of the most demanding I/O intensive applications that run on instances built on the Nitro System (p. 295). With the highest durability and lowest latency, Block Express is ideal for running performance-intensive, mission-critical workloads, such as Oracle, SAP HANA, Microsoft SQL Server, and SAS Analytics.

Block Express architecture increases performance and scale of io2 volumes. Block Express servers communicate with instances built on the Nitro System (p. 295) using the Scalable Reliable Datagram (SRD) networking protocol. This interface is implemented in the Nitro Card dedicated for Amazon EBS I/O function on the host hardware of the instance. It minimizes I/O delay and latency variation (network jitter), which provides faster and more consistent performance for your applications.

io2 Block Express volumes are designed to provide 99.999 percent volume durability with an annual failure rate (AFR) no higher than 0.001 percent, which translates to a single volume failure per 100,000 running volumes over a one-year period. io2 Block Express volumes are suited for workloads that benefit from a single volume that provides sub-millisecond latency, supports higher IOPS and throughput, and larger capacity than gp3 volumes.

Provisioned IOPS SSD (io2) Block Express volumes deliver their provisioned IOPS performance 99.9 percent of the time.

io2 Block Express volumes are supported on all instances built on the Nitro System (p. 295). For more information, see io2 Block Express volumes.

**Topics**

- Considerations (p. 2061)
- Performance (p. 2062)

**Considerations**

- io2 Block Express volumes are available in the following Regions: US East (Ohio) | US East (N. Virginia) | US West (N. California) | US West (Oregon) | Asia Pacific (Hong Kong) | Asia Pacific (Mumbai) | Asia Pacific (Seoul) | Asia Pacific (Singapore) | Asia Pacific (Sydney) | Asia Pacific (Tokyo) | Canada (Central) | Europe (Frankfurt) | Europe (Ireland) | Europe (London) | Europe (Stockholm) | Middle East (Bahrain).
• All io2 volumes created after November 21, 2023 are io2 Block Express volumes. io2 volumes created before November 21, 2023 can be converted to io2 Block Express volumes by modifying the IOPS or size of the volume (p. 2304).
• Instances built on the Nitro System (p. 295) can be attached to volumes up to 64 TiB in size. Other instance types can be attached to volumes up to 16 TiB in size.
• Instances built on the Nitro System (p. 295) can be attached to volumes provisioned with up to 256,000 IOPS. Other instance types can be attached to volumes provisioned with up to 64,000 IOPS, but can achieve up to 32,000 IOPS.
• To create an encrypted io2 volume, with a size larger than 16 TiB or IOPS greater than 64,000, from an unencrypted snapshot or shared encrypted snapshot, you must:
  1. Create an encrypted copy of that snapshot in your account
  2. Use that snapshot copy to create the volume

Performance

With io2 Block Express volumes, you can provision volumes with:

• Sub-millisecond average latency
• Storage capacity up to 64 TiB (65,536 GiB)
• Provisioned IOPS up to 256,000, with an IOPS:GiB ratio of 1,000:1. Maximum IOPS can be provisioned with volumes 256 GiB and larger (1,000 IOPS × 256 GiB = 256,000 IOPS).

  Note
  You can achieve up to 256,000 IOPS with instances built on the Nitro System (p. 295). On other instances, you can achieve performance up to 32,000 IOPS.
• Volume throughput up to 4,000 MiB/s. Throughput scales proportionally up to 0.256 MiB/s per provisioned IOPS. Maximum throughput can be achieved at 16,000 IOPS or higher.

Provisioned IOPS SSD (io1) volumes

Provisioned IOPS SSD (io1) volumes are designed to meet the needs of I/O-intensive workloads, particularly database workloads, that are sensitive to storage performance and consistency. Provisioned IOPS SSD volumes use a consistent IOPS rate, which you specify when you create the volume, and Amazon EBS delivers the provisioned performance 99.9 percent of the time.

io1 volumes are designed to provide 99.8 percent to 99.9 percent volume durability with an annual failure rate (AFR) no higher than 0.2 percent, which translates to a maximum of two volume failures per 1,000 running volumes over a one-year period.
io1 volumes are available for all Amazon EC2 instance types.

**Performance**

io1 volumes can range in size from 4 GiB to 16 TiB and you can provision from 100 IOPS up to 64,000 IOPS per volume. The maximum ratio of provisioned IOPS to requested volume size (in GiB) is 50:1. For example, a 100 GiB io1 volume can be provisioned with up to 5,000 IOPS.

The maximum IOPS can be provisioned for volumes that are 1,280 GiB or larger (50 × 1,280 GiB = 64,000 IOPS).

- io1 volumes provisioned with up to 32,000 IOPS support a maximum I/O size of 256 KiB and yield as much as 500 MiB/s of throughput. With the I/O size at the maximum, peak throughput is reached at 2,000 IOPS.
- io1 volumes provisioned with more than 32,000 IOPS (up to the maximum of 64,000 IOPS) yield a linear increase in throughput at a rate of 16 KiB per provisioned IOPS. For example, a volume provisioned with 48,000 IOPS can support up to 750 MiB/s of throughput (16 KiB per provisioned IOPS × 48,000 provisioned IOPS = 750 MiB/s).
- To achieve the maximum throughput of 1,000 MiB/s, a volume must be provisioned with 64,000 IOPS (16 KiB per provisioned IOPS × 64,000 provisioned IOPS = 1,000 MiB/s).
- You can achieve up to 64,000 IOPS only on instances built on the Nitro System (p. 295). On other instances, you can achieve performance up to 32,000 IOPS.

The following graph illustrates these performance characteristics:

Your per-I/O latency experience depends on the provisioned IOPS and on your workload profile. For the best I/O latency experience, ensure that you provision IOPS to meet the I/O profile of your workload.

**Throughput Optimized HDD and Cold HDD volumes**

The HDD-backed volumes provided by Amazon EBS fall into these categories:

- Throughput Optimized HDD — A low-cost HDD designed for frequently accessed, throughput-intensive workloads.
- Cold HDD — The lowest-cost HDD design for less frequently accessed workloads.

**Topics**

- Limitations on per-instance throughput (p. 2064)
- Throughput Optimized HDD volumes (p. 2064)
- Cold HDD volumes (p. 2066)
- Performance considerations when using HDD volumes (p. 2068)
- Monitor the burst bucket balance for volumes (p. 2070)

Limitations on per-instance throughput

Throughput for st1 and sc1 volumes is always determined by the smaller of the following:

- Throughput limits of the volume
- Throughput limits of the instance

As for all Amazon EBS volumes, we recommend that you select an appropriate EBS-optimized EC2 instance to avoid network bottlenecks. For more information, see Amazon EBS–optimized instances (p. 2339).

Throughput Optimized HDD volumes

Throughput Optimized HDD (st1) volumes provide low-cost magnetic storage that defines performance in terms of throughput rather than IOPS. This volume type is a good fit for large, sequential workloads such as Amazon EMR, ETL, data warehouses, and log processing. Bootable st1 volumes are not supported.

Throughput Optimized HDD (st1) volumes, though similar to Cold HDD (sc1) volumes, are designed to support frequently accessed data.

This volume type is optimized for workloads involving large, sequential I/O, and we recommend that customers with workloads performing small, random I/O use gp2. For more information, see Inefficiency of small read/writes on HDD (p. 2070).

Throughput Optimized HDD (st1) volumes attached to EBS-optimized instances are designed to offer consistent performance, delivering at least 90 percent of the expected throughput performance 99 percent of the time in a given year.

Throughput credits and burst performance

Like gp2, st1 uses a burst bucket model for performance. Volume size determines the baseline throughput of your volume, which is the rate at which the volume accumulates throughput credits. Volume size also determines the burst throughput of your volume, which is the rate at which you can spend credits when they are available. Larger volumes have higher baseline and burst throughput. The more credits your volume has, the longer it can drive I/O at the burst level.

The following diagram shows the burst bucket behavior for st1.
Subject to throughput and throughput-credit caps, the available throughput of an st1 volume is expressed by the following formula:

\[(\text{Volume size}) \times (\text{Credit accumulation rate per TiB}) = \text{Throughput}\]

For a 1-TiB st1 volume, burst throughput is limited to 250 MiB/s, the bucket fills with credits at 40 MiB/s, and it can hold up to 1 TiB-worth of credits.

Larger volumes scale these limits linearly, with throughput capped at a maximum of 500 MiB/s. After the bucket is depleted, throughput is limited to the baseline rate of 40 MiB/s per TiB.

On volume sizes ranging from 0.125 TiB to 16 TiB, baseline throughput varies from 5 MiB/s to a cap of 500 MiB/s, which is reached at 12.5 TiB as follows:

\[
\frac{40 \text{ MiB/s}}{12.5 \text{ TiB}} \times \frac{1 \text{ TiB}}{} = 500 \text{ MiB/s}
\]

Burst throughput varies from 31 MiB/s to a cap of 500 MiB/s, which is reached at 2 TiB as follows:

\[
\frac{250 \text{ MiB/s}}{2 \text{ TiB}} \times \frac{1 \text{ TiB}}{} = 500 \text{ MiB/s}
\]

The following table states the full range of base and burst throughput values for st1.

The following diagram plots the table values:

Note
When you create a snapshot of a Throughput Optimized HDD (st1) volume, performance may drop as far as the volume's baseline value while the snapshot is in progress.

For information about using CloudWatch metrics and alarms to monitor your burst bucket balance, see Monitor the burst bucket balance for volumes (p. 2070).

Cold HDD volumes

Cold HDD (sc1) volumes provide low-cost magnetic storage that defines performance in terms of throughput rather than IOPS. With a lower throughput limit than st1, sc1 is a good fit for large, sequential cold-data workloads. If you require infrequent access to your data and are looking to save costs, sc1 provides inexpensive block storage. Bootable sc1 volumes are not supported.

Cold HDD (sc1) volumes, though similar to Throughput Optimized HDD (st1) volumes, are designed to support infrequently accessed data.

Note
This volume type is optimized for workloads involving large, sequential I/O, and we recommend that customers with workloads performing small, random I/O use gp2. For more information, see Inefficiency of small read/writes on HDD (p. 2070).

Cold HDD (sc1) volumes attached to EBS-optimized instances are designed to offer consistent performance, delivering at least 90 percent of the expected throughput performance 99 percent of the time in a given year.

Throughput credits and burst performance

Like gp2, sc1 uses a burst bucket model for performance. Volume size determines the baseline throughput of your volume, which is the rate at which the volume accumulates throughput credits. Volume size also determines the burst throughput of your volume, which is the rate at which you can spend credits when they are available. Larger volumes have higher baseline and burst throughput. The more credits your volume has, the longer it can drive I/O at the burst level.
Subject to throughput and throughput-credit caps, the available throughput of an `sc1` volume is expressed by the following formula:

\[(\text{Volume size}) \times (\text{Credit accumulation rate per TiB}) = \text{Throughput}\]

For a 1-TiB `sc1` volume, burst throughput is limited to 80 MiB/s, the bucket fills with credits at 12 MiB/s, and it can hold up to 1 TiB-worth of credits.

Larger volumes scale these limits linearly, with throughput capped at a maximum of 250 MiB/s. After the bucket is depleted, throughput is limited to the baseline rate of 12 MiB/s per TiB.

On volume sizes ranging from 0.125 TiB to 16 TiB, baseline throughput varies from 1.5 MiB/s to a maximum of 192 MiB/s, which is reached at 16 TiB as follows:

\[
\frac{12 \text{ MiB/s}}{16 \text{ TiB}} \times \frac{16 \text{ TiB}}{1 \text{ TiB}} = 192 \text{ MiB/s}
\]

Burst throughput varies from 10 MiB/s to a cap of 250 MiB/s, which is reached at 3.125 TiB as follows:

\[
\frac{80 \text{ MiB/s}}{3.125 \text{ TiB}} \times \frac{3.125 \text{ TiB}}{1 \text{ TiB}} = 250 \text{ MiB/s}
\]

The following table states the full range of base and burst throughput values for `sc1`:

The following diagram plots the table values:

![Diagram](image)

**Note**

When you create a snapshot of a Cold HDD (sc1) volume, performance may drop as far as the volume's baseline value while the snapshot is in progress.

For information about using CloudWatch metrics and alarms to monitor your burst bucket balance, see Monitor the burst bucket balance for volumes (p. 2070).

Performance considerations when using HDD volumes

For optimal throughput results using HDD volumes, plan your workloads with the following considerations in mind.

**Comparing Throughput Optimized HDD and Cold HDD**

The st1 and sc1 bucket sizes vary according to volume size, and a full bucket contains enough tokens for a full volume scan. However, larger st1 and sc1 volumes take longer for the volume scan to
complete because of per-instance and per-volume throughput limits. Volumes attached to smaller instances are limited to the per-instance throughput rather than the st1 or sc1 throughput limits.

Both st1 and sc1 are designed for performance consistency of 90 percent of burst throughput 99 percent of the time. Non-compliant periods are approximately uniformly distributed, targeting 99 percent of expected total throughput each hour.

In general, scan times are expressed by this formula:

\[
\text{Volume size} \div \text{Throughput} = \text{Scan time}
\]

For example, taking the performance consistency guarantees and other optimizations into account, an st1 customer with a 5-TiB volume can expect to complete a full volume scan in 2.91 to 3.27 hours.

- **Optimal scan time**

\[
\frac{5 \text{ TiB}}{500 \text{ MiB/s}} = \frac{5 \text{ TiB}}{0.00047684 \text{ TiB/s}} = 10,486 \text{ seconds} = 2.91 \text{ hours}
\]

- **Maximum scan time**

\[
\frac{2.91 \text{ hours}}{(0.90)(0.99)} = 3.27 \text{ hours}
\]

Similarly, an sc1 customer with a 5-TiB volume can expect to complete a full volume scan in 5.83 to 6.54 hours.

- **Optimal scan time**

\[
\frac{5 \text{ TiB}}{250 \text{ MiB/s}} = \frac{5 \text{ TiB}}{0.000238418 \text{ TiB/s}} = 20,972 \text{ seconds} = 5.83 \text{ hours}
\]

- **Maximum scan time**

\[
\frac{5.83 \text{ hours}}{(0.90)(0.99)} = 6.54 \text{ hours}
\]

The following table shows ideal scan times for volumes of various size, assuming full buckets and sufficient instance throughput.

<table>

</table>

* These scan times assume an average queue depth (rounded to the nearest whole number) of four or more when performing 1 MiB of sequential I/O.

Therefore if you have a throughput-oriented workload that needs to complete scans quickly (up to 500 MiB/s), or requires several full volume scans a day, use st1. If you are optimizing for cost, your data is relatively infrequently accessed, and you don’t need more than 250 MiB/s of scanning performance, then use sc1.

**Inefficiency of small read/writes on HDD**

The performance model for st1 and sc1 volumes is optimized for sequential I/Os, favoring high-throughput workloads, offering acceptable performance on workloads with mixed IOPS and throughput, and discouraging workloads with small, random I/O.

For example, an I/O request of 1 MiB or less counts as a 1 MiB I/O credit. However, if the I/Os are sequential, they are merged into 1 MiB I/O blocks and count only as a 1 MiB I/O credit.

**Monitor the burst bucket balance for volumes**

You can monitor the burst bucket level for st1 and sc1 volumes using the Amazon EBS BurstBalance metric available in Amazon CloudWatch. This metric shows the throughput credits for st1 and sc1 remaining in the burst bucket. For more information about the BurstBalance metric and other metrics related to I/O, see I/O characteristics and monitoring (p. 2376). CloudWatch also allows you to set an alarm that notifies you when the BurstBalance value falls to a certain level. For more information, see Creating CloudWatch Alarms.

**Constraints on the size and configuration of an EBS volume**

The size of an Amazon EBS volume is constrained by the physics and arithmetic of block data storage, as well as by the implementation decisions of operating system (OS) and file system designers. AWS imposes additional limits on volume size to safeguard the reliability of its services.
The following sections describe the most important factors that limit the usable size of an EBS volume and offer recommendations for configuring your EBS volumes.

Contents

- Storage capacity (p. 2071)
- Service limitations (p. 2071)
- Partitioning schemes (p. 2072)
- Data block sizes (p. 2072)

Storage capacity

The following table summarizes the theoretical and implemented storage capacities for the most commonly used file systems on Amazon EBS, assuming a 4,096 byte block size.

<table>
<thead>
<tr>
<th>Partitioning scheme</th>
<th>Max addressable blocks</th>
<th>Theoretical max size (blocks × block size)</th>

</tr>
</tbody>
</table>

** [https://access.redhat.com/solutions/1532](https://access.redhat.com/solutions/1532)

† io2 Block Express volumes support up to 64 TiB for GPT partitions. For more information, see [Provisioned IOPS SSD (io2) Block Express volumes (p. 2061)](https://access.redhat.com/solutions/1532).

Service limitations

Amazon EBS abstracts the massively distributed storage of a data center into virtual hard disk drives. To an operating system installed on an EC2 instance, an attached EBS volume appears to be a physical hard disk drive containing 512-byte disk sectors. The OS manages the allocation of data blocks (or clusters) onto those virtual sectors through its storage management utilities. The allocation is in conformity with a volume partitioning scheme, such as master boot record (MBR) or GUID partition table (GPT), and within the capabilities of the installed file system (ext4, NTFS, and so on).

EBS is not aware of the data contained in its virtual disk sectors; it only ensures the integrity of the sectors. This means that AWS actions and OS actions are independent of each other. When you are selecting a volume size, be aware of the capabilities and limits of both, as in the following cases:

- EBS currently supports a maximum volume size of 64 TiB. This means that you can create an EBS volume as large as 64 TiB, but whether the OS recognizes all of that capacity depends on its own design characteristics and on how the volume is partitioned.
- Linux boot volumes may use either the MBR or GPT partitioning scheme. The AMI you launch an instance from determines the boot mode parameter and subsequently which partition scheme can be used for the boot volume. MBR supports boot volumes up to 2047 GiB (2 TiB - 1 GiB). GPT with GRUB 2 supports boot volumes 2 TiB or larger. If your Linux AMI uses MBR, your boot volume is limited
to 2047 GiB, but your non-boot volumes do not have this limit. For more information, see Make an Amazon EBS volume available for use on Linux (p. 2083) and Set the boot mode of an AMI.

**Partitioning schemes**

Among other impacts, the partitioning scheme determines how many logical data blocks can be uniquely addressed in a single volume. For more information, see Data block sizes (p. 2072). The common partitioning schemes in use are Master Boot Record (MBR) and GUID partition table (GPT). The important differences between these schemes can be summarized as follows.

**MBR**

MBR uses a 32-bit data structure to store block addresses. This means that each data block is mapped with one of $2^{32}$ possible integers. The maximum addressable size of a volume is given by the following formula:

$$2^{32} \times \text{Block size}$$

The block size for MBR volumes is conventionally limited to 512 bytes. Therefore:

$$2^{32} \times 512 \text{ bytes} = 2 \text{ TiB}$$

Engineering workarounds to increase this 2-TiB limit for MBR volumes have not met with widespread industry adoption. Consequently, Linux and Windows never detect an MBR volume as being larger than 2 TiB even if AWS shows its size to be larger.

**GPT**

GPT uses a 64-bit data structure to store block addresses. This means that each data block is mapped with one of $2^{64}$ possible integers. The maximum addressable size of a volume is given by the following formula:

$$2^{64} \times \text{Block size}$$

The block size for GPT volumes is commonly 4,096 bytes. Therefore:

$$2^{64} \times 4096 \text{ bytes} = 2^{64} \times 2^{12} \text{ bytes}$$

$$= 2^{76} \times 2^6 \text{ bytes}$$

$$= 64 \text{ ZiB}$$

Real-world computer systems don't support anything close to this theoretical maximum. Implemented file-system size is currently limited to 50 TiB for ext4 and 256 TiB for NTFS.

**Data block sizes**

Data storage on a modern hard drive is managed through logical block addressing, an abstraction layer that allows the operating system to read and write data in logical blocks without knowing much about the underlying hardware. The OS relies on the storage device to map the blocks to its physical sectors. EBS advertises 512-byte sectors to the operating system, which reads and writes data to disk using data blocks that are a multiple of the sector size.

The industry default size for logical data blocks is currently 4,096 bytes (4 KiB). Because certain workloads benefit from a smaller or larger block size, file systems support non-default block sizes that can be specified during formatting. Scenarios in which non-default block sizes should be used are outside the scope of this topic, but the choice of block size has consequences for the storage capacity of the volume. The following table shows storage capacity as a function of block size:
### Create an Amazon EBS volume

You can create an Amazon EBS volume and then attach it to any EC2 instance in the same Availability Zone. If you create an encrypted EBS volume, you can only attach it to supported instance types. For more information, see [Supported instance types](#). If you are creating a volume for a high-performance storage scenario, you should make sure to use a Provisioned IOPS SSD volume (io1 or io2) and attach it to an instance with enough bandwidth to support your application, such as an EBS-optimized instance. The same advice holds for Throughput Optimized HDD (st1) and Cold HDD (sc1) volumes. For more information, see [Amazon EBS-optimized instances](#).

Empty EBS volumes receive their maximum performance the moment that they are available and do not require initialization (formerly known as pre-warming). However, storage blocks on volumes that were created from snapshots must be initialized (pulled down from Amazon S3 and written to the volume) before you can access the block. This preliminary action takes time and can cause a significant increase in the latency of an I/O operation the first time each block is accessed. Volume performance is achieved after all blocks have been downloaded and written to the volume. For most applications, amortizing this cost over the lifetime of the volume is acceptable. To avoid this initial performance hit in a production environment, you can force immediate initialization of the entire volume or enable fast snapshot restore. For more information, see [Initialize Amazon EBS volumes](#).

### Methods of creating a volume

- Create and attach EBS volumes when you launch instances by specifying a block device mapping. For more information, see [Launch an instance using the new launch instance wizard](#) and [Block device mappings](#).
- Create an empty EBS volume and attach it to a running instance. For more information, see [Create an empty volume](#) below.
- Create an EBS volume from a previously created snapshot and attach it to a running instance. For more information, see [Create a volume from a snapshot](#) below.

### Topics

- [Create an empty volume](#)
- [Create a volume from a snapshot](#)

### Create an empty volume

Empty volumes receive their maximum performance the moment that they are available and do not require initialization.
You can create an empty EBS volume using one of the following methods.

Console

**To create an empty EBS volume using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Volumes**.
3. Choose **Create volume**.
4. For **Volume type**, choose the type of volume to create. For more information, see [Amazon EBS volume types](p. 2055).
   
   General Purpose SSD gp3 is the default selection.
5. For **Size**, enter the size of the volume, in GiB. For more information, see [Constraints on the size and configuration of an EBS volume](p. 2070).
6. (io1, io2, and gp3 only) For **IOPS**, enter the maximum number of input/output operations per second (IOPS) that the volume should provide.
7. (gp3 only) For **Throughput**, enter the throughput that the volume should provide, in MiB/s.
8. For **Availability Zone**, choose the Availability Zone in which to create the volume. A volume can be attached only to an instance that is in the same Availability Zone.
9. For **Snapshot ID**, keep the default value (**Don't create volume from a snapshot**).
10. (io1 and io2 only) To enable the volume for Amazon EBS Multi-Attach, select **Enable Multi-Attach**. For more information, see [Attach a volume to multiple instances with Amazon EBS Multi-Attach](p. 2077).
11. Set the encryption status for the volume.

   If your account is enabled for encryption by default ([p. 2320](#)), then encryption is automatically enabled and you can't disable it. You can choose the KMS key to use to encrypt the volume.

   If your account is not enabled for encryption by default, encryption is optional. To encrypt the volume, for **Encryption**, choose **Encrypt this volume** and then select the KMS key to use to encrypt the volume.

   **Note**

   Encrypted volumes can be attached only to instances that support Amazon EBS encryption. For more information, see [Amazon EBS encryption](p. 2316).
12. (Optional) To assign custom tags to the volume, in the **Tags** section, choose **Add tag**, and then enter a tag key and value pair. For more information, see [Tag your Amazon EC2 resources](p. 2507).
13. Choose **Create volume**.

   **Note**

   The volume is ready for use when the **Volume state** is **available**.
14. To use the volume, attach it to an instance. For more information, see [Attach an Amazon EBS volume to an instance](p. 2076).

AWS CLI

**To create an empty EBS volume using the AWS CLI**

Use the `create-volume` command.

The volume is ready for use when the state is available.

Tools for Windows PowerShell

**To create an empty EBS volume using the Tools for Windows PowerShell**

---

2074
Use the `New-EC2Volume` command.

The volume is ready for use when the state is available.

Create a volume from a snapshot

Volumes created from snapshots load lazily in the background. This means that there is no need to wait for all of the data to transfer from Amazon S3 to your EBS volume before the instance can start accessing an attached volume and all its data. If your instance accesses data that hasn't yet been loaded, the volume immediately downloads the requested data from Amazon S3, and then continues loading the rest of the volume data in the background. Volume performance is achieved after all blocks are downloaded and written to the volume. To avoid the initial performance hit in a production environment, see Initialize Amazon EBS volumes (p. 2379).

New EBS volumes that are created from encrypted snapshots are automatically encrypted. You can also encrypt a volume on-the-fly while restoring it from an unencrypted snapshot. Encrypted volumes can only be attached to instance types that support EBS encryption. For more information, see Supported instance types (p. 2318).

You can create a volume from a snapshot using one of the following methods.

Console

To create an EBS volume from a snapshot using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Choose Create volume.
4. For Volume type, choose the type of volume to create. For more information, see Amazon EBS volume types (p. 2055).
   General Purpose SSD gp3 is the default selection.
5. For Size, enter the size of the volume, in GiB. For more information, see Constraints on the size and configuration of an EBS volume (p. 2070).
6. For IOPS, enter the maximum number of input/output operations per second (IOPS) that the volume should provide. (io1, io2, and gp3 only)
7. For Throughput, enter the throughput that the volume should provide, in MiB/s. (gp3 only)
8. For Availability Zone, choose the Availability Zone in which to create the volume. A volume can be attached only to instances that are in the same Availability Zone.
9. For Snapshot ID, select the snapshot from which to create the volume.
10. Set the encryption status for the volume.

   If the selected snapshot is encrypted, or if your account is enabled for encryption by default (p. 2320), then encryption is automatically enabled and you can’t disable it. You can choose the KMS key to use to encrypt the volume.

   If the selected snapshot is unencrypted and your account is not enabled for encryption by default, encryption is optional. To encrypt the volume, for Encryption, choose Encrypt this volume and then select the KMS key to use to encrypt the volume.

   Note
   Encrypted volumes can be attached only to instances that support Amazon EBS encryption. For more information, see Amazon EBS encryption (p. 2316).
11. (Optional) To assign custom tags to the volume, in the Tags section, choose Add tag, and then enter a tag key and value pair. For more information, see Tag your Amazon EC2 resources (p. 2507).
12. Choose **Create Volume**.

**Note**
The volume is ready for use when the **Volume state** is **available**.

13. To use the volume, attach it to an instance. For more information, see [Attach an Amazon EBS volume to an instance](p. 2076).

**AWS CLI**

To create an EBS volume from a snapshot using the AWS CLI

Use the `create-volume` command.

The volume is ready for use when the state is available.

**Tools for Windows PowerShell**

To create an EBS volume from a snapshot using the Tools for Windows PowerShell

Use the `New-EC2Volume` command.

The volume is ready for use when the state is available.

**Attach an Amazon EBS volume to an instance**

You can attach an available EBS volume to one or more of your instances that is in the same Availability Zone as the volume.

For information about adding EBS volumes to your instance at launch, see [Instance block device mapping](p. 2459).

**Prerequisites**

- Determine how many volumes you can attach to your instance. The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. For more information, see [Instance volume limits](p. 2444).
- Determine whether you can attach your volume to multiple instances and enable Multi-Attach. For more information, see [Attach a volume to multiple instances with Amazon EBS Multi-Attach](p. 2077).
- If a volume is encrypted, you can attach it only to an instance that supports Amazon EBS encryption. For more information, see [Supported instance types](p. 2318).
- If a volume has an AWS Marketplace product code:
  - You can attach a volume only to a stopped instance.
  - You must be subscribed to the AWS Marketplace code that is on the volume.
  - The instance's configuration, such as its type and operating system, must support that specific AWS Marketplace code. For example, you cannot take a volume from a Windows instance and attach it to a Linux instance.
  - AWS Marketplace product codes are copied from the volume to the instance.

You can attach a volume to an instance using one of the following methods.

**Console**

To attach an EBS volume to an instance using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Volumes**.
3. Select the volume to attach and choose **Actions, Attach volume**.
   
   **Note**
   You can attach only volumes that are in the Available state.
4. For **Instance**, enter the ID of the instance or select the instance from the list of options.
   
   **Note**
   • The volume must be attached to an instance in the same Availability Zone.
   • If the volume is encrypted, it can only be attached to instance types that support Amazon EBS encryption. For more information, see Amazon EBS encryption (**p. 2316**).
5. For **Device name**, enter a supported device name for the volume. This device name is used by Amazon EC2. The block device driver for the instance might assign a different device name when mounting the volume. For more information, see Device names on Linux instances (**p. 2452**).
6. Choose **Attach volume**.
7. Connect to the instance and mount the volume. For more information, see Make an Amazon EBS volume available for use on Linux (**p. 2083**).

**AWS CLI**

**To attach an EBS volume to an instance using the AWS CLI**

Use the **attach-volume** command.

**Tools for Windows PowerShell**

**To attach an EBS volume to an instance using the Tools for Windows PowerShell**

Use the **Add-EC2Volume** command.

**Note**

• If you attempt to attach a number of volumes that exceeds the instance type’s volume limit, the request fails. For more information, see Instance volume limits (**p. 2444**).

• In some situations, you may find that a volume other than the volume attached to /dev/xvda or /dev/sda has become the root volume of your instance. This can happen when you have attached the root volume of another instance, or a volume created from the snapshot of a root volume, to an instance with an existing root volume. For more information, see Boot from the wrong volume.

**Attach a volume to multiple instances with Amazon EBS Multi-Attach**

Amazon EBS Multi-Attach enables you to attach a single Provisioned IOPS SSD (io1 or io2) volume to multiple instances that are in the same Availability Zone. You can attach multiple Multi-Attach enabled volumes to an instance or set of instances. Each instance to which the volume is attached has full read and write permission to the shared volume. Multi-Attach makes it easier for you to achieve higher application availability in applications that manage concurrent write operations.

**Contents**

• Considerations and limitations (**p. 478**)
• Performance (**p. 2079**)
Considerations and limitations

- Multi-Attach enabled volumes can be attached to up to 16 Linux instances built on the Nitro System (p. 295) that are in the same Availability Zone.
- The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. For more information, see Instance volume limits (p. 2444).
- Multi-Attach is supported exclusively on Provisioned IOPS SSD (io1 and io2) volumes (p. 2062).
- Multi-Attach for io1 volumes is available in the following Regions only: US East (N. Virginia), US West (Oregon), and Asia Pacific (Seoul).
- Multi-Attach for io2 is available in all Regions that support io2.

**Note**
For better performance, consistency, and durability at a lower cost, we recommend that you use io2 volumes.

- io1 volumes with Multi-Attach enabled are not supported with instances built on the Nitro System (p. 295) that support the Scalable Reliable Datagram (SRD) networking protocol only. To use Multi-Attach with these instance types, you must use io2 Block Express volumes.
- Standard file systems, such as XFS and EXT4, are not designed to be accessed simultaneously by multiple servers, such as EC2 instances. You should use a clustered file system to ensure data resiliency and reliability for your production workloads.
- Multi-Attach enabled io2 volumes support I/O fencing. I/O fencing protocols control write access in a shared storage environment to maintain data consistency. Your applications must provide write ordering for the attached instances to maintain data consistency. For more information, see NVMe reservations (p. 2082).

Multi-Attach enabled io1 volumes do not support I/O Fencing.
- Multi-Attach enabled volumes can't be created as boot volumes.
- Multi-Attach enabled volumes can be attached to one block device mapping per instance.
- Multi-Attach can't be enabled during instance launch using either the Amazon EC2 console or RunInstances API.
- Multi-Attach enabled volumes that have an issue at the Amazon EBS infrastructure layer are unavailable to all attached instances. Issues at the Amazon EC2 or networking layer might impact only some attached instances.
- The following table shows volume modification support for Multi-Attach enabled io1 and io2 volumes after creation.

<table>

Amazon Elastic Compute Cloud  
User Guide for Linux Instances  
EBS volumes

### Performance

Each attached instance is able to drive its maximum IOPS performance up to the volume's maximum provisioned performance. However, the aggregate performance of all of the attached instances can't exceed the volume's maximum provisioned performance. If the attached instances' demand for IOPS is higher than the volume's Provisioned IOPS, the volume will not exceed its provisioned performance.

For example, say you create an io2 Multi-Attach enabled volume with 80,000 provisioned IOPS and you attach it to an m7g.large instance that supports up to 40,000 IOPS, and an r7g.12xlarge instance that supports up to 60,000 IOPS. Each instance can drive its maximum IOPS as it is less than the volume's Provisioned IOPS of 80,000. However, if both instances drive I/O to the volume simultaneously, their combined IOPS can't exceed the volume's provisioned performance of 80,000 IOPS.

To achieve consistent performance, it is best practice to balance I/O driven from attached instances across the sectors of a Multi-Attach enabled volume.

### Work with Multi-Attach

Multi-Attach enabled volumes can be managed in much the same way that you would manage any other Amazon EBS volume. However, in order to use the Multi-Attach functionality, you must enable it for the volume. When you create a new volume, Multi-Attach is disabled by default.

### Contents

- **Enable Multi-Attach** (p. 2079)
- **Disable Multi-Attach** (p. 2081)
- **Attach a volume to instances** (p. 2081)
- **Delete on termination** (p. 2081)

### Enable Multi-Attach

You can enable Multi-Attach during volume creation. Use one of the following methods.

**Console**

**To enable Multi-Attach during volume creation**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Volumes**.
3. Choose **Create volume**.
4. For **Volume type**, choose ** Provisioned IOPS SSD (i1)** or ** Provisioned IOPS SSD (i2)**.
5. For **Size** and **IOPS**, choose the required volume size and the number of IOPS to provision.
6. For **Availability Zone**, choose the same Availability Zone that the instances are in.
7. For Amazon EBS Multi-Attach, choose Enable Multi-Attach.

8. (Optional) For Snapshot ID, choose the snapshot from which to create the volume.

9. Set the encryption status for the volume.

   If the selected snapshot is encrypted, or if your account is enabled for encryption by default (p. 2320), then encryption is automatically enabled and you can't disable it. You can choose the KMS key to use to encrypt the volume.

   If the selected snapshot is unencrypted and your account is not enabled for encryption by default, encryption is optional. To encrypt the volume, for Encryption, choose Encrypt this volume and then select the KMS key to use to encrypt the volume.

   **Note**
   You can attach encrypted volumes only to instances that support Amazon EBS encryption. For more information, see Amazon EBS encryption (p. 2316).

10. (Optional) To assign custom tags to the volume, in the Tags section, choose Add tag, and then enter a tag key and value pair. For more information, see Tag your Amazon EC2 resources (p. 2507).

11. Choose Create volume.

**Command line**

   **To enable Multi-Attach during volume creation**

   Use the create-volume command and specify the --multi-attach-enabled parameter.

   ```
   $ aws ec2 create-volume --volume-type io2 --multi-attach-enabled --size 100 --iops 2000 --region us-west-2 --availability-zone us-west-2b
   ```

   You can also enable Multi-Attach for io2 volumes after creation, but only if they are not attached to any instances.

   **Note**
   You can't enable Multi-Attach for io1 volumes after creation.

   Use one of the following methods to enable Multi-Attach for an io2 volume after creation.

**Console**

   **To enable Multi-Attach after creation**

   1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   2. In the navigation pane, choose Volumes.
   3. Select the volume and choose Actions, Modify volume.
   4. For Amazon EBS Multi-Attach, choose Enable Multi-Attach.
   5. Choose Modify.

**Command line**

   **To enable Multi-Attach after creation**

   Use the modify-volume command and specify the --multi-attach-enabled parameter.

   ```
   $ aws ec2 modify-volume --volume-id vol-1234567890abcdef0 --multi-attach-enabled
   ```
Disable Multi-Attach

You can disable Multi-Attach for an io2 volume only if it is attached to no more than one instance.

**Note**
You can't disable Multi-Attach for io1 volumes after creation.

Use one of the following methods to disable Multi-Attach for an io2 volume.

**Console**

To disable Multi-Attach after creation

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Volumes**.
3. Select the volume and choose **Actions, Modify volume**.
4. For **Amazon EBS Multi-Attach**, clear **Enable Multi-Attach**.
5. Choose **Modify**.

**Command line**

To disable Multi-Attach after creation

Use the `modify-volume` command and specify the `-no-multi-attach-enabled` parameter.

```
$ aws ec2 modify-volume --volume-id vol-1234567890abcdef0 --no-multi-attach-enabled
```

Attach a volume to instances

You attach a Multi-Attach enabled volume to an instance in the same way that you attach any other EBS volume. For more information, see [Attach an Amazon EBS volume to an instance (p. 2076)](#).

Delete on termination

Multi-Attach enabled volumes are deleted on instance termination if the last attached instance is terminated and if that instance is configured to delete the volume on termination. If the volume is attached to multiple instances that have different delete on termination settings in their volume block device mappings, the last attached instance's block device mapping setting determines the delete on termination behavior.

To ensure predictable delete on termination behavior, enable or disable delete on termination for all of the instances to which the volume is attached.

By default, when a volume is attached to an instance, the delete on termination setting for the block device mapping is set to false. If you want to turn on delete on termination for a Multi-Attach enabled volume, modify the block device mapping.

If you want the volume to be deleted when the attached instances are terminated, enable delete on termination in the block device mapping for all of the attached instances. If you want to retain the volume after the attached instances have been terminated, disable delete on termination in the block device mapping for all of the attached instances. For more information, see [Preserve data when an instance is terminated (p. 803)](#).

You can modify an instance's delete on termination setting at launch or after it has launched. If you enable or disable delete on termination during instance launch, the settings apply only to volumes that are attached at launch. If you attach a volume to an instance after launch, you must explicitly set the delete on termination behavior for that volume.
You can modify an instance's delete on termination setting using the command line tools only.

To modify the delete on termination setting for an existing instance

Use the `modify-instance-attribute` command and specify the `DeleteOnTermination` attribute in the `--block-device-mappings` option.

```bash
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --block-device-mappings file://mapping.json
```

Specify the following in `mapping.json`.

```json
[

  {
    "DeviceName": "/dev/sdf",
    "Ebs": {
      "DeleteOnTermination": true|false
    }
  }

]
```

Monitor a Multi-Attach enabled volume

You can monitor a Multi-Attach enabled volume using the CloudWatch Metrics for Amazon EBS volumes. For more information, see Amazon CloudWatch metrics for Amazon EBS (p. 2389).

Data is aggregated across all of the attached instances. You can't monitor metrics for individual attached instances.

Pricing and billing

There are no additional charges for using Amazon EBS Multi-Attach. You are billed the standard charges that apply to Provisioned IOPS SSD (io1 and io2) volumes. For more information, see Amazon EBS pricing.

NVMe reservations

Note

This topic provides information about using NVMe reservations with Linux instances. For information about using NVMe reservations with Windows instances, see the Amazon EC2 User Guide for Windows Instances.

Multi-Attach enabled io2 volumes support NVMe reservations, which is a set of industry-standard storage fencing protocols. These protocols enable you to create and manage reservations that control and coordinate access from multiple instances to a shared volume. Reservations are used by shared storage applications to ensure data consistency.

Topics

- Requirements (p. 2082)
- Enabling support for NVMe reservations (p. 2083)
- Supported NVMe Reservation commands (p. 2083)
- Pricing (p. 2083)

Requirements

NVMe reservations is supported with Multi-Attach enabled io2 volumes only. Multi-Attach enabled volumes can be attached only to instances built on the Nitro system.
NVMe reservations is supported with the following operating systems:

- SUSE Linux Enterprise 12 SP3 and later
- RHEL 8.3 and later
- Amazon Linux 2 and later

**Enabling support for NVMe reservations**

Support for NVMe reservations is enabled by default for all Multi-Attach enabled \texttt{io2} volumes created after \textit{September 18, 2023}.

To enable support for NVMe reservations for existing \texttt{io2} volumes created before September 18, 2023, you must detach all instances from the volume and then reattach the required instances. All attachments made after detaching all of the instances will have NVMe reservations enabled.

**Supported NVMe Reservation commands**

Amazon EBS supports the following NVMe Reservation commands:

**Reservation Register**

Registers, unregisters, or replaces a reservation key. A registration key is used to identify and authenticate an instance. Registering a reservation key with a volume creates an association between the instance and the volume. You must register the instance with the volume before that instance can acquire a reservation.

**Reservation Acquire**

Acquires a reservation on a volume, preempts a reservation held on a namespace, and aborts a reservation held on a volume. The following reservation types can be acquired:

- Write Exclusive Reservation
- Exclusive Access Reservation
- Write Exclusive - Registrants Only Reservation
- Exclusive Access - Registrants Only Reservation
- Write Exclusive - All Registrants Reservation
- Exclusive Access - All Registrants Reservation

**Reservation Release**

Releases or clears a reservation held on a volume.

**Reservation Report**

Describes the registration and reservation status of a volume.

**Pricing**

There are no additional costs for enabling and using Multi-Attach.

**Make an Amazon EBS volume available for use on Linux**

After you attach an Amazon EBS volume to your instance, it is exposed as a block device. You can format the volume with any file system and then mount it. After you make the EBS volume available for use, you can access it in the same ways that you access any other volume. Any data written to this file system is written to the EBS volume and is transparent to applications using the device.
You can take snapshots of your EBS volume for backup purposes or to use as a baseline when you create another volume. For more information, see Amazon EBS snapshots (p. 2107).

If the EBS volume you are preparing for use is greater than 2 TiB, you must use a GPT partitioning scheme to access the entire volume. For more information, see Constraints on the size and configuration of an EBS volume (p. 2070).

You can get directions for volumes on a Windows instance from Make a volume available for use on Windows in the Amazon EC2 User Guide for Windows Instances.

Format and mount an attached volume

Suppose that you have an EC2 instance with an EBS volume for the root device, /dev/xvda, and that you have just attached an empty EBS volume to the instance using /dev/sdf. Use the following procedure to make the newly attached volume available for use.

To format and mount an EBS volume on Linux

1. Connect to your instance using SSH. For more information, see Connect to your Linux instance (p. 811).
2. The device could be attached to the instance with a different device name than you specified in the block device mapping. For more information, see Device names on Linux instances (p. 2452). Use the lsblk command to view your available disk devices and their mount points (if applicable) to help you determine the correct device name to use. The output of lsblk removes the /dev/ prefix from full device paths.

   The following is example output for an instance built on the Nitro System (p. 295), which exposes EBS volumes as NVMe block devices. The root device is /dev/nvme0n1, which has two partitions named nvme0n1p1 and nvme0n1p128. The attached volume is /dev/nvme1n1, which has no partitions and is not yet mounted.

   
   ```
   [ec2-user ~]$ lsblk
   NAME          MAJ:MIN RM SIZE RO TYPE MOUNTPOINT
   nvme1n1       259:0    0  10G  0 disk
   nvme0n1       259:1    0   8G  0 disk
   -nvme0n1p1    259:2    0   8G  0 part /
   -nvme0n1p128  259:3    0   1M  0 part
   ```

   The following is example output for a T2 instance. The root device is /dev/xvda, which has one partition named xvda1. The attached volume is /dev/xvdf, which has no partitions and is not yet mounted.

   ```
   [ec2-user ~]$ lsblk
   NAME    MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
   xvda    202:0    0    8G  0 disk
   -xvda1  202:1    0    8G  0 part /
   xvdf    202:80   0    1G  0 disk
   ```

3. Determine whether there is a file system on the volume. New volumes are raw block devices, and you must create a file system on them before you can mount and use them. Volumes that were created from snapshots likely have a file system on them already; if you create a new file system on top of an existing file system, the operation overwrites your data.

   Use one or both of the following methods to determine whether there is a file system on the volume:

   - Use the file -s command to get information about a specific device, such as its file system type. If the output shows simply data, as in the following example output, there is no file system on the device
If the device has a file system, the command shows information about the file system type. For example, the following output shows a root device with the XFS file system.

If the output from these commands show that there is no file system on the device, you must create one.

4. (Conditional) If you discovered that there is a file system on the device in the previous step, skip this step. If you have an empty volume, use the `mkfs -t` command to create a file system on the volume.

**Warning**
Do not use this command if you’re mounting a volume that already has data on it (for example, a volume that was created from a snapshot). Otherwise, you’ll format the volume and delete the existing data.

If you get an error that `mkfs.xfs` is not found, use the following command to install the XFS tools and then repeat the previous command:

5. Use the `mkdir` command to create a mount point directory for the volume. The mount point is where the volume is located in the file system tree and where you read and write files to after you mount the volume. The following example creates a directory named `/data`.

6. Mount the volume or partition at the mount point directory you created in the previous step.

If the volume has no partitions, use the following command and specify the device name to mount the entire volume.
If the volume has partitions, use the following command and specify the partition name to mount a partition.

```
[ec2-user ~]$ sudo mount /dev/xvdf1 /data
```

7. Review the file permissions of your new volume mount to make sure that your users and applications can write to the volume. For more information about file permissions, see File security at The Linux Documentation Project.

8. The mount point is not automatically preserved after rebooting your instance. To automatically mount this EBS volume after reboot, see Automatically mount an attached volume after reboot (p. 2086).

### Automatically mount an attached volume after reboot

To mount an attached EBS volume on every system reboot, add an entry for the device to the `/etc/fstab` file.

You can use the device name, such as `/dev/xvd`, in `/etc/fstab`, but we recommend using the device's 128-bit universally unique identifier (UUID) instead. Device names can change, but the UUID persists throughout the life of the partition. By using the UUID, you reduce the chances that the system becomes unbootable after a hardware reconfiguration. For more information, see Identify the EBS device (p. 2336).

#### To mount an attached volume automatically after reboot

1. (Optional) Create a backup of your `/etc/fstab` file that you can use if you accidentally destroy or delete this file while editing it.

   ```
   [ec2-user ~]$ sudo cp /etc/fstab /etc/fstab.orig
   ```

2. Use the `blkid` command to find the UUID of the device. Make a note of the UUID of the device that you want to mount after reboot. You'll need it in the following step.

   For example, the following command shows that there are two devices mounted to the instance, and it shows the UUIDs for both devices.

   ```
   [ec2-user ~]$ sudo blkid
   /dev/xvda1: LABEL="/", UUID="ca774df7-756d-4261-a3f1-76038323e572", TYPE="xfs"
   PARTLABEL="Linux", PARTUUID="02dcd367-eb7c-4f2e-9a72-a3cf8f299c10"
   /dev/xvdf: UUID="aebf131c-6957-451e-8d34-ec978d9581ae", TYPE="xfs"
   ```

   For Ubuntu 18.04 use the `lsblk` command.

   ```
   [ec2-user ~]$ sudo lsblk -o +UUID
   ```

3. Open the `/etc/fstab` file using any text editor, such as `nano` or `vim`.

   ```
   [ec2-user ~]$ sudo vim /etc/fstab
   ```

4. Add the following entry to `/etc/fstab` to mount the device at the specified mount point. The fields are the UUID value returned by `blkid` (or `lsblk` for Ubuntu 18.04), the mount point, the file system, and the recommended file system mount options. For more information about the required fields, run `man fstab` to open the `fstab` manual.
In the following example, we mount the device with UUID aebf131c-6957-451e-8d34-ec978d9581ae to mount point /data and we use the xfs file system. We also use the defaults and nofail flags. We specify 0 to prevent the file system from being dumped, and we specify 2 to indicate that it is a non-root device.

```
UUID=aebf131c-6957-451e-8d34-ec978d9581ae /data xfs defaults,nofail 0 2
```

**Note**

If you ever boot your instance without this volume attached (for example, after moving the volume to another instance), the nofail mount option enables the instance to boot even if there are errors mounting the volume. Debian derivatives, including Ubuntu versions earlier than 16.04, must also add the nobootwait mount option.

5. To verify that your entry works, run the following commands to unmount the device and then mount all file systems in /etc/fstab. If there are no errors, the /etc/fstab file is OK and your file system will mount automatically after it is rebooted.

```
[ec2-user ~]$ sudo umount /data
[ec2-user ~]$ sudo mount -a
```

If you receive an error message, address the errors in the file.

**Warning**

Errors in the /etc/fstab file can render a system unbootable. Do not shut down a system that has errors in the /etc/fstab file.

If you are unsure how to correct errors in /etc/fstab and you created a backup file in the first step of this procedure, you can restore from your backup file using the following command.

```
[ec2-user ~]$ sudo mv /etc/fstab.orig /etc/fstab
```

**View information about an Amazon EBS volume**

You can view descriptive information about your EBS volumes. For example, you can view information about all volumes in a specific Region or view detailed information about a single volume, including its size, volume type, whether the volume is encrypted, which master key was used to encrypt the volume, and the specific instance to which the volume is attached.

You can get additional information about your EBS volumes, such as how much disk space is available, from the operating system on the instance.

**View volume information**

You can view information about a volume using one of the following methods.

**Console**

**To view information about a volume using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Volumes**.
3. To reduce the list, you can filter your volumes using tags and volume attributes. Choose the filter field, select a tag or volume attribute, and then select the filter value.
4. To view more information about a volume, choose its ID.
To view the EBS volumes that are attached to an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance.
4. On the Storage tab, the Block devices section lists the volumes that are attached to the instance. To view information about a specific volume, choose its ID in the Volume ID column.

Amazon EC2 Global View

You can use Amazon EC2 Global View to view your volumes across all Regions for which your AWS account is enabled. For more information, see Amazon EC2 Global View (p. 2505).

AWS CLI

To view information about an EBS volume using the AWS CLI

Use the describe-volumes command.

Tools for Windows PowerShell

To view information about an EBS volume using the Tools for Windows PowerShell

Use the Get-EC2Volume command.

Volume state

Volume state describes the availability of an Amazon EBS volume. You can view the volume state in the State column on the Volumes page in the console, or by using the describe-volumes AWS CLI command.

The possible volume states are:

creating

The volume is being created.

available

The volume is not attached to an instance.

in-use

The volume is attached to an instance.

deleting

The volume is being deleted.

deleted

The volume is deleted.

error

The underlying hardware related to your EBS volume has failed, and the data associated with the volume is unrecoverable. For information about how to restore the volume or recover the data on the volume, see My EBS volume has a status of ‘error’.

View volume metrics

You can get additional information about your EBS volumes from Amazon CloudWatch. For more information, see Amazon CloudWatch metrics for Amazon EBS (p. 2389).
View free disk space

You can get additional information about your EBS volumes, such as how much disk space is available, from the Linux operating system on the instance. For example, use the following command:

```
[ec2-user ~]$ df -hT /dev/xvda1
```

```
Filesystem     Type      Size  Used Avail Use% Mounted on
/dev/xvda1     xfs       8.0G  1.2G  6.9G  15% /
```

Tip

You can also use the CloudWatch agent to collect disk space usage metrics from an Amazon EC2 instance without connecting to the instance. For more information, see Create the CloudWatch agent configuration file and Installing the CloudWatch agent in the Amazon CloudWatch User Guide. If you need to monitor disk space usage for multiple instances, you can install and configure the CloudWatch agent on those instances using Systems Manager. For more information, see Installing the CloudWatch agent using Systems Manager.

For information about viewing free disk space on a Windows instance, see View free disk space in the Amazon EC2 User Guide for Windows Instances.

Replace a volume using a previous snapshot

Amazon EBS snapshots are the preferred backup tool on Amazon EC2 because of their speed, convenience, and cost. When creating a volume from a snapshot, you recreate its state at a specific point in time with the data saved up to that specific point intact. By attaching a volume created from a snapshot to an instance, you can duplicate data across Regions, create test environments, replace a damaged or corrupted production volume in its entirety, or retrieve specific files and directories and transfer them to another attached volume. For more information, see Amazon EBS snapshots (p. 2107).

You can use one of the following procedures to replace an Amazon EBS volume with another volume created from a previous snapshot of that volume.

Console

To replace a volume using the console

1. Create a volume from the snapshot and write down the ID of the new volume. For more information, see Create a volume from a snapshot (p. 2075).

   **Note**
   
   Ensure that you create the volume in the same Availability Zone as the instance. Volumes can only be attached to instances in the same Availability Zone.

2. On the Instances page, select the instance on which to replace the volume and write down the instance ID.

   With the instance still selected, choose the Storage tab. In the Block devices section, find the volume to replace and write down the device name for the volume, for example /dev/sda1.

   Choose the volume ID.

3. On the Volumes screen, select the volume and choose Actions, Detach volume, Detach.

4. Select the new volume that you created in step 1 and choose Actions, Attach volume.

   For Instance and Device name, enter the instance ID and device name that you wrote down in Step 2, and then choose Attach volume.

5. Connect to your instance and mount the volume. For more information, see Make an Amazon EBS volume available for use on Linux (p. 2083).
To replace a volume using the AWS CLI

1. Create a new volume from the snapshot. Use the `create-volume` command. For `--snapshot-id`, specify the ID of the snapshot to use. For `--availability-zone`, specify the same Availability Zone as the instance. Configure the remaining parameters as needed.

   **Note**
   Ensure that you create the volume in the same Availability Zone as the instance. Volumes can only be attached to instances in the same Availability Zone.

   ```
   $ aws ec2 create-volume
   --volume-type volume_type
   --size volume_size
   --snapshot-id snapshot_id
   --availability-zone az_id
   ```

   In the command output, note the ID of the new volume.

2. Get the device name of the volume to replace. Use the `describe-instances` command. For `--instance-ids`, specify the ID of the instance on which to replace the volume.

   ```
   $ aws ec2 describe-instances --instance-ids instance_id
   ```

   In BlockDeviceMappings in the command output, note DeviceName and VolumeId for the volume to replace.

3. Detach the volume to replace from the instance. Use the `detach-volume` command. For `--volume-id`, specify the ID of the volume to detach.

   ```
   $ aws ec2 detach-volume --volume-id volume_id
   ```

4. Attach the replacement volume to the instance. Use the `attach-volume` command. For `--volume-id`, specify the ID of the replacement volume. For `--instance-id`, specify the ID of the instance to which to attach the volume. For `--device`, specify the same device name that you noted previously.

   ```
   $ aws ec2 attach-volume
   --volume-id volume_id
   --instance-id instance_id
   --device device_name
   ```

5. Connect to your instance and mount the volume. For more information, see Make an Amazon EBS volume available for use on Linux (p. 2083).

Replace a root volume

Amazon EC2 enables you to replace the root Amazon EBS volume for a running instance while retaining the following:

- Data stored on instance store volumes — Instance store volumes remain attached to the instance after the root volume has been restored.
- Data stored on data (non-root) Amazon EBS volumes — Non-root Amazon EBS volumes remain attached to the instance after the root volume has been restored.
- Network configuration — All network interfaces remain attached to the instance and they retain their IP addresses, identifiers, and attachment IDs. When the instance becomes available, all pending
network traffic is flushed. Additionally, the instance remains on the same physical host, so it retains its public and private IP addresses and DNS name.

- IAM policies — IAM profiles and policies (such as tag-based policies) that are associated with the instance are retained and enforced.

Topics
- **How does it work?** (p. 2091)
- **Replace a root volume** (p. 2094)
- **View root volume replacement tasks** (p. 2096)

**How does it work?**

When you replace the root volume for an instance, a new (replacement) root volume is restored in one of the following ways:

- **To the initial launch state** — the volume is restored to its initial state at instance launch. For more information, see [Restore a root volume to its launch state](#).
- **From a snapshot** from the same lineage as the current root volume — this allows you to fix issues, such as root volume corruption or guest operating system network configuration errors. For more information, see [Replace a root volume using a snapshot](#).
- **From an AMI** that has the same key attributes as the instance — this allows you to perform operating system and application patching or upgrades. For more information, see [Replace a root volume using an AMI](#).

The original root volume is detached from the instance, and the new root volume is attached to the instance in its place. The instance's block device mapping is updated to reflect the ID of the replacement root volume. You can choose whether or not to keep the original root volume after the root volume replacement process has completed. If you choose delete the original root volume after the replacement process completes, the original root volume is automatically deleted and becomes unrecoverable. If you choose to keep the original root volume after the process completes, the volume remains provisioned in your account; you must manually delete it when you no longer need it.

If the root volume replacement task fails, the instance is rebooted and the original root volume remains attached to the instance.

**Considerations for root volume replacement**

- The instance must be in the **running** state.
- The instance is automatically rebooted during the process. The contents of the memory (RAM) is erased during the reboot. No manual reboots are required.
- You can’t replace the root volume if it is an instance store volume. Only instances with Amazon EBS root volumes are supported.
- You can replace the root volume for all virtualized instance types and EC2 Mac bare metal instances. All other bare metal instance types are not supported.
- You can use any snapshot that belongs to the same lineage as any of the instance's previous root volumes.
- If your account is enabled for [Amazon EBS encryption by default](#) in the current Region, the replacement root volume created by the root volume replacement task is always encrypted, regardless of the encryption status of the specified snapshot or the root volume of the specified AMI.
- The following table summarizes the possible encryption outcomes.
<table>
<thead>
<tr>
<th>Original root volume</th>
<th>Specified snapshot or AMI</th>
<th>Encryption by default</th>
<th>Replacement root volume</th>
<th>Encryption key used for replacement root volume</th>
</tr>

</tbody>
</table>

If the AMI or snapshot is owned by the account, the replacement volume is encrypted with the AMI or snapshot's KMS key. If AMI or snapshot is shared with the account, replacement volume is encrypted with the account's default KMS key for Amazon EBS encryption (p. 2319).
Topics

- Restore a root volume to its launch state (p. 2093)
- Replace a root volume using a snapshot (p. 2093)
- Replace a root volume using an AMI (p. 2093)

Restore a root volume to its launch state

You can perform a root volume replacement that replaces an instance's root volume with a replacement root volume that is restored to the original root volume's launch state. The replacement volume is automatically restored from the snapshot that was used to create the original volume during the instance launch.

The replacement root volume gets the same type, size, and delete on termination attributes as the original root volume.

Replace a root volume using a snapshot

You can perform a root volume replacement that replaces an instance's root volume with a replacement volume that is restored to a specific snapshot. This enables you to restore the root volume for an instance to a specific snapshot that you previously created from that root volume.

The replacement root volume gets the same type, size, and delete on termination attributes as the original root volume.

Considerations for using a snapshot

- You can only use snapshots that belong to the same lineage as the instance's current root volume.
- You can't use snapshot copies created from snapshots that were taken from the root volume.
- After successfully replacing the root volume, snapshots taken from the original root volume can still be used to replace the new (replacement) root volume.

Replace a root volume using an AMI

You can perform a root volume replacement using an AMI that you own or an AMI that is shared with you. The AMI must have the same product code, billing information, architecture type, and virtualization type as that of the instance.

If the instance is enabled for NitroTPM, ENA, or sriov-net, then you must use an AMI that supports those features. If the instance is not enabled for NitroTPM, ENA, or sriov-net, then you can select an AMI that does not support those features, or you can select an AMI that does support them, in which case support is added to the instance.

You can select an AMI with a different boot mode than that of the instance, as long as the instance supports the boot mode of the AMI. If the instance does not support the boot mode, the request fails. If the instance supports the boot mode, the new boot mode is propagated to the instance and its UEFI data is updated accordingly. If you manually modified the boot order or added a private UEFI Secure Boot key to load private kernel modules, the changes are lost during root volume replacement.

The replacement root volume gets the same volume type and delete on termination attribute as the original root volume, and it gets the size of the AMI root volume block device mapping.

Note

The size of the AMI root volume block device mapping must be equal to or greater than the size of the original root volume. If the size of the AMI root volume block device mapping is smaller than the size of the original root volume, the request fails.
After the root volume replacement task completes, the following new and updated information is reflected when you describe the instance using the console, AWS CLI or AWS SDKs:

- New AMI ID
- New volume ID for the root volume
- Updated boot mode configuration (if changed by the AMI)
- Updated NitroTPM configuration (if enabled by the AMI)
- Updated ENA configuration (if enabled by the AMI)
- Updated sriov-net configuration (if enabled by the AMI)

The new AMI ID is also reflected in the instance metadata.

**Considerations for using an AMI:**

- If you use an AMI that has multiple block device mappings, only the root volume of the AMI is used. The other (non-root) volumes are ignored.
- You can only use this feature if you have permissions to the AMI and its associated root volume snapshot. You cannot use this feature with AWS Marketplace AMIs.
- You can only use an AMI without a product code only if the instance does not have a product code.
- The size of the AMI root volume block device mapping must be equal to or greater than the size of the original root volume. If the size of the AMI root volume block device mapping is smaller than the size of the original root volume, the request fails.
- The instance identity documents for the instance are automatically updated.
- If the instance supports NitroTPM, the NitroTPM data for the instance is reset and new keys are generated.

**Replace a root volume**

When you replace the root volume for an instance, a root volume replacement task is created. You can use the root volume replacement task to monitor the progress and outcome of the replacement process. For more information, see [View root volume replacement tasks](#).

You can replace the root volume for an instance using one of the following methods.

**Note**

If you use the Amazon EC2 console, the functionality is available in the new console only.

**New console**

**To replace the root volume**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select the instance for which to replace the root volume and choose **Actions, Monitor and troubleshoot, Replace root volume**.

   **Note**
   
   The Replace root volume action is disabled if the selected instance is not in the running state.

4. In the Replace root volume screen, do one of the following:

   - To restore the replacement root volume to its initial launch state, choose **Create replacement task** without selecting a snapshot.
• To restore the replacement root volume to a specific snapshot, for Snapshot, select the snapshot to use, and then choose Create replacement task.

• To restore the replacement root volume using an AMI, for AMI, select the AMI to use, and then choose Create replacement task.

5. To delete the original root volume after the replacement task completes, select Delete replaced root volume.

AWS CLI

To restore the replacement root volume to the launch state

Use the create-replace-root-volume-task command. For --instance-id, specify the ID of the instance for which to replace the root volume. Omit the --snapshot-id and --image-id parameters. To delete the original root volume after it has been replaced, include --delete-replaced-root-volume and specify true.

```
$ aws ec2 create-replace-root-volume-task \
--instance-id i-1234567890abcdef0 \
--delete-replaced-root-volume true
```

To restore the replacement root volume to a specific snapshot

Use the create-replace-root-volume-task command. For --instance-id, specify the ID of the instance for which to replace the root volume. For --snapshot-id, specify the ID of the snapshot to use. To delete the original root volume after it has been replaced, include --delete-replaced-root-volume and specify true.

```
$ aws ec2 create-replace-root-volume-task \
--instance-id i-1234567890abcdef0 \
--snapshot-id snap-9876543210abcdef0 \
--delete-replaced-root-volume true
```

To restore the replacement root volume using an AMI

Use the create-replace-root-volume-task command. For --instance-id, specify the ID of the instance for which to replace the root volume. For --image-id, specify the ID of the AMI to use. To delete the original root volume after it has been replaced, include --delete-replaced-root-volume and specify true.

```
$ aws ec2 create-replace-root-volume-task \
--instance-id i-01234567890abcdef \n--image-id ami-09876543210abcdef \n--delete-replaced-root-volume true
```

Tools for Windows PowerShell

To restore the replacement root volume to the launch state

Use the New-EC2ReplaceRootVolumeTask command. For -InstanceId, specify the ID of the instance for which to replace the root volume. Omit the -SnapshotId and -ImageId parameters. To delete the original root volume after it has been replaced, include -DeleteReplacedRootVolume and specify $true.

```
PS C:\> New-EC2ReplaceRootVolumeTask -InstanceId i-1234567890abcdef0 -DeleteReplacedRootVolume $true
```

To restore the replacement root volume to a specific snapshot
Use the `New-EC2ReplaceRootVolumeTask` command. For `-InstanceId`, specify the ID of the instance for which to replace the root volume. For `-SnapshotId`, specify the ID of the snapshot to use. To delete the original root volume after it has been replaced, include `-DeleteReplacedRootVolume` and specify `$true`.

```powershell
PS C:\> New-EC2ReplaceRootVolumeTask -InstanceId i-1234567890abcdef0 -SnapshotId snap-9876543210abcdef0 -DeleteReplacedRootVolume $true
```

**To restore the replacement root volume using an AMI**

Use the `New-EC2ReplaceRootVolumeTask` command. For `-InstanceId`, specify the ID of the instance for which to replace the root volume. For `-ImageId`, specify the ID of the AMI to use. To delete the original root volume after it has been replaced, include `-DeleteReplacedRootVolume` and specify `$true`.

```powershell
PS C:\> New-EC2ReplaceRootVolumeTask -InstanceId i-1234567890abcdef0 -ImageId ami-09876543210abcdef -DeleteReplacedRootVolume $true
```

## View root volume replacement tasks

When you replace the root volume for an instance, a *root volume replacement task* is created. The root volume replacement task transitions through the following states during the process:

- **pending** — the replacement volume is being created.
- **in-progress** — the original volume is being detached and the replacement volume is being attached.
- **succeeded** — the replacement volume has been successfully attached to the instance and the instance is available.
- **failing** — the replacement task is in the process of failing.
- **failed** — the replacement task has failed, but the original root volume is still attached.
- **failing-detached** — the replacement task is in the process of failing and the instance might not have a root volume attached.
- **failed-detached** — the replacement task has failed and the instance doesn't have a root volume attached.

You can view the root volume replacement tasks for an instance using one of the following methods.

**Note**

If you use the Amazon EC2 console, the functionality is available in the new console only.

### Console

**To view the root volume replacement tasks**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose *Instances*.
3. Select the instance for which to view the root volume replacement tasks, and then choose the *Storage* tab.
4. In the *Storage* tab, expand *Recent root volume replacement tasks*.

### AWS CLI

**To view the status of a root volume replacement task**
Use the `describe-replace-root-volume-tasks` command and specify the IDs of the root volume replacement tasks to view.

```
$ aws ec2 describe-replace-root-volume-tasks
   --replace-root-volume-task-ids replacevol-1234567890abcdef0
```

```
{
    "ReplaceRootVolumeTasks": [
        {
            "ReplaceRootVolumeTaskId": "replacevol-1234567890abcdef0",
            "InstanceId": "i-1234567890abcdef0",
            "TaskState": "succeeded",
            "StartTime": "2020-11-06 13:09:54.0",
            "CompleteTime": "2020-11-06 13:10:14.0",
            "SnapshotId": "snap-01234567890abcdef",
            "DeleteReplacedRootVolume": "True"
        }
    ]
}
```

Alternatively, specify the `instance-id` filter to filter the results by instance.

```
$ aws ec2 describe-replace-root-volume-tasks
   --filters Name=instance-id,Values=i-1234567890abcdef0
```

Tools for Windows PowerShell

**To view the status of a root volume replacement task**

Use the `Get-EC2ReplaceRootVolumeTask` command and specify the IDs of the root volume replacement tasks to view.

```
PS C:\> Get-EC2ReplaceRootVolumeTask
   -ReplaceRootVolumeTaskIds replacevol-1234567890abcdef0
```

Alternatively, specify the `instance-id` filter to filter the results by instance.

```
PS C:\> Get-EC2ReplaceRootVolumeTask -Filters @{{Name = 'instance-id'; Values = 'i-1234567890abcdef0'}} | Format-Table
```

Monitor the status of your volumes

Amazon Web Services (AWS) automatically provides data that you can use to monitor your Amazon Elastic Block Store (Amazon EBS) volumes.

**Contents**

- [EBS volume status checks](#) (p. 2098)
- [EBS volume events](#) (p. 2099)
- [Work with an impaired volume](#) (p. 2101)
- [Work with the Auto-Enabled IO volume attribute](#) (p. 2102)

For additional monitoring information, see [Amazon CloudWatch metrics for Amazon EBS](#) (p. 2389) and [EventBridge for Amazon EBS](#) (p. 2400).
EBS volume status checks

Volume status checks enable you to better understand, track, and manage potential inconsistencies in the data on an Amazon EBS volume. They are designed to provide you with the information that you need to determine whether your Amazon EBS volumes are impaired, and to help you control how a potentially inconsistent volume is handled.

Volume status checks are automated tests that run every 5 minutes and return a pass or fail status. If all checks pass, the status of the volume is ok. If a check fails, the status of the volume is impaired. If the status is insufficient-data, the checks may still be in progress on the volume. You can view the results of volume status checks to identify any impaired volumes and take any necessary actions.

When Amazon EBS determines that a volume's data is potentially inconsistent, the default is that it disables I/O to the volume from any attached EC2 instances, which helps to prevent data corruption. After I/O is disabled, the next volume status check fails, and the volume status is impaired. In addition, you'll see an event that lets you know that I/O is disabled, and that you can resolve the impaired status of the volume by enabling I/O to the volume. We wait until you enable I/O to give you the opportunity to decide whether to continue to let your instances use the volume, or to run a consistency check using a command, such as fsck, before doing so.

Note
Volume status is based on the volume status checks, and does not reflect the volume state. Therefore, volume status does not indicate volumes in the error state (for example, when a volume is incapable of accepting I/O.) For information about volume states, see Volume state (p. 2088).

If the consistency of a particular volume is not a concern, and you'd prefer that the volume be made available immediately if it's impaired, you can override the default behavior by configuring the volume to automatically enable I/O. If you enable the Auto-Enable I/O volume attribute (autoEnableIo in the API), the volume status check continues to pass. In addition, you'll see an event that lets you know that the volume was determined to be potentially inconsistent, but that its I/O was automatically enabled. This enables you to check the volume's consistency or replace it at a later time.

The I/O performance status check compares actual volume performance to the expected performance of a volume. It alerts you if the volume is performing below expectations. This status check is available only for Provisioned IOPS SSD (io1 and io2) and General Purpose SSD (gp3) volumes that are attached to an instance. The status check is not valid for General Purpose SSD (gp2), Throughput Optimized HDD (st1), Cold HDD (sc1), or Magnetic (standard) volumes. The I/O performance status check is performed once every minute, and CloudWatch collects this data every 5 minutes. It might take up to 5 minutes from the moment that you attach an io1 or io2 volume to an instance for the status check to report the I/O performance status.

Important
While initializing Provisioned IOPS SSD volumes that were restored from snapshots, the performance of the volume may drop below 50 percent of its expected level, which causes the volume to display a warning state in the I/O Performance status check. This is expected, and you can ignore the warning state on Provisioned IOPS SSD volumes while you are initializing them. For more information, see Initialize Amazon EBS volumes (p. 2379).

The following table lists statuses for Amazon EBS volumes.

<table>
<thead>
<tr>
<th>Volume status</th>
<th>I/O enabled status</th>
<th>I/O performance status (io1, io2, and gp3 volumes only)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ok</td>
<td>Enabled (I/O Enabled or I/O Auto-Enabled)</td>
<td>Normal (Volume performance is as expected)</td>
</tr>
<tr>
<td>warning</td>
<td>Enabled (I/O Enabled or I/O Auto-Enabled)</td>
<td>Degraded (Volume performance is below expectations)</td>
</tr>
</tbody>
</table>
### Volume status

<table>
<thead>
<tr>
<th>Volume status</th>
<th>I/O enabled status</th>
<th>I/O performance status (io1, io2, and gp3 volumes only)</th>
</tr>
</thead>
<tbody>
<tr>
<td>impaired</td>
<td>Enabled (I/O Enabled or I/O Auto-Enabled)</td>
<td>Stalled (Volume performance is severely impacted)</td>
</tr>
<tr>
<td></td>
<td>Disabled (Volume is offline and pending recovery, or is waiting for the user to enable I/O)</td>
<td>Not Available (Unable to determine I/O performance because I/O is disabled)</td>
</tr>
<tr>
<td>insufficient-data</td>
<td>Enabled (I/O Enabled or I/O Auto-Enabled)</td>
<td>Insufficient Data</td>
</tr>
<tr>
<td></td>
<td>Insufficient Data</td>
<td></td>
</tr>
</tbody>
</table>

You can view and work with status checks using the following methods.

**Console**

**To view status checks**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Volumes.

   The Volume status column displays the operational status of each volume.
3. To view the status details of a specific volume, select it in the grid and choose the Status checks tab.
4. If you have a volume with a failed status check (status is impaired), see Work with an impaired volume (p. 2101).

Alternatively, you can choose Events in the navigator to view all the events for your instances and volumes. For more information, see EBS volume events (p. 2099).

**AWS CLI**

**To view volume status information**

Use the `describe-volume-status` command.

For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

**Tools for Windows PowerShell**

**To view volume status information**

Use the `Get-EC2VolumeStatus` command.

For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

**EBS volume events**

When Amazon EBS determines that a volume's data is potentially inconsistent, it disables I/O to the volume from any attached EC2 instances by default. This causes the volume status check to fail, and creates a volume status event that indicates the cause of the failure.
To automatically enable I/O on a volume with potential data inconsistencies, change the setting of the Auto-Enabled IO volume attribute (autoEnableIO in the API). For more information about changing this attribute, see Work with an impaired volume (p. 2101).

Each event includes a start time that indicates the time at which the event occurred, and a duration that indicates how long I/O for the volume was disabled. The end time is added to the event when I/O for the volume is enabled.

Volume status events include one of the following descriptions:

**Awaiting Action: Enable I/O**

Volume data is potentially inconsistent. I/O is disabled for the volume until you explicitly enable it. The event description changes to **IO Enabled** after you explicitly enable I/O.

**IO Enabled**

I/O operations were explicitly enabled for this volume.

**IO Auto-Enabled**

I/O operations were automatically enabled on this volume after an event occurred. We recommend that you check for data inconsistencies before continuing to use the data.

**Normal**

For io1, io2, and gp3 volumes only. Volume performance is as expected.

**Degraded**

For io1, io2, and gp3 volumes only. Volume performance is below expectations.

**Severely Degraded**

For io1, io2, and gp3 volumes only. Volume performance is well below expectations.

**Stalled**

For io1, io2, and gp3 volumes only. Volume performance is severely impacted.

You can view events for your volumes using the following methods.

**Console**

To view events for your volumes

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Events. All instances and volumes that have events are listed.
3. You can filter by volume to view only volume status. You can also filter on specific status types.
4. Select a volume to view its specific event.

**AWS CLI**

To view events for your volumes

Use the describe-volume-status command.

For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

**Tools for Windows PowerShell**

To view events for your volumes
Use the `Get-EC2VolumeStatus` command.

For more information about these command line interfaces, see *Access Amazon EC2* (p. 5).

If you have a volume where I/O is disabled, see *Work with an impaired volume* (p. 2101). If you have a volume where I/O performance is below normal, this might be a temporary condition due to an action you have taken (for example, creating a snapshot of a volume during peak usage, running the volume on an instance that cannot support the I/O bandwidth required, accessing data on the volume for the first time, etc.).

**Work with an impaired volume**

Use the following options if a volume is impaired because the volume's data is potentially inconsistent.

**Options**
- **Option 1: Perform a consistency check on the volume attached to its instance** (p. 2101)
- **Option 2: Perform a consistency check on the volume using another instance** (p. 2102)
- **Option 3: Delete the volume if you no longer need it** (p. 2102)

**Option 1: Perform a consistency check on the volume attached to its instance**

The simplest option is to enable I/O and then perform a data consistency check on the volume while the volume is still attached to its Amazon EC2 instance.

**To perform a consistency check on an attached volume**

1. Stop any applications from using the volume.
2. Enable I/O on the volume. Use one of the following methods.
   - **Console**
     1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
     2. In the navigation pane, choose *Events*.
     3. Select the volume on which to enable I/O operations.
     4. Choose *Actions, Enable I/O*.
   - **AWS CLI**
     Use the `enable-volume-io` command.
   - **Tools for Windows PowerShell**
     Use the `Enable-EC2VolumeIO` command.
3. Check the data on the volume.
   a. Run the `fsck` command.
   b. (Optional) Review any available application or system logs for relevant error messages.
   c. If the volume has been impaired for more than 20 minutes, you can contact the AWS Support Center. Choose *Troubleshoot*, and then in the *Troubleshoot Status Checks* dialog box, choose *Contact Support* to submit a support case.
Option 2: Perform a consistency check on the volume using another instance

Use the following procedure to check the volume outside your production environment.

**Important**
This procedure may cause the loss of write I/Os that were suspended when volume I/O was disabled.

**To perform a consistency check on a volume in isolation**

1. Stop any applications from using the volume.
2. Detach the volume from the instance. For more information, see [Detach an Amazon EBS volume from a Linux instance](p. 2104).
3. Enable I/O on the volume. Use one of the following methods.

   **Console**
   1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
   2. In the navigation pane, choose **Events**.
   3. Select the volume that you detached in the previous step.
   4. Choose **Actions, Enable I/O**.

   **AWS CLI**
   To enable I/O for a volume with the AWS CLI
   Use the `enable-volume-io` command.

   **Tools for Windows PowerShell**
   To enable I/O for a volume with the Tools for Windows PowerShell
   Use the `Enable-EC2VolumeIO` command.

4. Attach the volume to another instance. For more information, see [Launch your instance](p. 719) and [Attach an Amazon EBS volume to an instance](p. 2076).
5. Check the data on the volume.
   a. Run the `fsck` command.
   b. (Optional) Review any available application or system logs for relevant error messages.
   c. If the volume has been impaired for more than 20 minutes, you can contact the AWS Support Center. Choose **Troubleshoot**, and then in the troubleshooting dialog box, choose **Contact Support** to submit a support case.

Option 3: Delete the volume if you no longer need it

If you want to remove the volume from your environment, simply delete it. For information about deleting a volume, see [Delete an Amazon EBS volume](p. 2106).

If you have a recent snapshot that backs up the data on the volume, you can create a new volume from the snapshot. For more information, see [Create a volume from a snapshot](p. 2075).

Work with the Auto-Enabled IO volume attribute

When Amazon EBS determines that a volume's data is potentially inconsistent, it disables I/O to the volume from any attached EC2 instances by default. This causes the volume status check to fail, and
creates a volume status event that indicates the cause of the failure. If the consistency of a particular volume is not a concern, and you prefer that the volume be made available immediately if it's impaired, you can override the default behavior by configuring the volume to automatically enable I/O. If you enable the Auto-Enabled IO volume attribute (autoEnableIO in the API), I/O between the volume and the instance is automatically re-enabled and the volume's status check will pass. In addition, you'll see an event that lets you know that the volume was in a potentially inconsistent state, but that its I/O was automatically enabled. When this event occurs, you should check the volume's consistency and replace it if necessary. For more information, see EBS volume events (p. 2099).

You can view and modify the Auto-Enabled IO attribute of a volume using one of the following methods.

New console

**To view the Auto-Enabled IO attribute of a volume**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Select the volume and choose the Status checks tab.

   The Auto-enabled I/O field displays the current setting (Enabled or Disabled) for the selected volume.

**To modify the Auto-Enabled IO attribute of a volume**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Select the volume and choose Actions, Manage auto-enabled I/O.
4. To automatically enable I/O for an impaired volume, select the Auto-enable I/O for impaired volumes check box. To disable the feature, clear the check box.
5. Choose Update.

AWS CLI

**To view the autoEnableIO attribute of a volume**

Use the `describe-volume-attribute` command.

**To modify the autoEnableIO attribute of a volume**

Use the `modify-volume-attribute` command.

For more information about these command line interfaces, see Access Amazon EC2 (p. 5)

Tools for Windows PowerShell

**To view the autoEnableIO attribute of a volume**

Use the `Get-EC2VolumeAttribute` command.

**To modify the autoEnableIO attribute of a volume**

Use the `Edit-EC2VolumeAttribute` command.

For more information about these command line interfaces, see Access Amazon EC2 (p. 5)
**Detach an Amazon EBS volume from a Linux instance**

You need to detach an Amazon Elastic Block Store (Amazon EBS) volume from an instance before you can attach it to a different instance or delete it. Detaching a volume does not affect the data on the volume.

**Topics**

- Considerations (p. 478)
- Unmount and detach a volume (p. 2104)
- Troubleshoot (p. 2105)

**Considerations**

- You can detach an Amazon EBS volume from an instance explicitly or by terminating the instance. However, if the instance is running, you must first unmount the volume from the instance.
- If an EBS volume is the root device of an instance, you must stop the instance before you can detach the volume.
- You can reattach a volume that you detached (without unmounting it), but it might not get the same mount point. If there were writes to the volume in progress when it was detached, the data on the volume might be out of sync.
- After you detach a volume, you are still charged for volume storage as long as the storage amount exceeds the limit of the AWS Free Tier. You must delete a volume to avoid incurring further charges. For more information, see [Delete an Amazon EBS volume](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/delete-ebs-volume.html).

**Unmount and detach a volume**

Use the following procedures to unmount and detach a volume from an instance. This can be useful when you need to attach the volume to a different instance or when you need to delete the volume.

**Steps**

- **Step 1: Unmount the volume** (p. 2104)
- **Step 2: Detach the volume from the instance** (p. 2104)

**Step 1: Unmount the volume**

From your Linux instance, use the following command to unmount the /dev/sdh device.

```
[ec2-user ~]$ sudo umount -d /dev/sdh
```

**Step 2: Detach the volume from the instance**

To detach the volume from the instance, use one of the following methods:

**Console**

**To detach an EBS volume using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Volumes**.
3. Select the volume to detach and choose **Actions, Detach volume**.
4. When prompted for confirmation, choose **Detach**.

**AWS CLI**

**To detach an EBS volume from an instance using the AWS CLI**

After unmounting the volume, use the `detach-volume` command.

**Tools for Windows PowerShell**

**To detach an EBS volume from an instance using the Tools for Windows PowerShell**

After unmounting the volume, use the `Dismount-EC2Volume` command.

**Troubleshoot**

The following are common problems encountered when detaching volumes, and how to resolve them.

**Note**

To guard against the possibility of data loss, take a snapshot of your volume before attempting to unmount it. Forced detachment of a stuck volume can cause damage to the file system or the data it contains or an inability to attach a new volume using the same device name, unless you reboot the instance.

- If you encounter problems while detaching a volume through the Amazon EC2 console, it can be helpful to use the `describe-volumes` CLI command to diagnose the issue. For more information, see `describe-volumes`.
- If your volume stays in the `detaching` state, you can force the detachment by choosing **Force Detach**. Use this option only as a last resort to detach a volume from a failed instance, or if you are detaching a volume with the intention of deleting it. The instance doesn't get an opportunity to flush file system caches or file system metadata. If you use this option, you must perform the file system check and repair procedures.
- If you've tried to force the volume to detach multiple times over several minutes and it stays in the `detaching` state, you can post a request for help to **AWS re:Post**. To help expedite a resolution, include the volume ID and describe the steps that you've already taken.
- When you attempt to detach a volume that is still mounted, the volume can become stuck in the `busy` state while it is trying to detach. The following output from `describe-volumes` shows an example of this condition:

```
"Volumes": [
  {
    "AvailabilityZone": "us-west-2b",
    "Attachments": [
      {
        "AttachTime": "2016-07-21T23:44:52.000Z",
        "InstanceId": "i-fedc9876",
        "VolumeId": "vol-1234abcd",
        "State": "busy",
        "DeleteOnTermination": false,
        "Device": "/dev/sdf"
      }
    ]
  }...
]
```
Delete an Amazon EBS volume

You can delete an Amazon EBS volume that you no longer need. After deletion, its data is gone and the volume can’t be attached to any instance. So before deletion, you can store a snapshot of the volume, which you can use to re-create the volume later.

You can delete an EBS volume using one of the following methods.

Console

To delete an EBS volume using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Select the volume to delete and choose Actions, Delete volume.
   
   Note
   
   If Delete volume is greyed out, the volume is attached to an instance. You must detach the volume from the instance before it can be deleted.

4. In the confirmation dialog box, choose Delete.

AWS CLI

To delete an EBS volume using the AWS CLI

Use the delete-volume command.

Tools for Windows PowerShell

To delete an EBS volume using the Tools for Windows PowerShell

Use the Remove-EC2Volume command.

Fault testing on Amazon EBS

Use AWS Fault Injection Service and the Pause I/O action to temporarily stop I/O between an Amazon EBS volume and the instances to which it is attached to test how your workloads handle I/O interruptions. With AWS FIS, you can use controlled experiments to test your architecture and monitoring, such as Amazon CloudWatch alarms and OS timeout configurations, and improve resiliency to storage faults.

For more information about AWS FIS, see the AWS Fault Injection Service User Guide.
Considerations

Keep in mind the following considerations for pausing volume I/O:

- You can pause I/O for all Amazon EBS volume types that are attached to instances built on the Nitro System (p. 295).
- You can pause I/O for the root volume.
- You can pause I/O for Multi-Attach enabled volumes. If you pause I/O for a Multi-Attach enabled volume, I/O is paused between the volume and all of the instances to which it is attached.
- To test your OS timeout configuration, set the experiment duration equal to or greater than the value specified for `nvme_core.io_timeout`. For more information, see I/O operation timeout (p. 2338).
- If you drive I/O to a volume that has I/O paused, the following happens:
  - The volume's status transitions to impaired within 120 seconds. For more information, see Monitor the status of your volumes (p. 2097).
  - The CloudWatch metrics for queue length (VolumeQueueLength) will be non-zero. Any alarms or monitoring should monitor for a non-zero queue depth. For more information see Metrics for Amazon EBS volumes (p. 2390).
  - The CloudWatch metrics for VolumeReadOps or VolumeWriteOps will be 0, which indicates that the volume is no longer processing I/O.

Limitations

Keep in mind the following limitations for pausing volume I/O:

- Instance store volumes are not supported.
- Xen-based instances types are not supported.
- You can't pause I/O for volumes created on an Outpost in AWS Outposts, in an AWS Wavelength Zone, or in a Local Zone.

You can perform a basic experiment from the Amazon EC2 console, or you can perform more advanced experiments using the AWS FIS console. For more information about performing advanced experiments using the AWS FIS console, see Tutorials for AWS FIS in the AWS Fault Injection Service User Guide.

To perform a basic experiment using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Select the volume for which to pause I/O and choose Actions, Fault injection, Pause volume I/O.
4. For Duration, enter the duration for which to pause I/O between the volume and the instances. The field next to the Duration dropdown list shows the duration in ISO 8601 format.
5. In the Service access section, select the IAM service role for AWS FIS to assume to perform the experiment. You can use either the default role, or an existing role that you created. For more information, see Create an IAM role for AWS FIS experiments.
6. Choose Pause volume I/O. When prompted, enter start in the confirmation field and choose Start experiment.
7. Monitor the progress and impact of your experiment. For more information, see Monitoring AWS FIS in the AWS FIS User Guide.

Amazon EBS snapshots

You can back up the data on your Amazon EBS volumes by making point-in-time copies, known as Amazon EBS Snapshots. A snapshot is an incremental backup, which means that we save only the blocks
on the device that have changed since your most recent snapshot. This minimizes the time required to create the snapshot and saves on storage costs by not duplicating data.

**Important**
AWS does not automatically back up the data stored on your EBS volumes. For data resiliency and disaster recovery, it is your responsibility to create EBS snapshots on a regular basis, or to set up automatic snapshot creation by using Amazon Data Lifecycle Manager (p. 2211) or AWS Backup.

EBS snapshots are stored in Amazon S3, in S3 buckets that you can't access directly. You can create and manage your snapshots using the Amazon EC2 console or the Amazon EC2 API. You can't access your snapshots using the Amazon S3 console or the Amazon S3 API.

Each snapshot contains all of the information that is needed to restore your data (from the moment when the snapshot was taken) to a new EBS volume. When you create an EBS volume based on a snapshot, the new volume begins as an exact replica of the volume that was used to create the snapshot. The replicated volume loads data in the background so that you can begin using it immediately. If you access data that hasn't been loaded yet, the volume immediately downloads the requested data from Amazon S3, and then continues loading the rest of the volume's data in the background. For more information, see [Create Amazon EBS snapshots](#). When you delete a snapshot, only the data unique to that snapshot is removed. For more information, see [Delete an Amazon EBS snapshot](#).

For more information, see the Amazon EBS Snapshots product page.

**Snapshot events**
You can track the status of your EBS snapshots through CloudWatch Events. For more information, see [EBS snapshot events](#).

**Multi-volume snapshots**
Snapshots can be used to create a backup of critical workloads, such as a large database or a file system that spans across multiple EBS volumes. Multi-volume snapshots allow you to take exact point-in-time, data coordinated, and crash-consistent snapshots across multiple EBS volumes attached to an EC2 instance. You are no longer required to stop your instance or to coordinate between volumes to ensure crash consistency, because snapshots are automatically taken across multiple EBS volumes. For more information, see the steps for creating a multi-volume EBS snapshot under [Create Amazon EBS snapshots](#).

**Snapshot pricing**
Charges for your snapshots are based on the amount of data stored. Because snapshots are incremental, deleting a snapshot might not reduce your data storage costs. Data referenced exclusively by a snapshot is removed when that snapshot is deleted, but data referenced by other snapshots is preserved. For more information, see Amazon Elastic Block Store Volumes and Snapshots in the AWS Billing User Guide.

2108
How snapshots work

The first snapshot that you create from a volume is always a full snapshot. It includes all of the data blocks written to the volume at the time of creating the snapshot. Subsequent snapshots of the same volume are incremental snapshots. They include only changed and new data blocks written to the volume since the last snapshot was created.

The size of a full snapshot is determined by the size of the data being backed up, not the size of the source volume. Similarly, the storage costs associated with a full snapshot is determined by the size of the snapshot, not the size of the source volume. For example, you create the first snapshot of a 200 GiB Amazon EBS volume that contains only 50 GiB of data. This results in a full snapshot that is 50 GiB in size, and you are billed for 50 GiB snapshot storage.

Similarly, the size and storage costs of an incremental snapshot are determined by the size of any data that was written to the volume since the previous snapshot was created. Continuing this example, if you create a second snapshot of the 200 GiB volume after changing 20 GiB of data and adding 10 GiB of data, the incremental snapshot is 30 GiB in size. You are then billed for that additional 30 GiB snapshot storage.

For more information about snapshot pricing, see Amazon EBS pricing.

Important

When you archive an incremental snapshot, it is converted to a full snapshot that includes all of the blocks written to the volume at the time that the snapshot was created. It is then moved to the Amazon EBS Snapshots Archive tier. Snapshots in the archive tier are billed at a different rate from snapshots in the standard tier. For more information, see Pricing and billing (p. 2134).

The following sections show how an EBS snapshot captures the state of a volume at a point in time, and how subsequent snapshots of a changing volume create a history of those changes.

Multiple snapshots of the same volume

The diagram in this section shows Volume 1, which is 15 GiB in size, at three points in time. A snapshot is taken of each of these three volume states. The diagram specifically shows the following:

- In State 1, the volume has 10 GiB of data. Snap A is the first snapshot taken of the volume. Snap A is a full snapshot and the entire 10 GiB of data is backed up.
- In State 2, the volume still contains 10 GiB of data, but only 4 GiB have changed after Snap A was taken. Snap B is an incremental snapshot. It needs to back up only the 4 GiB that changed. The other 6 GiB of unchanged data, which are already backed up in Snap A, are referenced by Snap B rather than being backed up again. This is indicated by the dashed arrow.
- In State 3, 2 GiB of data have been added to the volume, for a total of 12 GiB, after Snap B was taken. Snap C is an incremental snapshot. It needs to back up only the 2 GiB that were added after Snap B was taken. As shown by the dashed arrows, Snap C also references the 4 GiB of data stored in Snap B, and the 6 GiB of data stored in Snap A.
The total storage required for the three snapshots is 16 GiB total. This accounts for 10 GiB for Snap A, 4 GiB for Snap B, and 2 GiB for Snap C.

Incremental snapshots of different volumes

The diagram in this section shows how incremental snapshots can be taken from different volumes.

1. **Vol 1**, which is 14 GiB in size, has 10 GiB of data. Because **Snap A** is the first snapshot taken of the volume, it is a full snapshot and the entire 10 GiB of data is backed up.

2. **Vol 2** is created from **Snap A**, so it is an exact replica of **Vol 1** at the time the snapshot was taken.

3. Over time, 4 GiB of data is added to **Vol 2** and the total size of its data is 14 GiB.

4. **Snap B** is taken from **Vol 2**. For **Snap B**, only the 4 GiB of data that was added after the volume was created from **Snap A** is backed up. The other 10 GiB of unchanged data, which is already stored in **Snap A**, is referenced by **Snap B** instead of being backed up again.

**Snap B** is an incremental snapshot of **Snap A**, even though it was created from a different volume.
Important
The diagram assumes that you own Vol 1 and Snap A, and that Vol 2 is encrypted with the same KMS key as Vol 1. If Vol 1 was owned by another AWS account and that account took Snap A and shared it with you, then Snap B would be a full snapshot. Or, if Vol 2 was encrypted with a different KMS key than Vol 1, then Snap B would be a full snapshot.

For more information about how data is managed when you delete a snapshot, see Delete an Amazon EBS snapshot (p. 2116).

Copy and share snapshots
You can share a snapshot across AWS accounts by modifying its access permissions. You can make copies of your own snapshots as well as snapshots that have been shared with you. For more information, see Share an Amazon EBS snapshot (p. 2156).

A snapshot is constrained to the AWS Region where it was created. After you create a snapshot of an EBS volume, you can use it to create new volumes in the same Region. For more information, see Create a volume from a snapshot (p. 2075). You can also copy snapshots across Regions, making it possible to use multiple Regions for geographical expansion, data center migration, and disaster recovery. You can copy any accessible snapshot that has a completed status. For more information, see Copy an Amazon EBS snapshot (p. 2128).
Encryption support for snapshots

EBS snapshots fully support EBS encryption.

- Snapshots of encrypted volumes are automatically encrypted.
- Volumes that you create from encrypted snapshots are automatically encrypted.
- Volumes that you create from an unencrypted snapshot that you own or have access to can be encrypted on-the-fly.
- When you copy an unencrypted snapshot that you own, you can encrypt it during the copy process.
- When you copy an encrypted snapshot that you own or have access to, you can reencrypt it with a different key during the copy process.
- The first snapshot you take of an encrypted volume that has been created from an unencrypted snapshot is always a full snapshot.
- The first snapshot you take of a reencrypted volume, which has a different CMK compared to the source snapshot, is always a full snapshot.

Complete documentation of possible snapshot encryption scenarios is provided in Create Amazon EBS snapshots (p. 2112) and in Copy an Amazon EBS snapshot (p. 2128).

For more information, see Amazon EBS encryption (p. 2316).

Create Amazon EBS snapshots

You can create a point-in-time snapshot of an EBS volume and use it as a baseline for new volumes or for data backup. If you make periodic snapshots of a volume, the snapshots are incremental—the new snapshot saves only the blocks that have changed since your last snapshot.

Snapshots occur asynchronously; the point-in-time snapshot is created immediately, but the status of the snapshot is pending until the snapshot is complete (when all of the modified blocks have been transferred to Amazon S3), which can take several hours for large initial snapshots or subsequent snapshots where many blocks have changed. While it is completing, an in-progress snapshot is not affected by ongoing reads and writes to the volume.

You can take a snapshot of an attached volume that is in use. However, snapshots only capture data that has been written to your Amazon EBS volume at the time the snapshot command is issued. This might exclude any data that has been cached by any applications or the operating system. If you can pause any file writes to the volume long enough to take a snapshot, your snapshot should be complete. However, if you can't pause all file writes to the volume, you should unmount the volume from within the instance, issue the snapshot command, and then remount the volume to ensure a consistent and complete snapshot. You can remount and use your volume while the snapshot status is pending.

To make snapshot management easier, you can tag your snapshots during creation or add tags afterward. For example, you can apply tags describing the original volume from which the snapshot was created, or the device name that was used to attach the original volume to an instance. For more information, see Tag your Amazon EC2 resources (p. 2507).

Snapshot encryption

Snapshots that are taken from encrypted volumes are automatically encrypted. Volumes that are created from encrypted snapshots are also automatically encrypted. The data in your encrypted volumes and any associated snapshots is protected both at rest and in motion. For more information, see Amazon EBS encryption (p. 2316).

By default, only you can create volumes from snapshots that you own. However, you can share your unencrypted snapshots with specific AWS accounts, or you can share them with the entire AWS community by making them public. For more information, see Share an Amazon EBS snapshot (p. 2156).
You can share an encrypted snapshot only with specific AWS accounts. For others to use your shared, encrypted snapshot, you must also share the CMK key that was used to encrypt it. Users with access to your encrypted snapshot must create their own personal copy of it and then use that copy. Your copy of a shared, encrypted snapshot can also be re-encrypted using a different key. For more information, see Share an Amazon EBS snapshot (p. 2156).

Multi-volume snapshots

You can create multi-volume snapshots, which are point-in-time snapshots for all, or some, of the volumes attached to an instance.

By default, when you create multi-volume snapshots from an instance, Amazon EBS creates snapshots of all the volumes (root and data (non-root)) that are attached to the instance. However, you can choose to create snapshots of a subset of the volumes that are attached to the instance.

You can tag your multi-volume snapshots as you would a single volume snapshot. We recommend you tag your multiple volume snapshots to manage them collectively during restore, copy, or retention. You can also choose to automatically copy tags from the source volume to the corresponding snapshots. This helps you to set the snapshot metadata, such as access policies, attachment information, and cost allocation, to match the source volume.

After the snapshots are created, each snapshot is treated as an individual snapshot. You can perform all snapshot operations, such as restore, delete, and copy across Regions or accounts, just as you would with a single volume snapshot.

Multi-volume, crash-consistent snapshots are typically restored as a set. It is helpful to identify the snapshots that are in a crash-consistent set by tagging your set with the instance ID, name, or other relevant details.

After creating your snapshots, they appear in your EC2 console created at the exact point-in-time.

If any one snapshot for the multi-volume snapshot set fails, all of the other snapshots display an error status and a createSnapshots CloudWatch event with a result of failed is sent to your AWS account. For more information, see Create snapshots (createSnapshots) (p. 2405).

Amazon Data Lifecycle Manager

You can create snapshot lifecycle policies to automate the creation and retention of snapshots of individual volumes and multi-volume snapshots of instances. For more information, see Amazon Data Lifecycle Manager (p. 2211).

Considerations

The following considerations apply to creating snapshots:

- When you create a snapshot for an EBS volume that serves as a root device, we recommend that you stop the instance before taking the snapshot.
- You cannot create snapshots from instances for which hibernation is enabled, or from hibernated instances. If you create a snapshot or AMI from an instance that is hibernated or has hibernation enabled, you might not be able to connect to a new instance that is launched from the AMI, or from an AMI that was created from the snapshot.
- Although you can take a snapshot of a volume while a previous snapshot of that volume is in the pending status, having multiple pending snapshots of a volume can result in reduced volume performance until the snapshots complete.
- There is a limit of one pending snapshot for a single st1 or sc1 volume, or five pending snapshots for a single volume of the other volume types. If you receive a
ConcurrentSnapshotLimitExceeded error while trying to create multiple concurrent snapshots of the same volume, wait for one or more of the pending snapshots to complete before creating another snapshot of that volume.

- When a snapshot is created from a volume with an AWS Marketplace product code, the product code is propagated to the snapshot.
- When creating multi-volume snapshot sets from instances, you can specify up to 127 data (non-root) volumes to exclude. The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. For more information, see Instance volume limits (p. 2444).

Create a snapshot

To create a snapshot from the specified volume, use one of the following methods.

Console

To create a snapshot using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots, Create snapshot.
3. For Resource type, choose Volume.
4. For Volume ID, select the volume from which to create the snapshot.
   The Encryption field indicates the selected volume's encryption status. If the selected volume is encrypted, the snapshot is automatically encrypted using the same KMS key. If the selected volume is unencrypted, the snapshot is not encrypted.
5. (Optional) For Description, enter a brief description for the snapshot.
6. (Optional) To assign custom tags to the snapshot, in the Tags section, choose Add tag, and then enter the key-value pair. You can add up to 50 tags.
7. Choose Create snapshot.

AWS CLI

To create a snapshot using the AWS CLI

Use the create-snapshot command.

Tools for Windows PowerShell

To create a snapshot using the Tools for Windows PowerShell

Use the New-EC2Snapshot command.

Create a multi-volume snapshot

When you create a multi-volume snapshot set from an instance, you can choose whether to copy the tags from the source volume to the corresponding snapshot. You can specify whether to create a snapshot of the root volume. You can also specify whether to create snapshots of all the data (non-root) volumes that are attached to the instance, or whether to create snapshots of a subset of those volumes.

Considerations

- Multi-volume snapshots support up to 128 Amazon EBS volumes for each instance, which includes the root volume and up to 127 data (non-root) volumes. The maximum number of Amazon EBS
volumes that you can attach to an instance depends on the instance type and instance size. For more information, see Instance volume limits (p. 2444).

To create a snapshot from the volumes of an instance, use one of the following methods.

Console

To create multi-volume snapshots using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots, Create snapshot.
3. For Resource type, choose Instance.
4. For Description, enter a brief description for the snapshots. This description is applied to all of the snapshots.
5. (Optional) By default, Amazon EBS creates a snapshot of the instance's root volume. If you do not want to create a snapshot of the instance's root volume, select Exclude root volume.
6. (Optional) By default, Amazon EBS creates snapshots of all the data (non-root) volumes attached to the instance. If you want to create snapshots of a subset of the data (non-root) volumes attached to the instance, select Exclude specific data volumes. The Attached data volumes section lists all of the data volumes that are currently attached to the selected instance.

In the Attached data volumes section, select the data volumes for which you do not want to create snapshots. Only the volumes that remain unselected will be included in the multi-volume snapshot set. You can exclude up to 127 volumes.

7. (Optional) To automatically copy tags from the source volumes to the corresponding snapshots, for Copy tags from source volume, select Copy tags. This sets snapshot metadata—such as access policies, attachment information, and cost allocation—to match the source volume.
8. (Optional) To assign additional custom tags to the snapshots, in the Tags section, choose Add tag, and then enter the key-value pair. You can add up to 50 tags.
9. Choose Create snapshot.

During snapshot creation, the snapshots are managed together. If one of the snapshots in the volume set fails, the other snapshots are moved to error status for the volume set. You can monitor the progress of your snapshots using CloudWatch Events. After the snapshot creation process completes, CloudWatch generates an event that contains the status and all of the relevant snapshot details for the affected instance.

AWS CLI

To create multi-volume snapshots using the AWS CLI, use the create-snapshots command.

If you do not want to create a snapshot of the root volume, for --instance-specification ExcludeBootVolume, specify true. If you do not want to create snapshots of all the data (non-root) volumes attached to the instance, for --instance-specification ExcludeDataVolumes, specify the IDs of the data volumes for which you do not want to create snapshots. You can specify up to 127 data (non-root) volumes to exclude.

Tools for Windows PowerShell:

To create multi-volume snapshots using the Tools for Windows PowerShell, use the New-EC2SnapshotBatch command.

If you do not want to create a snapshot of the root volume, for -InstanceSpecification_ExcludeBootVolume, specify 1. If you do not want to create snapshots of all the data (non-root) volumes attached to the instance, for -
InstanceSpecification_ExcludeDataVolumes, specify the IDs of the data volumes for which you do not want to create snapshots. You can specify up to 127 data (non-root) volumes to exclude.

If all of the snapshots complete successfully, a createSnapshots CloudWatch event with a result of succeeded is sent to your AWS account. If any one snapshot for the multi-volume snapshot set fails, all of the other snapshots display an error status and a createSnapshots CloudWatch event with a result of failed is sent to your AWS account. For more information, see Create snapshots (createSnapshots) (p. 2405).

Work with EBS snapshots

You can copy snapshots, share snapshots, and create volumes from snapshots. For more information, see the following:

- Copy an Amazon EBS snapshot (p. 2128)
- Share an Amazon EBS snapshot (p. 2156)
- Create a volume from a snapshot (p. 2075)

Delete an Amazon EBS snapshot

After you no longer need an Amazon EBS snapshot of a volume, you can delete it. Deleting a snapshot has no effect on the volume. Deleting a volume has no effect on the snapshots made from it.

Incremental snapshot deletion

If you make periodic snapshots of a volume, the snapshots are incremental. This means that only the blocks on the device that have changed after your most recent snapshot are saved in the new snapshot. Even though snapshots are saved incrementally, the snapshot deletion process is designed so that you need to retain only the most recent snapshot in order to create volumes.

If data was present on a volume held in an earlier snapshot or series of snapshots, and that data is subsequently deleted from the volume later on, the data is still considered to be unique data of the earlier snapshots. Unique data is only deleted from the sequence of snapshots if all snapshots that reference the unique data are deleted.

When you delete a snapshot, only the data that is referenced exclusively by that snapshot is removed. Unique data is only deleted if all of the snapshots that reference it are deleted. Deleting previous snapshots of a volume does not affect your ability to create volumes from later snapshots of that volume.

Deleting a snapshot might not reduce your organization's data storage costs. Other snapshots might reference that snapshot's data, and referenced data is always preserved. If you delete a snapshot containing data being used by a later snapshot, costs associated with the referenced data are allocated to the later snapshot. For more information about how snapshots store data, see How snapshots work (p. 2109) and the following example.

In the following diagram, Volume 1 is shown at three points in time. A snapshot has captured each of the first two states, and in the third, a snapshot has been deleted.

- In State 1, the volume has 10 GiB of data. Because Snap A is the first snapshot taken of the volume, the entire 10 GiB of data must be copied.
- In State 2, the volume still contains 10 GiB of data, but 4 GiB have changed. Snap B needs to copy and store only the 4 GiB that changed after Snap A was taken. The other 6 GiB of unchanged data, which are already copied and stored in Snap A, are referenced by Snap B rather than (again) copied. This is indicated by the dashed arrow.
In state 3, the volume has not changed since State 2, but Snapshot A has been deleted. The 6 GiB of data stored in Snapshot A that were referenced by Snapshot B have now been moved to Snapshot B, as shown by the heavy arrow. As a result, you are still charged for storing 10 GiB of data; 6 GiB of unchanged data preserved from Snap A and 4 GiB of changed data from Snap B.

**Deleting a snapshot with some of its data referenced by another snapshot**

![Diagram showing the process of deleting a snapshot with referenced data](image)

**Considerations**

The following considerations apply to deleting snapshots:

- You can't delete a snapshot of the root device of an EBS volume used by a registered AMI. You must first deregister the AMI before you can delete the snapshot. For more information, see [Deregister your AMI](#).
- You can't delete a snapshot that is managed by the AWS Backup service using Amazon EC2. Instead, use AWS Backup to delete the corresponding recovery points in the backup vault. For more information, see [Deleting backups](#) in the AWS Backup Developer Guide.
- You can create, retain, and delete snapshots manually, or you can use Amazon Data Lifecycle Manager to manage your snapshots for you. For more information, see [Amazon Data Lifecycle Manager](#).
- Although you can delete a snapshot that is still in progress, the snapshot must complete before the deletion takes effect. This might take a long time. If you are also at your concurrent snapshot limit, and you attempt to take an additional snapshot, you might get a ConcurrentSnapshotLimitExceeded error. For more information, see the [Service Quotas](#) for Amazon EBS in the Amazon Web Services General Reference.
Delete a snapshot

To delete a snapshot, use one of the following methods.

**Console**

**To delete a snapshot using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Snapshots**.
3. Select the snapshot to delete, and then choose **Actions, Delete snapshot**.
4. Choose **Delete**.

**AWS CLI**

**To delete a snapshot using the AWS CLI**

Use the `delete-snapshot` command.

**Tools for Windows PowerShell**

**To delete a snapshot using the Tools for Windows PowerShell**

Use the `Remove-EC2Snapshot` command.

Delete a multi-volume snapshot

To delete multi-volume snapshots, retrieve all of the snapshots for your multi-volume snapshot set using the tag you applied to the set when you created the snapshots. Then, delete the snapshots individually.

You will not be prevented from deleting individual snapshots in the multi-volume snapshot set. If you delete a snapshot while it is in the **pending** state, only that snapshot is deleted. The other snapshots in the multi-volume snapshot set still complete successfully.

Lock a snapshot

You can lock your Amazon EBS snapshots to protect them against accidental or malicious deletions, or to store them in WORM (write-once-read-many) format for a specific duration. While a snapshot is locked, it can't be deleted by any user, regardless of their IAM permissions. You can continue to use a locked snapshot in the same way that you would use any other snapshot.

**Note**

Snapshot lock has been assessed by Cohasset Associates for use in environments that are subject to SEC 17a-4, CFTC, and FINRA regulations. For more information about how snapshot lock relates to these regulations, see the [Cohasset Associates Compliance Assessment](https://www.cohasset.com/solutions/aws-snapshot-lock).

You can lock snapshots in one of two modes: **compliance mode** or **governance mode**, and they can be locked for a specific duration or until a specific date. For more information, see [Lock mode (p. 2119)](https://docs.aws.amazon.com/elasticbe...lockmode) and [Lock duration (p. 2120)](https://docs.aws.amazon.com/elasticbe...lockduration).

**Pricing**

You can lock and unlock snapshots at no additional cost. You pay the standard Amazon EBS snapshot storage costs for locked snapshots.
Lock mode
You can lock a snapshot in one of two modes:

**Governance mode**

After a snapshot is locked, users with appropriate IAM permissions can unlock the snapshot and modify the lock mode and lock duration or expiry date at any time. When you lock a snapshot in governance mode, the snapshot is locked immediately; there is no cooling-off period. To delete a snapshot after it has been locked in governance mode, you must first unlock the snapshot or you must wait for the lock to expire.

You can use governance mode to meet your organization's data governance requirements by ensuring that only certain users have permission to unlock snapshots and modify snapshot lock configurations. You can also use governance mode to test your lock configuration before locking a snapshot in compliance mode.

**Compliance mode**

When you lock a snapshot in compliance mode, you can optionally specify a cooling-off period that starts immediately after you lock the snapshot. During the cooling-off period, users with appropriate permissions can unlock the snapshot, change the lock mode, increase or decrease the cooling-off period, and increase or decrease the lock duration or expiry date. After the cooling-off period expires, you can't unlock the snapshot, change the lock mode, or decrease the lock duration or expire date; you can only increase the lock duration or expiry date. To delete a snapshot after it has been locked in compliance and the cooling-off period has expired, you must wait for the lock to expire.

**Note**

You can lock a snapshot in compliance mode without a cooling-off period by omitting the cooling-off period in the request. If you do this, the lock becomes effective immediately, and you can't unlock the snapshot, change the lock mode, or decrease the lock duration or expire date; you can only increase the lock duration or expiry date.

You can use compliance mode to protect snapshots that should not be deleted for a specific period for compliance reasons. Compliance mode offers the following benefits:

- It enables WORM (write-once, read-many) configuration for your snapshots.
- It provides an additional layer of defense that protects snapshots from accidental or malicious deletions.
It enforces retention periods, which prevent early deletions by privileged users, to meet your organization's data protection policies and procedures.

**Note**

The only way to delete a snapshot that is locked in compliance mode before its lock expires is to close the associated AWS account.

**Lock duration**

The lock duration is the period of time for which the snapshot is to remain locked. You can specify the lock duration as one of the following, but not both:

**Number of days**

The lock duration is specified as a number of days for which the snapshot is to remain locked. After the specified number of days has passed, the snapshot is automatically unlocked. The duration can range from 1 day to 36500 days (100 years).

**Lock expiration date**

The lock duration is determined by an expiration date in the future. The snapshot remains locked until the lock expiration date is reached. When the lock expiration date is reached, the snapshot is automatically unlocked.

**Cooling-off period**

The cooling-off period is an optional period of time that you can specify when you lock a snapshot in compliance mode. During the cooling-off period, users with appropriate permissions can unlock the snapshot, change the lock mode, increase or decrease the cooling-off period, and increase or decrease the lock duration. After the cooling-off period expires, users can't unlock the snapshot, change the lock mode, reinstate the cooling-off period, or decrease the lock duration, regardless of their permissions.

A snapshot can't be deleted during the cooling-off period.

If specified, the cooling-off period starts immediately after you lock the snapshot. If omitted, the snapshot is locked in compliance mode immediately without a cooling-off period.

The cooling-off period can range from 1 to 72 hours. To lock a snapshot in compliance mode immediately without a cooling-off period, do not specify a cooling-off period in the request.

**Lock state**

A snapshot lock can be in one of the following states:

- **compliance-cooloff** — The snapshot has been locked in compliance mode but it is still within the cooling-off period. The snapshot can't be deleted, but it can be unlocked and the lock settings can be modified by users with appropriate permissions.
- **governance** — The snapshot is locked in governance mode. The snapshot can't be deleted, but it can be unlocked and the lock settings can be modified by users with appropriate permissions.
- **compliance** — The snapshot is locked in compliance mode without a cooling-off period or the cooling-off period has expired. The snapshot can't be unlocked or deleted. The lock duration can only be increased by users with appropriate permissions.
- **expired** — The snapshot was locked in compliance or governance mode but the lock has expired. The snapshot is not locked and can be deleted.

**Considerations**

- You can lock a snapshot only if it is in the pending or completed state.
• If you lock a snapshot while it is in the pending state, and you lock it for a specific duration, the lock duration starts only when the snapshot reaches the completed state. The snapshot can't be deleted while it is in the pending state.

• If you lock a snapshot while it is in the pending state and the snapshot creation fails for any reason, the lock is canceled.

• If you extend the lock duration for a snapshot that is locked in compliance mode after the cooling-off period has expired, you can't specify another cooling-off period. If you specify a cooling-off period, the request fails.

• You can lock archived snapshots. And you can archive locked snapshots.

• You can lock snapshots that are associated with an AMI.

• You can deregister an AMI that has associated snapshots that are locked.

• You can delete the KMS key used to encrypt a locked snapshot.

• We recommend that you do not lock snapshots created by AWS Backup. AWS Backup already ensures that its snapshots are not deleted before their retention period expires. To add an additional layer of security for snapshots managed by AWS Backup, we recommend that you use AWS Backup Vault Lock. For more information, see AWS Backup Vault Lock.

• You can't lock snapshots during creation or during AMI registration.

• You can't lock local Amazon EBS snapshots on AWS Outposts.

• The only way to delete a snapshot that is locked in compliance mode before its lock expires is to close the associated AWS account.

   If you close your AWS account while you have locked snapshots, AWS suspends your account for 90 days with your snapshots intact. If you do not reopen your account within the 90 days, AWS deletes your snapshots, even if they are locked.

IAM permissions

By default, users don't have permission to work with snapshot locks. To allow users to use snapshot locks, you must create IAM policies that grant permission to use specific resources and API actions. For more information, see Creating IAM policies in the IAM User Guide.

Topics

• Required permissions (p. 2121)

• Restrict access with condition keys (p. 2122)

Required permissions

To work with snapshot locks, users need the following permissions.

• ec2:LockSnapshot — To lock snapshots.

• ec2:UnlockSnapshot — To unlock snapshots.

• ec2:DescribeLockedSnapshots — To view snapshot lock settings.

The following is an example IAM policy that gives users permission to lock and unlock snapshots, and to view snapshot lock settings. It includes the ec2:DescribeSnapshots permission for console users. If some permissions are not needed, you can remove them from the policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
    }]
}
```
To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:
  
  Create a permission set. Follow the instructions in Create a permission set in the AWS IAM Identity Center User Guide.

- Users managed in IAM through an identity provider:
  
  Create a role for identity federation. Follow the instructions in Creating a role for a third-party identity provider (federation) in the IAM User Guide.

- IAM users:
  
  Create a role that your user can assume. Follow the instructions in Creating a role for an IAM user in the IAM User Guide.

  (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the IAM User Guide.

Restrict access with condition keys

You can use condition keys to restrict how users are allowed to lock snapshots.

Topics

- ec2:SnapshotLockDuration (p. 2122)
- ec2:CoolOffPeriod (p. 2123)

ec2:SnapshotLockDuration

You can use the ec2:SnapshotLockDuration condition key to restrict users to specific lock durations when locking snapshots.

The following example policy restricts users to specifying a lock duration between 10 and 50 days.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:LockSnapshot",
      "Resource": "arn:aws:ec2:region::snapshot/*",
      "Condition": {
        "NumericGreaterThan": {
          "ebs:SnapshotLockDuration": 10
        }
      }
    }
  ]
}
```
ec2:CoolOffPeriod

You can use the ec2:CoolOffPeriod condition key to prevent users from locking snapshots in compliance mode without a cooling-off period.

The following example policy restricts users to specifying a cooling-off period greater than 48 hours when locking snapshots in compliance mode.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ec2:LockSnapshot",
            "Resource": "arn:aws:ec2:region::snapshot/*",
            "Condition": {
                "NumericGreaterThan": {
                    "ec2:CoolOffPeriod": 48
                }
            }
        }
    ]
}
```

**Work with snapshot lock**

**Topics**
- [Lock a snapshot](#)
- [Unlock a snapshot](#)
- [Update snapshot lock settings](#)
- [View snapshot lock settings](#)

**Lock a snapshot**

You can lock a snapshot that is in the pending or completed state. For more information, see [Considerations](#).

**Console**

**To lock a snapshot**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots.
3. Select the snapshot to lock and choose Actions, Snapshot settings, Manage snapshot lock.
4. Select Lock snapshot.
5. For Lock mode, choose either Governance mode or Compliance mode. For more information, see Lock mode.
6. For Lock duration, do one of the following:
   - To lock the snapshot for a specific period, choose Lock snapshot for, and then enter the period in either days or years.
   - To lock the snapshot until a specific date and time, choose Lock snapshot until, and then select the expiration date and time.

For more information, see Lock duration.
7. (Compliance mode only) For Cooling-off period, specify a cooling-off period during which you can unlock the snapshot and modify the lock configuration. For more information, see Cooling-off period (p. 2120).

8. (Compliance mode only) To confirm that you want to lock the snapshot in compliance mode and that you will not be able to unlock the snapshot after the cooling-off period expires, choose Acknowledge.

9. Choose Save lock settings.

AWS CLI

To lock a snapshot in governance mode

Use the lock-snapshot AWS CLI command. For --snapshot-id, specify the ID of the snapshot to lock. For --lock-mode, specify governance. To lock the snapshot for a specific period, for --lock-duration, specify the period for which to lock the snapshot. Or, to lock the snapshot until a specific date, for --expiration-date, specify the date and time at which the lock must expire, in the UTC time zone (YYYY-MM-DDThh:mm:ss.sssZ).

```bash
$ aws ec2 lock-snapshot --snapshot-id snapshot_id \
--lock-mode governance \
--lock-duration 1-36500_days | --expiration-date YYYY-MM-DDThh:mm:ss.sssZ
```

To lock a snapshot in compliance mode

Use the lock-snapshot AWS CLI command. For --snapshot-id, specify the ID of the snapshot to lock. For --lock-mode, specify compliance. For --cool-off-period, optionally specify a cooling-off period in hours. To lock the snapshot for a specific period, for --lock-duration, specify the period for which to lock the snapshot. Or, to lock the snapshot until a specific date, for --expiration-date, specify the date and time at which the lock must expire, in the UTC time zone (YYYY-MM-DDThh:mm:ss.sssZ).

```bash
$ aws ec2 lock-snapshot --snapshot-id snapshot_id \
--lock-mode compliance \
--cool-off-period 1-72_hours \
--lock-duration 1-36500_days | --expiration-date YYYY-MM-DDThh:mm:ss.sssZ
```

Unlock a snapshot

You can unlock a snapshot only if it is locked in governance mode, or if it is locked in compliance mode and it is still within the cooling-off period.

Console

To unlock a snapshot

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots.
3. Select the snapshot to unlock and choose Actions, Snapshot settings, Manage snapshot lock.
4. Choose Unlock snapshot and then choose Unlock snapshot again to confirm.

AWS CLI

To unlock a snapshot
Use the `unlock-snapshot` AWS CLI command. For `--snapshot-id`, specify the ID of the snapshot to unlock.

```
$ aws ec2 unlock-snapshot --snapshot-id snapshot_id
```

**Update snapshot lock settings**

The allowed updates depend on the lock state:

- **governance** — you can change the lock mode and increase or decrease the lock duration or expiration date.
- **compliance-cooloff** — you can change the lock mode, increase or decrease the cooling-off period, and increase or decrease the lock duration or expiration date.
- **compliance** — you can only increase the lock duration or expiration date.

**Console**

**To update snapshot lock settings**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots.
3. Select the snapshot for which to modify the lock settings and choose Actions, Snapshot settings, Manage snapshot lock.
4. Update the settings as needed, and then choose Save lock settings.

**AWS CLI**

**To update snapshot lock settings**

Use the `lock-snapshot` AWS CLI command. For `--snapshot-id`, specify the ID of the snapshot for which to update the lock settings. Then, specify only the options to modify.

**View snapshot lock settings**

Use one of the following methods to view the lock settings for a snapshot.

**Console**

**To view snapshot lock settings**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots.
3. Select the snapshot for which to view the lock settings and choose Actions, Snapshot settings, Manage snapshot lock.

**AWS CLI**

**To view snapshot lock settings**

Use the `describe-locked-snapshots` AWS CLI command. For `--snapshot-ids`, specify the IDs of the snapshots for which to view the lock settings.
Monitoring snapshot locks

You can use the following features to monitor snapshot locks.

Topics

- Monitoring snapshot locks using AWS CloudTrail (p. 2126)
- Monitoring snapshot locks using Amazon EventBridge (p. 2126)

Monitoring snapshot locks using AWS CloudTrail

You can monitor API calls for snapshot lock as events, including calls from the console and from code calls to the APIs. Using the information collected by CloudTrail, you can determine the request that was made, the IP address from which the request was made, who made the request, when it was made, and additional details.

For more information, see Logging API calls using AWS CloudTrail.

Monitoring snapshot locks using Amazon EventBridge

Amazon EBS emits events related to snapshot lock actions. You can use AWS Lambda and Amazon EventBridge to handle event notifications programmatically. Events are emitted on a best effort basis. For more information, see the Amazon EventBridge User Guide.

The following events are emitted:

- Successfully locked snapshot in governance or compliance mode.

```json
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Snapshot Notification",
  "source": "aws.ec2",
  "account": "012345678901",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2::us-west-2:snapshot/snap-01234567890abcdef"
  ],
  "detail": {
    "event": "lockSnapshot",
    "result": "succeeded",
    "snapshot_id": "arn:aws:ec2::us-west-2:snapshot/snap-01234567890abcdef",
    "source": "012345678901",
    "lockState": "compliance-cooloff",
    "lockCreatedOn": "yyyy-mm-ddThh:mm:ssZ",
    "lockExpiresOn": "yyyy-mm-ddThh:mm:ssZ",
    "lockDuration": 123,
    "lockStartDurationTime": "yyyy-mm-ddThh:mm:ssZ",
    "coolOffPeriod": 24,
    "coolOffPeriodExpiresOn": "yyyy-mm-ddThh:mm:ssZ"
  }
}
```

- Failed lock event when a snapshot is locked while it is in the pending state, and it fails to reach the completed state.
Lock expired

Cooling-off period expired after being locked in compliance mode.
Copy an Amazon EBS snapshot

With Amazon EBS, you can create point-in-time snapshots of volumes, which we store for you in Amazon S3. After you create a snapshot and it has finished copying to Amazon S3 (when the snapshot status is completed), you can copy it from one AWS Region to another, or within the same Region. Amazon S3 server-side encryption (256-bit AES) protects a snapshot's data in transit during a copy operation. The snapshot copy receives an ID that is different from the ID of the original snapshot.

To copy multi-volume snapshots to another AWS Region, retrieve the snapshots using the tag you applied to the multi-volume snapshot set when you created it. Then individually copy the snapshots to another Region.

If you would like another account to be able to copy your snapshot, you must either modify the snapshot permissions to allow access to that account or make the snapshot public so that all AWS accounts can copy it. For more information, see Share an Amazon EBS snapshot (p. 2156).

For information about copying an Amazon RDS snapshot, see Copying a DB Snapshot in the Amazon RDS User Guide.

Use cases

- Geographic expansion: Launch your applications in a new AWS Region.
- Migration: Move an application to a new Region, to enable better availability and to minimize cost.
- Disaster recovery: Back up your data and logs across different geographical locations at regular intervals. In case of disaster, you can restore your applications using point-in-time backups stored in the secondary Region. This minimizes data loss and recovery time.
- Encryption: Encrypt a previously unencrypted snapshot, change the key with which the snapshot is encrypted, or create a copy that you own in order to create a volume from it (for encrypted snapshots that have been shared with you).
- Data retention and auditing requirements: Copy your encrypted EBS snapshots from one AWS account to another to preserve data logs or other files for auditing or data retention. Using a different account helps prevent accidental snapshot deletions, and protects you if your main AWS account is compromised.

Contents

- Prerequisites (p. 2129)
- Considerations (p. 2129)
- Pricing (p. 2129)
- Incremental snapshot copying (p. 2129)
- Encryption and snapshot copying (p. 2130)
• **Copy a snapshot** (p. 2131)

**Prerequisites**

• You can copy any accessible snapshots that have a completed status, including shared snapshots and snapshots that you have created.

• You can copy AWS Marketplace, VM Import/Export, and Storage Gateway snapshots, but you must verify that the snapshot is supported in the destination Region.

• To copy an encrypted snapshot, your user must have the following permissions to use Amazon EBS encryption.
  - `kms:DescribeKey`
  - `kms:CreateGrant`
  - `kms:GenerateDataKey`
  - `kms:ReEncrypt`
  - `kms:Decrypt`

• To copy an encrypted snapshot shared from another AWS account, you must have permissions to use customer managed key that was used to encrypt the snapshot. For more information, see **Share a KMS key** (p. 2158).

**Considerations**

• There is a limit of 20 concurrent snapshot copy requests per destination Region. If you exceed this quota, you receive a `ResourceLimitExceeded` error. If you receive this error, wait for one or more of the copy requests to complete before making a new snapshot copy request.

• User-defined tags are not copied from the source snapshot to the new snapshot. You can add user-defined tags during or after the copy operation. For more information, see **Tag your Amazon EC2 resources** (p. 2507).

• Snapshots created by a snapshot copy operation have an arbitrary volume ID, such as `vol-ffff` or `vol-ffffffff`. These arbitrary volume IDs should not be used for any purpose.

• Resource-level permissions specified for the snapshot copy operation apply only to the new snapshot. You cannot specify resource-level permissions for the source snapshot. For an example, see **Example: Copying snapshots** (p. 1959).

**Pricing**

• For pricing information about copying snapshots across AWS Regions and accounts, see **Amazon EBS Pricing**.

• If you copy a snapshot and encrypt it to a new KMS key, a complete (non-incremental) copy is created. This results in additional storage costs.

• If you copy a snapshot to a new Region, a complete (non-incremental) copy is created. This results in additional storage costs. Subsequent copies of the same snapshot are incremental.

• The first snapshot copy from a snapshot in the same account and the same Region using the same customer managed key will be a complete (non-incremental) copy. This results in additional storage costs. Subsequent copies of the same snapshot are incremental.

**Incremental snapshot copying**

Whether a snapshot copy is incremental is determined by the most recently completed snapshot copy. When you copy a snapshot across Regions or accounts, the copy is an incremental copy if the following conditions are met:
• The snapshot was copied to the destination Region or account previously.
• The most recent snapshot copy still exists in the destination Region or account.
• All copies of the snapshot in the destination Region or account are either unencrypted or were encrypted using the same KMS key.

If the most recent snapshot copy was deleted, the next copy is a full copy, not an incremental copy. If a copy is still pending when you start another copy, the second copy starts only after the first copy finishes.

Snapshot copy operations within a single account and the same Region using a customer managed key will generate a complete (non-incremental) copy. Subsequent copies of the same snapshot are incremental.

Incremental snapshot copying reduces the time required to copy snapshots and saves on data transfer and storage costs by not duplicating data.

We recommend that you tag your snapshots with the volume ID and creation time so that you can keep track of the most recent snapshot copy of a volume in the destination Region or account.

To see whether your snapshot copies are incremental, check the `copySnapshot` CloudWatch event.

**Encryption and snapshot copying**

When you copy a snapshot, you can encrypt the copy or you can specify a KMS key that is different than the original, and the resulting copied snapshot uses the new KMS key. However, changing the encryption status of a snapshot during a copy operation could result in a full (not incremental) copy, which might incur greater data transfer and storage charges. For more information, see Incremental snapshot copying (p. 2129).

To copy an encrypted snapshot shared from another AWS account, you must have permissions to use the snapshot and the customer managed key (CMK) that was used to encrypt the snapshot. When using an encrypted snapshot that was shared with you, we recommend that you re-encrypt the snapshot by copying it using a KMS key that you own. This protects you if the original KMS key is compromised, or if the owner revokes it, which could cause you to lose access to any encrypted volumes that you created using the snapshot. For more information, see Share an Amazon EBS snapshot (p. 2156).

You apply encryption to EBS snapshot copies by setting the `Encrypted` parameter to `true`. (The `Encrypted` parameter is optional if encryption by default (p. 2320) is enabled).

Optionally, you can use `KmsKeyId` to specify a custom key to use to encrypt the snapshot copy. (The `Encrypted` parameter must also be set to `true`, even if encryption by default is enabled.) If `KmsKeyId` is not specified, the key that is used for encryption depends on the encryption state of the source snapshot and its ownership.

The following table describes the encryption outcomes for each possible combination of settings when copying snapshots that you own and snapshots that are shared with you.

<table>
<thead>
<tr>
<th>Encryption by default</th>
<th>Is Encrypted parameter set?</th>
<th>Source snapshot encryption status</th>
<th>Default (no KMS key specified)</th>
<th>Custom (KMS key specified)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disabled</td>
<td>No</td>
<td>Unencrypted</td>
<td>Unencrypted</td>
<td>N/A</td>
</tr>
<tr>
<td>Encrypted</td>
<td></td>
<td>Encrypted</td>
<td>Encrypted by AWS managed key</td>
<td></td>
</tr>
</tbody>
</table>

2130
Encryption by default | Is Encrypted parameter set? | Source snapshot encryption status | Default (no KMS key specified) | Custom (KMS key specified) |
---|---|---|---|---|
Yes | Unencrypted | Encrypted by default KMS key | Encrypted by specified KMS key** |
| | Encrypted | Encrypted by default KMS key | | |
Enabled | No | Unencrypted | Encrypted by default KMS key | N/A |
| | | | Encrypted by default KMS key | |
Yes | Unencrypted | Encrypted by default KMS key | Encrypted by specified KMS key** |
| | Encrypted | Encrypted by default KMS key | |

** This is the KMS key specified in the copy snapshot action. This KMS key is used instead of the default KMS key for the account and Region.

** Copy a snapshot**

To copy a snapshot, use one of the following methods.

**Console**

To copy a snapshot using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Snapshots**.
3. Select the snapshot to copy, and then choose **Actions, Copy snapshot**.
4. For **Description**, enter a brief description for the snapshot copy.
   By default, the description includes information about the source snapshot so that you can identify a copy from the original. You can change this description as needed.
5. For **Destination Region**, select the Region in which to create the snapshot copy.
6. Specify the encryption status for the snapshot copy.
   If the source snapshot is encrypted, or if your account is enabled for encryption by default (p. 2320), then the snapshot copy is automatically encrypted and you can't change its encryption status.
   If the source snapshot is unencrypted and your account is not enabled for encryption by default, encryption is optional. To encrypt the snapshot copy, for **Encryption**, select **Encrypt this snapshot**. Then, for **KMS key**, select the KMS key to use to encrypt the snapshot in the destination Region.
7. Choose **Copy snapshot**.

**AWS CLI**

To copy a snapshot using the AWS CLI
Use the `copy-snapshot` command.

Tools for Windows PowerShell

**To copy a snapshot using the Tools for Windows PowerShell**

Use the `Copy-EC2Snapshot` command.

**To check for failure**

If you attempt to copy an encrypted snapshot without having permissions to use the encryption key, the operation fails silently. The error state is not displayed in the console until you refresh the page. You can also check the state of the snapshot from the command line, as in the following example.

```
aws ec2 describe-snapshots --snapshot-id snap-0123abcd
```

If the copy failed because of insufficient key permissions, you see the following message: "StateMessage": "Given key ID is not accessible".

When copying an encrypted snapshot, you must have `DescribeKey` permissions on the default CMK. Explicitly denying these permissions results in copy failure. For information about managing CMK keys, see [Authentication and access control for AWS KMS](#).

**Archive Amazon EBS snapshots**

Amazon EBS Snapshots Archive is a new storage tier that you can use for low-cost, long-term storage of your rarely-accessed snapshots that do not need frequent or fast retrieval.

By default, when you create a snapshot, it is stored in the Amazon EBS Snapshot Standard tier (*standard tier*). Snapshots stored in the standard tier are incremental. This means that only the blocks on the volume that have changed after your most recent snapshot are saved.

When you archive a snapshot, the incremental snapshot is converted to a full snapshot, and it is moved from the standard tier to the Amazon EBS Snapshots Archive tier (*archive tier*). Full snapshots include all of the blocks that were written to the volume at the time when the snapshot was created.

When you need to access an archived snapshot, you can restore it from the archive tier to the standard tier, and then use it in the same way that you use any other snapshot in your account.

Amazon EBS Snapshots Archive offers up to 75 percent lower snapshot storage costs for snapshots that you plan to store for 90 days or longer and that you rarely need to access.

Some typical use cases include:

- Archiving the only snapshot of a volume, such as end-of-project snapshots
- Archiving full, point-in-time incremental snapshots for compliance reasons.
- Archiving monthly, quarterly, or yearly incremental snapshots.

**Topics**

- [Considerations and limitations (p. 2133)](#)
- [Pricing and billing (p. 2134)](#)
- [Quotas (p. 2135)](#)
- [Guidelines and best practices for archiving snapshots (p. 2136)](#)
- [Required IAM permissions (p. 2144)](#)
Considerations and limitations

Considerations

- The minimum archive period is 90 days. If you delete or permanently restore an archived snapshot before the minimum archive period of 90 days, you are billed for remaining days in the archive tier, rounded to the nearest hour. For more information, see Pricing and billing (p. 2134).
- It can take up to 72 hours to restore an archived snapshot from the archive tier to the standard tier, depending on the size of the snapshot.
- Archived snapshots are always full snapshots. A full snapshot contains all the blocks written to the volume at the time the snapshot was created. The full snapshot will likely be larger than the incremental snapshot from which it was created. However, if you have only one incremental snapshot of a volume on the standard tier, the size of the full snapshot in the archive tier will be the same size as the snapshot in standard tier. This is because the first snapshot taken of a volume is always a full snapshot.
- Archiving is recommended for monthly, quarterly, or yearly snapshots. Archiving daily incremental snapshots of a single volume can lead to higher costs when compared to keeping them in the standard tier.
- When a snapshot is archived, the data of the snapshot that is referenced by other snapshots in the snapshot lineage are retained in the standard tier. Data and storage costs associated with the referenced data that is retained on the standard tier are allocated to the next snapshot in the lineage. This ensures that subsequent snapshots in the lineage are not affected by the archival.
- If you delete an archived snapshot that matches a Recycle Bin retention rule, the archived snapshot is retained in the Recycle Bin for the retention period defined in the retention rule. To use the snapshot, you must first recover it from the Recycle Bin and then restore it from the archive tier. For more information, see Recycle Bin (p. 2467) and Pricing and billing (p. 2134).
- You can't use an archived snapshot in a block device mapping or to create an Amazon EBS volume.
- You can archive snapshots created by AWS Backup using the AWS Backup console, APIs, or command line tools. For more information, see Creating a backup plan in the AWS Backup Developer Guide.

Limitations

- You can archive snapshots that are in the completed state only.
- You can archive only snapshots that you own in your account. To archive a snapshot that is shared with you, first copy the snapshot to your account and then archive the snapshot copy.
- Before you can use an archived snapshot, you must first restore it to the standard tier. Restoring to the standard tier is required to create a volume from the snapshot through the CreateVolume and RunInstances API operations as well as to share or copy a snapshot. For more information, see Restore an archived snapshot (p. 2146).
- You can archive a snapshot that is associated with one or more AMIs only if all of the associated AMIs are disabled. For more information, see Disable an AMI (p. 228).
- You can’t enable a disabled AMI if the associated snapshots are temporarily restored. All of the associated snapshots must be permanently restored before you can enable the AMI.
- You can’t cancel the snapshot archive or snapshot restore process after it has been started.
- You can’t share archived snapshots. If you archive a snapshot that you have shared with other accounts, the accounts with which the snapshot is shared lose access after the snapshot is archived.
- You can’t copy an archived snapshot. If you need to copy an archived snapshot, you must first restore it.
- You can't enable fast snapshot restore for an archived snapshot. Fast snapshot restore is automatically disabled when a snapshot is archived. If you need to use fast snapshot restore, you must manually enable it after restoring the snapshot.

### Pricing and billing

Archived snapshots are billed at a rate of $0.0125 per GB-month. For example, if you archive a 100 GiB snapshot, you are billed $1.25 (100 GiB * $0.0125) per month.

Snapshot restores are billed at a rate of $0.03 per GB of data restored. For example, if you restore a 100 GiB snapshot from the archive tier, you are billed one time for $3 (100 GiB * $0.03).

After the snapshot is restored to the standard tier, the snapshot is billed at the standard rate for snapshots of $0.05 per GB-month.

For more information, see [Amazon EBS pricing](https://aws.amazon.com/ebs/pricing/).

### Billing for the minimum archive period

The minimum archive period is 90 days. If you delete or permanently restore an archived snapshot before the minimum archive period of 90 days, you are billed a pro-rated charge equal to the archive tier storage charge for the remaining days, rounded to the nearest hour. For example, if you delete or permanently restore an archived snapshot after 40 days, you are billed for the remaining 50 days of the minimum archive period.

**Note**

Temporarily restoring an archived snapshot before the minimum archive period of 90 days does not incur this charge.

### Temporary restores

When you temporarily restore a snapshot, the snapshot is restored from the archive tier to the standard tier, and a copy of the snapshot remains in the archive tier. You are billed for both the snapshot in the standard tier and the snapshot copy in the archive tier for the duration of the temporary restore period. When the temporarily restored snapshot is removed from the standard tier, you are no longer billed for it, and you are billed for the snapshot in the archive tier only.

### Permanent restores

When you permanently restore a snapshot, the snapshot is restored from the archive tier to the standard tier, and the snapshot is deleted from the archive tier. You are billed for the snapshot in the standard tier only.

### Deleting snapshots

If you delete a snapshot while it is being archived, you are billed for the snapshot data that has already been moved to the archive tier. This data is subject to the minimum archive period of 90 days and billed accordingly upon deletion. For example, if you archive a 100 GiB snapshot, and you delete the snapshot after only 40 GiB has been archived, you are billed $1.50 for the minimum archive period of 90 days for the 40 GiB that has already been archived ($0.0125 per GB-month * 40 GB * (90 days * 24 hours) / (24 hours/day * 30-day month)).

If you delete a snapshot while it is being restored from the archive tier, you are billed for the snapshot restore for the full size of the snapshot (snapshot size * $0.03). For example, if you restore a 100 GiB snapshot from the archive tier, and you delete the snapshot at any point before the snapshot restore completes, you are billed $3 (100 GiB snapshot size * $0.03).

### Recycle Bin
Archived snapshots are billed at the rate for archived snapshots while they are in the Recycle Bin. Archived snapshots that are in the Recycle Bin are subject to the minimum archive period of 90 days and they are billed accordingly if they are deleted by Recycle Bin before the minimum archive period. In other words, if a retention rule deletes an archived snapshot from the Recycle Bin before the minimum period of 90 days, you are billed for the remaining days.

If you delete a snapshot that matches a retention rule while the snapshot is being archived, the archived snapshot is retained in the Recycle Bin for the retention period defined in the retention rule. It is billed at the rate for archived snapshots.

If you delete a snapshot that matches a retention rule while the snapshot is being restored, the restored snapshot is retained in the Recycle Bin for the remainder of the retention period, and billed at the standard snapshot rate. To use the restored snapshot, you must first recover it from the Recycle Bin.

For more information, see Recycle Bin (p. 2467).

Cost tracking

Archived snapshots appear in the AWS Cost and Usage Report with their same resource ID and Amazon Resource Name (ARN). For more information, see the AWS Cost and Usage Report User Guide.

You can use the following usage types to identify the associated costs:

- SnapshotArchiveStorage — fee for monthly data storage
- SnapshotArchiveRetrieval — one-time fee for snapshot restores
- SnapshotArchiveEarlyDelete — fee for deleting or permanently restoring a snapshot before the minimum archive period (90 days)

Quotas

This section describes the default quotas for archived and in-progress snapshots.

<table>
<thead>
<tr>
<th>Quota</th>
<th>Default quota</th>

<tbody>
<tr>
<td>Archived snapshots per volume</td>
<td>25</td>
</tr>
<tr>
<td>Concurrent 25 in-progress snapshot archives per account</td>
<td></td>
</tr>
<tr>
<td>Concurrent 5 in-progress snapshot restores per account</td>
<td></td>
</tr>
</tbody>
</table>

If you need more than the default limits, complete the AWS Support Center Create case form to request a limit increase.
Guidelines and best practices for archiving snapshots

This section provides some guidelines and best practices for archiving snapshots.

Topics
- Archiving the only snapshot of a volume (p. 2136)
- Archiving incremental snapshots of a single volume (p. 2136)
- Archiving full snapshots for compliance reasons (p. 2137)
- Determining the reduction in standard tier storage costs (p. 2138)

Archiving the only snapshot of a volume

When you have only one snapshot of a volume, the snapshot is always the same size as the blocks written to the volume at the time the snapshot was created. When you archive such a snapshot, the snapshot in the standard tier is converted to an equivalent-sized full snapshot and it is moved from the standard tier to the archive tier.

Archiving these snapshots can help you save with lower storage costs. If you no longer need the source volume, you can delete the volume for further storage cost savings.

Archiving incremental snapshots of a single volume

When you archive an incremental snapshot, the snapshot is converted to a full snapshot and it is moved to the archive tier. For example, in the following image, if you archive Snap B, the snapshot is converted to a full snapshot that is 10 GiB in size and moved to the archive tier. Similarly, if you archive Snap C, the size of the full snapshot in the archive tier is 14 GiB.
If you are archiving snapshots to reduce your storage costs in the standard tier, you should not archive the first snapshot in a set of incremental snapshots. These snapshots are referenced by subsequent snapshots in the snapshot lineage. In most cases, archiving these snapshots will not reduce storage costs.

**Note**
You should not archive the last snapshot in a set of incremental snapshots. The last snapshot is the most recent snapshot taken of a volume. You will need this snapshot in the standard tier if you want to create volumes from it in the case of a volume corruption or loss.

If you archive a snapshot that contains data that is referenced by a later snapshot in the lineage, the data storage and storage costs associated with the referenced data are allocated to the later snapshot in the lineage. In this case, archiving the snapshot will not reduce data storage or storage costs. For example, in the preceding image, if you archive **Snap B**, its 4 GiB of data is attributed to **Snap C**. In this case, your overall storage costs will increase because you incur storage costs for the full version of **Snap C** in the archive tier, and your storage costs for the standard tier remain unchanged.

If you archive **Snap C**, your standard tier storage will decrease by 4 GiB because the data is not referenced by any other snapshots later in the lineage. And your archive tier storage will increase by 14 GiB because the snapshot is converted to a full snapshot.

**Archiving full snapshots for compliance reasons**
You might need to create full backups of volumes on a monthly, quarterly, or yearly basis for compliance reasons. For these backups, you might need standalone snapshots without backward or forward
EBS Snapshots Archive makes it cost-effective to archive these full snapshots for long-term retention.

Determining the reduction in standard tier storage costs

If you want to archive an incremental snapshot to reduce your storage costs, you should consider the size of the full snapshot in the archive tier and the reduction in storage in the standard tier. This section explains how to do this.

Important
The API responses are data accurate at the point-in-time when the APIs are called. API responses can differ as the data associated with a snapshot changes as a result of changes in the snapshot lineage.

To determine the reduction in storage and storage costs in the standard tier, use the following steps.

1. Check the size of the full snapshot. To determine the full size of the snapshot, use the `list-snapshot-blocks` command. For `--snapshot-id`, specify the ID of the snapshot that you want to archive.

   ```
   $ aws ebs list-snapshot-blocks --snapshot-id snapshot_id
   ```

   This returns information about all of the blocks in the specified snapshot. The `BlockIndex` of the last block returned by the command indicates the number of blocks in the snapshot. The number of blocks multiplied by 512 KiB, which is the snapshot block size, gives you a close approximation of the size of the full snapshot in the archive tier (blocks * 512 KiB = full snapshot size).

   For example, the following command lists the blocks for snapshot `snap-01234567890abcdef`.

   ```
   $ aws ebs list-snapshot-blocks --snapshot-id snap-01234567890abcdef
   ```

   The following is the command output, with some blocks omitted. The following output indicates that the snapshot includes about 16,383 blocks of data. This approximates to a full snapshot size of about 8 GiB (16,383 * 512 KiB = 7.99 GiB).

   ```
   {
     "VolumeSize": 8,
     "Blocks": [
       {
         "BlockToken": "ABgBAeShfaSRwG+RIWUG2pwmnCU/
                       YMnV7fGmxLbCWFEBEvmuqaSRmoYVat",
         "BlockIndex": 0
       },
       {
         "BlockToken": "ABgBATdTONyThPUAbQhbUQXsn5TGoY/
                       J17Gfe83j9W7s1upav0Tw9E1KpFh",
         "BlockIndex": 1
       },
       {
         "BlockToken": "EBEUmuqXsn5TGoY/QwmmCU/YMnV74eKE2TSen5TGoY/
                       E83j9WQhbUQXsn5T",
         "BlockIndex": 4
       },
       ...
       {
         "BlockToken": "yThPUAbQhbSV8xpwmnCU/
                       YMnV74eKE2TSFY1sKPVr50y47WEtDONyThPUA",
         "BlockIndex": 12890
       }
   }
   ```
2. Find the source volume from which the snapshot that you want to archive was created. Use the `describe-snapshots` command. For `--snapshot-id`, specify the ID of the snapshot that you want to archive. The `VolumeId` response parameter indicates the ID of the source volume.

   ```bash
   $ aws ec2 describe-snapshots --snapshot-id snapshot_id
   
   For example, the following command returns information about snapshot snap-09c9114207084f0d9.
   
   $ aws ec2 describe-snapshots --snapshot-id snap-09c9114207084f0d9
   
   The following is the command output, which indicates that snapshot snap-09c9114207084f0d9 was created from volume vol-0f3e2c292c52b85c3.
   ```

   ```json
   
   
   ```

   3. Find all of the snapshots created from the source volume. Use the `describe-snapshots` command. Specify the `volume-id` filter, and for the filter value, specify the volume ID from the previous step.

   ```bash
   $ aws ec2 describe-snapshots --filters "Name=volume-id, Values=volume_id"
   
   For example, the following command returns all snapshots created from volume vol-0f3e2c292c52b85c3.
   ```

   ```bash
   $ aws ec2 describe-snapshots --filters "Name=volume-id, Values=vol-0f3e2c292c52b85c3"
   ```
The following is the command output, which indicates that three snapshots were created from volume `vol-0f3e2c292c52b85c3`.

```json
{
    "Snapshots": [
        {
            "Description": "",
            "Tags": [],
            "Encrypted": false,
            "VolumeId": "vol-0f3e2c292c52b85c3",
            "State": "completed",
            "VolumeSize": 8,
            "StartTime": "2021-11-14T08:57:39.300Z",
            "Progress": "100%",
            "OwnerId": "123456789012",
            "SnapshotId": "snap-08ca60083f86816b0"
        },
        {
            "Description": "",
            "Tags": [],
            "Encrypted": false,
            "VolumeId": "vol-0f3e2c292c52b85c3",
            "State": "completed",
            "VolumeSize": 8,
            "StartTime": "2021-11-15T08:29:49.840Z",
            "Progress": "100%",
            "OwnerId": "123456789012",
            "SnapshotId": "snap-09c9114207084f0d9"
        },
        {
            "Description": "01",
            "Tags": [],
            "Encrypted": false,
            "VolumeId": "vol-0f3e2c292c52b85c3",
            "State": "completed",
            "VolumeSize": 8,
            "StartTime": "2021-11-16T07:50:08.042Z",
            "Progress": "100%",
            "OwnerId": "123456789012",
            "SnapshotId": "snap-024f49fe8dd853fa8"
        }
    ]
}
```

4. Using the output from the previous command, sort the snapshots by their creation times, from earliest to newest. The `StartTime` response parameter for each snapshot indicates its creation time, in UTC time format.

   For example, the snapshots returned in the previous step arranged by creation time, from earliest to newest, is as follows:
   
   1. `snap-08ca60083f86816b0` (earliest – created before the snapshot that you want to archive)
   2. `snap-09c9114207084f0d9` (the snapshot to archive)
   3. `snap-024f49fe8dd853fa8` (newest – created after the snapshot that you that want to archive)

5. Identify the snapshots that were created immediately before and after the snapshot that you want to archive. In this case, you want to archive snapshot `snap-09c9114207084f0d9`, which was the second incremental snapshot created in the set of three snapshots. Snapshot `snap-08ca60083f86816b0` was created immediately before, and snapshot `snap-024f49fe8dd853fa8` was created immediately after.
6. Find the unreferenced data in the snapshot that you want to archive. First, find the blocks that are different between the snapshot that was created immediately before the snapshot that you want to archive, and the snapshot that you want to archive. Use the `list-changed-blocks` command. For `--first-snapshot-id`, specify the ID of the snapshot that was created immediately before the snapshot that you want to archive. For `--second-snapshot-id`, specify the ID of the snapshot that you want to archive.

```
$ aws ebs list-changed-blocks --first-snapshot-id snapshot_created_before --second-snapshot-id snapshot_to_archive
```

For example, the following command shows the block indexes for the blocks that are different between snapshot `snap-08ca60083f86816b0` (the snapshot created before the snapshot you want to archive), and snapshot `snap-09c9114207084f0d9` (the snapshot you want to archive).

```
$ aws ebs list-changed-blocks --first-snapshot-id snap-08ca60083f86816b0 --second-snapshot-id snap-09c9114207084f0d9
```

The following shows the command output, with some blocks omitted.

```
{
  "BlockSize": 524288,
  "ChangedBlocks": [
    {
      "FirstBlockToken": "ABgBAX6y+WH6Xm9y5zqlYvETcmEzGmT0jNZG1cDiQxq1x0VeFbWxXsH3W4z/",
      "SecondBlockToken": "ABgBASy0bHHbNTERu+9USLxYK/81UT0dbHIUQfjQKwTwSKqkjP8NSGyNB",
      "BlockIndex": 4
    },
    {
      "FirstBlockToken": "ABgBAcfl+EfmQm1NgstqtfNygAxFx4DSO4LkLY00CHGBWcjJnpn90E9XX1",
      "SecondBlockToken": "ABgBAAdX0mtX6aBABa5EBy+8jFCESMpig7csKjb020cd08m2iNJV2Ue+cRwUqF",
      "BlockIndex": 5
    },
    {
      "FirstBlockToken": "ABgBAVBaFJmbP/eRHgh7vnJjAwyiyNui3MKZmEmx2SwC3AmM/fc6yCOA6b65",
      "SecondBlockToken": "ABgBA6wWkHktcZmsFm7GbaHyX61Ctcn2nppz4wYItZRM0a1M72fpXU0Yv",
      "BlockIndex": 13
    },
    {
      "FirstBlockToken": "ABgBAQGxwuf6z095L60pRVnOqPxmX97Wf60+iLtZ0dwPpGN39ijztLn",
      "SecondBlockToken": "ABgBAUdlItCIV7c6HGsTcckkKcw6mBHRc1nV+bKjiu/9UEStW7CD9w4J2td",
      "BlockIndex": 14
    },
    {
      "FirstBlockToken": "ABgBAZBfEv4EHS1a5X7TxA5X3mmB2G6CneIkwxpljzmgSHICG1FmZCyJXzE4z3",
      "SecondBlockToken": "ABgBAVWR7QqQ88AP2TtmNkg54AeSkaQVClDnpc91zBlNmSfW9ou1bEXWy",
      "BlockIndex": 15
    }
  ]
}
```
Next, use the same command to find blocks that are different between the snapshot that you want to archive and the snapshot that was created immediately after it. For --first-snapshot-id, specify the ID of the snapshot that you want to archive. For --second-snapshot-id, specify the ID of the snapshot that was created immediately after the snapshot that you want to archive.

```
$ aws ebs list-changed-blocks --first-snapshot-id snapshot_to_archive --second-snapshot-id snapshot_created_after
```

For example, the following command shows the block indexes of the blocks that are different between snapshot snap-09c9114207084f0d9 (the snapshot that you want to archive) and snapshot snap-024f49fe8dd853fa8 (the snapshot created after the snapshot that you want to archive).

```
$ aws ebs list-changed-blocks --first-snapshot-id snap-09c9114207084f0d9 --second-snapshot-id snap-024f49fe8dd853fa8
```

The following shows the command output, with some blocks omitted.
7. Compare the output returned by both commands in the previous step. If the same block index appears in both command outputs, it indicates that the block contains unreferenced data.

For example, the command output in the previous step indicates that blocks 4, 5, 13, and 14 are unique to snapshot `snap-09c9114207084f0d9` and that they are not referenced by any other snapshots in the snapshot lineage.

To determine the reduction in standard tier storage, multiply the number of blocks that appear in both command outputs by 512 KiB, which is the snapshot block size.
For example, if 9,950 block indexes appear in both command outputs, it indicates that you will decrease standard tier storage by around 4.85 GiB (9,950 blocks * 512 KiB = 4.85 GiB).

8. Determine the storage costs for storing the unreferenced blocks in the standard tier for 90 days. Compare this value with the cost of storing the full snapshot, described in from step 1, in the archive tier. You can determine your costs savings by comparing the values, assuming that you do not restore the full snapshot from the archive tier during the minimum 90-day period. For more information, see Pricing and billing (p. 2134).

**Required IAM permissions**

By default, users don’t have permission to use snapshot archiving. To allow users to use snapshot archiving, you must create IAM policies that grant permission to use specific resources and API actions. For more information, see Creating IAM policies in the IAM User Guide.

To use snapshot archiving, users need the following permissions.

- ec2:DescribeSnapshotTierStatus
- ec2:ModifySnapshotTier
- ec2:RestoreSnapshotTier

Console users might need additional permissions such as ec2:DescribeSnapshots.

To archive and restore encrypted snapshots, the following additional AWS KMS permissions are required.

- kms:CreateGrant
- kms:Decrypt
- kms:DescribeKey

The following is an example IAM policy that gives IAM users permission to archive, restore, and view encrypted and unencrypted snapshots. It includes the ec2:DescribeSnapshots permission for console users. If some permissions are not needed, you can remove them from the policy.

**Tip**

To follow the principle of least privilege, do not allow full access to kms:CreateGrant. Instead, use the kms:GrantIsForAWSResource condition key to allow the user to create grants on the KMS key only when the grant is created on the user’s behalf by an AWS service, as shown in the following example.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeSnapshotTierStatus",
        "ec2:ModifySnapshotTier",
        "ec2:RestoreSnapshotTier",
        "ec2:DescribeSnapshots",
        "kms:CreateGrant",
        "kms:Decrypt",
        "kms:DescribeKey"
      ],
      "Resource": "+",
      "Condition": {
        "Bool": {
          "kms:GrantIsForAWSResource": true
        }
      }
    }
  ]
}
```
To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:
  
  Create a permission set. Follow the instructions in Create a permission set in the AWS IAM Identity Center User Guide.

- Users managed in IAM through an identity provider:
  
  Create a role for identity federation. Follow the instructions in Creating a role for a third-party identity provider (federation) in the IAM User Guide.

- IAM users:
  
  Create a role that your user can assume. Follow the instructions in Creating a role for an IAM user in the IAM User Guide.

  (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the IAM User Guide.

Work with snapshot archiving

Topics

- Archive a snapshot (p. 2145)
- Restore an archived snapshot (p. 2146)
- Modify the restore period or restore type for a temporarily restored snapshot (p. 2148)
- View archived snapshots (p. 2149)

Archive a snapshot

You can archive any snapshot that is in the completed state and that you own in your account. You can't archive snapshots that are in the pending or error states, or snapshots that are shared with you. For more information, see Considerations and limitations (p. 2133).

If the snapshot is associated with one or more AMIs, then you must first disable those associated AMIs before you can archive the snapshot. For more information, see Disable an AMI (p. 228).

Archived snapshots retain their snapshot ID, encryption status, AWS Identity and Access Management (IAM) permissions, owner information, and resource tags. However, fast snapshot restore and snapshot sharing are automatically disabled after the snapshot is archived.

You can continue to use the snapshot while the archive is in process. As soon as the snapshot tiering status reaches the archival-complete state, you can no longer use the snapshot.

You can archive a snapshot using one of the following methods.

Console

To archive a snapshot

Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

1. In the navigation pane, choose Snapshots.
2. In the list of snapshots, select the snapshot to archive and then choose Actions, Archive snapshot.
3. To confirm, choose **Archive snapshot**.

**AWS CLI**

**To archive a snapshot**

Use the `modify-snapshot-tier` AWS CLI command. For `--snapshot-id`, specify the ID of the snapshot to archive. For `--storage-tier`, specify archive.

```
$ aws ec2 modify-snapshot-tier \
  --snapshot-id snapshot_id \
  --storage-tier archive
```

For example, the following command.archives snapshot `snap-01234567890abcedf`.

```
$ aws ec2 modify-snapshot-tier \
  --snapshot-id snap-01234567890abcedf \
  --storage-tier archive
```

The following is the command output. The `TieringStartTime` response parameter indicates the date and time at which the archive process was started, in UTC time format (YYYY-MM-DDTHH:MM:SSZ).

```json
{
  "SnapshotId": "snap-01234567890abcedf",
  "TieringStartTime": "2021-09-15T16:44:37.574Z"
}
```

**Restore an archived snapshot**

Before you can use an archived snapshot, you must first restore it to the standard tier. The restored snapshot has the same snapshot ID, encryption status, IAM permissions, owner information, and resource tags that it had before it was archived. After it is restored, you can use it in the same way that you use any other snapshot in your account. The restored snapshot is always a full snapshot.

When you restore a snapshot, you can choose to restore it **permanently** or **temporarily**.

If you restore a snapshot permanently, the snapshot is moved from the archive tier to the standard tier permanently. The snapshot remains restored and ready for use until you manually re-archive it or you manually delete it. When you permanently restore a snapshot, the snapshot is removed from the archive tier.

If you restore a snapshot temporarily, the snapshot is copied from the archive tier to the standard tier for a restore period that you specify. The snapshot remains restored and ready for use for the restore period only. During the restore period, a copy of the snapshot remains in the archive tier. After the period expires, the snapshot is automatically removed from the standard tier. You can increase or decrease the restore period or change the restore type to permanent at any time during the restore period. For more information, see [Modify the restore period or restore type for a temporarily restored snapshot](p. 2148).

If you are restoring snapshots that are associated with a disabled AMI, and you intend to use that AMI, you must first **permanently restore** all of the associated snapshots and then **enable the AMI** (p. 230) before you can use it. You can't enable an AMI if the associated snapshots are temporarily restored. You can use the following command to find all of the snapshots associated with an AMI.

```
$ aws ec2 describe-images --image-id ami_id \
```

2146
You can restore an archived snapshot using one of the following methods.

**Console**

**To restore a snapshot from the archive**

Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

1. In the navigation pane, choose **Snapshots**.
2. In the list of snapshots, select the archived snapshot to restore, and then choose **Actions**, **Restore snapshot from archive**.
3. Specify the type of restore to perform. For **Restore type**, do one of the following:
   - To restore the snapshot permanently, select **Permanent**.
   - To restore the snapshot temporarily, select **Temporary**, and then for **Temporary restore period**, enter the number of days for which to restore the snapshot.
4. To confirm, choose **Restore snapshot**.

**AWS CLI**

**To permanently restore an archived snapshot**

Use the `restore-snapshot-tier` AWS CLI command. For --snapshot-id, specify the ID of the snapshot to restore, and include the --permanent-restore option.

```bash
$ aws ec2 restore-snapshot-tier
   --snapshot-id snapshot_id
   --permanent-restore
```

For example, the following command permanently restores snapshot `snap-01234567890abcedf`.

```bash
$ aws ec2 restore-snapshot-tier
   --snapshot-id snap-01234567890abcedf
   --permanent-restore
```

The following is the command output.

```json
{
   "SnapshotId": "snap-01234567890abcedf",
   "IsPermanentRestore": true
}
```

**To temporarily restore an archived snapshot**

Use the `restore-snapshot-tier` AWS CLI command. Omit the --permanent-restore option. For --snapshot-id, specify the ID of the snapshot to restore, and for --temporary-restore-days, specify the number of days for which to restore the snapshot.

--temporary-restore-days must be specified in days. The allowed range is 1 - 180. If you do not specify a value, it defaults to 1 day.

```bash
$ aws ec2 restore-snapshot-tier
```
Modify the restore period or restore type for a temporarily restored snapshot

When you restore a snapshot temporarily, you must specify the number of days for which the snapshot is to remain restored in your account. After the restore period expires, the snapshot is automatically removed from the standard tier.

You can change the restore period for a temporarily restored snapshot at any time.

You can choose to either increase or decrease the restore period, or you can change the restore type from temporary to permanent.

If you change the restore period, the new restore period is effective from the current date. For example, if you specify a new restore period of 5 days, the snapshot will remain restored for five days from the current date.

**Note**
You can end a temporary restore early by setting the restore period to 1 day.

If you change the restore type from temporary to permanent, the snapshot copy is deleted from the archive tier, and the snapshot remains available in your account until you manually re-archive it or delete it.

You can modify the restore period for a snapshot using one of the following methods.

**Console**

To modify the restore period or restore type

Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

1. In the navigation pane, choose Snapshots.
2. In the list of snapshots, select the snapshot that you previously temporarily restored, and then choose Actions, Restore snapshot from archive.
3. For Restore type, do one of the following:
   - To change the restore type from temporary to permanent, select Permanent.
   - To increase or decrease the restore period, keep Temporary, and then for Temporary restore period, enter the new restore period in days.
4. To confirm, choose **Restore snapshot**.

**AWS CLI**

**To modify the restore period or change the restore type**

Use the `restore-snapshot-tier` AWS CLI command. For `--snapshot-id`, specify the ID of the snapshot that you previously temporarily restored. To change the restore type from temporary to permanent, specify `--permanent-restore` and omit `--temporary-restore-days`. To increase or decrease the restore period, omit `--permanent-restore` and for `--temporary-restore-days`, specify the new restore period in days.

**Example: Increase or decrease the restore period**

The following command changes the restore period for snapshot `snap-01234567890abcedf` to 10 days.

```
$ aws ec2 restore-snapshot-tier \
   --snapshot-id snap-01234567890abcedf \
   --temporary-restore-days 10
```

The following is the command output.

```
{
   "SnapshotId": "snap-01234567890abcedf",
   "RestoreDuration": 10,
   "IsPermanentRestore": false
}
```

**Example: Change restore type to permanent**

The following command changes the restore type for snapshot `snap-01234567890abcedf` from temporary to permanent.

```
$ aws ec2 restore-snapshot-tier \
   --snapshot-id snap-01234567890abcedf \
   --permanent-restore
```

The following is the command output.

```
{
   "SnapshotId": "snap-01234567890abcedf",
   "IsPermanentRestore": true
}
```

**View archived snapshots**

You can view storage tier information for snapshots using one of the following methods.

**Console**

**To view storage tier information for a snapshot**

Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

1. In the navigation pane, choose **Snapshots**.
2. In the list of snapshots, select the snapshot and choose the **Storage tier** tab.

The tab provides the following information:

- **Last tier change started on** — The date and time when the last archive or restore was started.
- **Tier change progress** — The progress of the last archive or restore action, as a percentage.
- **Storage tier** — The storage tier for the snapshot. Always **archive** for archived snapshots, and **standard** for snapshots stored on the standard tier, including temporarily restored snapshots.
- **Tiering status** — The status of the last archive or restore action.
- **Archive completed on** — The date and time when the archive completed.
- **Temporary restore expires on** — The date and time when a temporarily restored snapshot is set to expire.

**AWS CLI**

**To view archival information about an archived snapshot**

Use the `describe-snapshot-tier-status` AWS CLI command. Specify the `snapshot-id` filter, and for the filter value, specify the snapshot ID. Alternatively, to view all archived snapshots, omit the filter.

```
$ aws ec2 describe-snapshot-tier-status --filters "Name=snapshot-id, Values=snapshot_id"
```

The output includes the following response parameters:

- **Status** — The status of the snapshot. Always completed for archived snapshots. Only snapshots that are in the completed state can be archived.
- **LastTieringStartTime** — The date and time that the archival process started, in UTC time format (YYYY-MM-DDTHH:MM:SSZ).
- **LastTieringOperationState** — The current state of the archival process. Possible states include: archival-in-progress | archival-completed | archival-failed | permanent-restore-in-progress | permanent-restore-completed | permanent-restore-failed | temporary-restore-in-progress | temporary-restore-completed | temporary-restore-failed
- **LastTieringProgress** — The progress of the snapshot archival process, as a percentage.
- **StorageTier** — The storage tier for the snapshot. Always **archive** for archived snapshots, and **standard** for snapshots stored on the standard tier, including temporarily restored snapshots.
- **ArchivalCompleteTime** — The date and time that the archival process completed, in UTC time format (YYYY-MM-DDTHH:MM:SSZ).

**Example**

The following command displays information about snapshot `snap-01234567890abcedf`.

```
$ aws ec2 describe-snapshot-tier-status --filters "Name=snapshot-id, Values=snap-01234567890abcedf"
```

The following is the command output.

```json
{
   "SnapshotTierStatuses": [
   {
```

2150
To view archived and standard tier snapshots

Use the `describe-snapshot` AWS CLI command. For `--snapshot-ids`, specify the ID of the snapshot view.

```
$ aws ec2 describe-snapshots --snapshot-ids snapshot_id
```

For example, the following command displays information about snapshot `snap-01234567890abcedf`.

```
$ aws ec2 describe-snapshots --snapshot-ids snap-01234567890abcedf
```

The following is the command output. The `StorageTier` response parameter indicates whether the snapshot is currently archived. `archive` indicates that the snapshot is currently archived and stored in the archive tier, and `standard` indicates that the snapshot is currently not archived and that it is stored in the standard tier.

In the following example output, only Snap A is archived. Snap B and Snap C are not archived.

Additionally, the `RestoreExpiryTime` response parameter is returned only for snapshots that are temporarily restored from the archive. It indicates when temporarily restored snapshots are to be automatically removed from the standard tier. It is not returned for snapshots that are permanently restored.

In the following example output, Snap C is temporarily restored, and it will be automatically removed from the standard tier at 2021-09-19T21:00:00.000Z (September 19, 2021 at 21:00 UTC).
To view only snapshots that are stored in the archive tier or the standard tier

Use the `describe-snapshot` AWS CLI command. Include the `--filter` option, for the filter name, specify `storage-tier`, and for the filter value specify either `archive` or `standard`.

```
$ aws ec2 describe-snapshots --filters "Name=storage-tier,Values=archive,standard"
```

For example, the following command displays only archived snapshots.

```
$ aws ec2 describe-snapshots --filters "Name=storage-tier,Values=archive"
```

Monitor snapshot archiving

Amazon EBS emits events related to snapshot archiving actions. You can use AWS Lambda and Amazon CloudWatch Events to handle event notifications programmatically. Events are emitted on a best effort basis. For more information, see the Amazon CloudWatch Events User Guide.

The following events are available:

- `archiveSnapshot` — Emitted when a snapshot archive action succeeds or fails.

The following is an example of an event that is emitted when a snapshot archive action succeeds.

```
{
   "version": "0",
   "id": "01234567-0123-0123-0123-012345678901",
   "detail-type": "EBS Snapshot Notification",
   "source": "aws.ec2",
   "account": "123456789012",
   "time": "2021-05-25T13:12:22Z",
   "region": "us-east-1",
   "resources": [
      "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
   ],
}
The following is an example of an event that is emitted when a snapshot archive action fails.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "2021-05-25T13:12:22Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
    ],
    "detail": {
        "event": "archiveSnapshot",
        "result": "failed",
        "cause": "Source snapshot ID is not valid",
        "request-id": "1234567890",
        "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",
        "startTime": "2021-05-25T13:12:22Z",
        "endTime": "2021-05-45T15:30:00Z",
        "recycleBinExitTime": "2021-10-45T15:30:00Z"
    }
}
```

- **permanentRestoreSnapshot** — Emitted when a permanent restore action succeeds or fails.

The following is an example of an event that is emitted when a permanent restore action succeeds.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "2021-05-25T13:12:22Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
    ],
    "detail": {
        "event": "permanentRestoreSnapshot",
        "result": "succeeded",
        "cause": "",
        "request-id": "1234567890",
        "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",
        "startTime": "2021-05-25T13:12:22Z",
        "endTime": "2021-10-45T15:30:00Z"
    }
}
```

The following is an example of an event that is emitted when a permanent restore action fails.
• temporaryRestoreSnapshot — Emitted when a temporary restore action succeeds or fails.

The following is an example of an event that is emitted when a temporary restore action succeeds.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "2021-05-25T13:12:22Z",
    "region": "us-east-1",
    "resources": [
      "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
    ],
    "detail": {
      "event": "temporaryRestoreSnapshot",
      "result": "succeeded",
      "cause": "",
      "request-id": "1234567890",
      "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",
      "startTime": "2021-05-25T13:12:22Z",
      "endTime": "2021-05-4T15:30:00Z",
      "restoreExpiryTime": "2021-06-4T15:30:00Z",
      "recycleBinExitTime": "2021-10-4T15:30:00Z"
    }
}
```

The following is an example of an event that is emitted when a temporary restore action fails.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "2021-05-25T13:12:22Z",
    "region": "us-east-1",
    "resources": [
      "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
    ],
    "detail": {
      "event": "permanentRestoreSnapshot",
      "result": "failed",
      "cause": "Source snapshot ID is not valid",
      "request-id": "1234567890",
      "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",
      "startTime": "2021-05-25T13:12:22Z",
      "endTime": "2021-05-4T15:30:00Z",
      "recycleBinExitTime": "2021-10-4T15:30:00Z"
    }
}
```
• `restoreExpiry` — Emitted when the restore period for a temporarily restored snapshot expires.

The following is an example.

```
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Snapshot Notification",
  "source": "aws.ec2",
  "account": "123456789012",
  "time": "2021-05-25T13:12:22Z",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef"
  ],
  "detail": {
    "event": "restoreExpiry",
    "result": "succeeded",
    "cause": "",
    "request-id": "1234567890",
    "snapshot_id": "arn:aws:ec2:us-east-1::snapshot/snap-01234567890abcdef",
    "startTime": "2021-05-25T13:12:22Z",
    "endTime": "2021-05-45T15:30:00Z",
    "recycleBinExitTime": "2021-10-45T15:30:00Z"
  }
}
```

View Amazon EBS snapshot information

You can view detailed information about your snapshots using one of the following methods.

**Console**

*To view snapshot information using the console*

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Snapshots**.
3. To view only your snapshots that you own, in the top-left corner of the screen, choose **Owned by me**. You can also filter the list of snapshots using tags and other snapshot attributes. In the **Filter** field, select the attribute field, and then select or enter the attribute value. For example, to view only encrypted snapshots, select **Encryption**, and then enter `true`.
4. To view more information about a specific snapshot, choose its ID in the list.
AWS CLI

To view snapshot information using the AWS CLI

Use the `describe-snapshots` command.

**Example Example 1: Filter based on tags**

The following command describes the snapshots with the tag Stack=production.

```bash
aws ec2 describe-snapshots --filters Name=tag:Stack,Values=production
```

**Example Example 2: Filter based on volume**

The following command describes the snapshots created from the specified volume.

```bash
aws ec2 describe-snapshots --filters Name=volume-id,Values=vol-049df61146c4d7901
```

**Example Example 3: Filter based on snapshot age**

With the AWS CLI, you can use JMESPath to filter results using expressions. For example, the following command displays the IDs of all snapshots created by your AWS account (represented by `123456789012`) before the specified date (represented by `2020-03-31`). If you do not specify the owner, the results include all public snapshots.

```bash
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[?(StartTime<='2020-03-31')].[SnapshotId]" --output text
```

The following command displays the IDs of all snapshots created in the specified date range.

```bash
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[?(StartTime>='2019-01-01') && (StartTime<='2019-12-31')].[SnapshotId]" --output text
```

Tools for Windows PowerShell

To view snapshot information using the Tools for Windows PowerShell

Use the `Get-EC2Snapshot` command.

```powershell
PS C:\> Get-EC2Snapshot -SnapshotId snapshot_id
```

Share an Amazon EBS snapshot

You can modify the permissions of a snapshot if you want to share it with other AWS accounts. You can share snapshots publicly with all other AWS accounts, or you can share them privately with individual AWS accounts that you specify. Users that you have authorized can use the snapshots that you share to create their own EBS volumes, while your original snapshot remains unaffected.

**Important**

When you share a snapshot, you are giving others access to all of the data on the snapshot. Share snapshots only with people that you trust with all of your snapshot data.
To prevent the public sharing of snapshots, you can enable block public access for snapshots. For more information, see Block public access for snapshots (p. 2161).

Topics
- Before you share a snapshot (p. 2157)
- Share a snapshot (p. 2157)
- Share a KMS key (p. 2158)
- View snapshots that are shared with you (p. 2160)
- Use snapshots that are shared with you (p. 2160)
- Determine the use of snapshots that you share (p. 2161)

Before you share a snapshot

The following considerations apply to sharing snapshots:

- If block public access for snapshots is enabled for the Region, attempts to publicly share snapshots will be blocked. Snapshots can still be privately shared.
- Snapshots are constrained to the Region in which they were created. To share a snapshot with another Region, copy the snapshot to that Region and then share the copy. For more information, see Copy an Amazon EBS snapshot (p. 2128).
- You can't share snapshots that are encrypted with the default AWS managed key. You can only share snapshots that are encrypted with a customer managed key. For more information, see Creating Keys in the AWS Key Management Service Developer Guide.
- You can share only unencrypted snapshots publicly.
- When you share an encrypted snapshot, you must also share the customer managed key used to encrypt the snapshot. For more information, see Share a KMS key (p. 2158).

Share a snapshot

You can share a snapshot using one of the methods described in the section.

Console

To share a snapshot

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots.
3. Select the snapshot to share, and then choose Actions, Modify permissions.
4. Specify the snapshot's permissions. Current setting indicates the snapshot's current sharing permissions.
   - To share the snapshot publicly with all AWS accounts, choose Public.
   - To share the snapshot privately with specific AWS accounts, choose Private. Then, in the Sharing accounts section, choose Add account, and enter the 12-digit account ID (without hyphens) of the account to share with.
5. Choose Save changes.

AWS CLI

The permissions for a snapshot are specified using the createVolumePermission attribute of the snapshot. To make a snapshot public, set the group to all. To share a snapshot with a specific AWS account, set the user to the ID of the AWS account.
To share a snapshot publicly

Use the `modify-snapshot-attribute` command.

For `--attribute`, specify `createVolumePermission`. For `--operation-type`, specify `add`. For `--group-names`, specify `all`.

```
$ aws ec2 modify-snapshot-attribute --snapshot-id 1234567890abcdef0 --attribute createVolumePermission --operation-type add --group-names all
```

To share a snapshot privately

Use the `modify-snapshot-attribute` command.

For `--attribute`, specify `createVolumePermission`. For `--operation-type`, specify `add`. For `--user-ids`, specify the 12-digit IDs of the AWS accounts with which to share the snapshots.

```
$ aws ec2 modify-snapshot-attribute --snapshot-id 1234567890abcdef0 --attribute createVolumePermission --operation-type add --user-ids 123456789012
```

Tools for Windows PowerShell

The permissions for a snapshot are specified using the `createVolumePermission` attribute of the snapshot. To make a snapshot public, set the group to `all`. To share a snapshot with a specific AWS account, set the user to the ID of the AWS account.

To share a snapshot publicly

Use the `Edit-EC2SnapshotAttribute` command.

For `-Attribute`, specify `CreateVolumePermission`. For `-OperationType`, specify `Add`. For `-GroupName`, specify `all`.

```
PS C:\> Edit-EC2SnapshotAttribute -SnapshotId 1234567890abcdef0 -Attribute CreateVolumePermission -OperationType Add -GroupName all
```

To share a snapshot privately

Use the `Edit-EC2SnapshotAttribute` command.

For `-Attribute`, specify `CreateVolumePermission`. For `-OperationType`, specify `Add`. For `-UserId`, specify the 12-digit IDs of the AWS accounts with which to share the snapshots.

```
PS C:\> Edit-EC2SnapshotAttribute -SnapshotId 1234567890abcdef0 -Attribute CreateVolumePermission -OperationType Add -UserId 123456789012
```

Share a KMS key

When you share an encrypted snapshot, you must also share the customer managed key used to encrypt the snapshot. You can apply cross-account permissions to a customer managed key either when it is created or at a later time.

Users of your shared customer managed key who are accessing encrypted snapshots must be granted permissions to perform the following actions on the key:
EBS snapshots

- kms:DescribeKey
- kms:CreateGrant
- kms:GenerateDataKey
- kms:ReEncrypt
- kms:Decrypt

**Tip**

To follow the principle of least privilege, do not allow full access to kms:CreateGrant. Instead, use the kms:GrantIsForAWSResource condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service.

For more information about controlling access to a customer managed key, see [Using key policies in AWS KMS](https://docs.aws.amazon.com/kms/latest/developerguide/aws-kms-key-policies.html) in the AWS Key Management Service Developer Guide.

**To share customer managed key using the AWS KMS console**

2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. Choose **Customer managed keys** in the navigation pane.
4. In the **Alias** column, choose the alias (text link) of the customer managed key that you used to encrypt the snapshot. The key details open in a new page.
5. In the **Key policy** section, you see either the policy view or the default view. The policy view displays the key policy document. The default view displays sections for **Key administrators**, **Key deletion**, **Key Use**, and **Other AWS accounts**. The default view displays if you created the policy in the console and have not customized it. If the default view is not available, you'll need to manually edit the policy in the policy view. For more information, see [Viewing a Key Policy (Console)](https://docs.aws.amazon.com/kms/latest/developerguide/aws-kms-key-policies.html) in the AWS Key Management Service Developer Guide.

Use either the policy view or the default view, depending on which view you can access, to add one or more AWS account IDs to the policy, as follows:

- *(Policy view)* Choose **Edit**. Add one or more AWS account IDs to the following statements: "Allow use of the key" and "Allow attachment of persistent resources". Choose **Save changes**. In the following example, the AWS account ID 444455556666 is added to the policy.

```json
{
  "Sid": "Allow use of the key",
  "Effect": "Allow",
  "Principal": ["AWS": [
    "arn:aws:iam::111122223333:user/KeyUser",
    "arn:aws:iam::444455556666:root"
  ]],
  "Action": ["kms:Encrypt", "kms:Decrypt", "kms:ReEncrypt*", "kms:GenerateDataKey*", "kms:DescribeKey"],
  "Resource": "*"
},
{
  "Sid": "Allow attachment of persistent resources",
  "Effect": "Allow",
  "Principal": ["AWS": [
    "arn:aws:iam::111122223333:user/KeyUser",
```
View snapshots that are shared with you

You can view snapshots that are shared with you using one of the following methods.

Console

To view shared snapshots using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Snapshots.
3. Filter the listed snapshots. In the top-left corner of the screen, choose one of the following options:
   - Private snapshots — To view only snapshots that are shared with you privately.
   - Public snapshots — To view only snapshots that are shared with you publicly.

AWS CLI

To view snapshot permissions using the command line

Use the describe-snapshot-attribute command.

Tools for Windows PowerShell

To view snapshot permissions using the command line

Use the Get-EC2SnapshotAttribute command.

Use snapshots that are shared with you

To use a shared unencrypted snapshot

Locate the shared snapshot by ID or description. For more information, see View snapshots that are shared with you (p. 2160). You can use this snapshot as you would any other snapshot that you own in your account. For example, you can create a volume from the snapshot or copy it to a different Region.

To use a shared encrypted snapshot

Locate the shared snapshot by ID or description. For more information, see View snapshots that are shared with you (p. 2160). Create a copy of the shared snapshot in your account, and encrypt the copy with a KMS key that you own. You can then use the copy to create volumes or you can copy it to different Regions.
Determine the use of snapshots that you share

You can use AWS CloudTrail to monitor whether a snapshot that you have shared with others is copied or used to create a volume. The following events are logged in CloudTrail:

- **SharedSnapshotCopyInitiated** — A shared snapshot is being copied.
- **SharedSnapshotVolumeCreated** — A shared snapshot is being used to create a volume.

For more information about using CloudTrail, see Log Amazon EC2 and Amazon EBS API calls with AWS CloudTrail (p. 1339).

Block public access for snapshots

To prevent public sharing of your snapshots, you can enable *block public access for snapshots*. After you enable block public access for snapshots in a Region, any attempt to publicly share snapshots in that Region is automatically blocked. This can help you to improve the security of your snapshots and to protect your snapshot data from unauthorized or unintended access.

Block public access for snapshots can be enabled in one of two modes:

- **Block all sharing** — Blocks all public sharing of your snapshots. Users in the account can’t request new public sharing. Additionally, snapshots that were already publicly shared are treated as private and are no longer publicly available.
- **Block new sharing** — Blocks only new public sharing of your snapshots. Users in the account can’t request new public sharing. However, snapshots that were already publicly shared, remain publicly available.

Pricing

Block public access for snapshots can be enabled at no additional cost.

Contents

- Considerations (p. 2161)
- IAM permissions (p. 2162)
- Enable block public access for snapshots (p. 2163)
  - Configure block public access for snapshots (p. 2163)
  - View the setting for block public access for snapshots (p. 2164)
  - Disable block public access for snapshots (p. 2164)
- Monitor block public access for snapshots using Amazon EventBridge (p. 2165)

Considerations

- Block public access for snapshots does not prevent private snapshot sharing.
- If you enable block public access for snapshots in *block all sharing* mode, it does not change the permissions for snapshots that are already publicly shared. Instead, it prevents these snapshots from being publicly visible and publicly accessible. Therefore, the attributes for these snapshots still indicate that they are publicly shared, even though they are not publicly available.
- If block public access for snapshots is enabled in *block all sharing* mode, and you change the mode to *block new sharing*, or you disable block public access, all snapshots that were previously publicly shared are no longer treated as private and they become publicly accessible again.
- Block public access for snapshots is a Regional setting. It applies to all snapshots in the Region in which it is enabled. You need to enable block public access for snapshots in each Region in which you want to prevent the public sharing of your snapshots.
Block public access is an account-level setting. It applies to all users, including administrator users, in the account. You can't enable block public access for snapshots at the organization level.

Block public access for snapshots does not prevent the public sharing of EBS-backed AMIs. If you enable block public access for snapshots, users can still publicly share EBS-backed AMIs. If an EBS-backed AMI is publicly shared, users with access to that AMI can create volumes from its associated snapshots. To prevent public sharing of your AMIs, enable block public access for AMIs (p. 151).

Block public access for snapshots is not supported with local snapshots on AWS Outposts.

IAM permissions

By default, users don't have permission to work with block public access for snapshots. To allow users to work with block public access for snapshots, you must create IAM policies that grant permission to use specific API actions. Once the policies are created, you must add permissions to your users, groups, or roles.

To work with block public access for snapshots, users need the following permissions.

- ec2:EnableSnapshotBlockPublicAccess — Enable block public access for snapshots and modify the mode.
- ec2:DisableSnapshotBlockPublicAccess — Disable block public access for snapshots.
- ec2:GetSnapshotBlockPublicAccessState — View the block public access for snapshots setting for a Region.

The following is an example IAM policy. If some permissions are not needed, you can remove them from the policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [{
        "Effect": "Allow",
        "Action": [
            "ec2:EnableSnapshotBlockPublicAccess",
            "ec2:DisableSnapshotBlockPublicAccess",
            "ec2:GetSnapshotBlockPublicAccessState"
        ],
        "Resource": "*"
    }]
}
```

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

  Create a permission set. Follow the instructions in [Create a permission set](#) in the [AWS IAM Identity Center User Guide](#).

- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider (federation)](#) in the [IAM User Guide](#).

- IAM users:

  - Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the [IAM User Guide](#).
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user (console)](#) in the [IAM User Guide](#).
Enable block public access for snapshots

Use the following procedures to configure and monitor block public access for snapshots.

Tasks

- Configure block public access for snapshots (p. 2163)
- View the setting for block public access for snapshots (p. 2164)
- Disable block public access for snapshots (p. 2164)

Configure block public access for snapshots

Enable block public access for snapshots to prevent the public sharing of snapshots in the Region. After this feature is enabled, requests to publicly share snapshots in the Region are blocked.

**Important**

If block public access for snapshots is enabled in **block all sharing** mode, and you change the mode to **block new sharing**, all snapshots that were previously publicly shared are no longer treated as private and they become publicly accessible again.

Console

**To configure block public access for snapshots**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **EC2 Dashboard**, and then in **Account attributes** (on the right-hand side), choose **Data protection and security**.
3. In the **Block public access for EBS snapshots** section, choose **Manage**.
4. Select **Block public access** and then choose one of the following options:

   - **Block all public access** — To block all public sharing of your snapshots. Users in the account can't request new public sharing. Additionally, snapshots that were already publicly shared are treated as private and are no longer publicly available.
   - **Block new public sharing** — To block only new public sharing of your snapshots. Users in the account can't request new public sharing. However, snapshots that were already publicly shared, remain publicly available.
5. Choose **Update**.

AWS CLI

**To enable or modify block public access for snapshots**

Use the `enable-snapshot-block-public-access` command. For `--state` specify one of the following values:

- `block-all-sharing` — To block all public sharing of your snapshots. Users in the account can't request new public sharing. Additionally, snapshots that were already publicly shared are treated as private and are no longer publicly available.
- `block-new-sharing` — To block only new public sharing of your snapshots. Users in the account can't request new public sharing. However, snapshots that were already publicly shared, remain publicly available.

```
aws ec2 enable-snapshot-block-public-access --state block-all-sharing|block-new-sharing
```
View the setting for block public access for snapshots

Block public access can be in one of the following states for each Region in your account.

- **Block all sharing** — All public sharing of your snapshots is blocked. Users in the account can’t request new public sharing. Additionally, snapshots that were already publicly shared are treated as private and are not publicly available.
- **Block new sharing** — Only new public sharing of your snapshots is blocked. Users in the account can’t request new public sharing. However, snapshots that were already publicly shared, remain publicly available.
- **Unblocked** — Public sharing is not blocked. Users can publicly share snapshots.

Console

**To view the setting for block public access for snapshots**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **EC2 Dashboard**, and then in **Account attributes** (on the right-hand side), choose **Data protection and security**.
3. The **Block public access for EBS snapshots** section shows the current setting.

AWS CLI

**To view the setting for block public access for snapshots**

Use the `get-snapshot-block-public-access-state` command.

```
aws ec2 get-snapshot-block-public-access-state
```

Disable block public access for snapshots

Disable block public access for snapshots to allow public sharing of snapshots in the Region. After this feature is disabled, users can publicly share snapshots in the Region.

**Important**

If block public access for snapshots is enabled in **block all sharing** mode, and you disable block public access, all snapshots that were previously publicly shared are no longer treated as private and they become publicly accessible again.

Console

**To disable block public access for snapshots**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **EC2 Dashboard**, and then in **Account attributes** (on the right-hand side), choose **Data protection and security**.
3. In the **Block public access for EBS snapshots** section, choose **Manage**.
4. Clear **Block public access** and choose **Update**.

AWS CLI

**To disable block public access for snapshots**

```
aws ec2 set-snapshot-block-public-access
```
Use the `disable-snapshot-block-public-access` command.

```bash
aws ec2 disable-snapshot-block-public-access
```

**Monitor block public access for snapshots using Amazon EventBridge**

Amazon EBS emits events related to block public access for snapshots. You can use AWS Lambda and Amazon EventBridge to handle event notifications programmatically. Events are emitted on a best effort basis. For more information, see the [Amazon EventBridge User Guide](https://docs.aws.amazon.com/AmazonEventBridge/latest/userguide REGARDING BLOCKING PUBLIC ACCESS FOR SNAPSHOTS/).

The following events are emitted:

- **Enable block public access for snapshots in block all sharing mode**

  ```json
  
  {  
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Snapshot Block Public Access Enabled",
  "source": "aws.ec2",
  "account": "123456789012",
  "time": "2019-05-31T21:49:54Z",
  "region": "us-east-1",
  "detail": {  
  "SnapshotBlockPublicAccessState": "block-all-sharing",
  "message": "Block Public Access was successfully enabled in 'block-all-sharing' mode"
  }
  }
  ```

- **Enable block public access for snapshots in block new sharing mode**

  ```json
  
  {  
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Snapshot Block Public Access Enabled",
  "source": "aws.ec2",
  "account": "123456789012",
  "time": "2019-05-31T21:49:54Z",
  "region": "us-east-1",
  "detail": {  
  "SnapshotBlockPublicAccessState": "block-new-sharing",
  "message": "Block Public Access was successfully enabled in 'block-new-sharing' mode"
  }
  }
  ```

- **Disable block public access for snapshots**

  ```json
  
  {  
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Snapshot Block Public Access Disabled",
  "source": "aws.ec2",
  "account": "123456789012",
  "time": "2019-05-31T21:49:54Z",
  "region": "us-east-1",
  "detail": {  
  "SnapshotBlockPublicAccessState": "unblocked",
  "message": "Block Public Access was successfully disabled"
  }
  }
  ```
Recover snapshots from the Recycle Bin

Recover snapshots from the Recycle Bin is a data recovery feature that enables you to restore accidentally deleted Amazon EBS snapshots and EBS-backed AMIs. When using Recover Bin, if your resources are deleted, they are retained in the Recycle Bin for a time period that you specify before being permanently deleted.

You can restore a resource from the Recycle Bin at any time before its retention period expires. After you restore a resource from the Recycle Bin, the resource is removed from the Recycle Bin and you can use it in the same way that you use any other resource of that type in your account. If the retention period expires and the resource is not restored, the resource is permanently deleted from the Recycle Bin and it is no longer available for recovery.

Snapshots in the Recycle Bin are billed at the same rate as regular snapshots in your account. There are no additional charges for using Recycle Bin and retention rules. For more information, see Amazon EBS pricing.

For more information, see Recycle Bin (p. 2467).

Topics

- Permissions for working with snapshots in the Recycle Bin (p. 2166)
- View snapshots in the Recycle Bin (p. 2167)
- Restore snapshots from the Recycle Bin (p. 2168)

Permissions for working with snapshots in the Recycle Bin

By default, users don't have permission to work with snapshots that are in the Recycle Bin. To allow users to work with these resources, you must create IAM policies that grant permission to use specific resources and API actions. Once the policies are created, you must add permissions to your users, groups, or roles.

To view and recover snapshots that are in the Recycle Bin, users must have the following permissions:

- ec2:ListSnapshotsInRecycleBin
- ec2:RestoreSnapshotFromRecycleBin

To manage tags for snapshots in the Recycle Bin, users need the following additional permissions.

- ec2:CreateTags
- ec2:DeleteTags

To use the Recycle Bin console, users need the ec2:DescribeTags permission.

The following is an example IAM policy. It includes the ec2:DescribeTags permission for console users, and it includes the ec2:CreateTags and ec2:DeleteTags permissions for managing tags. If the permissions are not needed, you can remove them from the policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:ListSnapshotsInRecycleBin",
        "ec2:RestoreSnapshotFromRecycleBin"
      ],
      "Resource": "*"
    }
  ]
}
```
To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:

  Create a permission set. Follow the instructions in Create a permission set in the AWS IAM Identity Center User Guide.

- Users managed in IAM through an identity provider:

  Create a role for identity federation. Follow the instructions in Creating a role for a third-party identity provider (federation) in the IAM User Guide.

- IAM users:

  - Create a role that your user can assume. Follow the instructions in Creating a role for an IAM user in the IAM User Guide.
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in Adding permissions to a user (console) in the IAM User Guide.

For more information about the permissions needed to use Recycle Bin, see Permissions for working with Recycle Bin and retention rules (p. 2472).

View snapshots in the Recycle Bin

While a snapshot is in the Recycle Bin, you can view limited information about it, including:

- The ID of the snapshot.
- The snapshot description.
- The ID of the volume from which the snapshot was created.
- The date and time when the snapshot was deleted and it entered Recycle Bin.
- The date and time when the retention period expires. The snapshot will be permanently deleted from the Recycle Bin at this time.

You can view the snapshots in the Recycle Bin using one of the following methods.

Recycle Bin console

To view snapshots in the Recycle Bin using the console

1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation pane, choose Recycle Bin.
3. The grid lists all of the snapshots that are currently in the Recycle Bin. To view the details for a specific snapshot, select it in the grid and choose Actions, View details.
AWS CLI

To view snapshots in the Recycle Bin using the AWS CLI

Use the `list-snapshots-in-recycle-bin` AWS CLI command. Include the `--snapshot-id` option to view a specific snapshot. Or omit the `--snapshot-id` option to view all snapshots in the Recycle Bin.

```bash
$ aws ec2 list-snapshots-in-recycle-bin --snapshot-id snapshot_id
```

For example, the following command provides information about snapshot snap-01234567890abcdef in the Recycle Bin.

```bash
$ aws ec2 list-snapshots-in-recycle-bin --snapshot-id snap-01234567890abcdef
```

Example output:

```json
{
   "SnapshotRecycleBinInfo": [
   {
      "Description": "Monthly data backup snapshot",
      "RecycleBinEnterTime": "2021-12-01T13:00:00.000Z",
      "RecycleBinExitTime": "2021-12-15T13:00:00.000Z",
      "VolumeId": "vol-abcd1ef09876543210",
      "SnapshotId": "snap-01234567890abcdef"
   }
   ]
}
```

Restore snapshots from the Recycle Bin

You can't use a snapshot in any way while it is in the Recycle Bin. To use the snapshot, you must first restore it. When you restore a snapshot from the Recycle Bin, the snapshot is immediately available for use, and it is removed from the Recycle Bin. You can use a restored snapshot in the same way that you use any other snapshot in your account.

You can restore a snapshot from the Recycle Bin using one of the following methods.

Recycle Bin console

To restore a snapshot from the Recycle Bin using the console

1. Open the Recycle Bin console at `https://console.aws.amazon.com/rbin/home/`
2. In the navigation pane, choose Recycle Bin.
3. The grid lists all of the snapshots that are currently in the Recycle Bin. Select the snapshot to restore and and choose Recover.
4. When prompted, choose Recover.

AWS CLI

To restore a deleted snapshot from the Recycle Bin using the AWS CLI

Use the `restore-snapshot-from-recycle-bin` AWS CLI command. For `--snapshot-id`, specify the ID of the snapshot to restore.

```bash
$ aws ec2 restore-snapshot-from-recycle-bin --snapshot-id snapshot_id
```
For example, the following command restores snapshot snap-01234567890abcdef from the Recycle Bin.

```
$ aws ec2 restore-snapshot-from-recycle-bin --snapshot-id snap-01234567890abcdef
```

Example output:

```
{
    "SnapshotId": "snap-01234567890abcdef",
    "Description": "Monthly data backup snapshot",
    "Encrypted": false,
    "OwnerId": "111122223333",
    "Progress": "100%",
    "StartTime": "2021-12-01T13:00:00.000000+00:00",
    "State": "recovering",
    "VolumeId": "vol-ffffffff",
    "VolumeSize": 30
}
```

Amazon EBS local snapshots on Outposts

Amazon EBS snapshots are a point-in-time copy of your EBS volumes.

By default, snapshots of EBS volumes on an Outpost are stored in Amazon S3 in the Region of the Outpost. You can also use Amazon EBS local snapshots on Outposts to store snapshots of volumes on an Outpost locally in Amazon S3 on the Outpost itself. This ensures that the snapshot data resides on the Outpost, and on your premises. In addition, you can use AWS Identity and Access Management (IAM) policies and permissions to set up data residency enforcement policies to ensure that snapshot data does not leave the Outpost. This is especially useful if you reside in a country or region that is not yet served by an AWS Region and that has data residency requirements.

This topic provides information about working with Amazon EBS local snapshots on Outposts. For more information about Amazon EBS snapshots and about working with snapshots in an AWS Region, see Amazon EBS snapshots (p. 2107).

For more information about AWS Outposts, see AWS Outposts Features and the AWS Outposts User Guide. For pricing information, see AWS Outposts pricing.

Topics

- Frequently asked questions (p. 2169)
- Prerequisites (p. 2171)
- Considerations (p. 478)
- Controlling access with IAM (p. 2171)
- Working with local snapshots (p. 2173)

Frequently asked questions

1. What are local snapshots?

   By default, Amazon EBS snapshots of volumes on an Outpost are stored in Amazon S3 in the Region of the Outpost. If the Outpost is provisioned with Amazon S3 on Outposts, you can choose to store the snapshots locally on the Outpost itself. Local snapshots are incremental, which means that only the blocks of the volume that have changed after your most recent snapshot are saved. You can use these snapshots to restore a volume on the same Outpost as the snapshot at any time. For more information about Amazon EBS snapshots, see Amazon EBS snapshots (p. 2107).
2. Why should I use local snapshots?

Snapshots are a convenient way of backing up your data. With local snapshots, all of your snapshot
data is stored locally on the Outpost. This means that it does not leave your premises. This is
especially useful if you reside in a country or region that is not yet served by an AWS Region and that
has residency requirements.

Additionally, using local snapshots can help to reduce the bandwidth used for communication
between the Region and the Outpost in bandwidth constrained environments.

3. How do I enforce snapshot data residency on Outposts?

You can use AWS Identity and Access Management (IAM) policies to control the permissions that
principals (AWS accounts, IAM users, and IAM roles) have when working with local snapshots and
to enforce data residency. You can create a policy that prevents principals from creating snapshots
from Outpost volumes and instances and storing the snapshots in an AWS Region. Currently, copying
snapshots and images from an Outpost to a Region is not supported. For more information, see
Controlling access with IAM (p. 2171).

4. Are multi-volume, crash-consistent local snapshots supported?

Yes, you can create multi-volume, crash-consistent local snapshots from instances on an Outpost.

5. How do I create local snapshots?

You can create snapshots manually using the AWS Command Line Interface (AWS CLI) or the
Amazon EC2 console. For more information see, Working with local snapshots (p. 2173). You can
also automate the lifecycle of local snapshots using Amazon Data Lifecycle Manager. For more
information see, Automate snapshots on an Outpost (p. 2178).

6. Can I create, use, or delete local snapshots if my Outpost loses connectivity to its Region?

No. The Outpost must have connectivity with its Region as the Region provides the access,
authorization, logging, and monitoring services that are critical for your snapshots' health. If there
is no connectivity, you can't create new local snapshots, create volumes or launch instances from
existing local snapshots, or delete local snapshots.

7. How quickly is Amazon S3 storage capacity made available after deleting local snapshots?

Amazon S3 storage capacity becomes available within 72 hours after deleting local snapshots and
the volumes that reference them.

8. How can I ensure that I do not run out of Amazon S3 capacity on my Outpost?

We recommend that you use Amazon CloudWatch alarms to monitor your Amazon S3 storage
capacity, and delete snapshots and volumes that you no longer need to avoid running out of
storage capacity. If you are using Amazon Data Lifecycle Manager to automate the lifecycle of local
snapshots, ensure that your snapshot retention policies do not retain snapshots for longer than is
needed.

9. What happens if I run out of local Amazon S3 capacity on my Outposts?

If you run out of local Amazon S3 capacity on your Outposts, Amazon Data Lifecycle Manager
will not be able to successfully create local snapshots on the Outposts. Amazon Data Lifecycle
Manager will attempt to create the local snapshots on the Outposts, but the snapshots immediately
transition to the error state and they are eventually deleted by Amazon Data Lifecycle Manager.
We recommend that you use the SnapshotsCreateFailed Amazon CloudWatch metric to monitor
your snapshot lifecycle policies for snapshot creation failures. For more information, see Monitor
your policies using Amazon CloudWatch (p. 2295).

10. Can I use local snapshots and AMIs backed by local snapshots with Spot Instances and Spot Fleet?

No, you can't use local snapshots or AMIs backed by local snapshots to launch Spot Instances or a
Spot Fleet.
11. Can I use local snapshots and AMIs backed by local snapshots with Amazon EC2 Auto Scaling?

Yes, you can use local snapshots and AMIs backed by local snapshots to launch Auto Scaling groups in a subnet that is on the same Outpost as the snapshots. The Amazon EC2 Auto Scaling group service-linked role must have permission to use the KMS key used to encrypt the snapshots.

You can't use local snapshots or AMIs backed by local snapshots to launch Auto Scaling groups in an AWS Region.

Prerequisites

To store snapshots on an Outpost, you must have an Outpost that is provisioned with Amazon S3 on Outposts. For more information about Amazon S3 on Outposts, see Using Amazon S3 on Outposts in the Amazon Simple Storage Service User Guide.

Considerations

Keep the following in mind when working with local snapshots.

- Outposts must have connectivity to their AWS Region to use local snapshots.
- Snapshot metadata is stored in the AWS Region associated with the Outpost. This does not include any snapshot data.
- Snapshots stored on Outposts are encrypted by default. Unencrypted snapshots are not supported. Snapshots that are created on an Outpost and snapshots that are copied to an Outpost are encrypted using the default KMS key for the Region or a different KMS key that you specify at the time of the request.
- When you create a volume on an Outpost from a local snapshot, you cannot re-encrypt the volume using a different KMS key. Volumes created from local snapshots must be encrypted using the same KMS key as the source snapshot.
- After you delete local snapshots from an Outpost, the Amazon S3 storage capacity used by the deleted snapshots becomes available within 72 hours. For more information, see Delete local snapshots (p. 2178).
- You can't export local snapshots from an Outpost.
- You can't enable fast snapshot restore for local snapshots.
- EBS direct APIs are not supported with local snapshots.
- You can't copy local snapshots or AMIs from an Outpost to an AWS Region, from one Outpost to another, or within an Outpost. However, you can copy snapshots from an AWS Region to an Outpost. For more information, see Copy snapshots from an AWS Region to an Outpost (p. 2176).
- When copying a snapshot from an AWS Region to an Outpost, the data is transferred over the service link. Copying multiple snapshots simultaneously could impact other services running on the Outpost.
- You can't share local snapshots.
- You must use IAM policies to ensure that your data residency requirements are met. For more information, see Controlling access with IAM (p. 2171).
- Local snapshots are incremental backups. Only the blocks in the volume that have changed after your most recent snapshot are saved. Each local snapshot contains all of the information that is needed to restore your data (from the moment when the snapshot was taken) to a new EBS volume. For more information, see How snapshots work (p. 2109).
- You can't use IAM policies to enforce data residency for CopySnapshot and CopyImage actions.

Controlling access with IAM

You can use AWS Identity and Access Management (IAM) policies to control the permissions that principals (AWS accounts, IAM users, and IAM roles) have when working with local snapshots. The
following are example policies that you can use to grant or deny permission to perform specific actions with local snapshots.

Important
Copying snapshots and images from an Outpost to a Region is currently not supported. As a result, you currently can't use IAM policies to enforce data residency for CopySnapshot and CopyImage actions.

Topics
- Enforce data residency for snapshots (p. 2172)
- Prevent principals from deleting local snapshots (p. 2172)

Enforce data residency for snapshots

The following example policy prevents all principals from creating snapshots from volumes and instances on Outpost arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef and storing the snapshot data in an AWS Region. Principals can still create local snapshots. This policy ensures that all snapshots remain on the Outpost.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": [
        "ec2:CreateSnapshot",
        "ec2:CreateSnapshots"
      ],
      "Resource": "arn:aws:ec2:us-east-1::snapshot/*",
      "Condition": {
        "StringEquals": {
          "ec2:SourceOutpostArn": "arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef"
        },
        "Null": {
          "ec2:OutpostArn": "true"
        }
      }
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CreateSnapshot",
        "ec2:CreateSnapshots"
      ],
      "Resource": "*"
    }
  ]
}
```

Prevent principals from deleting local snapshots

The following example policy prevents all principals from deleting local snapshots that are stored on Outpost arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": [
        "ec2:DeleteSnapshot",
        "ec2:DeleteSnapshots"
      ],
      "Resource": "arn:aws:ec2:us-east-1::snapshot/*",
      "Condition": {
        "StringEquals": {
          "ec2:SourceOutpostArn": "arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef"
        },
        "Null": {
          "ec2:OutpostArn": "true"
        }
      }
    }
  ]
}
```
Working with local snapshots

The following sections explain how to use local snapshots.

Topics
- Rules for storing snapshots (p. 2173)
- Create local snapshots from volumes on an Outpost (p. 2174)
- Create multi-volume local snapshots from instances on an Outpost (p. 2174)
- Create AMIs from local snapshots (p. 2175)
- Copy snapshots from an AWS Region to an Outpost (p. 2176)
- Copy AMIs from an AWS Region to an Outpost (p. 2177)
- Create volumes from local snapshots (p. 2178)
- Launch instances from AMIs backed by local snapshots (p. 283)
- Delete local snapshots (p. 2178)
- Automate snapshots on an Outpost (p. 2178)

Rules for storing snapshots

The following rules apply to snapshot storage:

- If the most recent snapshot of a volume is stored on an Outpost, then all successive snapshots must be stored on the same Outpost.
- If the most recent snapshot of a volume is stored in an AWS Region, then all successive snapshots must be stored in the same Region. To start creating local snapshots from that volume, do the following:
  1. Create a snapshot of the volume in the AWS Region.
  2. Copy the snapshot to the Outpost from the AWS Region.
  3. Create a new volume from the local snapshot.
  4. Attach the volume to an instance on the Outpost.

For the new volume on the Outpost, the next snapshot can be stored on the Outpost or in the AWS Region. All successive snapshots must then be stored in that same location.

- Local snapshots, including snapshots created on an Outpost and snapshots copied to an Outpost from an AWS Region, can be used only to create volumes on the same Outpost.
• If you create a volume on an Outpost from a snapshot in a Region, then all successive snapshots of that new volume must be in the same Region.

• If you create a volume on an Outpost from a local snapshot, then all successive snapshots of that new volume must be on the same Outpost.

Create local snapshots from volumes on an Outpost

You can create local snapshots from volumes on your Outpost. You can choose to store the snapshots on the same Outpost as the source volume, or in the Region for the Outpost.

Local snapshots can be used to create volumes on the same Outpost only.

You can create local snapshots from volumes on an Outpost using one of the following methods.

Console

**To create local snapshots from volumes on an Outpost**

Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

1. In the navigation pane, choose Volumes.
2. Select the volume on the Outpost, and choose Actions, Create Snapshot.
3. (Optional) For Description, enter a brief description for the snapshot.
4. For Snapshot destination, choose AWS Outpost. The snapshot will be created on the same Outpost as the source volume. The Outpost ARN field shows the Amazon Resource Name (ARN) of the destination Outpost.
5. (Optional) Choose Add Tag to add tags to your snapshot. For each tag, provide a tag key and a tag value.
6. Choose Create Snapshot.

Command line

**To create local snapshots from volumes on an Outpost**

Use the `create-snapshot` command. Specify the ID of the volume from which to create the snapshot, and the ARN of the destination Outpost on which to store the snapshot. If you omit the Outpost ARN, the snapshot is stored in the AWS Region for the Outpost.

For example, the following command creates a local snapshot of volume `vol-1234567890abcdef0`, and stores the snapshot on Outpost `arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0`.

```
$ aws ec2 create-snapshot --volume-id vol-1234567890abcdef0 --outpost-arn arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0 --description "single volume local snapshot"
```

Create multi-volume local snapshots from instances on an Outpost

You can create crash-consistent multi-volume local snapshots from instances on your Outpost. You can choose to store the snapshots on the same Outpost as the source instance, or in the Region for the Outpost.

Multi-volume local snapshots can be used to create volumes on the same Outpost only.
You can create multi-volume local snapshots from instances on an Outpost using one of the following methods.

**Console**

**To create multi-volume local snapshots from instances on an Outpost**

Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

1. In the navigation pane, choose **Snapshots**.
2. Choose **Create Snapshot**.
3. For **Select resource type**, choose **Instance**.
4. For **Instance ID**, select the instance on the Outpost from which to create the snapshots.
5. (Optional) For **Description**, enter a brief description for the snapshots.
6. For **Snapshot destination**, choose **AWS Outpost**. The snapshots will be created on the same Outpost as the source instance. The **Outpost ARN** shows the ARN of the destination Outpost.
7. To exclude the instance's root volume from the multi-volume snapshot set, select **Exclude root volume**. If you do this, Amazon EBS will not create a snapshot of the instance's root volume.
8. To exclude specific data volumes from the multi-volume snapshot set, select **Exclude specific data volumes**. The **Attached data volumes** section lists all of the data volumes that are currently attached to the selected instance.
   
   In the **Attached data volumes** section, deselect the data volumes to exclude from the multi-volume snapshot set. Only the volumes that remain selected will be included in the multi-volume snapshot set.
9. (Optional) To automatically copy tags from the source volumes to the corresponding snapshots, for **Copy tags from source volume**, select **Copy tags**. This sets snapshot metadata—such as access policies, attachment information, and cost allocation—to match the source volume.
10. (Optional) To assign additional custom tags to the snapshots, in the **Tags** section, choose **Add tag**, and then enter the key-value pair. You can add up to 50 tags.
11. Choose **Create Snapshot**.

   During snapshot creation, the snapshots are managed together. If one of the snapshots in the volume set fails, the other snapshots in the volume set are moved to error status.

**Command line**

**To create multi-volume local snapshots from instances on an Outpost**

Use the `create-snapshots` command. Specify the ID of the instance from which to create the snapshots, and the ARN of the destination Outpost on which to store the snapshots. If you omit the Outpost ARN, the snapshots are stored in the AWS Region for the Outpost.

For example, the following command creates snapshots of the volumes attached to instance i-1234567890abcdef0 and stores the snapshots on Outpost arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0.

```
$ aws ec2 create-snapshots --instance-specification InstanceId=i-1234567890abcdef0 --outpost-arn arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0 --description "multi-volume local snapshots"
```

**Create AMIs from local snapshots**

You can create Amazon Machine Images (AMIs) using a combination of local snapshots and snapshots that are stored in the Region of the Outpost. For example, if you have an Outpost in us-east-1, you can
create an AMI with data volumes that are backed by local snapshots on that Outpost, and a root volume that is backed by a snapshot in the us-east-1 Region.

**Note**

- You can't create AMIs that include backing snapshots stored across multiple Outposts.
- You can't currently create AMIs directly from instances on an Outposts using `CreateImage` API or the Amazon EC2 console for Outposts that are enabled with Amazon S3 on Outposts.
- AMIs that are backed by local snapshots can be used to launch instances on the same Outpost only.

**To create an AMI on an Outpost from snapshots in a Region**

1. Copy the snapshots from the Region to the Outpost. For more information, see [Copy snapshots from an AWS Region to an Outpost](p. 2176).
2. Use the Amazon EC2 console or the `register-image` command to create the AMI using the snapshot copies on the Outpost. For more information, see [Creating an AMI from a snapshot](p. 2176).

**To create an AMI on an Outpost from an instance on an Outpost**

1. Create snapshots from the instance on the Outpost and store the snapshots on the Outpost. For more information, see [Create multi-volume local snapshots from instances on an Outpost](p. 2174).
2. Use the Amazon EC2 console or the `register-image` command to create the AMI using the local snapshots. For more information, see [Creating an AMI from a snapshot](p. 2176).

**To create an AMI in a Region from an instance on an Outpost**

1. Create snapshots from the instance on the Outpost and store the snapshots in the Region. For more information, see [Create local snapshots from volumes on an Outpost](p. 2174) or [Create multi-volume local snapshots from instances on an Outpost](p. 2174).
2. Use the Amazon EC2 console or the `register-image` command to create the AMI using the snapshot copies in the Region. For more information, see [Creating an AMI from a snapshot](p. 2176).

**Copy snapshots from an AWS Region to an Outpost**

You can copy snapshots from an AWS Region to an Outpost. You can do this only if the snapshots are in the Region for the Outpost. If the snapshots are in a different Region, you must first copy the snapshot to the Region for the Outpost, and then copy it from that Region to the Outpost.

**Note**

You can't copy local snapshots from an Outpost to a Region, from one Outpost to another, or within the same Outpost.

You can copy snapshots from a Region to an Outpost using one of the following methods.

**Console**

**To copy a snapshot from an AWS Region to an Outpost**

Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).

1. In the navigation pane, choose **Snapshots**.
2. Select the snapshot in the Region, and choose **Actions, Copy**.
3. For **Destination Region**, choose the Region for the destination Outpost.
4. For **Snapshot Destination**, choose **AWS Outpost**.

   The **Snapshot Destination** field only appears if you have Outposts in the selected destination Region. If the field does not appear, you do not have any Outposts in the selected destination Region.

5. For **Destination Outpost ARN**, enter the ARN of the Outpost to which to copy the snapshot.

6. (Optional) For **Description**, enter a brief description of the copied snapshot.

7. Encryption is enabled by default for the snapshot copy. Encryption cannot be disabled. For **KMS key**, choose the KMS key to use.

8. Choose **Copy**.

**Command line**

**To copy a snapshot from a Region to an Outpost**

Use the `copy-snapshot` command. Specify the ID of the snapshot to copy, the Region from which to copy the snapshot, and the ARN of the destination Outpost.

For example, the following command copies snapshot `snap-1234567890abcdef0` from the `us-east-1` Region to Outpost `arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0`.

```
$ aws ec2 copy-snapshot --source-region us-east-1 --source-snapshot-id snap-1234567890abcdef0 --destination-outpost-arn arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0 --description "Local snapshot copy"
```

**Copy AMIs from an AWS Region to an Outpost**

You can copy AMIs from an AWS Region to an Outpost. When you copy an AMI from a Region to an Outpost, all of the snapshots associated with the AMI are copied from the Region to the Outpost.

You can copy an AMI from a Region to an Outpost only if the snapshots associated with the AMI are in the Region for the Outpost. If the snapshots are in a different Region, you must first copy the AMI to the Region for the Outpost, and then copy it from that Region to the Outpost.

**Note**

You can’t copy an AMI from an Outpost to a Region, from one Outpost to another, or within an Outpost.

You can copy AMIs from a Region to an Outpost using the AWS CLI only.

**Command line**

**To copy an AMI from a Region to an Outpost**

Use the `copy-image` command. Specify the ID of the AMI to copy, the source Region, and the ARN of the destination Outpost.

For example, the following command copies AMI `ami-1234567890abcdef0` from the `us-east-1` Region to Outpost `arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0`.

```
$ aws ec2 copy-image --source-region us-east-1 --source-image-id ami-1234567890abcdef0 --name "Local AMI copy" --destination-outpost-arn arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0
```
Create volumes from local snapshots

You can create volumes on Outposts from local snapshots. Volumes must be created on the same Outpost as the source snapshots. You cannot use local snapshots to create volumes in the Region for the Outpost.

When you create a volume from a local snapshot, you cannot re-encrypt the volume using different KMS key. Volumes created from local snapshots must be encrypted using the same KMS key as the source snapshot.

For more information, see Create a volume from a snapshot (p. 2075).

Launch instances from AMIs backed by local snapshots

You can launch instances from AMIs that are backed by local snapshots. You must launch Instances on the same Outpost as the source AMI. For more information, see Launch an instance on your Outpost in the AWS Outposts User Guide.

Delete local snapshots

You can delete local snapshots from an Outpost. After you delete a snapshot from an Outpost, the Amazon S3 storage capacity used by the deleted snapshot becomes available within 72 hours after deleting the snapshot and the volumes that reference that snapshot.

Because Amazon S3 storage capacity does not become available immediately, we recommend that you use Amazon CloudWatch alarms to monitor your Amazon S3 storage capacity. Delete snapshots and volumes that you no longer need to avoid running out of storage capacity.

For more information about deleting snapshots, see Delete a snapshot (p. 2118).

Automate snapshots on an Outpost

You can create Amazon Data Lifecycle Manager snapshot lifecycle policies that automatically create, copy, retain, and delete snapshots of your volumes and instances on an Outpost. You can choose whether to store the snapshots in a Region or whether to store them locally on an Outpost. Additionally, you can automatically copy snapshots that are created and stored in an AWS Region to an Outpost.

The following table provides an overview of the supported features.

<table>
<thead>
<tr>
<th>Resource location</th>
<th>Snapshot destination</th>
<th>Cross-region copy To Region</th>
<th>Cross-region copy To Outpost</th>
<th>Fast snapshot restore</th>
<th>Cross-account sharing</th>
</tr>
</thead>
<tbody>
<tr>
<td>Region</td>
<td>Region</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Outpost</td>
<td>Region</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Outpost</td>
<td>Outpost</td>
<td>x</td>
<td>x</td>
<td>x</td>
<td>x</td>
</tr>
</tbody>
</table>

Considerations

- Only Amazon EBS snapshot lifecycle policies are currently supported. EBS-backed AMI policies and Cross-account sharing event policies are not supported.
- If a policy manages snapshots for volumes or instances in a Region, then snapshots are created in the same Region as the source resource.
- If a policy manages snapshots for volumes or instances on an Outpost, then snapshots can be created on the source Outpost, or in the Region for that Outpost.
A single policy can’t manage both snapshots in a Region and snapshots on an Outpost. If you need to automate snapshots in a Region and on an Outpost, you must create separate policies.

Fast snapshot restore is not supported for snapshots created on an Outpost, or for snapshots copied to an Outpost.

Cross-account sharing is not supported for snapshots created on an Outpost.

For more information about creating a snapshot lifecycle that manages local snapshots, see Automating snapshot lifecycles (p. 2223).

Use EBS direct APIs to access the contents of an EBS snapshot

You can use the Amazon Elastic Block Store (Amazon EBS) direct APIs to create EBS snapshots, write data directly to your snapshots, read data on your snapshots, and identify the differences or changes between two snapshots. If you're an independent software vendor (ISV) who offers backup services for Amazon EBS, the EBS direct APIs make it more efficient and cost-effective to track incremental changes on your EBS volumes through snapshots. This can be done without having to create new volumes from snapshots, and then use Amazon Elastic Compute Cloud (Amazon EC2) instances to compare the differences.

You can create incremental snapshots directly from data on-premises into EBS volumes and the cloud to use for quick disaster recovery. With the ability to write and read snapshots, you can write your on-premises data to an EBS snapshot during a disaster. Then after recovery, you can restore it back to AWS or on-premises from the snapshot. You no longer need to build and maintain complex mechanisms to copy data to and from Amazon EBS.

This user guide provides an overview of the elements that make up the EBS direct APIs, and examples of how to use them effectively. For more information about the actions, data types, parameters, and errors of the APIs, see the EBS direct APIs reference. For more information about the supported AWS Regions, endpoints, and service quotas for the EBS direct APIs, see Amazon EBS Endpoints and Quotas in the AWS General Reference.

Contents

- Understand the EBS direct APIs (p. 2179)
- IAM permissions for EBS direct APIs (p. 2181)
- Use EBS direct APIs (p. 2185)
- Pricing for EBS direct APIs (p. 2203)
- Using interface VPC endpoints with EBS direct APIs (p. 2204)
- Log API Calls for EBS direct APIs with AWS CloudTrail (p. 2204)
- Frequently asked questions (p. 2210)

Understand the EBS direct APIs

The following are the key elements that you should understand before getting started with the EBS direct APIs.

Snapshots

Snapshots are the primary means to back up data from your EBS volumes. With the EBS direct APIs, you can also back up data from your on-premises disks to snapshots. To save storage costs, successive snapshots are incremental, containing only the volume data that changed since the previous snapshot. For more information, see Amazon EBS snapshots (p. 2107).

Note

EBS direct APIs does not support public snapshots and local snapshots on Outposts.
Blocks

A block is a fragment of data within a snapshot. Each snapshot can contain thousands of blocks. All blocks in a snapshot are of a fixed size.

Block indexes

A block index is a logical index in units of 512 KiB blocks. To identify the block index, divide the logical offset of the data in the logical volume by the block size (logical offset of data/524288). The logical offset of the data must be 512 KiB aligned.

Block tokens

A block token is the identifying hash of a block within a snapshot, and it is used to locate the block data. Block tokens returned by EBS direct APIs are temporary. They change on the expiry timestamp specified for them, or if you run another ListSnapshotBlocks or ListChangedBlocks request for the same snapshot.

Checksum

A checksum is a small-sized datum derived from a block of data for the purpose of detecting errors that were introduced during its transmission or storage. The EBS direct APIs use checksums to validate data integrity. When you read data from an EBS snapshot, the service provides Base64-encoded SHA256 checksums for each block of data transmitted, which you can use for validation. When you write data to an EBS snapshot, you must provide a Base64 encoded SHA256 checksum for each block of data transmitted. The service validates the data received using the checksum provided. For more information, see Use checksums (p. 2197) later in this guide.

Encryption

Encryption protects your data by converting it into unreadable code that can be deciphered only by people who have access to the KMS key used to encrypt it. You can use the EBS direct APIs to read and write encrypted snapshots, but there are some limitations. For more information, see Use encryption (p. 2195) later in this guide.

API actions

The EBS direct APIs consists of six actions. There are three read actions and three write actions. The read actions are:

- **ListSnapshotBlocks** — returns the block indexes and block tokens of blocks in the specified snapshot
- **ListChangedBlocks** — returns the block indexes and block tokens of blocks that are different between two specified snapshots of the same volume and snapshot lineage.
- **GetSnapshotBlock** — returns the data in a block for the specified snapshot ID, block index, and block token.

The write actions are:

- **StartSnapshot** — starts a snapshot, either as an incremental snapshot of an existing one or as a new snapshot. The started snapshot remains in a pending state until it is completed using the CompleteSnapshot action.
- **PutSnapshotBlock** — adds data to a started snapshot in the form of individual blocks. You must specify a Base64-encoded SHA256 checksum for the block of data transmitted. The service validates the checksum after the transmission is completed. The request fails if the checksum computed by the service doesn't match what you specified.
- **CompleteSnapshot** — completes a started snapshot that is in a pending state. The snapshot is then changed to a completed state.
IAM permissions for EBS direct APIs

A user must have the following policies to use the EBS direct APIs. For more information, see Changing permissions for a user.

For more information about the EBS direct APIs resources, actions, and condition context keys for use in IAM permission policies, see Actions, resources, and condition keys for Amazon Elastic Block Store in the Service Authorization Reference.

**Important**

Be cautious when assigning the following policies to users. By assigning these policies, you might give access to a user who is denied access to the same resource through the Amazon EC2 APIs, such as the CopySnapshot or CreateVolume actions.

Permissions to read snapshots

The following policy allows the read EBS direct APIs to be used on all snapshots in a specific AWS Region. In the policy, replace `<Region>` with the Region of the snapshot.

```json
{
 "Version": "2012-10-17",
 "Statement": [
   {
     "Effect": "Allow",
     "Action": [
       "ebs:ListSnapshotBlocks",
       "ebs:ListChangedBlocks",
       "ebs:GetSnapshotBlock"
     ],
     "Resource": "arn:aws:ec2:<Region>::snapshot/*"
   }
 ]
}
```

The following policy allows the read EBS direct APIs to be used on snapshots with a specific key-value tag. In the policy, replace `<Key>` with the key value of the tag, and `<Value>` with the value of the tag.

```json
{
 "Version": "2012-10-17",
 "Statement": [
   {
     "Effect": "Allow",
     "Action": [
       "ebs:ListSnapshotBlocks",
       "ebs:ListChangedBlocks",
       "ebs:GetSnapshotBlock"
     ],
     "Resource": "arn:aws:ec2:*::snapshot/**",
     "Condition": {
       "StringEqualsIgnoreCase": {
         "aws:ResourceTag/<Key>": "<Value>"
       }
     }
   }
 ]
}
```

The following policy allows all of the read EBS direct APIs to be used on all snapshots in the account only within a specific time range. This policy authorizes use of the EBS direct APIs based on the aws:CurrentTime global condition key. In the policy, be sure to replace the date and time range shown with the date and time range for your policy.
For more information, see Changing permissions for a user in the IAM User Guide.

Permissions to write snapshots

The following policy allows the write EBS direct APIs to be used on all snapshots in a specific AWS Region. In the policy, replace <Region> with the Region of the snapshot.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ebs:StartSnapshot",
        "ebs:PutSnapshotBlock",
        "ebs:CompleteSnapshot"
      ],
      "Resource": "arn:aws:ec2:<Region>::snapshot/*"
    }
  ]
}
```

The following policy allows the write EBS direct APIs to be used on snapshots with a specific key-value tag. In the policy, replace <Key> with the key value of the tag, and <Value> with the value of the tag.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ebs:StartSnapshot",
        "ebs:PutSnapshotBlock",
        "ebs:CompleteSnapshot"
      ],
      "Resource": "arn:aws:ec2:*::snapshot/**",
      "Condition": {
        "StringEqualsIgnoreCase": {
          "aws:ResourceTag/<Key>": "<Value>
        }
      }
    }
  ]
}
```
The following policy allows all of the EBS direct APIs to be used. It also allows only the user tag key to be created for a new snapshot. This policy also ensures that the user has access to create tags. The StartSnapshot action is the only action that can specify tags.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ebs:*",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "ebs:ParentSnapshot": "arn:aws:ec2:*::*:snapshot/*"
                }
            }
        },{
            "Effect": "Allow",
            "Action": "ec2:CreateTags",
            "Resource": "*"
        }
    ]
}
```

The following policy allows all of the write EBS direct APIs to be used on all snapshots in the account only within a specific time range. This policy authorizes use of the EBS direct APIs based on the aws:CurrentTime global condition key. In the policy, be sure to replace the date and time range shown with the date and time range for your policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ebs:StartSnapshot",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:CurrentTime": "<your-time-range>"
                }
            }
        }
    ]
}
```
"ebs:PutSnapshotBlock",
"ebs:CompleteSnapshot"
],
"Resource": "arn:aws:ec2:*::snapshot/*",
"Condition": {
  "DateGreaterThan": {
    "aws:CurrentTime": "2018-05-29T00:00:00Z"
  },
  "DateLessThan": {
    "aws:CurrentTime": "2020-05-29T23:59:59Z"
  }
}
}
]
]

For more information, see Changing permissions for a user in the IAM User Guide.

Permissions to use AWS KMS keys

The following policy grants permission to decrypt an encrypted snapshot using a specific KMS key. It also grants permission to encrypt new snapshots using the default KMS key for EBS encryption. In the policy, replace <Region> with the Region of the KMS key, <AccountId> with the ID of the AWS account of the KMS key, and <KeyId> with the ID of the KMS key.

**Note**

By default, all principals in the account have access to the default AWS managed KMS key for Amazon EBS encryption, and they can use it for EBS encryption and decryption operations. If you are using a customer managed key, you must create a new key policy or modify the existing key policy for the customer managed key to grant the principal access to the customer managed key. For more information, see Key policies in AWS KMS in the AWS Key Management Service Developer Guide.

**Tip**

To follow the principle of least privilege, do not allow full access to kms:CreateGrant. Instead, use the kms:GrantIsForAWSResource condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service, as shown in the following example.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:GenerateDataKey",
        "kms:GenerateDataKeyWithoutPlaintext",
        "kms:ReEncrypt*",
        "kms:CreateGrant",
        "ec2:CreateTags",
        "kms:DescribeKey"
      ],
      "Resource": "arn:aws:kms:<Region>:<AccountId>:key/<KeyId>",
      "Condition": {
        "Bool": {
          "kms:GrantIsForAWSResource": true
        }
      }
    }
  ]
}
```
For more information, see Changing permissions for a user in the IAM User Guide.

Use EBS direct APIs

The following topics show how to read and write snapshots using the EBS direct APIs. You can read and write snapshots using the AWS CLI, AWS APIs, and AWS SDKs only. For more information, see:

- Installing the AWS CLI and Configuring the AWS CLI
- EBS direct APIs Reference
- AWS SDKs

Important
The EBS direct APIs require an AWS Signature Version 4 signature. For more information, see Use Signature Version 4 signing (p. 2197).

Topics
- Read snapshots with EBS direct APIs (p. 2185)
- Write snapshots with EBS direct APIs (p. 2191)
- Use encryption (p. 2195)
- Use Signature Version 4 signing (p. 2197)
- Use checksums (p. 2197)
- Idempotency for StartSnapshot API (p. 2198)
- Error retries (p. 2198)
- Optimize performance (p. 2200)
- EBS direct APIs service endpoints (p. 2200)

Read snapshots with EBS direct APIs

The following steps describe how to use the EBS direct APIs to read snapshots:

1. Use the ListSnapshotBlocks action to view all block indexes and block tokens of blocks in a snapshot. Or use the ListChangedBlocks action to view only the block indexes and block tokens of blocks that are different between two snapshots of the same volume and snapshot lineage. These actions help you identify the block tokens and block indexes of blocks for which you might want to get data.
2. Use the GetSnapshotBlock action, and specify the block index and block token of the block for which you want to get data.

The following examples show how to read snapshots using the EBS direct APIs.

Topics
- List blocks in a snapshot (p. 2185)
- List blocks that are different between two snapshots (p. 2187)
- Get block data from a snapshot (p. 2190)

List blocks in a snapshot

AWS CLI

The following list-snapshot-blocks example command returns the block indexes and block tokens of blocks that are in snapshot snap-0987654321. The --starting-block-index parameter
limits the results to block indexes greater than 1000, and the --max-results parameter limits the results to the first 100 blocks.

```bash
aws ebs list-snapshot-blocks --snapshot-id snap-0987654321 --starting-block-index 1000 --max-results 100
```

The following example response for the previous command lists the block indexes and block tokens in the snapshot. Use the `get-snapshot-block` command and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.

```json
{
  "Blocks": [
    {
      "BlockIndex": 1001,
      "BlockToken": "AAABAV3/PNhX0ynVdMYHUpPseta5vJLB1dtG6fbJv5OJ0sX855EzGTWos4a4"
    },
    {
      "BlockIndex": 1002,
      "BlockToken": "AAABATGQIgwr0WwIuqIMA/Sy7e/YoQFZsHejzGNvJkauzNgzeI13YHBFQ8"
    },
    {
      "BlockIndex": 1007,
      "BlockToken": "AAABAZ9CTuQtUvp/dXqRWw4d07e0gT3jvn66lW50W9duM0Miw6yQayzF2c"
    },
    {
      "BlockIndex": 1012,
      "BlockToken": "AAABAQdXzw0tVV6PNmsfo/YRIxo9JPR85XxPf1BLjg0Hec6pygYr61a1p0"
    },
    {
      "BlockIndex": 1030,
      "BlockToken": "AAABAaYvPax6mv+iGWLdTUJqTfWouQ7Dqz6nSD9L+GxnvpswA611D1523d"
    },
    {
      "BlockIndex": 1031,
      "BlockToken": "AAABATgW2C0XcFwUkJbUXMISPg59KvxxJGL+BWBC1kw6spzc3VqDta5sk3"
    },
    ...
  ],
  "ExpiryTime": 1576287332.806,
  "VolumeSize": 32212254720,
  "BlockSize": 524288
}
```

AWS API

The following `ListSnapshotBlocks` example request returns the block indexes and block tokens of blocks that are in snapshot `snap-0acEXAMPLEcf41648`. The `startingBlockIndex` parameter limits the results to block indexes greater than 1000, and the `maxResults` parameter limits the results to the first 100 blocks.

```bash
GET /snapshots/snap-0acEXAMPLEcf41648/blocks?maxResults=100&startingBlockIndex=1000 HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
User-Agent: <User agent parameter>
```
The following example response for the previous request lists the block indexes and block tokens in the snapshot. Use the GetSnapshotBlock action and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.

HTTP/1.1 200 OK

    },
    ...
  ],
  "ExpiryTime": 1.59298379649E9,
  "VolumeSize": 3
}

List blocks that are different between two snapshots

Keep the following in mind when making paginated requests to list the changed blocks between two snapshots:

- The response can include one or more empty ChangedBlocks arrays. For example:
  - Snapshot 1 — full snapshot with 1000 blocks with block indexes 0 - 999.
  - Snapshot 2 — incremental snapshot with only one changed block with block index 999.

Listing the changed blocks for these snapshots with StartingBlockIndex = 0 and MaxResults = 100 returns an empty array of ChangedBlocks. You must request the remaining results using nextToken until the changed block is returned in the tenth result set, which includes blocks with block indexes 900 - 999.

- The response can skip unwritten blocks in the snapshots. For example:
  - Snapshot 1 — full snapshot with 1000 blocks with block indexes 2000 - 2999.
  - Snapshot 2 — incremental snapshot with only one changed block with block index 2000.
Listing the changed blocks for these snapshots with StartingBlockIndex = 0 and MaxResults = 100, the response skips block indexes 0 - 1999 and includes block index 2000. The response will not include empty ChangedBlocks arrays.

AWS CLI

The following list-changed-blocks example command returns the block indexes and block tokens of blocks that are different between snapshots snap-1234567890 and snap-0987654321. The --starting-block-index parameter limits the results to block indexes greater than 0, and the --max-results parameter limits the results to the first 500 blocks.

```
aws ebs list-changed-blocks --first-snapshot-id snap-1234567890 --second-snapshot-id snap-0987654321 --starting-block-index 0 --max-results 500
```

The following example response for the previous command shows that block indexes 0, 6000, 6001, 6002, and 6003 are different between the two snapshots. Additionally, block indexes 6001, 6002, and 6003 exist only in the first snapshot ID specified, and not in the second snapshot ID because there is no second block token listed in the response.

Use the get-snapshot-block command and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.

```
{
    "ChangedBlocks": [
        {
            "BlockIndex": 0,
            "FirstBlockToken": "AAABAVahm9SOG60Dyi00RySznzZJjGjW/KN3uyGLS0Q0YwesbzbBbDn26gPmC",
            "SecondBlockToken": "AAABAf8o0o6Upi1rDB6J9I0aC7GyBuUTlvtCQxx0KV8qzUPQP7vcM6iWGSr"
        },
        {
            "BlockIndex": 6000,
            "FirstBlockToken": "AAABAbYSiZvJ0/R9tz8DuI6sZmclJn4kkazK81nFXVntPkd3VFLcMQsKe",
            "SecondBlockToken": "AAABAZnqTdzFmKRpsaMASdxviE/3jji2erq2eFDCgHmyNf777e1D9oVR"
        },
        {
            "BlockIndex": 6001,
            "FirstBlockToken": "AAABASBpSj2UD3PxmlJnt6zun4/T4sU2SBw8b5Q6FRXH褀AqEB8hJ0O"
        },
        {
            "BlockIndex": 6002,
            "FirstBlockToken": "AAABASqX4/NWjvNceoyMULjRd0Dnwb5swNmes1ukoP62crXvn47BY543aw"
        },
        {
            "BlockIndex": 6003,
            "FirstBlockToken": "AAABASmJ0O5JxAXOce25f4P1sdRty1DSx12TFEDunnePYUK0f4PBR0u1C2A"
        },
        ...
    ],
    "ExpiryTime": 1576308931.973,
    "VolumeSize": 32212254720,
    "BlockSize": 524288,
    "NextToken": "AAADARqElNng/sV98Cyl/bJDCxelJmLJNskHvLzVa00zph/QM3b132F/06Mdi/BbJnrBmp8h"
}
```
The following **ListChangedBlocks** example request returns the block indexes and block tokens of blocks that are different between snapshots snap-0acEXAMPLEcf41648 and snap-0c9EXAMPLE1b30e2f. The startingBlockIndex parameter limits the results to block indexes greater than 0, and the maxResults parameter limits the results to the first 500 blocks.

```plaintext
GET /snapshots/snap-0c9EXAMPLE1b30e2f/changedblocks?
firstSnapshotId=snap-0acEXAMPLEcf41648&maxResults=500&startingBlockIndex=0
HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
User-Agent: <User agent parameter>
X-Amz-Date: 20200617T232546Z
Authorization: <Authentication parameter>
```

The following example response for the previous request shows that block indexes 0, 3072, 6002, and 6003 are different between the two snapshots. Additionally, block indexes 6002, and 6003 exist only in the first snapshot ID specified, and not in the second snapshot ID because there is no second block token listed in the response.

Use the **GetSnapshotBlock** action and specify the block index and block token of the block for which you want to get data. The block tokens are valid until the expiry time listed.

```plaintext
HTTP/1.1 200 OK

},
...
"ExpiryTime": 1.592976647009E9,
}
```
Get block data from a snapshot

AWS CLI

The following `get-snapshot-block` example command returns the data in the block index 6001 with block token AAABASBpSJ2UAD3PLxJnCt6zun4/T4sU25Bnb8jB5Q6FRXHFqAIAqE04hJoR, in snapshot snap-1234567890. The binary data is output to the data file in the C:\Temp directory on a Windows computer. If you run the command on a Linux or Unix computer, replace the output path with /tmp/data to output the data to the data file in the /tmp directory.

```
aws ebs get-snapshot-block --snapshot-id snap-1234567890 --block-index 6001 --block-token AAABASBpSJ2UAD3PLxJnCt6zun4/T4sU25Bnb8jB5Q6FRXHFqAIAqE04hJoR C:/Temp/data
```

The following example response for the previous command shows the size of the data returned, the checksum to validate the data, and the algorithm of the checksum. The binary data is automatically saved to the directory and file you specified in the request command.

```
{
    "DataLength": "524288",
    "Checksum": "cf0Y6/Fn0Oa4VjQPOa/iD0zTF1PTKzxGv20KowXc=",
    "ChecksumAlgorithm": "SHA256"
}
```

AWS API

The following `GetSnapshotBlock` example request returns the data in the block index 3072 with block token AAUBARGCaufCqBRZC8teKPyGgkSv3vqv0jJ2xKD13lDFIytUXBLXYgTmkid, in snapshot snap-0c9EXAMPLE1b30e2f.

```
GET /snapshots/snap-0c9EXAMPLE1b30e2f/blocks/3072?blockToken=AAUBARGCaufCqBRZC8teKPyGgkSv3vqv0jJ2xKD13lDFIytUXBLXYgTmkid HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
User-Agent: <User agent parameter>
X-Amz-Date: 20200617T232838Z
Authorization: <Authentication parameter>
```

The following example response for the previous request shows the size of the data returned, the checksum to validate the data, and the algorithm used to generate the checksum. The binary data is transmitted in the body of the response and is represented as `BlockData` in the following example.

```
HTTP/1.1 200 OK
x-amzn-RequestId: 2d00b2fb-bd88-474d-a137-81c4e57d7b9f
x-amzn-Data-Length: 524288

Content-Type: application/octet-stream
Content-Length: 524288
Date: Wed, 17 Jun 2020 23:28:38 GMT
Connection: keep-alive

BlockData
```
Write snapshots with EBS direct APIs

The following steps describe how to use the EBS direct APIs to write incremental snapshots:

1. Use the StartSnapshot action and specify a parent snapshot ID to start a snapshot as an incremental snapshot of an existing one, or omit the parent snapshot ID to start a new snapshot. This action returns the new snapshot ID, which is in a pending state.

2. Use the PutSnapshotBlock action and specify the ID of the pending snapshot to add data to it in the form of individual blocks. You must specify a Base64-encoded SHA256 checksum for the block of data transmitted. The service computes the checksum of the data received and validates it with the checksum that you specified. The action fails if the checksums don't match.

3. When you're done adding data to the pending snapshot, use the CompleteSnapshot action to start an asynchronous workflow that seals the snapshot and moves it to a completed state.

Repeat these steps to create a new, incremental snapshot using the previously created snapshot as the parent.

For example, in the following diagram, snapshot A is the first new snapshot started. Snapshot A is used as the parent snapshot to start snapshot B. Snapshot B is used as the parent snapshot to start and create snapshot C. Snapshots A, B, and C are incremental snapshots. Snapshot A is used to create EBS volume 1. Snapshot D is created from EBS volume 1. Snapshot D is an incremental snapshot of A; it is not an incremental snapshot of B or C.

The following examples show how to write snapshots using the EBS direct APIs.

Topics
- Start a snapshot (p. 2191)
- Put data into a snapshot (p. 2193)
- Complete a snapshot (p. 2194)

Start a snapshot

AWS CLI

The following `start-snapshot` example command starts an 8 GiB snapshot, using snapshot `snap-123EXAMPLE1234567` as the parent snapshot. The new snapshot will be an incremental
snapshot of the parent snapshot. The snapshot moves to an error state if there are no put or complete requests made for the snapshot within the specified 60 minute timeout period. The 550e8400-e29b-41d4-a716-446655440000 client token ensures idempotency for the request. If the client token is omitted, the AWS SDK automatically generates one for you. For more information about idempotency, see Idempotency for StartSnapshot API (p. 2198).

aws ebs start-snapshot --volume-size 8 --parent-snapshot snap-123EXAMPLE1234567 --timeout 60 --client-token 550e8400-e29b-41d4-a716-446655440000

The following example response for the previous command shows the snapshot ID, AWS account ID, status, volume size in GiB, and size of the blocks in the snapshot. The snapshot is started in a pending state. Specify the snapshot ID in subsequent put-snapshot-block commands to write data to the snapshot, then use the complete-snapshot command to complete the snapshot and change its status to completed.

```json
{
    "SnapshotId": "snap-0aaEXAMPLEe306d62",
    "OwnerId": "111122223333",
    "Status": "pending",
    "VolumeSize": 8,
    "BlockSize": 524288
}
```

AWS API

The following StartSnapshot example request starts an 8 GiB snapshot, using snapshot snap-123EXAMPLE1234567 as the parent snapshot. The new snapshot will be an incremental snapshot of the parent snapshot. The snapshot moves to an error state if there are no put or complete requests made for the snapshot within the specified 60 minute timeout period. The 550e8400-e29b-41d4-a716-446655440000 client token ensures idempotency for the request. If the client token is omitted, the AWS SDK automatically generates one for you. For more information about idempotency, see Idempotency for StartSnapshot API (p. 2198).

```
POST /snapshots HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
User-Agent: <User agent parameter>
X-Amz-Date: 20200618T040724Z
Authorization: <Authentication parameter>

{
    "VolumeSize": 8,
    "ParentSnapshot": "snap-123EXAMPLE1234567",
    "ClientToken": "550e8400-e29b-41d4-a716-446655440000",
    "Timeout": 60
}
```

The following example response for the previous request shows the snapshot ID, AWS account ID, status, volume size in GiB, and size of the blocks in the snapshot. The snapshot is started in a pending state. Specify the snapshot ID in a subsequent PutSnapshotBlocks request to write data to the snapshot.

```
HTTP/1.1 201 Created
x-amzn-RequestId: 929e6eb9-7183-405a-9502-5b7da37c1b18
Content-Type: application/json
Content-Length: 181
Date: Thu, 18 Jun 2020 04:07:29 GMT
Connection: keep-alive
```
Put data into a snapshot

AWS CLI

The following `put-snapshot` example command writes 524288 Bytes of data to block index 1000 on snapshot `snap-0aaEXAMPLEe306d62`. The Base64 encoded `QOD3gmEOQXATfJx2Aa34W4FU2nZGyXfquetsUukt0w8DM=` checksum was generated using the SHA256 algorithm. The data that is transmitted is in the `/tmp/data` file.

```
aws ebs put-snapshot-block --snapshot-id snap-0aaEXAMPLEe306d62 --block-index 1000 --data-length 524288 --block-data /tmp/data --checksum QOD3gmEOQXATfJx2Aa34W4FU2nZGyXfquetsUukt0w8DM= --checksum-algorithm SHA256
```

The following example response for the previous command confirms the data length, checksum, and checksum algorithm for the data received by the service.

```
{
  "DataLength": "524288",
  "Checksum": "QOD3gmEOQXATfJx2Aa34W4FU2nZGyXfquetsUukt0w8DM=",
  "ChecksumAlgorithm": "SHA256"
}
```

AWS API

The following `PutSnapshot` example request writes 524288 Bytes of data to block index 1000 on snapshot `snap-052EXAMPLEc85d8dd`. The Base64 encoded `QOD3gmEOQXATfJx2Aa34W4FU2nZGyXfquetsUukt0w8DM=` checksum was generated using the SHA256 algorithm. The data is transmitted in the body of the request and is represented as `BlockData` in the following example.

```
PUT /snapshots/snap-052EXAMPLEc85d8dd/blocks/1000 HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
x-amz-Data-Length: 524288
x-amz-Checksum: QOD3gmEOQXATfJx2Aa34W4FU2nZGyXfquetsUukt0w8DM=
x-amz-Checksum-Algorithm: SHA256
User-Agent: <User agent parameter>
X-Amz-Date: 20200618T042215Z
X-Amz-Content-SHA256: UNSIGNED-PAYLOAD
Authorization: <Authentication parameter>

BlockData
```

The following is example response for the previous request confirms the data length, checksum, and checksum algorithm for the data received by the service.
Complete a snapshot

AWS CLI

The following `complete-snapshot` example command completes snapshot `snap-0aaEXAMPLEe306d62`. The command specifies that 5 blocks were written to the snapshot. The `6D3nmwi5f2F0wlh7xX8QprrrBFzDX8aacd0cA3KCM3c=` checksum represents the checksum for the complete set of data written to a snapshot. For more information about checksums, see Use checksums (p. 2197) earlier in this guide.

```bash
aws ebs complete-snapshot --snapshot-id snap-0aaEXAMPLEe306d62 --changed-blocks-count 5 --checksum 6D3nmwi5f2F0wlh7xX8QprrrBFzDX8aacd0cA3KCM3c= --checksum-algorithm SHA256 --checksum-aggregation-method LINEAR
```

The following is an example response for the previous command.

```
{}
```

AWS API

The following `CompleteSnapshot` example request completes snapshot `snap-052EXAMPLEc85d8dd`. The command specifies that 5 blocks were written to the snapshot. The `6D3nmwi5f2F0wlh7xX8QprrrBFzDX8aacd0cA3KCM3c=` checksum represents the checksum for the complete set of data written to a snapshot.

```http
POST /snapshots/completion/snap-052EXAMPLEc85d8dd HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
x-amz-ChangedBlocksCount: 5
x-amz-Checksum: 6D3nmwi5f2F0wlh7xX8QprrrBFzDX8aacd0cA3KCM3c=
x-amz-Checksum-Algorithm: SHA256
x-amz-Checksum-Aggregation-Method: LINEAR
User-Agent: <User agent parameter>
X-Amz-Date: 20200618T043158Z
Authorization: <Authentication parameter>
```

The following is an example response for the previous request.

```
HTTP/1.1 202 Accepted

```
Use encryption

When you start a new snapshot using StartSnapshot, the encryption status depends on the values that you specify for Encrypted, KmsKeyArn, and ParentSnapshotId, and whether your AWS account is enabled for encryption by default (p. 2320).

Note

- You might need additional IAM permissions to use the EBS direct APIs with encryption. For more information, see Permissions to use AWS KMS keys (p. 2184).
- If Amazon EBS encryption by default is enabled on your AWS account, you can’t create unencrypted snapshots.
- If Amazon EBS encryption by default is enabled on your AWS account, you cannot start a new snapshot using an unencrypted parent snapshot. You must first encrypt the parent snapshot by copying it. For more information, see Copy an Amazon EBS snapshot (p. 2128).

Encryption outcomes: Unencrypted parent snapshot

The following table describes the encryption outcome for each possible combination of settings when specifying an unencrypted parent snapshot.

<table>
<thead>
<tr>
<th>ParentSnapshot</th>
<th>Encrypted</th>
<th>KmsKeyArn</th>
<th>Encryption by default</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unencrypted</td>
<td>Omitted</td>
<td>Omitted</td>
<td>Enabled</td>
<td>The request fails with ValidationException.</td>

</table>

* This default KMS key could be a customer managed key or the default AWS managed KMS key for Amazon EBS encryption.

### Use Signature Version 4 signing

Signature Version 4 is the process to add authentication information to AWS requests sent by HTTP. For security, most requests to AWS must be signed with an access key, which consists of an access key ID and secret access key. These two keys are commonly referred to as your security credentials. For information about how to obtain credentials for your account, see [AWS security credentials](#).

If you intend to manually create HTTP requests, you must learn how to sign them. When you use the AWS Command Line Interface (AWS CLI) or one of the AWS SDKs to make requests to AWS, these tools automatically sign the requests for you with the access key that you specify when you configure the tools. When you use these tools, you don't need to learn how to sign requests yourself.

For more information, see [Signing AWS API requests](#) in the IAM User Guide.

### Use checksums

The GetSnapshotBlock action returns data that is in a block of a snapshot, and the PutSnapshotBlock action adds data to a block in a snapshot. The block data that is transmitted is not signed as part of the Signature Version 4 signing process. As a result, checksums are used to validate the integrity of the data as follows:

- When you use the GetSnapshotBlock action, the response provides a Base64-encoded SHA256 checksum for the block data using the `x-amz-Checksum` header, and the checksum algorithm using the `x-amz-Checksum-Algorithm` header. Use the returned checksum to validate the integrity of the data. If the checksum that you generate doesn’t match what Amazon EBS provided, you should consider the data not valid and retry your request.

- When you use the PutSnapshotBlock action, your request must provide a Base64-encoded SHA256 checksum for the block data using the `x-amz-Checksum` header, and the checksum algorithm using the `x-amz-Checksum-Algorithm` header. The checksum that you provide is validated against a checksum generated by Amazon EBS to validate the integrity of the data. If the checksums do not correspond, the request fails.

- When you use the CompleteSnapshot action, your request can optionally provide an aggregate Base64-encoded SHA256 checksum for the complete set of data added to the snapshot. Provide the checksum using the `x-amz-Checksum` header, the checksum algorithm using the `x-amz-Checksum-Algorithm` header, and the checksum aggregation method using the `x-amz-Checksum-Aggregation-Method` header. To generate the aggregated checksum using the linear aggregation method, arrange the checksums for each written block in ascending order of their block index, concatenate them to form a single string, and then generate the checksum on the entire string using the SHA256 algorithm.

The checksums in these actions are part of the Signature Version 4 signing process.
Idempotency for StartSnapshot API

Idempotency ensures that an API request completes only once. With an idempotent request, if the original request completes successful, the subsequent retries return the result from the original successful request and they have no additional effect.

The StartSnapshot API supports idempotency using a client token. A client token is a unique string that you specify when you make an API request. If you retry an API request with the same client token and the same request parameters after it has completed successfully, the result of the original request is returned. If you retry a request with the same client token, but change one or more of the request parameters, the ConflictException error is returned.

If you do not specify your own client token, the AWS SDKs automatically generates a client token for the request to ensure that it is idempotent.

A client token can be any string that includes up to 64 ASCII characters. You should not reuse the same client tokens for different requests.

To make an idempotent StartSnapshot request with your own client token using the API

Specify the ClientToken StartSnapshot request parameter.

```plaintext
POST /snapshots HTTP/1.1
Host: ebs.us-east-2.amazonaws.com
Accept-Encoding: identity
User-Agent: <<User agent parameter>>
X-Amz-Date: 20200618T040724Z
Authorization: <<Authentication parameter>>

{
  "VolumeSize": 8,
  "ParentSnapshot": snap-123EXAMPLE1234567,
  "ClientToken": "550e8400-e29b-41d4-a716-446655440000",
  "Timeout": 60
}
```

To make an idempotent StartSnapshot request with your own client token using the AWS CLI

Specify the client-token request parameter.

```
$ aws ebs start-snapshot --region us-east-2 --volume-size 8 --parent-snapshot snap-123EXAMPLE1234567 --timeout 60 --client-token 550e8400-e29b-41d4-a716-446655440000
```

Error retries

The AWS SDKs implement automatic retry logic for requests that return error responses. You can configure the retry settings for the AWS SDKs. For more information, see your SDK's documentation.

You can configure the AWS CLI to automatically retry some failed requests. For more information about configuring retries for the AWS CLI, see AWS CLI retries in the AWS Command Line Interface User Guide.

The AWS Query API does not support retry logic for failed requests. If you are using HTTP or HTTPS requests, you must implement retry logic in your client application.

For more information, see Error retries and exponential backoff in AWS in the AWS General Reference.

The following table shows the possible API error responses. Some API errors are retryable. Your client application should always retry failed requests that receive a retryable error.
<table>
<thead>
<tr>
<th>Error</th>
<th>Response code</th>
<th>Description</th>
<th>Thrown by</th>
<th>Retryable?</th>
</tr>
</thead>
<tbody>
<tr>
<td>InternalServerException</td>
<td>500</td>
<td>The request failed due to a network or AWS server-side issue.</td>
<td>All APIs</td>
<td>Yes</td>
</tr>
<tr>
<td>ThrottlingException</td>
<td>400</td>
<td>The number of API requests has exceeded the maximum allowed API request throttling limit for the account.</td>
<td>All APIs</td>
<td>Yes</td>
</tr>
<tr>
<td>RequestThrottleException</td>
<td>400</td>
<td>The number of API requests has exceeded the maximum allowed API request throttling limit for the snapshot.</td>
<td>GetSnapshotBlock, PutSnapshotBlock</td>
<td>Yes</td>
</tr>
<tr>
<td>ValidationException with message &quot;Failed to read block data&quot;</td>
<td>400</td>
<td>The provided data block was not readable.</td>
<td>PutSnapshotBlock</td>
<td>Yes</td>
</tr>
<tr>
<td>ValidationException with any other message</td>
<td>400</td>
<td>The request syntax is malformed, or the input does not satisfy the constraints specified by the AWS service.</td>

<tr>
<td>Error</td>
<td>Response code</td>
<td>Description</td>
<td>Thrown by</td>
<td>Retryable?</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------</td>
<td>------------</td>
</tr>
<tr>
<td>ServiceQuotaExceededException</td>
<td>402</td>
<td>The request failed because fulfilling the request would exceed one or more dependent service quotas for your account.</td>
<td>All APIs</td>
<td>No</td>
</tr>
<tr>
<td>InvalidSignatureException</td>
<td>403</td>
<td>The request authorization signature has expired. You can retry the request only after refreshing the authorization signature.</td>
<td>All APIs</td>
<td>No</td>
</tr>
</tbody>
</table>

**Optimize performance**

You can run API requests concurrently. Assuming PutSnapshotBlock latency is 100ms, then a thread can process 10 requests in one second. Furthermore, assuming your client application creates multiple threads and connections (for example, 100 connections), it can make 1000 (10 * 100) requests per second in total. This will correspond to a throughput of around 500 MB per second.

The following list contains few things to look for in your application:

- Is each thread using a separate connection? If the connections are limited on the application then multiple threads will wait for the connection to be available and you will notice lower throughput.
- Is there any wait time in the application between two put requests? This will reduce the effective throughput of a thread.
- The bandwidth limit on the instance – If bandwidth on the instance is shared by other applications, it could limit the available throughput for PutSnapshotBlock requests.

Be sure to take note of other workloads that might be running in the account to avoid bottlenecks. You should also build retry mechanisms into your EBS direct APIs workflows to handle throttling, timeouts, and service unavailability.

Review the EBS direct APIs service quotas to determine the maximum API requests that you can run per second. For more information, see [Amazon Elastic Block Store Endpoints and Quotas](#) in the AWS General Reference.

**EBS direct APIs service endpoints**

An **endpoint** is a URL that serves as an entry point for an AWS web service. EBS direct APIs supports the following endpoint types:

- IPv4 endpoints
- Dual-stack endpoints that support both IPv4 and IPv6
- FIPS endpoints
When you make a request, you can specify the endpoint and Region to use. If you do not specify an endpoint, the IPv4 endpoint is used by default. To use a different endpoint type, you must specify it in your request. For examples of how to do this, see Specifying endpoints (p. 2202).

For more information about Regions, see Regions and Availability Zones in the Amazon EC2 User Guide for Linux Instances. For a list of endpoints for EBS direct APIs, see Endpoints for the EBS direct APIs in the Amazon Web Services General Reference.

Topics
- IPv4 endpoints (p. 2201)
- Dual-stack (IPv4 and IPv6) endpoints (p. 2201)
- FIPS endpoints (p. 2202)
- Specifying endpoints (p. 2202)

IPv4 endpoints

IPv4 endpoints support IPv4 traffic only. IPv4 endpoints are available for all Regions.

If you specify the general endpoint, ebs.amazonaws.com, we use the endpoint for us-east-1. To use a different Region, specify its associated endpoint. For example, if you specify ebs.us-east-2.amazonaws.com as the endpoint, we direct your request to the us-east-2 endpoint.

IPv4 endpoint names use the following naming convention:

- ebs.region.amazonaws.com

For example, the IPv4 endpoint name for the us-west-1 Region is ebs.us-west-1.amazonaws.com. For a list of endpoints for EBS direct APIs, see Endpoints for the EBS direct APIs in the Amazon Web Services General Reference.

Pricing

You are not charged for data transferred directly between EBS direct APIs and Amazon EC2 instances using an IPv4 endpoint in the same Region. However, if there are intermediate services, such as AWS PrivateLink endpoints, NAT Gateway, or Amazon VPC Transit Gateways, you are charged their associated costs.

Dual-stack (IPv4 and IPv6) endpoints

Dual-stack endpoints support both IPv4 and IPv6 traffic. Dual-stack endpoints are available for all Regions.

To use IPv6, you must use a dual-stack endpoint. When you make a request to a dual-stack endpoint, the endpoint URL resolves to an IPv6 or an IPv4 address, depending on the protocol used by your network and client.

EBS direct APIs supports only regional dual-stack endpoints, which means that you must specify the Region as part of the endpoint name. Dual-stack endpoint names use the following naming convention:

- ebs.region.api.aws

For example, the dual-stack endpoint name for the eu-west-1 Region is ebs.eu-west-1.api.aws. For a list of endpoints for EBS direct APIs, see Endpoints for the EBS direct APIs in the Amazon Web Services General Reference.

Pricing
You are not charged for data transferred directly between EBS direct APIs and Amazon EC2 instances using a dual-stack endpoint in the same Region. However, if there are intermediate services, such as AWS PrivateLink endpoints, NAT Gateway, or Amazon VPC Transit Gateways, you are charged their associated costs.

**FIPS endpoints**

EBS direct APIs provides FIPS-validated IPv4 and dual-stack (IPv4 and IPv6) endpoints for the following Regions:

- us-east-1 — US East (N. Virginia)
- us-east-2 — US East (Ohio)
- us-west-1 — US West (N. California)
- us-west-2 — US West (Oregon)
- ca-central-1 — Canada (Central)

**FIPS IPv4 endpoints** use the following naming convention: ebs-fips.region.amazonaws.com. For example, the FIPS IPv4 endpoint for us-east-1 is ebs-fips.us-east-1.amazonaws.com.

**FIPS dual-stack endpoints** use the following naming convention: ebs-fips.region.api.aws. For example, the FIPS dual-stack endpoint for us-east-1 is ebs-fips.us-east-1.api.aws.

For more information about FIPS endpoints see, [FIPS endpoints](#) in the *Amazon Web Services General Reference*.

**Specifying endpoints**

This section provides some examples of how to specify an endpoint when making a request.

**AWS CLI**

The following examples show how to specify an endpoint for the us-east-2 Region using the AWS CLI.

- **Dual-stack**

  ```bash
  aws ebs list-snapshot-blocks --snapshot-id snap-0987654321 --starting-block-index 1000 --endpoint-url https://ebs.us-east-2.api.aws
  ```

- **IPv4**

  ```bash
  aws ebs list-snapshot-blocks --snapshot-id snap-0987654321 --starting-block-index 1000 --endpoint-url https://ebs.us-east-2.amazonaws.com
  ```

**AWS SDK for Java 2.x**

The following examples show how to specify an endpoint for the us-east-2 Region using the AWS SDK for Java 2.x.

- **Dual-stack**

  ```java
  AwsClientBuilder.EndpointConfiguration config = new
  AmazonEBS ebs = AmazonEBSClientBuilder.standard()
  .withEndpointConfiguration(config)
  .build();
  ```
IPv4

```java
AwsClientBuilder.EndpointConfiguration config = new
    AwsClientBuilder.EndpointConfiguration("https://
    ebs.us-east-2.amazonaws.com", "us-
    east-2");
AmazonEBS ebs = AmazonEBSClientBuilder.standard()
    .withEndpointConfiguration(config)
    .build();
```

AWS SDK for Go

The following examples show how to specify an endpoint for the us-east-2 Region using the AWS SDK for Go.

- **Dual-stack**

```go
sess := session.Must(session.NewSession())
svc := ebs.New(sess, &aws.Config{
    Region: aws.String(endpoints.UsEast1RegionID),
    Endpoint: aws.String("https://ebs.us-east-2.api.aws")
})
```

- **IPv4**

```go
sess := session.Must(session.NewSession())
svc := ebs.New(sess, &aws.Config{
    Region: aws.String(endpoints.UsEast1RegionID),
    Endpoint: aws.String("https://ebs.us-east-2.amazonaws.com")
})
```

## Pricing for EBS direct APIs

### Topics
- Pricing for APIs (p. 2203)
- Networking costs (p. 2203)

### Pricing for APIs

The price that you pay to use the EBS direct APIs depends on the requests you make. For more information, see Amazon EBS pricing.

- **ListChangedBlocks** and ListSnapshotBlocks APIs are charged per request. For example, if you make 100,000 ListSnapshotBlocks API requests in a Region that charges $0.0006 per 1,000 requests, you will be charged $0.06 ($0.0006 per 1,000 requests x 100).

- **GetSnapshotBlock** is charged per block returned. For example, if you make 100,000 GetSnapshotBlock API requests in a Region that charges $0.003 per 1,000 blocks returned, you will be charged $0.30 ($0.003 per 1,000 blocks returned x 100).

- **PutSnapshotBlock** is charged per block written. For example, if you make 100,000 PutSnapshotBlock API requests in a Region that charges $0.006 per 1,000 blocks written, you will be charged $0.60 ($0.006 per 1,000 blocks written x 100).

### Networking costs

### Data transfer costs
Data transferred directly between EBS direct APIs and Amazon EC2 instances in the same AWS Region is free when using non-FIPS endpoints. For more information, see AWS service endpoints. If other AWS services are in the path of your data transfer, you will be charged their associated data processing costs. These services include, but are not limited to, PrivateLink endpoints, NAT Gateway and Transit Gateway.

**VPC interface endpoints**

If you are using EBS direct APIs from Amazon EC2 instances or AWS Lambda functions in private subnets, you can use VPC interface endpoints, instead of using NAT gateways, to reduce network data transfer costs. For more information, see Using interface VPC endpoints with EBS direct APIs (p. 2204).

**Using interface VPC endpoints with EBS direct APIs**

You can establish a private connection between your VPC and EBS direct APIs by creating an interface VPC endpoint, powered by AWS PrivateLink. You can access EBS direct APIs as if it were in your VPC, without using an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC don’t need public IP addresses to communicate with EBS direct APIs.

We create an endpoint network interface in each subnet that you enable for the interface endpoint.

For more information, see Access AWS services through AWS PrivateLink in the AWS PrivateLink Guide.

**Considerations for EBS direct APIs VPC endpoints**

Before you set up an interface VPC endpoint for EBS direct APIs, review Considerations in the AWS PrivateLink Guide.

VPC endpoint policies are not supported for EBS direct APIs. By default, full access to EBS direct APIs is allowed through the endpoint. However, you can control access to the interface endpoint using security groups.

**Create an interface VPC endpoint for EBS direct APIs**

You can create a VPC endpoint for EBS direct APIs using either the Amazon VPC console or the AWS Command Line Interface (AWS CLI). For more information, see Create a VPC endpoint in the AWS PrivateLink Guide.

Create a VPC endpoint for EBS direct APIs using the following service name:

- `com.amazonaws.region.ebs`

If you enable private DNS for the endpoint, you can make API requests to EBS direct APIs using its default DNS name for the Region, for example, `ebs.us-east-1.amazonaws.com`.

**Log API Calls for EBS direct APIs with AWS CloudTrail**

The EBS direct APIs service is integrated with AWS CloudTrail. CloudTrail is a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls performed in EBS direct APIs as events. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon Simple Storage Service (Amazon S3) bucket. If you don't configure a trail, you can still view the most recent management events in the CloudTrail console in Event history. Data events are not captured in Event history. You can use the information collected by CloudTrail to determine the request that was made to EBS direct APIs, the IP address from which the request was made, who made the request, when it was made, and additional details.

For more information about CloudTrail, see the AWS CloudTrail User Guide.

**EBS direct APIs Information in CloudTrail**

CloudTrail is enabled on your AWS account when you create the account. When supported event activity occurs in EBS direct APIs, that activity is recorded in a CloudTrail event along with other AWS service
events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for EBS direct APIs, create a trail. A trail enables CloudTrail to deliver log files to an S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
- Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

Supported API actions

For EBS direct APIs, you can use CloudTrail to log two types of events:

- **Management events** — Management events provide visibility into management operations that are performed on snapshots in your AWS account. The following API actions are logged by default as management events in trails:
  - StartSnapshot
  - CompleteSnapshot

For more information about logging management events, see Logging management events for trails in the CloudTrail User Guide.

- **Data events** — These events provide visibility into the snapshot operations performed on or within a snapshot. The following API actions can optionally be logged as data events in trails:
  - ListSnapshotBlocks
  - ListChangedBlocks
  - GetSnapshotBlock
  - PutSnapshotBlock

Data events are not logged by default when you create a trail. You can use only advanced event selectors to record data events on EBS direct API calls. For more information, see Logging data events for trails in the CloudTrail User Guide.

**Note**

If you perform an action on a snapshot that is shared with you, data events are not sent to the AWS account that owns the snapshot.

Identity information

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentityElement.
Understand EBS direct APIs Log File Entries

A trail is a configuration that enables delivery of events as log files to an S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following are example CloudTrail log entries.

StartSnapshot

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",

Frequently asked questions

Can a snapshot be accessed using the EBS direct APIs if it has a pending status?

No. The snapshot can be accessed only if it has a completed status.

Are the block indexes returned by the EBS direct APIs in numerical order?

Yes. The block indexes returned are unique, and in numerical order.

Can I submit a request with a MaxResults parameter value of under 100?

No. The minimum MaxResult parameter value you can use is 100. If you submit a request with a MaxResult parameter value of under 100, and there are more than 100 blocks in the snapshot, then the API will return at least 100 results.

Can I run API requests concurrently?

You can run API requests concurrently. Be sure to take note of other workloads that might be running in the account to avoid bottlenecks. You should also build retry mechanisms into your EBS direct APIs workflows to handle throttling, timeouts, and service unavailability. For more information, see Optimize performance (p. 2200).

Review the EBS direct APIs service quotas to determine the API requests that you can run per second. For more information, see Amazon Elastic Block Store Endpoints and Quotas in the AWS General Reference.

When running the ListChangedBlocks action, is it possible to get an empty response even though there are blocks in the snapshot?

Yes. If the changed blocks are scarce in the snapshot, the response may be empty but the API will return a next page token value. Use the next page token value to continue to the next page of results. You can confirm that you have reached the last page of results when the API returns a next page token value of null.

If the NextToken parameter is specified together with a StartingBlockIndex parameter, which of the two is used?

The NextToken is used, and the StartingBlockIndex is ignored.

How long are the block tokens and next tokens valid?

Block tokens are valid for seven days, and next tokens are valid for 60 minutes.

Are encrypted snapshots supported?

Yes. Encrypted snapshots can be accessed using the EBS direct APIs.

To access an encrypted snapshot, the user must have access to the KMS key used to encrypt the snapshot, and the AWS KMS decrypt action. See the IAM permissions for EBS direct APIs (p. 2181) section earlier in this guide for the AWS KMS policy to assign to a user.
Are public snapshots supported?

Public snapshots are not supported.

Are Amazon EBS local snapshots on Outposts supported?

Amazon EBS local snapshots on Outposts are not supported.

Does list snapshot block return all block indexes and block tokens in a snapshot, or only those that have data written to them?

It returns only block indexes and tokens that have data written to them.

Can I get a history of the API calls made by the EBS direct APIs on my account for security analysis and operational troubleshooting purposes?

Yes. To receive a history of EBS direct APIs API calls made on your account, turn on AWS CloudTrail in the AWS Management Console. For more information, see Log API Calls for EBS direct APIs with AWS CloudTrail (p. 2204).

Automate the snapshot lifecycle

You can use Amazon Data Lifecycle Manager to automate the creation, retention, and deletion of snapshots that you use to back up your Amazon EBS volumes.

For more information, see Amazon Data Lifecycle Manager (p. 2211).

Amazon Data Lifecycle Manager

You can use Amazon Data Lifecycle Manager to automate the creation, retention, and deletion of EBS snapshots and EBS-backed AMIs. When you automate snapshot and AMI management, it helps you to:

- Protect valuable data by enforcing a regular backup schedule.
- Create standardized AMIs that can be refreshed at regular intervals.
- Retain backups as required by auditors or internal compliance.
- Reduce storage costs by deleting outdated backups.
- Create disaster recovery backup policies that back up data to isolated Regions or accounts.

When combined with the monitoring features of Amazon EventBridge and AWS CloudTrail, Amazon Data Lifecycle Manager provides a complete backup solution for Amazon EC2 instances and individual EBS volumes at no additional cost.

Important

- Amazon Data Lifecycle Manager can't manage snapshots or AMIs created by any other means.
- Amazon Data Lifecycle Manager can't automate the creation, retention, and deletion of instance store-backed AMIs.

</thead>
<tbody>
<tr>
<td>Custom lifecycle policies per Region</td>
<td>100</td>
</tr>
<tr>
<td>Default policies for EBS snapshots per Region</td>
<td>1</td>
</tr>
<tr>
<td>Default policies for EBS-backed AMIs per Region</td>
<td>1</td>
</tr>
<tr>
<td>Tags per resource</td>
<td>45</td>
</tr>
</tbody>
</table>

**How Amazon Data Lifecycle Manager works**

The following are the key elements of Amazon Data Lifecycle Manager.

**Elements**

- **Policies (p. 2212)**
- **Policy schedules (custom policies only) (p. 2213)**
- **Target resource tags (custom policies only) (p. 2214)**
- **Snapshots (p. 2214)**
- **EBS-backed AMIs (p. 2214)**
- **Amazon Data Lifecycle Manager tags (p. 2214)**

**Policies**

With Amazon Data Lifecycle Manager, you create policies to define your backup creation and retention requirements. These policies typically specify the following:

- **Policy type** — Defines the type of backup resources that the policy manages (snapshots or EBS-backed AMIs).
- **Target resources** — Defines the type of resources that are targeted by the policy (instances or EBS volumes).
- **Creation frequency** — Defines how often the policy runs and creates snapshots or AMIs.
- **Retention threshold** — Defines how long the policy retains snapshots or AMIs after creation.
- **Additional actions** — Defines additional actions that the policy should perform, such as cross-Region copying, archiving, or resource tagging.

Amazon Data Lifecycle Manager offers default policies and custom policies.
Default policies

Default policies back up all volumes and instances in a Region that do not have recent backups. You can optionally exclude volumes and instances by specifying exclusion parameters.

Amazon Data Lifecycle Manager supports the following default policies:

- Default policy for EBS snapshots — Targets volumes and automates the creation, retention, and deletion of snapshots.
- Default policy for EBS-backed AMIs — Targets instances and automates the creation, retention, and deregistration of EBS-backed AMIs.

You can have only one default policy per resource type in each account and AWS Region.

Custom policies

Custom policies target specific resources based on their assigned tags and support advanced features, such as fast snapshot restore, snapshot archiving, cross-account copying, and pre and post scripts. A custom policy can include up to 4 schedules, where each schedule can have its own creation frequency, retention threshold, and advanced feature configuration.

Amazon Data Lifecycle Manager supports the following custom policies:

- EBS snapshot policy — Targets volumes or instances and automates the creation, retention, and deletion of EBS snapshots.
- EBS-backed AMI policy — Targets instances and automates the creation, retention, and deregistration of EBS-backed AMIs.
- Cross-account copy event policy — Automates cross-Region copy actions for snapshots that are shared with you.

For more information, see Default policies vs custom policies (p. 2215).

Policy schedules (custom policies only)

Policy schedules define when snapshots or AMIs are created by the policy. Policies can have up to four schedules—one mandatory schedule, and up to three optional schedules.

Adding multiple schedules to a single policy lets you create snapshots or AMIs at different frequencies using the same policy. For example, you can create a single policy that creates daily, weekly, monthly, and yearly snapshots. This eliminates the need to manage multiple policies.

For each schedule, you can define the frequency, fast snapshot restore settings (snapshot lifecycle policies only), cross-Region copy rules, and tags. The tags that are assigned to a schedule are automatically assigned to the snapshots or AMIs that are created when the schedule is initiated. In addition, Amazon Data Lifecycle Manager automatically assigns a system-generated tag based on the schedule's frequency to each snapshot or AMI.

Each schedule is initiated individually based on its frequency. If multiple schedules are initiated at the same time, Amazon Data Lifecycle Manager creates only one snapshot or AMI and applies the retention settings of the schedule that has the highest retention period. The tags of all of the initiated schedules are applied to the snapshot or AMI.

- (Snapshot lifecycle policies only) If more than one of the initiated schedules is enabled for fast snapshot restore, then the snapshot is enabled for fast snapshot restore in all of the Availability Zones specified across all of the initiated schedules. The highest retention settings of the initiated schedules is used for each Availability Zone.
If more than one of the initiated schedules is enabled for cross-Region copy, the snapshot or AMI is copied to all Regions specified across all of the initiated schedules. The highest retention period of the initiated schedules is applied.

**Target resource tags (custom policies only)**

Amazon Data Lifecycle Manager custom policies use resource tags to identify the resources to back up. When you create a snapshot or EBS-backed AMI policy, you can specify multiple target resource tags. All resources of the specified type (instance or volume) that have at least one of the specified target resource tags will be targeted by the policy. For example, if you create a snapshot policy that targets volumes and you specify `purpose=prod`, `costcenter=prod`, and `environment=live` as target resource tags, then the policy will target all volumes that have any of those tag-key value pairs.

If you want to run multiple policies on a resource, you can assign multiple tags to the target resource, and then create separate policies that each target a specific resource tag.

You can't use the `\` or `=` characters in a tag key. Target resource tags are case sensitive. For more information, see [Tag your Amazon EC2 resources (p. 2507)](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/tagging.html).

**Snapshots**

Snapshots are the primary means to back up data from your EBS volumes. To save storage costs, successive snapshots are incremental, containing only the volume data that changed since the previous snapshot. When you delete one snapshot in a series of snapshots for a volume, only the data that's unique to that snapshot is removed. The rest of the captured history of the volume is preserved. For more information, see [Amazon EBS snapshots (p. 2107)](https://docs.aws.amazon.com/AmazonEBS/latest/UserGuide/snapshots.html).

**EBS-backed AMIs**

An Amazon Machine Image (AMI) provides the information that's required to launch an instance. You can launch multiple instances from a single AMI when you need multiple instances with the same configuration. Amazon Data Lifecycle Manager supports EBS-backed AMIs only. EBS-backed AMIs include a snapshot for each EBS volume that's attached to the source instance. For more information, see [Amazon Machine Images (AMI) (p. 112)](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/creating-amis.html).

**Amazon Data Lifecycle Manager tags**

Amazon Data Lifecycle Manager applies the following system tags to all snapshots and AMIs created by a policy, to distinguish them from snapshots and AMIs created by any other means:

- `aws:dlm:lifecycle-policy-id`
- `aws:dlm:lifecycle-schedule-name`
- `aws:dlm:expirationTime` — For snapshots created by an age-based schedule. Indicates when the snapshot is to be deleted from the standard tier.
- `dlm:managed`
- `aws:dlm:archived` — For snapshots that were archived by a schedule.
- `aws:dlm:pre-script` — For snapshots created with pre scripts.
- `aws:dlm:post-script` — For snapshots created with post scripts.

You can also specify custom tags to be applied to snapshots and AMIs on creation. You can't use the `\` or `=` characters in a tag key.

The target tags that Amazon Data Lifecycle Manager uses to associate volumes with a snapshot policy can optionally be applied to snapshots created by the policy. Similarly, the target tags that are used to associate instances with an AMI policy can optionally be applied to AMIs created by the policy.
Default policies vs custom policies

This section compares default policies and custom policies and highlights their similarities and differences.

1 For default policies:
- You can't copy tags to cross-Region copies.
- Copies use the same retention period as the source snapshot.
- Copies get the same encryption state as the source snapshot. If the destination Region is enabled for encryption by default, copies are always encrypted, even if the source snapshots are unencrypted. Copies are always encrypted with the default KMS key for the destination Region.

2 For default and custom policies:
- If a target instance or volume is deleted, Amazon Data Lifecycle Manager continues deleting snapshots up to, but not including, the last one based on the retention period. For default policies, you can extend deletion to include the last snapshot.
- If a policy is deleted or enters the error or disabled state, Amazon Data Lifecycle Manager stops deleting snapshots. For default policies, you can extend deletion to continue deleting snapshots, including the last one.

**EBS-backed AMI policy comparison**

The following table highlights the differences between the default policy for EBS-backed AMIs and custom EBS-backed AMI policies.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Default policy for EBS-backed AMIs</th>
<th>Custom EBS-backed AMI policy</th>
</tr>
</thead>

<td>Yes</td>
</tr>
<tr>
<td>Exclusion parameters</td>
<td>Yes, can exclude instances with specific tags.</td>
<td>No</td>
</tr>
<tr>
<td>Support multiple schedules</td>
<td>No</td>
<td>Yes, up to 4 schedules per policy.</td>
</tr>
<tr>
<td>Feature</td>
<td>Default policy for EBS-backed AMIs</td>
<td>Custom EBS-backed AMI policy</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td><strong>AMI creation frequency</strong></td>
<td>Every 1 to 7 days.</td>
<td>Daily, weekly, monthly, yearly, or custom frequency using a cron expression.</td>
</tr>
<tr>
<td><strong>Supported retention types</strong></td>
<td>Age-based retention only.</td>
<td>Age-based and count-based retention.</td>
</tr>
<tr>
<td><strong>AMIs retention</strong></td>
<td>2 to 14 days.</td>
<td>Up to 1000 AMIs (count-based) or up to 100 years (age-based).</td>
</tr>
<tr>
<td><strong>Support AMI deprecation</strong></td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Support cross-Region copying</strong></td>
<td>Yes, with default settings ¹</td>
<td>Yes, with custom settings</td>
</tr>
<tr>
<td><strong>Support extended deletion ²</strong></td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

¹ For default policies:
- You can't copy tags to cross-Region copies.
- Copies use the same retention period as the source AMI.
- Copies get the same encryption state as the source AMI. If the destination Region is enabled for encryption by default, copies are always encrypted, even if the source AMIs are unencrypted. Copies are always encrypted with the default KMS key for the destination Region.

² For default and custom policies:
- If a targeted instance is terminated, Amazon Data Lifecycle Manager continues deregistering AMIs up to, but not including, the last one based on the retention period. For default policies, you can extend deregistration to include the last AMI.
- If a policy is deleted or enters the error or disabled state, Amazon Data Lifecycle Manager stops deregistering AMIs. For default policies, you can extend deletion to continue deregistering AMIs, including the last one.

**Default policies**
To create periodic EBS-backed AMIs from instances, use the default policy for EBS-backed AMIs. To create snapshots of all volumes regardless of their attachment state, or if you want to exclude specific volumes, use the default policy for EBS snapshots.

This section explains how to create default policies.

**Topics**
- [Considerations (p. 2217)]
- [Default policy for EBS snapshots (p. 2218)]
- [Default policy for EBS-backed AMIs (p. 2220)]

**Considerations**
Keep the following in mind when working with default policies:
• Default policies do not back up target resources (instances or volumes) that have recent backups (snapshots or AMIs). The creation frequency determines which resources are backed up. A volume or instance is backed up only if its last snapshot or AMI is older than the policy's creation frequency. For example, if you specify a creation frequency of 3 days, the default policy for EBS snapshots will create a snapshot of a volume only if its last snapshot is older than 3 days.

• By default, default policies target all instances or volumes in the Region, unless exclusion parameters are specified.

• Default policies will create a minimum set of unique snapshots. For example, if you enable the EBS-backed AMI policy and the EBS snapshot policy, the snapshot policy will not duplicate snapshots of volumes that were already backed up by the EBS-backed AMI policy.

• Default policies will only start targeting resources that are at least 24 hours old.

• If you delete a volume or terminate an instance targeted by a default policy, Amazon Data Lifecycle Manager will continue to delete the previously created backups (snapshots or AMIs) according to the retention period up to, but not including, the last backup. You must manually delete this backup if it is not required.

If you want Amazon Data Lifecycle Manager to delete the last backup, you can enable extend deletion.

• If a default policy is deleted or enters the error or disabled state, Amazon Data Lifecycle Manager stops deleting the previously created backups (snapshots or AMIs). If you want Amazon Data Lifecycle Manager to continue deleting backups, including the last one, you must enable extend deletion before deleting the policy or before the policy's state changes to disabled or deleted.

• When you create and enable a default policy, Amazon Data Lifecycle Manager randomly assigns targeted resources to a four-hour time window. Targeted resources are backed up during their assigned window at the specified creation frequency. For example, if a policy has a creation frequency of 3 days, and a target resource is assigned to the 12:00 - 16:00 window, that resource will be backed up between 12:00 - 16:00 every 3 days.

**Default policy for EBS snapshots**

The following procedure shows you how to create a default policy for EBS snapshots.

**Console**

**To create a default policy for EBS snapshots**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation panel, choose **Lifecycle Manager** and then choose **Create lifecycle policy**.
3. For **Policy type**, choose **Default policy** and then choose **EBS snapshot policy**.
4. For **Description**, enter a brief description for the policy.
5. For **IAM role**, choose the IAM role that has permissions to manage snapshots.

   We recommend that you choose **Default** to use the default IAM role provided by Amazon Data Lifecycle Manager. However, you can also use a custom IAM role that you previously created.

6. For **Creation frequency**, specify how often you want the policy to run and create snapshots of your volumes.

   The frequency that you specify also determines which volumes are backed up. The policy will only back up volumes that have not been backed up by any other means within the specified frequency. For example, if you specify a creation frequency of 3 days, the policy will only create snapshots of volumes that have not been backed up within the last 3 days.

7. For **Retention period**, specify how long you want the policy to retain the snapshots that it creates. When a snapshot reaches the retention threshold, it is automatically deleted. The retention period must be greater than or equal to the creation frequency.
8. *(Optional)* Configure the **Exclusion parameters** to exclude specific volumes from the scheduled backups. Excluded volumes will not be backed up when the policy runs.

   a. To exclude boot volumes, select **Exclude boot volumes**. If you exclude boot volumes, only data (non-boot) volumes will be backed up by the policy. In other words, it will not create snapshots of volumes that are attached to instances as a boot volume.

   b. To exclude specific volume types, choose **Exclude specific volume types**, and then select the volume types to exclude. Only volumes of the remaining types will be backed up by the policy.

   c. To exclude volumes that have specific tags, choose **Add tag**, and then specify the tag keys and values. The policy will not create snapshots of volumes that have any of the specified tags.

9. *(Optional)* In the **Advanced settings**, specify additional actions that the policy should perform.

   a. To copy assigned tags from the source volumes to their snapshots, select **Copy tags from volumes**.

   b. With **Extend deletion** disabled:
      
      - If a source volume is deleted, Amazon Data Lifecycle Manager continues to delete previously created snapshots up to, but not including, the last one based on the retention period. If you want Amazon Data Lifecycle Manager to delete all snapshots, including the last one, select **Extend deletion**.

      - If a policy is deleted or enters the error or disabled state, Amazon Data Lifecycle Manager stops deleting snapshots. If you want Amazon Data Lifecycle Manager to continue deleting snapshots, including the last one, select **Extend deletion**.

      **Note**
      
      If you enable extend deletion, you override both behaviors described above simultaneously.

   c. To copy snapshots created by the policy to other Regions, select **Create cross-Region copy** and then select up to 3 destination Regions.

      - If the source snapshot is encrypted, or if encryption by default is enabled for the destination Region, the copied snapshots are encrypted using the default KMS key for EBS encryption in the destination Region.

      - If the source snapshot is unencrypted and encryption by default is disabled for the destination Region, the copied snapshots are unencrypted.

10. *(Optional)* To add a tag to the policy, choose **Add tag** and then specify the tag key and value pair.

11. Choose **Create default policy**.

    **Note**
    
    If you get the **Role with name AWSDataLifecycleManagerDefaultRole already exists** error, see [Troubleshooting (p. 2303)] for more information.

**AWS CLI**

**To create a default policy for EBS snapshots**

Use the `create-lifecycle-policy` command. You can specify the request parameters in one of two methods, depending on your use case or preferences:

- **Method 1**

  ```bash
  $ aws dlm create-lifecycle-policy
  ```
For example, to create a default policy for EBS snapshots that targets all volumes in the Region, uses the default IAM role, runs daily (default), and retains snapshots for 7 days (default), you need to specify the following parameters:

```
$ aws dlm create-lifecycle-policy
  --state ENABLED
  --description "Daily default snapshot policy"
  --execution-role-arn arn:aws:iam::account_id:role/AWSDataLifecycleManagerDefaultRole
  --default-policy VOLUME
```

**Method 2**

```
$ aws dlm create-lifecycle-policy
  --state ENABLED
  --description "policy_description"
  --execution-role-arn role_arn
  --default-policy VOLUME
  --policy-details file://policyDetails.json
```

Where `policyDetails.json` includes the following:

```
{
  "PolicyLanguage": "SIMPLIFIED",
  "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
  "ResourceType": "VOLUME",
  "CopyTags": true | false,
  "CreateInterval": creation_frequency_in_days (1-7),
  "RetainInterval": retention_period_in_days (2-14),
  "ExtendDeletion": true | false,
  "CrossRegionCopyTargets": ["TargetRegion":destination_region_code],
  "Exclusions": {
    "ExcludeBootVolume": true | false,
    "ExcludeVolumeTypes": ["standard | gp2 | gp3 | io1 | io2 | st1 | sc1"],
    "ExcludeTags": [{
      "Key": "exclusion_tag_key",
      "Value": "exclusion_tag_value"
    }]
  }
}
```

**Default policy for EBS-backed AMIs**

The following procedure shows you how to create a default policy for EBS-backed AMIs.
Console

To create a default policy for EBS-backed AMIs

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation panel, choose Lifecycle Manager and then choose Create lifecycle policy.
3. For Policy type, choose Default policy and then choose EBS-backed AMI policy.
4. For Description, enter a brief description for the policy.
5. For IAM role, choose the IAM role that has permissions to manage AMIs.

We recommend that you choose Default to use the default IAM role provided by Amazon Data Lifecycle Manager. However, you can also use a custom IAM role that you previously created.

6. For Creation frequency, specify how often you want the policy to run and create AMIs from your instances.

The frequency that you specify also determines which instances are backed up. The policy will only back up instances that have not been backed up by any other means within the specified frequency. For example, if you specify a creation frequency of 3 days, the policy will only create AMIs from instances that have not been backed up within the last 3 days.

7. For Retention period, specify how long you want the policy to retain the AMIs that it creates. When an AMI reaches the retention threshold, it is automatically deregistered and its associated snapshots are deleted. The retention period must be greater than or equal to the creation frequency.

8. (Optional) Configure the Exclusion parameters to exclude specific instances from the scheduled backups. Excluded instances will not be backed up when the policy runs.

   • To exclude instances that have specific tags, choose Add tag, and then specify the tag keys and values. The policy will not create AMIs from instances that have any of the specified tags.

9. (Optional) In the Advanced settings, specify additional actions that the policy should perform.

   a. To copy assigned tags from the source instances to their AMIs, select Copy tags from instances.

   b. With Extend deletion disabled:

      • If a source instance is terminated, Amazon Data Lifecycle Manager continues to deregister previously created AMIs up to, but not including, the last one based on the retention period. If you want Amazon Data Lifecycle Manager to deregister all AMIs, including the last one, select Extend deletion.

      • If a policy is deleted or enters the error or disabled state, Amazon Data Lifecycle Manager stops deregistering AMIs. If you want Amazon Data Lifecycle Manager to continue deregistering AMIs, including the last one, select Extend deletion.

         Note
         If you enable extended deletion, you override both behaviors described above simultaneously.

   c. To copy AMIs created by the policy to other Regions, select Create cross-Region copy and then select up to 3 destination Regions.

      • If the source AMI is encrypted, or if encryption by default is enabled for the destination Region, the copied AMIs are encrypted using the default KMS key for EBS encryption in the destination Region.

      • If the source AMI is unencrypted and encryption by default is disabled for the destination Region, the copied AMIs are unencrypted.
10. *(Optional)* To add a tag to the policy, choose **Add tag** and then specify the tag key and value pair.

11. Choose **Create default policy**.

**Note**
If you get the Role with name AWSDataLifecycleManagerDefaultRoleForAMIMangement already exists error, see **Troubleshooting (p. 2303)** for more information.

**AWS CLI**

**To create a default policy for EBS-backed AMIs**

Use the `create-lifecycle-policy` command. You can specify the request parameters in one of two methods, depending on your use case or preferences:

- **Method 1**

```bash
$ aws dlm create-lifecycle-policy \
--state ENABLED | DISABLED \
--description "policy_description" \
--execution-role-arn role_arn \
--default-policy INSTANCE \
--create-interval creation_frequency_in_days (1-7) \
--retain-interval retention_period_in_days (2-14) \
--copy-tags | --no-copy-tags \
--extend-deletion | --no-extend-deletion \
--cross-region-copy-targets TargetRegion=destination_region_code \
--exclusions ExcludeTags=[{Key=tag_key,Value=tag_value}]
```

For example, to create a default policy for EBS-backed AMIs that targets all instances in the Region, uses the default IAM role, runs daily (default), and retains AMIs for 7 days (default), you need to specify the following parameters:

```bash
$ aws dlm create-lifecycle-policy \
--state ENABLED \
--description "Daily default AMI policy" \
--execution-role-arn arn:aws:iam::account_id:role/AWSDataLifecycleManagerDefaultRoleForAMIMangement \
--default-policy INSTANCE
```

- **Method 2**

```bash
$ aws dlm create-lifecycle-policy \
--state ENABLED | DISABLED \
--description "policy_description" \
--execution-role-arn role_arn \
--default-policy INSTANCE \
--policy-details file://policyDetails.json
```

Where `policyDetails.json` includes the following:

```json
{
    "PolicyLanguage": "SIMPLIFIED",
    "PolicyType": "IMAGE_MANAGEMENT",
    "ResourceType": "INSTANCE",
    "CopyTags": true | false,
    "CreateInterval": creation_frequency_in_days (1-7),
    "RetainInterval": retention_period_in_days (2-14),
```
Custom policies

This section explains how to create custom EBS snapshot, EBS-backed AMI, and cross-account copy event policies.

Topics
• Automate snapshot lifecycles (p. 2223)
• Automate AMI lifecycles (p. 2265)
• Automate cross-account snapshot copies (p. 2271)

Automate snapshot lifecycles

The following procedure shows you how to use Amazon Data Lifecycle Manager to automate Amazon EBS snapshot lifecycles.

Topics
• Create a snapshot lifecycle policy (p. 2223)
• Considerations for snapshot lifecycle policies (p. 2233)
• Additional resources (p. 2236)
• Requirements for using pre and post scripts (p. 2237)
• Automating application-consistent snapshots with pre and post scripts (p. 2237)
• Other use cases for pre and post scripts (p. 2256)
• How pre and post scripts work (p. 2262)
• Identifying snapshots created with pre and post scripts (p. 2264)
• Monitoring pre and post script execution (p. 2264)

Create a snapshot lifecycle policy

Use one of the following procedures to create a snapshot lifecycle policy.

Console

To create a snapshot policy

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic Block Store, Lifecycle Manager, and then choose Create lifecycle policy.
3. On the Select policy type screen, choose EBS snapshot policy and then choose Next.
4. In the Target resources section, do the following:
   a. For Target resource types, choose the type of resource to back up. Choose Volume to create snapshots of individual volumes, or choose Instance to create multi-volume snapshots from the volumes attached to an instance.
b. (AWS Outpost customers only) Specify where the target resources are located.

For **Target resource location**, specify where the target resources are located.

- If the target resources are located in an AWS Region, choose **AWS Region**. Amazon Data Lifecycle Manager backs up all resources of the specified type that have matching target tags in the current Region only. If the resource is located in a Region, snapshots created by the policy will be stored in the same Region.
- If the target resources are located on an Outpost in your account, choose **AWS Outpost**. Amazon Data Lifecycle Manager backs up all resources of the specified type that have matching target tags across all of the Outposts in your account. If the resource is located on an Outpost, snapshots created by the policy can be stored in the same Region or on the same Outpost as the resource.
- If you do not have any Outposts in your account, this option is hidden and AWS Region is selected for you.

c. For **Target resource tags**, choose the resource tags that identify the volumes or instances to back up. Only resources that have the specified tag key and value pairs are backed up by the policy.

5. For **Description**, enter a brief description for the policy.

6. For **IAM role**, choose the IAM role that has permissions to manage snapshots and to describe volumes and instances. To use the default role provided by Amazon Data Lifecycle Manager, choose **Default role**. Alternatively, to use a custom IAM role that you previously created, choose **Choose another role** and then select the role to use.

7. For **Policy tags**, add the tags to apply to the lifecycle policy. You can use these tags to identify and categorize your policies.

8. For **Policy status**, choose **Enable** to start the policy runs at the next scheduled time, or **Disable policy** to prevent the policy from running. If you do not enable the policy now, it will not start creating snapshots until you manually enable it after creation.

9. (Policies that target instances only) Exclude volumes from multi-volume snapshot sets.

   By default, Amazon Data Lifecycle Manager will create snapshots of all the volumes attached to targeted instances. However, you can choose to create snapshots of a subset of the attached volumes. In the **Parameters** section, do the following:

   - If you do not want to create snapshots of the root volumes attached to the targeted instances, select **Exclude root volume**. If you select this option, only the data (non-root) volumes that are attached to targeted instances will be included in the multi-volume snapshot sets.
   - If you want to create snapshots of a subset of the data (non-root) volumes attached to the targeted instances, select **Exclude specific data volumes**, and then specify the tags that are to be used to identify the data volumes that should not be snapshotted. Amazon Data Lifecycle Manager will not create snapshots of data volumes that have any of the specified tags. Amazon Data Lifecycle Manager will create snapshots only of data volumes that do not have any of the specified tags.

10. Choose **Next**.

11. On the **Configure schedule** screen, configure the policy schedules. A policy can have up to 4 schedules. Schedule 1 is mandatory. Schedules 2, 3, and 4 are optional. For each policy schedule that you add, do the following:

   a. In the **Schedule details** section do the following:

      i. For **Schedule name**, specify a descriptive name for the schedule.
      
      ii. For **Frequency** and the related fields, configure the interval between policy runs.
You can configure policy runs on a daily, weekly, monthly, or yearly schedule. Alternatively, choose **Custom cron expression** to specify an interval of up to one year. For more information, see [Cron expressions](#) in the Amazon CloudWatch Events User Guide.

**Note**

If you need to enable **snapshot archiving** for the schedule, then you must select either the **monthly** or **yearly** frequency, or you must specify a cron expression with a creation frequency of at least 28 days.

If specify a monthly frequency that creates snapshots on a specific day in a specific week (for example, the second Thursday of the month), then for count-based schedule, the retention count for the archive tier must be 4 or more.

iii. For **Starting at**, specify the time at which the policy runs are scheduled to start. The first policy run starts within an hour after the scheduled time. The time must be entered in the `hh:mm` UTC format.

iv. For **Retention type**, specify the retention policy for snapshots created by the schedule.

You can retain snapshots based on either their total count or their age.

- (Count-based retention) If you do not enable snapshot archiving, the range is 1 to 1000. If you enable snapshot archiving, the range is 0 to 1000. If you specify a count of 0, snapshots are archived immediately after creation.
- (Age-based retention) If you do not enable snapshot archiving, the range is 1 day to 100 years. If you enable snapshot archiving, the range is 0 days to 100 years. If you specify 0 days, snapshots are archived immediately after creation.

**Note**

- All schedules must have the same retention type (age-based or count-based). You can specify the retention type for Schedule 1 only. Schedules 2, 3, and 4 inherit the retention type from Schedule 1. Each schedule can have its own retention count or period.
- If you enable fast snapshot restore, cross-Region copy, or snapshot sharing, then you must specify a retention count of 1 or more, or a retention period of 1 day or longer.
- If you enable snapshot archiving, this retention rule determines how long the snapshot remains in the standard tier before being archived. Once the standard tier retention threshold is met, the snapshot is converted to a full snapshot and it is moved to the archive tier.

v. **(AWS Outposts customers only)** Specify snapshot destination.

For **Snapshot destination**, specify the destination for snapshots created by the policy.

- If the policy targets resources in a Region, snapshots must be created in the same Region. AWS Region is selected for you.
- If the policy targets resources on an Outpost, you can choose to create snapshots on the same Outpost as the source resource, or in the Region that is associated with the Outpost.
- If you do not have any Outposts in your account, this option is hidden and AWS Region is selected for you.

b. Configure tagging for snapshots.

In the **Tagging** section, do the following:
i. To copy all of the user-defined tags from the source volume to the snapshots created by the schedule, select **Copy tags from source**.

ii. To specify additional tags to assign to snapshots created by this schedule, choose **Add tags**.

**c.** Configure pre and post scripts for application-consistent snapshots.

For more information, see **Automating application-consistent snapshots with pre and post scripts (p. 2237)**.

**d.** *(Policies that target volumes only)* Configure snapshot archiving.

In the **Snapshot archiving** section, do the following:

**Note**
You can enable snapshot archiving for only one schedule in a policy.

i. To enable snapshot archiving for the schedule, select **Archive snapshots created by this schedule**.

**Note**
You can enable snapshot archiving only if the snapshot creation frequency is monthly or yearly, or if you specify a cron expression with a creation frequency of at least 28 days.

ii. Specify the retention rule for snapshots in the archive tier.

- For **count-based schedules**, specify the number of snapshots to retain in the archive tier. When the retention threshold is reached, the oldest snapshot is permanently deleted from the archive tier. For example, if you specify 3, the schedule will retain a maximum of 3 snapshots in the archive tier. When the fourth snapshot is archived, the oldest of the three existing snapshots in the archive tier is deleted.

- For **age-based schedules**, specify the time period for which to retain snapshots in the archive tier. When the retention threshold is reached, the oldest snapshot is permanently deleted from the archive tier. For example, if you specify 120 days, the schedule will automatically delete snapshots from the archive tier when they reach that age.

**Important**
The minimum retention period for archived snapshots is 90 days. You must specify a retention rule that retains the snapshot for at least 90 days.

**e.** Enable fast snapshot restore.

To enable fast snapshot restore for snapshots created by the schedule, in the **Fast snapshot restore** section, select **Enable fast snapshot restore**. If you enable fast snapshot restore, you must choose the Availability Zones in which to enable it. If the schedule uses an age-based retention schedule, you must specify the period for which to enable fast snapshot restore for each snapshot. If the schedule uses count-based retention, you must specify the maximum number of snapshots to enable for fast snapshot restore.

If the schedule creates snapshots on an Outpost, you can't enable fast snapshot restore. Fast snapshot restore is not supported with local snapshots that are stored on an Outpost.

**Note**
You are billed for each minute that fast snapshot restore is enabled for a snapshot in a particular Availability Zone. Charges are pro-rated with a minimum of one hour.

**f.** Configure cross-Region copy.
To copy snapshots created by the schedule to an Outpost or to a different Region, in the Cross-Region copy section, select Enable cross-Region copy.

If the schedule creates snapshots in a Region, you can copy the snapshots to up to three additional Regions or Outposts in your account. You must specify a separate cross-Region copy rule for each destination Region or Outpost.

For each Region or Outpost, you can choose different retention policies and you can choose whether to copy all tags or no tags. If the source snapshot is encrypted, or if encryption by default is enabled, the copied snapshots are encrypted. If the source snapshot is unencrypted, you can enable encryption. If you do not specify a KMS key, the snapshots are encrypted using the default KMS key for EBS encryption in each destination Region. If you specify a KMS key for the destination Region, then the selected IAM role must have access to the KMS key.

**Note**
You must ensure that you do not exceed the number of concurrent snapshot copies per Region.

If the policy creates snapshots on an Outpost, then you can't copy the snapshots to a Region or to another Outpost and the cross-Region copy settings are not available.

g. Configure cross-account sharing.

In the Cross-account sharing, configure the policy to automatically share the snapshots created by the schedule with other AWS accounts. Do the following:

i. To enable sharing with other AWS accounts, select Enable cross-account sharing.

ii. To add the accounts with which to share the snapshots, choose Add account, enter the 12-digit AWS account ID, and choose Add.

iii. To automatically unshare shared snapshots after a specific period, select Unshare automatically. If you choose to automatically unshare shared snapshots, the period after which to automatically unshare the snapshots cannot be longer than the period for which the policy retains its snapshots. For example, if the policy's retention configuration retains snapshots for a period of 5 days, you can configure the policy to automatically unshare shared snapshots after periods up to 4 days. This applies to policies with age-based and count-based snapshot retention configurations.

If you do not enable automatic unsharing, the snapshot is shared until it is deleted.

**Note**
You can only share snapshots that are unencrypted or that are encrypted using a customer managed key. You can't share snapshots that are encrypted with the default EBS encryption KMS key. If you share encrypted snapshots, then you must also share the KMS key that was used to encrypt the source volume with the target accounts. For more information, see [Allowing users in other accounts to use a KMS key](https://docs.aws.amazon.com/developerguide/allowing-users-to-use-a-key.html) in the AWS Key Management Service Developer Guide.

h. To add additional schedules, choose Add another schedule, which is located at the top of the screen. For each additional schedule, complete the fields as described previously in this topic.

i. After you have added the required schedules, choose Review policy.

12. Review the policy summary, and then choose Create policy.

**Note**
If you get the Role with name AWSDataLifecycleManagerDefaultRole already exists error, see [Troubleshooting](p. 2305) for more information.
Use the `create-lifecycle-policy` command to create a snapshot lifecycle policy. For PolicyType, specify `EBS_SNAPSHOT_MANAGEMENT`.

**Note**
To simplify the syntax, the following examples use a JSON file, `policyDetails.json`, that includes the policy details.

**Example 1—Snapshot lifecycle policy with two schedules**

This example creates a snapshot lifecycle policy that creates snapshots of all volumes that have a tag key of `costcenter` with a value of `115`. The policy includes two schedules. The first schedule creates a snapshot every day at 03:00 UTC. The second schedule creates a weekly snapshot every Friday at 17:00 UTC.

```bash
aws dlm create-lifecycle-policy \
  --description "My volume policy" \
  --state ENABLED \
  --execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \
  --policy-details file://policyDetails.json
```

The following is an example of the `policyDetails.json` file.

```json
{
  "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
  "ResourceTypes": ["VOLUME"],
  "TargetTags": [{
    "Key": "costcenter",
    "Value": "115"
  }],
  "Schedules": [{
    "Name": "DailySnapshots",
    "TagsToAdd": [{
      "Key": "type",
      "Value": "myDailySnapshot"
    }],
    "CreateRule": {
      "Interval": 24,
      "IntervalUnit": "HOURS",
      "Times": [
        "03:00"
      ]
    },
    "RetainRule": {
      "Count": 5
    },
    "CopyTags": false
  },
  {
    "Name": "WeeklySnapshots",
    "TagsToAdd": [{
      "Key": "type",
      "Value": "myWeeklySnapshot"
    }],
    "CreateRule": {
      "CronExpression": "cron(0 17 ? * FRI *)"
    },
    "RetainRule": {
```
2228
If the request succeeds, the command returns the ID of the newly created policy. The following is example output.

```
{
  "PolicyId": "policy-0123456789abcdef0"
}
```

**Example 2—Snapshot lifecycle policy that targets instances and creates snapshots of a subset of data (non-root) volumes**

This example creates a snapshot lifecycle policy that creates multi-volume snapshot sets from instances tagged with `code=production`. The policy includes only one schedule. The schedule does not create snapshots of the data volumes that are tagged with `code=temp`.

```bash
aws dlm create-lifecycle-policy \
  --description "My volume policy" \
  --state ENABLED \
  --execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \
  --policy-details file:///policyDetails.json
```

The following is an example of the `policyDetails.json` file.

```
{
  "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
  "ResourceTypes": ["INSTANCE"],
  "TargetTags": [{"Key": "code", "Value": "production"}],
  "Parameters": {
    "ExcludeDataVolumeTags": [{"Key": "code", "Value": "temp"}],
  },
  "Schedules": [{
    "Name": "DailySnapshots",
    "TagsToAdd": [{"Key": "type", "Value": "myDailySnapshot"}],
    "CreateRule": {
      "Interval": 24,
      "IntervalUnit": "HOURS",
      "Times": ["03:00"]
    },
    "RetainRule": {
      "Count": 5
    },
    "CopyTags": false
  }]
}
```
If the request succeeds, the command returns the ID of the newly created policy. The following is example output.

```json
{
  "PolicyId": "policy-0123456789abcdef0"
}
```

Example 3—Snapshot lifecycle policy that automates local snapshots of Outpost resources

This example creates a snapshot lifecycle policy that creates snapshots of volumes tagged with `team=dev` across all of your Outposts. The policy creates the snapshots on the same Outposts as the source volumes. The policy creates snapshots every 12 hours starting at 00:00 UTC.

```
aws dlm create-lifecycle-policy
   --description "My local snapshot policy"
   --state ENABLED
   --execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole
   --policy-details file://policyDetails.json
```

The following is an example of the `policyDetails.json` file.

```json
{
  "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
  "ResourceTypes": "VOLUME",
  "ResourceLocations": "OUTPOST",
  "TargetTags": [{
    "Key": "team",
    "Value": "dev"
  }],
  "Schedules": [{
    "Name": "on-site backup",
    "CreateRule": {
      "Interval": 12,
      "IntervalUnit": "HOURS",
      "Times": [
        "00:00"
      ],
      "Location": [
        "OUTPOST_LOCAL"
      ],
      "RetainRule": {
        "Count": 1
      },
      "CopyTags": false
    }
  ]
}
```

Example 4—Snapshot lifecycle policy that creates snapshots in a Region and copies them to an Outpost

The following example policy creates snapshots of volumes that are tagged with `team=dev`. Snapshots are created in the same Region as the source volume. Snapshots are created every 12 hours starting at 00:00 UTC, and retains a maximum of 1 snapshot. The policy also copies the snapshots to Outpost `arn:aws:outposts:us-east-1:123456789012:outpost/`
op-1234567890abcdef0, encrypts the copied snapshots using the default encryption KMS key, and retains the copies for 1 month.

```shell
aws dlm create-lifecycle-policy \
  --description "Copy snapshots to Outpost" \
  --state ENABLED \
  --execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \
  --policy-details file://policyDetails.json
```

The following is an example of the policyDetails.json file.

```json
{
  "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
  "ResourceTypes": "VOLUME",
  "ResourceLocations": "CLOUD",
  "TargetTags": [{
    "Key": "team",
    "Value": "dev"
  }],
  "Schedules": [{
    "Name": "on-site backup",
    "CopyTags": false,
    "CreateRule": {
      "Interval": 12,
      "IntervalUnit": "HOURS",
      "Times": [
        "00:00"
      ],
      "Location": "CLOUD"
    },
    "RetainRule": {
      "Count": 1
    },
    "CrossRegionCopyRules" : [
      {
        "Target": "arn:aws:outposts:us-east-1:123456789012:outpost/op-1234567890abcdef0",
        "Encrypted": true,
        "CopyTags": true,
        "RetainRule": {
          "Interval": 1,
          "IntervalUnit": "MONTHS"
        }
      }
    ]
  }
}
```

Example 5—Snapshot lifecycle policy with an archive-enabled, age-based schedule

This example creates a snapshot lifecycle policy that targets volumes tagged with Name=Prod. The policy has one age-based schedule that creates snapshots on the first day of each month at 09:00. The schedule retains each snapshot in the standard tier for one day, after which it moves them to the archive tier. Snapshots are stored in the archive tier for 90 days before being deleted.

```shell
aws dlm create-lifecycle-policy \
  --description "Copy snapshots to Outpost" \
  --state ENABLED \
  --execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \
  --policy-details file://policyDetails.json
```
The following is an example of the `policyDetails.json` file.

```json
{
    "ResourceTypes": [ "VOLUME"],
    "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
    "Schedules": [
        {
            "Name": "sched1",
            "TagsToAdd": [ {
                "Key": "createdby",
                "Value": "dlm"
            } ],
            "CreateRule": { 
                "CronExpression": "cron(0 9 1 * ? *)"
            },
            "CopyTags": true,
            "RetainRule": { 
                "Interval": 1,
                "IntervalUnit": "DAYS"
            },
            "ArchiveRule": { 
                "RetainRule": { 
                    "RetentionArchiveTier": { 
                        "Interval": 90,
                        "IntervalUnit": "DAYS"
                    }
                }
            }
        }
    ],
    "TargetTags": [
        {
            "Key": "Name",
            "Value": "Prod"
        }
    ]
}
```

**Example 6—Snapshot lifecycle policy with an archive-enabled, count-based schedule**

This example creates a snapshot lifecycle policy that targets volumes tagged with `Purpose=Test`. The policy has one count-based schedule that creates snapshots on the first day of each month at 09:00. The schedule archives snapshots immediately after creation and retains a maximum of three snapshots in the archive tier.

```
aws dlm create-lifecycle-policy \
    --description "Copy snapshots to Outpost" \ 
    --state ENABLED \ 
    --execution-role-arn 
    arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \ 
    --policy-details file://policyDetails.json
```

The following is an example of the `policyDetails.json` file.

```json
{
    "ResourceTypes": [ "VOLUME"],
    "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
    "Schedules": [
        {
            "Name": "sched1",
            "TagsToAdd": [ {
                "Key": "createdby",
                "Value": "dlm"
            } ],
            "CreateRule": {
```

2232
Considerations for snapshot lifecycle policies

The following **general considerations** apply to snapshot lifecycle policies:

- Snapshot lifecycle policies target only instances or volumes that are in the same Region as the policy.
- The first snapshot creation operation starts within one hour after the specified start time. Subsequent snapshot creation operations start within one hour of their scheduled time.
- You can create multiple policies to back up a volume or instance. For example, if a volume has two tags, where tag A is the target for policy A to create a snapshot every 12 hours, and tag B is the target for policy B to create a snapshot every 24 hours, Amazon Data Lifecycle Manager creates snapshots according to the schedules for both policies. Alternatively, you can achieve the same result by creating a single policy that has multiple schedules. For example, you can create a single policy that targets only tag A, and specify two schedules — one for every 12 hours and one for every 24 hours.
- Target resource tags are case sensitive.
- If you remove the target tags from a resource that is targeted by a policy, Amazon Data Lifecycle Manager no longer manages existing snapshots in the standard tier and archive tier; you must manually delete them if they are no longer needed.
- If you create a policy that targets instances, and new volumes are attached to a target instance after the policy has been created, the newly-added volumes are included in the backup at the next policy run. All volumes attached to the instance at the time of the policy run are included.
- If you create a policy with a custom cron-based schedule that is configured to create only one snapshot, the policy will not automatically delete that snapshot when the retention threshold is reached. You must manually delete the snapshot if it is no longer needed.
- If you create an age-based policy where the retention period is shorter than the creation frequency, Amazon Data Lifecycle Manager will always retain the last snapshot until the next one is created. For example, if an age-based policy creates one snapshot every month with a retention period of seven days, Amazon Data Lifecycle Manager will retain each snapshot for one month, even though the retention period is seven days.

If you manually lock a snapshot created by such a policy, and the snapshot is still locked when its retention threshold is reached, Amazon Data Lifecycle Manager will continue to attempt to delete the snapshot.

The following considerations apply to **snapshot archiving (p. 2132)**:
You can enable snapshot archiving only for snapshot policies that target volumes.

You can specify an archiving rule for only one schedule for each policy.

If you are using the console, you can enable snapshot archiving only if the schedule has a monthly or yearly creation frequency, or if the schedule has a cron expression with a creation frequency of at least 28 days.

If you are using the AWS CLI, AWS API, or AWS SDK, you can enable snapshot archiving only if the schedule has a cron expression with a creation frequency of at least 28 days.

The minimum retention period in the archive tier is 90 days.

When a snapshot is archived, it is converted to a full snapshot when it is moved to the archive tier. This could result in higher snapshot storage costs. For more information, see Pricing and billing (p. 2134).

Fast snapshot restore and snapshot sharing are disabled for snapshots when they are archived.

If, in the case of a leap year, your retention rule results in an archive retention period of less than 90 days, Amazon Data Lifecycle Manager ensures that snapshots are retained for the minimum 90-day period.

If you manually archive a snapshot created by Amazon Data Lifecycle Manager, and the snapshot is still archived when the schedule's retention threshold is reached, Amazon Data Lifecycle Manager no longer manages that snapshot. However, if you restore the snapshot to the standard tier before the schedule's retention threshold is reached, the schedule will continue to manage the snapshot as per the retention rules.

If you permanently or temporarily restore a snapshot archived by Amazon Data Lifecycle Manager to the standard tier, and the snapshot is still in the standard tier when the schedule's retention threshold is reached, Amazon Data Lifecycle Manager no longer manages the snapshot. However, if you re-archive the snapshot before the schedule's retention threshold is reached, the schedule will delete the snapshot when the retention threshold is met.

Snapshots archived by Amazon Data Lifecycle Manager count towards your Archived snapshots per volume and In-progress snapshot archives per account quotas.

If a schedule is unable to archive a snapshot after retrying for 24 hours, the snapshot remains in the standard tier and it is scheduled for deletion based on the time that it would have been deleted from the archive tier. For example, if the schedule archives snapshots for 120 days, it remains in the standard tier for 120 days after the failed archiving before being permanently deleted. For count-based schedules, the snapshot does not count towards the schedule's retention count.

Snapshots must be archived in the same Region in which they were created. If you enabled cross-Region copy and snapshot archiving, Amazon Data Lifecycle Manager does not archive the snapshot copy.

Snapshots archived by Amazon Data Lifecycle Manager are tagged with the aws:dlm:archived=true system tag. Additionally, snapshots created by an archive-enabled, age-based schedule are tagged with the aws:dlm:expirationTime system tag, which indicates the date and time at which the snapshot is scheduled to be archived.

The following considerations apply to excluding root volumes and data (non-root) volumes:

If you choose to exclude boot volumes and you specify tags that consequently exclude all of the additional data volumes attached to an instance, then Amazon Data Lifecycle Manager will not create any snapshots for the affected instance, and it will emit a SnapshotsCreateFailed CloudWatch metric. For more information, see Monitor your policies using CloudWatch.

The following considerations apply to deleting volumes or terminating instances targeted by snapshot lifecycle policies:

If you delete a volume or terminate an instance targeted by a policy with a count-based retention schedule, Amazon Data Lifecycle Manager no longer manages snapshots in the standard tier and
archive tier that were created from the deleted volume or instance. You must manually delete those earlier snapshots if they are no longer needed.

- If you delete a volume or terminate an instance targeted by a policy with an age-based retention schedule, the policy continues to delete snapshots from the standard tier and archive tier that were created from the deleted volume or instance on the defined schedule, up to, but not including, the last snapshot. You must manually delete the last snapshot if it is no longer needed.

The following considerations apply to snapshot lifecycle policies and fast snapshot restore (p. 2329):

- Amazon Data Lifecycle Manager can enable fast snapshot restore only for snapshots with a size of 16 TiB or less. For more information, see Amazon EBS fast snapshot restore (p. 2329).
- A snapshot that is enabled for fast snapshot restore remains enabled even if you delete or disable the policy, disable fast snapshot restore for the policy, or disable fast snapshot restore for the Availability Zone. You must disable fast snapshot restore for these snapshots manually.
- If you enable fast snapshot restore for a policy and you exceed the maximum number of snapshots that can be enabled for fast snapshot restore, Amazon Data Lifecycle Manager creates snapshots as scheduled but does not enable them for fast snapshot restore. After a snapshot that is enabled for fast snapshot restore is deleted, the next snapshot that Amazon Data Lifecycle Manager creates is enabled for fast snapshot restore.
- When fast snapshot restore is enabled for a snapshot, it takes 60 minutes per TiB to optimize the snapshot. We recommend that you configure your schedules so that each snapshot is fully optimized before Amazon Data Lifecycle Manager creates the next snapshot.
- If you enable fast snapshot restore for a policy that targets instances, Amazon Data Lifecycle Manager enables fast snapshot restore for each snapshot in the multi-volume snapshot set individually. If Amazon Data Lifecycle Manager fails to enable fast snapshot restore for one of the snapshots in the multi-volume snapshot set, it will still attempt to enable fast snapshot restore for the remaining snapshots in the snapshot set.
- You are billed for each minute that fast snapshot restore is enabled for a snapshot in a particular Availability Zone. Charges are pro-rated with a minimum of one hour. For more information, see Pricing and Billing (p. 2334).

Note
Depending on the configuration of your lifecycle policies, you could have multiple snapshots enabled for fast snapshot restore in multiple Availability Zones simultaneously.

The following considerations apply to snapshot lifecycle policies and Multi-Attach (p. 2077) enabled volumes:

- When creating a lifecycle policy that targets instances that have the same Multi-Attach enabled volume, Amazon Data Lifecycle Manager initiates a snapshot of the volume for each attached instance. Use the timestamp tag to identify the set of time-consistent snapshots that are created from the attached instances.

The following considerations apply to sharing snapshots across accounts:

- You can only share snapshots that are unencrypted or that are encrypted using a customer managed key.
- You can't share snapshots that are encrypted with the default EBS encryption KMS key.
- If you share encrypted snapshots, you must also share the KMS key that was used to encrypt the source volume with the target accounts. For more information, see Allowing users in other accounts to use a KMS key in the AWS Key Management Service Developer Guide.

The following considerations apply to snapshots policies and snapshot archiving (p. 2132):
• If you manually archive a snapshot that was created by a policy, and that snapshot is in the archive tier when the policy’s retention threshold is reached, Amazon Data Lifecycle Manager will not delete the snapshot. Amazon Data Lifecycle Manager does not manage snapshots while they are stored in the archive tier. If you no longer need snapshots that are stored in the archive tier, you must manually delete them.

The following considerations apply to snapshot policies and Recycle Bin (p. 2467):

• If Amazon Data Lifecycle Manager deletes a snapshot and sends it to the Recycle Bin when the policy’s retention threshold is reached, and you manually restore the snapshot from the Recycle Bin, you must manually delete that snapshot when it is no longer needed. Amazon Data Lifecycle Manager will no longer manage the snapshot.

• If you manually delete a snapshot that was created by a policy, and that snapshot is in the Recycle Bin when the policy’s retention threshold is reached, Amazon Data Lifecycle Manager will not delete the snapshot. Amazon Data Lifecycle Manager does not manage the snapshots while they are stored in the Recycle Bin.

If the snapshot is restored from the Recycle Bin before the policy’s retention threshold is reached, Amazon Data Lifecycle Manager will delete the snapshot when the policy’s retention threshold is reached.

If the snapshot is restored from the Recycle Bin after the policy’s retention threshold is reached, Amazon Data Lifecycle Manager will no longer delete the snapshot. You must manually delete the snapshot when it is no longer needed.

The following considerations apply to snapshot lifecycle policies that are in the error state:

• For policies with age-based retention schedules, snapshots that are set to expire while the policy is in the error state are retained indefinitely. You must delete the snapshots manually. When you re-enable the policy, Amazon Data Lifecycle Manager resumes deleting snapshots as their retention periods expire.

• For policies with count-based retention schedules, the policy stops creating and deleting snapshots while it is in the error state. When you re-enable the policy, Amazon Data Lifecycle Manager resumes creating snapshots, and it resumes deleting snapshots as the retention threshold is met.

The following considerations apply to snapshot policies and snapshot lock (p. 2118):

• If you manually lock a snapshot created by Amazon Data Lifecycle Manager, and that snapshot is still locked when its retention threshold is reached, Amazon Data Lifecycle Manager no longer manages that snapshot. You must manually delete the snapshot if it is no longer needed.

• If you manually lock a snapshot that was created and enabled for fast snapshot restore by Amazon Data Lifecycle Manager, and the snapshot is still locked when its retention threshold is reached, Amazon Data Lifecycle Manager will not disable fast snapshot restore or delete the snapshot. You must manually disable fast snapshot restore and delete the snapshot if it is no longer needed.

• If you manually register a snapshot that was created by Amazon Data Lifecycle Manager with an AMI and then lock that snapshot, and that snapshot is still locked and associated with the AMI when its retention threshold is reached, Amazon Data Lifecycle Manager will continue to attempt to delete that snapshot. When the AMI is deregistered and the snapshot is unlocked, Amazon Data Lifecycle Manager will automatically delete the snapshot.

<td>Prepare Amazon Data Lifecycle Manager IAM role run pre and post scripts</td>
<td>✓ ✓ ✓</td>
</tr>
<tr>
<td>Create snapshot policy that targets instances and is configured for pre and post scripts</td>
<td>✓ ✓ ✓</td>
</tr>
</tbody>
</table>

Automating application-consistent snapshots with pre and post scripts

You can automate application-consistent snapshots with Amazon Data Lifecycle Manager by enabling pre and post scripts in your snapshot lifecycle policies that target instances.

Amazon Data Lifecycle Manager integrates with AWS Systems Manager (Systems Manager) to support application-consistent snapshots. Amazon Data Lifecycle Manager uses Systems Manager (SSM) command documents that include pre and post scripts to automate the actions needed to complete application-consistent snapshots. Before Amazon Data Lifecycle Manager initiates snapshot creation, it runs the commands in the pre script to freeze and flush I/O. After Amazon Data Lifecycle Manager initiates snapshot creation, it runs the commands in the post script to thaw I/O.

Using Amazon Data Lifecycle Manager, you can automate application-consistent snapshots of the following:

- Windows applications using Volume Shadow Copy Service (VSS)
- SAP HANA using an AWS managed SSDM document. For more information, see Amazon EBS snapshots for SAP HANA.
- Self-managed databases, such as MySQL and PostgreSQL, using SSM document templates
Getting started with application-consistent snapshots

This section explains the steps you need to follow to automate application-consistent snapshots using Amazon Data Lifecycle Manager.

Step 1: Prepare target instances

You need to prepare the targeted instances for application-consistent snapshots using Amazon Data Lifecycle Manager. Do one of the following, depending on your use case.

Prepare for VSS Backups

To prepare your target instances for VSS backups

1. Install the SSM Agent on your target instances, if it is not already installed. If SSM Agent is already installed on your target instances, skip this step.
   
   For more information, see [Manually installing SSM Agent on Amazon EC2 instances for Windows](#).

2. Ensure that the SSM Agent is running. For more information, see [Checking SSM Agent status and starting the agent](#).

3. Set up Systems Manager for Amazon EC2 instances. For more information, see [Setting up Systems Manager for Amazon EC2 instances](#) in the AWS Systems Manager User Guide.

4. Ensure the system requirements for VSS backups are met.

5. Attach a VSS-enabled instance profile to the target instances.

6. Install the VSS components.

Prepare for SAP HANA backups

To prepare your target instances for SAP HANA backups

1. Prepare the SAP HANA environment on your target instances.

   a. Set up your instance with SAP HANA. If you don't already have an existing SAP HANA environment, then you can refer to the [SAP HANA Environment Setup on AWS](#).

   b. Login to the SystemDB as a suitable administrator user.

   c. Create a database backup user to be used with Amazon Data Lifecycle Manager.

   ```
   CREATE USER username PASSWORD password NO FORCE_FIRST_PASSWORD_CHANGE;
   ```

   For example, the following command creates a user named dlm_user with password password.

   ```
   CREATE USER dlm_user PASSWORD password NO FORCE_FIRST_PASSWORD_CHANGE;
   ```

   d. Assign the BACKUP OPERATOR role to the database backup user that you created in the previous step.

   ```
   GRANT BACKUP OPERATOR TO username
   ```
For example, the following command assigns the role to a user named dlm_user.

```sql
GRANT BACKUP OPERATOR TO dlm_user
```

e. Log in to the operating system as the administrator, for example `sudo adm`

f. Create an `hdbuserstore` entry to store connection information so that the SAP HANA SSM document can connect to SAP HANA without users having to enter the information.

```bash
hdbuserstore set DLM_HANADB_SNAPSHOT_USER localhost:30013 username password
```

For example:

```bash
hdbuserstore set DLM_HANADB_SNAPSHOT_USER localhost:30013 dlm_user password
```

g. Test the connection.

```bash
hdbsql -U DLM_HANADB_SNAPSHOT_USER "select * from dummy"
```

2. Install the SSM Agent on your target instances, if it is not already installed. If SSM Agent is already installed on your target instances, skip this step.

For more information, see [Manually installing SSM Agent on Amazon EC2 instances for Linux](#).

3. Ensure that the SSM Agent is running. For more information, see [Checking SSM Agent status and starting the agent](#).

4. Set up Systems Manager for Amazon EC2 instances. For more information, see [Setting up Systems Manager for Amazon EC2 instances](#) in the AWS Systems Manager User Guide.

Prepare for custom SSM documents

**To prepare your target instances custom SSM documents**

1. Install the SSM Agent on your target instances, if it is not already installed. If SSM Agent is already installed on your target instances, skip this step.

   - (Linux instances) [Manually installing SSM Agent on Amazon EC2 instances for Linux](#)
   - (Windows instances) [Manually installing SSM Agent on Amazon EC2 instances for Windows](#)

2. Ensure that the SSM Agent is running. For more information, see [Checking SSM Agent status and starting the agent](#).

3. Set up Systems Manager for Amazon EC2 instances. For more information, see [Setting up Systems Manager for Amazon EC2 instances](#) in the AWS Systems Manager User Guide.

**Step 2: Prepare SSM document**

**Note**

This step is required only for custom SSM documents. It is not required for VSS Backup or SAP HANA. For VSS Backups and SAP HANA, Amazon Data Lifecycle Manager uses the AWS managed SSM document.

If you are automating application-consistent snapshots for a self-managed database, such as MySQL or PostgreSQL, you must create an SSM command document that includes a pre script to freeze and flush I/O before snapshot creation is initiated, and a post script to thaw I/O after snapshot creation is initiated.

If your MySQL or PostgreSQL database uses standard configurations, you can create an SSM command document using the sample SSM document content below. If your MySQL or PostgreSQL database uses
a non-standard configuration, you can use the sample content below as a starting point for your SSM command document and then customize it to meet your requirements. Alternatively, if you want to create a new SSM document from scratch, you can use the empty SSM document template below and add your pre and post commands in the appropriate document sections.

**Note the following:**

- It is your responsibility to ensure that the SSM document performs the correct and required actions for your database configuration.
- Snapshots are guaranteed to be application-consistent only if the pre and post scripts in your SSM document can successfully freeze, flush, and thaw I/O.
- The SSM document must include required fields for `allowedValues`, including `pre-script`, `post-script`, and `dry-run`. Amazon Data Lifecycle Manager will execute commands on your instance based on the contents of those sections. If your SSM document does not have those sections, then Amazon Data Lifecycle Manager will treat it as a failed execution.

### MySQL sample document content

Once you have your SSM document content, use one of the following procedures to create the custom SSM document.

Console

**To create the SSM command document**

2. In the navigation pane, choose Documents, then choose Create document, Command or Session.
3. For Name, enter a descriptive name for the document.
4. For Target type, select /AWS::EC2::Instance.
5. For Document type, select Command.
6. In the Content field, select YAML and then paste the document content.
7. In the Document tags section, add a tag with a tag key of DLMScriptsAccess, and a tag value of true.

**Important**

The DLMScriptsAccess:true tag is required by the AWSDataLifecycleManagerSSMFullAccess AWS managed policy used in Step 3: Prepare Amazon Data Lifecycle Manager IAM role. The policy uses the aws:ResourceTag condition key to restrict access to SSM documents that have this tag.
8. Choose Create document.

AWS CLI

**To create the SSM command document**

Use the create-document command. For --name, specify a descriptive name for the document. For --document-type, specify Command. For --content, specify the path to the .yaml file with the SSM document content. For --tags, specify "Key=DLMScriptsAccess,Value=true".

```
$ aws ssm create-document
   --content file://path/to/file/documentContent.yaml
   --name "document_name"
   --document-type "Command"
   --document-format YAML
   --tags "Key=DLMScriptsAccess,Value=true"
```

**Step 3: Prepare Amazon Data Lifecycle Manager IAM role**

**Note**

This step is needed if:
• You create or update a pre/post script-enabled snapshot policy that uses a custom IAM role.
• You use the command line to create or update a pre/post script-enabled snapshot policy that uses the default.

If you use the console to create or update a pre/post script-enabled snapshot policy that uses the default role for managing snapshots (AWSDataLifecycleManagerDefaultRole), skip this step. In this case, we automatically attach the AWSDataLifecycleManagerSSMFullAccess policy to that role.

You must ensure that the IAM role that you use for policy grants Amazon Data Lifecycle Manager permission to perform the SSM actions required to run pre and post scripts on instances targeted by the policy.

Amazon Data Lifecycle Manager provides a managed policy (AWSDataLifecycleManagerSSMFullAccess) that includes the required permissions. You can attach this policy to your IAM role for managing snapshots to ensure that it includes the permissions.

Important
The AWSDataLifecycleManagerSSMFullAccess managed policy uses the aws:ResourceTag condition key to restrict access to specific SSM documents when using pre and post scripts. To allow Amazon Data Lifecycle Manager to access the SSM documents, you must ensure that your SSM documents are tagged with DLMScriptsAccess:true.

Alternatively, you can manually create a custom policy or assign the required permissions directly to the IAM role that you use. You can use the same permissions that are defined in the AWSDataLifecycleManagerSSMFullAccess managed policy, however, the aws:ResourceTag condition key is optional. If you decide to not include that condition key, then you do not need to tag your SSM documents with DLMScriptsAccess:true.

Use one of the following methods to add the AWSDataLifecycleManagerSSMFullAccess policy to your IAM role.

Console

To attach the managed policy to your custom role

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation panel, choose Roles.
3. Search for and select your custom role for managing snapshots.
4. On the Permissions tab, choose Add permissions, Attach policies.
5. Search for and select the AWSDataLifecycleManagerSSMFullAccess managed policy, and then choose Add permissions.

AWS CLI

To attach the managed policy to your custom role

Use the attach-role-policy command. For --role-name, specify the name of your custom role. For --policy-arn, specify arn:aws:iam::aws:policy/AWSDataLifecycleManagerSSMFullAccess.

```
$ aws iam attach-role-policy \
--policy-arn arn:aws:iam::aws:policy/AWSDataLifecycleManagerSSMFullAccess \
--role-name your_role_name
```
Step 4: Create snapshot lifecycle policy

To automate application-consistent snapshots, you must create a snapshot lifecycle policy that targets instances, and configure pre and post scripts for that policy.

Console

To create the snapshot lifecycle policy

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic Block Store, Lifecycle Manager, and then choose Create lifecycle policy.
3. On the Select policy type screen, choose EBS snapshot policy and then choose Next.
4. In the Target resources section, do the following:
   a. For Target resource types, choose Instance.
   b. For Target resource tags, specify the resource tags that identify the instances to back up. Only resources that have the specified tags will be backed up.
5. For IAM role, either choose AWSDataLifecycleManagerDefaultRole (the default role for managing snapshots), or choose a custom role that you created and prepared for pre and post scripts.
6. Configure the schedules and additional options as needed. We recommend that you schedule snapshot creation times for time periods that match your workload, such as during maintenance windows.

For SAP HANA, we recommend that you enable fast snapshot restore.

Note
If you enable a schedule for VSS Backups, you can’t enable Exclude specific data volumes or Copy tags from source.

7. In the Pre and post scripts section, select Enable pre and post scripts, and then do the following, depending on your workload:
   - To create application-consistent snapshots of your Windows applications, select VSS Backup.
   - To create application-consistent snapshots of your SAP HANA workloads, select SAP HANA.
   - To create application-consistent snapshots of all other databases and workloads, including your self-managed MySQL or PostgreSQL databases, using a custom SSM document, select Custom SSM document.
     1. For Automate option, choose Pre and post scripts.
     2. For SSM document, select the SSM document that you prepared.
8. Depending on the option you selected, configure the following additional options:
   - **Script timeout** — (Custom SSM document only) The timeout period after which Amazon Data Lifecycle Manager fails the script run attempt if it has not completed. If a script does not complete within its timeout period, Amazon Data Lifecycle Manager fails the attempt. The timeout period applies to the pre and post scripts individually. The minimum and default timeout period is 10 seconds. And the maximum timeout period is 120 seconds.
   - **Retry failed scripts** — Select this option to retry scripts that do not complete within their timeout period. If the pre script fails, Amazon Data Lifecycle Manager retries entire snapshot creation process, including running the pre and post scripts. If the post script fails, Amazon Data Lifecycle Manager retries the post script only; in this case, the pre script will have completed and the snapshot might have been created.
   - **Default to crash-consistent snapshots** — Select this option to default to crash-consistent snapshots if the pre script fails to run. This is the default snapshot creation behavior for Amazon Data Lifecycle Manager if pre and post scripts is not enabled. If you enabled retries,
Amazon Data Lifecycle Manager will default to crash-consistent snapshots only after all retry attempts have been exhausted. If the pre script fails and you do not default to crash-consistent snapshots, Amazon Data Lifecycle Manager will not create snapshots for the instance during that schedule run.

**Note**

If you are creating snapshots for SAP HANA, then you might want to disabled this option. Crash-consistent snapshots of SAP HANA workloads can't restored in the same manner.

9. Choose **Create default policy**.

**Note**

If you get the **Role with name AWSDataLifecycleManagerDefaultRole already exists** error, see **Troubleshooting (p. 2303)** for more information.

**AWS CLI**

**To create the snapshot lifecycle policy**

Use the **create-lifecycle-policy** command, and include the **Scripts** parameters in **CreateRule**. For more information about the parameters, see the **Amazon Data Lifecycle Manager API Reference**.

```
$ aws dlm create-lifecycle-policy \\
--description "policy_description" \\
--state ENABLED \\
--execution-role-arn iam_role_arn \\
--policy-details file://policyDetails.json
```

Where **policyDetails.json** includes one of the following, depending on your use case:

- **VSS Backup**

  ```
  { 
  "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
  "ResourceTypes": [ 
  "INSTANCE"
  ],
  "TargetTags": [{
    "Key": "tag_key",
    "Value": "tag_value"
  }],
  "Schedules": [{
    "Name": "schedule_name",
    "CreateRule": {
      "CronExpression": "cron_for_creation_frequency",
      "Scripts": [{
        "ExecutionHandler" : "AWS_VSS_BACKUP",
        "ExecuteOperationOnScriptFailure": "true|false",
        "MaximumRetryCount": "retries (0-3)"
      }]
    },
    "RetainRule": {
      "Count": "retention_count"
    }
  }]
  }
  ```

- **SAP HANA backups**

  ```
  { 
  "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
  ```
With Amazon Data Lifecycle Manager, you can back up and restore VSS (Volume Shadow Copy Service)-enabled Windows applications running on Amazon EC2 instances. If the application has a VSS writer registered with Windows VSS, then Amazon Data Lifecycle Manager creates a snapshot that will be application consistent for that application.
**Note**

Amazon Data Lifecycle Manager currently supports application-consistent snapshots of resources running on Amazon EC2 only, specifically for backup scenarios where application data can be restored by replacing an existing instance with a new instance created from the backup. Not all instance types or applications are supported for VSS backups. For more information, see [What is AWS VSS?](#) in the [Amazon EC2 User Guide for Windows Instances](#).

**Unsupported instance types**

The following Amazon EC2 instance types are not supported for VSS backups. If your policy targets one of these instance types, Amazon Data Lifecycle Manager might still create VSS backups, but the snapshots might not be tagged with the required system tags. Without these tags, the snapshots will not be managed by Amazon Data Lifecycle Manager after creation. You might need to manually delete these snapshots.

- T3: t3.nano | t3.micro
- T3a: t3a.nano | t3a.micro
- T2: t2.nano | t2.micro

**Shared responsibility for application-consistent snapshots**

**You must ensure that:**

- The SSM Agent is installed, up-to-date, and running on your target instances
- Systems Manager has permissions to perform the required actions on the target instances
- Amazon Data Lifecycle Manager has permissions to perform the Systems Manager actions required to run pre and post scripts on the target instances.
- For custom workloads, such as self-managed MySQL and PostgreSQL databases, the SSM document that you use includes the correct and required actions for freezing, flushing, and thawing I/O for your database configuration.
- Snapshot creation times align with your workload schedule. For example, try to schedule snapshot creation during scheduled maintenance windows.

**Amazon Data Lifecycle Manager ensures that:**

- Snapshot creation is initiated within 60 minutes of the scheduled snapshot creation time.
- Pre scripts run before the snapshot creation is initiated.
- Post scripts run after the pre script succeeds and the snapshot creation has been initiated. Amazon Data Lifecycle Manager runs the post script only if the pre script succeeds. If the pre script fails, Amazon Data Lifecycle Manager will not run the post script.
- Snapshots are tagged with the appropriate tags on creation.
- CloudWatch metrics and events are emitted when scripts are initiated, and when they fail or succeed.

**Other use cases for pre and post scripts**

In addition to using pre and post scripts for automating application-consistent snapshots, you can use pre and post scripts together, or individually, to automate other administrative tasks before or after snapshot creation. For example:

- Using a pre script to apply patches before creating snapshots. This can help you create snapshots after applying your regular weekly or monthly software updates.
Note
If you choose to run a pre script only, **Default to crash-consistent snapshots** is enabled by default.

- Using a post script to apply patches after creating snapshots. This can help you create snapshots before applying your regular weekly or monthly software updates.

Getting started for other use cases

This section explains the steps you need perform when using pre and/or post scripts for **uses cases other than application-consistent snapshots**.

Step 1: Prepare target instances

To prepare your target instances for pre and/or post scripts

1. **Install the SSM Agent on your target instances, if it is not already installed.** If SSM Agent is already installed on your target instances, skip this step.
   - (Linux instances) [Manually installing SSM Agent on Amazon EC2 instances for Linux](#)
   - (Windows instances) [Manually installing SSM Agent on Amazon EC2 instances for Windows](#)
2. **Ensure that the SSM Agent is running.** For more information, see [Checking SSM Agent status and starting the agent](#).
3. **Set up Systems Manager for Amazon EC2 instances.** For more information, see [Setting up Systems Manager for Amazon EC2 instances](#) in the **AWS Systems Manager User Guide**.

Step 2: Prepare SSM document

You must create an SSM command document that includes the pre and/or post scripts with the commands you want to run.

You can create an SSM document using the empty SSM document template below and add your pre and post script commands in the appropriate document sections.

**Note the following:**

- It is your responsibility to ensure that the SSM document performs the correct and required actions for your workload.
- The SSM document must include required fields for allowedValues, including pre-script, post-script, and dry-run. Amazon Data Lifecycle Manager will execute commands on your instance based on the contents of those sections. If your SSM document does not have those sections, then Amazon Data Lifecycle Manager will treat it as a failed execution.

schemaVersion: '2.2'
description: SSM Document Template for Amazon Data Lifecycle Manager Pre/Post script feature
parameters:
  executionId:
    type: String
    default: None
    description: (Required) Specifies the unique identifier associated with a pre and/or post execution
    allowedPattern: ^([^a-fA-F0-9]([a-fA-F0-9][8]-[^a-fA-F0-9][4][a-fA-F0-9][4][a-fA-F0-9][4][a-fA-F0-9][4][a-fA-F0-9][12])]$
  command:
    # Data Lifecycle Manager will trigger the pre-script and post-script actions during policy execution.
    # 'dry-run' option is intended for validating the document execution without triggering any commands
    # on the instance. The following allowedValues will allow Data Lifecycle Manager to successfully
    # trigger pre and post script actions.
    type: String
    default: 'dry-run'
    description: (Required) Specifies whether pre-script and/or post-script should be executed.
    allowedValues:
      - pre-script
      - post-script
      - dry-run
mainSteps:
- action: aws:runShellScript
description: Run Database freeze/thaw commands
name: run_pre_post_scripts
precondition:
  StringEquals:
    - platformType
    - Linux
inputs:
  runCommand:
    - |
      #!/bin/bash

### Error Codes
###===============================================================================###
# The following Error codes will inform Data Lifecycle Manager of the type of error
# and help guide handling of the error.
# The Error code will also be emitted via AWS Eventbridge events in the 'cause' field.
# 1 Pre-script failed during execution - 201
# 2 Post-script failed during execution - 202
# 3 Auto thaw occurred before post-script was initiated - 203
# 4 Pre-script initiated while post-script was expected - 204
# 5 Post-script initiated while pre-script was expected - 205
# 6 Application not ready for pre or post-script initiation - 206
###===============================================================================###
### Global variables
###===============================================================================###
START=$(date +%s)
# For testing this script locally, replace the below with OPERATION="$1.
OPERATION={{ command }}
# Add all pre-script actions to be performed within the function below
execute_pre_script() {

2258
Step 3: Prepare Amazon Data Lifecycle Manager IAM role

**Note**

This step is needed if:

- You create or update a pre/post script-enabled snapshot policy that uses a custom IAM role.
- You use the command line to create or update a pre/post script-enabled snapshot policy that uses the default.

If you use the console to create or update a pre/post script-enabled snapshot policy that uses the default role for managing snapshots (**AWSDataLifecycleManagerDefaultRole**), skip this step. In this case, we automatically attach the **AWSDataLifecycleManagerSSMFullAccess** policy to that role.

You must ensure that that IAM role that you use for the policy grants Amazon Data Lifecycle Manager permission to perform the SSM actions required to run pre and post scripts on instances targeted by the policy.

Amazon Data Lifecycle Manager provides a managed policy (**AWSDataLifecycleManagerSSMFullAccess**) that includes the required permissions. You can attach this policy to your IAM role for managing snapshots to ensure that it includes the permissions.

**Important**

The **AWSDataLifecycleManagerSSMFullAccess** managed policy uses the `aws:ResourceTag` condition key to restrict access to specific SSM documents when using pre and post scripts. To allow Amazon Data Lifecycle Manager to access the SSM documents, you must ensure that your SSM documents are tagged with `DLMScriptsAccess:true`.

```bash
# Add all post-script actions to be performed within the function below
execute_post_script() {
  echo "INFO: Start execution of post-script"
}

# Debug logging for parameters passed to the SSM document
echo "INFO: ${OPERATION} starting at $(date) with executionId: ${EXECUTION_ID}"

# Based on the command parameter value execute the function that supports
# pre-script/post-script operation
case ${OPERATION} in
  pre-script)
    execute_pre_script
    ;;
  post-script)
    execute_post_script
    ;;
  dry-run)
    echo "INFO: dry-run option invoked - taking no action"
    ;;
  *)
    echo "ERROR: Invalid command parameter passed. Please use either pre-script,
           post-script, dry-run."
    exit 1 # return failure
    ;;
esac

END=$(date +%s)
# Debug Log for profiling the script time
echo "INFO: ${OPERATION} completed at $(date). Total runtime: ($(END) - ${START}))
      seconds."
```

**2259**
Alternatively, you can manually create a custom policy or assign the required permissions directly to the IAM role that you use. You can use the same permissions that are defined in the AWSDataLifecycleManagerSSMFullAccess managed policy, however, the aws:ResourceTag condition key is optional. If you decide to not use that condition key, then you do not need to tag your SSM documents with DLMScriptsAccess: true.

Use one of the following methods to add the AWSDataLifecycleManagerSSMFullAccess policy to your IAM role.

**Console**

**To attach the managed policy to your custom role**

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation panel, choose Roles.
3. Search for and select your custom role for managing snapshots.
4. On the Permissions tab, choose Add permissions, Attach policies.
5. Search for and select the AWSDataLifecycleManagerSSMFullAccess managed policy, and then choose Add permissions.

**AWS CLI**

**To attach the managed policy to your custom role**

Use the `attach-role-policy` command. For `--role-name`, specify the name of your custom role. For `--policy-arn`, specify `arn:aws:iam::aws:policy/AWSDataLifecycleManagerSSMFullAccess`.

```
$ aws iam attach-role-policy
--policy-arn arn:aws:iam::aws:policy/AWSDataLifecycleManagerSSMFullAccess
--role-name your_role_name
```

**Create snapshot lifecycle policy**

**Console**

**To create the snapshot lifecycle policy**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic Block Store, Lifecycle Manager, and then choose Create lifecycle policy.
3. On the Select policy type screen, choose EBS snapshot policy and then choose Next.
4. In the Target resources section, do the following:
   a. For Target resource types, choose Instance.
   b. For Target resource tags, specify the resource tags that identify the instances to back up. Only resources that have the specified tags will be backed up.
5. For IAM role, either choose AWSDataLifecycleManagerDefaultRole (the default role for managing snapshots), or choose a custom role that you created and prepared for pre and post scripts.
6. Configure the schedules and additional options as needed. We recommend that you schedule snapshot creation times for time periods that match your workload, such as during maintenance windows.
7. In the **Pre and post scripts** section, select **Enable pre and post scripts** and then do the following:
   
   a. Select **Custom SSM document**.
   b. For **Automate option**, choose the option that matches the scripts you want to run.
   c. For **SSM document**, select the SSM document that you prepared.

8. Configure the following additional options if needed:

   - **Script timeout** — The timeout period after which Amazon Data Lifecycle Manager fails the script run attempt if it has not completed. If a script does not complete within its timeout period, Amazon Data Lifecycle Manager fails the attempt. The timeout period applies to the pre and post scripts individually. The minimum and default timeout period is 10 seconds. And the maximum timeout period is 120 seconds.
   - **Retry failed scripts** — Select this option to retry scripts that do not complete within their timeout period. If the pre script fails, Amazon Data Lifecycle Manager retries entire snapshot creation process, including running the pre and post scripts. If the post script fails, Amazon Data Lifecycle Manager retries the post script only; in this case, the pre script will have completed and the snapshot might have been created.
   - **Default to crash-consistent snapshots** — Select this option to default to crash-consistent snapshots if the pre script fails to run. This is the default snapshot creation behavior for Amazon Data Lifecycle Manager if pre and post scripts is not enabled. If you enabled retries, Amazon Data Lifecycle Manager will default to crash-consistent snapshots only after all retry attempts have been exhausted. If the pre script fails and you do not default to crash-consistent snapshots, Amazon Data Lifecycle Manager will not create snapshots for the instance during that schedule run.

9. Choose **Create default policy**.

   **Note**
   If you get the **Role with name AWSDataLifecycleManagerDefaultRole already exists** error, see **Troubleshooting (p. 2303)** for more information.

**AWS CLI**

**To create the snapshot lifecycle policy**

Use the **create-lifecycle-policy** command, and include the **Scripts** parameters in **CreateRule**. For more information about the parameters, see the **Amazon Data Lifecycle Manager API Reference**.

```bash
$ aws dlm create-lifecycle-policy \
--description "policy_description" \
--state ENABLED \
--execution-role-arn iam_role_arn \
--policy-details file://policyDetails.json
```

Where **policyDetails.json** includes the following.

```json
{
   "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
   "ResourceTypes": [
      "INSTANCE"
   ],
   "TargetTags": [{
      "Key": "tag_key",
      "Value": "tag_value"
   }],
   "Schedules": [{
      "Name": "schedule_name",
      "CreateRule": {
```
How pre and post scripts work

The following image shows the process flow for pre and post scripts when using custom SSM documents. This does not apply to VSS Backups.

At the scheduled snapshot creation time, the following actions and cross-service interactions occur.

1. Amazon Data Lifecycle Manager initiates the pre script action by calling the SSM document and passing the pre-script parameter.
   
   **Note**
   Steps 1 to 3 occur only if you run pre scripts. If you run post scripts only, steps 1 to 3 are skipped.

2. Systems Manager sends pre script commands to the SSM Agent running on the target instances. The SSM Agent runs the commands on the instance, and sends status information back to Systems Manager.

   For example, if the SSM document is used to create application-consistent snapshots, the pre script might freeze and flush I/O to ensure that all buffered data is written to the volume before the snapshot is taken.

3. Systems Manager sends pre script command status updates to Amazon Data Lifecycle Manager. If the pre script fails, Amazon Data Lifecycle Manager takes one of the following actions, depending on how you configure the pre and post script options:
<table>
<thead>
<tr>
<th>Retries</th>
<th>Default to crash-consistent snapshots</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled with retries remaining</td>
<td>Enabled</td>
<td>Retry script until it succeeds or retries are exhausted</td>
</tr>
<tr>
<td>Exhausted without successful completion</td>
<td>Enabled</td>
<td>Create crash-consistent snapshots, and do not run post script.</td>
</tr>
<tr>
<td>Enabled with retries remaining</td>
<td>Disabled</td>
<td>Retry script until it succeeds or retries are exhausted</td>
</tr>
<tr>
<td>Exhausted without successful completion</td>
<td>Disabled</td>
<td>Skip snapshot creation for the target instance, and do not run post script.</td>
</tr>
<tr>
<td>Disabled</td>
<td>Enabled</td>
<td>Create crash-consistent snapshots, and do not run post script.</td>
</tr>
<tr>
<td>Disabled</td>
<td>Disabled</td>
<td>Skip snapshot creation for the target instance, and do not run post script.</td>
</tr>
</tbody>
</table>

4. Amazon Data Lifecycle Manager initiates snapshot creation.

5. Amazon Data Lifecycle Manager initiates the post script action by calling the SSM document and passing the `post-script` parameter.

**Note**

Steps 5 to 7 occur only if you run pre scripts. If you run post scripts only, steps 1 to 3 are skipped.

6. Systems Manager sends post script commands to the SSM Agent running on the target instances. The SSM Agent runs the commands on the instance, and sends status information back to Systems Manager.

For example, if the SSM document enables application-consistent snapshots, this post script might thaw I/O to ensure that your databases resume normal I/O operations after the snapshot has been taken.

7. If you run a post script and Systems Manager indicates that it completed successfully, the process completes.

If the post script fails, Amazon Data Lifecycle Manager takes one of the following actions, depending on how you configure the pre and post script options:

<table>
<thead>
<tr>
<th>Retries</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled with retries remaining</td>
<td>Retry post script until it succeeds or retries are exhausted</td>
</tr>
<tr>
<td>Exhausted without success</td>
<td>Skip post script</td>
</tr>
<tr>
<td>Disabled</td>
<td>Skip post script</td>
</tr>
</tbody>
</table>

Keep in mind that if the post script fails, the pre script (if enabled) will have completed successfully, and the snapshots might have been created. You might need to take further action on the instance to ensure that it is operating as expected. For example if the pre script paused and flushed I/O, but
the post script failed to thaw I/O, you might need to configure your database to auto-thaw I/O or you need to manually thaw I/O.

8. The snapshot creation process might complete after the post script completes. The time taken to complete the snapshot depends on the snapshot size.

Identifying snapshots created with pre and post scripts

Amazon Data Lifecycle Manager automatically assigns the following system tags to snapshots created with pre and post scripts.

- Key: aws:dlm:pre-script; Value: SUCCESS|FAILED
  A tag value of SUCCESS indicates that the pre script executed successfully. A tag value of FAILED indicates that the pre script did not execute successfully.
- Key: aws:dlm:post-script; Value: SUCCESS|FAILED
  A tag value of SUCCESS indicates that the post script executed successfully. A tag value of FAILED indicates that the post script did not execute successfully.

For custom SSM documents and SAP HANA backups, you can infer successful application-consistent snapshot creation if the snapshot is tagged with both aws:dlm:pre-script:SUCCESS and aws:dlm:post-script:SUCCESS.

Additionally, application-consistent snapshots created using VSS backup are automatically tagged with:

- Key: AppConsistent tag; Value: true|false
  A tag value of true indicates that the VSS backup succeeded and that the snapshots are application consistent. A tag value of false indicates that the VSS backup did not succeed and that the snapshots are not application consistent.

Monitoring pre and post script execution

Amazon CloudWatch metrics

Amazon Data Lifecycle Manager publishes the following CloudWatch metrics when pre and post scripts fail and succeed and when VSS backups fail and succeed.

- PreScriptStarted
- PreScriptCompleted
- PreScriptFailed
- PostScriptStarted
- PostScriptCompleted
- PostScriptFailed
- VSSBackupStarted
- VSSBackupCompleted
- VSSBackupFailed

For more information, see Monitor your policies using Amazon CloudWatch (p. 2295).

Amazon EventBridge

Amazon Data Lifecycle Manager emits the following Amazon EventBridge event when a pre or post script is initiated, succeeds, or fails.
Create an AMI lifecycle policy

Use one of the following procedures to create an AMI lifecycle policy.

Console

**To create an AMI policy**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic Block Store, Lifecycle Manager, and then choose Create lifecycle policy.
3. On the Select policy type screen, choose EBS-backed AMI policy, and then choose Next.
4. In the Target resources section, for Target resource tags, choose the resource tags that identify the volumes or instances to back up. The policy backs up only the resources that have the specified tag key and value pairs.
5. For Description, enter a brief description for the policy.
6. For IAM role, choose the IAM role that has permissions to manage AMIs and snapshot and to describe instances. To use the default role provided by Amazon Data Lifecycle Manager, choose Default role. Alternatively, to use a custom IAM role that you previously created, choose Choose another role, and then select the role to use.
7. For Policy tags, add the tags to apply to the lifecycle policy. You can use these tags to identify and categorize your policies.
8. For Policy status after creation, choose Enable policy to start running the policy at the next scheduled time, or Disable policy to prevent the policy from running. If you do not enable the policy now, it will not start creating AMIs until you manually enable it after creation.
9. In the Instance reboot section, indicate whether instances should be rebooted before AMI creation. To prevent the targeted instances from being rebooted, choose No. Choosing No could cause data consistency issues. To reboot instances before AMI creation, choose Yes. Choosing this ensures data consistency, but could result in multiple targeted instances rebooting simultaneously.
10. Choose Next.
11. On the Configure schedule screen, configure the policy schedules. A policy can have up to four schedules. Schedule 1 is mandatory. Schedules 2, 3, and 4 are optional. For each policy schedule that you add, do the following:
   a. In the Schedule details section do the following:
      i. For Schedule name, specify a descriptive name for the schedule.
      ii. For Frequency and the related fields, configure the interval between policy runs.
You can configure policy runs on a daily, weekly, monthly, or yearly schedule. Alternatively, choose **Custom cron expression** to specify an interval of up to one year. For more information, see [Cron expressions](https://docs.aws.amazon.com/AmazonCloudWatch/latest/events/Cron-Expressions.html) in the Amazon CloudWatch Events User Guide.

iii. For **Starting at**, specify the time to start the policy runs. The first policy run starts within an hour after the time that you schedule. You must enter the time in the `HH:MM` UTC format.

iv. For **Retention type**, specify the retention policy for AMIs created by the schedule.

You can retain AMIs based on either their total count or their age.

For count-based retention, the range is 1 to 1000. After the maximum count is reached, the oldest AMI is deregistered when a new one is created.

For age-based retention, the range is 1 day to 100 years. After the retention period of each AMI expires, it is deregistered.

**Note**
All schedules must have the same retention type. You can specify the retention type for Schedule 1 only. Schedules 2, 3, and 4 inherit the retention type from Schedule 1. Each schedule can have its own retention count or period.

b. **Configure tagging for AMIs.**

In the **Tagging** section, do the following:

i. To copy all of the user-defined tags from the source instance to the AMIs created by the schedule, select **Copy tags from source**.

ii. By default, AMIs created by the schedule are automatically tagged with the ID of the source instance. To prevent this automatic tagging from happening, for **Variable tags**, remove the `instance-id:$(instance-id)` tile.

iii. To specify additional tags to assign to AMIs created by this schedule, choose **Add tags**.

c. **Configure AMI deprecation.**

To deprecate AMIs when they should no longer be used, in the **AMI deprecation** section, select **Enable AMI deprecation for this schedule** and then specify the AMI deprecation rule. The AMI deprecation rule specifies when AMIs are to be deprecated.

If the schedule uses count-based AMI retention, you must specify the number of oldest AMIs to deprecate. The deprecation count must be less than or equal to the schedule's AMI retention count, and it can't be greater than 1000. For example, if the schedule is configured to retain a maximum of 5 AMIs, then you can configure the scheduled to deprecate up to 5 oldest AMIs.

If the schedule uses age-based AMI retention, you must specify the period after which AMIs are to be deprecated. The deprecation count must be less than or equal to the schedule's AMI retention period, and it can't be greater than 10 years (120 months, 520 weeks, or 3650 days). For example, if the schedule is configured to retain AMIs for 10 days, then you can configure the scheduled to deprecate AMIs after periods up to 10 days after creation.

d. **Configure cross-Region copying.**

To copy AMIs created by the schedule to different Regions, in the **Cross-Region copy** section, select **Enable cross-Region copy**. You can copy AMIs to up to three additional Regions in your account. You must specify a separate cross-Region copy rule for each destination Region.

For each destination Region, you can specify the following:
A retention policy for the AMI copy. When the retention period expires, the copy in the destination Region is automatically deregistered.

- Encryption status for the AMI copy. If the source AMI is encrypted, or if encryption by default is enabled, the copied AMIs are always encrypted. If the source AMI is unencrypted and encryption by default is disabled, you can optionally enable encryption. If you do not specify a KMS key, the AMIs are encrypted using the default KMS key for EBS encryption in each destination Region. If you specify a KMS key for the destination Region, then the selected IAM role must have access to the KMS key.

- A deprecation rule for the AMI copy. When the deprecation period expires, the AMI copy is automatically deprecated. The deprecation period must be less than or equal to the copy retention period, and it can't be greater than 10 years.

- Whether to copy all tags or no tags from the source AMI.

**Note**
Do not exceed the number of concurrent AMI copies per Region.

e. To add additional schedules, choose **Add another schedule**, which is located at the top of the screen. For each additional schedule, complete the fields as described previously in this topic.

f. After you have added the required schedules, choose **Review policy**.

12. Review the policy summary, and then choose **Create policy**.

**Note**
If you get the Role with name **AWSDataLifecycleManagerDefaultRoleForAMIManagement** already exists error, see **Troubleshooting (p. 2303)** for more information.

Command line

Use the **create-lifecycle-policy** command to create an AMI lifecycle policy. For **PolicyType**, specify **IMAGE_MANAGEMENT**.

**Note**
To simplify the syntax, the following examples use a JSON file, **policyDetails.json**, that includes the policy details.

**Example 1: Age-based retention and AMI deprecation**

This example creates an AMI lifecycle policy that creates AMIs of all instances that have a tag key of purpose with a value of production without rebooting the targeted instances. The policy includes one schedule that creates an AMI every day at 01:00 UTC. The policy retains AMIs for 2 days and deprecates them after 1 day. It also copies the tags from the source instance to the AMIs that it creates.

```
aws dlm create-lifecycle-policy \
   --description "My AMI policy" \
   --state ENABLED \
   --execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRoleForAMIManagement \
   --policy-details file://policyDetails.json
```

The following is an example of the **policyDetails.json** file.

```
{
   "PolicyType": "IMAGE_MANAGEMENT",
}
"ResourceTypes": [ "INSTANCE" ],
"TargetTags": [{ "Key": "purpose", "Value": "production" }],
"Schedules": [{ "Name": "DailyAMIs", "TagsToAdd": [{ "Key": "type", "Value": "myDailyAMI" }],
"CreateRule": { "Interval": 24,
"IntervalUnit": "HOURS",
"Times": [ "01:00" ]
},
"RetainRule": { "Interval": 2,
"IntervalUnit": "DAYS" },
"DeprecateRule": { "Interval": 1,
"IntervalUnit": "DAYS" },
"CopyTags": true }
],
"Parameters": { "NoReboot": true }
}

If the request succeeds, the command returns the ID of the newly created policy. The following is example output.

```
{
  "PolicyId": "policy-9876543210abcdef0"
}
```

**Example 2: Count-based retention and AMI deprecation with cross-Region copy**

This example creates an AMI lifecycle policy that creates AMIs of all instances that have a tag key of purpose with a value of production and reboots the target instances. The policy includes one schedule that creates an AMI every 6 hours starting at 17:30 UTC. The policy retains 3 AMIs and automatically deprecates the 2 oldest AMIs. It also has a cross-Region copy rule that copies AMIs to us-east-1, retains 2 AMI copies, and automatically deprecates the oldest AMI.

```
aws dlm create-lifecycle-policy --description "My AMI policy" --state ENABLED --execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRoleForAMIManagement --policy-details file://policyDetails.json
```

The following is an example of the policyDetails.json file.

```
{

Considerations for AMI lifecycle policies

The following general considerations apply to creating AMI lifecycle policies:

- AMI lifecycle policies target only instances that are in the same Region as the policy.
- The first AMI creation operation starts within one hour after the specified start time. Subsequent AMI creation operations start within one hour of their scheduled time.
- When Amazon Data Lifecycle Manager deregisters an AMI, it automatically deletes it backing snapshots.
- Target resource tags are case sensitive.
- If you remove the target tags from an instance that is targeted by a policy, Amazon Data Lifecycle Manager no longer manages existing AMIs in the standard; you must manually delete them if they are no longer needed.
- You can create multiple policies to back up an instance. For example, if an instance has two tags, where tag A is the target for policy A to create an AMI every 12 hours and tag B is the target for policy B to create an AMI every 24 hours. Amazon Data Lifecycle Manager creates AMIs according to the schedules for both policies. Alternatively, you can achieve the same result by creating a single policy that has multiple schedules. For example, you can create a single policy that targets only tag A, and specify two schedules — one for every 12 hours and one for every 24 hours.
• New volumes that are attached to a target instance after the policy has been created are automatically included in the backup at the next policy run. All volumes attached to the instance at the time of the policy run are included.

• If you create a policy with a custom cron-based schedule that is configured to create only one AMI, the policy will not automatically deregister that AMI when the retention threshold is reached. You must manually deregister the AMI if it is no longer needed.

• If you create an age-based policy where the retention period is shorter than the creation frequency, Amazon Data Lifecycle Manager will always retain the last AMI until the next one is created. For example, if an age-based policy creates one AMI every month with a retention period of seven days, Amazon Data Lifecycle Manager will retain each AMI for one month, even though the retention period is seven days.

• For count-based policies, Amazon Data Lifecycle Manager always creates AMIs according to the creation frequency before attempting to deregister the oldest AMI according to the retention policy.

• It can take several hours to successfully deregister an AMI and to delete its associated backing snapshots. If Amazon Data Lifecycle Manager creates the next AMI before the previously created AMI is successfully deregistered, you could temporarily retain a number of AMIs that is greater than your retention count.

The following considerations apply to terminating instances targeted by a policy:

• If you terminate an instance that was targeted by a policy with a count-based retention schedule, the policy no longer manages the AMIs that it previously created from the terminated instance. You must manually deregister those earlier AMIs if they are no longer needed.

• If you terminate an instance that was targeted by a policy with an age-based retention schedule, the policy continues to deregister AMIs that were previously created from the terminated instance on the defined schedule, up to, but not including, the last AMI. You must manually deregister the last AMI if it is no longer needed.

The following considerations apply to AMI policies and AMI deprecation:

• If you increase the AMI deprecation count for a schedule with count-based retention, the change is applied to all AMIs (existing and new) created by the schedule.

• If you increase the AMI deprecation period for a schedule with age-based retention, the change is applied to new AMIs only. Existing AMIs are not affected.

• If you remove the AMI deprecation rule from a schedule, Amazon Data Lifecycle Manager will not cancel deprecation for AMIs that were previously deprecated by that schedule.

• If you decrease the AMI deprecation count or period for a schedule, Amazon Data Lifecycle Manager will not cancel deprecation for AMIs that were previously deprecated by that schedule.

• If you manually deprecate an AMI that was created by an AMI policy, Amazon Data Lifecycle Manager will not override the deprecation.

• If you manually cancel deprecation for an AMI that was previously deprecated by an AMI policy, Amazon Data Lifecycle Manager will not override the cancellation.

• If an AMI is created by multiple conflicting schedules, and one or more of those schedules do not have an AMI deprecation rule, Amazon Data Lifecycle Manager will not deprecate that AMI.

• If an AMI is created by multiple conflicting schedules, and all of those schedules have an AMI deprecation rule, Amazon Data Lifecycle Manager will use the deprecation rule that results in the latest deprecation date.

The following considerations apply to AMI policies and Recycle Bin (p. 2467):

• If Amazon Data Lifecycle Manager deregisters an AMI and sends it to the Recycle Bin when the policy's retention threshold is reached, and you manually restore that AMI from the Recycle Bin, you must
manually deregister the AMI when it is no longer needed. Amazon Data Lifecycle Manager will no longer manage the AMI.

- If you manually deregister an AMI that was created by a policy, and that AMI is in the Recycle Bin when the policy's retention threshold is reached, Amazon Data Lifecycle Manager will not deregister the AMI. Amazon Data Lifecycle Manager does not manage AMIs while they are in the Recycle Bin.

If the AMI is restored from the Recycle Bin before the policy's retention threshold is reached, Amazon Data Lifecycle Manager will deregister the AMI when the policy's retention threshold is reached.

If the AMI is restored from the Recycle Bin after the policy's retention threshold is reached, Amazon Data Lifecycle Manager will no longer deregister the AMI. You must manually delete it when it is no longer needed.

The following considerations apply to AMI policies that are in the error state:

- For policies with age-based retention schedules, AMIs that are set to expire while the policy is in the error state are retained indefinitely. You must deregister the AMIs manually. When you re-enable the policy, Amazon Data Lifecycle Manager resumes deregistering AMIs as their retention periods expire.
- For policies with count-based retention schedules, the policy stops creating and deregistering AMIs while it is in the error state. When you re-enable the policy, Amazon Data Lifecycle Manager resumes creating AMIs, and it resumes deregistering AMIs as the retention threshold is met.

The following considerations apply to AMI policies and disabling AMIs (p. 227)

- If you disable an AMI created by Amazon Data Lifecycle Manager, and that AMI is disabled when its retention threshold is reached, Amazon Data Lifecycle Manager will deregister the AMI and delete its associated snapshots.
- If you disable an AMI created by Amazon Data Lifecycle Manager and you manually archive its associated snapshots, and those snapshots are archived when their retention threshold is met, Amazon Data Lifecycle Manager will not delete those snapshots and it will no longer manage them.

Additional resources

For more information, see the Automating Amazon EBS snapshot and AMI management using Amazon Data Lifecycle Manager AWS storage blog.

Automate cross-account snapshot copies

Automating cross-account snapshot copies enables you to copy your Amazon EBS snapshots to specific Regions in an isolated account and encrypt those snapshots with an encryption key. This enables you to protect yourself against data loss in the event of your account being compromised.

Automating cross-account snapshot copies involves two accounts:

- **Source account**—The source account is the account that creates and shares the snapshots with the target account. In this account, you must create an EBS snapshot policy that creates snapshots at set intervals and then shares them with other AWS accounts.
- **Target account**—The target account is the account with destination account with which the snapshots are shared, and it is the account that creates copies of the shared snapshots. In this account, you must create a cross-account copy event policy that automatically copies snapshots that are shared with it by one or more specified source accounts.

Topics

- Create cross-account snapshot copy policies (p. 2272)
To prepare the source and target accounts for cross-account snapshot copying, you need to perform the following steps:

**Step 1: Create the EBS snapshot policy (Source account)**

In the source account, create an EBS snapshot policy that will create the snapshots and share them with the required target accounts.

When you create the policy, ensure that you enable cross-account sharing and that you specify the target AWS accounts with which to share the snapshots. These are the accounts with which the snapshots are to be shared. If you are sharing encrypted snapshots, then you must give the selected target accounts permission to use the KMS key used to encrypt the source volume. For more information, see **Step 2: Share the customer managed key (Source account)** (p. 2272).

**Note**

You can only share snapshots that are unencrypted or that are encrypted using a customer managed key. You can’t share snapshots that are encrypted with the default EBS encryption KMS key. If you share encrypted snapshots, then you must also share the KMS key that was used to encrypt the source volume with the target accounts. For more information, see [Allowing users in other accounts to use a KMS key](#) in the AWS Key Management Service Developer Guide.

For more information about creating an EBS snapshot policy, see [Automate snapshot lifecycles](#) (p. 2223).

Use one of the following methods to create the EBS snapshot policy.

**Step 2: Share the customer managed key (Source account)**

If you are sharing encrypted snapshots, you must grant the IAM role and the target AWS accounts (that you selected in the previous step) permissions to use the customer managed key that was used to encrypt the source volume.

**Note**

Perform this step only if you are sharing encrypted snapshots. If you are sharing unencrypted snapshots, skip this step.

**Console**

2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed key** and then select the KMS key that you need to share with the target accounts.

   Make note of the KMS key ARN, you’ll need this later.

4. On the **Key policy** tab, scroll down to the **Key users** section. Choose **Add**, enter the name of the IAM role that you selected in the previous step, and then choose **Add**.
5. On the **Key policy** tab, scroll down to the **Other AWS accounts** section. Choose **Add other AWS accounts**, and then add all of the target AWS accounts that you chose to share the snapshots with in the previous step.
6. Choose **Save changes**.
Command line

Use the `get-key-policy` command to retrieve the key policy that is currently attached to the KMS key.

For example, the following command retrieves the key policy for a KMS key with an ID of 9d5e2b3d-e410-4a27-a958-19e220d83a1e and writes it to a file named `snapshotKey.json`.

```
$ aws kms get-key-policy \
   --policy-name default \
   --key-id 9d5e2b3d-e410-4a27-a958-19e220d83a1e \
   --query Policy \
   --output text > snapshotKey.json
```

Open the key policy using your preferred text editor. Add the ARN of the IAM role that you specified when you created the snapshot policy and the ARNs of the target accounts with which to share the KMS key.

For example, in the following policy, we added the ARN of the default IAM role, and the ARN of the root account for target account 222222222222.

**Tip**

To follow the principle of least privilege, do not allow full access to `kms:CreateGrant`. Instead, use the `kms:GrantIsForAWSResource` condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service, as shown in the following example.

```
{
   "Sid": "Allow use of the key",
   "Effect": "Allow",
   "Principal": {
      "AWS": [
         "arn:aws:iam::111111111111:role/service-role/AWSDataLifecycleManagerDefaultRole",
         "arn:aws:iam::222222222222:root"
      ],
   "Action": [
      "kms:Encrypt",
      "kms:Decrypt",
      "kms:ReEncrypt*",
      "kms:GenerateDataKey*",
      "kms:DescribeKey"
   ],
   "Resource": "*"
 },
{
   "Sid": "Allow attachment of persistent resources",
   "Effect": "Allow",
   "Principal": {
      "AWS": [
         "arn:aws:iam::111111111111:role/service-role/AWSDataLifecycleManagerDefaultRole",
         "arn:aws:iam::222222222222:root"
      ],
   "Action": [
      "kms:CreateGrant",
      "kms:ListGrants",
      "kms:RevokeGrant"
   ],
   "Resource": "*",
   "Condition": {
      "Bool": {
         "kms:GrantIsForAWSResource": "true"
      }
   }
}
Save and close the file. Then use the `put-key-policy` command to attach the updated key policy to the KMS key.

```
$ aws kms put-key-policy
   --policy-name default
   --key-id 9d5e2b3d-e410-4a27-a958-19e220d83a1e
   --policy file://snapshotKey.json
```

**Step 3: Create cross-account copy event policy (Target account)**

In the target account, you must create a cross-account copy event policy that will automatically copy snapshots that are shared by the required source accounts.

This policy runs in the target account only when one of the specified source accounts shares snapshot with the account.

Use one of the following methods to create the cross-account copy event policy.

**Console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Elastic Block Store, Lifecycle Manager**, and then choose **Create lifecycle policy**.
3. On the **Select policy type** screen, choose **Cross-account copy event policy**, and then choose **Next**.
4. For **Policy description**, enter a brief description for the policy.
5. For **Policy tags**, add the tags to apply to the lifecycle policy. You can use these tags to identify and categorize your policies.
6. In the **Event settings** section, define the snapshot sharing event that will cause the policy to run. Do the following:
   a. For **Sharing accounts**, specify the source AWS accounts from which you want to copy the shared snapshots. Choose **Add account**, enter the 12-digit AWS account ID, and then choose **Add**.
   b. For **Filter by description**, enter the required snapshot description using a regular expression. Only snapshots that are shared by the specified source accounts and that have descriptions that match the specified filter are copied by the policy. For more information, see [Specify snapshot description filters](p. 2278).
7. For **IAM role**, choose the IAM role that has permissions to perform snapshot copy actions. To use the default role provided by Amazon Data Lifecycle Manager, choose **Default role**. Alternatively, to use a custom IAM role that you previously created, choose **Choose another role** and then select the role to use.

   If you are copying encrypted snapshots, you must grant the selected IAM role permissions to use the encryption KMS key used to encrypt the source volume. Similarly, if you are encrypting the snapshot in the destination Region using a different KMS key, you must grant the IAM role permission to use the destination KMS key. For more information, see [Step 4: Allow IAM role to use the required KMS keys (Target account)](p. 2276).
8. In the **Copy action** section, define the snapshot copy actions that the policy should perform when it is activated. The policy can copy snapshots to up to three Regions. You must specify a separate copy rule for each destination Region. For each rule that you add, do the following:
a. For **Name**, enter a descriptive name for the copy action.
b. For **Target Region**, select the Region to which to copy the snapshots.
c. For **Expire**, specify how long to retain the snapshot copies in the target Region after creation.
d. To encrypt the snapshot copy, for **Encryption**, select **Enable encryption**. If the source snapshot is encrypted, or if encryption by default is enabled for your account, the snapshot copy is always encrypted, even if you do not enable encryption here. If the source snapshot is unencrypted and encryption by default is not enabled for your account, you can choose to enable or disable encryption. If you enable encryption, but do not specify a KMS key, the snapshots are encrypted using the default encryption KMS key in your account. If you specify a KMS key for the destination Region, you must have access to the KMS key.

9. To add additional snapshot copy actions, choose **Add new Regions**.

10. For **Policy status after creation**, choose **Enable policy** to start the policy runs at the next scheduled time, or **Disable policy** to prevent the policy from running. If you do not enable the policy now, it will not start copying snapshots until you manually enable it after creation.

11. Choose **Create policy**.

**Command line**

Use the `create-lifecycle-policy` command to create a policy. To create a cross-account copy event policy, for PolicyType, specify **EVENT_BASED_POLICY**.

For example, the following command creates a cross-account copy event policy in target account 222222222222. The policy copies snapshots that are shared by source account 111111111111. The policy copies snapshots to **sa-east-1** and **eu-west-2**. Snapshots copied to **sa-east-1** are unencrypted and they are retained for 3 days. Snapshots copied to **eu-west-2** are encrypted using KMS key 8af79514-350d-4c52-bac8-8985e84171c7 and they are retained for 1 month. The policy uses the default IAM role.

```
$ aws dlm create-lifecycle-policy \
   --description "Copy policy" \
   --state ENABLED \
   --execution-role-arn arn:aws:iam::222222222222:role/service-role/\n   AWSDataLifecycleManagerDefaultRole \
   --policy-details file://policyDetails.json
```

The following shows the contents of the `policyDetails.json` file.

```
{
   "PolicyType" : "EVENT_BASED_POLICY",
   "EventSource" : { 
      "Type" : "MANAGED_CWE", 
      "Parameters" : { 
         "EventType" : "shareSnapshot", 
         "SnapshotOwner" : ["111111111111"]
      }
   }
},
"Actions" : [{
   "Name" : "Copy Snapshot to Sao Paulo and London", 
   "CrossRegionCopy" : [{
      "Target" : "sa-east-1", 
      "EncryptionConfiguration" : { 
         "Encrypted" : false 
      },
      "RetainRule" : {
         "Interval" : 3,
         "IntervalUnit" : "DAYS"
      }
   }]
}
```
If the request succeeds, the command returns the ID of the newly created policy. The following is example output.

```
{
   "PolicyId": "policy-9876543210abcdef0"
}
```

Step 4: Allow IAM role to use the required KMS keys (Target account)

If you are copying encrypted snapshots, you must grant the IAM role (that you selected in the previous step) permissions to use the customer managed key that was used to encrypt the source volume.

**Note**

Only perform this step if you are copying encrypted snapshots. If you are copying unencrypted snapshots, skip this step.

Use one of the following methods to add the required policies to the IAM role.

**Console**

2. In the navigation pane, select Roles. Search for and select the IAM role that you selected when you created the cross-account copy event policy in the previous step. If you chose to use the default role, the role is named `AWSDataLifecycleManagerDefaultRole`.
3. Choose **Add inline policy** and then select the **JSON** tab.
4. Replace the existing policy with the following, and specify the ARN of the KMS key that was used to encrypt the source volumes and that was shared with you by the source account in Step 2.

   **Note**

   If you are copying from multiple source accounts, then you must specify the corresponding KMS key ARN from each source account.

   In the following example, the policy grants the IAM role permission to use KMS key 1234abcd-12ab-34cd-56ef-1234567890ab, which was shared by source account 111111111111, and KMS key 4567dcba-23ab-34cd-56ef-0987654321yz, which exists in target account 222222222222.

   **Tip**

   To follow the principle of least privilege, do not allow full access to `kms:CreateGrant`. Instead, use the `kms:GrantIsForAWSResource` condition key to
allow the user to create grants on the KMS key only when the grant is created on
the user's behalf by an AWS service, as shown in the following example.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "kms:RevokeGrant",
                "kms:CreateGrant",
                "kms:ListGrants"
            ],
            "Resource": [
                "arn:aws:kms:us-east-1:111111111111:key/1234abcd-12ab-34cd-56ef-1234567890ab",
                "arn:aws:kms:us-east-1:222222222222:key/4567dcba-23ab-34cd-56ef-0987654321yz"
            ],
            "Condition": {
                "Bool": {
                    "kms:GrantIsForAWSResource": "true"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncrypt*",
                "kms:GenerateDataKey*",
                "kms:DescribeKey"
            ],
            "Resource": [
                "arn:aws:kms:us-east-1:111111111111:key/1234abcd-12ab-34cd-56ef-1234567890ab",
                "arn:aws:kms:us-east-1:222222222222:key/4567dcba-23ab-34cd-56ef-0987654321yz"
            ]
        }
    ]
}
```

5. Choose **Review policy**

6. For **Name**, enter a descriptive name for the policy, and then choose **Create policy**.

**Command line**

Using your preferred text editor, create a new JSON file named `policyDetails.json`. Add the following policy and specify the ARN of the KMS key that was used to encrypt the source volumes and that was shared with you by the source account in Step 2.

**Note**

If you are copying from multiple source accounts, then you must specify the corresponding KMS key ARN from each source account.

In the following example, the policy grants the IAM role permission to use KMS key 1234abcd-12ab-34cd-56ef-1234567890ab, which was shared by source account 111111111111, and KMS key 4567dcba-23ab-34cd-56ef-0987654321yz, which exists in target account 222222222222.
Tip
To follow the principle of least privilege, do not allow full access to `kms:CreateGrant`. Instead, use the `kms:GrantIsForAWSResource` condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service, as shown in the following example.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "kms:RevokeGrant",
                "kms:CreateGrant",
                "kms:ListGrants"
            ],
            "Resource": [
                "arn:aws:kms:us-east-1:111111111111:key/1234abcd-12ab-34cd-56ef-1234567890ab",
                "arn:aws:kms:us-east-1:222222222222:key/4567dcba-23ab-34cd-56ef-0987654321yz"
            ],
            "Condition": {
                "Bool": {
                    "kms:GrantIsForAWSResource": "true"
                }
            }
        },
        {
            "Effect": "Allow",
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncrypt*",
                "kms:GenerateDataKey*",
                "kms:DescribeKey"
            ],
            "Resource": [
                "arn:aws:kms:us-east-1:111111111111:key/1234abcd-12ab-34cd-56ef-1234567890ab",
                "arn:aws:kms:us-east-1:222222222222:key/4567dcba-23ab-34cd-56ef-0987654321yz"
            ]
        }
    ]
}
```

Save and close the file. Then use the `put-role-policy` command to add the policy to the IAM role.

For example

```bash
$ aws iam put-role-policy
--role-name AWSDataLifecycleManagerDefaultRole 
--policy-name CopyPolicy 
--policy-document file://AdminPolicy.json
```

Specify snapshot description filters

When you create the snapshot copy policy in the target account, you must specify a snapshot description filter. The snapshot description filter enables you to specify an additional level of filtering that lets you control which snapshots are copied by the policy. This means that a snapshot is only copied by the policy
if it is shared by one of the specified source accounts, and it has a snapshot description that matches the specified filter. In other words, if a snapshot is shared by one of the specified course accounts, but it does not have a description that matches the specified filter, it is not copied by the policy.

The snapshot filter description must be specified using a regular expression. It is a mandatory field when creating cross-account copy event policies using the console and the command line. The following are example regular expressions that can be used:

- \.*—This filter matches all snapshot descriptions. If you use this expression the policy will copy all snapshots that are shared by one of the specified source accounts.
- Created for policy: policy-0123456789abcdef0.*—This filter matches only snapshots that are created by a policy with an ID of policy-0123456789abcdef0. If you use an expression like this, only snapshots that are shared with your account by one of the specified source accounts, and that have been created by a policy with the specified ID are copied by the policy.
- .*production.*—This filter matches any snapshot that has the word production anywhere in its description. If you use this expression the policy will copy all snapshots that are shared by one of the specified source accounts and that have the specified text in their description.

Considerations for cross-account snapshot copy policies

The following considerations apply to cross-account copy event policies:

- You can only copy snapshots that are unencrypted or that are encrypted using a customer managed key.
- You can create a cross-account copy event policy to copy snapshots that are shared outside of Amazon Data Lifecycle Manager.
- If you want to encrypt snapshots in the target account, then the IAM role selected for the cross-account copy event policy must have permission to use the required KMS key.

Additional resources

For more information, see the Automating copying encrypted Amazon EBS snapshots across AWS accounts AWS storage blog.

View, modify, and delete lifecycle policies

Use the following procedures to view, modify and delete existing lifecycle policies.

Topics
- View lifecycle policies (p. 2279)
- Modify lifecycle policies (p. 2280)
- Delete lifecycle policies (p. 2081)

View lifecycle policies

Use one of the following procedures to view a lifecycle policy.

Console

To view a lifecycle policy
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Elastic Block Store, Lifecycle Manager.
3. Select a lifecycle policy from the list. The Details tab displays information about the policy.
Command line

Use the `get-lifecycle-policy` command to display information about a lifecycle policy.

```
aws dlm get-lifecycle-policy --policy-id policy-0123456789abcdef0
```

The following is example output. It includes the information that you specified, plus metadata inserted by AWS.

```
{
  "Policy": {
    "Description": "My first policy",
    "DateCreated": "2018-05-15T00:16:21+0000",
    "State": "ENABLED",
    "ExecutionRoleArn": "arn:aws:iam::210774411744:role/AWSDataLifecycleManagerDefaultRole",
    "PolicyId": "policy-0123456789abcdef0",
    "DateModified": "2018-05-15T00:16:22+0000",
    "PolicyDetails": {
      "PolicyType": "EBS_SNAPSHOT_MANAGEMENT",
      "ResourceTypes": ["VOLUME"],
      "TargetTags": [
        {
          "Value": "115",
          "Key": "costcenter"
        }
      ],
      "Schedules": [
        {
          "TagsToAdd": [
            {
              "Value": "myDailySnapshot",
              "Key": "type"
            }
          ],
          "RetainRule": {
            "Count": 5
          },
          "CopyTags": false,
          "CreateRule": {
            "Interval": 24,
            "IntervalUnit": "HOURS",
            "Times": [
              "03:00"
            ]
          },
          "Name": "DailySnapshots"
        }
      ]
    }
  }
}
```

Modify lifecycle policies

Considerations for modifying policies

- If you modify an AMI or snapshot policy by removing its target tags, the volumes or instances with those tags are no longer managed by the policy.
- If you modify a schedule name, the snapshots or AMIs created under the old schedule name are no longer managed by the policy.
- If you modify an age-based retention schedule to use a new time interval, the new interval is used only for new snapshots or AMIs created after the change. The new schedule does not affect the retention schedule of snapshots or AMIs created before the change.
- You cannot change the retention schedule of a policy from count-based to age-based after creation. To make this change, you must create a new policy.
- If you disable a policy with an age-based retention schedule, the snapshots or AMIs that are set to expire while the policy is disabled are retained indefinitely. You must delete the snapshots or deregister the AMIs manually. When you re-enable the policy, Amazon Data Lifecycle Manager resumes deleting snapshots or deregistering AMIs as their retention periods expire.
- If you disable a policy with a count-based retention schedule, the policy stops creating and deleting snapshots or AMIs. When you re-enable the policy, Amazon Data Lifecycle Manager resumes creating snapshots and AMIs, and it resumes deleting snapshots or AMIs as the retention threshold is met.
- If you disable a policy that has a snapshot archiving-enabled policy, snapshots that are in the archive tier at the time of disabling the policy are no longer managed by Amazon Data Lifecycle Manager. You must manually delete the snapshot if they are no longer needed.
- If you enable snapshot archiving on a count-based schedule, the archiving rule applies to all new snapshots that are created and archived by the schedule, and also applies to existing snapshots that were previously created and archived by the schedule.
- If you enable snapshot archiving on an age-based schedule, the archiving rule applies only to new snapshots created after enabling snapshot archiving. Existing snapshots created before enabling snapshot archiving continue to be deleted from their respective storage tiers, according to the schedule set when those snapshots were originally created and archived.
- If you disable snapshot archiving for a count-based schedule, the schedule immediately stops archiving snapshots. Snapshots that were previously archived by the schedule remain in the archive tier and they will not be deleted by Amazon Data Lifecycle Manager.
- If you disable snapshot archiving for an age-based schedule, the snapshots created by the policy and that are scheduled to be archived are permanently deleted at the scheduled archive date and time, as indicated by the aws:dlm:expirationTime system tag.
- If you disable snapshot archiving for a schedule, the schedule immediately stops archiving snapshots. Snapshots that were previously archived by the schedule remain in the archive tier and they will not be deleted by Amazon Data Lifecycle Manager.
- If you modify the archive retention count for a count-based schedule, the new retention count includes existing snapshots that were previously archived by the schedule.
- If you modify the archive retention period for an age-based schedule, the new retention period applies only to snapshots that are archived after modifying the retention rule.

Use one of the following procedures to modify a lifecycle policy.

**Console**

**To modify a lifecycle policy**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Elastic Block Store, Lifecycle Manager**.
3. Select a lifecycle policy from the list.
4. Choose **Actions, Modify Lifecycle Policy**.
5. Modify the policy settings as needed. For example, you can modify the schedule, add or remove tags, or enable or disable the policy.
6. Choose **Update policy**.
Command line

Use the `update-lifecycle-policy` command to modify the information in a lifecycle policy. To simplify the syntax, this example references a JSON file, `policyDetailsUpdated.json`, that includes the policy details.

```bash
aws dlm update-lifecycle-policy \
  --state DISABLED \
  --execution-role-arn arn:aws:iam::12345678910:role/AWSDataLifecycleManagerDefaultRole \
  --policy-details file:///policyDetailsUpdated.json
```

The following is an example of the `policyDetailsUpdated.json` file.

```json
{
  "ResourceTypes": [
    "VOLUME"
  ],
  "TargetTags": [
    {
      "Key": "costcenter",
      "Value": "120"
    }
  ],
  "Schedules": [
    {
      "Name": "DailySnapshots",
      "TagsToAdd": [
        {
          "Key": "type",
          "Value": "myDailySnapshot"
        }
      ],
      "CreateRule": {
        "Interval": 12,
        "IntervalUnit": "HOURS",
        "Times": [
          "15:00"
        ],
      },
      "RetainRule": {
        "Count": 5
      },
      "CopyTags": false
    }
  ]
}
```

To view the updated policy, use the `get-lifecycle-policy` command. You can see that the state, the value of the tag, the snapshot interval, and the snapshot start time were changed.

**Delete lifecycle policies**

**Considerations for modifying policies**

- If you delete a policy, the snapshots or AMIs created by that policy are not automatically deleted. If you no longer need the snapshots or AMIs, you must delete them manually.
- If you delete a policy that has a snapshot archiving-enabled policy, snapshots that are in the archive tier at the time of deleting the policy are no longer managed by Amazon Data Lifecycle Manager. You must manually delete the snapshot if they are no longer needed.
If you delete a policy with an archive-enabled, age-based schedule, the snapshots created by the policy and that are scheduled to be archived are permanently deleted at the scheduled archive date and time, as indicated by the `aws:dlm:expirationtime` system tag.

Use one of the following procedures to delete a lifecycle policy.

Console

**To delete a lifecycle policy**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Elastic Block Store, Lifecycle Manager**.
3. Select a lifecycle policy from the list.
4. Choose **Actions, Delete Lifecycle Policy**.
5. When prompted for confirmation, choose **Delete Lifecycle Policy**.

Command line

Use the `delete-lifecycle-policy` command to delete a lifecycle policy and free up the target tags specified in the policy for reuse.

**Note**

You can delete snapshots created only by Amazon Data Lifecycle Manager.

```
aws dlm delete-lifecycle-policy --policy-id policy-0123456789abcdef0
```

The [Amazon Data Lifecycle Manager API Reference](https://aws.amazon.com/documentation/dlm/api-reference/) provides descriptions and syntax for each of the actions and data types for the Amazon Data Lifecycle Manager Query API.

Alternatively, you can use one of the AWS SDKs to access the API in a way that's tailored to the programming language or platform that you're using. For more information, see [AWS SDKs](https://aws.amazon.com/documentation/).

**AWS Identity and Access Management**

Access to Amazon Data Lifecycle Manager requires credentials. Those credentials must have permissions to access AWS resources, such as instances, volumes, snapshots, and AMIs. The following sections provide details about how you can use AWS Identity and Access Management (IAM), and help secure access to your resources.

**Topics**

- [AWS managed policies](#)
- [IAM service roles](#)
- [Permissions for users](#)
- [Permissions for encryption](#)

**AWS managed policies**

An AWS managed policy is a standalone policy that is created and administered by AWS. AWS managed policies are designed to provide permissions for many common use cases. AWS managed policies make it more efficient for you to assign appropriate permissions to users, groups, and roles, than if you had to write the policies yourself.
However, you can't change the permissions defined in AWS managed policies. AWS occasionally updates the permissions defined in an AWS managed policy. When this occurs, the update affects all principal entities (users, groups, and roles) that the policy is attached to.

Amazon Data Lifecycle Manager provides AWS managed policies for common use cases. These policies make it more efficient to define the appropriate permissions and control access to your resources. The AWS managed policies provided by Amazon Data Lifecycle Manager are designed to be attached to roles that you pass to Amazon Data Lifecycle Manager.

Topics
- AWSDataLifecycleManagerServiceRole (p. 2284)
- AWSDataLifecycleManagerServiceRoleForAMIManagement (p. 2285)
- AWSDataLifecycleManagerSSMFullAccess (p. 2286)
- AWS managed policy updates (p. 2287)

AWSDataLifecycleManagerServiceRole

The AWSDataLifecycleManagerServiceRole policy provides appropriate permissions to Amazon Data Lifecycle Manager to create and manage Amazon EBS snapshot policies and cross-account copy event policies.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CreateSnapshot",
        "ec2:CreateSnapshots",
        "ec2:DeleteSnapshot",
        "ec2:DescribeInstances",
        "ec2:DescribeVolumes",
        "ec2:DescribeSnapshots",
        "ec2:EnableFastSnapshotRestores",
        "ec2:DescribeFastSnapshotRestores",
        "ec2:DisableFastSnapshotRestores",
        "ec2:CopySnapshot",
        "ec2:ModifySnapshotAttribute",
        "ec2:DescribeSnapshotAttribute",
        "ec2:ModifySnapshotTier",
        "ec2:DescribeSnapshotTierStatus"
      ],
      "Resource": "*
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CreateTags"
      ],
      "Resource": "arn:aws:ec2:*::snapshot/*"
    },
    {
      "Effect": "Allow",
      "Action": ["events:PutRule",
      "events:DeleteRule",
      "events:DescribeRule",
      "events:EnableRule",
      "events:DisableRule",
      "events:ListTargetsByRule",
      "events:PutTargets"
    ]
  ]
}
```
AWSDataLifecycleManagerServiceRoleForAMIManagement

The AWSDataLifecycleManagerServiceRoleForAMIManagement policy provides appropriate permissions to Amazon Data Lifecycle Manager to create and manage Amazon EBS-backed AMI policies.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "ec2:CreateTags",
      "Resource": [
        "arn:aws:ec2:*::snapshot/*",
        "arn:aws:ec2:*::image/*"
      ]
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeImages",
        "ec2:DescribeInstances",
        "ec2:DescribeImageAttribute",
        "ec2:DescribeVolumes",
        "ec2:DescribeSnapshots"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "ec2:DeleteSnapshot",
      "Resource": "arn:aws:ec2:*::snapshot/*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:ResetImageAttribute",
        "ec2:DeregisterImage",
        "ec2:CreateImage",
        "ec2:CopyImage",
        "ec2:ModifyImageAttribute"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:EnableImageDeprecation",
        "ec2:DisableImageDeprecation"
      ],
      "Resource": "arn:aws:ec2:*::image/*"
    }
  ]
}
```
AWSDataLifecycleManagerSSMFullAccess

Provides Amazon Data Lifecycle Manager permission to perform the Systems Manager actions required to run pre and post scripts on all Amazon EC2 instances.

**Important**
The policy uses the `aws:ResourceTag` condition key to restrict access to specific SSM documents when using pre and post scripts. To allow Amazon Data Lifecycle Manager to access the SSM documents, you must ensure that your SSM documents are tagged with `DLMScriptsAccess:true`.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowSSMReadOnlyAccess",
      "Effect": "Allow",
      "Action": [
        "ssm:GetCommandInvocation",
        "ssm:ListCommands",
        "ssm:DescribeInstanceInformation"
      ],
      "Resource": "*"
    },
    {
      "Sid": "AllowTaggedSSMDocumentsOnly",
      "Effect": "Allow",
      "Action": [
        "ssm:SendCommand",
        "ssm:DescribeDocument",
        "ssm:GetDocument"
      ],
      "Resource": [
        "arn:aws:ssm:*:*:document/**
      ],
      "Condition": {
        "StringEquals": {
          "aws:ResourceTag/DLMScriptsAccess": "true"
        }
      }
    },
    {
      "Sid": "AllowSpecificAWSOwnedSSMDocuments",
      "Effect": "Allow",
      "Action": [
        "ssm:SendCommand",
        "ssm:DescribeDocument",
        "ssm:GetDocument"
      ],
      "Resource": [
        "arn:aws:ssm:*:*:document/AWSEC2-CreateVssSnapshot",
        "arn:aws:ssm:*:*:document/AWSSystemsManagerSAP-CreateDLMSnapshotForSAPHANA"
      ]
    },
    {
      "Sid": "AllowAllEC2Instances",
      "Effect": "Allow",
      "Action": [
        "ssm:SendCommand"
      ],
      "Resource": [
        "arn:aws:ec2:*:*:instance/**
      ]
    }
  ]
}
```
AWS managed policy updates

AWS services maintain and update AWS managed policies. You can't change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won't break your existing permissions.

The following table provides details about updates to AWS managed policies for Amazon Data Lifecycle Manager since this service began tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Document history (p. 2614).

<table>

IAM service roles

An AWS Identity and Access Management (IAM) role is similar to a user, in that it is an AWS identity with permissions policies that determine what the identity can and can't do in AWS. However, instead of being uniquely associated with one person, a role is intended to be assumable by anyone who needs it. A service role is a role that an AWS service assumes to perform actions on your behalf. As a service that performs backup operations on your behalf, Amazon Data Lifecycle Manager requires that you pass it a role to assume when performing policy operations on your behalf. For more information about IAM roles, see IAM Roles in the IAM User Guide.

The role that you pass to Amazon Data Lifecycle Manager must have an IAM policy with the permissions that enable Amazon Data Lifecycle Manager to perform actions associated with policy operations, such as creating snapshots and AMIs, copying snapshots and AMIs, deleting snapshots, and deregistering AMIs. Different permissions are required for each of the Amazon Data Lifecycle Manager policy types. The role must also have Amazon Data Lifecycle Manager listed as a trusted entity, which enables Amazon Data Lifecycle Manager to assume the role.

Topics

- Default service roles for Amazon Data Lifecycle Manager (p. 2288)
- Custom service roles for Amazon Data Lifecycle Manager (p. 2289)

Default service roles for Amazon Data Lifecycle Manager

Amazon Data Lifecycle Manager uses the following default service roles:

- **AWSDataLifecycleManagerDefaultRole**—default role for managing snapshots. It trusts only the dlm.amazonaws.com service to assume the role and it allows Amazon Data Lifecycle Manager to perform the actions required by snapshot and cross-account snapshot copy policies on your behalf. This role uses the AWSDataLifecycleManagerServiceRole AWS managed policy.
  
  **Note**
  The ARN format of the role differs depending on whether it was created using the console or the AWS CLI. If the role was created using the console, the ARN format is arn:aws:iam::<account_id>:role/service-role/AWSDataLifecycleManagerDefaultRole. If the role was created using the AWS CLI, the ARN format is arn:aws:iam::<account_id>:role/AWSDataLifecycleManagerDefaultRole.

- **AWSDataLifecycleManagerDefaultRoleForAMIManagement**—default role for managing AMIs. It trusts only the dlm.amazonaws.com service to assume the role and it allows Amazon Data Lifecycle Manager to perform the actions required by EBS-backed AMI policies on your behalf. This role uses the AWSDataLifecycleManagerServiceRoleForAMIManagement AWS managed policy.

If you are using the Amazon Data Lifecycle Manager console, Amazon Data Lifecycle Manager automatically creates the **AWSDataLifecycleManagerDefaultRole** service role the first time
you create a snapshot or cross-account snapshot copy policy, and it automatically creates the
AWSDataLifecycleManagerDefaultRoleForAMIManagement service role the first time you create an
EBS-backed AMI policy.

If you are not using the console, you can manually create the service roles using the create-default-role
command. For --resource-type, specify snapshot to create AWSDataLifecycleManagerDefaultRole, or
image to create AWSDataLifecycleManagerDefaultRoleForAMIManagement.

```bash
$ aws dlm create-default-role --resource-type snapshot|image
```

If you delete the default service roles, and then need to create them again, you can use the same process
to recreate them in your account.

Custom service roles for Amazon Data Lifecycle Manager

As an alternative to using the default service roles, you can create custom IAM roles with the required
permissions and then select them when you create a lifecycle policy.

To create a custom IAM role

1. Create roles with the following permissions.

   - Permissions required for managing snapshot lifecycle policies

```json
{
   "Version": "2012-10-17",
   "Statement": [
     {
       "Effect": "Allow",
       "Action": [
         "ec2:CreateSnapshot",
         "ec2:CreateSnapshots",
         "ec2:DeleteSnapshot",
         "ec2:DescribeInstances",
         "ec2:DescribeVolumes",
         "ec2:DescribeSnapshots",
         "ec2:EnableFastSnapshotRestores",
         "ec2:DescribeFastSnapshotRestores",
         "ec2:DisableFastSnapshotRestores",
         "ec2:CopySnapshot",
         "ec2:ModifySnapshotAttribute",
         "ec2:DescribeSnapshotAttribute",
         "ec2:ModifySnapshotTier",
         "ec2:DescribeSnapshotTierStatus"
       ],
       "Resource": "*"
     },
     {
       "Effect": "Allow",
       "Action": [
         "ec2:CreateTags"
       ],
       "Resource": "arn:aws:ec2:*::snapshot/*"
     },
     {
       "Effect": "Allow",
       "Action": [
         "events:PutRule",
         "events:DeleteRule",
         "events:DescribeRule",
         "events:EnableRule",
         "events:DisableRule",
         "events:ListTargetsByRule"
       ],
       "Resource": "*"
     }
   ]
}
```
• Permissions required for managing AMI lifecycle policies

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetCommandInvocation",
        "ssm:GetDocument",
        "ssm:DescribeInstanceInformation"
      ],
      "Resource": "arn:aws:events:*:*:rule/AwsDataLifecycleRule.managed-cwe.*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetCommandInvocation",
        "ssm:ListCommands",
        "ssm:DescribeInstanceInformation"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetCommandInvocation",
        "ssm:ListCommands",
        "ssm:DescribeInstanceInformation"
      ],
      "Resource": "arn:aws:events:*:*:rule/AwsDataLifecycleRule.managed-cwe.*"
    }
  ]
}
```
“Action”: “ec2:CreateTags”,
“Resource”: [
  “arn:aws:ec2:*::snapshot/*”,
  “arn:aws:ec2:*::image/*”
],
},
{
  “Effect”: “Allow”,
  “Action”: [
    “ec2:DescribeImages”,
    “ec2:DescribeInstances”,
    “ec2:DescribeImageAttribute”,
    “ec2:DescribeVolumes”,
    “ec2:DescribeSnapshots”
  ],
  “Resource”: “*”
},
{
  “Effect”: “Allow”,
  “Action”: “ec2:DeleteSnapshot”,
  “Resource”: “arn:aws:ec2:*::snapshot/*”
},
{
  “Effect”: “Allow”,
  “Action”: [
    “ec2:ResetImageAttribute”,
    “ec2:DeregisterImage”,
    “ec2:CreateImage”,
    “ec2:CopyImage”,
    “ec2:ModifyImageAttribute”
  ],
  “Resource”: “*”
},
{
  “Effect”: “Allow”,
  “Action”: [
    “ec2:EnableImageDeprecation”,
    “ec2:DisableImageDeprecation”
  ],
  “Resource”: “arn:aws:ec2:*::image/*”
}
}

For more information, see Creating a Role in the IAM User Guide.

2. Add a trust relationship to the roles.
   a. In the IAM console, choose Roles.
   b. Select the roles that you created, and then choose Trust relationships.
   c. Choose Edit Trust Relationship, add the following policy, and then choose Update Trust Policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "dlm.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```
We recommend that you use the `aws:SourceAccount` and `aws:SourceArn` condition keys to protect yourself against the confused deputy problem. For example, you could add the following condition block to the previous trust policy. The `aws:SourceAccount` is the owner of the lifecycle policy and the `aws:SourceArn` is the ARN of the lifecycle policy. If you don't know the lifecycle policy ID, you can replace that portion of the ARN with a wildcard (*) and then update the trust policy after you create the lifecycle policy.

```
"Condition": {
  "StringEquals": {
    "aws:SourceAccount": "account_id"
  },
  "ArnLike": {
    "aws:SourceArn": "arn:partition:dlm:region:account_id:policy/policy_id"
  }
}
```

Permissions for users

A user must have the following permissions to use Amazon Data Lifecycle Manager.

**Note**

- The `ec2:DescribeAvailabilityZones`, `ec2:DescribeRegions`, `kms:ListAliases`, and `kms:DescribeKey` permissions are required for console users only. If console access is not required, you can remove the permissions.
- The ARN format of the `AWSDataLifecycleManagerDefaultRole` role differs depending on whether it was created using the console or the AWS CLI. If the role was created using the console, the ARN format is `arn:aws:iam::account_id:role/service-role/AWSDataLifecycleManagerDefaultRole`. If the role was created using the AWS CLI, the ARN format is `arn:aws:iam::account_id:role/AWSDataLifecycleManagerDefaultRole`. The following policy assumes the role was created using the AWS CLI.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "dlm:*",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": [
        "arn:aws:iam::account_id:role/service-role/AWSDataLifecycleManagerDefaultRole",
        "arn:aws:iam::account_id:role/service-role/AWSDataLifecycleManagerDefaultRoleForAMIManagement"
      ]
    },
    {
      "Effect": "Allow",
      "Action": "iam:ListRoles",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": "iam:GetRole",
      "Resource": "*"
    }
  ]
}
```
Permissions for encryption

Consider the following when working with Amazon Data Lifecycle Manager and encrypted resources.

- If the source volume is encrypted, ensure that the Amazon Data Lifecycle Manager default roles (`AWSDataLifecycleManagerDefaultRole` and `AWSDataLifecycleManagerDefaultRoleForAMIManagement`) have permission to use the KMS keys used to encrypt the volume.
- If you enable **Cross Region copy** for unencrypted snapshots or AMIs backed by unencrypted snapshots, and choose to enable encryption in the destination Region, ensure that the default roles have permission to use the KMS key needed to perform the encryption in the destination Region.
- If you enable **Cross Region copy** for encrypted snapshots or AMIs backed by encrypted snapshots, ensure that the default roles have permission to use both the source and destination KMS keys.
- If you enable snapshot archiving for encrypted snapshots, ensure that the Amazon Data Lifecycle Manager default role (`AWSDataLifecycleManagerDefaultRole`) has permission to use the KMS key used to encrypt the snapshot.

For more information, see **Allowing users in other accounts to use a KMS key** in the *AWS Key Management Service Developer Guide*.

Monitor the lifecycle of snapshots and AMIs

You can use the following features to monitor the lifecycle of your snapshots and AMIs.

**Features**

- **Console and AWS CLI** (p. 2293)
- **AWS CloudTrail** (p. 2293)
- **Monitor your policies using CloudWatch Events** (p. 2294)
- **Monitor your policies using Amazon CloudWatch** (p. 2295)

**Console and AWS CLI**

You can view your lifecycle policies using the Amazon EC2 console or the AWS CLI. Each snapshot and AMI created by a policy has a timestamp and policy-related tags. You can filter snapshots and AMIs using these tags to verify that your backups are being created as you intend. For information about viewing lifecycle policies using the console, see **View lifecycle policies** (p. 2279).

**AWS CloudTrail**

With AWS CloudTrail, you can track user activity and API usage to demonstrate compliance with internal policies and regulatory standards. For more information, see the *AWS CloudTrail User Guide*.
Monitor your policies using CloudWatch Events

Amazon EBS and Amazon Data Lifecycle Manager emit events related to lifecycle policy actions. You can use AWS Lambda and Amazon CloudWatch Events to handle event notifications programmatically. Events are emitted on a best effort basis. For more information, see the Amazon CloudWatch Events User Guide.

The following events are available:

**Note**

No events are emitted for AMI lifecycle policy actions.

- **createSnapshot** — An Amazon EBS event emitted when a CreateSnapshot action succeeds or fails. For more information, see EventBridge for Amazon EBS (p. 2400).
- **DLM Policy State Change** — An Amazon Data Lifecycle Manager event emitted when a lifecycle policy enters an error state. The event contains a description of what caused the error.

The following is an example of an event when the permissions granted by the IAM role are insufficient.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-0123456789ab",
    "detail-type": "DLM Policy State Change",
    "source": "aws.dlm",
    "account": "123456789012",
    "time": "2018-05-25T13:12:22Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:dlm:us-east-1:123456789012:policy/policy-0123456789abcdef"
    ],
    "detail": {
        "state": "ERROR",
        "cause": "Role provided does not have sufficient permissions",
        "policy_id": "arn:aws:dlm:us-east-1:123456789012:policy/policy-0123456789abcdef"
    }
}
```

The following is an example of an event when a limit is exceeded.

```
{
    "version": "0",
    "id": "01234567-0123-0123-0123-0123456789ab",
    "detail-type": "DLM Policy State Change",
    "source": "aws.dlm",
    "account": "123456789012",
    "time": "2018-05-25T13:12:22Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:dlm:us-east-1:123456789012:policy/policy-0123456789abcdef"
    ],
    "detail": {
        "state": "ERROR",
        "cause": "Maximum allowed active snapshot limit exceeded",
        "policy_id": "arn:aws:dlm:us-east-1:123456789012:policy/policy-0123456789abcdef"
    }
}
```

- **DLM Pre Post Script Notification** — An event that is emitted when a pre or post script is initiated, succeeds, or fails.

The following is an example event when a VSS backup succeeds.
Monitor your policies using Amazon CloudWatch

You can monitor your Amazon Data Lifecycle Manager lifecycle policies using CloudWatch, which collects raw data and processes it into readable, near real-time metrics. You can use these metrics to see exactly how many Amazon EBS snapshots and EBS-backed AMIs are created, deleted, and copied by your policies over time. You can also set alarms that watch for certain thresholds, and send notifications or take actions when those thresholds are met.

Metrics are kept for a period of 15 months, so that you can access historical information and gain a better understanding of how your lifecycle policies perform over an extended period.

For more information about Amazon CloudWatch, see the Amazon CloudWatch User Guide.

Topics

- Supported metrics (p. 2295)
- View CloudWatch metrics for your policies (p. 2299)
- Graph metrics for your policies (p. 2300)
- Create a CloudWatch alarm for a policy (p. 2301)
- Example use cases (p. 216)
- Managing policies that report failed actions (p. 2303)

Supported metrics

The Data Lifecycle Manager namespace includes the following metrics for Amazon Data Lifecycle Manager lifecycle policies. The supported metrics differ by policy type.
All metrics can be measured on the DLMPolicyId dimension. The most useful statistics are sum and average, and the unit of measure is count.

Choose a tab to view the metrics supported by that policy type.

**EBS snapshot policies**

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourcesTargeted</td>
<td>The number of resources targeted by the tags specified in a snapshot or EBS-backed AMI policy.</td>
</tr>
<tr>
<td>SnapshotsCreateStarted</td>
<td>The number of snapshot create actions initiated by a snapshot policy. Each action is recorded only once, even if there are multiple subsequent retries. If a snapshot create action fails, Amazon Data Lifecycle Manager sends a SnapshotsCreateFailed metric.</td>
</tr>
<tr>
<td>SnapshotsCreateCompleted</td>
<td>The number of snapshots created by a snapshot policy. This includes successful retries within 60 minutes of the scheduled time.</td>
</tr>
<tr>
<td>SnapshotsCreateFailed</td>
<td>The number of snapshots that could not be created by a snapshot policy. This includes unsuccessful retries within 60 minutes from the scheduled time.</td>
</tr>
<tr>
<td>SnapshotsSharedCompleted</td>
<td>The number of snapshots shared across accounts by a snapshot policy.</td>
</tr>
<tr>
<td>SnapshotsDeleteCompleted</td>
<td>The number of snapshots deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy. It does not apply to cross-Region snapshot copies created by the policy. This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.</td>
</tr>
<tr>
<td>SnapshotsDeleteFailed</td>
<td>The number of snapshots that could not be deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy. It does not apply to cross-Region snapshot copies created by the policy. This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegionStarted</td>
<td>The number of cross-Region snapshot copy actions initiated by a snapshot policy.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegionCompleted</td>
<td>The number of cross-Region snapshot copies created by a snapshot policy. This includes successful retries within 24 hours of the scheduled time.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegionFailed</td>
<td>The number of cross-Region snapshot copies that could not be created by a snapshot policy. This includes unsuccessful retries within 24 hours from the scheduled time.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegionDeleteCompleted</td>
<td>The number of cross-Region snapshot copies deleted, as designated by the retention rule, by a snapshot policy.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegionDeleteFailed</td>
<td>The number of cross-Region snapshot copies that could not be deleted, as designated by the retention rule, by a snapshot policy.</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>snapshotsArchiveDeletionFailed</td>
<td>The number of archived snapshots that could not be deleted from the archive tier by a snapshot policy.</td>
</tr>
<tr>
<td>snapshotsArchiveScheduled</td>
<td>The number of snapshots that were scheduled to be archived by a snapshot policy.</td>
</tr>
<tr>
<td>snapshotsArchiveCompleted</td>
<td>The number of snapshots that were successfully archived by a snapshot policy.</td>
</tr>
<tr>
<td>snapshotsArchiveFailed</td>
<td>The number of snapshots that could not be archived by a snapshot policy.</td>
</tr>
<tr>
<td>snapshotsArchiveDeletionCompleted</td>
<td>The number of archived snapshots that were successfully deleted from the archive tier by a snapshot policy.</td>
</tr>
<tr>
<td>PreScriptStarted</td>
<td>The number of instances for which a pre script was successfully initiated. If script retries are enabled, this metric can be emitted multiple times per policy run.</td>
</tr>
<tr>
<td>PreScriptCompleted</td>
<td>The number of instances for which a pre script was successfully completed. The metric is emitted even if the pre script completes outside of the specified timeout period. If script retries are enabled, this metric can be emitted multiple times per policy run.</td>
</tr>
<tr>
<td>PreScriptFailed</td>
<td>The number of instances for which a pre script failed to complete successfully. The metric is emitted even if the pre script completes outside of the specified timeout period. If script retries are enabled, this metric can be emitted multiple times per policy run.</td>
</tr>
<tr>
<td>PostScriptStarted</td>
<td>The number of instances for which a post script was successfully initiated. If script retries are enabled, this metric can be emitted multiple times per policy run.</td>
</tr>
<tr>
<td>PostScriptCompleted</td>
<td>The number of instances for which a post script was successfully completed. The metric is emitted even if the post script completes outside of the specified timeout period. If script retries are enabled, this metric can be emitted multiple times per policy run.</td>
</tr>
<tr>
<td>PostScriptFailed</td>
<td>The number of instances for which a post script failed to complete successfully. The metric is emitted even if the post script completes outside of the specified timeout period. If script retries are enabled, this metric can be emitted multiple times per policy run.</td>
</tr>
<tr>
<td>VSSBackupStarted</td>
<td>The number of instances for which a VSS backup was successfully initiated. If script retries are enabled, this metric can be emitted multiple times per policy run.</td>
</tr>
</tbody>
</table>
## VSS Backup Completion Metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VSSBackupCompleted</td>
<td>The number of instances for which a VSS backup was successfully completed. The metric is emitted even if the VSS backup completes outside of the timeout period.</td>
</tr>
<tr>
<td></td>
<td>If script retries are enabled, this metric can be emitted multiple times per policy run.</td>
</tr>
<tr>
<td>VSSBackupFailed</td>
<td>The number of instances for which a VSS backup failed to complete successfully. The metric is emitted even if the VSS backup completes outside of the timeout period.</td>
</tr>
<tr>
<td></td>
<td>If script retries are enabled, this metric can be emitted multiple times per policy run.</td>
</tr>
</tbody>
</table>

## EBS-backed AMI Policies Metrics

The following metrics can be used with EBS-backed AMI policies:

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourcesTargeted</td>
<td>The number of resources targeted by the tags specified in a snapshot or EBS-backed AMI policy.</td>
</tr>
<tr>
<td>SnapshotsDeleteCompleted</td>
<td>The number of snapshots deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy. It does not apply to cross-Region snapshot copies created by the policy.</td>
</tr>
<tr>
<td></td>
<td>This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.</td>
</tr>
<tr>
<td>SnapshotsDeleteFailed</td>
<td>The number of snapshots that could not be deleted by a snapshot or EBS-backed AMI policy. This metric applies only to snapshots created by the policy. It does not apply to cross-Region snapshot copies created by the policy.</td>
</tr>
<tr>
<td></td>
<td>This metric includes snapshots that are deleted when an EBS-backed AMI policy deregisters AMIs.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegionDeleteCompleted</td>
<td>The number of cross-Region snapshot copies deleted, as designated by the retention rule, by a snapshot policy.</td>
</tr>
<tr>
<td>SnapshotsCopiedRegionDeleteFailed</td>
<td>The number of cross-Region snapshot copies that could not be deleted, as designated by the retention rule, by a snapshot policy.</td>
</tr>
<tr>
<td>ImagesCreateStarted</td>
<td>The number of <code>CreateImage</code> actions initiated by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesCreateCompleted</td>
<td>The number of AMIs created by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesCreateFailed</td>
<td>The number of AMIs that could not be created by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesDeregisterCompleted</td>
<td>The number of AMIs deregistered by an EBS-backed AMI policy.</td>
</tr>
<tr>
<td>ImagesDeregisterFailed</td>
<td>The number of AMIs that could not be deregistered by an EBS-backed AMI policy.</td>
</tr>
</tbody>
</table>
### Cross-account copy event policies

The following metrics can be used with cross-account copy event policies:

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SnapshotsCopiedAccountStarted</td>
<td>The number of cross-account snapshot copy actions initiated by a cross-account copy event policy.</td>
</tr>
<tr>
<td>SnapshotsCopiedAccountCompleted</td>
<td>The number of snapshots copied from another account by a cross-account copy event policy. This includes successful retries within 24 hours of the scheduled time.</td>
</tr>
<tr>
<td>SnapshotsCopiedAccountFailed</td>
<td>The number of snapshots that could not be copied from another account by a cross-account copy event policy. This includes unsuccessful retries within 24 hours of the scheduled time.</td>
</tr>
<tr>
<td>SnapshotsCopiedAccountDeleteCompleted</td>
<td>The number of cross-Region snapshot copies deleted, as designated by the retention rule, by a cross-account copy event policy.</td>
</tr>
<tr>
<td>SnapshotsCopiedAccountDeleteFailed</td>
<td>The number of cross-Region snapshot copies that could not be deleted, as designated by the retention rule, by a cross-account copy event policy.</td>
</tr>
</tbody>
</table>

### View CloudWatch metrics for your policies

You can use the AWS Management Console or the command line tools to list the metrics that Amazon Data Lifecycle Manager sends to Amazon CloudWatch.
Amazon EC2 console

**To view metrics using the Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Lifecycle Manager.
3. Select a policy in the grid and then choose the Monitoring tab.

CloudWatch console

**To view metrics using the Amazon CloudWatch console**

2. In the navigation pane, choose Metrics.
3. Select the EBS namespace and then select Data Lifecycle Manager metrics.

AWS CLI

**To list all the available metrics for Amazon Data Lifecycle Manager**

Use the `list-metrics` command.

```
$ aws cloudwatch list-metrics --namespace AWS/EBS
```

**To list all the metrics for a specific policy**

Use the `list-metrics` command and specify the DLMPolicyId dimension.

```
$ aws cloudwatch list-metrics --namespace AWS/EBS --dimensions Name=DLMPolicyId,Value=policy-abcdef01234567890
```

**To list a single metric across all policies**

Use the `list-metrics` command and specify the `--metric-name` option.

```
$ aws cloudwatch list-metrics --namespace AWS/EBS --metric-name SnapshotsCreateCompleted
```

**Graph metrics for your policies**

After you create a policy, you can open the Amazon EC2 console and view the monitoring graphs for the policy on the Monitoring tab. Each graph is based on one of the available Amazon EC2 metrics.

The following graphs metrics are available:

- Resources targeted (based on ResourcesTargeted)
- Snapshot creation started (based on SnapshotsCreateStarted)
- Snapshot creation completed (based on SnapshotsCreateCompleted)
- Snapshot creation failed (based on SnapshotsCreateFailed)
- Snapshot sharing completed (based on SnapshotsSharedCompleted)
- Snapshot deletion completed (based on SnapshotsDeleteCompleted)
Create a CloudWatch alarm for a policy

You can create a CloudWatch alarm that monitors CloudWatch metrics for your policies. CloudWatch will automatically send you a notification when the metric reaches a threshold that you specify. You can create a CloudWatch alarm using the CloudWatch console.

For more information about creating alarms using the CloudWatch console, see the following topic in the Amazon CloudWatch User Guide.

- Create a CloudWatch Alarm Based on a Static Threshold
- Create a CloudWatch Alarm Based on Anomaly Detection

Example use cases

The following are example use cases.

Topics

- Example 1: ResourcesTargeted metric (p. 2302)
Example 1: ResourcesTargeted metric

You can use the `ResourcesTargeted` metric to monitor the total number of resources that are targeted by a specific policy each time it is run. This enables you to trigger an alarm when the number of targeted resources is below or above an expected threshold.

For example, if you expect your daily policy to create backups of no more than 50 volumes, you can create an alarm that sends an email notification when the sum for `ResourcesTargeted` is greater than 50 over a 1 hour period. In this way, you can ensure that no snapshots have been unexpectedly created from volumes that have been incorrectly tagged.

You can use the following command to create this alarm:

```
$ aws cloudwatch put-metric-alarm \
  --alarm-name resource-targeted-monitor \
  --alarm-description "Alarm when policy targets more than 50 resources" \
  --metric-name ResourcesTargeted \
  --namespace AWS/EBS \
  --statistic Sum \
  --period 3600 \
  --threshold 50 \
  --comparison-operator GreaterThanThreshold \
  --dimensions "Name=DLMPolicyId,Value=policy_id" \
  --evaluation-periods 1 \
  --alarm-actions sns_topic_arn
```

Example 2: SnapshotDeleteFailed metric

You can use the `SnapshotDeleteFailed` metric to monitor for failures to delete snapshots as per the policy's snapshot retention rule.

For example, if you've created a policy that should automatically delete snapshots every twelve hours, you can create an alarm that notifies your engineering team when the sum of `SnapshotDeleteFailed` is greater than 0 over a 1 hour period. This could help to investigate improper snapshot retention and to ensure that your storage costs are not increased by unnecessary snapshots.

You can use the following command to create this alarm:

```
$ aws cloudwatch put-metric-alarm \
  --alarm-name snapshot-deletion-failed-monitor \
  --alarm-description "Alarm when snapshot deletions fail" \
  --metric-name SnapshotsDeleteFailed \
  --namespace AWS/EBS \
  --statistic Sum \
  --period 3600 \
  --threshold 0 \
  --comparison-operator GreaterThanThreshold \
  --dimensions "Name=DLMPolicyId,Value=policy_id" \
  --evaluation-periods 1 \
  --alarm-actions sns_topic_arn
```

Example 3: SnapshotsCopiedRegionFailed metric

Use the `SnapshotsCopiedRegionFailed` metric to identify when your policies fail to copy snapshots to other Regions.
For example, if your policy copies snapshots across Regions daily, you can create an alarm that sends an SMS to your engineering team when the sum of `SnapshotCrossRegionCopyFailed` is greater than 0 over a 1 hour period. This can be useful for verifying whether subsequent snapshots in the lineage were successfully copied by the policy.

You can use the following command to create this alarm:

```
$ aws cloudwatch put-metric-alarm
  --alarm-name snapshot-copy-region-failed-monitor
  --alarm-description "Alarm when snapshot copy fails"
  --metric-name SnapshotsCopiedRegionFailed
  --namespace AWS/EBS
  --statistic Sum
  --period 3600
  --threshold 0
  --comparison-operator GreaterThanThreshold
  --dimensions "Name=DLMPolicyId,Value=policy_id"
  --evaluation-periods 1
  --alarm-actions sns_topic_arn
```

Managing policies that report failed actions

For more information about what to do when one of your policies reports an unexpected non-zero value for a failed action metric, see the What should I do if Amazon Data Lifecycle Manager reports failed actions in CloudWatch metrics? AWS Knowledge Center article.

Troubleshooting

The following documentation can help you troubleshoot problems that you might encounter.

Topics

- Error: Role with name already exists (p. 2303)

Error: Role with name already exists

Description

You get the Role with name `AWSDataLifecycleManagerDefaultRole` already exists or Role with name `AWSDataLifecycleManagerDefaultRoleForAMIManagement` already exists error when you try to create a policy using the console.

Cause

The ARN format of the default role differs depending on whether it was created using the console or the AWS CLI. While the ARNs are different, the roles use the same role name, which results in a role naming conflict between the console and the AWS CLI.

Solution

To resolve this issue, do the following:

1. *(For snapshot policies enabled for pre and post scripts only)* Manually attach the `AWSDataLifecycleManagerSSMFullAccess` AWS managed policy to the `AWSDataLifecycleManagerDefaultRole` IAM role. For more information, see Adding IAM identity permissions.

2. When creating your Amazon Data Lifecycle Manager policy, for IAM role, select Choose another role, and then select either `AWSDataLifecycleManagerDefaultRole` (for a snapshot policy), or `AWSDataLifecycleManagerDefaultRoleForAMIManagement` (for an AMI policy).

3. Continue to create the policy as usual.
Amazon EBS provides the following data services.

**Data services**
- Amazon EBS Elastic Volumes (p. 2304)
- Amazon EBS encryption (p. 2316)
- Amazon EBS fast snapshot restore (p. 2329)

**Amazon EBS Elastic Volumes**

With Amazon EBS Elastic Volumes, you can increase the volume size, change the volume type, or adjust the performance of your EBS volumes. If your instance supports Elastic Volumes, you can do so without detaching the volume or restarting the instance. This enables you to continue using your application while the changes take effect.

There is no charge to modify the configuration of a volume. You are charged for the new volume configuration after volume modification starts. For more information, see the Amazon EBS Pricing page.

**Contents**
- Requirements when modifying volumes (p. 2304)
- Request modifications to your EBS volumes (p. 2306)
- Monitor the progress of volume modifications (p. 2309)
- Extend a Linux file system after resizing a volume (p. 2312)

**Requirements when modifying volumes**

The following requirements and limitations apply when you modify an Amazon EBS volume. To learn more about the general requirements for EBS volumes, see Constraints on the size and configuration of an EBS volume (p. 2070).

**Topics**
- Supported instance types (p. 2304)
- Requirements for Linux volumes (p. 2304)
- Limitations (p. 2305)

**Supported instance types**

Elastic Volumes are supported on the following instances:

- All current-generation instances (p. 287)
- The following previous-generation instances: C1, C3, C4, G2, I2, M1, M3, M4, R3, and R4

If your instance type does not support Elastic Volumes, see Modify an EBS volume if Elastic Volumes is not supported (p. 2309).

**Requirements for Linux volumes**

Linux AMIs require a GUID partition table (GPT) and GRUB 2 for boot volumes that are 2 TiB (2,048 GiB) or larger. Many Linux AMIs today still use the MBR partitioning scheme, which only supports boot volume sizes up to 2 TiB. If your instance does not boot with a boot volume larger than 2 TiB, the AMI you are using may be limited to a boot volume size of less than 2 TiB. Non-boot volumes do not have...
this limitation on Linux instances. For requirements affecting Windows volumes, see [Requirements for Windows volumes](https://docs.aws.amazon.com/AmazonEBS/latest/UserGuide/Windowsinstances-requirements.html) in the Amazon EC2 User Guide for Windows Instances.

Before attempting to resize a boot volume beyond 2 TiB, you can determine whether the volume is using MBR or GPT partitioning by running the following command on your instance:

```
[ec2-user ~]$ sudo gdisk -l /dev/xvda
```

An Amazon Linux instance with GPT partitioning returns the following information:

```
GPT fdisk (gdisk) version 0.8.10
Partition table scan:
  MBR: protective
  BSD: not present
  APM: not present
  GPT: present

Found valid GPT with protective MBR; using GPT.
```

A SUSE instance with MBR partitioning returns the following information:

```
GPT fdisk (gdisk) version 0.8.8
Partition table scan:
  MBR: MBR only
  BSD: not present
  APM: not present
  GPT: not present
```

**Limitations**

- There are limits to the maximum aggregated storage that can be requested across volume modifications. For more information, see [Amazon EBS service quotas](https://docs.aws.amazon.com/AmazonEBS/latest/UserGuide/service-quotas.html) in the Amazon Web Services General Reference.

- After modifying a volume, you must wait at least **six hours** and ensure that the volume is in the in-use or available state before you can modify the same volume.

- Modifying an EBS volume can take from a few minutes to a few hours, depending on the configuration changes being applied. An EBS volume that is 1 TiB in size can typically take up to six hours to be modified. However, the same volume could take 24 hours or longer in other situations. The time it takes for volumes to be modified doesn't always scale linearly. Therefore, a larger volume might take less time, and a smaller volume might take more time.

- If the volume was attached before November 3, 2016 23:40 UTC, you must initialize Elastic Volumes support. For more information, see [Initializing Elastic Volumes Support](https://docs.aws.amazon.com/AmazonEBS/latest/UserGuide/elastic-volumes-support.html) (p. 2308).

- If you encounter an error message while attempting to modify an EBS volume, or if you are modifying an EBS volume attached to a previous-generation instance type, take one of the following steps:
  - For a non-root volume, detach the volume from the instance, apply the modifications, and then re-attach the volume.
  - For a root volume, stop the instance, apply the modifications, and then restart the instance.
  - Modification time is increased for volumes that are not fully initialized. For more information see [Initialize Amazon EBS volumes](https://docs.aws.amazon.com/AmazonEBS/latest/UserGuide/initialize-ebs-volumes.html) (p. 2379).

- The new volume size can't exceed the supported capacity of its file system and partitioning scheme. For more information, see [Constraints on the size and configuration of an EBS volume](https://docs.aws.amazon.com/AmazonEBS/latest/UserGuide/ebs-volume-size.html) (p. 2070).

- If you modify the volume type of a volume, the size and performance must be within the limits of the target volume type. For more information, see [Amazon EBS volume types](https://docs.aws.amazon.com/AmazonEBS/latest/UserGuide/volume-types.html) (p. 2055).
• You can't decrease the size of an EBS volume. However, you can create a smaller volume and then migrate your data to it using an application-level tool such as rsync.
• After provisioning over 32,000 IOPS on an existing io1 or io2 volume, you might need to detach and re-attach the volume, or restart the instance to see the full performance improvements.
• Io2 volumes attached to instances built on the Nitro System (p. 295) support sizes up to 64 TiB and IOPS up to 256,000 IOPS. Io2 volumes attached to other instances support sizes up to 16 TiB and IOPS up to 64,000, but can achieve performance up to 32,000 IOPS only.
• You can't modify the volume type of Multi-Attach enabled io2 volumes.
• You can't modify the volume type, size, or Provisioned IOPS of Multi-Attach enabled io1 volumes.
• A root volume of type io1, io2, gp2, gp3, or standard can't be modified to an st1 or sc1 volume, even if it is detached from the instance.
• While m3.medium instances fully support volume modification, m3.large, m3.xlarge, and m3.2xlarge instances might not support all volume modification features.

Request modifications to your EBS volumes

With Elastic Volumes, you can dynamically increase the size, increase or decrease the performance, and change the volume type of your Amazon EBS volumes without detaching them.

Use the following process when modifying a volume:

1. (Optional) Before modifying a volume that contains valuable data, it is a best practice to create a snapshot of the volume in case you need to roll back your changes. For more information, see Create Amazon EBS snapshots (p. 2112).
2. Request the volume modification.
3. Monitor the progress of the volume modification. For more information, see Monitor the progress of volume modifications (p. 2309).
4. If the size of the volume was modified, extend the volume's file system to take advantage of the increased storage capacity. For more information, see Extend a Linux file system after resizing a volume (p. 2312).

Contents

• Modify an EBS volume using Elastic Volumes (p. 2306)
• Initialize Elastic Volumes support (if needed) (p. 2308)
• Modify an EBS volume if Elastic Volumes is not supported (p. 2309)

Modify an EBS volume using Elastic Volumes

Considerations

Keep the following in mind when modifying volumes:

• After modifying a volume, you must wait at least six hours and ensure that the volume is in the in-use or available state before you can modify the same volume.
• Modifying an EBS volume can take from a few minutes to a few hours, depending on the configuration changes being applied. An EBS volume that is 1 TiB in size can typically take up to six hours to be modified. However, the same volume could take 24 hours or longer in other situations. The time it takes for volumes to be modified doesn't always scale linearly. Therefore, a larger volume might take less time, and a smaller volume might take more time.
• You can't cancel a volume modification request after it has been submitted.
• You can only increase volume size. You can't decrease volume size.
- You can increase or decrease volume performance.
- If you are not changing the volume type, then volume size and performance modifications must be within the limits of the current volume type. If you are changing the volume type, then volume size and performance modifications must be within the limits of the target volume type.
- If you change the volume type from gp2 to gp3, and you do not specify IOPS or throughput performance, Amazon EBS automatically provisions either equivalent performance to that of the source gp2 volume, or the baseline gp3 performance, whichever is higher.

For example, if you modify a 500 GiB gp2 volume with 250 MiB/s throughput and 1500 IOPS to gp3 without specifying IOPS or throughput performance, Amazon EBS automatically provisions the gp3 volume with 3000 IOPS (baseline gp3 IOPS) and 250 MiB/s (to match the source gp2 volume throughput).

To modify an EBS volume, use one of the following methods.

**Console**

**To modify an EBS volume using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose *Volumes*.
3. Select the volume to modify and choose *Actions, Modify volume*.
4. The *Modify volume* screen displays the volume ID and the volume's current configuration, including type, size, IOPS, and throughput. Set new configuration values as follows:
   - To modify the type, choose a value for *Volume type*.
   - To modify the size, enter a new value for *Size*.
   - (gp3, io1, and io2 only) To modify the IOPS, enter a new value for *IOPS*.
   - (gp3 only) To modify the throughput, enter a new value for *Throughput*.
5. After you have finished changing the volume settings, choose *Modify*. When prompted for confirmation, choose *Modify*.
6. **Important**
   - If you've increased the size of your volume, then you must also extend the volume's partition to make use of the additional storage capacity. For more information, see [Extend a Linux file system after resizing a volume](p. 2312).

**AWS CLI**

**To modify an EBS volume using the AWS CLI**

Use the `modify-volume` command to modify one or more configuration settings for a volume. For example, if you have a volume of type gp2 with a size of 100 GiB, the following command changes its configuration to a volume of type io1 with 10,000 IOPS and a size of 200 GiB.

```bash
aws ec2 modify-volume --volume-type io1 --iops 10000 --size 200 --volume-id vol-1111111111111111
```

The following is example output:

```json
{
    "VolumeModification": {
        "TargetSize": 200,
        "TargetVolumeType": "io1",
        "ModificationState": "modifying",
```
Important
If you've increased the size of your volume, then you must also extend the volume's partition to make use of the additional storage capacity. For more information, see Extend a Linux file system after resizing a volume (p. 2312).

Initialize Elastic Volumes support (if needed)

Before you can modify a volume that was attached to an instance before November 3, 2016 23:40 UTC, you must initialize volume modification support using one of the following actions:

- Detach and attach the volume
- Stop and start the instance

Use one of the following procedures to determine whether your instances are ready for volume modification.

Console

To determine whether your instances are ready using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the navigation pane, choose Instances.
3. Choose the Show/Hide Columns icon (the gear). Select the Launch time attribute column and then choose Confirm.
4. Sort the list of instances by the Launch Time column. For each instance that was started before the cutoff date, choose the Storage tab and check the Attachment time column to see when its volumes were attached.

AWS CLI

To determine whether your instances are ready using the CLI

Use the following describe-instances command to determine whether the volume was attached before November 3, 2016 23:40 UTC.

```bash
aws ec2 describe-instances --query "Reservations[*].Instances[*].[InstanceId,LaunchTime<='2016-11-01',BlockDeviceMappings[*][Ebs.AttachTime<='2016-11-01']]
```

The first line of the output for each instance shows its ID and whether it was started before the cutoff date (True or False). The first line is followed by one or more lines that show whether each EBS volume was attached before the cutoff date (True or False). In the following example output, you must initialize volume modification for the first instance because it was started before the cutoff date and its root volume was attached before the cutoff date. The other instances are ready because they were started after the cutoff date.
Modify an EBS volume if Elastic Volumes is not supported

If you are using a supported instance type, you can use Elastic Volumes to dynamically modify the size, performance, and volume type of your Amazon EBS volumes without detaching them.

If you cannot use Elastic Volumes but you need to modify the root (boot) volume, you must stop the instance, modify the volume, and then restart the instance.

After the instance has started, you can check the file system size to see if your instance recognizes the larger volume space. On Linux, use the `df -h` command to check the file system size.

```
[ec2-user ~]$ df -h
Filesystem            Size  Used Avail Use% Mounted on
/dev/xvda1            7.9G  943M  6.9G  12% /
tmpfs                 1.9G     0  1.9G   0% /dev/shm
```

If the size does not reflect your newly expanded volume, you must extend the file system of your device so that your instance can use the new space. For more information, see Extend a Linux file system after resizing a volume (p. 2312).

Monitor the progress of volume modifications

When you modify an EBS volume, it goes through a sequence of states. The volume enters the modifying state, the optimizing state, and finally the completed state. At this point, the volume is ready to be further modified.

**Note**

Rarely, a transient AWS fault can result in a failed state. This is not an indication of volume health; it merely indicates that the modification to the volume failed. If this occurs, retry the volume modification.

While the volume is in the optimizing state, your volume performance is in between the source and target configuration specifications. Transitional volume performance will be no less than the source volume performance. If you are downgrading IOPS, transitional volume performance is no less than the target volume performance.

Volume modification changes take effect as follows:

- Size changes usually take a few seconds to complete and take effect after the volume has transitioned to the Optimizing state.
- Performance (IOPS) changes can take from a few minutes to a few hours to complete and are dependent on the configuration change being made.
- In some cases, it can take more than 24 hours for a new configuration to take effect, such as when the volume has not been fully initialized. Typically, a fully used 1-TiB volume takes about 6 hours to migrate to a new performance configuration.

To monitor the progress of a volume modification, use one of the following methods.
To monitor progress of a modification using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Volumes.
3. Select the volume.
4. The Volume state column and the Volume state field in the Details tab contain information in the following format: Volume state - Modification state (Modification progress %). The following image shows the volume and volume modification states.

The possible volume states are creating, available, in-use, deleting, deleted, and error.

The possible modification states are modifying, optimizing, and completed.

After the modification completes, only the volume state is displayed. The modification state and progress are no longer displayed.

AWS CLI

To monitor progress of a modification using the AWS CLI

Use the describe-volumes-modifications command to view the progress of one or more volume modifications. The following example describes the volume modifications for two volumes.

```
aws ec2 describe-volumes-modifications --volume-ids vol-11111111111111111 vol-22222222222222222
```

In the following example output, the volume modifications are still in the modifying state. Progress is reported as a percentage.

```
{
   "VolumesModifications": [ 
   {
      "TargetSize": 200,
      "TargetVolumeType": "io1",
      "ModificationState": "modifying",
      "VolumeId": "vol-11111111111111111",
      "TargetIops": 100000,
      "StartTime": "2017-01-19T22:21:02.959Z",
      "Progress": 0,
      "OriginalVolumeType": "gp2",
      "OriginalIops": 300,
      "OriginalSize": 100
   },
   {
      "TargetSize": 2000,
      "TargetVolumeType": "sc1",
      "ModificationState": "modifying",
      "VolumeId": "vol-22222222222222222"
   }
   
```
The next example describes all volumes with a modification state of either optimizing or completed, and then filters and formats the results to show only modifications that were initiated on or after February 1, 2017:

```bash
aws ec2 describe-volumes-modifications --filters Name=modification-state,Values="optimizing","completed" --query "VolumesModifications[?StartTime>='2017-02-01'].{ID:VolumeId,STATE:ModificationState}"
```

The following is example output with information about two volumes:

```json
[
  {
    "STATE": "optimizing",
    "ID": "vol-06397e7a0EXAMPLE"
  },
  {
    "STATE": "completed",
    "ID": "vol-ba74e18c2aEXAMPLE"
  }
]
```

CloudWatch Events console

With CloudWatch Events, you can create a notification rule for volume modification events. You can use your rule to generate a notification message using Amazon SNS or to invoke a Lambda function in response to matching events. Events are emitted on a best effort basis.

**To monitor progress of a modification using CloudWatch Events**

2. Choose **Events, Create rule**.
3. For **Build event pattern to match events by service**, choose **Custom event pattern**.
4. For **Build custom event pattern**, replace the contents with the following and choose **Save**.

```json
{
  "source": ["aws.ec2"],
  "detail-type": ["EBS Volume Notification"],
  "detail": {
    "event": ["modifyVolume"
  ]
}
}
```

The following is example event data:

```
2311
```
Extend a Linux file system after resizing a volume

Note
The following topic walks you through the process of extending XFS and Ext4 file systems for Linux. For information about other file systems, see their documentation for instructions.

After you increase the size of an EBS volume (p. 2306), you must use file system–specific commands to extend the file system to the new, larger size. You can do this as soon as the volume enters the optimizing state.

To extend a file system on Linux, you need to:

1. Extend the partition, if your volume has one.
2. Extend the file system.

Before you begin

• Create a snapshot of the volume, in case you need to roll back your changes. For more information, see Create Amazon EBS snapshots (p. 2112).
• Confirm that the volume modification succeeded and that it is in the optimizing or completed state. For more information, see Monitor the progress of volume modifications (p. 2309).
• Ensure that the volume is attached to the instance and that it is formatted and mounted. For more information, see Format and mount an attached volume (p. 2084).
• If you are using logical volumes on the Amazon EBS volume, you must use Logical Volume Manager (LVM) to extend the logical volume. For instructions about how to do this, see the Extend the logical volume section in the How do I create an LVM logical volume on an entire EBS volume? AWS Knowledge Center article.

Extend the file system of EBS volumes

Use the following procedure to extend the file system for a resized volume.

Note that device and partition naming differs for Xen instances and Nitro instances (p. 295). To determine whether your instance is Xen-based or Nitro-based, use the describe-instance-types AWS CLI command as follows:
nitro indicates that your instance in Nitro-based. xen or xen-on-nitro indicates that your instance is Xen-based.

**To extend the file system of EBS volumes**

1. Connect to your instance (p. 811).
2. Resize the partition, if needed. To do so:
   a. Check whether the volume has a partition. Use the `lsblk` command.

   **Nitro instance example**

   In the following example output, the root volume (nvme0n1) has two partitions (nvme0n1p1 and nvme0n1p128), while the additional volume (nvme0n1) has no partitions.

   ```bash
   [ec2-user ~]$: sudo lsblk
   NAME     MAJ:MIN  RM  SIZE     RO TYPE MOUNTPOINT
   nvme0n1   259:0    0   30G  0   disk /data
   nvme0n1   259:1    0   16G  0   disk
   ##nvme0n1p1 259:2    0   8G  0   part /
   ##nvme0n1p128 259:3    0   1M  0   part
   ```

   **Xen instance example**

   In the following example output, the root volume (xvda) has a partition (xvda1), while the additional volume (xvdf) has no partition.

   ```bash
   [ec2-user ~]$: sudo lsblk
   NAME   MAJ:MIN RM SIZE      RO TYPE MOUNTPOINT
   xvda   202:0    0   16G       0 disk
   ##xvda1 202:1    0   8G       0 part /
   xvdf   202:80   0   24G      0 disk
   ```

   If the volume has a partition, continue the procedure from the following step (2b). If the volume has no partitions, skip steps 2b, 2c, and 2d, and continue the procedure from step 3.

   **Troubleshooting tip**
   If you do not see the volume in the command output, ensure that the volume is attached to the instance (p. 2076), and that it is formatted and mounted (p. 2084).

   b. Check whether the partition needs to be extended. In the `lsblk` command output from the previous step, compare the partition size and the volume size.

   If the partition size is smaller than the volume size, continue to the next step. If the partition size is equal to the volume size, the partition can't be extended.

   **Troubleshooting tip**
   If the volume still reflects the original size, confirm that the volume modification succeeded (p. 2309).

   c. Extend the partition. Use the `growpart` command and specify the partition to extend.

   **Nitro instance example**

   For example, to extend a partition named nvme0n1p1, use the following command.
Important
Note the space between the device name (nvme0n1) and the partition number (1).

[ec2-user ~]$ sudo growpart /dev/nvme0n1 1

Xen instance example
For example, to extend a partition named xvda1, use the following command.

Important
Note the space between the device name (xvda) and the partition number (1).

[ec2-user ~]$ sudo growpart /dev/xvda 1

Troubleshooting tips

- mkdir: cannot create directory ‘/tmp/growpart.31171’: No space left on device FAILED: failed to make temp dir: Indicates that there is not enough free disk space on the volume for growpart to create the temporary directory it needs to perform the resize. Free up some disk space and then try again.

- must supply partition-number: Indicates that you specified an incorrect partition. Use the lsblk command to confirm the partition name, and ensure that you enter a space between the device name and the partition number.

- NOCHANGE: partition 1 is size 16773087. it cannot be grown: Indicates that the partition already extends the entire volume and can't be extended. Confirm that the volume modification succeeded (p. 2309).

d. Verify that the partition has been extended. Use the lsblk command. The partition size should now be equal to the volume size.

Nitro instance example
The following example output shows that both the volume (nvme0n1) and the partition (nvme0n1p1) are the same size (16 GB).

[ec2-user ~]$ sudo lsblk
NAME    MAJ:MIN RM SIZE RO TYPE MOUNTPOINT
nvme1n1 259:0    0  30G  0 disk /data
nvme0n1 259:1    0  16G  0 disk
##nvme0n1p1259:2    0  16G  0 part /
##nvme0n1p1259:3    0  1G  0 part /

Xen instance example
The following example output shows that both the volume (xvda) and the partition (xvda1) are the same size (16 GB).

[ec2-user ~]$ sudo lsblk
NAME   MAJ:MIN RM SIZE RO TYPE MOUNTPOINT
xvda   202:0    0  16G  0 disk
##xvda1 202:1    0  16G  0 part /
xvdf   202:80   0  24G  0 disk

3. Extend the file system.

a. Get the name, size, type, and mount point for the file system that you need to extend. Use the df -hT command.
Nitro instance example

The following example output shows that the /dev/nvme0n1p1 file system is 8 GB in size, its type is xfs, and its mount point is /

```
[ec2-user ~]$ df -hT
Filesystem     Type       Size  Used  Avail  Use%  Mounted on
/dev/nvme0n1p1  xfs      8.0G  1.6G  6.5G   20%  /
/dev/nvme1n1   xfs      8.0G   33M  8.0G    1%  /data
...  
```

Xen instance example

The following example output shows that the /dev/xvda1 file system is 8 GB in size, its type is ext4, and its mount point is /

```
[ec2-user ~]$ df -hT
Filesystem  Type   Size  Used  Avail  Use%  Mounted on
/dev/xvda1  ext4   8.0G  1.9G  6.2G   24%  /
/dev/xvdf1  xfs    24.0G 45M   8.0G   1%  /data
...  
```

b. The commands to extend the file system differ depending on the file system type. Choose the following correct command based on the file system type that you noted in the previous step.

- **[XFS file system]** Use the `xfs_growfs` command and specify the mount point of the file system that you noted in the previous step.

Nitro and Xen instance example

For example, to extend a file system mounted on /, use the following command.

```
[ec2-user ~]$ sudo xfs_growfs -d /
```

**Troubleshooting tips**

- `xfs_growfs: /data is not a mounted XFS filesystem`: Indicates that you specified the incorrect mount point, or the file system is not XFS. To verify the mount point and file system type, use the `df -hT` command.

- `data size unchanged, skipping`: Indicates that the file system already extends the entire volume. If the volume has no partitions, **confirm that the volume modification succeeded (p. 2309)**. If the volume has partitions, ensure that the partition was extended as described in step 2.

- **[Ext4 file system]** Use the `resize2fs` command and specify the name of the file system that you noted in the previous step.

Nitro instance example

For example, to extend a file system mounted named /dev/nvme0n1p1, use the following command.

```
[ec2-user ~]$ sudo resize2fs /dev/nvme0n1p1
```

Xen instance example

For example, to extend a file system mounted named /dev/xvda1, use the following command.

```
[ec2-user ~]$ sudo resize2fs /dev/xvda1
```
Troubleshooting tips

- `resize2fs`: Bad magic number in super-block while trying to open `/dev/xvda1`: Indicates that the file system is not Ext4. To verify the file system type, use the `df -hT` command.

- `open`: No such file or directory while opening `/dev/xvdb1`: Indicates that you specified an incorrect partition. To verify the partition, use the `df -hT` command.

- The filesystem is already 3932160 blocks long. Nothing to do!: Indicates that the file system already extends the entire volume. If the volume has no partitions, confirm that the volume modification succeeded (p. 2309). If the volume has partitions, ensure that the partition was extended, as described in step 2.

- [Other file system] See the documentation for your file system for instructions.

c. Verify that the file system has been extended. Use the `df -hT` command and confirm that the file system size is equal to the volume size.

Amazon EBS encryption

Use Amazon EBS encryption as a straight-forward encryption solution for your EBS resources associated with your EC2 instances. With Amazon EBS encryption, you aren't required to build, maintain, and secure your own key management infrastructure. Amazon EBS encryption uses AWS KMS keys when creating encrypted volumes and snapshots.

Encryption operations occur on the servers that host EC2 instances, ensuring the security of both data-at-rest and data-in-transit between an instance and its attached EBS storage.

You can attach both encrypted and unencrypted volumes to an instance simultaneously.

Contents

- How EBS encryption works (p. 2316)
- Requirements (p. 2318)
- Default KMS key for EBS encryption (p. 2319)
- Encryption by default (p. 2320)
- Encrypt EBS resources (p. 2322)
- Rotating AWS KMS keys (p. 2323)
- Encryption scenarios (p. 2324)
- Set encryption defaults using the API and CLI (p. 2329)

How EBS encryption works

You can encrypt both the boot and data volumes of an EC2 instance.

When you create an encrypted EBS volume and attach it to a supported instance type, the following types of data are encrypted:

- Data at rest inside the volume
- All data moving between the volume and the instance
Amazon Elastic Compute Cloud  
User Guide for Linux Instances  
EBS data services

- All snapshots created from the volume  
- All volumes created from those snapshots

Amazon EBS encrypts your volume with a data key using industry-standard AES-256 data encryption. The data key is generated by AWS KMS and then encrypted by AWS KMS with your AWS KMS key prior to being stored with your volume information. All snapshots, and any subsequent volumes created from those snapshots using the same AWS KMS key share the same data key. For more information, see Data keys in the AWS Key Management Service Developer Guide.

When a KMS key becomes unusable, the effect is almost immediate (subject to eventual consistency). The key state of the KMS key changes to reflect its new condition, and all requests to use the KMS key in cryptographic operations fail. For more information, see How unusable KMS keys affect data keys in the AWS Key Management Service Developer Guide.

Amazon EC2 works with AWS KMS to encrypt and decrypt your EBS volumes in slightly different ways depending on whether the snapshot from which you create an encrypted volume is encrypted or unencrypted.

**How EBS encryption works when the snapshot is encrypted**

When you create an encrypted volume from an encrypted snapshot that you own, Amazon EC2 works with AWS KMS to encrypt and decrypt your EBS volumes as follows:

1. Amazon EC2 sends a GenerateDataKeyWithoutPlaintext request to AWS KMS, specifying the KMS key that you chose for volume encryption.
2. If the volume is encrypted using the same KMS key as the snapshot, AWS KMS uses the same data key as the snapshot and encrypts it under that same KMS key. If the volume is encrypted using a different KMS key, AWS KMS generates a new data key and encrypts it under the KMS key that you specified. The encrypted data key is sent to Amazon EBS to be stored with the volume metadata.
3. When you attach the encrypted volume to an instance, Amazon EC2 sends a CreateGrant request to AWS KMS so that it can decrypt the data key.
4. AWS KMS decrypts the encrypted data key and sends the decrypted data key to Amazon EC2.
5. Amazon EC2 uses the plaintext data key in the Nitro hardware to encrypt disk I/O to the volume. The plaintext data key persists in memory as long as the volume is attached to the instance.

**How EBS encryption works when the snapshot is unencrypted**

When you create an encrypted volume from unencrypted snapshot, Amazon EC2 works with AWS KMS to encrypt and decrypt your EBS volumes as follows:

1. Amazon EC2 sends a CreateGrant request to AWS KMS, so that it can encrypt the volume that is created from the snapshot.
2. Amazon EC2 sends a GenerateDataKeyWithoutPlaintext request to AWS KMS, specifying the KMS key that you chose for volume encryption.
3. AWS KMS generates a new data key, encrypts it under the KMS key that you chose for volume encryption, and sends the encrypted data key to Amazon EBS to be stored with the volume metadata.
4. Amazon EC2 sends a Decrypt request to AWS KMS to get the encryption key to encrypt the volume data.
5. When you attach the encrypted volume to an instance, Amazon EC2 sends a CreateGrant request to AWS KMS, so that it can decrypt the data key.
6. When you attach the encrypted volume to an instance, Amazon EC2 sends a Decrypt request to AWS KMS, specifying the encrypted data key.
7. AWS KMS decrypts the encrypted data key and sends the decrypted data key to Amazon EC2.
8. Amazon EC2 uses the plaintext data key in the Nitro hardware to encrypt disk I/O to the volume. The plaintext data key persists in memory as long as the volume is attached to the instance.

For more information, see How Amazon Elastic Block Store (Amazon EBS) uses AWS KMS and Amazon EC2 example two in the AWS Key Management Service Developer Guide.

Requirements

Before you begin, verify that the following requirements are met.

Supported volume types

Encryption is supported by all EBS volume types. You can expect the same IOPS performance on encrypted volumes as on unencrypted volumes, with a minimal effect on latency. You can access encrypted volumes the same way that you access unencrypted volumes. Encryption and decryption are handled transparently, and they require no additional action from you or your applications.

Supported instance types

Amazon EBS encryption is available on all current generation (p. 287) and previous generation (p. 294) instance types.

Permissions for users

When you configure a KMS key as the default key for EBS encryption, the default KMS key policy allows any user with access to the required KMS actions to use this KMS key to encrypt or decrypt EBS resources. You must grant users permission to call the following actions in order to use EBS encryption:

- kms:CreateGrant
- kms:Decrypt
- kms:DescribeKey
- kms:GenerateDataKeyWithoutPlainText
- kms:ReEncrypt

Tip

To follow the principle of least privilege, do not allow full access to kms:CreateGrant. Instead, use the kms:GrantIsForAWSResource condition key to allow the user to create grants on the KMS key only when the grant is created on the user's behalf by an AWS service, as shown in the following example.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "kms:CreateGrant",
      "Resource": [
        "arn:aws:kms:us-east-2:123456789012:key/abcd1234-a123-456d-a12b-a123b4cd56ef"
      ],
      "Condition": {
        "Bool": {
          "kms:GrantIsForAWSResource": true
        }
      }
    }
  ]
}
```
For more information, see Allows access to the AWS account and enables IAM policies in the Default key policy section in the AWS Key Management Service Developer Guide.

Permissions for instances

When an instance attempts to interact with an encrypted AMI, volume, or snapshot, a KMS key grant is issued to the instance's identity-only role. The identity-only role is an IAM role that is used by the instance to interact with encrypted AMIs, volumes, or snapshots on your behalf.

Identity-only roles do not need to be manually created or deleted, and they have no policies associated with them. Additionally, you can't access the identity-only role credentials.

Note

Identity-only roles are not used by applications on your instance to access other AWS KMS encrypted resources, such as Amazon S3 objects or DynamoDB tables. These operations are done using the credentials of an Amazon EC2 instance role, or other AWS credentials that you have configured on your instance.

Identity-only roles are subject to service control policies (SCPs), and KMS key policies. If an SCP or KMS key denies the identity-only role access to a KMS key, you may fail to launch EC2 instances with encrypted volumes, or using encrypted AMIs or snapshots.

If you are creating an SCP or key policy that denies access based on network location using the aws:SourceIp, aws:VpcSourceIp, aws:SourceVpc, or aws:SourceVpce AWS global condition keys, then you must ensure that these policy statements do not apply to instance-only roles. For example policies, see Data Perimeter Policy Examples.

Identity-only role ARNs use the following format:

```
arn:aws-partition:iam::account_id:role/aws:ec2-infrastructure/instance_id
```

When a key grant is issued to an instance, the key grant is issued to the assumed-role session specific to that instance. The grantee principal ARN uses the following format:

```
arn:aws-partition:sts::account_id:assumed-role/aws:ec2-infrastructure/instance_id
```

Default KMS key for EBS encryption

Amazon EBS automatically creates a unique AWS managed key in each Region where you store AWS resources. This KMS key has the alias alias/aws/ebs. By default, Amazon EBS uses this KMS key for encryption. Alternatively, you can specify a symmetric customer managed encryption key that you created as the default KMS key for EBS encryption. Using your own KMS key gives you more flexibility, including the ability to create, rotate, and disable KMS keys.

Important

Amazon EBS does not support asymmetric encryption KMS keys. For more information, see Using symmetric and asymmetric encryption KMS keys in the AWS Key Management Service Developer Guide.

New console

To configure the default KMS key for EBS encryption for a Region

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region.
3. From the navigation pane, select **EC2 Dashboard**.
4. In the upper-right corner of the page, choose **Account Attributes, Data protection and security**.
5. Choose **Manage**.
6. For **Default encryption key**, choose a symmetric customer managed encryption key.
7. Choose **Update EBS encryption**.

Old console

**To configure the default KMS key for EBS encryption for a Region**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. From the navigation bar, select the Region.
3. From the navigation pane, select **EC2 Dashboard**.
4. In the upper-right corner of the page, choose **Account Attributes, Settings**.
5. Choose **Change the default key** and then choose an available KMS key.
6. Choose **Save settings**.

**Encryption by default**

You can configure your AWS account to enforce the encryption of the new EBS volumes and snapshot copies that you create. For example, Amazon EBS encrypts the EBS volumes created when you launch an instance and the snapshots that you copy from an unencrypted snapshot. For examples of transitioning from unencrypted to encrypted EBS resources, see [Encrypt unencrypted resources (p. 2323)](#).

Encryption by default has no effect on existing EBS volumes or snapshots.

**Considerations**

- Encryption by default is a Region-specific setting. If you enable it for a Region, you cannot disable it for individual volumes or snapshots in that Region.
- Amazon EBS encryption by default is supported on all [current generation (p. 287)](#) and [previous generation (p. 294)](#) instance types.
- If you copy a snapshot and encrypt it to a new KMS key, a complete (non-incremental) copy is created. This results in additional storage costs.
- When migrating servers using AWS Server Migration Service (SMS), do not turn on encryption by default. If encryption by default is already on and you are experiencing delta replication failures, turn off encryption by default. Instead, enable AMI encryption when you create the replication job.

**Amazon EC2 console**

**To enable encryption by default for a Region**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. From the navigation bar, select the Region.
3. From the navigation pane, select **EC2 Dashboard**.
4. In the upper-right corner of the page, choose **Account Attributes, Data protection and security**.
5. Choose **Manage**.
6. Select **Enable**. You keep the AWS managed key with the alias alias/aws/ebs created on your behalf as the default encryption key, or choose a symmetric customer managed encryption key.
7. Choose **Update EBS encryption**.

**AWS CLI**

**To view the encryption by default setting**

- For a specific Region

  ```
  $ aws ec2 get-ebs-encryption-by-default --region region
  ```

- For all Regions in your account

  ```
  $ for region in $(aws ec2 describe-regions --region us-east-1 --query "Regions[*].[RegionName]" --output text); do   default=$(aws ec2 get-ebs-encryption-by-default --region $region --query "[Encryption_By_Default:EbsEncryptionByDefault]" --output text); kms_key=$(aws ec2 get-ebs-default-kms-key-id --region $region | jq '.KmsKeyId'); echo "$region  --- $default  --- $kms_key"; done
  ```

**To enable encryption by default**

- For a specific Region

  ```
  $ aws ec2 enable-ebs-encryption-by-default --region region
  ```

- For all Regions in your account

  ```
  $ for region in $(aws ec2 describe-regions --region us-east-1 --query "Regions[*].[RegionName]" --output text); do   default=$(aws ec2 enable-ebs-encryption-by-default --region $region --query "[Encryption_By_Default:EbsEncryptionByDefault]" --output text); kms_key=$(aws ec2 get-ebs-default-kms-key-id --region $region | jq '.KmsKeyId'); echo "$region  --- $default  --- $kms_key"; done
  ```

**To disable encryption by default**

- For a specific Region

  ```
  $ aws ec2 disable-ebs-encryption-by-default --region region
  ```

- For all Regions in your account

  ```
  $ for region in $(aws ec2 describe-regions --region us-east-1 --query "Regions[*].[RegionName]" --output text); do   default=$(aws ec2 disable-ebs-encryption-by-default --region $region --query "[Encryption_By_Default:EbsEncryptionByDefault]" --output text); kms_key=$(aws ec2 get-ebs-default-kms-key-id --region $region | jq '.KmsKeyId'); echo "$region  --- $default  --- $kms_key"; done
  ```

**PowerShell**

**To view the encryption by default setting**

- For a specific Region

  ```
  PS C:\> Get-EC2EbsEncryptionByDefault -Region region
  ```
### EBS data services

- For all Regions in your account

```
PS C:\> (Get-EC2Region).RegionName | ForEach-Object { [PSCustomObject]@{ Region = $_; EC2EbsEncryptionByDefault = Get-EC2EbsEncryptionByDefault -Region $_; EC2EbsDefaultKmsKeyId = Get-EC2EbsDefaultKmsKeyId -Region $_; } } | Format-Table -AutoSize
```

#### To enable encryption by default

- For a specific Region

```
PS C:\> Enable-EC2EbsEncryptionByDefault -Region region
```

- For all Regions in your account

```
PS C:\> (Get-EC2Region).RegionName | ForEach-Object { [PSCustomObject]@{ Region = $_; EC2EbsEncryptionByDefault = Enable-EC2EbsEncryptionByDefault -Region $_; EC2EbsDefaultKmsKeyId = Get-EC2EbsDefaultKmsKeyId -Region $_; } } | Format-Table -AutoSize
```

#### To disable encryption by default

- For a specific Region

```
PS C:\> Disable-EC2EbsEncryptionByDefault -Region region
```

- For all Regions in your account

```
PS C:\> (Get-EC2Region).RegionName | ForEach-Object { [PSCustomObject]@{ Region = $_; EC2EbsEncryptionByDefault = Disable-EC2EbsEncryptionByDefault -Region $_; EC2EbsDefaultKmsKeyId = Get-EC2EbsDefaultKmsKeyId -Region $_; } } | Format-Table -AutoSize
```

You cannot change the KMS key that is associated with an existing snapshot or encrypted volume. However, you can associate a different KMS key during a snapshot copy operation so that the resulting copied snapshot is encrypted by the new KMS key.

### Encrypt EBS resources

You encrypt EBS volumes by enabling encryption, either using encryption by default (p. 2320) or by enabling encryption when you create a volume that you want to encrypt.

When you encrypt a volume, you can specify the symmetric encryption KMS key to use to encrypt the volume. If you do not specify a KMS key, the KMS key that is used for encryption depends on the encryption state of the source snapshot and its ownership. For more information, see the encryption outcomes table (p. 2327).

**Note**

If you are using the API or AWS CLI to specify a KMS key, be aware that AWS authenticates the KMS key asynchronously. If you specify a KMS key ID, an alias, or an ARN that is not valid, the action can appear to complete, but it eventually fails.

You cannot change the KMS key that is associated with an existing snapshot or volume. However, you can associate a different KMS key during a snapshot copy operation so that the resulting copied snapshot is encrypted by the new KMS key.
Encrypt an empty volume on creation

When you create a new, empty EBS volume, you can encrypt it by enabling encryption for the specific volume creation operation. If you enabled EBS encryption by default, the volume is automatically encrypted using your default KMS key for EBS encryption. Alternatively, you can specify a different symmetric encryption KMS key for the specific volume creation operation. The volume is encrypted by the time it is first available, so your data is always secured. For detailed procedures, see Create an Amazon EBS volume (p. 2073).

By default, the KMS key that you selected when creating a volume encrypts the snapshots that you make from the volume and the volumes that you restore from those encrypted snapshots. You cannot remove encryption from an encrypted volume or snapshot, which means that a volume restored from an encrypted snapshot, or a copy of an encrypted snapshot, is always encrypted.

Public snapshots of encrypted volumes are not supported, but you can share an encrypted snapshot with specific accounts. For detailed directions, see Share an Amazon EBS snapshot (p. 2156).

Encrypt unencrypted resources

You cannot directly encrypt existing unencrypted volumes or snapshots. However, you can create encrypted volumes or snapshots from unencrypted volumes or snapshots. If you enable encryption by default, Amazon EBS automatically encrypts new volumes and snapshots using your default KMS key for EBS encryption. Otherwise, you can enable encryption when you create an individual volume or snapshot, using either the default KMS key for Amazon EBS encryption or a symmetric customer managed encryption key. For more information, see Create an Amazon EBS volume (p. 2073) and Copy an Amazon EBS snapshot (p. 2128).

To encrypt the snapshot copy to a customer managed key, you must both enable encryption and specify the KMS key, as shown in Copy an unencrypted snapshot (encryption by default not enabled) (p. 2325).

Important

Amazon EBS does not support asymmetric encryption KMS keys. For more information, see Using Symmetric and Asymmetric encryption KMS keys in the AWS Key Management Service Developer Guide.

You can also apply new encryption states when launching an instance from an EBS-backed AMI. This is because EBS-backed AMIs include snapshots of EBS volumes that can be encrypted as described. For more information, see Use encryption with EBS-backed AMIs (p. 239).

Rotating AWS KMS keys

Cryptographic best practices discourage extensive reuse of encryption keys. To create new cryptographic material for your KMS key, you can create new KMS key, and then change your applications or aliases to use the new KMS key. Or, you can enable automatic key rotation for an existing KMS key.

When you enable automatic key rotation for a KMS key, AWS KMS generates new cryptographic material for the KMS key every year. AWS KMS saves all previous versions of the cryptographic material so you can decrypt any data encrypted with that KMS key. AWS KMS does not delete any rotated key material until you delete the KMS key.

When you use a rotated KMS key to encrypt data, AWS KMS uses the current key material. When you use the rotated KMS key to decrypt data, AWS KMS uses the version of the key material that was used to encrypt it. You can safely use a rotated KMS key in applications and AWS services without code changes.

Note

Automatic key rotation is supported only for symmetric customer managed keys with key material that AWS KMS creates. AWS KMS automatically rotates AWS managed keys every year. You can't enable or disable key rotation for AWS managed keys.
For more information, see Rotating KMS key in the AWS Key Management Service Developer Guide.

Encryption scenarios

When you create an encrypted EBS resource, it is encrypted by your account's default KMS key for EBS encryption unless you specify a different customer managed key in the volume creation parameters or the block device mapping for the AMI or instance. For more information, see Default KMS key for EBS encryption (p. 2319).

The following examples illustrate how you can manage the encryption state of your volumes and snapshots. For a full list of encryption cases, see the encryption outcomes table (p. 2327).

Examples

- Restore an unencrypted volume (encryption by default not enabled) (p. 2324)
- Restore an unencrypted volume (encryption by default enabled) (p. 2324)
- Copy an unencrypted snapshot (encryption by default not enabled) (p. 2325)
- Copy an unencrypted snapshot (encryption by default enabled) (p. 2325)
- Re-encrypt an encrypted volume (p. 2326)
- Re-encrypt an encrypted snapshot (p. 2326)
- Migrate data between encrypted and unencrypted volumes (p. 2327)
- Encryption outcomes (p. 2327)

Restore an unencrypted volume (encryption by default not enabled)

Without encryption by default enabled, a volume restored from an unencrypted snapshot is unencrypted by default. However, you can encrypt the resulting volume by setting the Encrypted parameter and, optionally, the KmsKeyId parameter. The following diagram illustrates the process.

If you leave out the KmsKeyId parameter, the resulting volume is encrypted using your default KMS key for EBS encryption. You must specify a KMS key ID to encrypt the volume to a different KMS key.

For more information, see Create a volume from a snapshot (p. 2075).

Restore an unencrypted volume (encryption by default enabled)

When you have enabled encryption by default, encryption is mandatory for volumes restored from unencrypted snapshots, and no encryption parameters are required for your default KMS key to be used. The following diagram shows this simple default case:
If you want to encrypt the restored volume to a symmetric customer managed encryption key, you must supply both the Encrypted and KmsKeyId parameters as shown in "Restore an unencrypted volume (encryption by default not enabled)" (p. 2324).

Copy an unencrypted snapshot (encryption by default not enabled)

Without encryption by default enabled, a copy of an unencrypted snapshot is unencrypted by default. However, you can encrypt the resulting snapshot by setting the Encrypted parameter and, optionally, the KmsKeyId parameter. If you omit KmsKeyId, the resulting snapshot is encrypted by your default KMS key. You must specify a KMS key ID to encrypt the volume to a different symmetric encryption KMS key.

The following diagram illustrates the process.

You can encrypt an EBS volume by copying an unencrypted snapshot to an encrypted snapshot and then creating a volume from the encrypted snapshot. For more information, see "Copy an Amazon EBS snapshot" (p. 2128).

Copy an unencrypted snapshot (encryption by default enabled)

When you have enabled encryption by default, encryption is mandatory for copies of unencrypted snapshots, and no encryption parameters are required if your default KMS key is used. The following diagram illustrates this default case:
Re-encrypt an encrypted volume

When the CreateVolume action operates on an encrypted snapshot, you have the option of re-encrypting it with a different KMS key. The following diagram illustrates the process. In this example, you own two KMS keys, KMS key A and KMS key B. The source snapshot is encrypted by KMS key A. During volume creation, with the KMS key ID of KMS key B specified as a parameter, the source data is automatically decrypted, then re-encrypted by KMS key B.

For more information, see Create a volume from a snapshot (p. 2075).

Re-encrypt an encrypted snapshot

The ability to encrypt a snapshot during copying allows you to apply a new symmetric encryption KMS key to an already-encrypted snapshot that you own. Volumes restored from the resulting copy are only accessible using the new KMS key. The following diagram illustrates the process. In this example, you own two KMS keys, KMS key A and KMS key B. The source snapshot is encrypted by KMS key A. During copy, with the KMS key ID of KMS key B specified as a parameter, the source data is automatically re-encrypted by KMS key B.
In a related scenario, you can choose to apply new encryption parameters to a copy of a snapshot that has been shared with you. By default, the copy is encrypted with a KMS key shared by the snapshot's owner. However, we recommend that you create a copy of the shared snapshot using a different KMS key that you control. This protects your access to the volume if the original KMS key is compromised, or if the owner revokes the KMS key for any reason. For more information, see Encryption and snapshot copying (p. 2130).

Migrate data between encrypted and unencrypted volumes

When you have access to both an encrypted and an unencrypted volume, you can freely transfer data between them. EC2 carries out the encryption and decryption operations transparently.

For example, use the rsync command to copy the data. In the following command, the source data is located in /mnt/source and the destination volume is mounted at /mnt/destination.

```
[ec2-user ~]$ sudo rsync -avh --progress /mnt/source/ /mnt/destination/
```

Encryption outcomes

The following table describes the encryption outcome for each possible combination of settings.

<table>
<thead>
<tr>
<th>Is encryption enabled?</th>
<th>Is encryption by default enabled?</th>

* Encrypted by a specified customer managed key**
Amazon Elastic Compute Cloud
User Guide for LinuxInstances
EBS data services

* This is the default customer managed key used for EBS encryption for the AWS account and Region. By default this is a unique AWS managed key for EBS, or you can specify a customer managed key. For more information, see Default KMS key for EBS encryption (p. 2319).

** This is a customer managed key specified for the volume at launch time. This customer managed key is used instead of the default customer managed key for the AWS account and Region.

Set encryption defaults using the API and CLI

You can manage encryption by default and the default KMS key using the following API actions and CLI commands.

<table>
<thead>
<tr>
<th>API action</th>
<th>CLI command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DisableEbsEncryptionByDefault</td>

<td>Resets the AWS managed key as the default KMS key used to encrypt EBS volumes.</td>
</tr>
</tbody>
</table>

Amazon EBS fast snapshot restore

Amazon EBS fast snapshot restore (FSR) enables you to create a volume from a snapshot that is fully initialized at creation. This eliminates the latency of I/O operations on a block when it is accessed for the first time. Volumes that are created using fast snapshot restore instantly deliver all of their provisioned performance.

To get started, enable fast snapshot restore for specific snapshots in specific Availability Zones. Each snapshot and Availability Zone pair refers to one fast snapshot restore. When you create a volume from one of these snapshots in one of its enabled Availability Zones, the volume is restored using fast snapshot restore.

Fast snapshot restore must be explicitly enabled on a per-snapshot basis. If you create a new snapshot from a volume that was restored from a fast snapshot restore-enabled snapshot, the new snapshot is not automatically enabled for fast snapshot restore. You must explicitly enable it for the new snapshot.

The number of volumes that you can restore with the full performance benefit of fast snapshot restore is determined by volume creation credits for the snapshot. For more information see Volume creation credits (p. 2330).

You can enable fast snapshot restore for snapshots that you own and for public and private snapshots that are shared with you.
Considerations

• Fast snapshot restore is not supported with AWS Outposts, Local Zones, and Wavelength Zones.
• Fast snapshot restore can be enabled on snapshots with a size of 16 TiB or less.
• Volumes provisioned with performance up to 64,000 IOPS and 1,000 MiB/s throughput receive the full performance benefit of fast snapshot restore. For volumes provisioned with performance greater than 64,000 IOPS or 1,000 MiB/s throughput, we recommend that you initialize the volume (p. 2379) to receive its full performance.

Volume creation credits

The number of volumes that receive the full performance benefit of fast snapshot restore is determined by the volume creation credits for the snapshot. There is one credit bucket per snapshot per Availability Zone. Each volume that you create from a snapshot with fast snapshot restore enabled consumes one credit from the credit bucket. You must have at least one credit in the bucket to create an initialized volume from the snapshot. If you create a volume but there is less than one credit in the bucket, the volume is created without benefit of fast snapshot restore.

When you enable fast snapshot restore for a snapshot that is shared with you, you get a separate credit bucket for the shared snapshot in your account. If you create volumes from the shared snapshot, the credits are consumed from your credit bucket; they are not consumed from the snapshot owner’s credit bucket.

The size of a credit bucket and the rate at which it refills depends on the size of the snapshot, not the size of the volumes created from the snapshot.

When you enable fast snapshot restore for a snapshot, the credit bucket starts with zero credits, and it gets filled at a set rate until it reaches its maximum credit capacity. Also, as you consume credits, the credit bucket is refilled over time until it reaches its maximum credit capacity.

The fill rate for a credit bucket is calculated as follows:

\[
\text{MIN} \left(10, \left(\frac{1024}{\text{snapshot\_size\_gib}}\right)\right)
\]

And the size of the credit bucket is calculated as follows:

\[
\text{MAX} \left(1, \text{MIN} \left(10, \left(\frac{1024}{\text{snapshot\_size\_gib}}\right)\right)\right)
\]

For example, if you enable fast snapshot restore for a snapshot with a size of 128 GiB, the fill rate is 0.1333 credits per minute.

\[
\text{MIN} \left(10, \left(\frac{1024}{128}\right)\right) = \text{MIN} \left(10, 8\right) = 8 \text{ credits per hour} = 0.1333 \text{ credits per minute}
\]
And the maximum size of the credit bucket is 8 credits.

\[
\text{MAX} \left(1, \text{MIN} \left(10, \left(1024 \div 128\right)\right)\right) \\
= \text{MAX} \left(1, \text{MIN} \left(10, 8\right)\right) \\
= \text{MAX} \left(1, 8\right) \\
= 8 \text{ credits}
\]

In this example, when you enable fast snapshot restore, the credit bucket starts with zero credits. After 8 minutes, the credit bucket has enough credits to create one initialized volume (0.1333 credits × 8 minutes = 1.066 credits). When the credit bucket is full, you can create 8 initialized volumes simultaneously (8 credits). When the bucket is below its maximum capacity, it refills with 0.1333 credits per minute.

You can use Cloudwatch metrics to monitor the size of your credit buckets and the number of credits available in each bucket. For more information, see Metrics for fast snapshot restore (p. 2398).

After you create a volume from a snapshot with fast snapshot restore enabled, you can describe the volume using describe-volumes and check the fastRestored field in the output to determine whether the volume was created as an initialized volume using fast snapshot restore.

Manage fast snapshot restore

Topics
- Enable or disable fast snapshot restore (p. 2331)
- View the fast snapshot restore state for a snapshot (p. 2332)
- View volumes restored using fast snapshot restore (p. 2333)

Enable or disable fast snapshot restore

Fast snapshot restore is disabled for a snapshot by default. You can enable or disable fast snapshot restore for snapshots that you own and for snapshots that are shared with you. When you enable or disable fast snapshot restore for a snapshot, the changes apply to your account only.

**Note**
When you enable fast snapshot restore for a snapshot, your account is billed for each minute that fast snapshot restore is enabled in a particular Availability Zone. Charges are pro-rated and have a minimum of one hour.

When you delete a snapshot that you own, fast snapshot restore is automatically disabled for that snapshot in your account. If you enabled fast snapshot restore for a snapshot that is shared with you, and the snapshot owner deletes or unshares it, fast snapshot restore is automatically disabled for the shared snapshot in your account.

If you enabled fast snapshot restore for a snapshot that is shared with you, and it has been encrypted using a custom CMK, fast snapshot restore is not automatically disabled for the snapshot when the snapshot owner revokes your access to the custom CMK. You must manually disable fast snapshot restore for that snapshot.

Use one of the following methods to enable or disable fast snapshot restore for a snapshot that you own or for a snapshot that is shared with you.

**Console**

**To enable or disable fast snapshot restore**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Snapshots.
3. Select the snapshot, and choose Actions, Manage fast snapshot restore.
4. The **Fast snapshot restore settings** section lists all of the Availability Zones in which you can enable fast snapshot restore for the selected snapshot. The **Current status** volume indicates whether fast snapshot restore is current enabled or disabled for each zone.

To enable fast snapshot restore in a zone where it is currently disabled, select the zone, choose **Enable**, and then to confirm, choose **Enable**.

To disable fast snapshot restore in a zone where it is currently enabled, select the zone, and then choose **Disable**.

5. After you have made the required changes, choose **Close**.

**AWS CLI**

**To manage fast snapshot restore using the AWS CLI**

- `enable-fast-snapshot-restores`
- `disable-fast-snapshot-restores`
- `describe-fast-snapshot-restores`

**Note**
After you enable fast snapshot restore for a snapshot, it enters the optimizing state. Snapshots that are in the optimizing state provide some performance benefits when using them to restore volumes. They start to provide the full performance benefits of fast snapshot restore only after they enter the enabled state.

**View the fast snapshot restore state for a snapshot**

Fast snapshot restore for a snapshot can be in one of the following states.

- enabling — A request was made to enable fast snapshot restore.
- optimizing — Fast snapshot restore is being enabled. It takes 60 minutes per TiB to optimize a snapshot. Snapshots in this state offer some performance benefit when restoring volumes.
- enabled — Fast snapshot restore is enabled. Snapshots that are in this state and that have sufficient volume creation credits offer the full performance benefit when restoring volumes.
- disabling — A request was made to disable fast snapshot restore, or a request to enable fast snapshot restore failed.
- disabled — Fast snapshot restore is disabled. You can enable fast snapshot restore again as needed.

Use one of the following methods to view the state of fast snapshot restore for a snapshot that you own or for a snapshot that is shared with you.

**Console**

**To view the state of fast snapshot restore using the console**

1. Open the Amazon EC2 console at `https://console.aws.amazon.com/ec2/`.
2. In the navigation pane, choose **Snapshots**.
3. Select the snapshot.
4. On the **Details** tab, **Fast snapshot restore**, indicates the state of fast snapshot restore.

**AWS CLI**

**To view snapshots with fast snapshot restore enabled using the AWS CLI**
Use the `describe-fast-snapshot-restores` command to describe the snapshots that are enabled for fast snapshot restore.

```
aws ec2 describe-fast-snapshot-restores --filters Name=state,Values=enabled
```

The following is example output.

```
{
    "FastSnapshotRestores": [
        {
            "SnapshotId": "snap-0e946653493cb0447",
            "AvailabilityZone": "us-east-2a",
            "State": "enabled",
            "StateTransitionReason": "Client.UserInitiated - Lifecycle state transition",
            "OwnerId": "123456789012",
            "EnablingTime": "2020-01-25T23:57:49.596Z",
            "OptimizingTime": "2020-01-25T23:58:25.573Z",
            "EnabledTime": "2020-01-25T23:59:29.852Z"
        },
        {
            "SnapshotId": "snap-0e946653493cb0447",
            "AvailabilityZone": "us-east-2b",
            "State": "enabled",
            "StateTransitionReason": "Client.UserInitiated - Lifecycle state transition",
            "OwnerId": "123456789012",
            "EnablingTime": "2020-01-25T23:57:49.596Z",
            "OptimizingTime": "2020-01-25T23:58:25.573Z",
            "EnabledTime": "2020-01-25T23:59:29.852Z"
        }
    ]
}
```

View volumes restored using fast snapshot restore

When you create a volume from a snapshot that is enabled for fast snapshot restore in the Availability Zone for the volume, it is restored using fast snapshot restore.

Use the `describe-volumes` command to view volumes that were created from a snapshot that is enabled for fast snapshot restore.

```
aws ec2 describe-volumes --filters Name=fast-restored,Values=true
```

The following is example output.

```
{
    "Volumes": [
        {
            "Attachments": [],
            "AvailabilityZone": "us-east-2a",
            "CreateTime": "2020-01-26T00:34:11.093Z",
            "Encrypted": true,
            "KmsKeyId": "arn:aws:kms:us-west-2:123456789012:key/8c5b2c63-b9bc-45a3-a87a-5513e232e843",
            "Size": 20,
            "SnapshotId": "snap-0e946653493cb0447",
            "State": "available",
            "VolumeId": "vol-0d371921d4ca797b0",
```
Monitor fast snapshot restore

Amazon EBS emits Amazon CloudWatch events when the fast snapshot restore state for a snapshot changes. For more information, see EBS fast snapshot restore events (p. 2408).

Fast snapshot restore quotas

You can enable up to 5 snapshots for fast snapshot restore per Region. The quota applies to snapshots that you own and snapshots that are shared with you. If you enable fast snapshot restore for a snapshot that is shared with you, it counts towards your fast snapshot restore quota. It does not count towards the snapshot owner's fast snapshot restore quota.

Pricing and Billing

You are billed for each minute that fast snapshot restore is enabled for a snapshot in a particular Availability Zone. Charges are pro-rated with a minimum of one hour.

For example, if you enable fast snapshot restore for one snapshot in US-East-1a for one month (30 days), you are billed $540 (1 snapshot x 1 AZ x 720 hours x $0.75 per hour). If you enable fast snapshot restore for two snapshots in us-east-1a, us-east-1b, and us-east-1c for the same period, you are billed $3240 (2 snapshots x 3 AZs x 720 hours x $0.75 per hour).

If you enable fast snapshot restore for a public or private snapshot that is shared with you, your account is billed; the snapshot owner is not billed. When a snapshot that is shared with you is deleted or unshared by the snapshot owner, fast snapshot restore is disabled for the snapshot in your account and billing is stopped.

For more information, see Amazon EBS pricing.

Amazon EBS and NVMe on Linux instances

EBS volumes are exposed as NVMe block devices on instances built on the Nitro System (p. 295). The device names are /dev/nvme0n1, /dev/nvme1n1, and so on. The device names that you specify in a block device mapping are renamed using NVMe device names (/dev/nvme[0-26]n1). The block device driver can assign NVMe device names in a different order than you specified for the volumes in the block device mapping.

The EBS performance guidance stated in Amazon EBS Product Details are valid regardless of the block-device interface.

For information about EBS volumes and NVME on Windows instances, see the User Guide for Windows Instances.

Contents

- Install or upgrade the NVMe driver (p. 2335)
- Identify the EBS device (p. 2336)
- Work with NVMe EBS volumes (p. 2338)
- I/O operation timeout (p. 2338)
Install or upgrade the NVMe driver

To access NVMe volumes, the NVMe drivers must be installed. Instances can support NVMe EBS volumes, NVMe instance store volumes, both types of NVMe volumes, or no NVMe volumes. For more information, see Summary of networking and storage features (p. 297).

The following AMIs include the required NVMe drivers:

- Amazon Linux 2
- Amazon Linux AMI 2018.03
- Ubuntu 14.04 or later with linux-aws kernel
  
  **Note**
  
  AWS Graviton-based instance types require Ubuntu 18.04 or later with linux-aws kernel

- Red Hat Enterprise Linux 6.5 or later
- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later

For more information about NVMe drivers on Windows instances, see Amazon EBS and NVMe on Windows Instances in the Amazon EC2 User Guide for Windows Instances.

**To confirm that your instance has the NVMe driver**

You can confirm that your instance has the NVMe driver using the following command.

- Amazon Linux, RHEL, CentOS, and SUSE Linux Enterprise Server

  $ modinfo nvme

  If the instance has the NVMe driver, the command returns information about the driver.

- Amazon Linux 2 and Ubuntu

  $ ls /sys/module/ | grep nvme

  If the instance has the NVMe driver, the command returns the installed drivers.

**To update the NVMe driver**

If your instance has the NVMe driver, you can update the driver to the latest version using the following procedure.

1. Connect to your instance.
2. Update your package cache to get necessary package updates as follows.

   - For Amazon Linux 2, Amazon Linux, CentOS, and Red Hat Enterprise Linux:

     [ec2-user ~]$ sudo yum update -y
For Ubuntu and Debian:

```
[ec2-user ~]$ sudo apt-get update -y
```

3. Ubuntu 16.04 and later include the `linux-aws` package, which contains the NVMe and ENA drivers required by Nitro-based instances. Upgrade the `linux-aws` package to receive the latest version as follows:

```
[ec2-user ~]$ sudo apt-get install --only-upgrade -y linux-aws
```

For Ubuntu 14.04, you can install the latest `linux-aws` package as follows:

```
[ec2-user ~]$ sudo apt-get install linux-aws
```

4. Reboot your instance to load the latest kernel version.

```
sudo reboot
```

5. Reconnect to your instance after it has rebooted.

**Identify the EBS device**

EBS uses single-root I/O virtualization (SR-IOV) to provide volume attachments on Nitro-based instances using the NVMe specification. These devices rely on standard NVMe drivers on the operating system. These drivers typically discover attached devices during instance boot, and create device nodes based on the order in which the devices respond, not on how the devices are specified in the block device mapping. In Linux, NVMe device names follow the pattern `/dev/nvme<x>n<y>`, where `<x>` is the enumeration order, and, for EBS, `<y>` is 1. Occasionally, devices can respond to discovery in a different order in subsequent instance starts, which causes the device name to change. Additionally, the device name assigned by the block device driver can be different from the name specified in the block device mapping.

We recommend that you use stable identifiers for your EBS volumes within your instance, such as one of the following:

- For Nitro-based instances, the block device mappings that are specified in the Amazon EC2 console when you are attaching an EBS volume or during `AttachVolume` or `RunInstances` API calls are captured in the vendor-specific data field of the NVMe controller identification. With Amazon Linux AMIs later than version 2017.09.01, we provide a `udev` rule that reads this data and creates a symbolic link to the block-device mapping.
- The EBS volume ID and the mount point are stable between instance state changes. The NVMe device name can change depending on the order in which the devices respond during instance boot. We recommend using the EBS volume ID and the mount point for consistent device identification.
- NVMe EBS volumes have the EBS volume ID set as the serial number in the device identification. Use the `lsblk -o +SERIAL` command to list the serial number.
- The NVMe device name format can vary depending on whether the EBS volume was attached during or after the instance launch. NVMe device names for volumes attached after instance launch include the `/dev/` prefix, while NVMe device names for volumes attached during instance launch do not include the `/dev/` prefix. If you are using an Amazon Linux or FreeBSD AMI, use the `sudo ebsnvme-id /dev/nvme0n1 -u` command for a consistent NVMe device name. For other distributions, use the `sudo nvme id-ctrl -v /dev/nvme0n1` command to determine the NVMe device name.
- When a device is formatted, a UUID is generated that persists for the life of the filesystem. A device label can be specified at the same time. For more information, see [Make an Amazon EBS volume available for use on Linux](p. 2083) and [Boot from the wrong volume](p. 2578).
Amazon Linux AMIs

With Amazon Linux AMI 2017.09.01 or later (including Amazon Linux 2), you can run the `ebsnvme-id` command as follows to map the NVMe device name to a volume ID and device name:

The following example shows the command and output for a volume attached during instance launch. Note that the NVMe device name does not include the `/dev/` prefix.

```
[ec2-user ~]$ sudo /sbin/ebsnvme-id /dev/nvme0n1
Volume ID: vol-01324f611e2463981
sda
```

The following example shows the command and output for a volume attached after instance launch. Note that the NVMe device name includes the `/dev/` prefix.

```
[ec2-user ~]$ sudo /sbin/ebsnvme-id /dev/nvme1n1
Volume ID: vol-064784f1011136656
/dev/sdf
```

Amazon Linux also creates a symbolic link from the device name in the block device mapping (for example, `/dev/sdf`), to the NVMe device name.

FreeBSD AMIs

Starting with FreeBSD 12.2-RELEASE, you can run the `ebsnvme-id` command as shown above. Pass either the name of the NVMe device (for example, `nvme0`) or the disk device (for example, `nvd0` or `nda0`). FreeBSD also creates symbolic links to the disk devices (for example, `/dev/aws/disk/ebs/volume_id`).

Other Linux AMIs

With a kernel version of 4.2 or later, you can run the `nvme id-ctrl` command as follows to map an NVMe device to a volume ID. First, install the NVMe command line package, `nvme-cli`, using the package management tools for your Linux distribution. For download and installation instructions for other distributions, refer to the documentation specific to your distribution.

The following example gets the volume ID and NVMe device name for a volume that was attached during instance launch. Note that the NVMe device name does not include the `/dev/` prefix. The device name is available through the NVMe controller vendor-specific extension (bytes 384:4095 of the controller identification):

```
[ec2-user ~]$ sudo nvme id-ctrl -v /dev/nvme0n1
NVME Identify Controller:
  vid : 0x1d0f
  ssvid : 0x1d0f
  sn : vol01234567890abcdef
  mn : Amazon Elastic Block Store
  ...
  0000: 2f 64 65 76 2f 73 64 6a 20 20 20 20 20 20 20 20 "sda..."
```

The following example gets the volume ID and NVMe device name for a volume that was attached after instance launch. Note that the NVMe device name includes the `/dev/` prefix.

```
[ec2-user ~]$ sudo nvme id-ctrl -v /dev/nvme1n1
NVME Identify Controller:
  vid : 0x1d0f
  ssvid : 0x1d0f
  sn : volabcdef01234567890
  mn : Amazon Elastic Block Store
```

2337
Work with NVMe EBS volumes

To format and mount an NVMe EBS volume, see Make an Amazon EBS volume available for use on Linux (p. 2083).

If you are using Linux kernel 4.2 or later, any change you make to the volume size of an NVMe EBS volume is automatically reflected in the instance. For older Linux kernels, you might need to detach and attach the EBS volume or reboot the instance for the size change to be reflected. With Linux kernel 3.19 or later, you can use the `hdparm` command as follows to force a rescan of the NVMe device:

```
[ec2-user ~]$ sudo hdparm -z /dev/nvme
```

When you detach an NVMe EBS volume, the instance does not have an opportunity to flush the file system caches or metadata before detaching the volume. Therefore, before you detach an NVMe EBS volume, you should first sync and unmount it. If the volume fails to detach, you can attempt a force-detect command as described in Detach an Amazon EBS volume from a Linux instance (p. 2104).

I/O operation timeout

EBS volumes attached to Nitro-based instances use the default NVMe driver provided by the operating system. Most operating systems specify a timeout for I/O operations submitted to NVMe devices. The default timeout is 30 seconds and can be changed using the `nvme_core.io_timeout` boot parameter. For most Linux kernels earlier than version 4.6, this parameter is `nvme.io_timeout`.

If I/O latency exceeds the value of this timeout parameter, the Linux NVMe driver fails the I/O and returns an error to the filesystem or application. Depending on the I/O operation, your filesystem or application can retry the error. In some cases, your filesystem might be remounted as read-only.

For an experience similar to EBS volumes attached to Xen instances, we recommend setting `nvme_core.io_timeout` to the highest value possible. For current kernels, the maximum is 4294967295, while for earlier kernels the maximum is 255. Depending on the version of Linux, the timeout might already be set to the supported maximum value. For example, the timeout is set to 4294967295 by default for Amazon Linux AMI 2017.09.01 and later.

You can verify the maximum value for your Linux distribution by writing a value higher than the suggested maximum to `/sys/module/nvme_core/parameters/io_timeout` and checking for the Numerical result out of range error when attempting to save the file.

Abort command

The `Abort` command is an NVMe Admin command that is issued to abort a specific command that was previously submitted to the controller. This command is typically issued by the device driver to storage devices that have exceeded the I/O operation timeout threshold. Amazon EC2 instance types that
support the `Abort` command by default will abort a specific command that was previously submitted to the controller of the attached Amazon EBS device to which an `Abort` command is issued.

The following instance types support the `Abort` command for all attached Amazon EBS volumes by default: R5b, R6i, M6i, M6a, C6gn, C6i, X2gd, X2iezn, Im4gn, Is4gen.

Other instance types take no action when `Abort` commands are issued to attached Amazon EBS volumes.

Amazon EBS devices with NVMe device version 1.4 or higher support the `Abort` command.

For more information, see section 5.1 Abort command of the NVM Express Base Specification.

### Amazon EBS–optimized instances

An Amazon EBS–optimized instance uses an optimized configuration stack and provides additional, dedicated capacity for Amazon EBS I/O. This optimization provides the best performance for your EBS volumes by minimizing contention between Amazon EBS I/O and other traffic from your instance.

EBS–optimized instances deliver dedicated bandwidth to Amazon EBS. When attached to an EBS–optimized instance, General Purpose SSD (gp2 and gp3) volumes are designed to deliver at least 90% of their provisioned IOPS performance 99% of the time in a given year, and Provisioned IOPS SSD (io1 and io2) volumes are designed to deliver at least 90% of their provisioned IOPS performance 99.9% of the time in a given year. Both Throughput Optimized HDD (st1) and Cold HDD (sc1) deliver at least 90% of their expected throughput performance 99% of the time in a given year. Non-compliant periods are approximately uniformly distributed, targeting 99% of expected total throughput each hour. For more information, see Amazon EBS volume types (p. 2055).

**Important**

An instance's EBS performance is bounded by the instance's performance limits, or the aggregated performance of its attached volumes, whichever is smaller. To achieve maximum EBS performance, an instance must have attached volumes that provide a combined performance equal to or greater than the maximum instance performance. For example, to achieve 80,000 IOPS for r6i.16xlarge, the instance must have at least 5 gp3 volumes provisioned with 16,000 IOPS each (5 volumes x 16,000 IOPS = 80,000 IOPS).

### Supported instance types

The following tables show which instance types support EBS optimization. They include the dedicated bandwidth to Amazon EBS, the typical maximum aggregate throughput that can be achieved on that connection with a streaming read workload and 128 KiB I/O size, and the maximum IOPS the instance can support if you are using a 16 KiB I/O size.

Choose an EBS–optimized instance that provides more dedicated Amazon EBS throughput than your application needs; otherwise, the connection between Amazon EBS and Amazon EC2 can become a performance bottleneck.

**Topics**

- [EBS optimized by default](#)
- [EBS optimization supported](#)
EBS optimized by default

The following tables list the instance types that support EBS optimization and EBS optimization is enabled by default. There is no need to enable EBS optimization and no effect if you disable EBS optimization.

**Note**
You can also view this information programatically using the AWS CLI. For more information, see View instances types that support EBS optimization (p. 2371).

**Topics**
- General purpose (p. 2340)
- Compute optimized (p. 2348)
- Memory optimized (p. 2355)
- Storage optimized (p. 2364)
- Accelerated computing (p. 2367)

### General purpose

**Important**
Instances indicated with an asterisk (*) can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.
Instances not indicated with an asterisk can sustain the maximum performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

### Compute optimized

**Important**

Instances indicated with an asterisk (*) can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance.

Instances not indicated with an asterisk can sustain the maximum performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

### Memory optimized

**Important**

Instances indicated with an asterisk (*) can support maximum performance for 30 minutes at least once every 24 hours, after which they revert to their baseline performance. Instances not indicated with an asterisk can sustain the maximum performance indefinitely. If your workload requires sustained maximum performance for longer than 30 minutes, use one of these instances.

## EBS optimization supported

The following table lists the instance types that support EBS optimization but EBS optimization is not enabled by default. You can enable EBS optimization when you launch these instances or after they are running. Instances must have EBS optimization enabled to achieve the level of performance described. When you enable EBS optimization for an instance that is not EBS-optimized by default, you pay an additional low, hourly fee for the dedicated capacity. For pricing information, see EBS-Optimized Instances on the [Amazon EC2 Pricing, On-Demand Pricing page](https://aws.amazon.com/ec2/pricing/on-demand/).

**Note**

You can also view this information programatically using the AWS CLI. For more information, see View instances types that support EBS optimization (p. 2371).

</tbody>
</table>

The i2.8xlarge, c3.8xlarge, and r3.8xlarge instances do not have dedicated EBS bandwidth and therefore do not offer EBS optimization. On these instances, network traffic and Amazon EBS traffic share the same 10-gigabit network interface.

**Get maximum performance**

You can use the EBSIOBalance% and EBSByteBalance% metrics to help you determine whether your instances are sized correctly. You can view these metrics in the CloudWatch console and set an alarm that is triggered based on a threshold you specify. These metrics are expressed as a percentage. Instances with a consistently low balance percentage are candidates to size up. Instances where the balance percentage never drops below 100% are candidates for downsizing. For more information, see [Monitor your instances using CloudWatch](p. 1298).

The high memory instances are designed to run large in-memory databases, including production deployments of the SAP HANA in-memory database, in the cloud. To maximize EBS performance, use high memory instances with an even number of io1 or io2 volumes with identical provisioned performance. For example, for IOPS heavy workloads, use four io1 or io2 volumes with 40,000 provisioned IOPS to get the maximum 160,000 instance IOPS. Similarly, for throughput heavy workloads, use six io1 or io2 volumes with 48,000 provisioned IOPS to get the maximum 4,750 MB/s throughput. For additional recommendations, see [Storage Configuration for SAP HANA](#).

**Considerations**

- G4dn, i3en, Inf1, M5a, M5ad, R5a, R5ad, T3, T3a, and Z1d instances launched after February 26, 2020 provide the maximum performance listed in the table above. To get the maximum performance from an instance launched before February 26, 2020, stop and start it.
- C5, C5d, C5n, M5, M5d, M5n, M5dn, R5, R5d, R5n, R5dn, and P3dn instances launched after December 3, 2019 provide the maximum performance listed in the table above. To get the maximum performance from an instance launched before December 3, 2019, stop and start it.
- u-6tb1.metal, u-9tb1.metal, and u-12tb1.metal instances launched after March 12, 2020 provide the performance in the table above. Instances of these types launched before March 12, 2020 might provide lower performance. To get the maximum performance from an instance launched before March 12, 2020, contact your account team to upgrade the instance at no additional cost.

View instances types that support EBS optimization

You can use the AWS CLI to view the instances types in the current Region that support EBS optimization.

To view the instance types that support EBS optimization and that have it enabled by default

Use the following `describe-instance-types` command.

```bash
aws ec2 describe-instance-types \
--filters Name=ebs-info.ebs-optimized-support,Values=default --output=table
```

Example output for eu-west-1:

```
<table>
<thead>
<tr>
<th></th>
<th>DescribeInstanceTypes</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>InstanceType</td>
</tr>
<tr>
<td></td>
<td>m5dn.8xlarge</td>
</tr>
<tr>
<td></td>
<td>m6gd.xlarge</td>
</tr>
<tr>
<td></td>
<td>c4.4xlarge</td>
</tr>
<tr>
<td></td>
<td>r4.16xlarge</td>
</tr>
<tr>
<td></td>
<td>m5ad.large</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>
```

To view the instance types that support EBS optimization but do not have it enabled by default

Use the following `describe-instance-types` command.

```bash
aws ec2 describe-instance-types \
--filters Name=ebs-info.ebs-optimized-support,Values=supported --output=table
```

Example output for eu-west-1:

```
<table>
<thead>
<tr>
<th></th>
<th>DescribeInstanceTypes</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>InstanceType</td>
</tr>
<tr>
<td></td>
<td>i2.2xlarge</td>
</tr>
<tr>
<td></td>
<td>m2.4xlarge</td>
</tr>
<tr>
<td></td>
<td>m2.2xlarge</td>
</tr>
</tbody>
</table>
```

2371
Enable EBS optimization at launch

You can enable optimization for an instance by setting its attribute for EBS optimization.

To enable Amazon EBS optimization when launching an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance.
3. In Step 1: Choose an Amazon Machine Image (AMI), select an AMI.
4. In Step 2: Choose an Instance Type, select an instance type that is listed as supporting Amazon EBS optimization.
5. In Step 3: Configure Instance Details, complete the fields that you need and choose Launch as EBS-optimized instance. If the instance type that you selected in the previous step doesn’t support Amazon EBS optimization, this option is not present. If the instance type that you selected is Amazon EBS–optimized by default, this option is selected and you can’t deselect it.
6. Follow the directions to complete the wizard and launch your instance.

To enable EBS optimization when launching an instance using the command line

You can use one of the following commands with the corresponding option. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- run-instances with --ebs-optimized (AWS CLI)
- New-EC2Instance with -EbsOptimized (AWS Tools for Windows PowerShell)

Enable EBS optimization for an existing instance

You can enable or disable optimization for an existing instance by modifying its Amazon EBS–optimized instance attribute. If the instance is running, you must stop it first.

Warning
When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

To enable EBS optimization for an existing instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and select the instance.
3. To stop the instance, choose Actions, Instance state, Stop instance. It can take a few minutes for the instance to stop.
4. With the instance still selected, choose Actions, Instance settings, Change instance type.
5. For Change Instance Type, do one of the following:
   - If the instance type of your instance is Amazon EBS–optimized by default, EBS-optimized is selected and you can't change it. You can choose Cancel, because Amazon EBS optimization is already enabled for the instance.
   - If the instance type of your instance supports Amazon EBS optimization, choose EBS-optimized and then choose Apply.
   - If the instance type of your instance does not support Amazon EBS optimization, you can't choose EBS-optimized. You can select an instance type from Instance type that supports Amazon EBS optimization, choose EBS-optimized, and then choose Apply.
6. Choose Instance state, Start instance.

To enable EBS optimization for an existing instance using the command line

1. If the instance is running, use one of the following commands to stop it:
   - stop-instances (AWS CLI)
   - Stop-EC2Instance (AWS Tools for Windows PowerShell)
2. To enable EBS optimization, use one of the following commands with the corresponding option:
   - modify-instance-attribute with --ebs-optimized (AWS CLI)
   - Edit-EC2InstanceAttribute with -EbsOptimized (AWS Tools for Windows PowerShell)

Amazon EBS volume performance on Linux instances

Several factors, including I/O characteristics and the configuration of your instances and volumes, can affect the performance of Amazon EBS. Customers who follow the guidance on our Amazon EBS and Amazon EC2 product detail pages typically achieve good performance out of the box. However, there are some cases where you may need to do some tuning in order to achieve peak performance on the platform. This topic discusses general best practices as well as performance tuning that is specific to certain use cases. We recommend that you tune performance with information from your actual workload, in addition to benchmarking, to determine your optimal configuration. After you learn the basics of working with EBS volumes, it's a good idea to look at the I/O performance you require and at your options for increasing Amazon EBS performance to meet those requirements.

AWS updates to the performance of EBS volume types might not immediately take effect on your existing volumes. To see full performance on an older volume, you might first need to perform a ModifyVolume action on it. For more information, see Modifying the Size, IOPS, or Type of an EBS Volume on Linux.

Contents
- Amazon EBS performance tips (p. 2373)
- I/O characteristics and monitoring (p. 2376)
- Initialize Amazon EBS volumes (p. 2379)
- RAID configuration on Linux (p. 2381)
- Benchmark EBS volumes (p. 2385)

Amazon EBS performance tips

These tips represent best practices for getting optimal performance from your EBS volumes in a variety of user scenarios.
Use EBS-optimized instances

On instances without support for EBS-optimized throughput, network traffic can contend with traffic between your instance and your EBS volumes; on EBS-optimized instances, the two types of traffic are kept separate. Some EBS-optimized instance configurations incur an extra cost (such as C3, R3, and M3), while others are always EBS-optimized at no extra cost (such as M4, C4, C5, and D2). For more information, see Amazon EBS–optimized instances (p. 2339).

Understand how performance is calculated

When you measure the performance of your EBS volumes, it is important to understand the units of measure involved and how performance is calculated. For more information, see I/O characteristics and monitoring (p. 2376).

Understand your workload

There is a relationship between the maximum performance of your EBS volumes, the size and number of I/O operations, and the time it takes for each action to complete. Each of these factors (performance, I/O, and latency) affects the others, and different applications are more sensitive to one factor or another. For more information, see Benchmark EBS volumes (p. 2385).

Be aware of the performance penalty When initializing volumes from snapshots

There is a significant increase in latency when you first access each block of data on a new EBS volume that was created from a snapshot. You can avoid this performance hit using one of the following options:

- Access each block prior to putting the volume into production. This process is called initialization (formerly known as pre-warming). For more information, see Initialize Amazon EBS volumes (p. 2379).
- Enable fast snapshot restore on a snapshot to ensure that the EBS volumes created from it are fully-initialized at creation and instantly deliver all of their provisioned performance. For more information, see Amazon EBS fast snapshot restore (p. 2329).

Factors that can degrade HDD performance

When you create a snapshot of a Throughput Optimized HDD (st1) or Cold HDD (sc1) volume, performance may drop as far as the volume's baseline value while the snapshot is in progress. This behavior is specific to these volume types. Other factors that can limit performance include driving more throughput than the instance can support, the performance penalty encountered while initializing volumes created from a snapshot, and excessive amounts of small, random I/O on the volume. For more information about calculating throughput for HDD volumes, see Amazon EBS volume types (p. 2055).

Your performance can also be impacted if your application isn't sending enough I/O requests. This can be monitored by looking at your volume's queue length and I/O size. The queue length is the number of pending I/O requests from your application to your volume. For maximum consistency, HDD-backed volumes must maintain a queue length (rounded to the nearest whole number) of 4 or more when performing 1 MiB sequential I/O. For more information about ensuring consistent performance of your volumes, see I/O characteristics and monitoring (p. 2376).

Increase read-ahead for high-throughput, read-heavy workloads on st1 and sc1

Some workloads are read-heavy and access the block device through the operating system page cache (for example, from a file system). In this case, to achieve the maximum throughput, we recommend that you configure the read-ahead setting to 1 MiB. This is a per-block-device setting that should only be applied to your HDD volumes.

To examine the current value of read-ahead for your block devices, use the following command:
Block device information is returned in the following format:

<table>
<thead>
<tr>
<th>RO</th>
<th>RA</th>
<th>SSZ</th>
<th>BSZ</th>
<th>StartSec</th>
<th>Size</th>
<th>Device</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>256</td>
<td>512</td>
<td>4096</td>
<td>4096</td>
<td>8587820544</td>
<td>/dev/&lt;device&gt;</td>
</tr>
</tbody>
</table>

The device shown reports a read-ahead value of 256 (the default). Multiply this number by the sector size (512 bytes) to obtain the size of the read-ahead buffer, which in this case is 128 KiB. To set the buffer value to 1 MiB, use the following command:

```
[ec2-user ~]$ sudo blockdev --setra 2048 /dev/<device>
```

Verify that the read-ahead setting now displays 2,048 by running the first command again.

Only use this setting when your workload consists of large, sequential I/Os. If it consists mostly of small, random I/Os, this setting will actually degrade your performance. In general, if your workload consists mostly of small or random I/Os, you should consider using a General Purpose SSD (gp2 and gp3) volume rather than an st1 or sc1 volume.

**Use a modern Linux kernel**

Use a modern Linux kernel with support for indirect descriptors. Any Linux kernel 3.8 and above has this support, as well as any current-generation EC2 instance. If your average I/O size is at or near 44 KiB, you may be using an instance or kernel without support for indirect descriptors. For information about deriving the average I/O size from Amazon CloudWatch metrics, see [I/O characteristics and monitoring](p. 2376).

To achieve maximum throughput on st1 or sc1 volumes, we recommend applying a value of 256 to the `xen_blkfront.max` parameter (for Linux kernel versions below 4.6) or the `xen_blkfront.max_indirect_segments` parameter (for Linux kernel version 4.6 and above). The appropriate parameter can be set in your OS boot command line.

For example, in an Amazon Linux AMI with an earlier kernel, you can add it to the end of the kernel line in the GRUB configuration found in `/boot/grub/menu.lst`:

```
kerneld /boot/vmlinuz-4.4.5-15.26.amzn1.x86_64 root=LABEL=/ console=ttyS0 xen_blkfront.max=256
```

For a later kernel, the command would be similar to the following:

```
kerneld /boot/vmlinuz-4.9.20-11.31.amzn1.x86_64 root=LABEL=/ console=tty1 console=ttyS0 xen_blkfront.max_indirect_segments=256
```

Reboot your instance for this setting to take effect.

For more information, see [Configuring GRUB](p. 274). Other Linux distributions, especially those that do not use the GRUB boot loader, may require a different approach to adjusting the kernel parameters.

For more information about EBS I/O characteristics, see the [Amazon EBS: Designing for Performance](p. 2376) re:Invent presentation on this topic.

**Use RAID 0 to maximize utilization of instance resources**

Some instance types can drive more I/O throughput than what you can provision for a single EBS volume. You can join multiple volumes together in a RAID 0 configuration to use the available bandwidth for these instances. For more information, see [RAID configuration on Linux](p. 2391).
Track performance using Amazon CloudWatch

Amazon Web Services provides performance metrics for Amazon EBS that you can analyze and view with Amazon CloudWatch and status checks that you can use to monitor the health of your volumes. For more information, see Monitor the status of your volumes (p. 2097).

I/O characteristics and monitoring

On a given volume configuration, certain I/O characteristics drive the performance behavior for your EBS volumes. SSD-backed volumes—General Purpose SSD (gp2 and gp3) and Provisioned IOPS SSD (io1 and io2)—deliver consistent performance whether an I/O operation is random or sequential. HDD-backed volumes—Throughput Optimized HDD (st1) and Cold HDD (sc1)—deliver optimal performance only when I/O operations are large and sequential. To understand how SSD and HDD volumes will perform in your application, it is important to know the connection between demand on the volume, the quantity of IOPS available to it, the time it takes for an I/O operation to complete, and the volume's throughput limits.

Topics
- IOPS (p. 2376)
- Volume queue length and latency (p. 2377)
- I/O size and volume throughput limits (p. 2377)
- Monitor I/O characteristics using CloudWatch (p. 2378)
- Related resources (p. 2379)

IOPS

IOPS are a unit of measure representing input/output operations per second. The operations are measured in KiB, and the underlying drive technology determines the maximum amount of data that a volume type counts as a single I/O. I/O size is capped at 256 KiB for SSD volumes and 1,024 KiB for HDD volumes because SSD volumes handle small or random I/O much more efficiently than HDD volumes.

When small I/O operations are physically sequential, Amazon EBS attempts to merge them into a single I/O operation up to the maximum I/O size. Similarly, when I/O operations are larger than the maximum I/O size, Amazon EBS attempts to split them into smaller I/O operations. The following table shows some examples.

<table>
<thead>
<tr>
<th>Volume type</th>
<th>Maximum I/O size</th>
<th>I/O operations from your application</th>
<th>Number of IOPS</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSD</td>
<td>256 KiB</td>
<td>1 x 1024 KiB I/O operation</td>
<td>4 (1,024+256=4)</td>
<td>Amazon EBS splits the 1,024 I/O operation into four smaller 256 KiB operations.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>8 x sequential 32 KiB I/O operations</td>
<td>1 (8x32=256)</td>
<td>Amazon EBS merges the eight sequential 32 KiB I/O operations into a single 256 KiB operation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>8 random 32 KiB I/O operations</td>
<td>8</td>
<td>Amazon EBS counts random I/O operations.</td>
</tr>
</tbody>
</table>
Volume type | Maximum I/O size | I/O operations from your application | Number of IOPS | Notes |
--- | --- | --- | --- | --- |
HDD | 1,024 KiB | 1 x 1024 KiB I/O operation | 1 | The I/O operation is already equal to the maximum I/O size. It is not merged or split. |
| | | 8 x sequential 128 KiB I/O operations | 1 (8x128=1,024) | Amazon EBS merges the eight sequential 128 KiB I/O operations into a single 1,024 KiB I/O operation. |
| | | 8 random 32 KiB I/O operations | 8 | Amazon EBS counts random I/O operations separately. |

Consequently, when you create an SSD-backed volume supporting 3,000 IOPS (either by provisioning a Provisioned IOPS SSD volume at 3,000 IOPS or by sizing a General Purpose SSD volume at 1,000 GiB), and you attach it to an EBS-optimized instance that can provide sufficient bandwidth, you can transfer up to 3,000 I/Os of data per second, with throughput determined by I/O size.

**Volume queue length and latency**

The volume queue length is the number of pending I/O requests for a device. Latency is the true end-to-end client time of an I/O operation, in other words, the time elapsed between sending an I/O to EBS and receiving an acknowledgement from EBS that the I/O read or write is complete. Queue length must be correctly calibrated with I/O size and latency to avoid creating bottlenecks either on the guest operating system or on the network link to EBS.

Optimal queue length varies for each workload, depending on your particular application's sensitivity to IOPS and latency. If your workload is not delivering enough I/O requests to fully use the performance available to your EBS volume, then your volume might not deliver the IOPS or throughput that you have provisioned.

Transaction-intensive applications are sensitive to increased I/O latency and are well-suited for SSD-backed volumes. You can maintain high IOPS while keeping latency down by maintaining a low queue length and a high number of IOPS available to the volume. Consistently driving more IOPS to a volume than it has available can cause increased I/O latency.

Throughput-intensive applications are less sensitive to increased I/O latency, and are well-suited for HDD-backed volumes. You can maintain high throughput to HDD-backed volumes by maintaining a high queue length when performing large, sequential I/O.

**I/O size and volume throughput limits**

For SSD-backed volumes, if your I/O size is very large, you may experience a smaller number of IOPS than you provisioned because you are hitting the throughput limit of the volume. For example, a gp2 volume under 1,000 GiB with burst credits available has an IOPS limit of 3,000 and a volume throughput limit of 250 MiB/s. If you are using a 256 KiB I/O size, your volume reaches its throughput limit at 1000
EBS performance

IOPS (1000 x 256 KiB = 250 MiB). For smaller I/O sizes (such as 16 KiB), this same volume can sustain 3,000 IOPS because the throughput is well below 250 MiB/s. (These examples assume that your volume's I/O is not hitting the throughput limits of the instance.) For more information about the throughput limits for each EBS volume type, see Amazon EBS volume types (p. 2055).

For smaller I/O operations, you may see a higher-than-provisioned IOPS value as measured from inside your instance. This happens when the instance operating system merges small I/O operations into a larger operation before passing them to Amazon EBS.

If your workload uses sequential I/Os on HDD-backed s1 and sc1 volumes, you may experience a higher than expected number of IOPS as measured from inside your instance. This happens when the instance operating system merges sequential I/Os and counts them in 1,024 KiB-sized units. If your workload uses small or random I/Os, you may experience a lower throughput than you expect. This is because we count each random, non-sequential I/O toward the total IOPS count, which can cause you to hit the volume's IOPS limit sooner than expected.

Important
Whatever your EBS volume type, if you are not experiencing the IOPS or throughput you expect in your configuration, ensure that your EC2 instance bandwidth is not the limiting factor. You should always use a current-generation, EBS-optimized instance (or one that includes 10 Gb/s network connectivity) for optimal performance. For more information, see Amazon EBS-optimized instances (p. 2339). Another possible cause for not experiencing the expected IOPS is that you are not driving enough I/O to the EBS volumes.

Monitor I/O characteristics using CloudWatch

You can monitor these I/O characteristics with each volume's CloudWatch volume metrics (p. 2390). Important metrics to consider include the following:

- VolumeStalledIODCheck
- BurstBalance
- VolumeReadBytes | VolumeWriteBytes
- VolumeReadOps | VolumeWriteOps
- VolumeQueueLength

VolumeStalledIODCheck monitors the status of your EBS volumes to determine when your volumes are impaired. The metric is a binary value that will return a 0 (pass) or a 1 (fail) status based on whether or not the EBS volume can complete I/O operations. This check detects underlying issues with the Amazon EBS infrastructure, such as the following:

- Hardware or software issues on the storage subsystems underlying the EBS volumes
- Hardware issues on the physical host that impact reachability of the EBS volumes from your EC2 instance
- Connectivity issues between the instance and EBS volumes

If the VolumeStalledIODCheck metric fails, you can either wait for AWS to resolve the issue, or you can take actions, such as replacing the affected volume or stopping and restarting the instance to which the volume is attached. In most cases, when this metric fails, EBS will automatically diagnose and recover your volume within a few minutes. You can use the Pause I/O action in AWS Fault Injection Service to run controlled experiments to test your architecture and monitoring based on this metric to improve your resiliency to storage faults.

You can measure Amazon EBS storage I/O latency using VolumeReadOps, VolumeWriteOps, VolumeTotalReadTime, and VolumeTotalWriteTime. You can use the following formula to monitor the average I/O latency of your volume:
Average I/O latency in ms/op = \((\text{VolumeTotalReadTime} + \text{VolumeTotalWriteTime}) / (\text{VolumeReadOps} + \text{VolumeWriteOps})\)

If your I/O latency is higher than you require, check your driven IOPS and make sure that your application is not trying to drive more IOPS than you have provisioned. You can use the following formula to monitor the average driven IOPS on your volume:

Estimated average IOPS in ops/s = \((\text{Sum(VolumeReadOps) + Sum(VolumeWriteOps)}) / (\text{Period - Sum(VolumeIdleTime)})\)

If your application requires a greater number of IOPS than your volume can provide, you should consider using one of the following:

- A gp3, io2, or io1 volume that is provisioned with enough IOPS to achieve the required latency
- A larger gp2 volume that provides enough baseline IOPS performance

HDD-backed st1 and sc1 volumes are designed to perform best with workloads that take advantage of the 1,024 KiB maximum I/O size. To determine your volume's average I/O size, divide `VolumeWriteBytes` by `VolumeWriteOps`. The same calculation applies to read operations. If average I/O size is below 64 KiB, increasing the size of the I/O operations sent to an st1 or sc1 volume should improve performance.

**Note**
If average I/O size is at or near 44 KiB, you might be using an instance or kernel without support for indirect descriptors. Any Linux kernel 3.8 and above has this support, as well as any current-generation instance.

BurstBalance displays the burst bucket balance for gp2, st1, and sc1 volumes as a percentage of the remaining balance. When your burst bucket is depleted, volume I/O (for gp2 volumes) or volume throughput (for st1 and sc1 volumes) is throttled to the baseline. Check the BurstBalance value to determine whether your volume is being throttled for this reason. For a complete list of the available Amazon EBS metrics, see Amazon CloudWatch metrics for Amazon EBS and Amazon EBS metrics for Nitro-based instances.

**Related resources**
For more information about Amazon EBS I/O characteristics, see the following re:Invent presentation: Amazon EBS: Designing for Performance.

**Initialize Amazon EBS volumes**
Empty EBS volumes receive their maximum performance the moment that they are created and do not require initialization (formerly known as pre-warming).

For volumes that were created from snapshots, the storage blocks must be pulled down from Amazon S3 and written to the volume before you can access them. This preliminary action takes time and can cause a significant increase in the latency of I/O operations the first time each block is accessed. Volume performance is achieved after all blocks have been downloaded and written to the volume.

**Important**
While initializing Provisioned IOPS SSD volumes that were created from snapshots, the performance of the volume may drop below 50 percent of its expected level, which causes the volume to display a warning state in the I/O Performance status check. This is expected, and you can ignore the warning state on Provisioned IOPS SSD volumes while you are initializing them. For more information, see EBS volume status checks.

For most applications, amortizing the initialization cost over the lifetime of the volume is acceptable. To avoid this initial performance hit in a production environment, you can use one of the following options:
• Force the immediate initialization of the entire volume. For more information, see Initialize Amazon EBS volumes on Linux (p. 2380).
• Enable fast snapshot restore on a snapshot to ensure that the EBS volumes created from it are fully-initialized at creation and instantly deliver all of their provisioned performance. For more information, see Amazon EBS fast snapshot restore (p. 2329).

Initialize Amazon EBS volumes on Linux

Empty EBS volumes receive their maximum performance the moment that they are available and do not require initialization (formerly known as pre-warming). For volumes that have been created from snapshots, use the dd or fio utilities to read from all of the blocks on a volume. All existing data on the volume will be preserved.

For information about initializing Amazon EBS volumes on Windows, see Initializing Amazon EBS volumes on Windows.

To initialize a volume created from a snapshot on Linux

1. Attach the newly-restored volume to your Linux instance.
2. Use the lsblk command to list the block devices on your instance.

```
[ec2-user ~]$ lsblk
NAME   MAJ:MIN RM SIZE RO TYPE MOUNTPOINT
xvdf   202:80  0  30G  0 disk
xvda1 202:1   0   8G  0 disk /
```

Here you can see that the new volume, /dev/xvdf, is attached, but not mounted (because there is no path listed under the MOUNTPOINT column).

3. Use the dd or fio utilities to read all of the blocks on the device. The dd command is installed by default on Linux systems, but fio is considerably faster because it allows multi-threaded reads.

   **Note**
   This step may take several minutes up to several hours, depending on your EC2 instance bandwidth, the IOPS provisioned for the volume, and the size of the volume.

   **[dd]** The if (input file) parameter should be set to the drive you wish to initialize. The of (output file) parameter should be set to the Linux null virtual device, /dev/null. The bs parameter sets the block size of the read operation; for optimal performance, this should be set to 1 MB.

   **Important**
   Incorrect use of dd can easily destroy a volume's data. Be sure to follow precisely the example command below. Only the if=/dev/xvdf parameter will vary depending on the name of the device you are reading.

```
[ec2-user ~]$ sudo dd if=/dev/xvdf of=/dev/null bs=1M
```

   **[fio]** If you have fio installed on your system, use the following command to initialize your volume. The --filename (input file) parameter should be set to the drive you wish to initialize.

```
[ec2-user ~]$ sudo fio --filename=/dev/xvdf --rw=read --bs=1M --iodepth=32 --ioengine=libaio --direct=1 --name=volume-initialize
```

To install fio on Amazon Linux, use the following command:

```
sudo yum install -y fio
```
To install **fio** on Ubuntu, use the following command:

```
sudo apt-get install -y fio
```

When the operation is finished, you will see a report of the read operation. Your volume is now ready for use. For more information, see Make an Amazon EBS volume available for use on Linux (p. 2083).

**RAID configuration on Linux**

With Amazon EBS, you can use any of the standard RAID configurations that you can use with a traditional bare metal server, as long as that particular RAID configuration is supported by the operating system for your instance. This is because all RAID is accomplished at the software level.

Amazon EBS volume data is replicated across multiple servers in an Availability Zone to prevent the loss of data from the failure of any single component. This replication makes Amazon EBS volumes ten times more reliable than typical commodity disk drives. For more information, see Amazon EBS Availability and Durability in the Amazon EBS product detail pages.

**Note**

You should avoid booting from a RAID volume. Grub is typically installed on only one device in a RAID array, and if one of the mirrored devices fails, you may be unable to boot the operating system.

If you need to create a RAID array on a Windows instance, see RAID configuration on Windows in the Amazon EC2 User Guide for Windows Instances.

**Contents**

- RAID configuration options (p. 2381)
- Create a RAID 0 array on Linux (p. 2382)
- Create snapshots of volumes in a RAID array (p. 2385)

**RAID configuration options**

Creating a RAID 0 array allows you to achieve a higher level of performance for a file system than you can provision on a single Amazon EBS volume. Use RAID 0 when I/O performance is of the utmost importance. With RAID 0, I/O is distributed across the volumes in a stripe. If you add a volume, you get the straight addition of throughput and IOPS. However, keep in mind that performance of the stripe is limited to the worst performing volume in the set, and that the loss of a single volume in the set results in a complete data loss for the array.

The resulting size of a RAID 0 array is the sum of the sizes of the volumes within it, and the bandwidth is the sum of the available bandwidth of the volumes within it. For example, two 500 GiB io1 volumes with 4,000 provisioned IOPS each create a 1000 GiB RAID 0 array with an available bandwidth of 8,000 IOPS and 1,000 MiB/s of throughput.

**Important**

RAID 5 and RAID 6 are not recommended for Amazon EBS because the parity write operations of these RAID modes consume some of the IOPS available to your volumes. Depending on the configuration of your RAID array, these RAID modes provide 20-30% fewer usable IOPS than a RAID 0 configuration. Increased cost is a factor with these RAID modes as well; when using identical volume sizes and speeds, a 2-volume RAID 0 array can outperform a 4-volume RAID 6 array that costs twice as much.

RAID 1 is also not recommended for use with Amazon EBS. RAID 1 requires more Amazon EC2 to Amazon EBS bandwidth than non-RAID configurations because the data is written to
multiple volumes simultaneously. In addition, RAID 1 does not provide any write performance improvement.

**Create a RAID 0 array on Linux**

This documentation provides a basic RAID 0 setup example.

Before you perform this procedure, you need to decide how large your RAID 0 array should be and how many IOPS you want to provision.

Use the following procedure to create a RAID 0 array. Note that you can get directions for Windows instances from [Create a RAID 0 array on Windows](#) in the Amazon EC2 User Guide for Windows Instances.

**To create a RAID 0 array on Linux**

1. Create the Amazon EBS volumes for your array. For more information, see [Create an Amazon EBS volume](#).
   
   **Important**
   
   Create volumes with identical size and IOPS performance values for your array. Make sure you do not create an array that exceeds the available bandwidth of your EC2 instance. For more information, see [Amazon EBS–optimized instances](#).

2. Attach the Amazon EBS volumes to the instance that you want to host the array. For more information, see [Attach an Amazon EBS volume to an instance](#).

3. Use the **mdadm** command to create a logical RAID device from the newly attached Amazon EBS volumes. Substitute the number of volumes in your array for `number_of_volumes` and the device names for each volume in the array (such as `/dev/xvdf`) for `device_name`. You can also substitute `MY_RAID` with your own unique name for the array.

   **Note**
   
   You can list the devices on your instance with the **lsblk** command to find the device names.

   To create a RAID 0 array, run the following command (note the `--level=0` option to stripe the array):

   ```bash
   [ec2-user ~]$ sudo mdadm --create --verbose /dev/md0 --level=0 --name=MY_RAID --raid-devices=number_of_volumes device_name1 device_name2
   ```

   **Tip**
   
   If you get the `mdadm: command not found` error, use the following command to install `mdadm`: `sudo yum install mdadm`.

4. Allow time for the RAID array to initialize and synchronize. You can track the progress of these operations with the following command:

   ```bash
   [ec2-user ~]$ sudo cat /proc/mdstat
   ```

   The following is example output:

   ```
   Personalities : [raid0]
   md0 : active raid0 xvdc[1] xvdb[0]
   4191072 blocks super 1.2 512k chunks
   unused devices: <none>
   ```

   In general, you can display detailed information about your RAID array with the following command:

   ```bash
   [ec2-user ~]$ sudo mdadm --detail /dev/md0
   ```
The following is example output:

```
/dev/md0:
  Version : 1.2
  Creation Time : Wed May 19 11:12:56 2021
  Raid Level : raid0
  Array Size : 41910272 (39.97 GiB 42.92 GB)
  Raid Devices : 2
  Total Devices : 2
  Persistence : Superblock is persistent
  Update Time : Wed May 19 11:12:56 2021
  State : clean
  Active Devices : 2
  Working Devices : 2
  Failed Devices : 0
  Spare Devices : 0
  Chunk Size : 512K
  Consistency Policy : none
  Name : MY_RAID
  UUID : 646aa723:db31bbcc7:13c43d9f:d5c51e0c
  Events : 0
  Number   Major   Minor   RaidDevice State
  0     202       16        0      active sync   /dev/sdb
  1     202       32        1      active sync   /dev/sdc
```

5. Create a file system on your RAID array, and give that file system a label to use when you mount it later. For example, to create an ext4 file system with the label `MY_RAID`, run the following command:

```
[ec2-user ~]$ sudo mkfs.ext4 -L MY_RAID /dev/md0
```

Depending on the requirements of your application or the limitations of your operating system, you can use a different file system type, such as ext3 or XFS (consult your file system documentation for the corresponding file system creation command).

6. To ensure that the RAID array is reassembled automatically on boot, create a configuration file to contain the RAID information:

```
[ec2-user ~]$ sudo mdadm --detail --scan | sudo tee -a /etc/mdadm.conf
```

**Note**
If you are using a Linux distribution other than Amazon Linux, you might need to modify this command. For example, you might need to place the file in a different location, or you might need to add the `--examine` parameter. For more information, run `man mdadm.conf` on your Linux instance.

7. Create a new ramdisk image to properly preload the block device modules for your new RAID configuration:

```
[ec2-user ~]$ sudo dracut -H -f /boot/initramfs-$(uname -r).img $(uname -r)
```

8. Create a mount point for your RAID array.

```
[ec2-user ~]$ sudo mkdir -p /mnt/raid
```
9. Finally, mount the RAID device on the mount point that you created:

```
[ec2-user ~]$ sudo mount LABEL=MY_RAID /mnt/raid
```

Your RAID device is now ready for use.

10. (Optional) To mount this Amazon EBS volume on every system reboot, add an entry for the device to the `/etc/fstab` file.

   a. Create a backup of your `/etc/fstab` file that you can use if you accidentally destroy or delete this file while you are editing it.

```
[ec2-user ~]$ sudo cp /etc/fstab /etc/fstab.orig
```

   b. Open the `/etc/fstab` file using your favorite text editor, such as `nano` or `vim`.

   c. Comment out any lines starting with "UUID=" and, at the end of the file, add a new line for your RAID volume using the following format:

```
device_label mount_point file_system_type fs_mntops fs_freq fs_passno
```

The last three fields on this line are the file system mount options, the dump frequency of the file system, and the order of file system checks done at boot time. If you don't know what these values should be, then use the values in the example below for them (defaults, nofail 0 2). For more information about `/etc/fstab` entries, see the `fstab` manual page (by entering `man fstab` on the command line). For example, to mount the ext4 file system on the device with the label MY_RAID at the mount point `/mnt/raid`, add the following entry to `/etc/fstab`.

```
LABEL=MY_RAID       /mnt/raid   ext4    defaults,nofail        0       2
```

   d. After you've added the new entry to `/etc/fstab`, you need to check that your entry works. Run the `sudo mount -a` command to mount all file systems in `/etc/fstab`.

```
[ec2-user ~]$ sudo mount -a
```

If the previous command does not produce an error, then your `/etc/fstab` file is OK and your file system will mount automatically at the next boot. If the command does produce any errors, examine the errors and try to correct your `/etc/fstab`.

   Note

If you ever intend to boot your instance without this volume attached (for example, so this volume could move back and forth between different instances), you should add the nofail mount option that allows the instance to boot even if there are errors in mounting the volume. Debian derivatives, such as Ubuntu, must also add the nobootwait mount option.

```
LABEL=MY_RAID /mnt/raid ext4 defaults,nofail 0 2
```

   e. (Optional) If you are unsure how to correct `/etc/fstab` errors, you can always restore your backup `/etc/fstab` file with the following command.

```
[ec2-user ~]$ sudo mv /etc/fstab.orig /etc/fstab
```
Create snapshots of volumes in a RAID array

If you want to back up the data on the EBS volumes in a RAID array using snapshots, you must ensure that the snapshots are consistent. This is because the snapshots of these volumes are created independently. To restore EBS volumes in a RAID array from snapshots that are out of sync would degrade the integrity of the array.

To create a consistent set of snapshots for your RAID array, use EBS multi-volume snapshots. Multi-volume snapshots allow you to take point-in-time, data coordinated, and crash-consistent snapshots across multiple EBS volumes attached to an EC2 instance. You do not have to stop your instance to coordinate between volumes to ensure consistency because snapshots are automatically taken across multiple EBS volumes. For more information, see the steps for creating multi-volume snapshots under Creating Amazon EBS snapshots.

Benchmark EBS volumes

You can test the performance of Amazon EBS volumes by simulating I/O workloads. The process is as follows:

1. Launch an EBS-optimized instance.
2. Create new EBS volumes.
3. Attach the volumes to your EBS-optimized instance.
4. Configure and mount the block device.
5. Install a tool to benchmark I/O performance.
7. Delete your volumes and terminate your instance so that you don’t continue to incur charges.

Important
Some of the procedures result in the destruction of existing data on the EBS volumes you benchmark. The benchmarking procedures are intended for use on volumes specially created for testing purposes, not production volumes.

Set up your instance

To get optimal performance from EBS volumes, we recommend that you use an EBS-optimized instance. EBS-optimized instances deliver dedicated throughput between Amazon EC2 and Amazon EBS, with instance. EBS-optimized instances deliver dedicated bandwidth between Amazon EC2 and Amazon EBS, with specifications depending on the instance type. For more information, see Amazon EBS–optimized instances (p. 2339).

To create an EBS-optimized instance, choose **Launch as an EBS-Optimized instance** when launching the instance using the Amazon EC2 console, or specify **--ebs-optimized** when using the command line. Be sure that you launch a current-generation instance that supports this option. For more information, see Amazon EBS–optimized instances (p. 2339).

Set up Provisioned IOPS SSD or General Purpose SSD volumes

To create Provisioned IOPS SSD (io1 and io2) or General Purpose SSD (gp2 and gp3) volumes using the Amazon EC2 console, for **Volume type**, choose **Provisioned IOPS SSD (io1)**, **Provisioned IOPS SSD (io2)**, **General Purpose SSD (gp2)**, or **General Purpose SSD (gp3)**. At the command line, specify io1, io2, gp2, or gp3 for the **--volume-type** parameter. For io1, io2, and gp3 volumes, specify the number of I/O operations per second (IOPS) for the **--iops** parameter. For more information, see Amazon EBS volume types (p. 2055) and Create an Amazon EBS volume (p. 2073).

For the example tests, we recommend that you create a RAID 0 array with 6 volumes, which offers a high level of performance. Because you are charged by gigabytes provisioned (and the number of
provisioned IOPS for io1, io2, and gp3 volumes), not the number of volumes, there is no additional cost for creating multiple, smaller volumes and using them to create a stripe set. If you're using Oracle Orion to benchmark your volumes, it can simulate striping the same way that Oracle ASM does, so we recommend that you let Orion do the striping. If you are using a different benchmarking tool, you need to stripe the volumes yourself.

For instructions on how to create a RAID 0 array with 6 volumes, see Create a RAID 0 array on Linux (p. 2382).

Set up Throughput Optimized HDD (st1) or Cold HDD (sc1) volumes

To create an st1 volume, choose Throughput Optimized HDD when creating the volume using the Amazon EC2 console, or specify --type st1 when using the command line. To create an sc1 volume, choose Cold HDD when creating the volume using the Amazon EC2 console, or specify --type sc1 when using the command line. For information about creating EBS volumes, see Create an Amazon EBS volume (p. 2073). For information about attaching these volumes to your instance, see Attach an Amazon EBS volume to an instance (p. 2076).

AWS provides a JSON template for use with AWS CloudFormation that simplifies this setup procedure. Access the template and save it as a JSON file. AWS CloudFormation allows you to configure your own SSH keys and offers an easier way to set up a performance test environment to evaluate st1 volumes. The template creates a current-generation instance and a 2 TiB st1 volume, and attaches the volume to the instance at /dev/xvdf.

To create an HDD volume using the template

3. Choose Upload a Template to Amazon S3 and select the JSON template you previously obtained.
4. Give your stack a name like "ebs-perf-testing", and select an instance type (the default is r3.8xlarge) and SSH key.
5. Choose Next twice, and then choose Create Stack.
6. After the status for your new stack moves from CREATE_IN_PROGRESS to COMPLETE, choose Outputs to get the public DNS entry for your new instance, which will have a 2 TiB st1 volume attached to it.
7. Connect using SSH to your new stack as user ec2-user, with the hostname obtained from the DNS entry in the previous step.
8. Proceed to Install benchmark tools (p. 2386).

Install benchmark tools

The following table lists some of the possible tools you can use to benchmark the performance of EBS volumes.

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fio</td>
<td>For benchmarking I/O performance. (Note that fio has a dependency on libaio-devel.)</td>
</tr>
</tbody>
</table>

To install fio on Amazon Linux, run the following command:

```
[ec2-user ~]$ sudo yum install -y fio
```

To install fio on Ubuntu, run the following command:
### Tool | Description
--- | ---
 sudo apt-get install -y fio |

**Oracle Orion Calibration Tool**

For calibrating the I/O performance of storage systems to be used with Oracle databases.

These benchmarking tools support a wide variety of test parameters. You should use commands that approximate the workloads your volumes will support. These commands provided below are intended as examples to help you get started.

**Choose the volume queue length**

Choosing the best volume queue length based on your workload and volume type.

#### Queue length on SSD-backed volumes

To determine the optimal queue length for your workload on SSD-backed volumes, we recommend that you target a queue length of 1 for every 1000 IOPS available (baseline for General Purpose SSD volumes and the provisioned amount for Provisioned IOPS SSD volumes). Then you can monitor your application performance and tune that value based on your application requirements.

Increasing the queue length is beneficial until you achieve the provisioned IOPS, throughput or optimal system queue length value, which is currently set to 32. For example, a volume with 3,000 provisioned IOPS should target a queue length of 3. You should experiment with tuning these values up or down to see what performs best for your application.

#### Queue length on HDD-backed volumes

To determine the optimal queue length for your workload on HDD-backed volumes, we recommend that you target a queue length of at least 4 while performing 1MiB sequential I/Os. Then you can monitor your application performance and tune that value based on your application requirements. For example, a 2 TiB st1 volume with burst throughput of 500 MiB/s and IOPS of 500 should target a queue length of 4, 8, or 16 while performing 1,024 KiB, 512 KiB, or 256 KiB sequential I/Os respectively. You should experiment with tuning these values up or down to see what performs best for your application.

**Disable C-states**

Before you run benchmarking, you should disable processor C-states. Temporarily idle cores in a supported CPU can enter a C-state to save power. When the core is called on to resume processing, a certain amount of time passes until the core is again fully operational. This latency can interfere with processor benchmarking routines. For more information about C-states and which EC2 instance types support them, see Processor state control for your EC2 instance.

**Disable C-states on Linux**

You can disable C-states on Amazon Linux, RHEL, and CentOS as follows:

1. Get the number of C-states.

   ```bash
   $ cpupower idle-info | grep "Number of idle states:"
   ```

2. Disable the C-states from c1 to cN. Ideally, the cores should be in state c0.

   ```bash
   $ for i in `seq 1 $((N-1))`; do cpupower idle-set -d $i; done
   ```
Perform benchmarking

The following procedures describe benchmarking commands for various EBS volume types.

Run the following commands on an EBS-optimized instance with attached EBS volumes. If the EBS volumes were created from snapshots, be sure to initialize them before benchmarking. For more information, see Initialize Amazon EBS volumes (p. 2379).

When you are finished testing your volumes, see the following topics for help cleaning up: Delete an Amazon EBS volume (p. 2106) and Terminate your instance (p. 800).

Benchmark Provisioned IOPS SSD and General Purpose SSD volumes

Run fio on the RAID 0 array that you created.

The following command performs 16 KB random write operations.

```
[ec2-user ~]$ sudo fio --directory=/mnt/p_iops_vol0 --ioengine=psync --name fio_test_file --direct=1 --rw=randwrite --bs=16k --size=1G --numjobs=16 --time_based --runtime=180 --group_reporting --norandommap
```

The following command performs 16 KB random read operations.

```
[ec2-user ~]$ sudo fio --directory=/mnt/p_iops_vol0 --name fio_test_file --direct=1 --rw=randread --bs=16k --size=1G --numjobs=16 --time_based --runtime=180 --group_reporting --norandommap
```

For more information about interpreting the results, see this tutorial: Inspecting disk IO performance with fio.

Benchmark st1 and sc1 volumes

Run fio on your st1 or sc1 volume.

**Note**

Prior to running these tests, set buffered I/O on your instance as described in Increase read-ahead for high-throughput, read-heavy workloads on st1 and sc1 (p. 2374).

The following command performs 1 MiB sequential read operations against an attached st1 block device (for example, /dev/xvdf):

```
[ec2-user ~]$ sudo fio --filename=/dev/<device> --direct=1 --rw=read --randrepeat=0 --ioengine=libaio --bs=1024k --iodepth=8 --time_based=1 --runtime=180 --name=fio_direct_read_test
```

The following command performs 1 MiB sequential write operations against an attached st1 block device:

```
[ec2-user ~]$ sudo fio --filename=/dev/<device> --direct=1 --rw=write --randrepeat=0 --ioengine=libaio --bs=1024k --iodepth=8 --time_based=1 --runtime=180 --name=fio_direct_write_test
```

Some workloads perform a mix of sequential reads and sequential writes to different parts of the block device. To benchmark such a workload, we recommend that you use separate, simultaneous fio jobs for reads and writes, and use the fio offset_increment option to target different block device locations for each job.
Running this workload is a bit more complicated than a sequential-write or sequential-read workload. Use a text editor to create a fio job file, called fio_rw_mix.cfg in this example, that contains the following:

```
[global]
clocksource=clock_gettime
randrepeat=0
runtime=180

[sequential-write]
bs=1M
ioengine=libaio
direct=1
iodepth=8
filename=/dev/<device>
do_verify=0
clock_gettime
rwmixread=0
rwmixwrite=100

[sequential-read]
bs=1M
ioengine=libaio
direct=1
iodepth=8
filename=/dev/<device>
do_verify=0
clock_gettime
rwmixread=100
rwmixwrite=0
offset=100g
```

Then run the following command:

```
[ec2-user ~]$ sudo fio fio_rw_mix.cfg
```

For more information about interpreting the results, see this tutorial: [Inspecting disk I/O performance with fio](#).

Multiple fio jobs for direct I/O, even though using sequential read or write operations, can result in lower than expected throughput for st1 and sc1 volumes. We recommend that you use one direct I/O job and use the iodepth parameter to control the number of concurrent I/O operations.

### Amazon CloudWatch metrics for Amazon EBS

Amazon CloudWatch metrics are statistical data that you can use to view, analyze, and set alarms on the operational behavior of your volumes.

Data is available automatically in 1-minute periods at no charge.

When you get data from CloudWatch, you can include a Period request parameter to specify the granularity of the returned data. This is different than the period that we use when we collect the data (1-minute periods). We recommend that you specify a period in your request that is equal to or greater than the collection period to ensure that the returned data is valid.

You can get the data using either the CloudWatch API or the Amazon EC2 console. The console takes the raw data from the CloudWatch API and displays a series of graphs based on the data. Depending on your needs, you might prefer to use either the data from the API or the graphs in the console.

**Topics**
The AWS/EBS namespace includes the following metrics for EBS volumes that are attached to all instance types. All Amazon EBS volume types automatically send 1-minute metrics to CloudWatch, but only when the volume is attached to an instance.

To get information about the available disk space from the operating system on an instance, see View free disk space (p. 2089).

**Note**
Some metrics have differences on instances that are built on the Nitro System. For a list of these instance types, see Instances built on the Nitro System (p. 295).

### EBS CloudWatch metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Units</th>
<th>Dimensions</th>
<th>Meaningful statistics</th>
</tr>
</thead>
</table>
| VolumeThroughputPercentage  | The percentage of I/O operations per second (IOPS) delivered of the total IOPS provisioned for an Amazon EBS volume. Provisioned IOPS SSD volumes deliver their provisioned performance 99.9 percent of the time. During a write, if there are no other pending I/O requests in a minute, the metric value will be 100 percent. Also, a volume's I/O performance may become degraded temporarily due to an action you have taken (for example, creating a snapshot of a volume during peak usage, running the volume on a non-EBS-optimized instance, or accessing data on the volume for the first time). | Percent  | VolumeId   | • Average  
• Minimum | Maximum |
| VolumeConsumedReadWriteOps  | The total amount of read and write operations (normalized to 256K capacity units) consumed in a specified period of time. I/O operations that are smaller than 256K each count as 1 consumed IOPS. I/O operations that are larger than 256K are counted in 256K capacity units. For example, a 1024K I/O would count as 4 consumed IOPS. | Count   | VolumeId   | • Average  
• Sum  
• Minimum | Maximum |
### EBS CloudWatch metrics

### Metrics for Nitro instances

The AWS/EC2 namespace includes additional Amazon EBS metrics for volumes that are attached to Nitro-based instances that are not bare metal instances.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBSReadOps</td>
<td>Completed read operations from all Amazon EBS volumes attached to the instance in a specified period of time. To calculate the average read I/O operations per second (Read IOPS) for the period, divide the total operations in the period by the number of seconds in that period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to calculate the Read IOPS. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function DIFF_TIME to find the operations per second. For example, if you have graphed EBSReadOps</td>
</tr>
<tr>
<td>Metric</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>EBSWriteOps</td>
<td>Completed write operations to all EBS volumes attached to the instance in a specified period of time.</td>
</tr>
<tr>
<td></td>
<td>To calculate the average write I/O operations per second (Write IOPS) for the period, divide the total operations in the period by the number of seconds in that period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to calculate the Write IOPS. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function DIFF_TIME to find the operations per second. For example, if you have graphed EBSWriteOps in CloudWatch as m1, the metric math formula m1/(DIFF_TIME(m1)) returns the metric in operations/second. For more information about DIFF_TIME and other metric math functions, see Use metric math in the Amazon CloudWatch User Guide.</td>
</tr>
<tr>
<td>EBSReadBytes</td>
<td>Bytes read from all EBS volumes attached to the instance in a specified period of time.</td>
</tr>
</tbody>
</table>
# EBS CloudWatch metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBSWriteBytes</td>
<td>Bytes written to all EBS volumes attached to the instance in a specified period of time. The number reported is the number of bytes written during the period. If you are using basic (5-minute) monitoring, you can divide this number by 300 to find Write Bytes/second. If you have detailed (1-minute) monitoring, divide it by 60. You can also use the CloudWatch metric math function DIFF_TIME to find the bytes per second. For example, if you have graphed EBSWriteBytes in CloudWatch as m1, the metric math formula m1/(DIFF_TIME(m1)) returns the metric in bytes/second. For more information about DIFF_TIME and other metric math functions, see Use metric math in the Amazon CloudWatch User Guide. Unit: Bytes</td>
</tr>
<tr>
<td>EBSIOBalance%</td>
<td>Provides information about the percentage of I/O credits remaining in the burst bucket. This metric is available for basic monitoring only. This metric is available only for some <em>.4xlarge instance sizes and smaller that burst to their maximum performance for only 30 minutes at least once every 24 hours. For a complete list of instance sizes that support this metric, see the instances types indicated with an asterisk (</em>) in the Instance size column in the EBS optimized by default (p. 2340) table. The Sum statistic is not applicable to this metric. Unit: Percent</td>
</tr>
<tr>
<td>EBSByteBalance%</td>
<td>Provides information about the percentage of throughput credits remaining in the burst bucket. This metric is available for basic monitoring only. This metric is available only for some <em>.4xlarge instance sizes and smaller that burst to their maximum performance for only 30 minutes at least once every 24 hours. For a complete list of instance sizes that support this metric, see the instances types indicated with an asterisk (</em>) in the Instance size column in the EBS optimized by default (p. 2340) table. The Sum statistic is not applicable to this metric. Unit: Percent</td>
</tr>
</tbody>
</table>

## Metrics for fast snapshot restore

AWS/EBS namespace includes the following metrics for fast snapshot restore (p. 2329).
Amazon Elastic Compute Cloud
User Guide for Linux Instances
EBS CloudWatch metrics

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
<th>Units</th>
<th>Dimensions</th>
<th>Meaningful statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>FastSnapshotRestoreCreditsBucketSize</td>
<td>The maximum number of volume create credits that can be accumulated. This metric is reported per snapshot per Availability Zone.</td>
<td></td>
<td>SnapshotId, Availability</td>
<td>• Average</td>
</tr>
<tr>
<td>FastSnapshotRestoreCreditsBalance</td>
<td>The number of volume create credits available. This metric is reported per snapshot per Availability Zone.</td>
<td></td>
<td>SnapshotId, Availability</td>
<td>• Average</td>
</tr>
</tbody>
</table>

Note: The most meaningful statistic is Average. The results for the Minimum and Maximum statistics are the same as for Average and could be used instead.

Amazon EC2 console graphs

After you create a volume, you can view the volume’s monitoring graphs in the Amazon EC2 console. Select a volume on the Volumes page in the console and choose Monitoring. The following table lists the graphs that are displayed. The column on the right describes how the raw data metrics from the CloudWatch API are used to produce each graph. The period for all the graphs is 5 minutes.

<table>
<thead>
<tr>
<th>Graph</th>
<th>Description using raw metrics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Read throughput (KiB/s)</td>
<td>Sum(VolumeReadBytes) / Period / 1024</td>
</tr>
<tr>
<td>Write throughput (KiB/s)</td>
<td>Sum(VolumeWriteBytes) / Period / 1024</td>
</tr>
<tr>
<td>Read operations (Ops/s)</td>
<td>Sum(VolumeReadOps) / Period</td>
</tr>
<tr>
<td>Write operations (Ops/s)</td>
<td>Sum(VolumeWriteOps) / Period</td>
</tr>
<tr>
<td>Average queue length (Operations)</td>
<td>Avg(VolumeQueueLength)</td>
</tr>
<tr>
<td>Time spent idle (%)</td>
<td>Sum(VolumeIdleTime) / Period × 100</td>
</tr>
<tr>
<td>Average read size (KiB/op)</td>
<td>Avg(VolumeReadBytes) / 1024</td>
</tr>
<tr>
<td>Average write size (KiB/op)</td>
<td>Avg(VolumeWriteBytes) / 1024</td>
</tr>
</tbody>
</table>

For Nitro-based instances, the following formula derives Average Read Size using CloudWatch Metric Math:

\[
\frac{(\text{Sum(VolumeReadBytes)})}{(\text{Sum(VolumeReadOps))}} \div 1024
\]

The VolumeReadBytes and VolumeReadOps metrics are available in the EBS CloudWatch console.

2399
### Graph

<table>
<thead>
<tr>
<th>Graph</th>
<th>Description using raw metrics</th>
</tr>
</thead>
</table>
| Average read latency (ms/op) | $\text{Avg}(\text{VolumeTotalReadTime}) \times 1000$  
For Nitro-based instances, the following formula derives Average Read Latency using CloudWatch Metric Math:  
$\frac{(\text{Sum}(\text{VolumeTotalReadTime}) / \text{Sum}(\text{VolumeReadOps}))}{1000}$  
The VolumeTotalReadTime and VolumeReadOps metrics are available in the EBS CloudWatch console. |
| Average write latency (ms/op) | $\text{Avg}(\text{VolumeTotalWriteTime}) \times 1000$  
For Nitro-based instances, the following formula derives Average Write Latency using CloudWatch Metric Math:  
$\frac{(\text{Sum}(\text{VolumeTotalWriteTime}) / \text{Sum}(\text{VolumeWriteOps}))}{1000}$  
The VolumeTotalWriteTime and VolumeWriteOps metrics are available in the EBS CloudWatch console. |

For the average latency graphs and average size graphs, the average is calculated over the total number of operations (read or write, whichever is applicable to the graph) that completed during the period.

### EventBridge for Amazon EBS

Amazon EBS sends events to Amazon EventBridge for actions performed on volumes and snapshots. With EventBridge, you can establish rules that trigger programmatic actions in response to these events. For example, you can create a rule that sends a notification to your email when a snapshot is enabled for fast snapshot restore.

Events in EventBridge are represented as JSON objects. The fields that are unique to the event are contained in the "detail" section of the JSON object. The "event" field contains the event name. The "result" field contains the completed status of the action that triggered the event. For more information, see Amazon EventBridge event patterns in the Amazon EventBridge User Guide.

For more information, see [What Is Amazon EventBridge?](#) in the Amazon EventBridge User Guide.

#### Events

- [EBS volume events](#) (p. 2401)
- [EBS volume modification events](#) (p. 2403)
- [EBS snapshot events](#) (p. 2404)
- [EBS Snapshots Archive events](#) (p. 2408)
- [EBS fast snapshot restore events](#) (p. 2408)
- [Using AWS Lambda to handle EventBridge events](#) (p. 2409)
EBS volume events

Amazon EBS sends events to EventBridge when the following volume events occur.

Events

- Create volume (createVolume) (p. 2401)
- Delete volume (deleteVolume) (p. 2402)
- Volume attach or reattach (attachVolume, reattachVolume) (p. 2402)

Create volume (createVolume)

The createVolume event is sent to your AWS account when an action to create a volume completes. However, it is not saved, logged, or archived. This event can have a result of either available or failed. Creation will fail if an invalid AWS KMS key was provided, as shown in the examples below.

Event data

The listing below is an example of a JSON object emitted by EBS for a successful createVolume event.

```
{  "version": "0",  "id": "01234567-0123-0123-0123-012345678901",  "detail-type": "EBS Volume Notification",  "source": "aws.ec2",  "account": "012345678901",  "time": "yyyy-mm-ddThh:mm:ssZ",  "region": "us-east-1",  "resources": [    "arn:aws:ec2:us-east-1:012345678901:volume/vol-01234567"  ],  "detail": {    "result": "available",    "cause": "",    "event": "createVolume",    "request-id": "01234567-0123-0123-0123-0123456789ab"  }}
```

The listing below is an example of a JSON object emitted by EBS after a failed createVolume event. The cause for the failure was a disabled KMS key.

```
```
The following is an example of a JSON object that is emitted by EBS after a failed `createVolume` event. The cause for the failure was a KMS key pending import.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-0123456789ab",
    "detail-type": "EBS Volume Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "sa-east-1",
    "resources": [
    ],
    "detail": {
        "event": "createVolume",
        "result": "failed",
        "cause": "arn:aws:kms:sa-east-1:0123456789ab:key/01234567-0123-0123-0123-0123456789ab is pending import.",
        "request-id": "01234567-0123-0123-0123-0123456789ab",
    }
}
```

**Delete volume (deleteVolume)**

The `deleteVolume` event is sent to your AWS account when an action to delete a volume completes. However it is not saved, logged, or archived. This event has the result `deleted`. If the deletion does not complete, the event is never sent.

**Event data**

The listing below is an example of a JSON object emitted by EBS for a successful `deleteVolume` event.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-0123456789ab",
    "detail-type": "EBS Volume Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2:us-east-1:012345678901:volume/vol-01234567"
    ],
    "detail": {
        "result": "deleted",
        "cause": "",
        "event": "deleteVolume",
        "request-id": "01234567-0123-0123-0123-0123456789ab"
    }
}
```

**Volume attach or reattach (attachVolume, reattachVolume)**

The `attachVolume` or `reattachVolume` event is sent to your AWS account if a volume fails to attach or reattach to an instance. However it is not saved, logged, or archived. If you use a KMS key to encrypt an EBS volume and the KMS key becomes invalid, EBS will emit an event if that KMS key is later used to attach or reattach to an instance, as shown in the examples below.
Event data

The listing below is an example of a JSON object emitted by EBS after a failed attachVolume event. The cause for the failure was a KMS key pending deletion.

**Note**

AWS may attempt to reattach to a volume following routine server maintenance.

```json
{
"version": "0",
"id": "01234567-0123-0123-0123-0123456789ab",
"detail-type": "EBS Volume Notification",
"source": "aws.ec2",
"account": "012345678901",
"time": "yyyy-mm-ddThh:mm:ssZ",
"region": "us-east-1",
"resources": [
  "arn:aws:kms:us-east-1:0123456789ab:key/01234567-0123-0123-0123456789ab"
],
"detail": {
  "event": "attachVolume",
  "result": "failed",
  "cause": "arn:aws:kms:us-east-1:0123456789ab:key/01234567-0123-0123-0123456789ab
is pending deletion.",
  "request-id": ""
}
}
```

The listing below is an example of a JSON object emitted by EBS after a failed reattachVolume event. The cause for the failure was a KMS key pending deletion.

```json
{
"version": "0",
"id": "01234567-0123-0123-0123-0123456789ab",
"detail-type": "EBS Volume Notification",
"source": "aws.ec2",
"account": "012345678901",
"time": "yyyy-mm-ddThh:mm:ssZ",
"region": "us-east-1",
"resources": [
  "arn:aws:kms:us-east-1:0123456789ab:key/01234567-0123-0123-0123456789ab"
],
"detail": {
  "event": "reattachVolume",
  "result": "failed",
  "cause": "arn:aws:kms:us-east-1:0123456789ab:key/01234567-0123-0123-0123456789ab
is pending deletion.",
  "request-id": ""
}
}
```

**EBS volume modification events**

Amazon EBS sends modifyVolume events to EventBridge when a volume is modified. However it is not saved, logged, or archived.

```json
{
"version": "0",
"id": "01234567-0123-0123-0123-012345678901",
"detail-type": "EBS Volume Notification",
"source": "aws.ec2",
"account": "012345678901",
"time": "yyyy-mm-ddThh:mm:ssZ",
"region": "us-east-1",
"resources": [
  "arn:aws:kms:us-east-1:0123456789ab:key/01234567-0123-0123-0123456789ab"
],
"detail": {
  "event": "modifyVolume",
  "result": "failed",
  "cause": "arn:aws:kms:us-east-1:0123456789ab:key/01234567-0123-0123-0123456789ab
is pending deletion.",
  "request-id": ""
}
}
```
EBS snapshot events

Amazon EBS sends events to EventBridge when the following volume events occur.

Events
- Create snapshot (createSnapshot) (p. 2404)
- Create snapshots (createSnapshots) (p. 2405)
- Copy snapshot (copySnapshot) (p. 2406)
- Share snapshot (shareSnapshot) (p. 2407)

Create snapshot (createSnapshot)

The createSnapshot event is sent to your AWS account when an action to create a snapshot completes. However it is not saved, logged, or archived. This event can have a result of either succeeded or failed.

Event data

The listing below is an example of a JSON object emitted by EBS for a successful createSnapshot event. In the detail section, the source field contains the ARN of the source volume. The startTime and endTime fields indicate when creation of the snapshot started and completed.

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "012345678901",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": [
        "arn:aws:ec2::us-west-2:snapshot/snap-01234567"
    ],
    "detail": {
        "event": "createSnapshot",
        "result": "succeeded",
        "cause": "",
        "request-id": "0123456-0123-0123-0123-01234567890a"
    }
}
```
Create snapshots (createSnapshots)

The createSnapshots event is sent to your AWS account when an action to create a multi-volume snapshot completes. This event can have a result of either succeeded or failed.

Event data

The listing below is an example of a JSON object emitted by EBS for a successful createSnapshots event. In the detail section, the source field contains the ARNs of the source volumes of the multi-volume snapshot set. The startTime and endTime fields indicate when creation of the snapshot started and completed.

```json
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Multi-Volume Snapshots Completion Status",
  "source": "aws.ec2",
  "account": "012345678901",
  "time": "yyyyMMddThhmmssZ",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2::us-east-1:snapshot/snap-01234567",
    "arn:aws:ec2::us-east-1:snapshot/snap-012345678"
  ],
  "detail": {
    "event": "createSnapshots",
    "result": "succeeded",
    "cause": "",
    "request-id": "",
    "startTime": "yyyyMMddThhmmssZ",
    "endTime": "yyyyMMddThhmmssZ",
    "snapshots": [
      {
        "snapshot_id": "arn:aws:ec2::us-east-1:snapshot/snap-01234567",
        "source": "arn:aws:ec2::us-east-1:volume/vol-01234567",
        "status": "completed"
      },
      {
        "snapshot_id": "arn:aws:ec2::us-east-1:snapshot/snap-012345678",
        "source": "arn:aws:ec2::us-east-1:volume/vol-012345678",
        "status": "completed"
      }
    ]
  }
}
```

The listing below is an example of a JSON object emitted by EBS after a failed createSnapshots event. The cause for the failure was one or more snapshots for the multi-volume snapshot set failed to complete. The values of snapshot_id are the ARNs of the failed snapshots. startTime and endTime represent when the create-snapshots action started and ended.

```json
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Multi-Volume Snapshots Completion Status",
  "source": "aws.ec2",
  "account": "012345678901",
  "time": "yyyyMMddThhmmssZ",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2::us-east-1:snapshot/snap-01234567",
    "arn:aws:ec2::us-east-1:snapshot/snap-012345678"
  ],
  "detail": {
    "event": "createSnapshots",
    "result": "failed",
    "cause": "Failed to create one or more snapshots",
    "request-id": "",
    "startTime": "yyyyMMddThhmmssZ",
    "endTime": "yyyyMMddThhmmssZ",
    "snapshots": [
      {
        "snapshot_id": "arn:aws:ec2::us-east-1:snapshot/snap-01234567",
        "source": "arn:aws:ec2::us-east-1:volume/vol-01234567",
        "status": "failed"
      },
      {
        "snapshot_id": "arn:aws:ec2::us-east-1:snapshot/snap-012345678",
        "source": "arn:aws:ec2::us-east-1:volume/vol-012345678",
        "status": "failed"
      }
    ]
  }
}
```
Copy snapshot (copySnapshot)

The copySnapshot event is sent to your AWS account when an action to copy a snapshot completes. However it is not saved, logged, or archived. This event can have a result of either succeeded or failed.

If you are copying the snapshot across Regions, then the event is emitted in the destination Region.

Event data

The listing below is an example of a JSON object emitted by EBS after a successful copySnapshot event. The value of snapshot_id is the ARN of the newly created snapshot. In the detail section, the value of source is the ARN of the source snapshot. startTime and endTime represent when the copy-snapshot action started and ended. incremental indicates whether the snapshot is an incremental snapshot (true), or a full snapshot (false).

```json
{
    "version": "0",
    "id": "01234567-0123-0123-0123-012345678901",
    "detail-type": "EBS Snapshot Notification",
    "source": "aws.ec2",
    "account": "123456789012",
    "time": "yyyy-mm-ddThh:mm:ssZ",
    "region": "us-east-1",
    "resources": ["arn:aws:ec2::us-west-2:snapshot/snap-01234567"],
    "detail": {
        "event": "copySnapshot",
        "result": "succeeded",
        "cause": "",
        "request-id": "",
        "snapshot_id": "arn:aws:ec2::us-west-2:snapshot/snap-01234567",
        "source": "arn:aws:ec2::eu-west-1:snapshot/snap-76543210",
        "startTime": "yyyy-mm-ddThh:mm:ssZ",
        "endTime": "yyyy-mm-ddThh:mm:ssZ",
        "incremental": "true"
    }
}
```
The listing below is an example of a JSON object emitted by EBS after a failed copySnapshot event. The cause for the failure was an invalid source snapshot ID. The value of snapshot_id is the ARN of the failed snapshot. In the detail section, the value of source is the ARN of the source snapshot. startTime and endTime represent when the copy-snapshot action started and ended.

```
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Snapshot Notification",
  "source": "aws.ec2",
  "account": "123456789012",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2::us-west-2:snapshot/snap-01234567",
  ],
  "detail": {
    "event": "copySnapshot",
    "result": "failed",
    "cause": "Source snapshot ID is not valid",
    "request-id": "",
    "snapshot_id": "arn:aws:ec2::us-west-2:snapshot/snap-01234567",
    "source": "arn:aws:ec2::eu-west-1:snapshot/snap-76543210",
    "startTime": "yyyy-mm-ddThh:mm:ssZ",
    "endTime": "yyyy-mm-ddThh:mm:ssZ"
  }
}
```

**Share snapshot (shareSnapshot)**

The shareSnapshot event is sent to your AWS account when another account shares a snapshot with it. However it is not saved, logged, or archived. The result is always succeeded.

**Event data**

The following is an example of a JSON object emitted by EBS after a completed shareSnapshot event. In the detail section, the value of source is the AWS account number of the user that shared the snapshot with you. startTime and endTime represent when the share-snapshot action started and ended. The shareSnapshot event is emitted only when a private snapshot is shared with another user. Sharing a public snapshot does not trigger the event.

```
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Snapshot Notification",
  "source": "aws.ec2",
  "account": "012345678901",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2::us-west-2:snapshot/snap-01234567"
  ],
  "detail": {
    "event": "shareSnapshot",
    "result": "succeeded",
    "cause": "",
    "request-id": "",
    "snapshot_id": "arn:aws:ec2::us-west-2:snapshot/snap-01234567",
    "source": "012345678901",
    "startTime": "yyyy-mm-ddThh:mm:ssZ",
    "endTime": "yyyy-mm-ddThh:mm:ssZ"
  }
}
```
EBS Snapshots Archive events

Amazon EBS emits events related to snapshot archiving actions. For more information, see Monitor snapshot archiving (p. 2152).

EBS fast snapshot restore events

Amazon EBS sends events to EventBridge when the state of fast snapshot restore for a snapshot changes. Events are emitted on a best effort basis.

The following is example data for this event.

```
{
  "version": "0",
  "id": "01234567-0123-0123-0123-012345678901",
  "detail-type": "EBS Fast Snapshot Restore State-change Notification",
  "source": "aws.ec2",
  "account": "123456789012",
  "time": "yyyy-mm-ddThh:mm:ssZ",
  "region": "us-east-1",
  "resources": [
    "arn:aws:ec2:us-east-1::snapshot/snap-03a55cf56513fa1b6"
  ],
  "detail": {
    "snapshot-id": "snap-1234567890abcdef0",
    "state": "optimizing",
    "zone": "us-east-1a",
    "message": "Client.UserInitiated - Lifecycle state transition",
  }
}
```

The possible values for state are enabling, optimizing, enabled, disabling, and disabled.

The possible values for message are as follows:

Client.InvalidSnapshot.InvalidState - The requested snapshot transitioned to an invalid state (Error)

A request to enable fast snapshot restore failed and the state transitioned to disabling or disabled. Fast snapshot restore cannot be enabled for this snapshot.

Client.UserInitiated

The state successfully transitioned to enabling or disabling.

Client.UserInitiated - Lifecycle state transition

The state successfully transitioned to optimizing, enabled, or disabled.

Server.InsufficientCapacity - There was insufficient capacity available to satisfy the request

A request to enable fast snapshot restore failed due to insufficient capacity, and the state transitioned to disabling or disabled. Wait and then try again.

Server.InternalError - An internal error caused the operation to fail

A request to enable fast snapshot restore failed due to an internal error, and the state transitioned to disabling or disabled. Wait and then try again.
Client.InvalidSnapshot.InvalidState - The requested snapshot was deleted or access permissions were revoked

The fast snapshot restore state for the snapshot has transitioned to disabling or disabled because the snapshot was deleted or unshared by the snapshot owner. Fast snapshot restore cannot be enabled for a snapshot that has been deleted or is no longer shared with you.

Using AWS Lambda to handle EventBridge events

You can use Amazon EBS and Amazon EventBridge to automate your data-backup workflow. This requires you to create an IAM policy, a AWS Lambda function to handle the event, and an EventBridge rule that matches incoming events and routes them to the Lambda function.

The following procedure uses the createSnapshot event to automatically copy a completed snapshot to another Region for disaster recovery.

To copy a completed snapshot to another Region

1. Create an IAM policy, such as the one shown in the following example, to provide permissions to use the CopySnapshot action and write to the EventBridge log. Assign the policy to the user that will handle the EventBridge event.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "logs:CreateLogGroup",
        "logs:CreateLogStream",
        "logs:PutLogEvents"
      ],
      "Resource": "arn:aws:logs:*:*:*
    },
    {
      "Effect": "Allow",
      "Action": [
        "ec2:CopySnapshot"
      ],
      "Resource": "*"
    }
  ]
}
```

2. Define a function in Lambda that will be available from the EventBridge console. The sample Lambda function below, written in Node.js, is invoked by EventBridge when a matching createSnapshot event is emitted by Amazon EBS (signifying that a snapshot was completed). When invoked, the function copies the snapshot from us-east-2 to us-east-1.

```javascript
// Sample Lambda function to copy an EBS snapshot to a different Region

var AWS = require('aws-sdk');
var ec2 = new AWS.EC2();

// define variables
var destinationRegion = 'us-east-1';
var sourceRegion = 'us-east-2';
console.log('Loading function');

//main function
exports.handler = (event, context, callback) => {
```
// Get the EBS snapshot ID from the event details
var snapshotArn = event.detail.snapshot_id.split('/');
const snapshotId = snapshotArn[1];
const description = `Snapshot copy from ${snapshotId} in ${sourceRegion}.`;
console.log(`snapshotId: ${snapshotId}`);

// Load EC2 class and update the configuration to use destination Region to
// initiate the snapshot.
AWS.config.update({region: destinationRegion});
var ec2 = new AWS.EC2();

// Prepare variables for ec2.modifySnapshotAttribute call
const copySnapshotParams = {
  Description: description,
  DestinationRegion: destinationRegion,
  SourceRegion: sourceRegion,
  SourceSnapshotId: snapshotId
};

// Execute the copy snapshot and log any errors
ec2.copySnapshot(copySnapshotParams, (err, data) => {
  if (err) {
    const errorMessage = `Error copying snapshot ${snapshotId} to Region
    ${destinationRegion}.`;
    console.log(errorMessage);
    console.log(err);
    callback(errorMessage);
  } else {
    const successMessage = `Successfully started copy of snapshot ${snapshotId}
    to Region ${destinationRegion}.`;
    console.log(successMessage);
    console.log(data);
    callback(null, successMessage);
  }
});

To ensure that your Lambda function is available from the EventBridge console, create it in the
Region where the EventBridge event will occur. For more information, see the AWS Lambda
Developer Guide.

3. Open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
4. In the navigation pane, choose Rules, and then choose Create rule.
5. For Step 1: Define rule detail, do the following:
   a. Enter values for Name and Description.
   b. For Event bus, keep default.
   c. Ensure that Enable the rule on the selected event bus is toggled on.
   d. For Event type, select Rule with an event pattern.
   e. Choose Next.
6. For Step 2: Build event pattern, do the following:
   a. For Event source, select AWS events or EventBridge partner events.
   b. In the Event pattern section, for Event source, ensure that AWS service is selected, and for
   AWS service, select EC2.
   c. For Event type, select EBS Snapshot Notification, select Specific event(s), and then choose
createSnapshot.
   d. Select Specific result(s) and then choose succeeded.
   e. Choose Next.
7. For **Step 3: Select targets**, do the following:
   
a. For **Target types**, choose **AWS service**.

b. For **Select target**, choose **Lambda function**, and for **Function** select the function that you created earlier.

c. Choose Next

8. For **Step 4: Configure tags**, specify tags for the rule if needed, and then choose **Next**.

9. For **Step 5: Review and create**, review the rule and then choose **Create rule**.

Your rule should now appear on the **Rules** tab. In the example shown, the event that you configured should be emitted by EBS the next time you copy a snapshot.

**Amazon EBS quotas**

To view the quotas for your Amazon EBS resources, open the Service Quotas console at [https://console.aws.amazon.com/servicequotas/](https://console.aws.amazon.com/servicequotas/). In the navigation pane, choose **AWS services**, and select **Amazon Elastic Block Store (Amazon EBS)**.

For a list of Amazon EBS service quotas, see [Amazon Elastic Block Store service quotas](https://aws.amazon.com/documentation/elastic-block-store/) in the **AWS General Reference**.

**Amazon EC2 instance store**

An **instance store** provides temporary block-level storage for your instance. This storage is located on disks that are physically attached to the host computer. Instance store is ideal for temporary storage of information that changes frequently, such as buffers, caches, scratch data, and other temporary content. It can also be used to store temporary data that you replicate across a fleet of instances, such as a load-balanced pool of web servers.

An instance store consists of one or more instance store volumes exposed as block devices. The size of an instance store as well as the number of devices available varies by instance type and instance size. For more information, see [Instance store volumes](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/instance-store-volumes.html) (p. 2414).

The virtual devices for instance store volumes are ephemeral[0-23]. Instance types that support one instance store volume have ephemeral0. Instance types that support two or more instance store volumes have ephemeral0, ephemeral1, and so on.
Instance store volume and data lifetime

The number, size, and type of instance store volumes are determined by the instance type and instance size. For more information, see Instance store volumes (p. 2414).

Instance store volumes are attached only at instance launch. You can't attach instance store volumes after launch. You can't detach an instance store volume from one instance and attach it to a different instance.

An instance store volume exists only during the lifetime of the instance to which it is attached. You can't configure an instance store volume to persist beyond the lifetime of its associated instance.

The data on an instance store volume persists even if the instance is rebooted. However, the data does not persist if the instance is stopped, hibernated, or terminated. When the instance is stopped, hibernated, or terminated, every block of the instance store volume is cryptographically erased.

Instance store pricing

Instance store volumes are included as part of the instance's usage cost.

Contents

- Instance store volume and data lifetime (p. 2412)
- Instance store volumes (p. 2414)
- Add instance store volumes to your EC2 instance (p. 2427)
- SSD instance store volumes (p. 2430)
- Instance store swap volumes (p. 2432)
- Optimize disk performance for instance store volumes (p. 2434)
Therefore, do not rely on instance store volumes for valuable, long-term data. If you need to retain the data stored on an instance store volume beyond the lifetime of the instance, you need to manually copy that data to more persistent storage, such as an Amazon EBS volume, an Amazon S3 bucket, or an Amazon EFS file system.

There are some events that can result in your data not persisting throughout the lifetime of the instance. The following table indicates whether data on instance store volumes is persisted during specific events, for both virtualized and bare metal instances.

<table>
<thead>
<tr>
<th>Event</th>
<th>What happens to your data</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>User-initiated instance lifecycle events</strong></td>
<td></td>

<td>The data persists upon reboot</td>
</tr>
</tbody>
</table>

* If the new instance type supports instance store, the instance gets the number of instance store volumes supported by the new instance type, but the data does not transfer to the new instance. If the new instance type does not support instance store, the instance does not get the instance store volumes.

** The data is not included in the EBS-backed AMI, and it is not included on instance store volumes attached to instances launched from that AMI.
*** The data is included in the AMI bundle that is uploaded to Amazon S3. When you launch an instance from that AMI, the instance gets the instance store volumes bundled in the AMI with the data they contained at the time the AMI was created.

† Termination protection and stop protection do not protect instances against instance stops or terminations as a result of shutdowns initiated through the operating system on the instance. Data stored on instance store volumes does not persist in both instance stop and termination events.

### Instance store volumes

The number, size, and type of instance store volumes are determined by the instance type and instance size. Some instance types, such as M6, C6, and R6, do not support instance store volumes, while other instance types, such as M5d, C6gd, and R6gd, do support instance store volumes. You can't attach more instance store volumes to an instance than is supported by its instance type. For the instance types that do support instance store volumes, the number and size of the instance store volumes vary by instance size. For example, m5d.1large supports 1 x 75 GB instance store volume, while m5d.24xlarge supports 4 x 900 GB instance store volumes.

For instance types with NVMe instance store volumes, all of the supported instance store volumes are automatically attached to the instance at launch. For instance types with non-NVMe instance store volumes, such as C1, C3, M1, M2, M3, R3, D2, H1, I2, G2, X1, and X1e, you must manually specify the block device mappings for the instance store volumes that you want to attach at launch. Then, after the instance has launched, you must format and mount the attached instance store volumes (p. 2429) before you can use them. You can't attach an instance store volume after you launch the instance.

Some instance types use NVMe or SATA-based solid state drives (SSD), while others use SATA-based hard disk drives (HDD). SSDs deliver high random I/O performance with very low latency, but you don't need the data to persist when the instance terminates or you can take advantage of fault-tolerant architectures. For more information, see SSD instance store volumes (p. 2430).

The data on NVMe instance store volumes and some HDD instance store volumes is encrypted at rest. For more information, see Data protection in Amazon EC2 (p. 1933).

### Available instance store volumes

The following table provides the quantity, size, type, and performance optimizations of instance store volumes available on each supported instance type.

#### Topics
- General purpose (p. 2414)
- Compute optimized (p. 2417)
- Memory optimized (p. 2419)
- Storage optimized (p. 2422)
- Accelerated computing (p. 2425)

* Volumes attached to certain instances suffer a first-write penalty unless initialized. For more information, see [Optimize disk performance for instance store volumes](p. 2434).

** For more information, see [Instance store volume TRIM support](p. 2432).

† The c1.medium and m1.small instance types also include a 900 MB instance store swap volume, which may not be automatically enabled at boot time. For more information, see [Instance store swap volumes](p. 2432).

### Instance store volume performance

The following documentation describes the I/O performance of the instance store volumes.

- General purpose instances (p. 326)
- Compute optimized instances (p. 382)
- Memory optimized instances (p. 410)
- Storage optimized instances (p. 424)
- Accelerated computing instances (p. 440)

### To query instance store volume information using the AWS CLI

You can use the `describe-instance-types` AWS CLI command to display information about an instance type, such as its instance store volumes. The following example displays the total size of instance storage for all R5 instances with instance store volumes.

```bash
aws ec2 describe-instance-types
  --filters "Name=instance-type,Values=r5*" "Name=instance-storage-supported,Values=true"
  --query "InstanceTypes[][InstanceType, InstanceStorageInfo.TotalSizeInGB]"
  --output table
```

Example output
The following example displays the complete instance storage details for the specified instance type.

```bash
aws ec2 describe-instance-types
   --filters "Name=instance-type,Values=r5d.4xlarge"
   --query "InstanceTypes[].InstanceStorageInfo"
```

The example output shows that this instance type has two 300 GB NVMe SSD volumes, for a total of 600 GB of instance storage.

```
[
    {
        "TotalSizeInGB": 600,
        "Disks": [
            {
                "SizeInGB": 300,
                "Count": 2,
                "Type": "ssd"
            }
        ],
        "NvmeSupport": "required"
    }
]
```

**Add instance store volumes to your EC2 instance**

For instance types with **NVMe instance store volumes**, all of the supported instance store volumes are automatically attached to the instance at launch. They are automatically enumerated and assigned a device name on instance launch.

For instance types with **non-NVMe instance store volumes**, such as C1, C3, M1, M2, M3, R3, D2, H1, I2, G2, X1, and X1e, you must manually specify the block device mappings for the instance store volumes that you want to attach at launch. Block device mappings can be specified in the instance launch request or in the AMI used to launch the instance. The block device mapping includes a device name and the volume that it maps to. For more information, see [Block device mappings](p. 2454)

**Important**

Instance store volumes can be attached to an instance only when you launch it. You can't attach instance store volumes to an instance after you've launched it.

After you launch an instance, you must ensure that the instance store volumes for your instance are formatted and mounted before you can use them. The root volume of an instance store-backed instance is mounted automatically.

**Consideration for root volumes**
A block device mapping always specifies the root volume for the instance. The root volume is either an Amazon EBS volume or an instance store volume. The root volume is mounted automatically. For instances with an instance store volume for the root volume, the size of this volume varies by AMI, but the maximum size is 10 GB. For more information, see Storage for the root device (p. 115).

Contents
- Add instance store volumes to an AMI (p. 2428)
- Add non-NVME instance store volumes to an instance (p. 2429)
- Make instance store volumes available on your instance (p. 2429)

Add instance store volumes to an AMI

You can create an AMI with a block device mapping that includes instance store volumes.

If you launch an instance that supports non-NVMe instance store volumes using an AMI that specifies instance store volume block device mappings, the instance includes the instance store volumes. If the number of instance store volume block device mappings in the AMI exceeds the number of instance store volumes available to the instance, the additional instance store volume block device mappings are ignored.

If you launch an instance that supports NVMe instance store volumes using an AMI that specifies instance store volume block device mappings, the instance store volume block device mappings are ignored. Instances that support NVMe instance store volumes get all of their supported instance store volumes, regardless of the block device mappings specified in the instance launch request and the AMI.

Considerations
- For M3 instances, specify instance store volumes in the block device mapping of the instance, not the AMI. Amazon EC2 might ignore instance store volume block device mappings in the AMI.
- When you launch an instance, you can omit non-NVMe instance store volumes specified in the AMI block device mapping or add instance store volumes.

New console

To add instance store volumes to an Amazon EBS-backed AMI using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and select the instance.
3. Choose Actions, Image and templates, Create image.
4. On the Create image page, enter a meaningful name and description for your image.
5. For each instance store volume to add, choose Add volume, from Volume type select an instance store volume, and from Device select a device name. (For more information, see Device names on Linux instances (p. 2452).) The number of available instance store volumes depends on the instance type. For instances with NVMe instance store volumes, the device mapping of these volumes depends on the order in which the operating system enumerates the volumes.
6. Choose Create image.

AWS CLI

To add instance store volumes to an AMI using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- create-image or register-image (AWS CLI)
Add instance store volumes

- New-EC2Image and Register-EC2Image (AWS Tools for Windows PowerShell)

Add non-NVME instance store volumes to an instance

When you launch an instance that supports **non-NVMe instance store volumes** you must specify block device mappings for the instance store volumes to attach. The block device mappings must be specified in the instance launch request or in the AMI used to launch the instance.

If the AMI includes block device mappings for the instance store volumes, you do not need to specify block device mappings in the instance launch request, unless you need more instance store volumes than is included in the AMI.

If the AMI does not include block device mappings for instance store volumes, then you must specify the block device mappings in the instance launch request.

**Considerations**

- For M3 instances, you might receive instance store volumes even if you do not specify them in the block device mapping for the instance.

To specify block device mappings in the instance launch request, use one of the following methods.

**Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. From the dashboard, choose **Launch instance**.
3. In the **Application and OS Images** section, select the AMI to use.
4. In the **Configure storage** section, the **Instance store volumes** section lists the instance store volumes that can be attached to the instance. The number of available instance store volumes depends on the instance type.
5. For each instance store volume to attach, for **Device name**, select the device name to use.
6. Configure the remaining instance settings as needed, and then choose **Launch instance**.

**Command line**

You can use one of the following options commands with the corresponding option.

- `-block-device-mappings` with **run-instances** (AWS CLI)
- `-BlockDeviceMapping` with **New-EC2Instance** (AWS Tools for Windows PowerShell)

Make instance store volumes available on your instance

After you launch an instance with attached instance store volumes, you must mount the volumes before you can access them.

For Linux instances, many instance store volumes are pre-formatted with the ext3 file system. SSD-based instance store volumes that support TRIM instruction are not pre-formatted with any file system. However, you can format volumes with the file system of your choice after you launch your instance. For more information, see **Instance store volume TRIM support** (p. 2432). For Windows instances, we reformat the instance store volumes with the NTFS file system.

You can confirm that the instance store devices are available from within the instance itself using instance metadata. For more information, see **View the instance block device mapping for instance store volumes** (p. 2462).
For Linux instances, you can view and mount the instance store volumes as described in the following procedure.

**To make an instance store volume available on Linux**

1. Connect to the instance using an SSH client. For more information, see Connect to your Linux instance (p. 811).
2. Use the `df -h` command to view the volumes that are formatted and mounted.

   ```
   $ df -h
   Filesystem      Size  Used Avail Use% Mounted on
   devtmpfs        3.8G   72K  3.8G   1% /dev
   tmpfs           3.8G     0  3.8G   0% /dev/shm
   /dev/nvme0n1p1  7.9G  1.2G  6.6G  15% /
   ```

3. Use the `lsblk` command to view any volumes that were mapped at launch but not formatted and mounted.

   ```
   $ lsblk
   NAME          MAJ:MIN RM  SIZE RO TYPE MOUNTPOINT
   nvme0n1       259:1    0    8G  0 disk
   ##nvme0n1p1   259:2    0    8G  0 part /
   ##nvme0n1p128 259:3    0   1M  0 part
   nvme1n1       259:0    0 69.9G  0 disk
   ```

4. To format and mount an instance store volume that was mapped only, do the following:
   a. Create a file system on the device using the `mkfs` command.

      ```
      $ sudo mkfs -t xfs /dev/nvme1n1
      ```
   b. Create a directory on which to mount the device using the `mkdir` command.

      ```
      $ sudo mkdir /data
      ```
   c. Mount the device on the newly created directory using the `mount` command.

      ```
      $ sudo mount /dev/nvme1n1 /data
      ```

   For instructions on how to mount an attached volume automatically after reboot, see Automatically mount an attached volume after reboot (p. 2086).

**SSD instance store volumes**

To ensure the best IOPS performance from your SSD instance store volumes on Linux, we recommend that you use the most recent version of Amazon Linux, or another Linux AMI with a kernel version of 3.8 or later. If you do not use a Linux AMI with a kernel version of 3.8 or later, your instance won't achieve the maximum IOPS performance available for these instance types.

Like other instance store volumes, you must map the SSD instance store volumes for your instance when you launch it. The data on an SSD instance volume persists only for the life of its associated instance. For more information, see Add instance store volumes to your EC2 instance (p. 2427).

**NVMe SSD volumes**

Some instances offer non-volatile memory express (NVMe) solid state drives (SSD) instance store volumes. For more information about the type of instance store volume supported by each instance type, see Instance store volumes (p. 2414).
To access NVMe volumes, the NVMe drivers (p. 2335) must be installed. The following AMIs meet this requirement:

- Amazon Linux 2023
- Amazon Linux 2
- Amazon Linux AMI 2018.03 and later
- Ubuntu 14.04 or later with `linux-aws` kernel

**Note**
AWS Graviton-based instance types require Ubuntu 18.04 or later with `linux-aws` kernel

- Red Hat Enterprise Linux 7.4 or later
- SUSE Linux Enterprise Server 12 SP2 or later
- CentOS 7.4.1708 or later
- FreeBSD 11.1 or later
- Debian GNU/Linux 9 or later

- Bottlerocket

After you connect to your instance, you can list the NVMe devices using the `lspci` command. The following is example output for an `i3.8xlarge` instance, which supports four NVMe devices.

```
[ec2-user ~]$ lspci
00:00.0 Host bridge: Intel Corporation 440FX - 82441FX PMC [Natoma] (rev 02)
00:01.0 ISA bridge: Intel Corporation 82371SB PIIX3 ISA [Natoma/Triton II]
00:01.1 IDE interface: Intel Corporation 82371SB PIIX3 IDE [Natoma/Triton II]
00:01.3 Bridge: Intel Corporation 82371AB/EB/MB PIIX4 ACPI (rev 01)
00:02.0 VGA compatible controller: Cirrus Logic GD 5466
00:03.0 Ethernet controller: Device 1d0f:ec20
00:17.0 Non-Volatile memory controller: Device 1d0f:cd01
00:18.0 Non-Volatile memory controller: Device 1d0f:cd01
00:19.0 Non-Volatile memory controller: Device 1d0f:cd01
00:1a.0 Non-Volatile memory controller: Device 1d0f:cd01
00:1f.0 Unassigned class [ff80]: XenSource, Inc. Xen Platform Device (rev 01)
```

If you are using a supported operating system but you do not see the NVMe devices, verify that the NVMe module is loaded using the following command.

- Amazon Linux, Amazon Linux 2, Ubuntu 14/16, Red Hat Enterprise Linux, SUSE Linux Enterprise Server, CentOS 7

```
$ lsmod | grep nvme
nvme          48813  0
```

- Ubuntu 18

```
$ cat /lib/modules/$(uname -r)/modules.builtin | grep nvme
s/nvme/host/nvme-core.ko
kernel/drivers/nvme/host/nvme.ko
kernel/drivers/nvmem/nvmem_core.ko
```

The NVMe volumes are compliant with the NVMe 1.0e specification. You can use the NVMe commands with your NVMe volumes. With Amazon Linux, you can install the `nvme-cli` package from the repo using the `yum install` command. With other supported versions of Linux, you can download the `nvme-cli` package if it's not available in the image.
The data on NVMe instance storage is encrypted using an XTS-AES-256 block cipher implemented in a hardware module on the instance. The encryption keys are generated using the hardware module and are unique to each NVMe instance storage device. All encryption keys are destroyed when the instance is stopped or terminated and cannot be recovered. You cannot disable this encryption and you cannot provide your own encryption key.

Non-NVMe SSD volumes

The following instances support instance store volumes that use non-NVMe SSDs to deliver high random I/O performance: C3, G2, I2, M3, R3, and X1. For more information about the instance store volumes supported by each instance type, see Instance store volumes (p. 2414).

Instance store volume TRIM support

Some instance types support SSD volumes with TRIM. For more information, see Instance store volumes (p. 2414).

Instance store volumes that support TRIM are fully trimmed before they are allocated to your instance. These volumes are not formatted with a file system when an instance launches, so you must format them before they can be mounted and used. For faster access to these volumes, you should skip the TRIM operation when you format them.

With instance store volumes that support TRIM, you can use the TRIM command to notify the SSD controller when you no longer need data that you've written. This provides the controller with more free space, which can reduce write amplification and increase performance. On Linux, use the `fstrim` command to enable periodic TRIM.

Instance store swap volumes

Swap space in Linux can be used when a system requires more memory than it has been physically allocated. When swap space is enabled, Linux systems can swap infrequently used memory pages from physical memory to swap space (either a dedicated partition or a swap file in an existing file system) and free up that space for memory pages that require high-speed access.

**Note**

Using swap space for memory paging is not as fast or efficient as using RAM. If your workload is regularly paging memory into swap space, you should consider migrating to a larger instance type with more RAM. For more information, see Change the instance type (p. 479).

The `c1.medium` and `m1.small` instance types have a limited amount of physical memory to work with, and they are given a 900 MiB swap volume at launch time to act as virtual memory for Linux AMIs. Although the Linux kernel sees this swap space as a partition on the root device, it is actually a separate instance store volume, regardless of your root device type.

Amazon Linux automatically enables and uses this swap space, but your AMI may require some additional steps to recognize and use this swap space. To see if your instance is using swap space, you can use the `swapon -s` command.

```
[ec2-user ~]$ swapon -s
Filename   Type      Size  Used  Priority
/dev/xvda3  partition 917500  0      -1
```

The above instance has a 900 MiB swap volume attached and enabled. If you don't see a swap volume listed with this command, you may need to enable swap space for the device. Check your available disks using the `lsblk` command.

```
[ec2-user ~]$ lsblk
```

2432
Here, the swap volume xvda3 is available to the instance, but it is not enabled (notice that the MOUNTPOINT field is empty). You can enable the swap volume with the `swapon` command.

**Note**

You must prepend `/dev/` to the device name listed by `lsblk`. Your device may be named differently, such as sda3, sde3, or xvde3. Use the device name for your system in the command below.

```
[ec2-user ~]$ sudo swapon /dev/xvda3
```

Now the swap space should show up in `lsblk` and `swapon -s` output.

```
[ec2-user ~]$ lsblk
NAME    MAJ:MIN  RM  SIZE   RO TYPE MOUNTPOINT
xvda1   202:1   0   8G   0 disk /           
xvda3   202:3   0  896M  0 disk [SWAP]
```

```
[ec2-user ~]$ swapon -s
Filename                       Type  Size  Used Priority
/dev/xvda3                     partition 917500  0      -1
```

You also need to edit your `/etc/fstab` file so that this swap space is automatically enabled at every system boot.

```
[ec2-user ~]$ sudo vim /etc/fstab
```

Append the following line to your `/etc/fstab` file (using the swap device name for your system):

```
/dev/xvda3 none    swap    sw  0       0
```

**To use an instance store volume as swap space**

Any instance store volume can be used as swap space. For example, the m3.medium instance type includes a 4 GB SSD instance store volume that is appropriate for swap space. If your instance store volume is much larger (for example, 350 GB), you may consider partitioning the volume with a smaller swap partition of 4-8 GB and the rest for a data volume.

**Note**

This procedure applies only to instance types that support instance storage. For a list of supported instance types, see [Instance store volumes](#).

1. List the block devices attached to your instance to get the device name for your instance store volume.

```
[ec2-user ~]$ lsblk -p
NAME    MAJ:MIN  RM  SIZE   RO TYPE MOUNTPOINT
/dev/xvdb 202:16   0  4G   0 disk /media/ephemeral0
/dev/xvda1 202:1   0   8G   0 disk /           
```

In this example, the instance store volume is `/dev/xvdb`. Because this is an Amazon Linux instance, the instance store volume is formatted and mounted at `/media/ephemeral0`; not all Linux operating systems do this automatically.

2. (Optional) If your instance store volume is mounted (it lists a MOUNTPOINT in the `lsblk` command output), unmount it with the following command.
Optimize disk performance

3. Set up a Linux swap area on the device with the `mkswap` command.

   ```bash
   [ec2-user ~]$ sudo umount /dev/xvdb
   [ec2-user ~]$ sudo mkswap /dev/xvdb
   mkswap: /dev/xvdb: warning: wiping old ext3 signature.
   Setting up swapspace version 1, size = 4188668 KiB
   no label, UUID=b4f63d28-67ed-46f0-b5e5-6928319e620b
   ```

4. Enable the new swap space.

   ```bash
   [ec2-user ~]$ sudo swapon /dev/xvdb
   ```

5. Verify that the new swap space is being used.

   ```bash
   [ec2-user ~]$ sudo swapon -s
   Filename    Type  Size Used Priority
   /dev/xvdb                               partition 4188668 0 -1
   ```

6. Edit your `/etc/fstab` file so that this swap space is automatically enabled at every system boot.

   ```bash
   [ec2-user ~]$ sudo vim /etc/fstab
   ```

   If your `/etc/fstab` file has an entry for `/dev/xvdb` (or `/dev/sdb`) change it to match the line below; if it does not have an entry for this device, append the following line to your `/etc/fstab` file (using the swap device name for your system):

   ```text
   /dev/xvdb none    swap    sw  0       0
   ```

   **Important**
   Instance store volume data is lost when an instance is stopped or hibernated; this includes the instance store swap space formatting created in Step 3 (p. 2434). If you stop and restart an instance that has been configured to use instance store swap space, you must repeat Step 1 (p. 2433) through Step 5 (p. 2434) on the new instance store volume.

### Optimize disk performance for instance store volumes

Because of the way that Amazon EC2 virtualizes disks, the first write to any location on some instance store volumes performs more slowly than subsequent writes. For most applications, amortizing this cost over the lifetime of the instance is acceptable. However, if you require high disk performance, we recommend that you initialize your drives by writing once to every drive location before production use.

**Note**
Some instance types with direct-attached solid state drives (SSD) and TRIM support provide maximum performance at launch time, without initialization. For information about the instance store for each instance type, see Instance store volumes (p. 2414).

If you require greater flexibility in latency or throughput, we recommend using Amazon EBS.

To initialize the instance store volumes, use the following `dd` commands, depending on the store to initialize (for example, `/dev/sdb` or `/dev/nvme1n1`).

**Note**
Make sure to unmount the drive before performing this command.

---

2434
Initialization can take a long time (about 8 hours for an extra large instance).

To initialize the instance store volumes, use the following commands on the m1.large, m1.xlarge, c1.xlarge, m2.xlarge, m2.2xlarge, and m2.4xlarge instance types:

```
dd if=/dev/zero of=/dev/sdb bs=1M
dd if=/dev/zero of=/dev/sdc bs=1M
dd if=/dev/zero of=/dev/sdd bs=1M
dd if=/dev/zero of=/dev/sde bs=1M
```

To perform initialization on all instance store volumes at the same time, use the following command:

```
dd if=/dev/zero bs=1M|tee /dev/sdb|tee /dev/sdc|tee /dev/sde > /dev/sdd
```

Configuring drives for RAID initializes them by writing to every drive location. When configuring software-based RAID, make sure to change the minimum reconstruction speed:

```
echo $((30*1024)) > /proc/sys/dev/raid/speed_limit_min
```

## File storage

Cloud file storage is a method for storing data in the cloud that provides servers and applications access to data through shared file systems. This compatibility makes cloud file storage ideal for workloads that rely on shared file systems and provides simple integration without code changes.

There are many file storage solutions that exist, ranging from a single node file server on a compute instance using block storage as the underpinnings with no scalability or few redundancies to protect the data, to a do-it-yourself clustered solution, to a fully-managed solution. The following content introduces some of the storage services provided by AWS for use with Linux.

### Contents

- Use Amazon S3 with Amazon EC2 (p. 2435)
- Use Amazon EFS with Amazon EC2 (p. 2437)
- Use Amazon FSx with Amazon EC2 (p. 2440)

## Use Amazon S3 with Amazon EC2

Amazon S3 is a repository for internet data. Amazon S3 provides access to reliable, fast, and inexpensive data storage infrastructure. It is designed to make web-scale computing easier by enabling you to store and retrieve any amount of data, at any time, from within Amazon EC2 or anywhere on the web. Amazon S3 stores data objects redundantly on multiple devices across multiple facilities and allows concurrent read or write access to these data objects by many separate clients or application threads. You can use the redundant data stored in Amazon S3 to recover quickly and reliably from instance or application failures.

Amazon EC2 uses Amazon S3 for storing Amazon Machine Images (AMIs). You use AMIs for launching EC2 instances. In case of instance failure, you can use the stored AMI to immediately launch another instance, thereby allowing for fast recovery and business continuity.

Amazon EC2 also uses Amazon S3 to store snapshots (backup copies) of the data volumes. You can use snapshots for recovering data quickly and reliably in case of application or system failures. You can also use snapshots as a baseline to create multiple new data volumes, expand the size of an existing
data volume, or move data volumes across multiple Availability Zones, thereby making your data usage highly scalable. For more information about using data volumes and snapshots, see Amazon Elastic Block Store (p. 2050).

Objects are the fundamental entities stored in Amazon S3. Every object stored in Amazon S3 is contained in a bucket. Buckets organize the Amazon S3 namespace at the highest level and identify the account responsible for that storage. Amazon S3 buckets are similar to internet domain names. Objects stored in the buckets have a unique key value and are retrieved using a URL. For example, if an object with a key value /photos/mygarden.jpg is stored in the DOC-EXAMPLE-BUCKET1 bucket, then it is addressable using the URL https://DOC-EXAMPLE-BUCKET1.s3.amazonaws.com/photos/mygarden.jpg.

For more information about the features of Amazon S3, see the Amazon S3 product page.

Usage examples

Note
We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints.

Given the benefits of Amazon S3 for storage, you might decide to use this service to store files and data sets for use with EC2 instances. There are several ways to move data to and from Amazon S3 to your instances. In addition to the examples discussed below, there are a variety of tools that people have written that you can use to access your data in Amazon S3 from your computer or your instance. Some of the common ones are discussed in the AWS forums.

If you have permission, you can copy a file to or from Amazon S3 and your instance using one of the following methods.

GET or wget

Note
This method works for public objects only. If the object is not public, you receive an ERROR 403: Forbidden message. If you receive this error, you must use either the Amazon S3 console, AWS CLI, AWS API, AWS SDK, or AWS Tools for Windows PowerShell, and you must have the required permissions. For more information, see Identity and access management in Amazon S3 and Downloading an object in the Amazon S3 User Guide.

The wget utility is an HTTP and FTP client that allows you to download public objects from Amazon S3. It is installed by default in Amazon Linux and most other distributions, and available for download on Windows. To download an Amazon S3 object, use the following command, substituting the URL of the object to download.

```bash
[ec2-user ~]$ wget https://my_bucket.s3.amazonaws.com/path-to-file
```

AWS Command Line Interface

The AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services. The AWS CLI enables users to authenticate themselves and download restricted items from Amazon S3 and also to upload items. For more information, such as how to install and configure the tools, see the AWS Command Line Interface detail page.

The aws s3 cp command is similar to the Unix cp command. You can copy files from Amazon S3 to your instance, copy files from your instance to Amazon S3, and copy files from one Amazon S3 location to another.

Use the following command to copy an object from Amazon S3 to your instance.
[ec2-user ~]$ aws s3 cp s3://my_bucket/my_folder/my_file.ext my_copied_file.ext

Use the following command to copy an object from your instance back into Amazon S3.

[ec2-user ~]$ aws s3 cp my_copied_file.ext s3://my_bucket/my_folder/my_file.ext

The `aws s3 sync` command can synchronize an entire Amazon S3 bucket to a local directory location. This can be helpful for downloading a data set and keeping the local copy up-to-date with the remote set. If you have the proper permissions on the Amazon S3 bucket, you can push your local directory back up to the cloud when you are finished by reversing the source and destination locations in the command.

Use the following command to download an entire Amazon S3 bucket to a local directory on your instance.

[ec2-user ~]$ aws s3 sync s3://remote_S3_bucket local_directory

**Amazon S3 API**

If you are a developer, you can use an API to access data in Amazon S3. For more information, see the Amazon Simple Storage Service User Guide. You can use this API and its examples to help develop your application and integrate it with other APIs and SDKs, such as the boto Python interface.

**Use Amazon EFS with Amazon EC2**

Amazon EFS provides scalable file storage for use with Amazon EC2. You can use an EFS file system as a common data source for workloads and applications running on multiple instances. For more information, see the Amazon Elastic File System product page.

For a tutorial on how to create a file system using the Amazon EFS console, see Getting started with Amazon Elastic File System in the Amazon Elastic File System User Guide.

**Important**

Amazon EFS is not supported on Windows instances.

**Tasks**

- Create an EFS file system using Amazon EFS Quick Create (p. 2437)
- Test the EFS file system (p. 2439)
- Delete the EFS file system (p. 2440)

**Create an EFS file system using Amazon EFS Quick Create**

You can create an EFS file system and mount it to your instance when you launch your instance using the Amazon EFS Quick Create feature of the Amazon EC2 launch instance wizard (p. 720).

When you create an EFS file system using EFS Quick Create, the file system is created with the following service recommended settings:

- Automatic backups turned on. For more information, see Using AWS Backup to back up and restore Amazon EFS file systems in the Amazon Elastic File System User Guide.
- Mount targets in each default subnet in the selected VPC, using the VPC’s default security group. For more information, see Managing file system network accessibility in the Amazon Elastic File System User Guide.
- General Purpose performance mode. For more information, see Performance modes in the Amazon Elastic File System User Guide.
• Bursting throughput mode. For more information, see Throughput modes in the Amazon Elastic File System User Guide.

• Encryption of data at rest enabled using your default key for Amazon EFS (aws/elasticfilesystem). For more information, see Encrypting data at rest in the Amazon Elastic File System User Guide.

• Amazon EFS lifecycle management enabled with a 30-day policy. For more information, see Amazon EFS lifecycle management in the Amazon Elastic File System User Guide.

New console

To create an EFS file system using Amazon EFS Quick Create

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch instance.
3. (Optional) Under Name and tags, for Name, enter a name to identify your instance.
4. Under Application and OS Images (Amazon Machine Image), choose a Linux operating system, and then for Amazon Machine Image (AMI), select a Linux AMI.
5. Under Instance type, for Instance type, select an instance type or keep the default.
6. Under Key pair (login), for Key pair name, choose an existing key pair or create a new one.
7. Under Network settings, choose Edit (at right), and then for Subnet, select a subnet.

   Note
   You must select a subnet before you can add an EFS file system.

8. Under Configure storage, choose Edit (at bottom right), and then do the following:
   a. Make sure that EFS is selected.
   b. Choose Add shared file system.

      Troubleshooting tip
      If Add shared file system is not visible, you must first select a subnet.
   c. For File system, select an existing file system, or choose Create new shared file system and create a file system using Amazon EFS Quick Create.
   d. For Mount point, specify a mount point or keep the default.
   e. To enable access to the file system, select Automatically create and attach security groups. By selecting this check box, the necessary security groups will automatically be created and attached to the instance and the mount targets of the file system, as follows:
      • Instance security group – Includes an outbound rule that allows traffic over the NFS 2049 port, but includes no inbound rules.
      • File system mount targets security group – Includes an inbound rule that allows traffic over the NFS 2049 port from the instance security group (described above), and an outbound rule that allows traffic over the NFS 2049 port.

      You can choose to manually create and attach the security groups. If you want to manually create and attach the security groups, clear Automatically create and attach the required security groups.
   f. To automatically mount the shared file system when the instance launches, select Automatically mount shared file system by attaching required user data script. To view the user data that is automatically generated, expand Advanced details, and scroll down to User data.

      Note
      If you added user data before selecting this check box, the original user data is overwritten by the user data that is automatically generated.
9. Configure any other instance configuration settings as needed.
10. In the Summary panel, review your instance configuration, and then choose Launch instance.
    For more information, see Launch an instance using the new launch instance wizard (p. 720)

Old console

**To create an EFS file system using Amazon EFS Quick Create**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. Choose Launch Instance.
3. On the Choose an AMI page, choose a Linux AMI.
4. On the Choose an Instance Type page, select an instance type and then choose Next: Configure Instance Details.
5. On the Configure Instance Details page, for File systems, choose Create new file system, enter a name for the new file system, and then choose Create.

To enable access to the file system, the following security groups are automatically created and attached to the instance and the mount targets of the file system.

- **Instance security group**—Includes no inbound rules and an outbound rule that allows traffic over the NFS 2049 port.
- **File system mount targets security group**—Includes an inbound rule that allows traffic over the NFS 2049 port from the instance security group (described above), and an outbound rule that allows traffic over the NFS 2049 port.

You can also choose to manually create and attach the security groups. To do this, clear Automatically create and attach the required security groups.

Configure the remaining settings as needed and choose Next: Add Storage.

6. On the Add Storage page, make any necessary changes, and then choose Next: Add Tags.
7. On the Add Tags page, specify any tags if necessary, and then choose Next: Configure Security Group.
8. On the Configure Security Group page, review the security groups and then choose Review and Launch.
9. On the Review Instance Launch page, review the settings, and then choose Launch to choose a key pair and to launch your instance.

**Test the EFS file system**

You can connect to your instance and verify that the file system is mounted to the directory that you specified (for example, /mnt/efs).

**To verify that the file system is mounted**

1. Connect to your instance. For more information, see Connect to your Linux instance (p. 811).
2. From the terminal window for the instance, run the `df -T` command to verify that the EFS file system is mounted.

```
$ df -T
Filesystem     Type           1K-blocks   Used     Available Use% Mounted on
/dev/xvda1     ext4          8123812  1949800     6073764   25% /
devtmpfs       devtmpfs      4078468     56     4078412    1% /dev
tmpfs          tmpfs         4089312       0     4089312    0% /dev/shm
```

2439
Note that the name of the file system, shown in the example output as *efs-dns*, has the following form.

```
file-system-id.efs.aws-region.amazonaws.com: /
```

3. (Optional) Create a file in the file system from the instance, and then verify that you can view the file from another instance.

   a. From the instance, run the following command to create the file.

   ```
   $ sudo touch /mnt/efs/test-file.txt
   ```

   b. From the other instance, run the following command to view the file.

   ```
   $ ls /mnt/efs
   test-file.txt
   ```

Delete the EFS file system

If you no longer need your file system, you can delete it.

To delete the file system

2. Select the file system to delete.
3. Choose *Actions, Delete file system*.
4. When prompted for confirmation, enter the file system ID and choose *Delete file system*.

Use Amazon FSx with Amazon EC2

The Amazon FSx family of services makes it easy to launch, run, and scale shared storage powered by popular commercial and open-source file systems. You can use the *new launch instance wizard* to automatically attach the following types of Amazon FSx file systems to your Amazon EC2 instances at launch:

- Amazon FSx for NetApp ONTAP provides fully managed shared storage in the AWS Cloud with the popular data access and management capabilities of NetApp ONTAP.
- Amazon FSx for OpenZFS provides fully managed cost-effective shared storage powered by the popular OpenZFS file system.

**Note**

- This functionality is available in the new launch instance wizard only. For more information, see *Launch an instance using the new launch instance wizard* (p. 720)
- Amazon FSx for Windows File Server and Amazon FSx for Lustre file systems can't be mounted at launch. You must mount these file systems manually after launch.

You can choose to mount an existing file system that you created previously, or you can create a new file system to mount to an instance at launch.
Security groups and user data script

When you mount an Amazon FSx file system to an instance using the launch instance wizard, you can choose whether to automatically create and attach the security groups needed to enable access to the file system, and whether to automatically include the user data scripts needed to mount the file system and make it available for use.

Security groups

If you choose to automatically create the security groups that are needed to enable access to the file system, the launch instance wizard creates and attaches two security groups - one security group is attached to the instance, and the other is attached to the file system. For more information about the security group requirements, see FSx for ONTAP file system access control with Amazon VPC and FSx for OpenZFS file system access control with Amazon VPC.

We add the tag Name=instance-sg-1 to the security group that is created and attached to the instance. The value in the tag is automatically incremented each time the launch instance wizard creates a security group for Amazon FSx file systems.

The security group includes the following output rules, but no inbound rules.

### Outbound rules

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Port number</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>4049</td>
<td>file system security group</td>
</tr>
<tr>
<td>TCP</td>
<td>635</td>
<td>file system security group</td>
</tr>
<tr>
<td>TCP</td>
<td>2049</td>
<td>file system security group</td>
</tr>
<tr>
<td>TCP</td>
<td>111</td>
<td>file system security group</td>
</tr>
<tr>
<td>TCP</td>
<td>4045 - 4046</td>
<td>file system security group</td>
</tr>
<tr>
<td>TCP</td>
<td>20001 - 20003</td>
<td>file system security group</td>
</tr>
<tr>
<td>TCP</td>
<td>2049</td>
<td>file system security group</td>
</tr>
</tbody>
</table>
The security group that is created and attached to the file system is tagged with Name=fsx-sg-1. The value in the tag is automatically incremented each time the launch instance wizard creates a security group for Amazon FSx file systems.

The security group includes the following rules.

### Inbound rules

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Port number</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>UDP</td>
<td>2049</td>
<td>instance security group</td>
</tr>
<tr>

<tr>
<td>TCP</td>
<td>20001 - 20003</td>
<td>instance security group</td>
</tr>
<tr>
<td>TCP</td>
<td>111</td>
<td>instance security group</td>
</tr>
</tbody>
</table>

### Outbound rules

<table>
<thead>
<tr>
<th>Protocol type</th>
<th>Port number</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>All</td>
<td>All</td>
<td>0.0.0.0/0</td>
</tr>
</tbody>
</table>

### User data script

If you choose to automatically attach user data scripts, the launch instance wizard adds the following user data to the instance. This script installs the necessary packages, mounts the file system, and updates your instance settings so that the file system will automatically re-mount whenever the instance restarts.

```bash
#cloud-config
package_update: true
package_upgrade: true
runcmd:
- yum install -y nfs-utils
- apt-get -y install nfs-common
- svm_id_1=svm_id
- file_system_id_1=file_system_id
```
Mount an Amazon FSx file system at launch

To mount a new or existing Amazon FSx file system at launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and then choose Launch instance to open the launch instance wizard.
3. In the Application and OS Images section, select the AMI to use.
4. In the Instance type section, select the instance type.
5. In the Key pair section, select an existing key pair or create a new one.
6. In the Network settings section, do the following:
   a. Choose Edit.
   b. If you want to mount an existing file system, for Subnet, choose the file system's preferred subnet. We recommend that you launch the instance into the same Availability Zone as the file system's preferred subnet to optimize performance.

   If you want to create a new file system to mount to an instance, for Subnet, choose the subnet into which to launch the instance.

   **Important**
   You must select a subnet to enable the Amazon FSx functionality in the new launch instance wizard. If you do not select a subnet, you will not be able to mount an existing file system or create a new one.

7. In the Storage section, do the following:
   a. Configure the volumes as needed.
   b. Expand the File systems section and select FSx.
   c. Choose Add shared file system.
   d. For File system, select the file system to mount.

   **Note**
   The list displays all Amazon FSx for NetApp ONTAP and Amazon FSx for OpenZFS file systems in your account in the selected Region.

   e. To automatically create and attach the security groups needed to enable access to the file system, select Automatically create and attach security groups. If you prefer to create the security groups manually, clear the check box. For more information, see Security groups (p. 2441).

   f. To automatically attach the user data scripts needed to mount the file system, select Automatically mount shared file system by attaching required user data script. If you prefer to provide the user data scripts manually, clear the check box. For more information, see User data script (p. 2442).
8. In the **Advanced** section, configure the additional instance settings as needed.
9. Choose **Launch**.

## Instance volume limits

The maximum number of Amazon EBS volumes that you can attach to an instance depends on the instance type and instance size. When considering how many volumes to attach to your instance, you should consider whether you need increased I/O bandwidth or increased storage capacity.

### Bandwidth versus capacity

For consistent and predictable bandwidth use cases, use Amazon EBS–optimized instances (p. 2339) with General Purpose SSD volumes (p. 2058) or Provisioned IOPS SSD volumes (p. 2061). For maximum performance, match the IOPS you have provisioned for your volumes with the bandwidth available for your instance type.

For RAID configurations, you might find that arrays larger than 8 volumes have diminished performance returns due to increased I/O overhead. Test your individual application performance and tune it as required.

### Topics

- [Volume limits for instances built on the Nitro System](#)
- [Volume limits for Xen-based instances](#)

### Volume limits for instances built on the Nitro System

#### Dedicated Amazon EBS volume limit

The following Nitro instance types have a dedicated Amazon EBS volume limit of up to 128 attachments, depending on instance size. The limit is not shared with other device attachments. In other words, you can attach any number of Amazon EBS volumes up to the volume attachment limit, regardless of the number of attached devices, such as NVMe instance store volumes and network interfaces.

- General purpose: M7a, M7i
- Compute optimized: C7a, C7i
- Memory optimized: R7a, R7i, R7iz

The volume limits depend on the instance size. The following table shows the limit for each instance size.

<table>
<thead>
<tr>
<th>Instance size</th>
<th>Volume limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>medium</td>
<td>large</td>
</tr>
<tr>
<td>2xlarge</td>
<td>4xlarge</td>
</tr>
<tr>
<td>16xlarge</td>
<td>48</td>
</tr>
<tr>
<td>24xlarge</td>
<td>64</td>
</tr>
<tr>
<td>32xlarge</td>
<td>88</td>
</tr>
<tr>
<td>48xlarge</td>
<td>128</td>
</tr>
<tr>
<td>metal-16xl</td>
<td>metal-24xl</td>
</tr>
<tr>
<td>metal-32xl</td>
<td>metal-48xl</td>
</tr>
</tbody>
</table>
Shared Amazon EBS volume limit

All other Nitro instance types have a volume attachment limit that is shared between Amazon EBS volumes, network interfaces, and NVMe instance store volumes. You can attach any number of Amazon EBS volumes up to that limit, less the number of attached network interfaces and NVMe instance store volumes. Keep in mind that every instance must have at least one network interface, and that NVMe instance store volumes are automatically attached at launch.

Most of these instances support a maximum of 28 attachments. For example, if you have no additional network interface attachments on an m5.xlarge instance, you can attach up to 27 EBS volumes (28 volume limit - 1 network interface). If you have two additional network interfaces on an m5.xlarge instance, you can attach up to 25 EBS volumes (28 volume limit - 3 network interfaces). Similarly, if you have two additional network interfaces on an m5d.xlarge instance, which has 1 NVMe instance store volume, you can attach up to 24 EBS volumes (28 volume limit - 3 network interfaces - 1 NVMe instance store volume).

The following exceptions apply:

- DL2q instances support a maximum of 19 EBS volumes.
- Most bare metal instances support a maximum of 31 EBS volumes.
- High memory virtualized instances support a maximum of 27 EBS volumes.
- High memory bare metal instances support a maximum of 19 EBS volumes.
- inf1.xlarge and inf1.2xlarge instances support a maximum of 26 EBS volumes.
- inf1.6xlarge instances support a maximum of 23 EBS volumes.
- mac1.metal instances support a maximum of 16 EBS volumes.
- inf1.24xlarge instances support a maximum of 11 EBS volumes.
- g5.48xlarge instances support a maximum of 9 EBS volumes.
- d3.8xlarge and d3en.12xlarge instances support a maximum of 3 EBS volumes.
- For accelerated computing instances, the attached accelerators count towards the shared volume limit. For example, for p4d.24xlarge instances, which have a shared volume limit of 28, 8 GPUs, and 8 NVMe instance store volumes, you can attach up to 11 Amazon EBS volumes (28 volume limit - 1 network interface - 8 GPUs - 8 NVMe instance store volumes).

Volume limits for Xen-based instances

Attaching more than 40 volumes to a Xen-based Linux instance can cause boot failures. This number includes the root volume, plus any attached instance store volumes and Amazon EBS volumes.

If you experience boot problems on an instance with a large number of volumes, stop the instance, detach any volumes that are not essential to the boot process, start the instance, and then reattach the volumes after the instance is running.

**Important**  
Attaching more than 40 volumes to a Xen-based Linux instance is supported on a best effort basis only and is not guaranteed.

Amazon EC2 instance root volume

When you launch an instance, we create a root volume for the instance. The root volume contains the image used to boot the instance. Each instance has a single root volume. You can add storage volumes to your instances when you launch them or after they are running.
We reserve specific device names for root volumes. For more information, see Device names on Linux instances (p. 2452).

Contents
- Root volume type (p. 2446)
- Choose an AMI by root volume type (p. 2447)
- Determine the root device type of your instance (p. 2448)
- Change the root volume to persist (p. 2449)
- Change the initial size of the root volume (p. 2451)

Root volume type

You can launch an instance from either an instance store-backed AMI or an Amazon EBS-backed AMI. The description of an AMI includes which type of AMI it is; you'll see the root device referred to in some places as either ebs (for Amazon EBS-backed) or instance store (for instance store-backed). This is important because there are significant differences between what you can do with each type of AMI. For more information about these differences, see Storage for the root device (p. 115). We recommend that you use AMIs backed by Amazon EBS, because these instances launch faster and use persistent storage.

Amazon EBS-backed instances

Instances that use Amazon EBS for the root volume automatically have an Amazon EBS volume attached. When you launch an Amazon EBS-backed instance, we create an Amazon EBS volume for each Amazon EBS snapshot referenced by the AMI you use. You can optionally use other Amazon EBS volumes or instance store volumes, depending on the instance type.

An Amazon EBS-backed instance can be stopped and later restarted without affecting data stored in the attached volumes. There are various instance- and volume-related tasks you can do when an Amazon EBS-backed instance is in a stopped state. For example, you can modify the properties of the instance, change its size, or update the kernel it is using, or you can attach your root volume to a different running instance for debugging or any other purpose. For more information, see Amazon EBS volumes (p. 2052).

Limitation

You can't use st1 or sc1 EBS volumes as root volumes.

Instance failure

If an Amazon EBS-backed instance fails, you can restore your session by following one of these methods:
Choose an AMI by root volume type

- Stop and then start again (try this method first).
- Automatically snapshot all relevant volumes and create a new AMI. For more information, see Create an Amazon EBS-backed Linux AMI (p. 173).
- Attach the volume to the new instance by following these steps:
  1. Create a snapshot of the root volume.
  2. Register a new AMI using the snapshot.
  3. Launch a new instance from the new AMI.
  4. Detach the remaining Amazon EBS volumes from the old instance.
  5. Reattach the Amazon EBS volumes to the new instance.

### Instance store-backed instances

Instances that use instance stores for the root volume automatically have one or more instance store volumes available, with one volume serving as the root volume. When an instance is launched, the image that is used to boot the instance is copied to the root volume. Note that you can optionally use additional instance store volumes, depending on the instance type.

Any data on the instance store volumes persists as long as the instance is running, but this data is deleted when the instance is terminated (instance store-backed instances do not support the Stop action) or if it fails (such as if an underlying drive has issues). For more information, see Amazon EC2 instance store (p. 2411).

#### Requirement

Only the following instance types support an instance store volume as the root volume: C3, D2, G2, I2, M3, and R3.

#### Instance failure

After an instance store-backed instance fails or terminates, it cannot be restored. If you plan to use Amazon EC2 instance store-backed instances, we highly recommend that you distribute the data on your instance stores across multiple Availability Zones. You should also back up critical data from your instance store volumes to persistent storage on a regular basis.

### Choose an AMI by root volume type

The AMI that you specify when you launch your instance determines the type of root device volume that your instance has. You can view AMIs by root device type using one of the following methods.
To choose an Amazon EBS-backed AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose AMIs.
3. From the filter lists, select the image type (such as Public images). In the search bar, choose Platform to select the operating system (such as Amazon Linux) and Root device type to select the root volume type (ebs).
4. (Optional) To get additional information to help you make your choice, choose the Preferences icon, toggle the columns to display, and choose Confirm.
5. Choose an AMI and write down its AMI ID.

To choose an instance store-backed AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose AMIs.
3. From the filter lists, select the image type (such as Public images). In the search bar, choose Platform to select the operating system (such as Amazon Linux), and Root device type to select the root volume type (instance-store).
4. (Optional) To get additional information to help you make your choice, choose the Preferences icon, toggle the columns to display, and choose Confirm.
5. Choose an AMI and write down its AMI ID.

AWS CLI

To verify the type of the root device volume of an AMI using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- describe-images (AWS CLI)
- Get-EC2Image (AWS Tools for Windows PowerShell)

Determine the root device type of your instance

Console

To determine the root device type of an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and select the instance.
3. On the Storage tab, under Root device details, check the value of Root device type as follows:
   - If the value is EBS, this is an Amazon EBS-backed instance.
   - If the value is INSTANCE-STORE, this is an instance store-backed instance.

AWS CLI

To determine the root device type of an instance using the command line

You can use one of the following commands. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).
Change the root volume to persist

By default, the root volume for an AMI backed by Amazon EBS is deleted when the instance terminates. You can change the default behavior to ensure that the volume persists after the instance terminates. To change the default behavior, set the DeleteOnTermination attribute to false using a block device mapping.

Tasks

- Configure the root volume to persist during instance launch (p. 2449)
- Configure the root volume to persist for an existing instance (p. 2450)
- Confirm that a root volume is configured to persist (p. 2451)

Configure the root volume to persist during instance launch

You can configure the root volume to persist when you launch an instance using the Amazon EC2 console or the command line tools.

Console

To configure the root volume to persist when you launch an instance using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and then choose Launch instances.
3. Choose an Amazon Machine Image (AMI), choose and instance type, choose a key pair, and configure your network settings.
4. For Configure storage, choose Advanced.
5. Expand the root volume.
6. For Delete on termination, choose No.
7. When you are finished configuring your instance, choose Launch instance.

AWS CLI

To configure the root volume to persist when you launch an instance using the AWS CLI

Use the run-instances command and include a block device mapping that sets the DeleteOnTermination attribute to false.

```
$ aws ec2 run-instances --block-device-mappings file://mapping.json ...other parameters...
```

Specify the following in mapping.json.

```json
[
  {
    "DeviceName": "/dev/sda1",
    "Ebs": {
      "DeleteOnTermination": false
    }
  }
]
```
Tools for Windows PowerShell

**To configure the root volume to persist when you launch an instance using the Tools for Windows PowerShell**

Use the `New-EC2Instance` command and include a block device mapping that sets the `DeleteOnTermination` attribute to `false`.

```powershell
C:\> $ebs = New-Object Amazon.EC2.Model.EbsBlockDevice
C:\> $ebs.DeleteOnTermination = $false
C:\> $bdm = New-Object Amazon.EC2.Model.BlockDeviceMapping
C:\> $bdm.DeviceName = "dev/xvda"
C:\> $bdm.Ebs = $ebs
C:\> New-EC2Instance -ImageId ami-0abcdef1234567890 -BlockDeviceMapping $bdm ...
```

**Configure the root volume to persist for an existing instance**

You can configure the root volume to persist for a running instance using the command line tools only.

**AWS CLI**

**To configure the root volume to persist for an existing instance using the AWS CLI**

Use the `modify-instance-attribute` command with a block device mapping that sets the `DeleteOnTermination` attribute to `false`.

```shell
aws ec2 modify-instance-attribute --instance-id i-1234567890abcdef0 --block-device-mappings file://mapping.json
```

Specify the following in `mapping.json`.

```json
[
  {
    "DeviceName": "/dev/xvda",
    "Ebs": {
      "DeleteOnTermination": false
    }
  }
]
```

**Tools for Windows PowerShell**

**To configure the root volume to persist for an existing instance using the AWS Tools for Windows PowerShell**

Use the `Edit-EC2InstanceAttribute` command with a block device mapping that sets the `DeleteOnTermination` attribute to `false`.

```powershell
C:\> $ebs = New-Object Amazon.EC2.Model.EbsInstanceBlockDeviceSpecification
C:\> $ebs.DeleteOnTermination = $false
C:\> $bdm = New-Object Amazon.EC2.Model.InstanceBlockDeviceMappingSpecification
C:\> $bdm.DeviceName = "/dev/xvda"
C:\> $bdm.Ebs = $ebs
C:\> Edit-EC2InstanceAttribute -InstanceId i-1234567890abcdef0 -BlockDeviceMapping $bdm
```
Confirm that a root volume is configured to persist

You can confirm that a root volume is configured to persist using the Amazon EC2 console or the command line tools.

**Console**

**To confirm that a root volume is configured to persist using the Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances** and then select the instance.
3. In the **Storage** tab, under **Block devices**, locate the entry for the root volume. If **Delete on termination** is **No**, the volume is configured to persist.

**AWS CLI**

**To confirm that a root volume is configured to persist using the AWS CLI**

Use the `describe-instances` command and verify that the `DeleteOnTermination` attribute in the `BlockDeviceMappings` response element is set to `false`.

```
$ aws ec2 describe-instances --instance-id i-1234567890abcdef0
```

```json
...
"BlockDeviceMappings": [

   { "DeviceName": "/dev/sda1",
     "Ebs": {
         "Status": "attached",
         "DeleteOnTermination": false,
         "VolumeId": "vol-1234567890abcdef0",
         "AttachTime": "2013-07-19T02:42:39.000Z"
     }
   },
...
```

**Tools for Windows PowerShell**

**To confirm that a root volume is configured to persist using the AWS Tools for Windows PowerShell**

Use the `Get-EC2Instance` and verify that the `DeleteOnTermination` attribute in the `BlockDeviceMappings` response element is set to `false`.

```
C:\> (Get-EC2Instance -InstanceId i-i-1234567890abcdef0).Instances.BlockDeviceMappings.Ebs
```

Change the initial size of the root volume

By default, the size of the root volume is determined by the size of the snapshot. You can increase the initial size of the root volume using the block device mapping of the instance as follows.

1. Determine the device name of the root volume specified in the AMI, as described in [View the EBS volumes in an AMI block device mapping](p. 2458).
2. Confirm the size of the snapshot specified in the AMI block device mapping, as described in View Amazon EBS snapshot information (p. 2155).

3. Override the size of the root volume using the instance block device mapping, as described in Update the block device mapping when launching an instance (p. 2459), specifying a volume size that is larger than the snapshot size.

For example, the following entry for the instance block device mapping increases the size of the root volume, /dev/xvda, to 100 GiB. You can omit the snapshot ID in the instance block device mapping because the snapshot ID is already specified in the AMI block device mapping.

```json
{
    "DeviceName": "/dev/xvda",
    "Ebs": {
        "VolumeSize": 100
    }
}
```

For more information, see Block device mappings (p. 2454).

## Device names on Linux instances

When you attach a volume to your instance, you include a device name for the volume. This device name is used by Amazon EC2. The block device driver for the instance assigns the actual volume name when mounting the volume, and the name assigned can be different from the name that Amazon EC2 uses.

The number of volumes that your instance can support is determined by the operating system. For more information, see Instance volume limits (p. 2444).

### Contents
- Available device names (p. 2452)
- Device name considerations (p. 2453)

For information about device names on Windows instances, see Device naming on Windows instances in the Amazon EC2 User Guide for Windows Instances.

### Available device names

There are two types of virtualization available for Linux instances: paravirtual (PV) and hardware virtual machine (HVM). The virtualization type of an instance is determined by the AMI used to launch the instance. All instance types support HVM AMIs. Some previous generation instance types support PV AMIs. Be sure to note the virtualization type of your AMI because the recommended and available device names that you can use depend on the virtualization type of your instance. For more information, see Linux AMI virtualization types (p. 117).

The following table lists the available device names that you can specify in a block device mapping or when attaching an EBS volume.

<table>
<thead>
<tr>
<th>Virtualization type</th>
<th>Available</th>
<th>Reserved for root volume</th>
<th>Recommended for EBS volumes</th>
<th>Instance store volumes</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>/dev/sd[a-z][1-15]</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Device name considerations

Keep the following in mind when selecting a device name:

- Although you can attach your EBS volumes using the device names used to attach instance store volumes, we strongly recommend that you don’t because the behavior can be unpredictable.
- The number of NVMe instance store volumes for an instance depends on the size of the instance. NVMe instance store volumes are automatically enumerated and assigned an NVMe device name (/dev/nvme[0-26]n1).
- Depending on the block device driver of the kernel, the device could be attached with a different name than you specified. For example, if you specify a device name of /dev/sdh, your device could be renamed /dev/xvdh or /dev/hdh. In most cases, the trailing letter remains the same. In some versions of Red Hat Enterprise Linux (and its variants, such as CentOS), the trailing letter could change (/dev/sda could become /dev/xvde). In these cases, the trailing letter of each device name is incremented the same number of times. For example, if /dev/sdb is renamed /dev/z/xvd/f, then /dev/sdc is renamed /dev/xvdf. Amazon Linux creates a symbolic link for the name you specified to the renamed device. Other operating systems could behave differently.
- HVM AMIs do not support the use of trailing numbers on device names, except for /dev/sda1, which is reserved for the root device, and /dev/sda2. While using /dev/sda2 is possible, we do not recommend using this device mapping with HVM instances.
- When using PV AMIs, you cannot attach volumes that share the same device letters both with and without trailing digits. For example, if you attach a volume as /dev/sdc and another volume as /dev/sdc1, only /dev/sdc is visible to the instance. To use trailing digits in device names, you must use trailing digits on all device names that share the same base letters (such as /dev/sdc1, /dev/sdc2, /dev/sdc3).
• Some custom kernels might have restrictions that limit use to /dev/sd[f-p] or /dev/sd[f-p][1-6]. If you're having trouble using /dev/sd[q-z] or /dev/sd[q-z][1-6], try switching to /dev/sd[f-p] or /dev/sd[f-p][1-6].

Block device mappings

Each instance that you launch has an associated root device volume, which is either an Amazon EBS volume or an instance store volume. You can use block device mapping to specify additional EBS volumes or instance store volumes to attach to an instance when it's launched. You can also attach additional EBS volumes to a running instance; see Attach an Amazon EBS volume to an instance (p. 2076). However, the only way to attach instance store volumes to an instance is to use block device mapping to attach the volumes as the instance is launched.

For more information about root device volumes, see Change the root volume to persist (p. 2449).

Contents

• Block device mapping concepts (p. 2454)
• AMI block device mapping (p. 2457)
• Instance block device mapping (p. 2459)

Block device mapping concepts

A block device is a storage device that moves data in sequences of bytes or bits (blocks). These devices support random access and generally use buffered I/O. Examples include hard disks, CD-ROM drives, and flash drives. A block device can be physically attached to a computer or accessed remotely as if it were physically attached to the computer.

Amazon EC2 supports two types of block devices:

• Instance store volumes (virtual devices whose underlying hardware is physically attached to the host computer for the instance)
• EBS volumes (remote storage devices)

A block device mapping defines the block devices (instance store volumes and EBS volumes) to attach to an instance. You can specify a block device mapping as part of creating an AMI so that the mapping is used by all instances launched from the AMI. Alternatively, you can specify a block device mapping when you launch an instance, so this mapping overrides the one specified in the AMI from which you launched the instance. Note that all NVMe instance store volumes supported by an instance type are automatically enumerated and assigned a device name on instance launch; including them in your block device mapping has no effect.

Contents

• Block device mapping entries (p. 2454)
• Block device mapping instance store caveats (p. 2455)
• Example block device mapping (p. 2456)
• How devices are made available in the operating system (p. 2456)

Block device mapping entries

When you create a block device mapping, you specify the following information for each block device that you need to attach to the instance:
The device name used within Amazon EC2. The block device driver for the instance assigns the actual volume name when mounting the volume. The name assigned can be different from the name that Amazon EC2 recommends. For more information, see Device names on Linux instances (p. 2452).

For Instance store volumes, you also specify the following information:

- The virtual device: ephemeral[0-23]. Note that the number and size of available instance store volumes for your instance varies by instance type.

For NVMe instance store volumes, the following information also applies:

- These volumes are automatically enumerated and assigned a device name; including them in your block device mapping has no effect.

For EBS volumes, you also specify the following information:

- The ID of the snapshot to use to create the block device (snap-xxxxxxxx). This value is optional as long as you specify a volume size. You can't specify the ID of an archived snapshot.
- The size of the volume, in GiB. The specified size must be greater than or equal to the size of the specified snapshot.
- Whether to delete the volume on instance termination (true or false). The default value is true for the root device volume and false for attached volumes. When you create an AMI, its block device mapping inherits this setting from the instance. When you launch an instance, it inherits this setting from the AMI.
- The volume type, which can be gp2 and gp3 for General Purpose SSD, io1 and io2 for Provisioned IOPS SSD, st1 for Throughput Optimized HDD, sc1 for Cold HDD, or standard for Magnetic.
- The number of input/output operations per second (IOPS) that the volume supports. (Used only with io1 and io2 volumes.)

Block device mapping instance store caveats

There are several caveats to consider when launching instances with AMIs that have instance store volumes in their block device mappings.

- Some instance types include more instance store volumes than others, and some instance types contain no instance store volumes at all. If your instance type supports one instance store volume, and your AMI has mappings for two instance store volumes, then the instance launches with one instance store volume.
- Instance store volumes can only be mapped at launch time. You cannot stop an instance without instance store volumes (such as the t2.micro), change the instance to a type that supports instance store volumes, and then restart the instance with instance store volumes. However, you can create an AMI from the instance and launch it on an instance type that supports instance store volumes, and map those instance store volumes to the instance.
- If you launch an instance with instance store volumes mapped, and then stop the instance and change it to an instance type with fewer instance store volumes and restart it, the instance store volume mappings from the initial launch still show up in the instance metadata. However, only the maximum number of supported instance store volumes for that instance type are available to the instance.

Note
When an instance is stopped, all data on the instance store volumes is lost.

- Depending on instance store capacity at launch time, M3 instances may ignore AMI instance store block device mappings at launch unless they are specified at launch. You should specify instance store block device mappings at launch time, even if the AMI you are launching has the instance store
volumes mapped in the AMI, to ensure that the instance store volumes are available when the instance launches.

Example block device mapping

This figure shows an example block device mapping for an EBS-backed instance. It maps /dev/sdb to ephemeral0 and maps two EBS volumes, one to /dev/sdh and the other to /dev/sdj. It also shows the EBS volume that is the root device volume, /dev/sda1.

How devices are made available in the operating system

Device names like /dev/sdh and xvdh are used by Amazon EC2 to describe block devices. The block device mapping is used by Amazon EC2 to specify the block devices to attach to an EC2 instance. After a block device is attached to an instance, it must be mounted by the operating system before you can access the storage device. When a block device is detached from an instance, it is unmounted by the operating system and you can no longer access the storage device.

With a Linux instance, the device names specified in the block device mapping are mapped to their corresponding block devices when the instance first boots. The instance type determines which instance store volumes are formatted and mounted by default. You can mount additional instance store volumes at launch, as long as you don't exceed the number of instance store volumes available for your instance type. For more information, see Amazon EC2 instance store (p. 2411). The block device driver for the
instance determines which devices are used when the volumes are formatted and mounted. For more information, see Attach an Amazon EBS volume to an instance (p. 2076).

AMI block device mapping

Each AMI has a block device mapping that specifies the block devices to attach to an instance when it is launched from the AMI. To add more block devices to an AMI, you must create your own AMI.

Contents

• Specify a block device mapping for an AMI (p. 2457)
  • View the EBS volumes in an AMI block device mapping (p. 2458)

Specify a block device mapping for an AMI

There are two ways to specify volumes in addition to the root volume when you create an AMI. If you've already attached volumes to a running instance before you create an AMI from the instance, the block device mapping for the AMI includes those same volumes. For EBS volumes, the existing data is saved to a new snapshot, and it's this new snapshot that's specified in the block device mapping. For instance store volumes, the data is not preserved.

For an EBS-backed AMI, you can add EBS volumes and instance store volumes using a block device mapping. For an instance store-backed AMI, you can add instance store volumes only by modifying the block device mapping entries in the image manifest file when registering the image.

Note
For M3 instances, you must specify instance store volumes in the block device mapping for the instance when you launch it. When you launch an M3 instance, instance store volumes specified in the block device mapping for the AMI may be ignored if they are not specified as part of the instance block device mapping.

To add volumes to an AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose Instances.
3. Select an instance and choose Actions, Image and templates, Create image.
4. Enter a name and a description for the image.
5. The instance volumes appear under Instance volumes. To add another volume, choose Add volume.
6. For Volume type, choose the volume type. For Device choose the device name. For an EBS volume, you can specify additional details, such as a snapshot, volume size, volume type, IOPS, and encryption state.
7. Choose Create image.

To add volumes to an AMI using the command line

Use the create-image AWS CLI command to specify a block device mapping for an EBS-backed AMI. Use the register-image AWS CLI command to specify a block device mapping for an instance store-backed AMI.

Specify the block device mapping using the --block-device-mappings parameter. Arguments encoded in JSON can be supplied either directly on the command line or by reference to a file:

```
--block-device-mappings [mapping, ...]
```
To add an instance store volume, use the following mapping.

```json
{
   "DeviceName": "/dev/sdf",
   "VirtualName": "ephemeral0"
}
```

To add an empty 100 GiB gp2 volume, use the following mapping.

```json
{
   "DeviceName": "/dev/sdg",
   "Ebs": {
      "VolumeSize": 100
   }
}
```

To add an EBS volume based on a snapshot, use the following mapping.

```json
{
   "DeviceName": "/dev/sdh",
   "Ebs": {
      "SnapshotId": "snap-xxxxxxxx"
   }
}
```

To omit a mapping for a device, use the following mapping.

```json
{
   "DeviceName": "/dev/sdj",
   "NoDevice": ""
}
```

Alternatively, you can use the `-BlockDeviceMapping` parameter with the following commands (AWS Tools for Windows PowerShell):

- `New-EC2Image`
- `Register-EC2Image`

View the EBS volumes in an AMI block device mapping

You can easily enumerate the EBS volumes in the block device mapping for an AMI.

To view the EBS volumes for an AMI using the console

1. Open the Amazon EC2 console.
2. In the navigation pane, choose AMIs.
3. Choose EBS images from the Filter list to get a list of EBS-backed AMIs.
4. Select the desired AMI, and look at the Details tab. At a minimum, the following information is available for the root device:
   - Root Device Type (ebs)
   - Root Device Name (for example, /dev/sda1)
   - Block Devices (for example, /dev/sda1=snap-1234567890abcdef0:8:true)
If the AMI was created with additional EBS volumes using a block device mapping, the **Block Devices** field displays the mapping for those additional volumes as well. (This screen doesn't display instance store volumes.)

**To view the EBS volumes for an AMI using the command line**

Use the `describe-images` (AWS CLI) command or `Get-EC2Image` (AWS Tools for Windows PowerShell) command to enumerate the EBS volumes in the block device mapping for an AMI.

### Instance block device mapping

By default, an instance that you launch includes any storage devices specified in the block device mapping of the AMI from which you launched the instance. You can specify changes to the block device mapping for an instance when you launch it, and these updates overwrite or merge with the block device mapping of the AMI.

**Limitations**

- For the root volume, you can only modify the following: volume size, volume type, and the **Delete on Termination** flag.
- When you modify an EBS volume, you can't decrease its size. Therefore, you must specify a snapshot whose size is equal to or greater than the size of the snapshot specified in the block device mapping of the AMI.

**Contents**

- Update the block device mapping when launching an instance (p. 2459)
- Update the block device mapping of a running instance (p. 2461)
- View the EBS volumes in an instance block device mapping (p. 2461)
- View the instance block device mapping for instance store volumes (p. 2462)

### Update the block device mapping when launching an instance

You can add EBS volumes and instance store volumes to an instance when you launch it. Note that updating the block device mapping for an instance doesn't make a permanent change to the block device mapping of the AMI from which it was launched.

**To add volumes to an instance using the console**

1. Open the Amazon EC2 console.
2. From the dashboard, choose **Launch Instance**.
3. On the **Choose an Amazon Machine Image (AMI)** page, select the AMI to use and choose **Select**.
4. Follow the wizard to complete the **Choose an Instance Type** and **Configure Instance Details** pages.
5. On the **Add Storage** page, you can modify the root volume, EBS volumes, and instance store volumes as follows:
   - To change the size of the root volume, locate the **Root** volume under the **Type** column, and change its **Size** field.
   - To suppress an EBS volume specified by the block device mapping of the AMI used to launch the instance, locate the volume and click its **Delete** icon.
   - To add an EBS volume, choose **Add New Volume**, choose **EBS** from the **Type** list, and fill in the fields (**Device**, **Snapshot**, and so on).
• To suppress an instance store volume specified by the block device mapping of the AMI used to launch the instance, locate the volume, and choose its **Delete** icon.

• To add an instance store volume, choose **Add New Volume**, select **Instance Store** from the **Type** list, and select a device name from **Device**.

6. Complete the remaining wizard pages, and choose **Launch**.

**To add volumes to an instance using the AWS CLI**

Use the `run-instances` AWS CLI command with the `--block-device-mappings` option to specify a block device mapping for an instance at launch.

For example, suppose that an EBS-backed AMI specifies the following block device mapping:

- `/dev/sdb` = ephemeral0
- `/dev/sdh` = snap-1234567890abcdef0
- `/dev/sdj` = 100

To prevent `/dev/sdj` from attaching to an instance launched from this AMI, use the following mapping.

```json
{
  "DeviceName": "/dev/sdj",
  "NoDevice": ""
}
```

To increase the size of `/dev/sdh` to 300 GiB, specify the following mapping. Notice that you don't need to specify the snapshot ID for `/dev/sdh`, because specifying the device name is enough to identify the volume.

```json
{
  "DeviceName": "/dev/sdh",
  "Ebs": {
    "VolumeSize": 300
  }
}
```

To increase the size of the root volume at instance launch, first call `describe-images` with the ID of the AMI to verify the device name of the root volume. For example, "RootDeviceName": "/dev/xvda".

To override the size of the root volume, specify the device name of the root device used by the AMI and the new volume size.

```json
{
  "DeviceName": "/dev/xvda",
  "Ebs": {
    "VolumeSize": 100
  }
}
```

To attach an additional instance store volume, `/dev/sdc`, specify the following mapping. If the instance type doesn't support multiple instance store volumes, this mapping has no effect. If the instance supports NVMe instance store volumes, they are automatically enumerated and assigned an NVMe device name.

```json
{
  "DeviceName": "/dev/sdc",
  "VirtualName": "ephemeral1"
}
```
To add volumes to an instance using the AWS Tools for Windows PowerShell

Use the -BlockDeviceMapping parameter with the New-EC2Instance command (AWS Tools for Windows PowerShell).

Update the block device mapping of a running instance

You can use the modify-instance-attribute AWS CLI command to update the block device mapping of a running instance. You do not need to stop the instance before changing this attribute.

```bash
aws ec2 modify-instance-attribute --instance-id i-1a2b3c4d --block-device-mappings file://mapping.json
```

For example, to preserve the root volume at instance termination, specify the following in mapping.json.

```json
[
  {
    "DeviceName": "/dev/sda1",
    "Ebs": {
      "DeleteOnTermination": false
    }
  }
]
```

Alternatively, you can use the -BlockDeviceMapping parameter with the Edit-EC2InstanceAttribute command (AWS Tools for Windows PowerShell).

View the EBS volumes in an instance block device mapping

You can easily enumerate the EBS volumes mapped to an instance.

**Note**

For instances launched before the release of the 2009-10-31 API, AWS can't display the block device mapping. You must detach and reattach the volumes so that AWS can display the block device mapping.

**To view the EBS volumes for an instance using the console**

1. Open the Amazon EC2 console.
2. In the navigation pane, choose **Instances**.
3. In the search box, enter **Root device type**, and then choose **EBS**. This displays a list of EBS-backed instances.
4. Select the desired instance and look at the details displayed in the **Storage** tab. At a minimum, the following information is available for the root device:
   - **Root device type** (for example, EBS)
   - **Root device name** (for example, /dev/xvda)
   - **Block devices** (for example, /dev/xvda, /dev/sdf, and /dev/sdj)

   If the instance was launched with additional EBS volumes using a block device mapping, they appear under **Block devices**. Any instance store volumes do not appear on this tab.
5. To display additional information about an EBS volume, choose its volume ID to go to the volume page. For more information, see View information about an Amazon EBS volume (p. 2087).
To view the EBS volumes for an instance using the command line

Use the `describe-instances` (AWS CLI) command or `Get-EC2Instance` (AWS Tools for Windows PowerShell) command to enumerate the EBS volumes in the block device mapping for an instance.

**View the instance block device mapping for instance store volumes**

When you view the block device mapping for your instance, you can see only the EBS volumes, not the instance store volumes. The method you use to view the instance store volumes for your instance depends on the volume type.

**NVMe instance store volumes**

You can use the NVMe command line package, `nvme-cli`, to query the NVMe instance store volumes in the block device mapping. Download and install the package on your instance, and then run the following command.

```
[ec2-user ~]$ sudo nvme list
```

The following is example output for an instance. The text in the Model column indicates whether the volume is an EBS volume or an instance store volume. In this example, both `/dev/nvme1n1` and `/dev/nvme2n1` are instance store volumes.

<table>
<thead>
<tr>
<th>Node</th>
<th>SN</th>
<th>Model</th>
<th>Namespace</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/dev/nvme0n1</code></td>
<td>vol06afcf3f8715b7a597</td>
<td>Amazon Elastic Block Store</td>
<td>1</td>
</tr>
<tr>
<td><code>/dev/nvme1n1</code></td>
<td>AWS2C1436F5159EB6614</td>
<td>Amazon EC2 NVMe Instance Storage</td>
<td>1</td>

<td></td>
</tr>
</tbody>
</table>

**HDD or SSD instance store volumes**

You can use instance metadata to query the HDD or SSD instance store volumes in the block device mapping. NVMe instance store volumes are not included.

The base URI for all requests for instance metadata is `http://169.254.169.254/latest/`. For more information, see Instance metadata and user data (p. 1004).

First, connect to your running instance. From the instance, use this query to get its block device mapping.

**IMDSv2**

```
```

**IMDSv1**

```
```

The response includes the names of the block devices for the instance. For example, the output for an instance store–backed m1.small instance looks like this.

```
ami
```
Torn write prevention

Torn write prevention is a block storage feature designed by AWS to improve the performance of your I/O-intensive relational database workloads and reduce latency without negatively impacting data resiliency. Relational databases that use InnoDB or XtraDB as the database engine, such as MySQL and MariaDB, will benefit from torn write prevention.

Typically, relational databases that use pages larger than the power fail atomicity of the storage device use data logging mechanisms to protect against torn writes. MariaDB and MySQL use a doublewrite buffer file to log data before writing it to data tables. In the event of incomplete or torn writes, as a result of operating system crashes or power loss during write transactions, the database can recover the data from the doublewrite buffer. The additional I/O overhead associated with writing to the doublewrite buffer impacts database performance and application latency, and it reduces the number transactions that can be processed per second. For more information about doublewrite buffer, see the MariaDB and MySQL documentation.

With torn write prevention, data is written to storage in all-or-nothing write transactions, which eliminates the need for using the doublewrite buffer. This prevents partial, or torn, data from being written to storage in the event of operating system crashes or power loss during write transactions. The number of transactions processed per second can be increased by up to 30 percent, and write latency can be decreased by up to 50 percent, without compromising the resiliency of your workloads.

Pricing

There are no additional costs for using torn write prevention.
Supported block sizes and block boundary alignments

Torn write prevention supports write operations for 4 KiB, 8 KiB, and 16 KiB blocks of data. The data block start logical block address (LBA) must be aligned to the respective block boundary size of 4 KiB, 8 KiB, or 16 KiB. For example, for 16 KiB write operations, the data block start LBA must be aligned to a block boundary size of 16 KiB.

The following table shows support across storage and instance types.

<table>
<thead>
<tr>
<th></th>
<th>4 KiB blocks</th>
<th>8 KiB blocks</th>
<th>16 KiB blocks</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Instance store volumes</strong></td>
<td>All NVMe instance store volumes attached to current generation I-family instances (p. 287).</td>
<td>I4i, Im4gn, and Is4gen instances supported by AWS Nitro SSD.</td>
<td>All Amazon EBS volumes attached to nitro-based instances (p. 295).</td>
</tr>
<tr>
<td><strong>Amazon EBS volumes</strong></td>
<td>All Amazon EBS volumes attached to</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

To confirm whether your instance and volume support torn write prevention, query to check if the instance supports torn write prevention and other details, like supported block and boundary sizes. For more information, see Check torn write prevention support and configuration (p. 2464).

Requirements

For torn write prevention to work properly, an I/O operation must meet size, alignment, and boundary requirements, as specified in the NTWPU, NTWGU, NTWBU fields. You must configure your operating system to ensure that the specific storage subsystem (file system, LVM, RAID, etc) does not modify I/O properties down the storage stack, including block merges, splits, or block address relocation, before being submitted to the device.

Torn write prevent has been tested with the following configuration:

- An instance type and storage type that supports the required block size.
- Amazon Linux 2 with kernel version 5.10 or later.
- ext4 with bigalloc enabled and a cluster size of 16 KiB, and the most recent ext4 utilities (e2fsprogs 1.46.5 or later).
- O_DIRECT file access mode to bypass Linux kernel buffer cache.

Note

You do not need to disable I/O merging for MySQL and MariaDB workloads.

Check torn write prevention support and configuration

To confirm whether your instance and volume supports torn write prevention, and to view the NVMe namespace vendor specific data that contains torn write prevention information, use the following command.

```
$ sudo nvme id-ns -v device_name
```
Configure your software stack for torn write prevention

Configure your software stack for torn write prevention

Torn write prevention is enabled by default on supported instance types with supported volumes (p. 2464). You do not need to enabled any additional settings to enable your volume or instance for torn write prevention.
Note
There is no performance impact on workloads that do not support torn write prevention. You do not need to make any changes for these workloads. Workloads that do support torn write prevention, but are not configured to use it, continue to use the doublewrite buffer and do not receive any performance benefits.

To configure your MySQL or MariaDB software stack to disable the doublewrite buffer and use torn write prevention, complete the following steps:

1. Configure your volume to use ext4 file system with the BigAlloc option and set the cluster size to 4 KiB, 8 KiB, or 16 KiB. Using BigAlloc with a cluster size of 4 KiB, 8 KiB, or 16 KiB ensures that the file system allocates files that align with the respective boundary.

   ```
   $ mkfs.ext4 -O bigalloc -C 4096|8192|16384 device_name
   ```

   Note
   For MySQL and MariaDB, you must use `-C 16384` to match the database page size. Setting allocation granularity to a value other than a multiple of the page size can result in allocations that might be mismatched with torn write prevention boundaries of the storage device.

   For example:

   ```
   $ mkfs.ext4 -O bigalloc -C 16384 /dev/nvme1n1
   ```

2. Configure InnoDB to use the `0_DIRECT` flushing method and turn off InnoDB doublewrite. Use your preferred text editor to open `/etc/my.cnf`, and update the `innodb_flush_method` and `innodb_doublewrite` parameters as follows:

   ```
   innodb_flush_method=0_DIRECT
   innodb_doublewrite=0
   ```

   Important
   If you are using Logical Volume Manager (LVM) or other storage virtualization layer, make sure that the starting offsets of the volumes are aligned on 16 KiB multiples. This is relative to the underlying NVMe storage to account for the metadata headers and superblocks used by the storage virtualization layer. If you add an offset to the LVM physical volume, it can cause misalignment between the file system allocations and the NVMe device's offsets, which would invalidate torn write prevention. For more information, see `--dataalignmentoffset` in the Linux manual page.
Resources and tags

Amazon EC2 provides different resources that you can create and use. Some of these resources include images, instances, volumes, and snapshots. When you create a resource, we assign the resource a unique resource ID.

Some resources can be tagged with values that you define, to help you organize and identify them.

The following topics describe resources and tags, and how you can work with them.

Contents
- Recycle Bin (p. 2467)
- Resource locations (p. 2497)
- Resource IDs (p. 2498)
- List and filter your resources (p. 2499)
- Amazon EC2 Global View (p. 2505)
- Tag your Amazon EC2 resources (p. 2507)
- Amazon EC2 service quotas (p. 2523)
- Amazon EC2 usage reports (p. 2524)

Recycle Bin

Recycle Bin is a data recovery feature that enables you to restore accidentally deleted Amazon EBS snapshots and EBS-backed AMIs. When using Recycle Bin, if your resources are deleted, they are retained in the Recycle Bin for a time period that you specify before being permanently deleted.

You can restore a resource from the Recycle Bin at any time before its retention period expires. After you restore a resource from the Recycle Bin, the resource is removed from the Recycle Bin and you can use it in the same way that you use any other resource of that type in your account. If the retention period expires and the resource is not restored, the resource is permanently deleted from the Recycle Bin and it is no longer available for recovery.

Using Recycle Bin helps to ensure business continuity by protecting your business-critical data against accidental deletion.

Topics
- How does it work? (p. 2468)
- Supported resources (p. 2468)
- Considerations (p. 2469)
- Quotas (p. 2471)
- Related services (p. 2471)
- Pricing (p. 2471)
- Required IAM permissions (p. 2471)
How does it work?

To enable and use Recycle Bin, you must create retention rules in the AWS Regions in which you want to protect your resources. Retention rules specify the following:

- The resource type that you want to protect.
- The resources that you want to retain in the Recycle Bin when they are deleted.
- The retention period for which to retain resources in the Recycle Bin before they are permanently deleted.

With Recycle Bin, you can create two types of retention rules:

- **Tag-level retention rules** — A tag-level retention rule uses resource tags to identify the resources that are to be retained in the Recycle Bin. For each retention rule, you specify one or more tag key and value pairs. Resources of the specified type that are tagged with at least one of the tag key and value pairs that are specified in the retention rule are automatically retained in the Recycle Bin upon deletion. Use this type of retention rule if you want to protect specific resources in your account based on their tags.

- **Region-level retention rules** — A Region-level retention rule does not have any resource tags specified. It applies to all of the resources of the specified type in the Region in which the rule is created, even if the resources are not tagged. Use this type of retention rule if you want to protect all resources of a specific type in a specific Region.

While a resource is in the Recycle Bin, you have the ability to restore it for use at any time.

The resource remains in the Recycle Bin until one of the following happens:

- You manually restore it for use. When you restore a resource from the Recycle Bin, the resource is removed from the Recycle Bin and it immediately becomes available for use. You can use restored resources in the same way as any other resource of that type in your account.

- The retention period expires. If the retention period expires, and the resource has not been restored from the Recycle Bin, the resource is permanently deleted from the Recycle Bin and it can no longer be viewed or restored.

Supported resources

Recycle Bin supports the following resource types:

- Amazon EBS snapshots
  
  **Important**
  
  Recycle Bin retention rules also apply to archived snapshots in the archive storage tier. If you delete an archived snapshot that matches a retention rule, that snapshot is retained in the Recycle Bin for the period defined in the retention rule. Archived snapshots are billed at the rate for archived snapshots while they are in the Recycle Bin.

- Amazon EBS-backed Amazon Machine Images (AMIs)
  
  **Note**
  
  Retention rules also apply to disabled AMIs.
Considerations

The following considerations apply when working with Recycle Bin and retention rules.

General considerations

- **Important** When you create your first retention rule, it can take up to 30 minutes for the rule to become active and for it to start retaining resources. After you create the first retention rule, subsequent retention rules become active and start retaining resources almost immediately.

- If a resource matches more than one retention rule upon deletion, then the retention rule with the longest retention period takes precedence.

- You can't manually delete a resource from the Recycle Bin. The resource will be automatically deleted when its retention period expires.

- While a resource is in the Recycle Bin, you can only view it, restore it, or modify its tags. To use the resource in any other way, you must first restore it.

- If any AWS service, such as AWS Backup or Amazon Data Lifecycle Manager, deletes a resource that matches a retention rule, that resource is automatically retained by Recycle Bin.

- When a resource is sent to the Recycle Bin, the following system-generate tag is assigned to the resource:
  - Tag key — `aws:recycle-bin:resource-in-bin`
  - Tag value — `true`

  You can't manually edit or delete this tag. When the resource is restored from the Recycle Bin, the tag is automatically removed.

Considerations for snapshots

- **Important** If you have retention rules for AMIs and for their associated snapshots, make the retention period for the snapshots the same or longer than the retention period for the AMIs. This ensures that Recycle Bin does not delete the snapshots associated with an AMI before deleting the AMI itself, as this would make the AMI unrecoverable.

- If a snapshot is enabled for fast snapshot restore when it is deleted, fast snapshot restore is automatically disabled shortly after the snapshot is sent to the Recycle Bin.

- If you restore the snapshot before fast snapshot restore is disabled for the snapshot, it remains enabled.

- If you restore the snapshot, after fast snapshot restore has been disabled, it remains disabled. If needed, you must manually re-enable fast snapshot restore.

- If a snapshot is shared when it is deleted, it is automatically unshared when it is sent to the Recycle Bin. If you restore the snapshot, all of the previous sharing permissions are automatically restored.

- If a snapshot that was created by another AWS service, such as AWS Backup is sent to the Recycle Bin and you later restore that snapshot from the Recycle Bin, it is no longer managed by the AWS service that created it. You must manually delete the snapshot if it is no longer needed.

Considerations for AMIs

- Only Amazon EBS-backed AMIs are supported.

- **Important** If you have retention rules for AMIs and for their associated snapshots, make the retention period for the snapshots the same or longer than the retention period for the AMIs. This
ensures that Recycle Bin does not delete the snapshots associated with an AMI before deleting the AMI itself, as this would make the AMI unrecoverable.

- If an AMI is shared when it is deleted, it is automatically unshared when it is sent to the Recycle Bin. If you restore the AMI, all of the previous sharing permissions are automatically restored.
- Before you can restore an AMI from the Recycle Bin, you must first restore all of its associated snapshots from the Recycle Bin and ensure that they are in the available state.
- If the snapshots that are associated with the AMI are deleted from the Recycle Bin, the AMI is no longer recoverable. The AMI will be deleted when the retention period expires.
- If an AMI that was created by another AWS service, such as AWS Backup, is sent to the Recycle Bin and you later restore that AMI from the Recycle Bin, it is no longer managed by the AWS service that created it. You must manually delete the AMI if it is no longer needed.

**Considerations for Amazon Data Lifecycle Manager snapshot policies**

- If Amazon Data Lifecycle Manager deletes a snapshot that matches a retention rule, that snapshot is automatically retained by Recycle Bin.
- If Amazon Data Lifecycle Manager deletes a snapshot and sends it to the Recycle Bin when the policy's retention threshold is reached, and you manually restore the snapshot from the Recycle Bin, you must manually delete that snapshot when it is no longer needed. Amazon Data Lifecycle Manager will no longer manage the snapshot.
- If you manually delete a snapshot that was created by a policy, and that snapshot is in the Recycle Bin when the policy's retention threshold is reached, Amazon Data Lifecycle Manager will not delete the snapshot. Amazon Data Lifecycle Manager does not manage the snapshots while they are stored in the Recycle Bin.

If the snapshot is restored from the Recycle Bin before the policy's retention threshold is reached, Amazon Data Lifecycle Manager will delete the snapshot when the policy's retention threshold is reached.

If the snapshot is restored from the Recycle Bin after the policy's retention threshold is reached, Amazon Data Lifecycle Manager will no longer delete the snapshot. You must manually delete the snapshot when it is no longer needed.

**Considerations for AWS Backup**

- If AWS Backup deletes a snapshot that matches a retention rule, that snapshot is automatically retained by Recycle Bin.

**Considerations for archived snapshots**

- Recycle Bin retention rules also apply to archived snapshots in the archive storage tier. If you delete an archived snapshot that matches a retention rule, that snapshot is retained in the Recycle Bin for the period defined in the retention rule.

Archived snapshots are billed at the rate for archived snapshots while they are in the Recycle Bin.

If a retention rule deletes an archived snapshot from the Recycle Bin before the minimum archive period of 90 days, you are billed for the remaining days. For more information, see [Pricing and billing](p. 2134).

To use an archived snapshot that is in the Recycle Bin, you must first recover the snapshot from the Recycle Bin and then restore it from the archive tier to the standard tier.
Quotas

The following quotas apply to Recycle Bin.

<table>
<thead>
<tr>
<th>Quota</th>
<th>Default quota</th>
</tr>
</thead>
<tbody>
<tr>
<td>Retention rules per Region</td>
<td>250</td>
</tr>
<tr>
<td>Tag key and value pairs per retention rule</td>
<td>50</td>
</tr>
</tbody>
</table>

Related services

Recycle Bin works with the following services:

- AWS CloudTrail — Enables you to record events that occur in Recycle Bin. For more information, see Monitor Recycle Bin using AWS CloudTrail (p. 2487).

Pricing

Resources in the Recycle Bin are billed at their standard rates. There are no additional charges for using Recycle Bin and retention rules. For more information, see Amazon EBS pricing.

Note

Some resources might still appear in the Recycle Bin console or in the AWS CLI and API output for a short period after their retention periods have expired and they have been permanently deleted. You are not billed for these resources. Billing stops as soon as the retention period expires.

You can use the following AWS generated cost allocation tags for cost tracking and allocation purposes when using AWS Billing and Cost Management.

- Key: aws:recycle-bin:resource-in-bin
- Value: true

For more information, see AWS-generated cost allocation tags in the AWS Billing and Cost Management User Guide.

Required IAM permissions

By default, users don't have permission to work with Recycle Bin, retention rules, or with resources that are in the Recycle Bin. To allow users to work with these resources, you must create IAM policies that grant permission to use specific resources and API actions. Once the policies are created, you must add permissions to your users, groups, or roles.

Topics

- Permissions for working with Recycle Bin and retention rules (p. 2472)
- Permissions for working with resources in the Recycle Bin (p. 2473)
- Condition keys for Recycle Bin (p. 2473)
Permissions for working with Recycle Bin and retention rules

To work with Recycle Bin and retention rules, users need the following permissions.

- `rbin:CreateRule`
- `rbin:UpdateRule`
- `rbin:GetRule`
- `rbin:ListRules`
- `rbin:DeleteRule`
- `rbin:TagResource`
- `rbin:UntagResource`
- `rbin:ListTagsForResource`
- `rbin:LockRule`
- `rbin:UnlockRule`

To use the Recycle Bin console, users need the `tag:GetResources` permission.

The following is an example IAM policy that includes the `tag:GetResources` permission for console users. If some permissions are not needed, you can remove them from the policy.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "rbin:CreateRule",
            "rbin:UpdateRule",
            "rbin:GetRule",
            "rbin:ListRules",
            "rbin:DeleteRule",
            "rbin:TagResource",
            "rbin:UntagResource",
            "rbin:ListTagsForResource",
            "rbin:LockRule",
            "rbin:UnlockRule",
            "tag:GetResources"
         ],
         "Resource": "*
      }
   ]
}
```

To provide access, add permissions to your users, groups, or roles:

- Users and groups in AWS IAM Identity Center:
  Create a permission set. Follow the instructions in [Create a permission set](#) in the [AWS IAM Identity Center User Guide](#).

- Users managed in IAM through an identity provider:
  Create a role for identity federation. Follow the instructions in [Creating a role for a third-party identity provider (federation)](#) in the [IAM User Guide](#).

- IAM users:
  - Create a role that your user can assume. Follow the instructions in [Creating a role for an IAM user](#) in the [IAM User Guide](#).
  - (Not recommended) Attach a policy directly to a user or add a user to a user group. Follow the instructions in [Adding permissions to a user (console)](#) in the [IAM User Guide](#).
Permissions for working with resources in the Recycle Bin

For more information about the IAM permissions needed to work with resources in the Recycle Bin, see the following:

- Permissions for working with snapshots in the Recycle Bin (p. 2166)
- Permissions for working with AMIs in the Recycle Bin (p. 236)

Condition keys for Recycle Bin

Recycle Bin defines the following condition keys that you can use in the Condition element of an IAM policy to control the conditions under which the policy statement applies. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

Topics

- rbin:Request/ResourceType condition key (p. 2473)
- rbin:Attribute/ResourceType condition key (p. 2474)

rbin:Request/ResourceType condition key

The rbin:Request/ResourceType condition key can be used to filter access on CreateRule and ListRules requests based on the value specified for the ResourceType request parameter.

Example 1 - CreateRule

The following sample IAM policy allows IAM principals to make CreateRule requests only if the value specified for the ResourceType request parameter is EBS_SNAPSHOT or EC2_IMAGE. This allows the principal to create new retention rules for snapshots and AMIs only.

```
{
  "Version" : "2012-10-17",
  "Statement" : [
    {
      "Effect" : "Allow",
      "Action" : ["rbin:CreateRule"],
      "Resource" : "*",
      "Condition" : {
        "StringEquals" : {
          "rbin:Request/ResourceType" : ["EBS_SNAPSHOT", "EC2_IMAGE"]
        }
      }
    }
  ]
}
```

Example 2 - ListRules

The following sample IAM policy allows IAM principals to make ListRules requests only if the value specified for the ResourceType request parameter is EBS_SNAPSHOT. This allows the principal to list retention rules for snapshots only, and it prevents them from listing retention rules for any other resource type.

```
{
  "Version" : "2012-10-17",
  "Statement" : [
    {
      "Effect" : "Allow",
      "Action" : ["rbin:ListRules"],
      "Resource" : "*",
      "Condition" : {
        "StringEquals" : {
          "rbin:Request/ResourceType" : ["EBS_SNAPSHOT"]
        }
      }
    }
  ]
}
```
Required IAM permissions

"Statement" : [
    {  
        "Effect" : "Allow",
        "Action" : [  
            "rbin:ListRules"
        ],
        "Resource" : "*",
        "Condition" : {
            "StringEquals" : {
                "rbin:Request/ResourceType" : "EBS_SNAPSHOT"
            }
        }
    }
]

rbin:Attribute/ResourceType condition key

The rbin:Attribute/ResourceType condition key can be used to filter access on DeleteRule, GetRule, UpdateRule, LockRule, UnlockRule, TagResource, UntagResource, and ListTagsForResource requests based on the value of the retention rule's ResourceType attribute.

Example 1 - UpdateRule

The following sample IAM policy allows IAM principals to make UpdateRule requests only if the ResourceType attribute of the requested retention rule is EBS_SNAPSHOT or EC2_IMAGE. This allows the principal to update retention rules for snapshots and AMIs only.

```
{
    "Version" : "2012-10-17",
    "Statement" : [
        {  
            "Effect" : "Allow",
            "Action" : [  
                "rbin:UpdateRule"
            ],
            "Resource" : "*",
            "Condition" : {
                "StringEquals" : {
                    "rbin:Attribute/ResourceType" : ['EBS_SNAPSHOT', 'EC2_IMAGE']
                }
            }
        }
    ]
}
```

Example 2 - DeleteRule

The following sample IAM policy allows IAM principals to make DeleteRule requests only if the ResourceType attribute of the requested retention rule is EBS_SNAPSHOT. This allows the principal to delete retention rules for snapshots only.

```
{
    "Version" : "2012-10-17",
    "Statement" : [
        {  
            "Effect" : "Allow",
            "Action" : [  
                "rbin:DeleteRule"
            ],
            "Resource" : "*",
            "Condition" : {
```

Work with retention rules

To enable and use Recycle Bin, you must create *retention rules* in the AWS Regions in which you want to protect your resources. Retention rules specify the following:

- The resource type that you want to protect.
- The resources that you want to retain in the Recycle Bin when they are deleted.
- The retention period for which to retain resources in the Recycle Bin before they are permanently deleted.

With Recycle Bin, you can create two types of retention rules:

- **Tag-level retention rules** — A tag-level retention rule uses resource tags to identify the resources that are to be retained in the Recycle Bin. For each retention rule, you specify one or more tag key and value pairs. Resources of the specified type that are tagged with at least one of the tag key and value pairs that are specified in the retention rule are automatically retained in the Recycle Bin upon deletion. Use this type of retention rule if you want to protect specific resources in your account based on their tags.

- **Region-level retention rules** — A Region-level retention rule does not have any resource tags specified. It applies to all of the resources of the specified type in the Region in which the rule is created, even if the resources are not tagged. Use this type of retention rule if you want to protect all resources of a specific type in a specific Region.

After you create a retention rule, resources that match its criteria are automatically retained in the Recycle Bin for the specified retention period after they are deleted.

**Topics**

- [Create a retention rule](#)
- [View Recycle Bin retention rules](#)
- [Update retention rules](#)
- [Lock retention rules](#)
- [Unlock retention rules](#)
- [Tag retention rules](#)
- [View retention rule tags](#)
- [Remove tags from retention rules](#)
- [Delete Recycle Bin retention rules](#)

**Create a retention rule**

When you create a retention rule, you must specify the following required parameters:

- The resource type that is to be protected by the retention rule.
- The resources that are to be protected by the retention rule. You can create retention rules at the tag level and the Region level.

```json
"StringEquals" : {
    "rbin:Attribute/ResourceType" : "EBS_SNAPSHOT"
  }
}
```
To create a tag-level retention rule, specify the resource tags that identify the resources to protect. You can specify up to 50 tags for each rule, and add the same tag key and value pair to a maximum of five retention rules.

To create a Region-level retention rule, do not specify any tag key and value pairs. In this case, all resources of the specified type are protected.

The period to retain the resources in the Recycle Bin after they are deleted. The period can be up to 1 year (365 days).

You can also specify the following optional parameters:

- An optional name for the retention rule. The name can be up to 255 characters long.
- An optional description for the retention rule. The description can be up to 255 characters long.

**Note**
We recommend that you do not include personally identifying, confidential, or sensitive information in the retention rule description.

- Optional retention rule tags to help identify and organize your retention rules. You can assign up to 50 tags to each rule.

You can also optionally lock retention rules on creation. If you lock a retention rule on creation, you must also specify the unlock delay period, which can be 7 to 30 days. Retention rules remain unlocked by default unless you explicitly lock them.

Retention rules function only in the Regions in which they are created. If you intend to use Recycle Bin in other Regions, you must create additional retention rules in those Regions.

You can create a Recycle Bin retention rule using one of the following methods.

Recycle Bin console

**To create a retention rule**

2. In the navigation pane, choose Retention rules, and then choose Create retention rule.
3. In the Rule details section, do the following:
   a. *(Optional)* For Retention rule name, enter a descriptive name for the retention rule.
   b. *(Optional)* For Retention rule description, enter a brief description for the retention rule.
4. In the Rule settings section, do the following:
   a. For Resource type, select choose the type of resource for the retention rule to protect. The retention rule will retain only resources of this type in the Recycle Bin.
   b. Do one of the following:
      - To create a Region-level retention rule that matches all deleted resources of the specified type in the Region, select Apply to all resources. The retention rule will retain all deleted resources of the specified in the Recycle Bin upon deletion, even if the resources do not have any tags.
      - To create a tag-level retention rule, for Resource tags to match, enter the tag key and value pairs to use to identify resource of the specified type that are to be retained in the Recycle Bin. Only resources of the specified type that have at least one of the specified tag key and value pairs will be retained by the retention rule.
      - For Retention period, enter the number of days for which the retention rule is to retain resources in the Recycle Bin.
5. *(Optional)* To lock the retention rule, for **Rule lock settings**, select **Lock**, and then for **Unlock delay period**, specify the unlock delay period in days. A locked retention rule can't be modified or deleted. To modify or delete the rule, you must first unlock it and then wait for the unlock delay period to expire. For more information, see [Lock retention rules](p. 2480).

   To leave the retention rule unlocked, for **Rule lock settings**, keep **Unlock** selected. An unlocked retention rule can be modified or deleted at any time. For more information, see [Unlock retention rules](p. 2481).

6. *(Optional)* In the **Tags** section, do the following:
   
   - To tag the rule with custom tags, choose **Add tag** and then enter the tag key and value pair.

7. Choose **Create retention rule**.

**AWS CLI**

**To create a retention rule**

Use the `create-rule` AWS CLI command. For `--retention-period`, specify the number of days to retain deleted snapshots in the Recycle Bin. For `--resource-type`, specify `EBS_SNAPSHOT` for snapshots or `EC2_IMAGE` for AMIs. To create a tag-level retention rule, for `--resource-tags`, specify the tags to use to identify the snapshots that are to be retained. To create a Region-level retention rule, omit `--resource-tags`. To lock a retention rule, include `--lock-configuration`, and specify the unlock delay period in days.

```
$ aws rbin create-rule \
--retention-period RetentionPeriodValue=number_of_days,RetentionPeriodUnit=DAYS \
--resource-type EBS_SNAPSHOT|EC2_IMAGE \
--description "rule_description" \
--lock-configuration \
'UnlockDelay={UnlockDelayUnit=DAYS,UnlockDelayValue=unlock_delay_in_days}' \
--resource-tags ResourceTagKey=tag_key,ResourceTagValue=tag_value
```

**Example 1**

The following example command creates an unlocked Region-level retention rule that retains all deleted snapshots for a period of 7 days.

```
$ aws rbin create-rule \
--retention-period RetentionPeriodValue=7,RetentionPeriodUnit=DAYS \
--resource-type EBS_SNAPSHOT \n--description "Match all snapshots"
```

**Example 2**

The following example command creates a tag-level rule that retains deleted snapshots that are tagged with `purpose=production` for a period of 7 days.

```
$ aws rbin create-rule \
--retention-period RetentionPeriodValue=7,RetentionPeriodUnit=DAYS \
--resource-type EBS_SNAPSHOT \n--description "Match snapshots with a specific tag" \n--resource-tags ResourceTagKey=purpose,ResourceTagValue=production
```

**Example 3**

The following example command creates a locked Region-level retention rule that retains all deleted snapshots for a period of 7 days. The retention rule is locked with an unlock delay period of 7 days.
View Recycle Bin retention rules

You can view Recycle Bin retention rules using one of the following methods.

Recycle Bin console

**To view retention rules**

2. In the navigation pane, choose Retention rules.
3. The grid lists all of the retention rules for the selected Region. To view more information about a specific retention rule, select it in the grid.

AWS CLI

**To view all of your retention rules**

Use the `list-rules` AWS CLI command, and for `--resource-type`, specify `EBS_SNAPSHOT` for snapshots or `EC2_IMAGE` for AMIs.

```
$ aws rbin list-rules --resource-type EBS_SNAPSHOT|EC2_IMAGE
```

**Example**

The following example command provides lists all retention rules that retain snapshots.

```
$ aws rbin list-rules --resource-type EBS_SNAPSHOT
```

**To view information for a specific retention rule**

Use the `get-rule` AWS CLI command.

```
$ aws rbin get-rule --identifier rule_ID
```

**Example**

The following example command provides information about retention rule pwxIkFcvge4.

```
$ aws rbin get-rule --identifier pwxIkFcvge4
```

Update retention rules

You can update an unlocked retention rule's description, resource tags, and retention period at any time after creation. You can't update a retention rule's resource type or unlock delay period, even if the retention rule is unlocked.
You can't update a locked retention rule in any way. If you need to modify a locked retention rule, you must first unlock it and wait for the unlock delay period to expire.

If you need to modify the unlock delay period for a locked retention rule, you must unlock the retention rule (p. 2481), and wait for the current unlock delay period to expire. When the unlock delay period is expired, you must relock the retention rule (p. 2480) and specify the new unlock delay period.

**Note**

We recommend that you do not include personally identifying, confidential, or sensitive information in the retention rule description.

After you update a retention rule, the changes only apply to new resources that it retains. The changes do not affect resources that it previously sent to the Recycle Bin. For example, if you update a retention rule's retention period, only snapshots that are deleted after the update are retained for the new retention period. Snapshots that it sent to the Recycle Bin before the update are still retained for the previous (old) retention period.

You can update a retention rule using one of the following methods.

**Recycle Bin console**

**To update a retention rule**

1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation pane, choose Retention rules.
3. In the grid, select the retention rule to update, and choose Actions, Edit retention rule.
4. In the Rule details section, update Retention rule name and Retention rule description as needed.
5. In the Rule settings section, update the Resource type, Resource tags to match, and Retention period as needed.
6. In the Tags section, add or remove retention rule tags as needed.
7. Choose Save retention rule.

**AWS CLI**

**To update a retention rule**

Use the update-rule AWS CLI command. For --identifier, specify the ID of the retention rule to update. For --resource-types, specify EBS_SNAPSHOT for snapshots or EC2_IMAGE for AMIs.

```
$ aws rbin update-rule \
--identifier rule_ID \
--retention-period RetentionPeriodValue=number_of_days,RetentionPeriodUnit=DAYS \
--resource-type EBS_SNAPSHOT|EC2_IMAGE \
--description "rule_description"
```

**Example**

The following example command updates retention rule 6lsJ2Fa9nh9 to retain all snapshots for 7 days and updates its description.

```
$ aws rbin update-rule \
--identifier 6lsJ2Fa9nh9 \
--retention-period RetentionPeriodValue=7,RetentionPeriodUnit=DAYS \
--resource-type EBS_SNAPSHOT \
--description "Retain for three weeks"
```
Lock retention rules

Recycle Bin lets you lock Region-level retention rules at any time.

Note
You can't lock tag-level retention rules.

A locked retention rule can't be modified or deleted, even by users who have the required IAM permissions. Lock your retention rules to help protect them against accidental or malicious modifications and deletions.

When you lock a retention rule, you must specify an unlock delay period. This is the period of time that you must wait after unlocking the retention rule before you can modify or delete it. You cannot modify or delete the retention rule during the unlock delay period. You can modify or delete the retention rule only after the unlock delay period has expired.

You can't change the unlock delay period after the retention rule has been locked. If your account permissions have been compromised, the unlock delay period gives you additional time to detect and respond to security threats. The length of this period should be longer than the time it takes for you to identify and respond to security breaches. To set the right duration, you can review previous security incidents and the time needed to identify and remediate an account breach.

We recommend that you use Amazon EventBridge rules to notify you of retention rule lock state changes. For more information, see Monitor Recycle Bin using Amazon EventBridge (p. 2485).

Considerations

- You can lock Region-level retention rules only.
- You can lock an unlocked retention rule at any time.
- The unlock delay period must be 7 to 30 days.
- You can re-lock a retention rule during the unlock delay period. Relocking the retention rule resets the unlock delay period.

You can lock a Region-level retention rule using one of the following methods.

Recycle Bin console

To lock a retention rule

1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation panel, choose Retention rules.
3. In the grid, select the unlocked retention rule to lock, and choose Actions, Edit retention rule lock.
4. In the Edit retention rule lock screen, choose Lock, and then for Unlock delay period, specify the unlock delay period in days.
5. Select the I acknowledge that locking the retention rule will prevent it from being modified or deleted check box, and then choose Save.

AWS CLI

To lock an unlocked retention rule

Use the lock-rule AWS CLI command. For --identifier, specify the ID of the retention rule to lock. For --lock-configuration, specify the unlock delay period in days.

$ aws rbin lock-rule \
Unlock retention rules

You can't modify or delete a locked retention rule. If you need to modify a locked retention rule, you must first unlock it. After you have unlocked the retention rule, you must wait for the unlock delay period to expire before you modify or delete it. You can't modify or delete a retention rule during the unlock delay period.

An unlocked retention rule can be modified and deleted at any time by a user who has the required IAM permissions. Leaving your retention rules unlocked could expose them to accidental or malicious modifications and deletions.

Considerations

- You can re-lock a retention rule during the unlock delay period.
- You can re-lock a retention rule after the unlock delay period has expired.
- You can't bypass the unlock delay period.
- You can't change the unlock delay period after the initial lock.

We recommend that you use Amazon EventBridge rules to notify you of retention rule lock state changes. For more information, see Monitor Recycle Bin using Amazon EventBridge (p. 2485).

You can unlock a locked Region-level retention rule using one of the following methods.

Recycle Bin console

To unlock a retention rule

1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation panel, choose Retention rules.
3. In the grid, select the locked retention rule to unlock, and choose Actions, Edit retention rule lock.
4. On the Edit retention rule lock screen, choose Unlock, and then choose Save.

AWS CLI

To unlock a locked retention rule

Use the unlock-rule AWS CLI command. For --identifier, specify the ID of the retention rule to unlock.

$ aws rbin unlock-rule \n--identifier rule_ID

Example

The following example command locks retention rule 6lsJ2Fa9nh9 and sets the unlock delay period to 15 days.

```bash
$ aws rbin lock-rule \n--identifier 6lsJ2Fa9nh9 \n--lock-configuration 'UnlockDelay={UnlockDelayUnit=DAYS,UnlockDelayValue=15}'
```
Example
The following example command unlocks retention rule 6lsJ2Fa9nh9

```
$ aws rbin unlock-rule \
   --identifier 6lsJ2Fa9nh9
```

Tag retention rules
You can assign custom tags to your retention rules to categorize them in different ways, for example, by purpose, owner, or environment. This helps you to efficiently find a specific retention rule based on the custom tags that you assigned.

You can assign a tag to a retention rule using one of the following methods.

Recycle Bin console

To tag a retention rule
1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation pane, choose Retention rules.
3. Select the retention rule to tag, choose the Tags tab, and then choose Manage tags.
4. Choose Add tag. For Key, enter the tag key. For Value, enter the tag value.
5. Chose Save.

AWS CLI

To tag a retention rule
Use the tag-resource AWS CLI command. For --resource-arn, specify the Amazon Resource Name (ARN) of the retention rule to tag, and for --tags, specify the tag key and value pair.

```
$ aws rbin tag-resource \
   --resource-arn retention_rule_arn \
   --tags key=tag_key,value=tag_value
```

Example
The following example command tags retention rule arn:aws:rbin:us-east-1:123456789012:rule/n0oSBBtItF3 with tag purpose=production.

```
$ aws rbin tag-resource \
   --resource-arn arn:aws:rbin:us-east-1:123456789012:rule/n0oSBBtItF3 \
   --tags key=purpose,value=production
```

View retention rule tags
You can view the tags assigned to a retention rule using one of the following methods.

Recycle Bin console

To view tags for a retention rule
1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation pane, choose Retention rules.
Work with retention rules

3. Select the retention rule for which to view the tags, and choose the Tags tab.

AWS CLI

To view the tags assigned to a retention rule

Use the list-tags-for-resource AWS CLI command. For --resource-arn, specify the ARN of the retention rule.

```
$ aws rbin list-tags-for-resource --resource-arn retention_rule_arn
```

Example

The following example command lists the tags for retention rule arn:aws:rbin:us-east-1:123456789012:rule/nOoSBBtItF3.

```
$ aws rbin list-tags-for-resource --resource-arn arn:aws:rbin:us-east-1:123456789012:rule/nOoSBBtItF3
```

Remove tags from retention rules

You can remove tags from a retention rule using one of the following methods.

Recycle Bin console

To remove a tag from a retention rule

1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation pane, choose Retention rules.
3. Select the retention rule from which to remove the tag, choose the Tags tab, and then choose Manage tags.
4. Choose Remove next to the tag to remove.
5. Choose Save.

AWS CLI

To remove a tag from a retention rule

Use the untag-resource AWS CLI command. For --resource-arn, specify the ARN of the retention rule. For --tagkeys, specify the tags keys of the tags to remove.

```
$ aws rbin untag-resource \ --resource-arn retention_rule_arn \ --tagkeys tag_key
```

Example

The following example command removes tags that have a tag key of purpose from retention rule arn:aws:rbin:us-east-1:123456789012:rule/nOoSBBtItF3.

```
$ aws rbin untag-resource \ --resource-arn arn:aws:rbin:us-east-1:123456789012:rule/nOoSBBtItF3 \ --tagkeys purpose
```
Delete Recycle Bin retention rules

You can delete a retention rule at any time. When you delete a retention rule, it no longer retains new resources in the Recycle Bin after they have been deleted. Resources that were sent to the Recycle Bin before the retention rule was deleted continue to be retained in the Recycle Bin according to the retention period defined in the retention rule. When the period expires, the resource is permanently deleted from the Recycle Bin.

You can delete a retention rule using one of the following methods.

Recycle Bin console

To delete a retention rule

1. Open the Recycle Bin console at https://console.aws.amazon.com/rbin/home/
2. In the navigation pane, choose Retention rules.
3. In the grid, select the retention rule to delete, and choose Actions, Delete retention rule.
4. When prompted, enter the confirmation message and choose Delete retention rule.

AWS CLI

To delete a retention rule

Use the delete-rule AWS CLI command. For --identifier, specify the ID of the retention rule to delete.

```bash
$ aws rbin delete-rule --identifier rule_ID
```

Example

The following example command deletes retention rule 6lsJ2Fa9nh9.

```bash
$ aws rbin delete-rule --identifier 6lsJ2Fa9nh9
```

Work with resources in the Recycle Bin

Recycle Bin supports the following resource types:

- Amazon EBS snapshots
- Amazon EBS-backed Amazon Machine Images (AMIs)

Topics

- Work with snapshots in the Recycle Bin (p. 2484)
- Work with AMIs in the Recycle Bin (p. 2485)

This section includes links to the topics that explain how to work with the supported resource types.

Work with snapshots in the Recycle Bin

For more information about working with snapshots in the Recycle Bin, see Recover snapshots from the Recycle Bin (p. 2166).
Work with AMIs in the Recycle Bin

For more information about working with AMIs in the Recycle Bin, see Recover AMIs from the Recycle Bin (p. 236).

Monitor Recycle Bin

You can use the following features to monitor the Recycle Bin.

Topics

- Monitor Recycle Bin using Amazon EventBridge (p. 2485)
- Monitor Recycle Bin using AWS CloudTrail (p. 2487)

Monitor Recycle Bin using Amazon EventBridge

Recycle Bin sends events to Amazon EventBridge for actions performed on retention rules. With EventBridge, you can establish rules that initiate programmatic actions in response to these events. For example, you can create a EventBridge rule that sends a notification to your email when a retention rule is unlocked and it enters its unlock delay period. For more information, see Creating Amazon EventBridge rules that react to events.

Events in EventBridge are represented as JSON objects. The fields that are unique to the event are contained in the detail section of the JSON object. The event field contains the event name. The result field contains the completed status of the action that initiated the event. For more information, see Amazon EventBridge event patterns in the Amazon EventBridge User Guide.

For more information about Amazon EventBridge, see What Is Amazon EventBridge? in the Amazon EventBridge User Guide.

Events

- RuleLocked (p. 2485)
- RuleChangeAttempted (p. 2486)
- RuleUnlockScheduled (p. 2486)
- RuleUnlockingNotice (p. 2487)
- RuleUnlocked (p. 2487)

RuleLocked

The following is an example of an event that Recycle Bin generates when a retention rule is successfully locked. This event can be generated by CreateRule and LockRule requests. The API that generated the event is noted in the api-name field.

```json
{
    "version": "0",
    "id": "exampleb-b491-4cf7-a9f1-bf370example",
    "detail-type": "Recycle Bin Rule Locked",
    "source": "aws.rbin",
    "account": "123456789012",
    "time": "2022-08-10T16:37:50Z",
    "region": "us-west-2",
    "resources": [
        "arn:aws:rbin:us-west-2:123456789012:rule/a12345abcde"
    ],
    "detail":
```
RuleChangeAttempted

The following is an example of an event that Recycle Bin generates for unsuccessful attempts to modify or delete a locked rule. This event can be generated by `DeleteRule` and `UpdateRule` requests. The API that generated the event is noted in the `api-name` field.

```
{
    "version": "0",
    "id": "exampleb-b491-4cf7-a9f1-bf370example",
    "detail-type": "Recycle Bin Rule Change Attempted",
    "source": "aws.rbin",
    "account": "123456789012",
    "time": "2022-08-10T16:37:50Z",
    "region": "us-west-2",
    "resources": [
        "arn:aws:rbin:us-west-2:123456789012:rule/a12345abcde"
    ],
    "detail": {
        "detail-version": "1.0.0",
        "rule-id": "a12345abcde",
        "rule-description": "locked account level rule",
        "unlock-delay-period": "30 days",
        "api-name": "DeleteRule"
    }
}
```

RuleUnlockScheduled

The following is an example of an event that Recycle Bin generates when a retention rule is unlocked and it starts its unlock delay period.

```
{
    "version": "0",
    "id": "exampleb-b491-4cf7-a9f1-bf370example",
    "detail-type": "Recycle Bin Rule Unlock Scheduled",
    "source": "aws.rbin",
    "account": "123456789012",
    "time": "2022-08-10T16:37:50Z",
    "region": "us-west-2",
    "resources": [
        "arn:aws:rbin:us-west-2:123456789012:rule/a12345abcde"
    ],
    "detail": {
        "detail-version": "1.0.0",
        "rule-id": "a12345abcde",
        "rule-description": "locked account level rule",
        "unlock-delay-period": "30 days",
        "scheduled-unlock-time": "2022-09-10T16:37:50Z",

        "api-name": "DeleteRule"
    }
}
```
RuleUnlockingNotice

The following is an example of an event that Recycle Bin generates daily while a retention rule is in its unlock delay period, until the day before the unlock delay period expires.

```
{
  "version": "0",
  "id": "exampleb-b491-4cf7-a9f1-bf37@example",
  "detail-type": "Recycle Bin Rule Unlocking Notice",
  "source": "aws.rbin",
  "account": "123456789012",
  "time": "2022-08-10T16:37:50Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:rbin:us-west-2:123456789012:rule/a12345abcde"
  ],
  "detail":
  {
    "detail-version": "1.0.0",
    "rule-id": "a12345abcde",
    "rule-description": "locked account level rule",
    "unlock-delay-period": "30 days",
    "scheduled-unlock-time": "2022-09-10T16:37:50Z"
  }
}
```

RuleUnlocked

The following is an example of an event that Recycle Bin generates when the unlock delay period for a retention rule expires and the retention rule can be modified or deleted.

```
{
  "version": "0",
  "id": "exampleb-b491-4cf7-a9f1-bf37@example",
  "detail-type": "Recycle Bin Rule Unlocked",
  "source": "aws.rbin",
  "account": "123456789012",
  "time": "2022-08-10T16:37:50Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:rbin:us-west-2:123456789012:rule/a12345abcde"
  ],
  "detail":
  {
    "detail-version": "1.0.0",
    "rule-id": "a12345abcde",
    "rule-description": "locked account level rule",
    "unlock-delay-period": "30 days",
    "scheduled-unlock-time": "2022-09-10T16:37:50Z"
  }
}
```

Monitor Recycle Bin using AWS CloudTrail

The Recycle Bin service is integrated with AWS CloudTrail. CloudTrail is a service that provides a record of actions taken by a user, role, or an AWS service. CloudTrail captures all API calls performed in Recycle Bin as events. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon Simple Storage Service (Amazon S3) bucket. If you don't configure a trail, you can still view the most recent management events in the CloudTrail console in Event history. You can use the information collected by CloudTrail to determine the request that was made to Recycle Bin, the IP address from which the request was made, who made the request, when it was made, and additional details.
Recycle Bin information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When supported event activity occurs in Recycle Bin, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for Recycle Bin, create a trail. A trail enables CloudTrail to deliver log files to an S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see Overview for creating a trail in the AWS CloudTrail User Guide.

Supported API actions

For Recycle Bin, you can use CloudTrail to log the following API actions as management events.

- CreateRule
- UpdateRule
- GetRules
- ListRule
- DeleteRule
- TagResource
- UntagResource
- ListTagsForResource
- LockRule
- UnlockRule

For more information about logging management events, see Logging management events for trails in the CloudTrail User Guide.

Identity information

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root user or user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentityElement.

Understand Recycle Bin log file entries

A trail is a configuration that enables delivery of events as log files to an S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following are example CloudTrail log entries.
CreateRule

```
{

Resource locations

Amazon EC2 resources are specific to the AWS Region or Availability Zone in which they reside.

<table>
<thead>
<tr>
<th>Resource</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon EC2 resource identifiers</td>
<td>Regional</td>
<td>Each resource identifier, such as an AMI ID, instance ID, EBS volume ID, or EBS snapshot ID, is tied to its Region and can be used only in the Region where you created the resource.</td>
</tr>
<tr>
<td>User-supplied resource names</td>
<td>Regional</td>
<td>Each resource name, such as a security group name or key pair name, is tied to its Region and can be used</td>
</tr>
</tbody>
</table>
Resource IDs

When resources are created, we assign each resource a unique resource ID. A resource ID takes the form of a resource identifier (such as snap for a snapshot) followed by a hyphen and a unique combination of letters and numbers.

Each resource identifier, such as an AMI ID, instance ID, EBS volume ID, or EBS snapshot ID, is tied to its Region and can be used only in the Region where you created the resource.

You can use resource IDs to find your resources in the Amazon EC2 console. If you are using a command line tool or the Amazon EC2 API to work with Amazon EC2, resource IDs are required for certain commands. For example, if you are using the `stop-instances` AWS CLI command to stop an instance, you must specify the instance ID in the command.
Resource ID length

Prior to January 2016, the IDs assigned to newly created resources of certain resource types used 8 characters after the hyphen (for example, i-1a2b3c4d). From January 2016 to June 2018, we changed the IDs of these resource types to use 17 characters after the hyphen (for example, i-1234567890abcdef0). Depending on when your account was created, you might have some existing resources with short IDs, however, any new resources will receive the longer IDs.

List and filter your resources

You can get a list of some types of resources using the Amazon EC2 console. You can get a list of each type of resource using its corresponding command or API action. If you have many resources, you can filter the results to include, or exclude, only the resources that match certain criteria.

Contents

- List and filter resources using the console (p. 2499)
- List and filter using the CLI and API (p. 2503)
- View resources across Regions using Amazon EC2 Global View (p. 2505)

List and filter resources using the console

Contents

- List resources using the console (p. 2499)
- Filter resources using the console (p. 2499)

List resources using the console

You can view the most common Amazon EC2 resource types using the console. To view additional resources, use the command line interface or the API actions.

To list EC2 resources using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose the option that corresponds to the resource type. For example, to list your instances, choose Instances.

   The page displays all resources of the selected resource type.

Filter resources using the console

To filter a list of resources

1. In the navigation pane, select a resource type (for example, Instances).
2. Choose the search field.
3. Select the filter from the list.
4. Select an operator, for example, = (Equals). Some attributes have more available operators to select. Note that not all screens support selecting an operator.
5. Select a filter value.
6. To edit a selected filter, choose the filter token (blue box), make the required edits, and then choose Apply. Note that not all screens support editing the selected filter.
7. When you are finished, remove the filter.

The search and filter functionality differs slightly between the old and new Amazon EC2 console.

**New console**

The new console supports two types of filtering.

- **API filtering** happens on the server side. The filtering is applied on the API call, which reduces the number of resources returned by the server. It allows for quick filtering across large sets of resources, and it can reduce data transfer time and cost between the server and the browser. API filtering supports = (equals) and : (contains) operators, and is always case sensitive.

- **Client filtering** happens on the client side. It enables you to filter down on data that is already available in the browser (in other words, data that has already been returned by the API). Client filtering works well in conjunction with an API filter to filter down to smaller data sets in the browser. In addition to = (equals) and : (contains) operators, client filtering can also support range operators, such as >= (greater than or equal), and negation (inverse) operators, such as != (does not equal).

The new Amazon EC2 console supports the following types of searches:

**Search by keyword**

Searching by keyword is a free text search that lets you search for a value across all of your resources’ attributes or tags, without specifying an attribute or tag key to search.

**Note**

All keyword searches use **client filtering**.

To search by keyword, enter or paste what you’re looking for in the search field, and then choose **Enter**. For example, searching for 123 matches all instances that have 123 in any of their attributes, such as an IP address, instance ID, VPC ID, or AMI ID, or in any of their tags, such as the Name. If your free text search returns unexpected matches, apply additional filters.

**Search by attribute**

Searching by an attribute lets you search a specific attribute across all of your resources.

**Note**

Attribute searches use either **API filtering** or **client filtering**, depending on the selected attribute. When performing an attribute search, the attributes are grouped accordingly.

For example, you can search the **Instance state** attribute for all of your instances to return only instances that are in the stopped state. To do this:

1. In the search field on the **Instances** screen, start entering **Instance state**. As you enter the characters, the two types of filters appear for **Instance state: API filters** and **Client filters**.
2. To search on the server side, choose **Instance state** under **API filters**. To search on the client side, choose **Instance state (client)** under **Client filters**.

   A list of possible operators for the selected attribute appears.

3. Choose the **=** (Equals) operator.

   A list of possible values for the selected attribute and operator appears.

4. Choose **stopped** from the list.

**Search by tag**

Searching by a tag lets you filter the resources in the currently displayed table by a tag key or a tag value.

Tag searches use either **API filtering or client filtering**, depending on the settings in the Preferences window.

**To ensure API filtering for tags**

1. Open the **Preferences** window.
2. Clear the **Use regular expression matching** check box. If this check box is selected, client filtering is performed.
3. Select the **Use case sensitive matching** check box. If this check box is cleared, client filtering is performed.
4. Choose **Confirm**.

When searching by tag, you can use the following values:

- **(empty)** – Find all resources with the specified tag key, but there must be no tag value.
- **All values** – Find all resources with the specified tag key and any tag value.
- **Not tagged** – Find all resources that do not have the specified tag key.
- **The displayed value** – Find all resources with the specified tag key and the specified tag value.

You can use the following techniques to enhance or refine your searches:

**Inverse search**

Inverse searches let you search for resources that do **not** match a specified value. In the **Instances** and **AMIs** screens, inverse searches are performed by selecting the ! = (Does not equal) or !: (Does not contain) operator and then selecting a value. In other screens, inverse searches are performed by prefixing the search keyword with the exclamation mark (!) character.

**Note**

Inverse search is supported with keyword searches and attribute searches on **client** filters only. It is not supported with attribute searches on **API** filters.

For example, you can search the **Instance state** attribute for all of your instances to exclude all instances that are in the **terminated** state. To do this:

1. In the search field on the **Instances** screen, start entering **Instance state**. As you enter the characters, the two types of filters appear for **Instance state: API filters** and **Client filters**.
2. Under **Client filters**, choose **Instance state (client)**. Inverse search is only supported on **client** filters.

   A list of possible operators for the selected attribute appears.

3. Choose **!=** (Does not equal), and then choose **terminated**.
To filter instances based on an instance state attribute, you can also use the search icons (🔍) in the **Instance state** column. The search icon with a plus sign (+) displays all the instances that match that attribute. The search icon with a minus sign (-) excludes all instances that match that attribute.

Here is another example of using the inverse search: To list all instances that are not assigned the security group named **launch-wizard-1**, under **Client filters**, search by the **Security group name** attribute, choose !=, and in the search bar, enter **launch-wizard-1**.

**Partial search**

With partial searches, you can search for partial string values. To perform a partial search, enter only a part of the keyword that you want to search for. On the **Instances** and **AMIs** screens, partial searches can only be performed with the : (Contains) operator. On other screens, you can select the client filter attribute and immediately enter only a part of the keyword that you want to search for. For example, on the **Instance type** screen, to search for all **t2.micro**, **t2.small**, and **t2.medium** instances, search by the **Instance Type** attribute, and for the keyword, enter **t2**.

**Regular expression search**

To use regular expression searches, you must select the **Use regular expression matching** check box in the Preferences window.

Regular expressions are useful when you need to match the values in a field with a specific pattern. For example, to search for a value that starts with s, search for ^s. To search for a value that ends with xyz, search for xyz$. Or to search for a value that starts with a number that is followed by one or more characters, search for [0-9]+.*.

**Note**

Regular expression search is supported with keyword searches and attribute searches on client filters only. It is not supported with attribute searches on API filters.

**Case-sensitive search**

To use case-sensitive searches, you must select the **Use case sensitive matching** check box in the **Preferences** window. The case-sensitive preference only applies to client and tag filters.

**Note**

API filters are always case-sensitive.

**Wildcard search**

Use the * wildcard to match zero or more characters. Use the ? wildcard to match zero or one character. For example, if you have a data set with the values prod, prods, and production, a search of prod* matches all values, whereas prod? matches only prod and prods. To use the literal values, escape them with a backslash (\). For example, "prod\*" would match prod*.

**Note**

Wildcard search is supported with attribute and tag searches on API filters only. It is not supported with keyword searches, and with attribute and tag searches on client filters.

**Combining searches**

In general, multiple filters with the same attribute are automatically joined with OR. For example, searching for **Instance State** : Running and **Instance State** : Stopped returns all instances that are either running OR stopped. To join search with AND, search across different attributes. For example, searching for **Instance State** : Running and **Instance Type** : **c4.large** returns only instances that are of type **c4.large** AND that are in the running state.

**Old console**

The old Amazon EC2 console supports the following types of searches:
Search by keyword

Searching by keyword is a free text search that lets you search for a value across all of your resources' attributes. To search by keyword, enter or paste what you're looking for in the search field, and then choose Enter. For example, searching for 123 matches all instances that have 123 in any of their attributes, such as an IP address, instance ID, VPC ID, or AMI ID. If your free text search returns unexpected matches, apply additional filters.

Search by attributes

Searching by an attribute lets you search a specific attribute across all of your resources. For example, you can search the State attribute for all of your instances to return only instances that are in the stopped state. To do this:
1. In the search field on the Instances screen, start entering Instance  State. As you enter characters, a list of matching attributes appears.
2. Select Instance State from the list. A list of possible values for the selected attribute appears.
3. Select Stopped from the list.

You can use the following techniques to enhance or refine your searches:

Inverse search

Inverse searches let you search for resources that do not match a specified value. Inverse searches are performed by prefixing the search keyword with the exclamation mark (!) character. For example, to list all instances that are not terminated, search by the Instance State attribute, and for the keyword, enter !Terminated.

Partial search

With partial searches, you can search for partial string values. To perform a partial search, enter only a part of the keyword you want to search for. For example, to search for all t2.micro, t2.small, and t2.medium instances, search by the Instance Type attribute, and for the keyword, enter t2.

Regular expression search

Regular expressions are useful when you need to match the values in a field with a specific pattern. For example, to search for all instances that have an attribute value that starts with s, search for ^s. Or to search for all instances that have an attribute value that ends with xyz, search for xyz$.

Regular expression searches are not case-sensitive.

Combining searches

In general, multiple filters with the same attribute are automatically joined with OR. For example, searching for Instance State : Running and Instance State : Stopped returns all instances that are either running OR stopped. To join search with AND, search across different attributes. For example, searching for Instance State : Running and Instance Type : c4.large returns only instances that are of type c4.large AND that are in the stopped state.

List and filter using the CLI and API

Each resource type has a corresponding CLI command and API action that you use to list resources of that type. The resulting lists of resources can be long, so it can be faster and more useful to filter the results to include only the resources that match specific criteria.

Filtering considerations

- You can specify multiple filters and multiple filter values in a single request.
- You can use wildcards with the filter values. An asterisk (*) matches zero or more characters, and a question mark (?) matches zero or one character.
Filter values are case sensitive.
Your search can include the literal values of the wildcard characters; you just need to escape them with a backslash before the character. For example, a value of `*amazon?\` searches for the literal string `*amazon?\`.

### Supported filters

To see the supported filters for each Amazon EC2 resource, see the following documentation:

- **AWS CLI**: The `describe` commands in the [AWS CLI Command Reference-Arazon EC2](https://docs.aws.amazon.com/cli/latest/reference/ec2/describe-instances.html).
- **Query API**: The `Describe` API actions in the [Amazon EC2 API Reference](https://docs.aws.amazon.com/AWSEC2/latest/APIReference/)

### Example: Specify a single filter

You can list your Amazon EC2 instances using `describe-instances`. Without filters, the response contains information for all of your resources. You can use the following command to include only the running instances in your output.

```bash
aws ec2 describe-instances --filters Name=instance-state-name,Values=running
```

To list only the instance IDs for your running instances, add the `--query` parameter as follows.

```bash
aws ec2 describe-instances --filters Name=instance-state-name,Values=running --query "Reservations[*].Instances[*].InstanceId" --output text
```

The following is example output.

```
  i-0ef1f57f78d4775a4
  i-0626d4edd54f1286d
  i-04a636d18e83cfacb
```

### Example: Specify multiple filters or filter values

If you specify multiple filters or multiple filter values, the resource must match all filters to be included in the results.

You can use the following command to list all instances whose type is either `m5.large` or `m5d.large`.

```bash
aws ec2 describe-instances --filters Name=instance-type,Values=m5.large,m5d.large
```

You can use the following command to list all stopped instances whose type is `t2.micro`.

```bash
aws ec2 describe-instances --filters Name=instance-state-name,Values=stopped Name=instance-type,Values=t2.micro
```

### Example: Use wildcards in a filter value

If you specify database as the filter value for the description filter when describing EBS snapshots using `describe-snapshots`, the command returns only the snapshots whose description is “database”.

```bash
aws ec2 describe-snapshots --filters Name=description,Values=database
```
The * wildcard matches zero or more characters. If you specify *database* as the filter value, the command returns only snapshots whose description includes the word database.

```shell
aws ec2 describe-snapshots --filters Name=description,Values=*database*
```

The ? wildcard matches exactly 1 character. If you specify database? as the filter value, the command returns only snapshots whose description is "database" or "database" followed by one character.

```shell
aws ec2 describe-snapshots --filters Name=description,Values=database?
```

If you specify database????, the command returns only snapshots whose description is "database" followed by up to four characters. It excludes descriptions with "database" followed by five or more characters.

```shell
aws ec2 describe-snapshots --filters Name=description,Values=database????
```

**Example Example: Filter based on date**

With the AWS CLI, you can use JMESPath to filter results using expressions. For example, the following `describe-snapshots` command displays the IDs of all snapshots created by your AWS account (represented by `123456789012`) before the specified date (represented by `2020-03-31`). If you do not specify the owner, the results include all public snapshots.

```shell
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[? (StartTime<='2020-03-31')].[SnapshotId]" --output text
```

The following command displays the IDs of all snapshots created in the specified date range.

```shell
aws ec2 describe-snapshots --filters Name=owner-id,Values=123456789012 --query "Snapshots[? (StartTime>='2019-01-01') && (StartTime<='2019-12-31')].[SnapshotId]" --output text
```

**Filter based on tags**

For examples of how to filter a list of resources according to their tags, see [Work with tags using the command line (p. 2516)](#).

**View resources across Regions using Amazon EC2 Global View**

Amazon EC2 Global View enables you to view and search for Amazon EC2 and Amazon VPC resources in a single AWS Region, or across multiple Regions simultaneously in a single console. For more information, see [Amazon EC2 Global View (p. 2505)](#).

**Amazon EC2 Global View**

Amazon EC2 Global View enables you to view some of your Amazon EC2 and Amazon VPC resources across a single AWS Region, or across multiple Regions in a single console. Amazon EC2 Global View also provides global search functionality that lets you search for specific resources or specific resource types across multiple Regions simultaneously.

Amazon EC2 Global View does not let you modify resources in any way.

**Supported resources**
Using Amazon EC2 Global View, you can view a global summary of the following resources across all of the Regions for which your AWS account is enabled.

- Auto Scaling groups
- DHCP option set
- Egress-only internet gateways
- Elastic IPs
- Endpoint services
- Instances
- Internet gateways
- Managed prefix lists
- NAT gateways
- Network ACLs
- Network interfaces
- Route tables
- Security groups
- Subnets
- Volumes
- VPCs
- VPC endpoints
- VPC peering connections

**Required permissions**

A user must have the following permissions to use Amazon EC2 Global View.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "autoscaling:DescribeAutoScalingGroups",
        "ec2:DescribeRegions",
        "ec2:DescribeDhcpOptions",
        "ec2:DescribeEgressOnlyInternetGateways",
        "ec2:DescribeAddresses",
        "ec2:DescribeVpcEndpointServices",
        "ec2:DescribeInstances",
        "ec2:DescribeInternetGateways",
        "ec2:DescribePrefixLists",
        "ec2:DescribeNatGateways",
        "ec2:DescribeNetworkAcls",
        "ec2:DescribeNetworkInterfaces",
        "ec2:DescribeRouteTables",
        "ec2:DescribeSecurityGroups",
        "ec2:DescribeSubnets",
        "ec2:DescribeVolumes",
        "ec2:DescribeVpcs",
        "ec2:DescribeVpcEndpoints",
        "ec2:DescribeVpcPeeringConnections"
      ],
      "Resource": "*
    }
  ]
}
```
To use Amazon EC2 Global View

Open the Amazon EC2 Global View console at https://console.aws.amazon.com/ec2globalview/home.

Important
You cannot use a private window in Firefox to access Amazon EC2 Global View.

The console consists of the following:

- **Region explorer**—This tab includes the following sections:
  - **Summary**—Provides a high-level overview of your resources across all Regions.

  **Enabled Regions** indicates the number of Regions for which your AWS account is enabled. The remaining fields indicate the number of resources that you currently have in those Regions. Choose any of the links to view the resources of that type across all Regions. For example, if the link below the **Instances** label is 29 in 10 Regions, it indicates that you currently have 29 instances across 10 Regions. Choose the link to view a list of all 29 instances.

- **Resource region counts**—Lists all of the AWS Regions (including those for which your account is not enabled) and provides totals for each resource type for each Region.

  Choose a Region name to view all resources of all types for that specific Region. For example, choose **Africa (Cape Town) af-south-1** to view all VPCs, subnets, instances, security groups, volumes, and Auto Scaling groups in that Region. Alternatively, select a Region and choose **View resources for selected Region**.

  Choose the value for a specific resource type in a specific Region to view only resources of that type in that Region. For example, choose the value for **Instances** for **Africa (Cape Town) af-south-1** to view only the instances in that Region.

- **Global search**—This tab enables you to search for specific resources or specific resource types across a single Region or across multiple Regions. It also enables you to view details for a specific resource.

  To search for resources, enter the search criteria in the field preceding the grid. You can search by Region, by resource type, and by the tags assigned to resources.

  To view the details for a specific resource, select it in the grid. You can also choose the resource ID of a resource to open it in its respective console. For example, choose an instance ID to open the instance in the Amazon EC2 console, or choose a subnet ID to open the subnet in the Amazon VPC console.

Tip
If you only use specific Regions or resource types, you can customize Amazon EC2 Global View to display only those Regions and resource types. To customize the displayed Regions and resource types, in the navigation panel, choose **Settings**, and then on the **Resources** and **Regions** tabs, select the Regions and resource types that you do not want to be displayed in Amazon EC2 Global View.

Tag your Amazon EC2 resources

To help you manage your instances, images, and other Amazon EC2 resources, you can assign your own metadata to each resource in the form of tags. Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. This is useful when you have many resources of the same type—you can quickly identify a specific resource based on the tags that you've assigned to it. This topic describes tags and shows you how to create them.

Warning
Tag keys and their values are returned by many different API calls. Denying access to DescribeTags doesn't automatically deny access to tags returned by other APIs. As a best practice, we recommend that you do not include sensitive data in your tags.
Tag basics

A tag is a label that you assign to an AWS resource. Each tag consists of a key and an optional value, both of which you define.

Tags enable you to categorize your AWS resources in different ways, for example, by purpose, owner, or environment. For example, you could define a set of tags for your account’s Amazon EC2 instances that helps you track each instance’s owner and stack level.

The following diagram illustrates how tagging works. In this example, you’ve assigned two tags to each of your instances—one tag with the key Owner and another with the key Stack. Each tag also has an associated value.

We recommend that you devise a set of tag keys that meets your needs for each resource type. Using a consistent set of tag keys makes it easier for you to manage your resources. You can search and filter
the resources based on the tags you add. For more information about how to implement an effective resource tagging strategy, see the Tagging Best Practices AWS Whitepaper.

Tags don't have any semantic meaning to Amazon EC2 and are interpreted strictly as a string of characters. Also, tags are not automatically assigned to your resources. You can edit tag keys and values, and you can remove tags from a resource at any time. You can set the value of a tag to an empty string, but you can't set the value of a tag to null. If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value. If you delete a resource, any tags for the resource are also deleted.

**Note**
After you delete a resource, its tags might remain visible in the console, API, and CLI output for a short period. These tags will be gradually disassociated from the resource and be permanently deleted.

## Tag your resources

You can tag most Amazon EC2 resources that already exist in your account. The following table lists the resources that support tagging.

If you're using the Amazon EC2 console, you can apply tags to resources by using the Tags tab on the relevant resource screen, or you can use the Tags Editor in the AWS Resource Groups console. Some resource screens enable you to specify tags for a resource when you create the resource; for example, a tag with a key of Name and a value that you specify. In most cases, the console applies the tags immediately after the resource is created (rather than during resource creation). The console might organize resources according to the Name tag, but this tag doesn't have any semantic meaning to the Amazon EC2 service.

If you're using the Amazon EC2 API, the AWS CLI, or an AWS SDK, you can use the CreateTags EC2 API action to apply tags to existing resources. Additionally, some resource-creating actions enable you to specify tags for a resource when the resource is created. If tags cannot be applied during resource creation, we roll back the resource creation process. This ensures that resources are either created with tags or not created at all, and that no resources are left untagged at any time. By tagging resources at the time of creation, you can eliminate the need to run custom tagging scripts after resource creation. For more information about enabling users to tag resources on creation, see Grant permission to tag resources during creation (p. 1945).

The following table describes the Amazon EC2 resources that can be tagged, and the resources that can be tagged on creation using the Amazon EC2 API, the AWS CLI, or an AWS SDK.

</table>
You can tag instances, volumes, elastic graphics, network interfaces, and Spot Instance requests on creation using the Amazon EC2 launch instance wizard (p. 723) in the Amazon EC2 console. You can tag your EBS volumes on creation using the Volumes screen, or EBS snapshots using the Snapshots screen. Alternatively, use the resource-creating Amazon EC2 APIs (for example, RunInstances) to apply tags when creating your resource.

You can apply tag-based resource-level permissions in your IAM policies to the Amazon EC2 API actions that support tagging on creation to implement granular control over the users and groups that can tag resources on creation. Your resources are properly secured from creation—tags are applied immediately to your resources, therefore any tag-based resource-level permissions controlling the use of resources are immediately effective. Your resources can be tracked and reported on more accurately. You can enforce the use of tagging on new resources, and control which tag keys and values are set on your resources.

</table>
You can also apply resource-level permissions to the CreateTags and DeleteTags Amazon EC2 API actions in your IAM policies to control which tag keys and values are set on your existing resources. For more information, see Example: Tag resources (p. 1977).

For more information about tagging your resources for billing, see Using cost allocation tags in the AWS Billing User Guide.

Tag restrictions

The following basic restrictions apply to tags:

- Maximum number of tags per resource – 50
- For each resource, each tag key must be unique, and each tag key can have only one value.
- Maximum key length – 128 Unicode characters in UTF-8
- Maximum value length – 256 Unicode characters in UTF-8
- Allowed characters
  - Although EC2 allows for any character in its tags, other AWS services are more restrictive. The allowed characters across all AWS services are: letters (a-z, A-Z), numbers (0-9), and spaces representable in UTF-8, and the following characters: + - = . _ : / @.
  - If you enable instance tags in instance metadata, instance tag keys can only use letters (a-z, A-Z), numbers (0-9), and the following characters: + - = . _ : @. Instance tag keys can't contain spaces or /, and can't comprise only . (one period), . . (two periods), or _index. For more information, see Work with instance tags in instance metadata (p. 2519).
- Tag keys and values are case-sensitive.
- The aws: prefix is reserved for AWS use. If a tag has a tag key with this prefix, then you can't edit or delete the tag's key or value. Tags with the aws: prefix do not count against your tags per resource limit.

You can't terminate, stop, or delete a resource based solely on its tags; you must specify the resource identifier. For example, to delete snapshots that you tagged with a tag key called DeleteMe, you must use the DeleteSnapshots action with the resource identifiers of the snapshots, such as snap-1234567890abcdef0.

When you tag public or shared resources, the tags you assign are available only to your AWS account; no other AWS account will have access to those tags. For tag-based access control to shared resources, each AWS account must assign its own set of tags to control access to the resource.

You can't tag all resources. For more information, see Tagging support for Amazon EC2 resources (p. 2509).

Tags and access management

If you're using AWS Identity and Access Management (IAM), you can control which users in your AWS account have permission to create, edit, or delete tags. For more information, see Grant permission to tag resources during creation (p. 1945).

You can also use resource tags to implement attribute-based control (ABAC). You can create IAM policies that allow operations based on the tags for the resource. For more information, see Control access to EC2 resources using resource tags (p. 1947).

Tag your resources for billing

You can use tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. For more information about setting up a cost...
allocation report with tags, see Monthly cost allocation report in the AWS Billing User Guide. To see the cost of your combined resources, you can organize your billing information based on resources that have the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information, see Using cost allocation tags in the AWS Billing User Guide.

Note
If you've just enabled reporting, data for the current month is available for viewing after 24 hours.

Cost allocation tags can indicate which resources are contributing to costs, but deleting or deactivating resources doesn't always reduce costs. For example, snapshot data that is referenced by another snapshot is preserved, even if the snapshot that contains the original data is deleted. For more information, see Amazon Elastic Block Store volumes and snapshots in the AWS Billing User Guide.

Note
Elastic IP addresses that are tagged do not appear on your cost allocation report.

Work with tags using the console

You can use the Amazon EC2 console to display the tags of an individual resource, and to apply or remove tags from one resource at a time.

You can use the Tag Editor in the AWS Resource Groups console to display the tags of all of your Amazon EC2 resources across all Regions. You can view tags by resource and by resource type, and you can see which resource types are associated with a specified tag. You can apply or remove tags from multiple resources and multiple resource types at a time. The Tag Editor provides a central, unified way to create and manage your tags. For more information, see the Tagging AWS Resources User Guide.

Tasks
- Display tags (p. 2513)
- Add and delete tags on an individual resource (p. 2514)
- Add and delete tags for multiple resources (p. 2514)
- Add a tag when you launch an instance (p. 2515)
- Filter a list of resources by tag (p. 2516)

Display tags

You can display the tags of an individual resource in the Amazon EC2 console. To display the tags of all your resources, use the Tag Editor in the AWS Resource Groups console.

Display tags of an individual resource

When you select a resource-specific page in the Amazon EC2 console, it displays a list of those resources. For example, if you select instances from the navigation pane, the console displays your Amazon EC2 instances. When you select a resource from one of these lists (for example, an instance), if the resource supports tags, you can view and manage its tags. On most resource pages, you can view the tags by choosing the Tags tab.

You can add a column to the resource list to display all values for tags with the same key. You can use this column to sort and filter the resource list by the tag.

New console

To add a column to the resource list to display your tags

1. In the EC2 console, choose the Preferences gear-shaped icon in the top right corner of the screen.
2. In the Preferences dialog box, for Tag columns (at bottom left), select one or more tag keys, and then choose Confirm.

Old console

There are two ways to add a new column to the resource list to display your tags:

- On the Tags tab, select Show Column. A new column is added to the console.
- Choose the Show/Hide Columns gear-shaped icon, and in the Show/Hide Columns dialog box, select the tag key under Your Tag Keys.

Display tags for multiple resources

You can display tags across multiple resources by using the Tag Editor in the AWS Resource Groups console. For more information, see the Tagging AWS Resources User Guide.

Add and delete tags on an individual resource

You can manage tags for an individual resource directly from the resource's page.

To add a tag to an individual resource

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region where the resource to tag is located. For more information, see Resource locations (p. 2497).
3. In the navigation pane, select a resource type (for example, Instances).
4. Select the resource from the resource list and choose the Tags tab.
5. Choose Manage tags, and then choose Add new tag. Enter the key and value for the tag. Choose Add new tag again for each additional tag to add. When you are finished adding tags, choose Save.

To delete a tag from an individual resource

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region where the resource to untag is located. For more information, see Resource locations (p. 2497).
3. In the navigation pane, choose a resource type (for example, Instances).
4. Select the resource from the resource list and choose the Tags tab.
5. Choose Manage tags. For each tag to remove, choose Remove. When you are finished removing tags, choose Save.

Add and delete tags for multiple resources

To add a tag to multiple resources

2. For Regions, select one or more Regions where the resources to tag are located.
3. For Resource types, select the type of resources to tag (for example, AWS::EC2::Instance).
4. Choose Search resources.
5. Under Resource search results, select the check box next to each resource to tag.
6. Choose Manage tags of selected resources.
7. Under **Edit tags of all selected resources**, choose **Add tag**, and then enter the new tag key and value. Choose **Add tag** again for each additional tag to add.

   **Note**
   If you add a new tag with the same tag key as an existing tag, the new tag overwrites the existing tag.

8. Choose **Review and apply tag changes**.

9. Choose **Apply changes to all selected**.

**To remove a tag from multiple resources**

2. For **Regions**, select the Regions where the resources to untag are located.
3. For **Resource types**, select the type of resources to untag (for example, `AWS::EC2::Instance`).
4. Choose **Search resources**.
5. Under **Resource search results**, select the check box next to each resource to untag.
6. Choose **Manage tags of selected resources**.
7. Under **Edit tags of all selected resources**, next to the tag to remove, choose **Remove tag**.
8. Choose **Review and apply tag changes**.
9. Choose **Apply changes to all selected**.

**Add a tag when you launch an instance**

**New console**

**To add a tag using the launch instance wizard**

1. From the navigation bar, select the Region for the instance. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. Select the Region that meets your needs. For more information, see Resource locations (p. 2497).
2. Choose **Launch instance**.
3. Under **Name and tags**, you can enter a descriptive name for your instance and specify tags.

   The instance name is a tag, where the key is **Name**, and the value is the name that you specify. You can tag the instance, volumes, elastic graphics, and network interfaces. For Spot Instances, you can tag the Spot Instance request only.

   Specifying an instance name and additional tags is optional.

   • For **Name**, enter a descriptive name for the instance. If you don't specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.
   • To add additional tags, choose **Add additional tags**. Choose **Add tag**, and then enter a key and value, and select the resource type to tag. Choose **Add tag** again for each additional tag to add.

4. Under **Application and OS Images (Amazon Machine Image)**, choose the operating system (OS) for your instance and an AMI. For more information, see Application and OS Images (Amazon Machine Image) (p. 723).
5. Under **Key pair (login)**, for **Key pair name**, choose an existing key pair or create a new one.
6. Either keep all the other fields at their default values or choose specific values for your desired instance configuration. For information about the fields, see Launch an instance using defined parameters (p. 722).
7. In the **Summary** panel, review your settings, and then choose **Launch instance**.

**Old console**

**To add a tag using the launch instance wizard**

1. From the navigation bar, select the Region for the instance. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't. Select the Region that meets your needs. For more information, see [Resource locations](p. 2497).
2. Choose **Launch Instance**.
3. The **Choose an Amazon Machine Image (AMI)** page displays a list of basic configurations called Amazon Machine Images (AMIs). Select the AMI to use and choose **Select**. For more information, see [Find a Linux AMI](p. 141).
4. On the **Configure Instance Details** page, configure the instance settings as necessary, and then choose **Next: Add Storage**.
5. On the **Add Storage** page, you can specify additional storage volumes for your instance. Choose **Next: Add Tags** when done.
6. On the **Add Tags** page, specify tags for the instance, the volumes, or both. Choose **Add another tag** to add more than one tag to your instance. Choose **Next: Configure Security Group** when you are done.
7. On the **Configure Security Group** page, you can choose from an existing security group that you own, or let the wizard create a new security group for you. Choose **Review and Launch** when you are done.
8. Review your settings. When you’re satisfied with your selections, choose **Launch**. Select an existing key pair or create a new one, select the acknowledgment check box, and then choose **Launch Instances**.

**Filter a list of resources by tag**

You can filter your list of resources based on one or more tag keys and tag values.

**To filter a list of resources by tag in the Amazon EC2 console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, select a resource type (for example, **Instances**).
3. Choose the search field.
4. In the list, under **Tags**, choose the tag key.
5. Choose the corresponding tag value from the list.
6. When you are finished, remove the filter.

For more information about using filters in the Amazon EC2 console, see [List and filter your resources](p. 2499).

**To filter multiple resources across multiple Regions by tag using the Tag Editor**

You can use the **Tag Editor** in the AWS Resource Groups console to filter multiple resources across multiple Regions by tag. For more information, see [Finding resources to tag](in the Tagging AWS Resources User Guide).

**Work with tags using the command line**

You can add tags to many EC2 resources when you create them, using the tag specifications parameter for the create command. You can view the tags for a resource using the describe command for the
resource. You can also add, update, or delete tags for your existing resources using the following commands.

<table>
<thead>
<tr>
<th>Task</th>
<th>AWS CLI</th>
<th>AWS Tools for Windows PowerShell</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add or overwrite one or more tags</td>
<td>create-tags</td>
<td>New-EC2Tag</td>
</tr>
<tr>
<td>Delete one or more tags</td>
<td>delete-tags</td>
<td>Remove-EC2Tag</td>
</tr>
<tr>
<td>Describe one or more tags</td>
<td>describe-tags</td>
<td>Get-EC2Tag</td>
</tr>
</tbody>
</table>

Tasks

- Add tags on resource creation (p. 2517)
- Add tags to an existing resource (p. 2518)
- Describe tagged resources (p. 2519)

### Add tags on resource creation

The following examples demonstrate how to apply tags when you create resources.

**Note**

The way you enter JSON-formatted parameters on the command line differs depending on your operating system.

- Linux, macOS, or Unix and Windows PowerShell – Use single quotes (') to enclose the JSON data structure.
- Windows – Omit the single quotes when using the commands with the Windows command line.

For more information, see Specifying parameter values for the AWS CLI.

**Example Example: Launch an instance and apply tags to the instance and volume**

The following run-instances command launches an instance and applies a tag with the key `webserver` and the value `production` to the instance. The command also applies a tag with the key `cost-center` and the value `cc123` to any EBS volume that's created (in this case, the root volume).

```bash
aws ec2 run-instances \
   --image-id ami-abc12345 \
   --count 1 \
   --instance-type t2.micro \
   --key-name MyKeyPair \
   --subnet-id subnet-6e7f829e \
   --tag-specifications 'ResourceType=instance,Tags=[{Key=webserver,Value=production}]' \
   'ResourceType=volume,Tags=[{Key=cost-center,Value=cc123}]'
```

You can apply the same tag keys and values to both instances and volumes during launch. The following command launches an instance and applies a tag with a key of `cost-center` and a value of `cc123` to both the instance and any EBS volume that's created.

```bash
aws ec2 run-instances \
   --image-id ami-abc12345 \
   --count 1 \
   --instance-type t2.micro \
   --key-name MyKeyPair \
   --subnet-id subnet-6e7f829e \
   --tag-specifications 'ResourceType=instance,Tags=[{Key=cost-center,Value=cc123}]'
```
Work with tags using the command line

```
--key-name MyKeyPair \
--subnet-id subnet-6e7f829e \
--tag-specifications 'ResourceType=instance,Tags=[{Key=cost-center,Value=cc123}]' \
'ResourceType=volume,Tags=[{Key=cost-center,Value=cc123}]'
```

**Example Example: Create a volume and apply a tag**

The following `create-volume` command creates a volume and applies two tags: `purpose=production` and `cost-center=cc123`.

```
aws ec2 create-volume \
  --availability-zone us-east-1a \
  --volume-type gp2 \
  --tag-specifications 'ResourceType=volume,Tags=[{Key=purpose,Value=production}, \
  {Key=cost-center,Value=cc123}]'
```

**Add tags to an existing resource**

The following examples demonstrate how to add tags to an existing resource using the `create-tags` command.

**Example Example: Add a tag to a resource**

The following command adds the tag `Stack=production` to the specified image, or overwrites an existing tag for the AMI where the tag key is `Stack`. If the command succeeds, no output is returned.

```
aws ec2 create-tags \
  --resources ami-78a54011 \
  --tags Key=Stack,Value=production
```

**Example Example: Add tags to multiple resources**

This example adds (or overwrites) two tags for an AMI and an instance. One of the tags contains just a key (`webserver`), with no value (we set the value to an empty string). The other tag consists of a key (`stack`) and value (`Production`). If the command succeeds, no output is returned.

```
aws ec2 create-tags \
  --resources ami-1a2b3c4d i-1234567890abcdef0 \
  --tags Key=webserver,Value= Key=stack,Value=Production
```

**Example Example: Add tags with special characters**

This example adds the tag `[Group]=test` to an instance. The square brackets ([ and ]) are special characters, which must be escaped.

If you are using Linux or OS X, to escape the special characters, enclose the element with the special character with double quotes ("), and then enclose the entire key and value structure with single quotes (').

```
aws ec2 create-tags \
  --resources i-1234567890abcdef0 \
  --tags 'Key="[Group]",Value=test'
```

If you are using Windows, to escape the special characters, enclose the element that has special characters with double quotes ("), and then precede each double quote character with a backslash (\) as follows:
Work with instance tags in instance metadata

You can access an instance’s tags from the instance metadata. By accessing tags from the instance metadata, you no longer need to use the DescribeInstances or DescribeTags API calls to retrieve tag information, which reduces your API transactions per second, and lets your tag retrievals scale with
the number of instances that you control. Furthermore, local processes that are running on an instance can view the instance's tag information directly from the instance metadata.

By default, tags are not available from the instance metadata; you must explicitly allow access. You can allow access at instance launch, or after launch on a running or stopped instance. You can also allow access to tags by specifying this in a launch template. Instances that are launched by using the template allow access to tags in the instance metadata.

If you add or remove an instance tag, the instance metadata is updated while the instance is running, without needing to stop and then start the instance.

**Topics**
- Allow access to tags in instance metadata (p. 2520)
- Turn off access to tags in instance metadata (p. 2520)
- View if access to tags in instance metadata is allowed (p. 2521)
- Retrieve tags from instance metadata (p. 2522)

**Allow access to tags in instance metadata**

By default, there is no access to instance tags in the instance metadata. For each instance, you must explicitly allow access by using one of the following methods.

**To allow access to tags in instance metadata using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**.
3. Select an instance, and then choose Actions, **Instance settings**, Allow tags in instance metadata.
4. To allow access to tags in instance metadata, select the **Allow** check box.
5. Choose **Save**.

**To allow access to tags in instance metadata at launch using the AWS CLI**

Use the **run-instances** command and set `InstanceMetadataTags` to `enabled`.

```
aws ec2 run-instances \
  --image-id ami-0abcdef1234567890 \
  --instance-type c3.large \
  ... \
  --metadata-options "InstanceMetadataTags=enabled"
```

**To allow access to tags in instance metadata on a running or stopped instance using the AWS CLI**

Use the **modify-instance-metadata-options** command and set `--instance-metadata-tags` to `enabled`.

```
aws ec2 modify-instance-metadata-options \
  --instance-id i-123456789example \
  --instance-metadata-tags enabled
```

**Turn off access to tags in instance metadata**

To turn off access to instance tags in the instance metadata, use one of the following methods. You don't need to turn off access to instance tags on instance metadata at launch because it's turned off by default.
To turn off access to tags in instance metadata using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select an instance, and then choose Actions, Instance settings, Allow tags in instance metadata.
4. To turn off access to tags in instance metadata, clear the Allow check box.
5. Choose Save.

To turn off access to tags in instance metadata using the AWS CLI

Use the modify-instance-metadata-options command and set --instance-metadata-tags to disabled.

```bash
aws ec2 modify-instance-metadata-options \
  --instance-id i-123456789example \
  --instance-metadata-tags disabled
```

View if access to tags in instance metadata is allowed

For each instance, you can use the Amazon EC2 console or AWS CLI to view whether access to instance tags from the instance metadata is allowed.

To view if access to tags in instance metadata is allowed using the console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select an instance.
3. On the Details tab, check the Allow tags in instance metadata field. If the value is Enabled, tags in instance metadata is allowed. If the value is Disabled, tags in instance metadata is not allowed.

To view if access to tags in instance metadata is allowed using the AWS CLI

Use the describe-instances command and specify the instance ID.

```bash
aws ec2 describe-instances \
  --instance-ids i-1234567890abcdef0
```

The following example output is truncated for space. The "InstanceMetadataTags" parameter indicates whether tags in instance metadata is allowed. If the value is enabled, tags in instance metadata is allowed. If the value is disabled, tags in instance metadata is not allowed.

```json
{
  "Reservations": [
    {
      "Groups": [],
      "Instances": [
        {
          "AmiLaunchIndex": 0,
          "ImageId": "ami-0abcdef1234567890",
          "InstanceId": "i-1234567890abcdef0",
          ...
        }
      ],
      "MetadataOptions": {
        "State": "applied",
        "HttpTokens": "optional",
        "HttpPutResponseHopLimit": 1,
```

2521
Retrieve tags from instance metadata

If instance tags are allowed in the instance metadata, the tags/instance category is accessible from the instance metadata. For examples on how to retrieve tags from the instance metadata, see Get the instance tags for an instance (p. 1028).

Add tags to a resource using CloudFormation

With Amazon EC2 resource types, you specify tags using either a Tags or TagSpecifications property.

The following examples add the tag Stack=Production to AWS::EC2::Instance using its Tags property.

Example Example: Tags in YAML

```
Tags:
  - Key: "Stack"
    Value: "Production"
```

Example Example: Tags in JSON

```
"Tags": [
  {
    "Key": "Stack",
    "Value": "Production"
  }
]
```

The following examples add the tag Stack=Production to AWS::EC2::LaunchTemplate LaunchTemplateData using its TagSpecifications property.

Example Example: TagSpecifications in YAML

```
TagSpecifications:
  - ResourceType: "instance"
    Tags:
      - Key: "Stack"
        Value: "Production"
```

Example Example: TagSpecifications in JSON

```
"TagSpecifications": [
  {
    "ResourceType": "instance",
    "Tags": [
      {
        "Key": "Stack",
        "Value": "Production"
      }
    ]
  }
]
Amazon EC2 service quotas

Amazon EC2 provides different resources that you can use. These resources include images, instances, volumes, and snapshots. When you create your AWS account, we set default quotas (also referred to as limits) on these resources on a per-Region basis. For example, there is a maximum number of instances that you can launch in a Region. So if you were to launch an instance in the US West (Oregon) Region, for example, the request must not cause your usage to exceed your maximum number of instances in that Region.

The Service Quotas console is a central location where you can view and manage your quotas for AWS services, and request a quota increase for many of the resources that you use. Use the quota information that we provide to manage your AWS infrastructure. Plan to request any quota increases in advance of the time that you'll need them.

For more information, see Amazon EC2 endpoints and quotas in the Amazon Web Services General Reference. For information about Amazon EBS quotas, see Amazon EBS quotas (p. 2411).

View your current quotas

You can view your quotas for each Region using the Service Quotas console.

To view your current quotas using the Service Quotas console

2. From the navigation bar (at the top of the screen), select a Region.

<table>
<thead>
<tr>
<th>Region</th>
<th>Region ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
</tr>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
</tr>
<tr>
<td>US West (N. California)</td>
<td>us-west-1</td>
</tr>
<tr>
<td>US West (Oregon)</td>
<td>us-west-2</td>
</tr>
<tr>
<td>Africa (Cape Town)</td>
<td>af-south-1</td>
</tr>
<tr>
<td>Asia Pacific (Hong Kong)</td>
<td>ap-east-1</td>
</tr>
<tr>
<td>Asia Pacific (Jakarta)</td>
<td>ap-southeast-3</td>
</tr>
</tbody>
</table>
3. Use the filter field to filter the list by resource name. For example, enter **On-Demand** to locate the quotas for On-Demand Instances.

4. To view more information, choose the quota name to open the details page for the quota.

### Request an increase

You can request a quota increase for each Region.

**To request an increase using the Service Quotas console**

2. From the navigation bar (at the top of the screen), select a Region.
3. Use the filter field to filter the list by resource name. For example, enter **On-Demand** to locate the quotas for On-Demand Instances.
4. If the quota is adjustable, choose the quota and then choose **Request quota increase**.
5. For **Change quota value**, enter the new quota value.
6. Choose **Request**.
7. To view any pending or recently resolved requests in the console, choose **Dashboard** from the navigation pane. For pending requests, choose the status of the request to open the request receipt. The initial status of a request is **Pending**. After the status changes to **Quota requested**, you'll see the case number with AWS Support. Choose the case number to open the ticket for your request.

For more information, including how to use the AWS CLI or SDKs to request a quota increase, see [Requesting a quota increase](#) in the **Service Quotas User Guide**.

### Restriction on email sent using port 25

On all instances, Amazon EC2 restricts outbound traffic to public IP addresses over port 25 by default. You can request that this restriction be removed. For more information, see [How do I remove the restriction on port 25 from my Amazon EC2 instance or AWS Lambda function?](#) in the AWS Knowledge Center.

**Note**

This restriction does not apply to outbound traffic sent over port 25 to:

- IP addresses in the primary CIDR block of the VPC in which the originating network interface exists.

### Amazon EC2 usage reports

AWS provides a free reporting tool called AWS Cost Explorer that enables you to analyze the cost and usage of your EC2 instances and the usage of your Reserved Instances. You can view data up to the last 12 months, and forecast how much you are likely to spend for the next three months. You can use Cost Explorer to see patterns in how much you spend on AWS resources over time, identify areas that need further inquiry, and see trends that you can use to understand your costs. You also can specify time ranges for the data, and view time data by day or by month.

Here's an example of some of the questions that you can answer when using Cost Explorer:
Track your Free Tier usage

You can use Amazon EC2 without incurring charges if you've been an AWS customer for less than 12 months and you stay within the AWS Free Tier usage limits. It's important to track your Free Tier usage to avoid billing surprises. If you exceed the Free Tier limits, you'll incur standard pay-as-you-go charges.

Note
If you've been an AWS customer for more than 12 months, you're no longer eligible for Free Tier usage and you won't see the EC2 Free Tier box that is described in the following procedure.

To track your Free Tier usage

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose EC2 Dashboard.
3. Find the EC2 Free Tier box (at top right).
4. In the **EC2 Free Tier** box, check your Free Tier usage, as follows:

- Under **EC2 Free Tier offers in use**, take note of the warnings:
  - **End of month forecast** – This warns that you will incur charges this month if you continue with your current usage pattern.
  - **Exceeds Free Tier** – This warns that you’ve exceeded your Free Tier limits and you’re already incurring charges.

- Under **Offer usage (monthly)**, take note of your usage of Linux instances, Windows instances, and EBS storage. The percentage indicates how much of your Free Tier limits you’ve used this month. If you’re at 100%, you will incur charges for further use.

  **Note**
  
  This information appears only after you’ve created an instance. However, usage information is not updated in real time; it’s updated three times a day.

5. To avoid incurring further charges, delete any resources that are either incurring charges now, or will incur charges if you exceed your Free Tier limit usage.
For the instructions to delete your instance, go to the next step in this tutorial.

To check if you have resources in other Regions that might be incurring charges, in the EC2 Free Tier box, choose View Global EC2 resources to open the EC2 Global View. For more information, see Amazon EC2 Global View (p. 2505).

6. To view your resource usage for all AWS services under the AWS Free Tier, at the bottom of the EC2 Free Tier box, choose View all AWS Free Tier offers. For more information, see Using the AWS Free Tier in the AWS Billing User Guide.
Troubleshoot EC2 instances

The following documentation can help you troubleshoot problems that you might have with your instance.

Contents

- Troubleshoot instance launch issues (p. 2528)
- Troubleshoot connecting to your instance (p. 2532)
- Troubleshoot stopping your instance (p. 2550)
- Troubleshoot instance termination (shutting down) (p. 2553)
- Troubleshoot instances with failed status checks (p. 2554)
- Troubleshoot an unreachable instance (p. 2575)
- Boot from the wrong volume (p. 2578)
- Use EC2Rescue for Linux (p. 2579)
- EC2 Serial Console for Linux instances (p. 2589)
- Send a diagnostic interrupt (for advanced users) (p. 2608)

For additional help with Windows instances, see Troubleshoot Windows instances in the Amazon EC2 User Guide for Windows Instances.

Troubleshoot instance launch issues

The following issues prevent you from launching an instance.

Launch Issues

- Invalid device name (p. 2528)
- Instance limit exceeded (p. 2529)
- Insufficient instance capacity (p. 2529)
- The requested configuration is currently not supported. Please check the documentation for supported configurations. (p. 2530)
- Instance terminates immediately (p. 2530)
- Insufficient permissions (p. 2531)

Invalid device name

Description

You get the Invalid device name `device_name` error when you try to launch a new instance.

Cause

If you get this error when you try to launch an instance, the device name specified for one or more volumes in the request has an invalid device name. Possible causes include:
Instance limit exceeded

Description
You get the `InstanceLimitExceeded` error when you try to launch a new instance or restart a stopped instance.

Cause
If you get an `InstanceLimitExceeded` error when you try to launch a new instance or restart a stopped instance, you have reached the limit on the number of instances that you can launch in a Region. When you create your AWS account, we set default limits on the number of instances you can run on a per-Region basis.

Solution
You can request an instance limit increase on a per-region basis. For more information, see Amazon EC2 service quotas (p. 2523).

Insufficient instance capacity

Description
You get the `InsufficientInstanceCapacity` error when you try to launch a new instance or restart a stopped instance.

Cause
If you get this error when you try to launch an instance or restart a stopped instance, AWS does not currently have enough available On-Demand capacity to fulfill your request.
Solution

To resolve the issue, try the following:

- Wait a few minutes and then submit your request again; capacity can shift frequently.
- Submit a new request with a reduced number of instances. For example, if you're making a single request to launch 15 instances, try making 3 requests for 5 instances, or 15 requests for 1 instance instead.
- If you're launching an instance, submit a new request without specifying an Availability Zone.
- If you're launching an instance, submit a new request using a different instance type (which you can resize at a later stage). For more information, see Change the instance type (p. 479).
- If you are launching instances into a cluster placement group, you can get an insufficient capacity error. For more information, see Work with placement groups (p. 1576).

The requested configuration is currently not supported. Please check the documentation for supported configurations.

Description

You get the Unsupported error when you try to launch a new instance because the instance configuration is not supported.

Cause

The error message provides additional details. For example, an instance type or instance purchasing option might not be supported in the specified Region or Availability Zone.

Solution

Try a different instance configuration. To search for an instance type that meets your requirements, see Find an Amazon EC2 instance type (p. 473).

Instance terminates immediately

Description

Your instance goes from the pending state to the terminated state.

Cause

The following are a few reasons why an instance might immediately terminate:

- You've exceeded your EBS volume limits. For more information, see Instance volume limits (p. 2444).
- An EBS snapshot is corrupted.
- The root EBS volume is encrypted and you do not have permissions to access the KMS key for decryption.
- A snapshot specified in the block device mapping for the AMI is encrypted and you do not have permissions to access the KMS key for decryption or you do not have access to the KMS key to encrypt the restored volumes.
• The instance store-backed AMI that you used to launch the instance is missing a required part (an image.part.xx file).

For more information, get the termination reason using one of the following methods.

**To get the termination reason using the Amazon EC2 console**

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and select the instance.
3. On the first tab, find the reason next to State transition reason.

**To get the termination reason using the AWS Command Line Interface**

1. Use the `describe-instances` command and specify the instance ID.

   ```bash
   aws ec2 describe-instances --instance-id instance_id
   ```

2. Review the JSON response returned by the command and note the values in the StateReason response element.

   The following code block shows an example of a StateReason response element.

   ```json
   "StateReason": {
      "Code": "Server.InternalError"
   },
   ```

**To get the termination reason using AWS CloudTrail**

For more information, see Viewing events with CloudTrail event history in the AWS CloudTrail User Guide.

**Solution**

Depending on the termination reason, take one of the following actions:

- **Client.VolumeLimitExceeded: Volume limit exceeded** — Delete unused volumes. You can submit a request to increase your volume limit.
- **Client.InternalError: Client error on launch** — Ensure that you have the permissions required to access the AWS KMS keys used to decrypt and encrypt volumes. For more information, see Using key policies in AWS KMS in the AWS Key Management Service Developer Guide.

**Insufficient permissions**

**Description**

You get the "errorMessage": "You are not authorized to perform this operation." error when you try to launch a new instance, and the launch fails.

**Cause**

If you get this error when you try to launch an instance, you don't have the required IAM permissions to launch the instance.
Possible missing permissions include:

- ec2:RunInstances
- iam:PassRole

Other permissions might also be missing. For the list of permissions required to launch an instance, see the example IAM policies under Example: Use the EC2 launch instance wizard (p. 1986) and Launch instances (RunInstances) (p. 1960).

**Solution**

To resolve the issue:

- If you are making requests as an IAM user, verify that you have the following permissions:
  - ec2:RunInstances with a wildcard resource ("*")
  - iam:PassRole with the resource matching the role ARN (for example, `arn:aws:iam::999999999999:role/ExampleRoleName`)
- If you don't have the preceding permissions, edit the IAM policy associated with the IAM role or user to add the missing required permissions.

If your issue is not resolved and you continue receiving a launch failure error, you can decode the authorization failure message included in the error. The decoded message includes the permissions that are missing from the IAM policy. For more information, see How can I decode an authorization failure message after receiving an "UnauthorizedOperation" error during an EC2 instance launch?

**Troubleshoot connecting to your instance**

The following information and common errors can help you troubleshoot connecting to your Linux instance.

To troubleshoot connecting to Windows instances, see Troubleshoot Windows instances in the Amazon EC2 User Guide for Windows Instances.

**Connection problems and errors**

- Common causes for connection issues (p. 2533)
- Error connecting to your instance: Connection timed out (p. 2534)
- Error: unable to load key ... Expecting: ANY PRIVATE KEY (p. 2537)
- Error: User key not recognized by server (p. 2538)
- Error: Permission denied or connection closed by [instance] port 22 (p. 2539)
- Error: Unprotected private key file (p. 2541)
- Error: Private key must begin with "-----BEGIN RSA PRIVATE KEY-----" and end with "-----END RSA PRIVATE KEY-----" (p. 2542)
- Error: Server refused our key or No supported authentication methods available (p. 2542)
- Cannot ping instance (p. 2543)
- Error: Server unexpectedly closed network connection (p. 2543)
- Error: Host key validation failed for EC2 Instance Connect (p. 2544)
- Can't connect to Ubuntu instance using EC2 Instance Connect (p. 2545)
- I've lost my private key. How can I connect to my Linux instance? (p. 2545)
Common causes for connection issues

We recommend that you start to troubleshoot instance connection problems by verifying that you have accurately performed the following tasks.

**Verify the username for your instance**

You can connect to your instance using the username for your user account or the default username for the AMI that you used to launch your instance.

- **Get the username for your user account.**
  
  For more information about how to create a user account, see Manage users on your Linux instance (p. 907).

- **Get the default username for the AMI that you used to launch your instance:**

<table>
<thead>
<tr>
<th>AMI used to launch instance</th>
<th>Default username</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Linux 2023</td>
<td><code>ec2-user</code></td>
</tr>
<tr>

</table>

**Verify that your security group rules allow traffic**

Ensure that the security group associated with your instance allows incoming SSH traffic from your IP address. The default security group for the VPC does not allow incoming SSH traffic by default. The security group created by the launch instance wizard enables SSH traffic by default. For steps to add a rule for inbound SSH traffic to your Linux instance, see Authorize inbound traffic for your Linux instances (p. 2005). For steps to verify, see Error connecting to your instance: Connection timed out (p. 2534).

**Verify that your instance is ready**

After you launch an instance, it can take a few minutes for the instance to be ready so that you can connect to it. Check your instance to make sure it is running and has passed its status checks.

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose **Instances**, and then select your instance.
3. Verify the following:
   a. In the **Instance state** column, verify that your instance is in the **running** state.
   b. In the **Status check** column, verify that your instance has passed the two status checks.

**Verify that you've satisfied all prerequisites to connect**

Ensure that you have all the information you need to connect. For more information, see [Connect to your Linux instance](p. 811).

For prerequisites specific to connection types, such as SSH, EC2 Instance Connect, OpenSSH, PuTTY, and more, see the following options.

**Linux or macOS X**

If your local computer operating system is Linux or macOS X, check the specific prerequisites for the following connection options:

- [SSH client](p. 816)
- [EC2 Instance Connect](p. 831)
- [AWS Systems Manager Session Manager]

**Windows**

If your local computer operating system is Windows, check the specific prerequisites for the following connection options:

- [OpenSSH](p. 819)
- [PuTTY](p. 821)
- [AWS Systems Manager Session Manager]
- [Windows Subsystem for Linux](p. 827)

**Error connecting to your instance: Connection timed out**

If you try to connect to your instance and get the error message `Network error: Connection timed out` or `Error connecting to [instance], reason: -> Connection timed out: connect, try the following:

**Check your security group rules.**

You need a security group rule that allows inbound traffic from your local computer's public IPv4 address on the proper port.

**New console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances**, and then select your instance.
3. On the **Security** tab at the bottom of the console page, under **Inbound rules**, check the list of rules that are in effect for the selected instance.
   - For Linux instances: Verify that there is a rule that allows traffic from your local computer to port 22 (SSH).
• For Windows instances: Verify that there is a rule that allows traffic from your local computer to port 3389 (RDP).

If your security group does not have a rule that allows inbound traffic from your local computer, add a rule to your security group. For more information, see Authorize inbound traffic for your Linux instances (p. 2005).

4. For the rule that allows inbound traffic, check the Source field. If the value is a single IP address, and if the IP address is not static, a new IP address will be assigned each time you restart your computer. This will result in the rule not including your computer's IP address traffic. The IP address might not be static if your computer is on a corporate network, or you're connecting through an internet service provider (ISP), or your computer IP address is dynamic and changes each time you restart your computer. To ensure that your security group rule allows inbound traffic from your local computer, instead of specifying a single IP address for Source, rather specify the range of IP addresses used by your client computers.

For more information about security group rules, see Security group rules in the Amazon VPC User Guide.

Old console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select your instance.
3. In the Description tab at the bottom of the console page, next to Security groups, select view inbound rules to display the list of rules that are in effect for the selected instance.

• For Linux instances: When you select view inbound rules, a window will appear that displays the port(s) to which traffic is allowed. Verify that there is a rule that allows traffic from your computer to port 22 (SSH).

• For Windows instances: When you select view inbound rules, a window will appear that displays the port(s) to which traffic is allowed. Verify that there is a rule that allows traffic from your computer to port 3389 (RDP).

If your security group does not have a rule that allows inbound traffic, add a rule to your security group. For more information, see Authorize inbound traffic for your Linux instances (p. 2005).

4. Each time you restart your local computer, a new IP address (and host name) can be assigned. If your security group has a rule that allows inbound traffic from a single IP address, this address might not be static if your computer is on a corporate network or if you are connecting through an internet service provider (ISP). Instead, specify the range of IP addresses used by client computers.

For more information about security group rules, see Security group rules in the Amazon VPC User Guide.

Check the route table for the subnet.

You need a route that sends all traffic destined outside the VPC to the internet gateway for the VPC.

New console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select your instance.
3. On the Networking tab, make note of the values for VPC ID and Subnet ID.
4. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

5. In the navigation pane, choose **Internet Gateways**. Verify that there is an internet gateway attached to your VPC. Otherwise, choose **Create internet gateway**, enter a name for the internet gateway, and choose **Create internet gateway**. Then, for the internet gateway you created, choose **Actions, Attach to VPC**, select your VPC, and then choose **Attach internet gateway** to attach it to your VPC.

6. In the navigation pane, choose **Subnets**, and then select your subnet.

7. On the **Route table** tab, verify that there is a route with 0.0.0.0/0 as the destination and the internet gateway for your VPC as the target. If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (::/0) that points to the internet gateway. Otherwise, do the following:

   a. Choose the ID of the route table (rtb-xxxxxxxx) to navigate to the route table.
   
   b. On the **Routes** tab, choose **Edit routes**. Choose **Add route**, use 0.0.0.0/0 as the destination and the internet gateway as the target. For IPv6, choose **Add route**, use ::/0 as the destination and the internet gateway as the target.
   
   c. Choose **Save routes**.

Old console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.

2. In the navigation pane, choose **Instances**, and then select your instance.

3. In the **Description** tab, write down the values of **VPC ID** and **Subnet ID**.

4. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

5. In the navigation pane, choose **Internet Gateways**. Verify that there is an internet gateway attached to your VPC. Otherwise, choose **Create Internet Gateway** to create an internet gateway. Select the internet gateway, and then choose **Attach to VPC** and follow the directions to attach it to your VPC.

6. In the navigation pane, choose **Subnets**, and then select your subnet.

7. On the **Route Table** tab, verify that there is a route with 0.0.0.0/0 as the destination and the internet gateway for your VPC as the target. If you're connecting to your instance using its IPv6 address, verify that there is a route for all IPv6 traffic (::/0) that points to the internet gateway. Otherwise, do the following:

   a. Choose the ID of the route table (rtb-xxxxxxxx) to navigate to the route table.
   
   b. On the **Routes** tab, choose **Edit routes**. Choose **Add route**, use 0.0.0.0/0 as the destination and the internet gateway as the target. For IPv6, choose **Add route**, use ::/0 as the destination and the internet gateway as the target.
   
   c. Choose **Save routes**.

Check the network access control list (ACL) for the subnet.

The network ACLs must allow inbound traffic from your local IP address on port 22 (for Linux instances) or port 3389 (for Windows instances). It must also allow outbound traffic to the ephemeral ports (1024-65535).

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.

2. In the navigation pane, choose **Subnets**.

3. Select your subnet.

4. On the **Network ACL** tab, for **Inbound rules**, verify that the rules allow inbound traffic from your computer on the required port. Otherwise, delete or modify the rule that is blocking the traffic.
5. For **Outbound rules**, verify that the rules allow outbound traffic to your computer on the ephemeral ports. Otherwise, delete or modify the rule that is blocking the traffic.

**If your computer is on a corporate network**

Ask your network administrator whether the internal firewall allows inbound and outbound traffic from your computer on port 22 (for Linux instances) or port 3389 (for Windows instances).

If you have a firewall on your computer, verify that it allows inbound and outbound traffic from your computer on port 22 (for Linux instances) or port 3389 (for Windows instances).

**Check that your instance has a public IPv4 address.**

If not, you can associate an Elastic IP address with your instance. For more information, see Elastic IP addresses (p. 1392).

**Check the CPU load on your instance; the server may be overloaded.**

AWS automatically provides data such as Amazon CloudWatch metrics and instance status, which you can use to see how much CPU load is on your instance and, if necessary, adjust how your loads are handled. For more information, see Monitor your instances using CloudWatch (p. 1298).

- If your load is variable, you can automatically scale your instances up or down using Auto Scaling and Elastic Load Balancing.
- If your load is steadily growing, you can move to a larger instance type. For more information, see Change the instance type (p. 479).

**To connect to your instance using an IPv6 address, check the following:**

- Your subnet must be associated with a route table that has a route for IPv6 traffic (: : /0) to an internet gateway.
- Your security group rules must allow inbound traffic from your local IPv6 address on the proper port (22 for Linux and 3389 for Windows).
- Your network ACL rules must allow inbound and outbound IPv6 traffic.
- If you launched your instance from an older AMI, it might not be configured for DHCPv6 (IPv6 addresses are not automatically recognized on the network interface). For more information, see Configure IPv6 on your instances in the Amazon VPC User Guide.
- Your local computer must have an IPv6 address, and must be configured to use IPv6.

**Error: unable to load key ... Expecting: ANY PRIVATE KEY**

If you try to connect to your instance and get the error message, *unable to load key ... Expecting: ANY PRIVATE KEY*, the file in which the private key is stored is incorrectly configured. If the private key file ends in .pem, it might still be incorrectly configured. A possible cause for an incorrectly configured private key file is a missing certificate.

**If the private key file is incorrectly configured, follow these steps to resolve the error**

1. Create a new key pair. For more information, see Create a key pair using Amazon EC2 (p. 2009).

   **Note**
   
   Alternatively, you can create a new key pair using a third-party tool. For more information, see Create a key pair using a third-party tool and import the public key to Amazon EC2 (p. 2012).
2. Add the new key pair to your instance. For more information, see \textit{I've lost my private key. How can I connect to my Linux instance? (p. 2545)}.

3. Connect to your instance using the new key pair.

\textbf{Error: User key not recognized by server}

\textbf{If you use SSH to connect to your instance}

- Use \texttt{ssh -vvv} to get triple verbose debugging information while connecting:

\begin{verbatim}
ssh -vvv -i path/key-pair-name.pem instance-user-name@ec2-203-0-113-25.compute-1.amazonaws.com
\end{verbatim}

The following sample output demonstrates what you might see if you were trying to connect to your instance with a key that was not recognized by the server:

\begin{verbatim}
\end{verbatim}

\textbf{If you use PuTTY to connect to your instance}

- Verify that your private key (.pem) file has been converted to the format recognized by PuTTY (.ppk).

For more information about converting your private key, see \textit{Connect to your Linux instance from Windows with PuTTY (p. 821)}.

\textbf{Note}

In PuTTYgen, load your private key file and select \textit{Save Private Key} rather than \textit{Generate}.

- Verify that you are connecting with the appropriate user name for your AMI. Enter the user name in the \textit{Host name} box in the \textit{PuTTY Configuration} window.
Error: Permission denied or connection closed by [instance] port 22

If you connect to your instance using SSH and get any of the following errors, Host key not found in [directory], Permission denied (publickey), Authentication failed, permission denied, or Connection closed by [instance] port 22, verify that you are connecting with the appropriate user name for your AMI and that you have specified the proper private key (.pem) file for your instance.

The appropriate user names are as follows:

<table>
<thead>
<tr>
<th>AMI used to launch instance</th>
<th>Default username</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Linux 2023</td>
<td>ec2-user</td>
</tr>
<tr>
<td>Amazon Linux 2</td>
<td></td>
</tr>
<tr>
<td>Amazon Linux</td>
<td></td>
</tr>
<tr>
<td>CentOS</td>
<td>centos or ec2-user</td>
</tr>
<tr>
<td>Debian</td>
<td>admin</td>
</tr>
<tr>
<td>Fedora</td>
<td>fedora or ec2-user</td>
</tr>
<tr>
<td>RHEL</td>
<td>ec2-user or root</td>
</tr>
<tr>
<td>SUSE</td>
<td>ec2-user or root</td>
</tr>
<tr>
<td>Ubuntu</td>
<td>ubuntu</td>
</tr>
<tr>
<td>Oracle</td>
<td>ec2-user</td>
</tr>
<tr>
<td>Bitnami</td>
<td>bitnami</td>
</tr>
<tr>
<td>Rocky Linux</td>
<td>rocky</td>
</tr>
<tr>
<td>Other</td>
<td>Check with the AMI provider</td>
</tr>
</tbody>
</table>

- Verify that you have an inbound security group rule to allow inbound traffic to the appropriate port. For more information, see Authorizing Network Access to Your Instances (p. 2005).
Error: Permission denied or connection closed by [instance] port 22

<table>
<thead>
<tr>
<th>AMI used to launch instance</th>
<th>Default username</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUSE</td>
<td>ec2-user or root</td>
</tr>
<tr>
<td>Ubuntu</td>
<td>ubuntu</td>
</tr>
<tr>
<td>Oracle</td>
<td>ec2-user</td>
</tr>
<tr>
<td>Bitnami</td>
<td>bitnami</td>
</tr>
<tr>
<td>Rocky Linux</td>
<td>rocky</td>
</tr>
<tr>
<td>Other</td>
<td>Check with the AMI provider</td>
</tr>
</tbody>
</table>

For example, to use an SSH client to connect to an Amazon Linux instance, use the following command:

```
ssh -i /path/key-pair-name.pem instance-user-name@ec2-203-0-113-25.compute-1.amazonaws.com
```

Confirm that you are using the private key file that corresponds to the key pair that you selected when you launched the instance.

New console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and then select your instance.
3. On the Details tab, under Instance details, verify the value of Key pair name.
4. If you did not specify a key pair when you launched the instance, you can terminate the instance and launch a new instance, ensuring that you specify a key pair. If this is an instance that you have been using but you no longer have the .pem file for your key pair, you can replace the key pair with a new one. For more information, see I've lost my private key. How can I connect to my Linux instance? (p. 2545).

Old console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances and then select your instance.
3. In the Description tab, verify the value of Key pair name.
4. If you did not specify a key pair when you launched the instance, you can terminate the instance and launch a new instance, ensuring that you specify a key pair. If this is an instance that you have been using but you no longer have the .pem file for your key pair, you can replace the key pair with a new one. For more information, see I've lost my private key. How can I connect to my Linux instance? (p. 2545).

If you generated your own key pair, ensure that your key generator is set up to create RSA keys. DSA keys are not accepted.

If you get a Permission denied (publickey) error and none of the above applies (for example, you were able to connect previously), the permissions on the home directory of your instance may have been changed. Permissions for /home/instance-user-name/.ssh/authorized_keys must be limited to the owner only.

To verify the permissions on your instance

1. Stop your instance and detach the root volume. For more information, see Stop and start your instance (p. 768) and Detach an Amazon EBS volume from a Linux instance (p. 2104).
2. Launch a temporary instance in the same Availability Zone as your current instance (use a similar or the same AMI as you used for your current instance), and attach the root volume to the temporary instance. For more information, see Attach an Amazon EBS volume to an instance (p. 2076).

3. Connect to the temporary instance, create a mount point, and mount the volume that you attached. For more information, see Make an Amazon EBS volume available for use on Linux (p. 2083).

4. From the temporary instance, check the permissions of the /home/instance-user-name/ directory of the attached volume. If necessary, adjust the permissions as follows:

```
[ec2-user ~]$ chmod 600 mount_point/home/instance-user-name/.ssh/authorized_keys
```

```
[ec2-user ~]$ chmod 700 mount_point/home/instance-user-name/.ssh
```

```
[ec2-user ~]$ chmod 700 mount_point/home/instance-user-name
```

5. Unmount the volume, detach it from the temporary instance, and re-attach it to the original instance. Ensure that you specify the correct device name for the root volume; for example, /dev/xvda.

6. Start your instance. If you no longer require the temporary instance, you can terminate it.

### Error: Unprotected private key file

Your private key file must be protected from read and write operations from any other users. If your private key can be read or written to by anyone but you, then SSH ignores your key and you see the following warning message below.

```
@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@
@         WARNING: UNPROTECTED PRIVATE KEY FILE!          @
@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@
Permissions 0777 for '.ssh/my_private_key.pem' are too open.
It is required that your private key files are NOT accessible by others.
This private key will be ignored.
bad permissions: ignore key: .ssh/my_private_key.pem
Permission denied (publickey).
```

If you see a similar message when you try to log in to your instance, examine the first line of the error message to verify that you are using the correct public key for your instance. The above example uses the private key .ssh/my_private_key.pem with file permissions of 0777, which allow anyone to read or write to this file. This permission level is very insecure, and so SSH ignores this key.

If you are connecting from macOS or Linux, run the following command to fix this error, substituting the path for your private key file.

```
[ec2-user ~]$ chmod 0400 .ssh/my_private_key.pem
```

If you are connecting from Windows, perform the following steps on your local computer.

1. Navigate to your .pem file.
2. Right-click on the .pem file and select Properties.
3. Choose the Security tab.
4. Select Advanced.
5. Verify that you are the owner of the file. If not, change the owner to your username.
6. Select **Disable inheritance** and Remove all inherited permissions from this object.
7. Select **Add**, **Select a principal**, enter your username, and select **OK**.
8. From the **Permission Entry** window, grant **Read** permissions and select **OK**.
9. Click **Apply** to ensure all settings are saved.
10. Select **OK** to close the **Advanced Security Settings** window.
11. Select **OK** to close the **Properties** window.
12. You should be able to connect to your Linux instance from Windows via SSH.

From a Windows command prompt, run the following commands.

1. From the command prompt, navigate to the file path location of your .pem file.
2. Run the following command to reset and remove explicit permissions:

   ```
   icacls.exe $path /reset
   ```

3. Run the following command to grant Read permissions to the current user:

   ```
   icacls.exe $path /GRANT:R "$(env:USERNAME):(R)"
   ```

4. Run the following command to disable inheritance and remove inherited permissions.

   ```
   icacls.exe $path /inheritance:r
   ```

5. You should be able to connect to your Linux instance from Windows via SSH.

**Error: Private key must begin with "-----BEGIN RSA PRIVATE KEY-----" and end with "-----END RSA PRIVATE KEY-----"**

If you use a third-party tool, such as **ssh-keygen**, to create an RSA key pair, it generates the private key in the OpenSSH key format. When you connect to your instance, if you use the private key in the OpenSSH format to decrypt the password, you’ll get the error **Private key must begin with "-----BEGIN RSA PRIVATE KEY-----" and end with "-----END RSA PRIVATE KEY-----"**.

To resolve the error, the private key must be in the PEM format. Use the following command to create the private key in the PEM format:

```
ssh-keygen -m PEM
```

**Error: Server refused our key or No supported authentication methods available**

If you use PuTTY to connect to your instance and get either of the following errors, **Error: Server refused our key** or **Error: No supported authentication methods available**, verify that you are connecting with the appropriate user name for your AMI. Type the user name in **User name** in the **PuTTY Configuration** window.

The appropriate user names are as follows:
### AMI used to launch instance | Default username
--- | ---
Amazon Linux 2023 | `ec2-user`
Amazon Linux 2 | `ec2-user`
Amazon Linux | `ec2-user`
CentOS | `centos` or `ec2-user`
Debian | `admin`
Fedora | `fedora` or `ec2-user`
RHEL | `ec2-user` or `root`
SUSE | `ec2-user` or `root`
Ubuntu | `ubuntu`
Oracle | `ec2-user`
Bitnami | `bitnami`
Rocky Linux | `rocky`
Other | Check with the AMI provider

You should also verify that:

- You are using the latest version of PuTTY. For more information, see the [PuTTY web page](https://www.putty.org/).
- Your private key (.pem) file has been correctly converted to the format recognized by PuTTY (.ppk). For more information about converting your private key, see [Connect to your Linux instance from Windows with PuTTY (p. 821)](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/puTTY.html).

### Cannot ping instance

The ping command is a type of ICMP traffic — if you are unable to ping your instance, ensure that your inbound security group rules allow ICMP traffic for the Echo Request message from all sources, or from the computer or instance from which you are issuing the command.

If you are unable to issue a `ping` command from your instance, ensure that your outbound security group rules allow ICMP traffic for the Echo Request message to all destinations, or to the host that you are attempting to ping.

Ping commands can also be blocked by a firewall or time out due to network latency or hardware issues. You should consult your local network or system administrator for help with further troubleshooting.

### Error: Server unexpectedly closed network connection

If you are connecting to your instance with PuTTY and you receive the error "Server unexpectedly closed network connection," verify that you have enabled keepalives on the Connection page of the PuTTY Configuration to avoid being disconnected. Some servers disconnect clients when they do not receive any data within a specified period of time. Set the Seconds between keepalives to 59 seconds.
If you still experience issues after enabling keepalives, try to disable Nagle's algorithm on the Connection page of the PuTTY Configuration.

**Error: Host key validation failed for EC2 Instance Connect**

If you rotate your instance host keys, the new host keys are not automatically uploaded to the AWS trusted host keys database. This causes host key validation to fail when you try to connect to your instance using the EC2 Instance Connect browser-based client, and you're unable to connect to your instance.

To resolve the error, you must run the `eic_harvest_hostkeys` script on your instance, which uploads your new host key to EC2 Instance Connect. The script is located at `/opt/aws/bin/` on Amazon Linux 2 instances, and at `/usr/share/ec2-instance-connect/` on Ubuntu instances.

**Amazon Linux 2**

**To resolve the host key validation failed error on an Amazon Linux 2 instance**

1. Connect to your instance using SSH.

   You can connect by using the EC2 Instance Connect CLI or by using the SSH key pair that was assigned to your instance when you launched it and the default user name of the AMI that you used to launch your instance. For Amazon Linux 2, the default user name is `ec2-user`.

   For example, if your instance was launched using Amazon Linux 2, your instance's public DNS name is `ec2-a-b-c-d.us-west-2compute.amazonaws.com`, and the key pair is `my_ec2_private_key.pem`, use the following command to SSH into your instance:

   ```
   $ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
   ```

   For more information about connecting to your instance, see [Connect to your Linux instance from Linux or macOS using SSH](#).

2. Navigate to the following folder.

   ```
   [ec2-user ~]$ cd /opt/aws/bin/
   ```

3. Run the following command on your instance.

   ```
   [ec2-user ~]$ ./eic_harvest_hostkeys
   ```

   Note that a successful call results in no output.

   You can now use the EC2 Instance Connect browser-based client to connect to your instance.

**Ubuntu**

**To resolve the host key validation failed error on an Ubuntu instance**

1. Connect to your instance using SSH.

   You can connect by using the EC2 Instance Connect CLI or by using the SSH key pair that was assigned to your instance when you launched it and the default user name of the AMI that you used to launch your instance. For Ubuntu, the default user name is `ubuntu`.

   ```
   $ ssh -i my_ec2_private_key.pem ec2-user@ec2-a-b-c-d.us-west-2compute.amazonaws.com
   ```

   For more information about connecting to your instance, see [Connect to your Linux instance from Linux or macOS using SSH](#).
Can't connect to Ubuntu instance using EC2 Instance Connect

For example, if your instance was launched using Ubuntu, your instance's public DNS name is ec2-a-b-c-d.us-west-2.compute.amazonaws.com, and the key pair is my_ec2_private_key.pem, use the following command to SSH into your instance:

```
$ ssh -i my_ec2_private_key.pem ubuntu@ec2-a-b-c-d.us-west-2.compute.amazonaws.com
```

For more information about connecting to your instance, see Connect to your Linux instance from Linux or macOS using SSH (p. 816).

2. Navigate to the following folder.

```
[ec2-user ~]$ cd /usr/share/ec2-instance-connect/
```

3. Run the following command on your instance.

```
[ec2-user ~]$ ./eic_harvest_hostkeys
```

Note that a successful call results in no output.

You can now use the EC2 Instance Connect browser-based client to connect to your instance.

Can't connect to Ubuntu instance using EC2 Instance Connect

If you use EC2 Instance Connect to connect to your Ubuntu instance and you get an error when attempting to connect, you can use the following information to try to fix the issue.

Possible cause

The ec2-instance-connect package on the instance is not the latest version.

Solution

Update the ec2-instance-connect package on the instance to the latest version, as follows:

1. Connect (p. 811) to your instance using a method other than EC2 Instance Connect.
2. Run the following command on your instance to update the ec2-instance-connect package to the latest version.

```
apt update && apt upgrade
```

I've lost my private key. How can I connect to my Linux instance?

If you lose the private key for an EBS-backed instance, you can regain access to your instance. You must stop the instance, detach its root volume and attach it to another instance as a data volume, modify the authorized_keys file with a new public key, move the volume back to the original instance, and restart the instance. For more information about launching, connecting to, and stopping instances, see Instance lifecycle (p. 714).

This procedure is only supported for instances with EBS root volumes. If the root device is an instance store volume, you cannot use this procedure to regain access to your instance; you must have the private
key to connect to the instance. To determine the root device type of your instance, open the Amazon EC2 console, choose **Instances**, select the instance, choose the **Storage** tab, and in the **Root device details** section, check the value of **Root device type**.

The value is either EBS or INSTANCE-STORE.

In addition to the following steps, there are other ways to connect to your Linux instance if you lose your private key. For more information, see [How can I connect to my Amazon EC2 instance if I lost my SSH key pair after its initial launch?](#).

**Steps for connecting to an EBS-backed instance with a different key pair**

- **Step 1: Create a new key pair** (p. 2546)
- **Step 2: Get information about the original instance and its root volume** (p. 2546)
- **Step 3: Stop the original instance** (p. 2546)
- **Step 4: Launch a temporary instance** (p. 2547)
- **Step 5: Detach the root volume from the original instance and attach it to the temporary instance** (p. 2547)
- **Step 6: Add the new public key to authorized_keys on the original volume mounted to the temporary instance** (p. 2548)
- **Step 7: Unmount and detach the original volume from the temporary instance, and reattach it to the original instance** (p. 2549)
- **Step 8: Connect to the original instance using the new key pair** (p. 2550)
- **Step 9: Clean up** (p. 2550)

**Step 1: Create a new key pair**

Create a new key pair using either the Amazon EC2 console or a third-party tool. If you want to name your new key pair exactly the same as the lost private key, you must first delete the existing key pair. For information about creating a new key pair, see [Create a key pair using Amazon EC2](#) or [Create a key pair using a third-party tool and import the public key to Amazon EC2](#).

**Step 2: Get information about the original instance and its root volume**

Make note of the following information because you’ll need it to complete this procedure.

**To get information about your original instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. Choose **Instances** in the navigation pane, and then select the instance that you’d like to connect to. (We’ll refer to this as the **original** instance.)
3. On the **Details** tab, make note of the instance ID and AMI ID.
4. On the **Networking** tab, make note of the Availability Zone.
5. On the **Storage** tab, under **Root device name**, make note of the device name for the root volume (for example, `/dev/xvda`). Then, under **Block devices**, find this device name and make note of the volume ID (for example, `vol-0a1234b5678c910de`).

**Step 3: Stop the original instance**

Choose **Instance state**, **Stop instance**. If this option is disabled, either the instance is already stopped or its root device is an instance store volume.
Warning
When you stop an instance, the data on any instance store volumes is erased. To keep data from instance store volumes, be sure to back it up to persistent storage.

Step 4: Launch a temporary instance

New console

To launch a temporary instance

1. In the navigation pane, choose Instances, and then choose Launch instances.
2. In the Name and tags section, for Name, enter Temporary.
3. In the Application and OS Images section, select the same AMI that you used to launch the original instance. If this AMI is unavailable, you can create an AMI that you can use from the stopped instance. For more information, see Create an Amazon EBS-backed Linux AMI (p. 173).
4. In the Instance type section, keep the default instance type.
5. In the Key pair section, for Key pair name, select the existing key pair to use or create a new one.
6. In the Network settings section, choose Edit, and then for Subnet, select a subnet in the same Availability Zone as the original instance.
7. In the Summary panel, choose Launch.

Old console

Choose Launch instances, and then use the launch wizard to launch a temporary instance with the following options:

- On the Choose an AMI page, select the same AMI that you used to launch the original instance. If this AMI is unavailable, you can create an AMI that you can use from the stopped instance. For more information, see Create an Amazon EBS-backed Linux AMI (p. 173).
- On the Choose an Instance Type page, leave the default instance type that the wizard selects for you.
- On the Configure Instance Details page, specify the same Availability Zone as the original instance. If you're launching an instance in a VPC, select a subnet in this Availability Zone.
- On the Add Tags page, add the tag Name=Temporary to the instance to indicate that this is a temporary instance.
- On the Review page, choose Launch. Choose the key pair that you created in Step 1, then choose Launch Instances.

Step 5: Detach the root volume from the original instance and attach it to the temporary instance

1. In the navigation pane, choose Volumes and select the root device volume for the original instance (you made note of its volume ID in a previous step). Choose Actions, Detach volume, and then choose Detach. Wait for the state of the volume to become available. (You might need to choose the Refresh icon.)
2. With the volume still selected, choose Actions, and then choose Attach volume. Select the instance ID of the temporary instance, make note of the device name specified under Device name (for example, /dev/sdf), and then choose Attach volume.
I've lost my private key. How can I connect to my Linux instance?

Note
If you launched your original instance from an AWS Marketplace AMI and your volume contains AWS Marketplace codes, you must first stop the temporary instance before you can attach the volume.

Step 6: Add the new public key to authorized_keys on the original volume mounted to the temporary instance

1. Connect to the temporary instance.
2. From the temporary instance, mount the volume that you attached to the instance so that you can access its file system. For example, if the device name is /dev/sdf, use the following commands to mount the volume as /mnt/tempvol.

   Note
   The device name might appear differently on your instance. For example, devices mounted as /dev/sdf might show up as /dev/xvdf on the instance. Some versions of Red Hat (or its variants, such as CentOS) might even increment the trailing letter by 4 characters, where /dev/sdf becomes /dev/xvdk.

   a. Use the `lsblk` command to determine if the volume is partitioned.

      ```
      [ec2-user ~]$ lsblk
      NAME      MAJ:MIN RM  SIZE RO TYPE          MOUNTPOINT
      xvda      202:0    0  8G  0 disk          
      #xvda1    202:1    0  8G  0 part /       
      xvdf      202:80   0 101G 0 disk         
      #xvdf1    202:81   0 101G 0 part         
      xvdg      202:96   0   30G 0 disk        
      In the preceding example, /dev/xvda and /dev/xvdf are partitioned volumes, and /dev/xvdg is not. If your volume is partitioned, you mount the partition (/dev/xvdf1) instead of the raw device (/dev/xvdf) in the next steps.
     ```

   b. Create a temporary directory to mount the volume.

      ```
      [ec2-user ~]$ sudo mkdir /mnt/tempvol
     ```

   c. Mount the volume (or partition) at the temporary mount point, using the volume name or device name that you identified earlier. The required command depends on your operating system's file system. Note that the device name might appear differently on your instance. See the note in Step 6 for more information.

      - Amazon Linux, Ubuntu, and Debian

      ```
      [ec2-user ~]$ sudo mount /dev/xvdf1 /mnt/tempvol
      ```

      - Amazon Linux 2, CentOS, SUSE Linux 12, and RHEL 7.x

      ```
      [ec2-user ~]$ sudo mount -o nouuid /dev/xvdf1 /mnt/tempvol
      ```

   Note
   If you get an error stating that the file system is corrupt, run the following command to use the `fsck` utility to check the file system and repair any issues:
I've lost my private key. How can I connect to my Linux instance?

```
[ec2-user ~]$ sudo fsck /dev/xvdf1
```

3. From the temporary instance, use the following command to update authorized_keys on the mounted volume with the new public key from the authorized_keys for the temporary instance.

   **Important**
   The following examples use the Amazon Linux user name ec2-user. You might need to substitute a different user name, such as ubuntu for Ubuntu instances.

   ```
   [ec2-user ~]$ cp .ssh/authorized_keys /mnt/tempvol/home/ec2-user/.ssh/authorized_keys
   ```

   If this copy succeeded, you can go to the next step.

   (Optional) Otherwise, if you don't have permission to edit files in /mnt/tempvol, you must update the file using sudo and then check the permissions on the file to verify that you are able to log into the original instance. Use the following command to check the permissions on the file.

   ```
   [ec2-user ~]$ sudo ls -l /mnt/tempvol/home/ec2-user/.ssh
   ```

   In this example output, 222 is the user ID and 500 is the group ID. Next, use sudo to re-run the copy command that failed.

   ```
   [ec2-user ~]$ sudo cp .ssh/authorized_keys /mnt/tempvol/home/ec2-user/.ssh/authorized_keys
   ```

   Run the following command again to determine whether the permissions changed.

   ```
   [ec2-user ~]$ sudo ls -l /mnt/tempvol/home/ec2-user/.ssh
   ```

   If the user ID and group ID have changed, use the following command to restore them.

   ```
   [ec2-user ~]$ sudo chown 222:500 /mnt/tempvol/home/ec2-user/.ssh/authorized_keys
   ```

**Step 7: Unmount and detach the original volume from the temporary instance, and reattach it to the original instance**

1. From the temporary instance, unmount the volume that you attached so that you can reattach it to the original instance. For example, use the following command to unmount the volume at /mnt/tempvol.

   ```
   [ec2-user ~]$ sudo umount /mnt/tempvol
   ```

2. Detach the volume from the temporary instance (you unmounted it in the previous step): From the Amazon EC2 console, choose Volumes in the navigation pane, select the root device volume for the original instance (you made note of the volume ID in a previous step), choose Actions, Detach volume, and then choose Detach. Wait for the state of the volume to become available. (You might need to choose the Refresh icon.)

3. Reattach the volume to the original instance: With the volume still selected, choose Actions, Attach volume. Select the instance ID of the original instance, specify the device name that you noted
earlier in Step 2 (p. 2546) for the original root device attachment (/dev/sda1 or /dev/xvda), and then choose Attach volume.

**Important**
If you don't specify the same device name as the original attachment, you cannot start the original instance. Amazon EC2 expects the root device volume at sda1 or /dev/xvda.

**Step 8: Connect to the original instance using the new key pair**

Select the original instance, choose Instance state, Start instance. After the instance enters the running state, you can connect to it using the private key file for your new key pair.

**Note**
If the name of your new key pair and corresponding private key file is different from the name of the original key pair, ensure that you specify the name of the new private key file when you connect to your instance.

**Step 9: Clean up**

(Optional) You can terminate the temporary instance if you have no further use for it. Select the temporary instance, and choose Instance state, Terminate instance.

**Troubleshoot stopping your instance**

If you have stopped your Amazon EBS-backed instance and it appears stuck in the stopping state, there may be an issue with the underlying host computer.

There is no cost for instance usage while an instance is in the stopping state or in any other state except running. You are only charged for instance usage when an instance is in the running state.

**Force stop the instance**

Force the instance to stop using either the console or the AWS CLI.

**Note**
You can force an instance to stop using the console only while the instance is in the stopping state. You can force an instance to stop using the AWS CLI while the instance is in any state, except shutting-down and terminated.

**New console**

**To force stop the instance using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose Instances and select the stuck instance.
3. Choose Instance state, Force stop instance, Stop.

**Note**
If your instance is in the stopping state. If your instance is in another state (except shutting-down and terminated), you can use the AWS CLI to force stop your instance.

**Old console**

**To force stop the instance using the console**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
In the navigation pane, choose **Instances** and select the stuck instance.
3. Choose **Instance State, Stop, Yes, Forcefully Stop**.

**AWS CLI**

To force stop the instance using the AWS CLI

Use the `stop-instances` command and the `--force` option as follows:

```
aws ec2 stop-instances --instance-ids i-0123ab456c789d01e --force
```

If, after 10 minutes, the instance has not stopped, post a request for help on AWS re:Post. To help expedite a resolution, include the instance ID, and describe the steps that you’ve already taken. Alternatively, if you have a support plan, create a technical support case in the **Support Center**.

**Create a replacement instance**

To attempt to resolve the problem while you are waiting for assistance from AWS re:Post or the Support Center, create a replacement instance. Create an AMI of the stuck instance, and launch a new instance using the new AMI.

**Important**

Creating a replacement instance is recommended if it’s registering **system status checks** (p. 1267) only, as instance status checks will result in the AMI copying over an exact replica of the broken OS. Once you’ve confirmed the status message, create the AMI and launch a new instance using the new AMI.

**New console**

To create a replacement instance using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances** and select the stuck instance.
3. Choose **Actions, Image and templates, Create image**.
4. On the **Create image** page, do the following:
   a. Enter a name and description for the AMI.
   b. Choose **No reboot**.
   c. Choose **Create image**.

   For more information, see [Create a Linux AMI from an instance](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/CreatingAAMI.html) (p. 175).
5. Launch a new instance from the AMI and verify that the new instance is working.
6. Select the stuck instance, and choose **Actions, Instance state, Terminate instance**. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

**Old console**

To create a replacement instance using the console

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation pane, choose **Instances** and select the stuck instance.
Amazon Elastic Compute Cloud
User Guide for Linux Instances
Create a replacement instance

4. In the Create Image dialog box, fill in the following fields, and then choose Create Image:
   a. Specify a name and description for the AMI.
   b. Choose No reboot.

   For more information, see Create a Linux AMI from an instance (p. 175).

5. Launch a new instance from the AMI and verify that the new instance is working.
6. Select the stuck instance, and choose Actions, Instance State, Terminate. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

AWS CLI

To create a replacement instance using the CLI

1. Create an AMI from the stuck instance using the create-image (AWS CLI) command and the --no-reboot option as follows:

   ```
   aws ec2 create-image --instance-id i-0123ab456c789d01e --name "AMI" --description "AMI for replacement instance" --no-reboot
   ```

2. Launch a new instance from the AMI using the run-instances (AWS CLI) command as follows:

   ```
   aws ec2 run-instances --image-id ami-1a2b3c4d --count 1 --instance-type c3.large --key-name MyKeyPair --security-groups MySecurityGroup
   ```

3. Verify that the new instance is working.
4. Terminate the stuck instance using the terminate-instances (AWS CLI) command as follows:

   ```
   aws ec2 terminate-instances --instance-ids i-1234567890abcdef0
   ```

If you are unable to create an AMI from the instance as described in the previous procedure, you can set up a replacement instance as follows:

(Alternate) To create a replacement instance using the console

1. Select the instance and choose Description, Block devices. Select each volume and make note of its volume ID. Be sure to note which volume is the root volume.
2. In the navigation pane, choose Volumes. Select each volume for the instance, and choose Actions, Create Snapshot.
3. In the navigation pane, choose Snapshots. Select the snapshot that you just created, and choose Actions, Create Volume.
4. Launch an instance with the same operating system as the stuck instance. Note the volume ID and device name of its root volume.
5. In the navigation pane, choose Instances, select the instance that you just launched, and choose Instance state, Stop instance.
6. In the navigation pane, choose Volumes, select the root volume of the stopped instance, and choose Actions, Detach Volume.
7. Select the root volume that you created from the stuck instance, choose Actions, Attach Volume, and attach it to the new instance as its root volume (using the device name that you made note of). Attach any additional non-root volumes to the instance.
8. In the navigation pane, choose Instances and select the replacement instance. Choose Instance state, Start instance. Verify that the instance is working.

9. Select the stuck instance, choose Instance state, Terminate instance. If the instance also gets stuck terminating, Amazon EC2 automatically forces it to terminate within a few hours.

Troubleshoot instance termination (shutting down)

You are not billed for any instance usage while an instance is not in the running state. In other words, when you terminate an instance, you stop incurring charges for that instance as soon as its state changes to shutting-down.

Instance terminates immediately

Several issues can cause your instance to terminate immediately on start-up. See Instance terminates immediately (p. 2530) for more information.

Delayed instance termination

If your instance remains in the shutting-down state longer than a few minutes, it might be delayed due to shutdown scripts being run by the instance.

Another possible cause is a problem with the underlying host computer. If your instance remains in the shutting-down state for several hours, Amazon EC2 treats it as a stuck instance and forcibly terminates it.

If it appears that your instance is stuck terminating and it has been longer than several hours, post a request for help to AWS re:Post. To help expedite a resolution, include the instance ID and describe the steps that you've already taken. Alternatively, if you have a support plan, create a technical support case in the Support Center.

Terminated instance still displayed

After you terminate an instance, it remains visible for a short while before being deleted. The state shows as terminated. If the entry is not deleted after several hours, contact Support.

Error: The instance may not be terminated. Modify its 'disableApiTermination' instance attribute

If you try to terminate an instance and get the The instance instance_id may not be terminated. Modify its 'disableApiTermination' instance attribute error message, it indicates that the instance has been enabled for termination protection. Termination protection prevents the instance from being accidentally terminated. For more information, see Enable termination protection (p. 800).

You must disable termination protection before you can terminate the instance.

To disable termination protection using the Amazon EC2 console, select the instance and then choose Actions, Instance Settings, Change Termination Protection.

To disable termination protection using the AWS CLI, use the following command:

$ aws ec2 modify-instance-attribute --instance-id instance_id --no-disable-api-termination
Instances automatically launched or terminated

Generally, the following behaviors mean that you've used Amazon EC2 Auto Scaling, EC2 Fleet, or Spot Fleet to scale your computing resources automatically based on criteria that you've defined:

- You terminate an instance and a new instance launches automatically.
- You launch an instance and one of your instances terminates automatically.
- You stop an instance and it terminates and a new instance launches automatically.

To stop automatic scaling, see the Amazon EC2 Auto Scaling User Guide, EC2 Fleet (p. 1089), or Create a Spot Fleet request (p. 1185).

Troubleshoot instances with failed status checks

The following information can help you troubleshoot issues if your instance fails a status check. First determine whether your applications are exhibiting any problems. If you verify that the instance is not running your applications as expected, review the status check information and the system logs.

For examples of problems that can cause status checks to fail, see Status checks for your instances (p. 1267).

Contents

- Review status check information (p. 2555)
- Retrieve the system logs (p. 2555)
- Troubleshoot system log errors for Linux-based instances (p. 2556)
- Out of memory: kill process (p. 2556)
- ERROR: mmu_update failed (Memory management update failed) (p. 2557)
- I/O error (block device failure) (p. 2558)
- I/O ERROR: neither local nor remote disk (Broken distributed block device) (p. 2559)
- request_module: runaway loop modprobe (Looping legacy kernel modprobe on older Linux versions) (p. 2560)
- "FATAL: kernel too old" and "fsck: No such file or directory while trying to open /dev" (Kernel and AMI mismatch) (p. 2560)
- "FATAL: Could not load /lib/modules" or "BusyBox" (Missing kernel modules) (p. 2561)
- ERROR Invalid kernel (EC2 incompatible kernel) (p. 2562)
- fsck: No such file or directory while trying to open... (File system not found) (p. 2563)
- General error mounting filesystems (failed mount) (p. 2565)
- VFS: Unable to mount root fs on unknown-block (Root filesystem mismatch) (p. 2566)
- Error: Unable to determine major/minor number of root device... (Root file system/device mismatch) (p. 2567)
- XENBUS: Device with no driver... (p. 2568)
- ... days without being checked, check forced (File system check required) (p. 2569)
- fsck died with exit status... (Missing device) (p. 2570)
- GRUB prompt (grubdom>) (p. 2570)
- Bringing up interface eth0: Device eth0 has different MAC address than expected, ignoring, (Hard-coded MAC address) (p. 2572)
Review status check information

To investigate impaired instances using the Amazon EC2 console

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and then select your instance.
3. In the details pane, choose Status Checks to see the individual results for all System Status Checks and Instance Status Checks.

If a system status check has failed, you can try one of the following options:

- Create an instance recovery alarm. For more information, see Create alarms that stop, terminate, reboot, or recover an instance (p. 1322).
- If you changed the instance type to an instance built on the Nitro System (p. 295), status checks fail if you migrated from an instance that does not have the required ENA and NVMe drivers. For more information, see Compatibility for changing the instance type (p. 482).
- For an instance using an Amazon EBS-backed AMI, stop and restart the instance.
- For an instance using an instance-store backed AMI, terminate the instance and launch a replacement.
- Wait for Amazon EC2 to resolve the issue.
- Post your issue to AWS re:Post.
- If your instance is in an Auto Scaling group, the Amazon EC2 Auto Scaling service automatically launches a replacement instance. For more information, see Health Checks for Auto Scaling Instances in the Amazon EC2 Auto Scaling User Guide.
- Retrieve the system log and look for errors.

Retrieve the system logs

If an instance status check fails, you can reboot the instance and retrieve the system logs. The logs may reveal an error that can help you troubleshoot the issue. Rebooting clears unnecessary information from the logs.

To reboot an instance and retrieve the system log

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances, and select your instance.
3. Choose Instance state, Reboot instance. It might take a few minutes for your instance to reboot.
4. Verify that the problem still exists; in some cases, rebooting may resolve the problem.
5. When the instance is in the running state, choose Actions, Monitor and troubleshoot, Get system log.
6. Review the log that appears on the screen, and use the list of known system log error statements below to troubleshoot your issue.
7. If your experience differs from our check results, or if you are having an issue with your instance that our checks did not detect, choose Submit feedback on the Status Checks tab to help us improve our detection tests.
8. If your issue is not resolved, you can post your issue to AWS re:Post.
Troubleshoot system log errors for Linux-based instances

For Linux-based instances that have failed an instance status check, such as the instance reachability check, verify that you followed the steps above to retrieve the system log. The following list contains some common system log errors and suggested actions you can take to resolve the issue for each error.

Memory Errors

- Out of memory: kill process (p. 2556)
- ERROR: mmu_update failed (Memory management update failed) (p. 2557)

Device Errors

- I/O error (block device failure) (p. 2558)
- I/O ERROR: neither local nor remote disk (Broken distributed block device) (p. 2559)

Kernel Errors

- request_module: runaway loop modprobe (Looping legacy kernel modprobe on older Linux versions) (p. 2560)
- "FATAL: kernel too old" and "fsck: No such file or directory while trying to open /dev" (Kernel and AMI mismatch) (p. 2560)
- "FATAL: Could not load /lib/modules" or "BusyBox" (Missing kernel modules) (p. 2561)
- ERROR Invalid kernel (EC2 incompatible kernel) (p. 2562)

File System Errors

- fsck: No such file or directory while trying to open... (File system not found) (p. 2563)
- General error mounting filesystems (failed mount) (p. 2565)
- VFS: Unable to mount root fs on unknown-block (Root filesystem mismatch) (p. 2566)
- Error: Unable to determine major/minor number of root device... (Root file system/device mismatch) (p. 2567)
- XENBUS: Device with no driver... (p. 2568)
- ... days without being checked, check forced (File system check required) (p. 2569)
- fsck died with exit status... (Missing device) (p. 2570)

Operating System Errors

- GRUB prompt (grubdom>) (p. 2570)
- Bringing up interface eth0: Device eth0 has different MAC address than expected, ignoring. (Hard-coded MAC address) (p. 2572)
- Unable to load SELinux Policy. Machine is in enforcing mode. Halting now. (SELinux misconfiguration) (p. 2573)
- XENBUS: Timeout connecting to devices (Xenbus timeout) (p. 2574)

Out of memory: kill process

An out-of-memory error is indicated by a system log entry similar to the one shown below.
**ERROR: mmu_update failed (Memory management update failed)**

Memory management update failures are indicated by a system log entry similar to the following:

```
... Press 'ESC' to enter the menu... 0   [H[] Booting 'Amazon Linux 2011.09 (2.6.35.14-95.38.amzn1.i686)'

root (hd0)

Filesystem type is ext2fs, using whole disk

kernel /boot/vmlinux-2.6.35.14-95.38.amzn1.i686 root=LABEL=/ console=hvc0 LANG=en_US.UTF-8 KEYTABLE=us
```
initrd /boot/initramfs-2.6.35.14-95.38.amzn1.i686.img

**ERROR: mmu_update failed with rc=-22**

**Potential cause**

Issue with Amazon Linux

**Suggested action**

Post your issue to the [Developer Forums](http://developerforums) or contact [AWS Support](http://aws-support).

### I/O error (block device failure)

An input/output error is indicated by a system log entry similar to the following example:

```
[9943662.053217] end_request: I/O error, dev sde, sector 52428288
[9943664.191262] end_request: I/O error, dev sde, sector 52428168
[9943664.191285] Buffer I/O error on device md0, logical block 209713024
[9943664.191297] Buffer I/O error on device md0, logical block 209713025

**Potential causes**

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Potential cause</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon EBS-backed</td>
<td>A failed Amazon EBS volume</td>
</tr>
<tr>
<td>Instance store-backed</td>
<td>A failed physical drive</td>
</tr>
</tbody>
</table>

**Suggested actions**

For this instance type | Do this
--- | ---
Amazon EBS-backed | Use the following procedure:
1. Stop the instance.
2. Detach the volume.
3. Attempt to recover the volume.
I/O ERROR: neither local nor remote disk (Broken distributed block device)

An input/output error on the device is indicated by a system log entry similar to the following example:

```
...  
block drbd1: Local I0 failed in request_timer_fn. Detaching...  
Abort journal on device drbd1-8.  
block drbd1: I0 ERROR: neither local nor remote disk  
Buffer I/O error on device drbd1, logical block 557056  
lost page write due to I/O error on drbd1  
JBD2: I/O error detected when updating journal superblock for drbd1-8.
```

**Potential causes**

<table>
<thead>
<tr>
<th>Instance type</th>

</tr>
</thead>
<tbody>
<tr>
<td>Amazon EBS-backed</td>
<td>A failed Amazon EBS volume</td>
</tr>
<tr>
<td>Instance store-backed</td>
<td>A failed physical drive</td>
</tr>
</tbody>
</table>

**Suggested action**

Terminate the instance and launch a new instance.

For an Amazon EBS-backed instance you can recover data from a recent snapshot by creating an image from it. Any data added after the snapshot cannot be recovered.
request_module: runaway loop modprobe (Looping legacy kernel modprobe on older Linux versions)

This condition is indicated by a system log similar to the one shown below. Using an unstable or old Linux kernel (for example, 2.6.16-xenU) can cause an interminable loop condition at startup.

```
Linux version 2.6.16-xenU (builder@xenbat.amazonsa) (gcc version 4.0.1 20050727 (Red Hat 4.0.1-5)) #1 SMP Mon May 28 03:41:49 SAST 2007

BIOS-provided physical RAM map:
  Xen: 0000000000000000 - 0000000026700000 (usable)
0MB HIGHMEM available.
...
request_module: runaway loop modprobe binfmt-464c
request_module: runaway loop modprobe binfmt-464c
request_module: runaway loop modprobe binfmt-464c
request_module: runaway loop modprobe binfmt-464c
request_module: runaway loop modprobe binfmt-464c
```

Begin: Waiting for root file system... ...
Done.
Gave up waiting for root device. Common problems:
- Boot args (cat /proc/cmdline)
  - Check rootdelay= (did the system wait long enough?)
  - Check root= (did the system wait for the right device?)
- Missing modules (cat /proc/modules; ls /dev)
FATAL: Could not load /lib/modules/2.6.34-4-virtual/modules.dep: No such file or directory
### Potential causes

One or more of the following conditions can cause this problem:

- Missing ramdisk
- Missing correct modules from ramdisk
- Amazon EBS root volume not correctly attached as /dev/sda1

### Suggested actions

<table>
<thead>
<tr>
<th>For this instance type</th>

fsck: No such file or directory while trying to open... (File system not found)

This condition is indicated by a system log similar to the one shown below.

Welcome to Fedora
Press 'I' to enter interactive startup.
Setting clock : Wed Oct 26 05:52:05 EDT 2011 [ OK ]
Starting udev: [ OK ]
Setting hostname localhost: [ OK ]
No devices found
Setting up Logical Volume Management: File descriptor 7 left open
  No volume groups found
Checking filesystems

Checking all file systems.

```
[/sbin/fsck.ext3 (1) -- /] fsck.ext3 -a /dev/sda1
/dev/sda1: clean, 82081/1310720 files, 2141116/2621440 blocks
[/sbin/fsck.ext3 (1) -- /mnt/dbbackups] fsck.ext3 -a /dev/sdh
fsck.ext3: No such file or directory while trying to open /dev/sdh

/dev/sdh:
The superblock could not be read or does not describe a correct ext2 filesystem. If the device is valid and it really contains an ext2 filesystem (and not swap or ufs or something else), then the superblock is corrupt, and you might try running e2fsck with an alternate superblock:

e2fsck -b 8193 <device>
```

[FAILED]

*** An error occurred during the file system check.
*** Dropping you to a shell; the system will reboot
*** when you leave the shell.
Give root password for maintenance
(or type Control-D to continue):

Potential causes

- A bug exists in ramdisk filesystem definitions /etc/fstab
- Misconfigured filesystem definitions in /etc/fstab
- Missing/failed drive

Suggested actions

... days without being checked, check forced (File system check required)

This condition is indicated by a system log similar to the one shown below.

```
... Checking filesystems
Checking all file systems.
[/sbin/fsck.ext3 (1) -- /] fsck.ext3 -a /dev/sda1
/dev/sda1 has gone 361 days without being checked, check forced
```

Potential causes

Filesystem check time passed; a filesystem check is being forced.

Suggested actions

- Wait until the filesystem check completes. A filesystem check can take a long time depending on the size of the root filesystem.
- Modify your filesystems to remove the filesystem check (fsck) enforcement using tune2fs or tools appropriate for your filesystem.
fsck died with exit status... (Missing device)

This condition is indicated by a system log similar to the one shown below.

```
Cleaning up ifupdown....
Loading kernel modules...done.
...
Activating lvm and md swap...done.
Checking file systems...fsck from util-linux-ng 2.16.2
/sbin/fsck.xfs: /dev/sdh does not exist
fsck died with exit status 8
[31mfailed (code 8).[39;49m
```

<td>10. Start the instance.</td>
</tr>
</tbody>
</table>

### Instance store-backed

Option 1: Modify the AMI and relaunch the instance:

1. Create the new AMI with a GRUB configuration file at the standard location (/boot/grub/menu.lst).
2. Pick the appropriate GRUB image, (hd0-1st drive or hd00 – 1st drive, 1st partition).
3. Verify that your version of GRUB supports the underlying file system type and upgrade GRUB if necessary.
4. Terminate the instance and launch a new instance using the AMI you created.

Option 2: Terminate the instance and launch a new instance, specifying the correct kernel.

**Note** To recover data from the existing instance, contact [AWS Support](mailto:aws-support@amazon.com).

---

**Bringing up interface eth0: Device eth0 has different MAC address than expected, ignoring. (Hard-coded MAC address)**

This condition is indicated by a system log similar to the one shown below.

```
Bringing up loopback interface: [ OK ]
Bringing up interface eth0: Device eth0 has different MAC address than expected, ignoring. [FAILED]
Starting auditd: [ OK ]
```

**Potential causes**

There is a hardcoded interface MAC in the AMI configuration.
Unable to load SELinux Policy. Machine is in enforcing mode. Halting now. (SELinux misconfiguration)

This condition is indicated by a system log similar to the one shown below.

```plaintext
audit(1313445102.626:2): enforcing=1 old_enforcing=0 auid=4294967295
Unable to load SELinux Policy. Machine is in enforcing mode. Halting now.
Kernel panic - not syncing: Attempted to kill init!
```

Potential causes

SELinux has been enabled in error:

- Supplied kernel is not supported by GRUB
- Fallback kernel does not exist

**Troubleshoot an unreachable instance**

You can use the following methods to troubleshoot an unreachable Linux instance. For information about troubleshooting an unreachable Windows instance, see Troubleshoot an unreachable instance.

**Contents**

- Instance reboot (p. 2575)
- Instance console output (p. 2575)
- Capture a screenshot of an unreachable instance (p. 2576)
- Instance recovery when a host computer fails (p. 2577)

**Instance reboot**

The ability to reboot instances that are otherwise unreachable is valuable for both troubleshooting and general instance management.

Just as you can reset a computer by pressing the reset button, you can reset EC2 instances using the Amazon EC2 console, CLI, or API. For more information, see Reboot your instance (p. 796)

**Instance console output**

Console output is a valuable tool for problem diagnosis. It is especially useful for troubleshooting kernel problems and service configuration issues that could cause an instance to terminate or become unreachable before its SSH daemon can be started.

For Linux/Unix, the instance console output displays the exact console output that would normally be displayed on a physical monitor attached to a computer. The console output returns buffered information that was posted shortly after an instance transition state (start, stop, reboot, and terminate). The posted output is not continuously updated; only when it is likely to be of the most value.

For Windows instances, the instance console output includes the last three system event log errors.
You can optionally retrieve the latest serial console output at any time during the instance lifecycle. This option is only supported on instances built on the Nitro System (p. 295). It is not supported through the Amazon EC2 console.

**Note**

Only the most recent 64 KB of posted output is stored, which is available for at least 1 hour after the last posting.

Only the instance owner can access the console output. You can retrieve the console output for your instances using the console or the command line.

Use one of the following methods to get console output.

**Console**

**To get console output**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the left navigation pane, choose **Instances**, and select the instance.
3. Choose **Actions**, **Monitor and troubleshoot**, **Get system log**.

**Command line**

**To get console output**

You can use one of the following commands. For more information about these command line interfaces, see [Access Amazon EC2 (p. 5)](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/access-amazon-ec2.html).

- `get-console-output` (AWS CLI)
- `Get-EC2ConsoleOutput` (AWS Tools for Windows PowerShell)

For more information about common system log errors, see [Troubleshoot system log errors for Linux-based instances (p. 2556)](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/troubleshoot-system-log-errors.html).

**Capture a screenshot of an unreachable instance**

If you are unable to reach your instance via SSH or RDP, you can capture a screenshot of your instance and view it as an image. The image can provide visibility as to the status of the instance, and allows for quicker troubleshooting. You can generate screenshots while the instance is running or after it has crashed. There is no data transfer cost for this screenshot. The image is generated in JPG format and is no larger than 100 kb. This feature is not supported when the instance is using an NVIDIA GRID driver, is on bare metal instances (instances of type **.metal**), or is powered by Arm-based Graviton or Graviton 2 processors.

This feature is available in the following Regions:

- US East (N. Virginia) Region
- US East (Ohio) Region
- US West (Oregon) Region
- US West (N. California) Region
- Africa (Cape Town) Region
- Asia Pacific (Hong Kong) Region
- Asia Pacific (Hyderabad) Region
- Asia Pacific (Mumbai) Region
- Asia Pacific (Seoul) Region
To access the instance console
1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the left navigation pane, choose Instances.
3. Select the instance to capture.
4. Choose Actions, Monitor and troubleshoot.
5. Choose Get instance screenshot.

Right-click the image to download and save it.

To capture a screenshot using the command line
You can use one of the following commands. The returned content is base64-encoded. For more information about these command line interfaces, see Access Amazon EC2 (p. 5).

- get-console-screenshot (AWS CLI)
- GetConsoleScreenshot (Amazon EC2 Query API)

Instance recovery when a host computer fails
If there is an unrecoverable issue with the hardware of an underlying host computer, AWS may schedule an instance stop event. You are notified of such an event ahead of time by email.

To recover an Amazon EBS-backed instance running on a host computer that failed
1. Back up any important data on your instance store volumes to Amazon EBS or Amazon S3.
2. Stop the instance.
3. Start the instance.
4. Restore any important data.

For more information, see Stop and start your instance (p. 768).

To recover an instance store-backed instance running on a host computer that failed
1. Create an AMI from the instance.
2. Upload the image to Amazon S3.
3. Back up important data to Amazon EBS or Amazon S3.
4. Terminate the instance.
5. Launch a new instance from the AMI.
6. Restore any important data to the new instance.

For more information, see Create an instance store-backed Linux AMI (p. 178).

Boot from the wrong volume

In some situations, you may find that a volume other than the volume attached to /dev/xvda or /dev/sda has become the root volume of your instance. This can happen when you have attached the root volume of another instance, or a volume created from the snapshot of a root volume, to an instance with an existing root volume.

This is due to how the initial ramdisk in Linux works. It chooses the volume defined as / in the /etc/fstab, and in some distributions, this is determined by the label attached to the volume partition. Specifically, you find that your /etc/fstab looks something like the following:

```
LABEL=/ / ext4 defaults,noatime 1 1
tmpfs /dev/shm tmpfs defaults 0 0
devpts /dev/pts devpts gid=5,mode=620 0 0
sysfs /sys sysfs defaults 0 0
proc /proc proc defaults 0 0
```

If you check the label of both volumes, you see that they both contain the / label:

```
[ec2-user ~]$ sudo e2label /dev/xvda1 / 
[ec2-user ~]$ sudo e2label /dev/xvdf1 /
```

In this example, you could end up having /dev/xvdf1 become the root device that your instance boots to after the initial ramdisk runs, instead of the /dev/xvda1 volume from which you had intended to boot. To solve this, use the same `e2label` command to change the label of the attached volume that you do not want to boot from.

In some cases, specifying a UUID in /etc/fstab can resolve this. However, if both volumes come from the same snapshot, or the secondary is created from a snapshot of the primary volume, they share a UUID.

```
[ec2-user ~]$ sudo blkid 
/dev/xvda1: LABEL="/" UUID=73947a77-ddbe-4dc7-bd8f-3fe0bc840778 TYPE="ext4" PARTLABEL="Linux" PARTUUID=d55925ee-72c8-41e7-b514-7084e28f7334 
/dev/xvdf1: LABEL="old/" UUID=73947a77-ddbe-4dc7-bd8f-3fe0bc840778 TYPE="ext4" PARTLABEL="Linux" PARTUUID=d55925ee-72c8-41e7-b514-7084e28f7334
```

To change the label of an attached ext4 volume

1. Use the `e2label` command to change the label of the volume to something other than /.

```
[ec2-user ~]$ sudo e2label /dev/xvdf1 old/
```
2. Verify that the volume has the new label.

```
[ec2-user ~]$ sudo e2label /dev/xvdf1
old/
```

To change the label of an attached xfs volume

- Use the `xfs_admin` command to change the label of the volume to something other than `/`.

```
[ec2-user ~]$ sudo xfs_admin -L old/ /dev/xvdf1
writing all SBs
new label = "old/"
```

After changing the volume label as shown, you should be able to reboot the instance and have the proper volume selected by the initial ramdisk when the instance boots.

**Important**
If you intend to detach the volume with the new label and return it to another instance to use as the root volume, you must perform the above procedure again and change the volume label back to its original value. Otherwise, the other instance does not boot because the ramdisk is unable to find the volume with the label `/`.

---

**Use EC2Rescue for Linux**

EC2Rescue for Linux is an easy-to-use, open-source tool that can be run on an Amazon EC2 Linux instance to diagnose and troubleshoot common issues using its library of over 100 modules. A few generalized use cases for EC2Rescue for Linux include gathering syslog and package manager logs, collecting resource utilization data, and diagnosing/remediating known problematic kernel parameters and common OpenSSH issues.

The AWS Support - TroubleshootSSH runbook installs EC2Rescue for Linux and then uses the tool to check or attempt to fix common issues that prevent a remote connection to a Linux machine via SSH. For more information, and to run this automation, see [AWS Support - TroubleshootSSH](#).

If you are using a Windows instance, see [EC2Rescue for Windows Server](#).

**Contents**

- [Install EC2Rescue for Linux](#) (p. 2579)
- [Work with EC2Rescue for Linux](#) (p. 2583)
- [Develop EC2Rescue modules](#) (p. 2585)

**Install EC2Rescue for Linux**

**Note**
We require TLS 1.2 and recommend TLS 1.3. Your client must meet this requirement to download from Amazon Simple Storage Service (Amazon S3). For more information, see [TLS 1.2 to become the minimum TLS protocol level for all AWS API endpoints](#).

The EC2Rescue for Linux tool can be installed on an Amazon EC2 Linux instance that meets the following prerequisites.
Prerequisites

- Supported operating systems:
  - Amazon Linux 2
  - Amazon Linux 2016.09+
  - SUSE Linux Enterprise Server 12+
  - RHEL 7+
  - Ubuntu 16.04+
- Software requirements:
  - Python 2.7.9+ or 3.2+

The AWSSupport-TroubleshootSSH runbook installs EC2Rescue for Linux and then uses the tool to check or attempt to fix common issues that prevent a remote connection to a Linux machine via SSH. For more information, and to run this automation, see AWS Support-TroubleshootSSH.

If your system has the required Python version, you can install the standard build. Otherwise, you can install the bundled build, which includes a minimal copy of Python.

To install the standard build

1. From a working Linux instance, download the EC2Rescue for Linux tool:
   ```bash
   curl -O https://s3.amazonaws.com/ec2rescuelinux/ec2rl.tgz
   ```
2. (Optional) Before proceeding, you can optionally verify the signature of the EC2Rescue for Linux installation file. For more information, see (Optional) Verify the signature of EC2Rescue for Linux (p. 2580).
3. Download the sha256 hash file:
   ```bash
   curl -O https://s3.amazonaws.com/ec2rescuelinux/ec2rl.tgz.sha256
   ```
4. Verify the integrity of the tarball:
   ```bash
   sha256sum -c ec2rl.tgz.sha256
   ```
5. Unpack the tarball:
   ```bash
   tar -xzvf ec2rl.tgz
   ```
6. Verify the installation by listing out the help file:
   ```bash
   cd ec2rl-<version_number>
   ./ec2rl help
   ```

To install the bundled build

For a link to the download and a list of limitations, see EC2Rescue for Linux on github.

(Optional) Verify the signature of EC2Rescue for Linux

The following is the recommended process of verifying the validity of the EC2Rescue for Linux package for Linux-based operating systems.
When you download an application from the internet, we recommend that you authenticate the identity of the software publisher and check that the application has not been altered or corrupted after it was published. This protects you from installing a version of the application that contains a virus or other malicious code.

If, after running the steps in this topic, you determine that the software for EC2Rescue for Linux is altered or corrupted, do not run the installation file. Instead, contact Amazon Web Services.

EC2Rescue for Linux files for Linux-based operating systems are signed using GnuPG, an open-source implementation of the Pretty Good Privacy (OpenPGP) standard for secure digital signatures. GnuPG (also known as GPG) provides authentication and integrity checking through a digital signature. AWS publishes a public key and signatures that you can use to verify the downloaded EC2Rescue for Linux package. For more information about PGP and GnuPG (GPG), see http://www.gnupg.org.

The first step is to establish trust with the software publisher. Download the public key of the software publisher, check that the owner of the public key is who they claim to be, and then add the public key to your keyring. Your keyring is a collection of known public keys. After you establish the authenticity of the public key, you can use it to verify the signature of the application.

Tasks
- Install the GPG tools (p. 2581)
- Authenticate and import the public key (p. 2581)
- Verify the signature of the package (p. 2582)

Install the GPG tools

If your operating system is Linux or Unix, the GPG tools may already be installed. To test whether the tools are installed on your system, enter `gpg2` at a command prompt. If the GPG tools are installed, you see a GPG command prompt. If the GPG tools are not installed, you see an error stating that the command cannot be found. You can install the GnuPG package from a repository.

To install GPG tools on Debian-based Linux
- From a terminal, run the following command:

```
apt-get install gnupg2
```

To install GPG tools on Red Hat–based Linux
- From a terminal, run the following command:

```
yum install gnupg2
```

Authenticate and import the public key

The next step in the process is to authenticate the EC2Rescue for Linux public key and add it as a trusted key in your GPG keyring.

To authenticate and import the EC2Rescue for Linux public key
1. At a command prompt, use the following command to obtain a copy of our public GPG build key:

```
curl -0 https://s3.amazonaws.com/ec2rescuelinux/ec2rl.key
```
2. At a command prompt in the directory where you saved ec2rl.key, use the following command to import the EC2Rescue for Linux public key into your keyring:

```bash
gpg2 --import ec2rl.key
```

The command returns results similar to the following:

```
  gpg: /home/ec2-user/.gnupg/trustdb.gpg: trustdb created
  gpg: key 2FAE2A1C: public key "ec2autodiag@amazon.com <EC2 Rescue for Linux>" imported
  gpg: Total number processed: 1
  gpg:       imported: 1  (RSA: 1)
```

### Verify the signature of the package

After you've installed the GPG tools, authenticated and imported the EC2Rescue for Linux public key, and verified that the EC2Rescue for Linux public key is trusted, you are ready to verify the signature of the EC2Rescue for Linux installation script.

#### To verify the EC2Rescue for Linux installation script signature

1. At a command prompt, run the following command to download the signature file for the installation script:

   ```bash
curl -O https://s3.amazonaws.com/ec2rescuelinux/ec2rl.tgz.sig
```

2. Verify the signature by running the following command at a command prompt in the directory where you saved ec2rl.tgz.sig and the EC2Rescue for Linux installation file. Both files must be present.

   ```bash
gpg2 --verify ./ec2rl.tgz.sig
```

The output should look something like the following:

```
  gpg: Signature made Thu 12 Jul 2018 01:57:51 AM UTC using RSA key ID 6991ED45
  gpg: Good signature from "ec2autodiag@amazon.com <EC2 Rescue for Linux>"
  gpg: WARNING: This key is not certified with a trusted signature!
  gpg: There is no indication that the signature belongs to the owner.
  Primary key fingerprint: E528 BCC9 0DBF 5AFA 0F6C  C36A F780 4843 2FAE 2A1C
  Subkey fingerprint: 966B 0D27 85E9 AEEC 1146  7A9D 8851 1153 6991 ED45
```

If the output contains the phrase **Good signature from "ec2autodiag@amazon.com <EC2 Rescue for Linux>"**, it means that the signature has successfully been verified, and you can proceed to run the EC2Rescue for Linux installation script.

If the output includes the phrase **BAD signature**, check whether you performed the procedure correctly. If you continue to get this response, contact Amazon Web Services and do not run the installation file that you downloaded previously.

The following are details about the warnings that you might see:

- **WARNING: This key is not certified with a trusted signature! There is no indication that the signature belongs to the owner.** This refers to your personal level of trust in your belief that you possess an authentic public key for EC2Rescue for Linux. In an ideal world, you would visit an Amazon
Web Services office and receive the key in person. However, more often you download it from a website. In this case, the website is an Amazon Web Services website.

- `gpg2: no ultimately trusted keys found`. This means that the specific key is not "ultimately trusted" by you (or by other people whom you trust).

For more information, see [http://www.gnupg.org](http://www.gnupg.org).

## Work with EC2Rescue for Linux

The following are common tasks you can perform to get started using this tool.

### Tasks

- [Run EC2Rescue for Linux](p. 2583)
- [Upload the results](p. 2584)
- [Create backups](p. 2584)
- [Get help](p. 2584)

### Run EC2Rescue for Linux

You can run EC2Rescue for Linux as shown in the following examples.

#### Example Example: Run all modules

To run all modules, run EC2Rescue for Linux with no options:

```
./ec2rl run
```

Some modules require root access. If you are not a root user, use `sudo` to run these modules as follows:

```
sudo ./ec2rl run
```

#### Example Example: Run a specific module

To run only specific modules, use the `--only-modules` parameter:

```
./ec2rl run --only-modules=module_name --arguments
```

For example, this command runs the `dig` module to query the `amazon.com` domain:

```
./ec2rl run --only-modules=dig --domain=amazon.com
```

#### Example Example: View the results

You can view the results in `/var/tmp/ec2rl`:

```
cat /var/tmp/ec2rl/logfile_location
```

For example, view the log file for the `dig` module:

```
cat /var/tmp/ec2rl/2017-05-11T15_39_21.893145/mod_out/run/dig.log
```
Upload the results

If AWS Support has requested the results or to share the results from an S3 bucket, upload them using the EC2Rescue for Linux CLI tool. The output of the EC2Rescue for Linux commands should provide the commands that you need to use.

**Example Example: Upload results to AWS Support**

```
./ec2rl upload --upload-directory=/var/tmp/ec2rl/2017-05-11T15_39_21.893145 --support-url="URLProvidedByAWSSupport"
```

**Example Example: Upload results to an S3 bucket**

```
./ec2rl upload --upload-directory=/var/tmp/ec2rl/2017-05-11T15_39_21.893145 --presigned-url="YourPresignedS3URL"
```

For more information about generating pre-signed URLs for Amazon S3, see [Uploading Objects Using Pre-Signed URLs](#).

Create backups

Create a backup for your instance, one or more volumes, or a specific device ID using the following commands.

**Example Example: Back up an instance using an Amazon Machine Image (AMI)**

```
./ec2rl run --backup=ami
```

**Example Example: Back up all volumes associated with the instance**

```
./ec2rl run --backup=allvolumes
```

**Example Example: Back up a specific volume**

```
./ec2rl run --backup=volumeID
```

Get help

EC2Rescue for Linux includes a help file that gives you information and syntax for each available command.

**Example Example: Display the general help**

```
./ec2rl help
```

**Example Example: List the available modules**

```
./ec2rl list
```

**Example Example: Display the help for a specific module**

```
./ec2rl help module_name
```

For example, use the following command to show the help file for the `dig` module:
Develop EC2Rescue modules

Modules are written in YAML, a data serialization standard. A module's YAML file consists of a single document, representing the module and its attributes.

Add module attributes

The following table lists the available module attributes.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the module. The name should be less than or equal to 18 characters in length.</td>
</tr>
<tr>
<td>version</td>
<td>The version number of the module.</td>
</tr>
<tr>
<td>title</td>
<td>A short, descriptive title for the module. This value should be less than or equal to 50 characters in length.</td>
</tr>
<tr>
<td>helptext</td>
<td>The extended description of the module. Each line should be less than or equal to 75 characters in length. If the module consumes arguments, required or optional, include them in the helptext value. For example:</td>
</tr>
<tr>
<td></td>
<td>helptext: !!str</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>placement</td>
<td>The stage in which the module should be run. Supported values:</td>
</tr>
<tr>
<td></td>
<td>• prediagnostic</td>
</tr>
<tr>
<td></td>
<td>• run</td>
</tr>
<tr>
<td></td>
<td>• postdiagnostic</td>
</tr>
<tr>
<td>language</td>
<td>The language that the module code is written in. Supported values:</td>
</tr>
<tr>
<td></td>
<td>• bash</td>
</tr>
<tr>
<td></td>
<td>• python</td>
</tr>
</tbody>
</table>

**Note**
Python code must be compatible with both Python 2.7.9+ and Python 3.2.
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>remediation</td>
<td>Indicates whether the module supports remediation. Supported values are <code>True</code> or <code>False</code>. The module defaults to <code>False</code> if this is absent, making it an optional attribute for those modules that do not support remediation.</td>
</tr>
<tr>
<td>content</td>
<td>The entirety of the script code.</td>
</tr>
<tr>
<td>constraint</td>
<td>The name of the object containing the constraint values.</td>
</tr>
<tr>
<td>domain</td>
<td>A descriptor of how the module is grouped or classified. The set of included modules uses the following domains:</td>
</tr>
<tr>
<td></td>
<td>- application</td>
</tr>
<tr>
<td></td>
<td>- net</td>
</tr>
<tr>
<td></td>
<td>- os</td>
</tr>
<tr>
<td></td>
<td>- performance</td>
</tr>
<tr>
<td>class</td>
<td>A descriptor of the type of task performed by the module. The set of included modules uses the following classes:</td>
</tr>
<tr>
<td></td>
<td>- collect (collects output from programs)</td>
</tr>
<tr>
<td></td>
<td>- diagnose (pass/fail based on a set of criteria)</td>
</tr>
<tr>
<td></td>
<td>- gather (copies files and writes to specific file)</td>
</tr>
<tr>
<td>distro</td>
<td>The list of Linux distributions that this module supports. The set of included modules uses the following distributions:</td>
</tr>
<tr>
<td></td>

</tbody>
</table>
Add environment variables

The following table lists the available environment variables.

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EC2RL_CALLPATH</td>
<td>The path to ec2rl.py. This path can be used to locate the lib directory and use vendored Python modules.</td>
</tr>
<tr>
<td>EC2RL_WORKDIR</td>
<td>The main tmp directory for the diagnostic tool. Default value: /var/tmp/ec2rl.</td>
</tr>
<tr>
<td>EC2RL_RUNDIR</td>
<td>The directory where all output is stored. Default value: /var/tmp/ec2rl/ &lt;date&amp;timestamp&gt;.</td>
</tr>
<tr>
<td>EC2RL_GATHEREDDIR</td>
<td>The root directory for placing gathered module data. Default value:/var/tmp/ec2rl/ &lt;date&amp;timestamp&gt;/mod_out/gathered/.</td>
</tr>
<tr>
<td>EC2RL_NET_DRIVER</td>
<td>The driver in use for the first, alphabetically ordered, non-virtual network interface on the instance. Examples:</td>
</tr>
<tr>
<td></td>
<td>• xen_netfront</td>
</tr>
<tr>
<td></td>
<td>• ixgbevf</td>
</tr>
<tr>
<td></td>
<td>• ena</td>
</tr>
<tr>
<td>EC2RL_SUDO</td>
<td>True if EC2Rescue for Linux is running as root; otherwise, false.</td>
</tr>
</tbody>
</table>
Use YAML syntax

The following should be noted when constructing your module YAML files:

- The triple hyphen (---) denotes the explicit start of a document.
- The !ec2rlcore.module.Module tag tells the YAML parser which constructor to call when creating the object from the data stream. You can find the constructor inside the module.py file.
- The !!str tag tells the YAML parser to not attempt to determine the type of data, and instead interpret the content as a string literal.
- The pipe character (|) tells the YAML parser that the value is a literal-style scalar. In this case, the parser includes all whitespace. This is important for modules because indentation and newline characters are kept.
- The YAML standard indent is two spaces, which can be seen in the following examples. Ensure that you maintain standard indentation (for example, four spaces for Python) for your script and then indent the entire content two spaces inside the module file.

Example modules

Example one (mod.d/ps.yaml):

```yaml
--- !ec2rlcore.module.Module
# Module document. Translates directly into an almost-complete Module object
name: !!str ps
path: !!str
version: !!str 1.0

EC2 Serial Console for Linux instances

With the EC2 serial console, you have access to your Amazon EC2 instance's serial port, which you can use to troubleshoot boot, network configuration, and other issues. The serial console does not require your instance to have any networking capabilities. With the serial console, you can enter commands to an instance as if your keyboard and monitor are directly attached to the instance's serial port. The serial console session lasts during instance reboot and stop. During reboot, you can view all of the boot messages from the start.

Access to the serial console is not available by default. Your organization must grant account access to the serial console and configure IAM policies to grant your users access to the serial console. Serial console access can be controlled at a granular level by using instance IDs, resource tags, and other IAM levers. For more information, see Configure access to the EC2 Serial Console (p. 2594).

The serial console can be accessed by using the EC2 console or the AWS CLI.

The serial console is available at no additional cost.

If you are using a Windows instance, see EC2 Serial Console for Windows instances in the Amazon EC2 User Guide for Windows Instances.

Topics
- Prerequisites (p. 2589)
- Configure access to the EC2 Serial Console (p. 2594)
- Connect to the EC2 Serial Console (p. 2600)
- Disconnect from the EC2 Serial Console (p. 2604)
- Troubleshoot your Linux instance using the EC2 Serial Console (p. 2605)

Prerequisites

To connect to the EC2 Serial Console and use your chosen tool for troubleshooting, the following prerequisites must be in place:
AWS Regions

Supported in all AWS Regions except Israel (Tel Aviv).

Wavelength Zones and AWS Outposts

Not supported.

Local Zones

Supported in the following Local Zones:

- Los Angeles, US

  Local Zone names: us-west-2-lax-1a, us-west-2-lax-1b

  Parent Region: US West (Oregon)

Instance types

Supported instance types:

- All virtualized instances built on the Nitro System (p. 296).
- All bare metal instances except:
  - General purpose: a1.metal, mac1.metal, mac2.metal
  - Accelerated computing: g5g.metal

Grant access

You must complete the configuration tasks to grant access to the EC2 Serial Console. For more information, see Configure access to the EC2 Serial Console (p. 2594).

Support for browser-based client

To connect to the serial console using the browser-based client (p. 2600), your browser must support WebSocket. If your browser does not support WebSocket, connect to the serial console using your own key and an SSH client. (p. 2601)
Instance state

Must be running.

You can’t connect to the serial console if the instance is in the pending, stopping, stopped, shutting-down, or terminated state.

For more information about the instance states, see Instance lifecycle (p. 714).

Amazon EC2 Systems Manager

If the instance uses Amazon EC2 Systems Manager, then SSM Agent version 3.0.854.0 or later must be installed on the instance. For information about SSM Agent, see Working with SSM Agent in the AWS Systems Manager User Guide.

sshd server

You do not need an sshd server installed or running on your instance.

Configure your chosen troubleshooting tool

To troubleshoot your Linux instance via the serial console, you can use GRUB or SysRq. Before you can use these tools, you must first perform configuration steps on every instance on which you’ll use them.

For the instructions to configure your chosen troubleshooting tool on Windows, see Configure your chosen troubleshooting tool in the Amazon EC2 User Guide for Windows Instances.

Tools

- Configure GRUB (p. 2591)
- Configure SysRq (p. 2593)

Configure GRUB

Before you can use GRUB via the serial console, you must configure your instance to use GRUB via the serial console.

To configure GRUB, choose one of the following procedures based on the AMI that was used to launch the instance.

Amazon Linux 2

To configure GRUB on an Amazon Linux 2 instance

1. Connect to your Linux instance (p. 811)
2. Add or change the following options in /etc/default/grub:
   - Set GRUB_TIMEOUT=1.
   - Add GRUB_TERMINAL="console serial".
   - Add GRUB_SERIAL_COMMAND="serial --speed=115200".

   The following is an example of /etc/default/grub. You might need to change the configuration based on your system setup.
Amazon Elastic Compute Cloud
User Guide for Linux Instances
Prerequisites

GRUB_CMDLINE_LINUX_DEFAULT="console=tty0 console=ttyS0,115200n8 net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff rd.shell=0" GRUB_TIMEOUT=1 GRUB_DISABLE_RECOVERY="true" GRUB_TERMINAL="console serial" GRUB_SERIAL_COMMAND="serial --speed=115200"

3. Apply the updated configuration by running the following command.

[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg

Ubuntu

To configure GRUB on an Ubuntu instance

1. Connect (p. 811) to your instance.
2. Add or change the following options in /etc/default/grub.d/50-cloudimg-settings.cfg:
   • Set GRUB_TIMEOUT=1.
   • Add GRUB_TIMEOUT_STYLE=menu.
   • Add GRUB_TERMINAL="console serial".
   • Remove GRUB_HIDDEN_TIMEOUT.
   • Add GRUB_SERIAL_COMMAND="serial --speed=115200".

The following is an example of /etc/default/grub.d/50-cloudimg-settings.cfg. You might need to change the configuration based on your system setup.

# Cloud Image specific Grub settings for Generic Cloud Images # CLOUD_IMG: This file was created/modified by the Cloud Image build process

# Set the recordfail timeout
GRUB_RECORDFAIL_TIMEOUT=0

# Do not wait on grub prompt
GRUB_TIMEOUT=1
GRUB_TIMEOUT_STYLE=menu

# Set the default commandline
GRUB_CMDLINE_LINUX_DEFAULT="console=tty1 console=ttyS0 nvme_core.io_timeout=4294967295"

# Set the grub console type
GRUB_TERMINAL="console serial"
GRUB_SERIAL_COMMAND="serial --speed=115200"

3. Apply the updated configuration by running the following command.

[ec2-user ~]$ sudo update-grub

RHEL

To configure GRUB on a RHEL instance

1. Connect (p. 811) to your instance.
2. Add or change the following options in /etc/default/grub:

- Remove GRUB_TERMINAL_OUTPUT.
- Add GRUB_TERMINAL="console serial".
- Add GRUB_SERIAL_COMMAND="serial --speed=115200".

The following is an example of /etc/default/grub. You might need to change the configuration based on your system setup.

```
GRUB_TIMEOUT=1
GRUB_DISTRIBUTOR="$(sed 's, release .*$,,g' /etc/system-release)"
GRUB_DEFAULT=saved
GRUB_DISABLE_SUBMENU=true
GRUB_CMDLINE_LINUX="console=tty0 console=ttyS0,115200n8 net.ifnames=0 rd.blacklist=nouveau nvme_core.io_timeout=4294967295 crashkernel=auto"
GRUB_DISABLE_RECOVERY="true"
GRUB_ENABLE_BLSCFG=true
GRUB_TERMINAL="console serial"
GRUB_SERIAL_COMMAND="serial --speed=115200"
```

3. Apply the updated configuration by running the following command.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

CentOS

For instances that are launched using a CentOS AMI, GRUB is configured for the serial console by default.

The following is an example of /etc/default/grub. Your configuration might be different based on your system setup.

```
GRUB_TIMEOUT=1
GRUB_DISTRIBUTOR="$(sed 's, release .*$,,g' /etc/system-release)"
GRUB_DEFAULT=saved
GRUB_DISABLE_SUBMENU=true
GRUB_TERMINAL="serial console"
GRUB_SERIAL_COMMAND="serial --speed=115200"
GRUB_CMDLINE_LINUX="console=tty0 crashkernel=auto console=ttyS0,115200"
GRUB_DISABLE_RECOVERY="true"
```

Configure SysRq

To configure SysRq, you enable the SysRq commands for the current boot cycle. To make the configuration persistent, you can also enable the SysRq commands for subsequent boots.

**To enable all SysRq commands for the current boot cycle**

1. Connect (p. 811) to your instance.
2. Run the following command.

```
[ec2-user ~]$ sudo sysctl -w kernel.sysrq=1
```

**Note**
This setting will clear on the next reboot.
To enable all SysRq commands for subsequent boots

1. Create the file `/etc/sysctl.d/99-sysrq.conf` and open it in your favorite editor.

   ```
   [ec2-user ~]$ sudo vi /etc/sysctl.d/99-sysrq.conf
   ```

2. Add the following line.

   ```
   kernel.sysrq=1
   ```

3. Reboot the instance to apply the changes.

   ```
   [ec2-user ~]$ sudo reboot
   ```

4. At the login prompt, enter the user name of the password-based user that you set up previously (p. 2599), and then press Enter.

5. At the Password prompt, enter the password, and then press Enter.

Configure access to the EC2 Serial Console

To configure access to the serial console, you must grant serial console access at the account level and then configure IAM policies to grant access to your users. You must also configure a password-based user on every instance so that your users can use the serial console for troubleshooting.

Before commencing, be sure to check the prerequisites (p. 2589).

**Topics**

- Levels of access to the EC2 Serial Console (p. 2594)
- Manage account access to the EC2 Serial Console (p. 2595)
- Configure IAM policies for EC2 Serial Console access (p. 2597)
- Set an OS user password (p. 2599)

Levels of access to the EC2 Serial Console

By default, there is no access to the serial console at the account level. You need to explicitly grant access to the serial console at the account level. For more information, see Manage account access to the EC2 Serial Console (p. 2595).

You can use a service control policy (SCP) to allow access to the serial console within your organization. You can then have granular access control at the user level by using an IAM policy to control access. By using a combination of SCP and IAM policies, you have different levels of access control to the serial console.

**Organization level**

You can use a service control policy (SCP) to allow access to the serial console for member accounts within your organization. For more information about SCPs, see Service control policies in the AWS Organizations User Guide.

**Instance level**

You can configure the serial console access policies by using IAM PrincipalTag and ResourceTag constructions and by specifying instances by their ID. For more information, see Configure IAM policies for EC2 Serial Console access (p. 2597).
User level

You can configure access at the user level by configuring an IAM policy to allow or deny a specified user the permission to push the SSH public key to the serial console service of a particular instance. For more information, see [Configure IAM policies for EC2 Serial Console access (p. 2597)].

OS level

You can set a user password at the guest OS level. This provides access to the serial console for some use cases. However, to monitor the logs, you don't need a password-based user. For more information, see [Set an OS user password (p. 2599)].

Manage account access to the EC2 Serial Console

By default, there is no access to the serial console at the account level. You need to explicitly grant access to the serial console at the account level.

Topics

- [Grant permission to users to manage account access (p. 2595)]
- [View account access status to the serial console (p. 2595)]
- [Grant account access to the serial console (p. 2596)]
- [Deny account access to the serial console (p. 2596)]

Grant permission to users to manage account access

To allow your users to manage account access to the EC2 serial console, you need to grant them the required IAM permissions.

The following policy grants permissions to view the account status, and to allow and prevent account access to the EC2 serial console.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ec2:GetSerialConsoleAccessStatus",
            "ec2:EnableSerialConsoleAccess",
            "ec2:DisableSerialConsoleAccess"
         ],
         "Resource": "*"
      }
   ]
}
```

For more information, see [Creating IAM policies in the IAM User Guide].

View account access status to the serial console

To view account access status to the serial console (console)

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. On the left navigation pane, choose **EC2 Dashboard**.
3. From **Account attributes**, choose **EC2 Serial Console**.

   The **EC2 Serial Console access** field indicates whether account access is **Allowed** or **Prevented**.
The following screenshot shows that the account is prevented from using the EC2 serial console.

![EC2 Serial Console settings](image)

**To view account access status to the serial console (AWS CLI)**

Use the `get-serial-console-access-status` command to view account access status to the serial console.

```
aws ec2 get-serial-console-access-status --region us-east-1
```

In the following output, `true` indicates that the account is allowed access to the serial console.

```
{
  "SerialConsoleAccessEnabled": true
}
```

**Grant account access to the serial console**

**To grant account access to the serial console (console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. On the left navigation pane, choose **EC2 Dashboard**.
3. From **Account attributes**, choose **EC2 Serial Console**.
4. Choose **Manage**.
5. To allow access to the EC2 serial console of all instances in the account, select the **Allow** check box.
6. Choose **Update**.

**To grant account access to the serial console (AWS CLI)**

Use the `enable-serial-console-access` command to allow account access to the serial console.

```
aws ec2 enable-serial-console-access --region us-east-1
```

In the following output, `true` indicates that the account is allowed access to the serial console.

```
{
  "SerialConsoleAccessEnabled": true
}
```

**Deny account access to the serial console**

**To deny account access to the serial console (console)**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. On the left navigation pane, choose **EC2 Dashboard**.
3. From **Account attributes**, choose **EC2 Serial Console**.
4. Choose **Manage**.
5. To prevent access to the EC2 serial console of all instances in the account, clear the **Allow** check box.
6. Choose **Update**.

**To deny account access to the serial console (AWS CLI)**

Use the `disable-serial-console-access` command to prevent account access to the serial console.

```bash
aws ec2 disable-serial-console-access --region us-east-1
```

In the following output, `false` indicates that the account is denied access to the serial console.

```
{
  "SerialConsoleAccessEnabled": false
}
```

**Configure IAM policies for EC2 Serial Console access**

By default, your users do not have access to the serial console. Your organization must configure IAM policies to grant your users the required access. For more information, see `Creating IAM policies` in the **IAM User Guide**.

For serial console access, create a JSON policy document that includes the `ec2-instance-connect:SendSerialConsoleSSHPublicKey` action. This action grants a user permission to push the public key to the serial console service, which starts a serial console session. We recommend restricting access to specific EC2 instances. Otherwise, all users with this permission can connect to the serial console of all EC2 instances.

**Example IAM policies**

- **Explicitly allow access to the serial console** (p. 2597)
- **Explicitly deny access to the serial console** (p. 2598)
- **Use resource tags to control access to the serial console** (p. 2598)

**Explicitly allow access to the serial console**

By default, no one has access to the serial console. To grant access to the serial console, you need to configure a policy to explicitly allow access. We recommend configuring a policy that restricts access to specific instances.

The following policy allows access to the serial console of a specific instance, identified by its instance ID.

Note that the `DescribeInstances`, `DescribeInstanceTypes`, and `GetSerialConsoleAccessStatus` actions do not support resource-level permissions, and therefore all resources, indicated by the * (asterisk), must be specified for these actions.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowDescribeInstances",
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeInstances",
        "ec2:DescribeInstanceTypes",
```
Configure access to the EC2 Serial Console

Explicitly deny access to the serial console

The following IAM policy allows access to the serial console of all instances, denoted by the * (asterisk), and explicitly denies access to the serial console of a specific instance, identified by its ID.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowSerialConsoleAccess",
            "Effect": "Allow",
            "Action": [
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey",
                "ec2:DescribeInstances",
                "ec2:DescribeInstanceTypes",
                "ec2:GetSerialConsoleAccessStatus"
            ],
            "Resource": "*"
        },
        {
            "Sid": "DenySerialConsoleAccess",
            "Effect": "Deny",
            "Action": [
                "ec2-instance-connect:SendSerialConsoleSSHPublicKey"
            ],
            "Resource": "arn:aws:ec2:region:account-id:instance/i-0598c7d356eba48d7"
        }
    ]
}
```

Use resource tags to control access to the serial console

You can use resource tags to control access to the serial console of an instance.

Attribute-based access control is an authorization strategy that defines permissions based on tags that can be attached to users and AWS resources. For example, the following policy allows a user to initiate a serial console connection for an instance only if that instance's resource tag and the principal's tag have the same SerialConsole value for the tag key.

For more information about using tags to control access to your AWS resources, see Controlling access to AWS resources in the IAM User Guide.

Note that the DescribeInstances, DescribeInstanceTypes, and GetSerialConsoleAccessStatus actions do not support resource-level permissions, and therefore all resources, indicated by the * (asterisk), must be specified for these actions.

```json
{
}
```
Set an OS user password

You can connect to the serial console without a password. However, to use the serial console for troubleshooting an instance, the instance must have a password-based OS user.

You can set the password for any OS user, including the root user. Note that the root user can modify all files, while each OS user might have limited permissions.

You must set a user password for every instance for which you will use the serial console. This is a one-time requirement for each instance.

**Note**

The following instructions are applicable only if you launched your instance using an AMI provided by AWS because, by default, AMIs provided by AWS are not configured with a password-based user. If you launched your instance using an AMI that already has the root user password configured, you can skip these instructions.

**To set an OS user password**

1. Connect (p. 811) to your instance. You can use any method for connecting to your instance, except the EC2 Serial Console connection method.
2. To set the password for a user, use the `passwd` command. In the following example, the user is root.

   ```bash
   [ec2-user ~]$ sudo passwd root
   ```

   The following is example output.

   
   Changing password for user root.
   New password:

3. At the New password prompt, enter the new password.
4. At the prompt, re-enter the password.
Connect to the EC2 Serial Console

You can connect to the serial console of your EC2 instance by using the Amazon EC2 console or via SSH. After connecting to the serial console, you can use it for troubleshooting boot, network configuration, and other issues. For more information about troubleshooting, see Troubleshoot your Linux instance using the EC2 Serial Console (p. 2605).

Considerations

- Only 1 active serial console connection is supported per instance.
- The serial console connection typically lasts for 1 hour unless you disconnect from it. However, during system maintenance, Amazon EC2 will disconnect the serial console session.
- It takes 30 seconds to tear down a session after you've disconnected from the serial console in order to allow a new session.
- Supported serial console port for Linux: ttyS0
- When you connect to the serial console, you might observe a slight drop in your instance's throughput.

Topics

- Connect using the browser-based client (p. 2600)
- Connect using your own key and SSH client (p. 2601)
- EC2 Serial Console endpoints and fingerprints (p. 2602)

Connect using the browser-based client

You can connect to your EC2 instance's serial console by using the browser-based client. You do this by selecting the instance in the Amazon EC2 console and choosing to connect to the serial console. The browser-based client handles the permissions and provides a successful connection.

EC2 serial console works from most browsers, and supports keyboard and mouse input.

Before connecting, make sure you have completed the prerequisites (p. 2589).

To connect to your instance's serial port using the browser-based client (Amazon EC2 console)

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation pane, choose Instances.
3. Select the instance and choose Actions, Monitor and troubleshoot, EC2 Serial Console, Connect. Alternatively, select the instance and choose Connect, EC2 Serial Console, Connect.
   An in-browser terminal window opens.
4. Press Enter. If a login prompt returns, you are connected to the serial console.
   If the screen remains black, you can use the following information to help resolve issues with connecting to the serial console:

   - Check that you have configured access to the serial console. For more information, see Configure access to the EC2 Serial Console (p. 2594).
   - Use SysRq to connect to the serial console. SysRq does not require that you connect via the browser-based client. For more information, see Troubleshoot your Linux instance using SysRq (p. 2606).
   - Restart getty. If you have SSH access to your instance, then connect to your instance using SSH, and restart getty using the following command.
Connect to the EC2 Serial Console

1. **Reboot your instance.** You can reboot your instance by using SysRq, the EC2 console, or the AWS CLI. For more information, see Troubleshoot your Linux instance using SysRq (p. 2606) or Reboot your instance (p. 796).

2. At the `login` prompt, enter the user name of the password-based user that you set up previously (p. 2599), and then press **Enter**.

3. At the `Password` prompt, enter the password, and then press **Enter**.

   You are now logged onto the instance and can use the serial console for troubleshooting.

**Connect using your own key and SSH client**

You can use your own SSH key and connect to your instance from the SSH client of your choice while using the serial console API. This enables you to benefit from the serial console capability to push a public key to the instance.

Before connecting, make sure you have completed the prerequisites (p. 2589).

**To connect to an instance's serial console using SSH**

1. **Push your SSH public key to the instance to start a serial console session**

   Use the `send-serial-console-ssh-public-key` command to push your SSH public key to the instance. This starts a serial console session.

   If a serial console session has already been started for this instance, the command fails because you can only have one session open at a time. It takes 30 seconds to tear down a session after you've disconnected from the serial console in order to allow a new session.

   ```bash
   $ aws ec2-instance-connect send-serial-console-ssh-public-key
   --instance-id i-001234a4bf70dec41EXAMPLE
   --serial-port 0
   --ssh-public-key file://my_key.pub
   --region us-east-1
   ```

2. **Connect to the serial console using your private key**

   Use the `ssh` command to connect to the serial console before the public key is removed from the serial console service. You have 60 seconds before it is removed.

   Use the private key that corresponds to the public key.

   The user name format is `instance-id.port0`, which comprises the instance ID and port 0. In the following example, the user name is `i-001234a4bf70dec41EXAMPLE.port0`.

   The endpoint of the serial console service is different for each Region. See the EC2 Serial Console endpoints and fingerprints (p. 2602) table for each Region's endpoint. In the following example, the serial console service is in the us-east-1 Region.

   ```bash
   $ ssh -i my_key i-001234a4bf70dec41EXAMPLE.port0@serial-console.ec2-instance-connect.us-east-1.aws
   ```

3. **(Optional) Verify the fingerprint**

   When you connect for the first time to the serial console, you are prompted to verify the fingerprint. You can compare the serial console fingerprint with the fingerprint that's displayed for verification. If
these fingerprints don't match, someone might be attempting a "man-in-the-middle" attack. If they match, you can confidently connect to the serial console.

The following fingerprint is for the serial console service in the us-east-1 Region. For the fingerprints for each Region, see EC2 Serial Console endpoints and fingerprints (p. 2602).

SHA256:dXwn5ma/xadVMEmBZeRu5l2gx+yI5LDi3aLUcz0FMmw

Note
The fingerprint only appears the first time you connect to the serial console.

4. Press Enter. If a prompt returns, you are connected to the serial console.

If the screen remains black, you can use the following information to help resolve issues with connecting to the serial console:

- **Check that you have configured access to the serial console.** For more information, see Configure access to the EC2 Serial Console (p. 2594).
- **Use SysRq to connect to the serial console.** SysRq does not require that you connect via SSH. For more information, see Troubleshoot your Linux instance using SysRq (p. 2606).
- **Restart getty.** If you have SSH access to your instance, then connect to your instance using SSH, and restart getty using the following command.

```
[ec2-user ~]$ sudo systemctl restart serial-getty@ttyS0
```

- **Reboot your instance.** You can reboot your instance by using SysRq, the EC2 console, or the AWS CLI. For more information, see Troubleshoot your Linux instance using SysRq (p. 2606) or Reboot your instance (p. 796).

5. At the login prompt, enter the user name of the password-based user that you set up previously (p. 2599), and then press Enter.

6. At the Password prompt, enter the password, and then press Enter.

You are now logged onto the instance and can use the serial console for troubleshooting.

### EC2 Serial Console endpoints and fingerprints

The following are the service endpoints and fingerprints for EC2 Serial Console. To connect programmatically to an instance's serial console, you use an EC2 Serial Console endpoint. The EC2 Serial Console endpoints and fingerprints are unique for each AWS Region.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>

</tbody>
</table>
### Disconnect from the EC2 Serial Console

If you no longer need to be connected to your instance’s EC2 Serial Console, you can disconnect from it. When you disconnect from the serial console, any shell session running on the instance will continue to run. If you want to end the shell session, you’ll need to end it before disconnecting from the serial console.

#### Considerations

- The serial console connection typically lasts for 1 hour unless you disconnect from it. However, during system maintenance, Amazon EC2 will disconnect the serial console session.

</table>
Troubleshoot your instance using the EC2 Serial Console

- It takes 30 seconds to tear down a session after you've disconnected from the serial console in order to allow a new session.

The way to disconnect from the serial console depends on the client.

**Browser-based client**

To disconnect from the serial console, close the serial console in-browser terminal window.

**Standard OpenSSH client**

To disconnect from the serial console, use the following command to close the SSH connection. This command must be run immediately following a new line.

```
$ -.n
```

The command that you use for closing an SSH connection might be different depending on the SSH client that you're using.

**Troubleshoot your Linux instance using the EC2 Serial Console**

By using EC2 Serial Console, you can troubleshoot boot, network configuration, and other issues by connecting to your instance's serial port.

Before commencing, be sure to check the [prerequisites](p. 2589).

**Topics**

- [Troubleshoot your Linux instance using GRUB](p. 2605)
- [Troubleshoot your Linux instance using SysRq](p. 2606)

For information about troubleshooting your Windows instance, see [Troubleshoot your Windows instance using the EC2 Serial Console](#) in the *Amazon EC2 User Guide for Windows Instances*.

**Troubleshoot your Linux instance using GRUB**

GNU GRUB (short for GNU GRand Unified Bootloader, commonly referred to as GRUB) is the default boot loader for most Linux operating systems. From the GRUB menu, you can select which kernel to boot into, or modify menu entries to change how the kernel will boot. This can be useful when troubleshooting a failing instance.

The GRUB menu is displayed during the boot process. The menu is not accessible via normal SSH, but you can access it via the EC2 Serial Console.

Before you can use GRUB, make sure you have completed the [prerequisites](p. 2589), which include granting access to the serial console and configuring GRUB.

**Use GRUB**

After GRUB is configured, connect to the serial console and reboot the instance with the reboot command. During reboot, you see the GRUB menu. Press any key when the GRUB menu appears to stop the boot process, allowing you to interact with the GRUB menu.

**Topics**
Troubleshoot your instance using the EC2 Serial Console

- **Single user mode (p. 2606)**
- **Emergency mode (p. 2606)**

### Single user mode

Single user mode will boot the kernel at a lower runlevel. For example, it might mount the filesystem but not activate the network, giving you the opportunity to perform the maintenance necessary to fix the instance.

**To boot into single user mode**

1. **Connect (p. 2600)** to the instance's serial console.
2. Reboot the instance using the following command.
   ```bash
   [ec2-user ~]$ sudo reboot
   ```
3. During reboot, when the GRUB menu appears, press any key to stop the boot process.
4. In the GRUB menu, use the arrow keys to select the kernel to boot into, and press `e` on your keyboard.
5. Use the arrow keys to locate your cursor on the line containing the kernel. The line begins with either `linux` or `linux16` depending on the AMI that was used to launch the instance. For Ubuntu, two lines begin with `linux`, which must both be modified in the next step.
6. At the end of the line, add the word `single`.
   
   The following is an example for Amazon Linux 2.
   ```bash
   linux /boot/vmlinuz-4.16.193-149.317.amzn2.aarch64 root=UUID=d33f9c9a-
   dadd-4499-958d-ebbf42c3e499 ro console=tty0 console=ttyS0,115200n8 net.ifname=
   s=0 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff rd.she=
   ll=0 single
   ```
7. Press `Ctrl+X` to boot into single user mode.
8. At the login prompt, enter the user name of the password-based user that you set up previously (p. 2599), and then press `Enter`.
9. At the Password prompt, enter the password, and then press `Enter`.

### Emergency mode

Emergency mode is similar to single user mode except that the kernel runs at the lowest runlevel possible.

To boot into emergency mode, follow the steps in **Single user mode (p. 2606)** in the preceding section, but at step 6 add the word `emergency` instead of `single`.

### Troubleshoot your Linux instance using SysRq

The System Request (SysRq) key, which is sometimes referred to as "magic SysRq", can be used to directly send the kernel a command, outside of a shell, and the kernel will respond, regardless of what the kernel is doing. For example, if the instance has stopped responding, you can use the SysRq key to tell the kernel to crash or reboot. For more information, see [Magic SysRq key](https://en.wikipedia.org/wiki/Magic_SysRq_key) in Wikipedia.

Before you can use SysRq, make sure you have completed the **prerequisites (p. 2589)**, which include granting access to the serial console and configuring SysRq.
Use SysRq

You can use SysRq commands in the EC2 Serial Console browser-based client or in an SSH client. The command to send a break request is different for each client.

To use SysRq, choose one of the following procedures based on the client that you are using.

Browser-based client

To use SysRq in the serial console browser-based client

1. [Connect](p. 2600) to the instance’s serial console.
2. To send a break request, press CTRL+0 (zero). If your keyboard supports it, you can also send a break request using the Pause or Break key.
   
   ```
   [ec2-user ~]$ CTRL+0
   ```

3. To issue a SysRq command, press the key on your keyboard that corresponds to the required command. For example, to display a list of SysRq commands, press h.
   
   ```
   [ec2-user ~]$ h
   ```

   The h command outputs something similar to the following.

   ```
   [ 1169.389495] sysrq: HELP : loglevel(0-9) reboot(b) crash(c) terminate-all-tasks(e) memory-full-oom-kill(f) kill-all-tasks(i) thaw-filesystems(j) sak(k) show-backtrace-all-active-cpus(l) show-memory-usage(m) nice-all-RT-tasks(n) poweroff(o) show-registers(p) show-all-timers(q) unraw(r) sync(s) show-task-states(t) unmount(u) show-blocked-tasks(w) dump-ftrace-buffer(z)
   ```

SSH client

To use SysRq in an SSH client

1. [Connect](p. 2600) to the instance’s serial console.
2. To send a break request, press ~B (tilde, followed by uppercase B).
   
   ```
   [ec2-user ~]$ ~B
   ```

3. To issue a SysRq command, press the key on your keyboard that corresponds to the required command. For example, to display a list of SysRq commands, press h.
   
   ```
   [ec2-user ~]$ h
   ```

   The h command outputs something similar to the following.

   ```
   [ 1169.389495] sysrq: HELP : loglevel(0-9) reboot(b) crash(c) terminate-all-tasks(e) memory-full-oom-kill(f) kill-all-tasks(i) thaw-filesystems(j) sak(k) show-backtrace-all-active-cpus(l) show-memory-usage(m) nice-all-RT-tasks(n) poweroff(o) show-registers(p) show-all-timers(q) unraw(r) sync(s) show-task-states(t) unmount(u) show-blocked-tasks(w) dump-ftrace-buffer(z)
   ```
Send a diagnostic interrupt (for advanced users)

**Warning**

Diagnostic interrupts are intended for use by advanced users. Incorrect usage could negatively impact your instance. Sending a diagnostic interrupt to an instance could trigger an instance to crash and reboot, which could lead to the loss of data.

You can send a diagnostic interrupt to an unreachable or unresponsive Linux instance to manually trigger a *kernel panic*.

Linux operating systems typically crash and reboot when a kernel panic occurs. The specific behavior of the operating system depends on its configuration. A kernel panic can also be used to cause the instance's operating system kernel to perform tasks, such as generating a crash dump file. You can then use the information in the crash dump file to conduct root cause analysis and debug the instance.

The crash dump data is generated locally by the operating system on the instance itself.

Before sending a diagnostic interrupt to your instance, we recommend that you consult the documentation for your operating system and then make the necessary configuration changes.

Contents

- Supported instance types (p. 2608)
- Prerequisites (p. 2608)
- Send a diagnostic interrupt (p. 2611)

Supported instance types

Diagnostic interrupt is supported on all Nitro-based instance types, except those powered by AWS Graviton processors. For more information, see [Instances built on the Nitro System](#) (p. 295) and [AWS Graviton](#).

Prerequisites

Before using a diagnostic interrupt, you must configure your instance's operating system. This ensures that it performs the actions that you need when a kernel panic occurs.

To configure Amazon Linux 2 to generate a crash dump when a kernel panic occurs

1. Connect to your instance.
2. Install *kexec* and *kdump*.

   ```
   [ec2-user ~]$ sudo yum install kexec-tools -y
   ```
3. Configure the kernel to reserve an appropriate amount of memory for the secondary kernel. The amount of memory to reserve depends on the total available memory of your instance. Open the `/etc/default/grub` file using your preferred text editor, locate the line that starts with `GRUB_CMDLINE_LINUX_DEFAULT`, and then add the `crashkernel` parameter in the following format: `crashkernel=memory_to_reserve`. For example, to reserve 160MB, modify the `grub` file as follows:
4. Save the changes and close the `grub` file.
5. Rebuild the GRUB2 configuration file.

```
[ec2-user ~]$ sudo grub2-mkconfig -o /boot/grub2/grub.cfg
```

6. On instances based on Intel and AMD processors, the `send-diagnostic-interrupt` command sends an unknown non-maskable interrupt (NMI) to the instance. You must configure the kernel to crash when it receives the unknown NMI. Open the `/etc/sysctl.conf` file using your preferred text editor and add the following.

```
kernel.unknown_nmi_panic=1
```

7. Reboot and reconnect to your instance.
8. Verify that the kernel has been booted with the correct `crashkernel` parameter.

```
$ grep crashkernel /proc/cmdline
```

The following example output indicates successful configuration.

```
BOOT_IMAGE=/boot/vmlinuz-4.14.128-112.105.amzn2.x86_64 root=UUID=a1e1011e-e38f-408e-878b-fed395b47ad6 ro crashkernel=160M console=tty0 console=ttyS0,115200n8 net.ifnames=0 biosdevname=0 nvme_core.io_timeout=4294967295 rd.emergency=poweroff rd.shell=0
```

9. Verify that the `kdump` service is running.

```
[ec2-user ~]$ systemctl status kdump.service
```

The following example output shows the result if the `kdump` service is running.

```
kdump.service - Crash recovery kernel arming
   Loaded: loaded (/usr/lib/systemd/system/kdump.service; enabled; vendor preset: enabled)
   Active: active (exited) since Fri 2019-05-24 23:29:13 UTC; 22s ago
     Process: 2503 ExecStart=/usr/bin/kdumpctl start (code=exited, status=0/SUCCESS)
Main PID: 2503 (code=exited, status=0/SUCCESS)
```

**Note**

By default, the crash dump file is saved to `/var/crash/`. To change the location, modify the `/etc/kdump.conf` file using your preferred text editor.

**To configure Amazon Linux to generate a crash dump when a kernel panic occurs**

1. Connect to your instance.
2. Install `kexec` and `kdump`.

```
[ec2-user ~]$ sudo yum install kexec-tools -y
```
3. Configure the kernel to reserve an appropriate amount of memory for the secondary kernel. The amount of memory to reserve depends on the total available memory of your instance.

```
$ sudo grubby --args="crashkernel=memory_to_reserve" --update-kernel=ALL
```

For example, to reserve 160MB for the crash kernel, use the following command.

```
$ sudo grubby --args="crashkernel=160M" --update-kernel=ALL
```

4. On instances based on Intel and AMD processors, the send-diagnostic-interrupt command sends an unknown non-maskable interrupt (NMI) to the instance. You must configure the kernel to crash when it receives the unknown NMI. Open the `/etc/sysctl.conf` file using your preferred text editor and add the following.

```
kernel.unknown_nmi_panic=1
```

5. Reboot and reconnect to your instance.

6. Verify that the kernel has been booted with the correct `crashkernel` parameter.

```
$ grep crashkernel /proc/cmdline
```

The following example output indicates successful configuration.

```
root=LABEL=/ console=tty1 console=ttyS0 selinux=0 nvme_core.io_timeout=4294967295
LANG=en_US.UTF-8 KEYTABLE=us crashkernel=160M
```

7. Verify that the `kdump` service is running.

```
[ec2-user ~]$ sudo service kdump status
```

If the service is running, the command returns the *Kdump is operational* response.

**Note**
By default, the crash dump file is saved to `/var/crash/`. To change the location, modify the `/etc/kdump.conf` file using your preferred text editor.

To configure SUSE Linux Enterprise, Ubuntu, or Red Hat Enterprise Linux

See the following websites:

- [SUSE Linux Enterprise](#)
- [Ubuntu](#)
- [Red Hat Enterprise Linux (RHEL)](#)

**Note**
On instances based on Intel and AMD processors, the send-diagnostic-interrupt command sends an unknown non-maskable interrupt (NMI) to the instance. You must configure the kernel to crash when it receives the unknown NMI. Add the following to your configuration file.

```
kernell.unknown_nmi_panic=1
```
Send a diagnostic interrupt

After you have completed the necessary configuration changes, you can send a diagnostic interrupt to your instance using the AWS CLI or Amazon EC2 API.

To send a diagnostic interrupt to your instance (AWS CLI)

Use the `send-diagnostic-interrupt` command and specify the instance ID.

```
aws ec2 send-diagnostic-interrupt --instance-id i-1234567890abcdef0
```

<tr>
<td><strong>EC2 Instance Connect support for CentOS, macOS, and RHEL</strong></td>
<td>You can now install EC2 Instance Connect on supported CentOS, macOS, and RHEL AMIs.</td>
<td>December 6, 2023</td>
</tr>
<tr>
<td><strong>Hibernation support for C7a, C7i, R7a, R7i, and R7iz</strong></td>
<td>Hibernate your newly-launched instances running on C7a, C7i, R7a, R7i, and R7iz instance types.</td>
<td>December 1, 2023</td>
</tr>
<tr>
<td><strong>Amazon Q EC2 instance type selector</strong></td>
<td>Amazon Q EC2 instance type selector considers your use case, workload type, and CPU manufacturer preference, as well as how you prioritize price and performance. It then uses this data to provide guidance and suggestions for Amazon EC2 instance types that are best suited for your new workloads.</td>
<td>November 28, 2023</td>
</tr>
<tr>
<td><strong>EC2 Free Tier</strong></td>
<td>You can track your EC2 Free Tier usage from the EC2 Dashboard.</td>
<td>November 26, 2023</td>
</tr>
<tr>
<td><strong>Console-to-Code</strong></td>
<td>Console-to-Code can help you get started with your automation code. Console-to-Code records your console actions, and then uses generative AI to suggest code in your preferred infrastructure-as-code format. You can use the code as a starting point, customizing it to make it production-ready for your specific use case.</td>
<td>November 26, 2023</td>
</tr>
<tr>
<td><strong>Configurable idle connection tracking timeouts</strong></td>
<td>Security group connections that remain idle can lead to connection tracking exhaustion and cause connections not to be tracked and packets to be dropped. You can now set the timeout in seconds for security group connection tracking on an Elastic network interface.</td>
<td>November 17, 2023</td>
</tr>
<tr>
<td><strong>AWSDataLifecycleManagerSSMFullAccess updated policy</strong></td>
<td>Updated the policy to support application-consistent snapshots for SAP HANA using the AWS managed policy.</td>
<td>November 17, 2023</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------</td>

</table>
History for previous years

The following table describes important additions to the Amazon EC2 documentation in 2018 and earlier years.

<table>
<thead>
<tr>
<th>Feature</th>
<th>API version</th>
<th>Description</th>
<th>Release date</th>
</tr>
</thead>
<tbody>
<tr>
<td>Partition placement groups</td>
<td>2016-11-15</td>
<td>Partition placement groups spread instances across logical partitions, ensuring that instances in one partition do not share underlying hardware with instances in other partitions. For more information, see [Partition placement groups (p. 1573)].</td>
<td>20 December 2018</td>
</tr>
<tr>
<td>p3dn.24xlarge instances</td>
<td>2016-11-15</td>
<td>New p3dn.24xlarge instances provide 100 Gbps of network bandwidth.</td>
<td>7 December 2018</td>
</tr>
<tr>
<td>Hibernate EC2 Linux instances</td>
<td>2016-11-15</td>
<td>You can hibernate a Linux instance if it's enabled for hibernation and it meets the hibernation prerequisites. For more information, see [Hibernate your On-Demand Instance or Spot Instance (p. 775)].</td>
<td>28 November 2018</td>
</tr>
<tr>
<td>Feature</td>

<td>Description</td>
<td>Release date</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>Amazon Elastic Inference Accelerators</td>
<td>2016-11-15</td>
<td>You can attach an Amazon EI accelerator to your instances to add GPU-powered acceleration to reduce the cost of running deep learning inference. For more information, see Amazon Elastic Inference (p. 1083).</td>
<td>28 November 2018</td>
</tr>
<tr>
<td>Instances featuring 100 Gbps of network bandwidth</td>
<td>2016-11-15</td>
<td>New C5n instances can utilize up to 100 Gbps of network bandwidth.</td>
<td>26 November 2018</td>
</tr>
<tr>
<td>Instances featuring Arm-based Processors</td>
<td>2016-11-15</td>
<td>New A1 instances deliver significant cost savings and are ideally suited for scale-out and Arm-based workloads.</td>
<td>26 November 2018</td>
</tr>
<tr>
<td>Spot console recommends a fleet of instances</td>
<td>2016-11-15</td>
<td>The Spot console recommends a fleet of instances based on Spot best practice (instance diversification) to meet the minimum hardware specifications (vCPUs, memory, and storage) for your application need. For more information, see Create a Spot Fleet request (p. 1185).</td>
<td>20 November 2018</td>
</tr>
<tr>
<td>New EC2 Fleet request type: instant</td>
<td>2016-11-15</td>
<td>EC2 Fleet now supports a new request type, instant, that you can use to synchronously provision capacity across instance types and purchase models. The instant request returns the launched instances in the API response, and takes no further action, enabling you to control if and when instances are launched. For more information, see EC2 Fleet request types (p. 1091).</td>
<td>14 November 2018</td>
</tr>
<tr>
<td>Instances featuring AMD EPYC processors</td>
<td>2016-11-15</td>
<td>New general purpose (M5a) and memory optimized instances (R5a) offer lower-priced options for microservices, small to medium databases, virtual desktops, development and test environments, business applications, and more.</td>
<td>6 November 2018</td>
</tr>
<tr>
<td>Spot savings information</td>
<td>2016-11-15</td>
<td>You can view the savings made from using Spot Instances for a single Spot Fleet or for all Spot Instances. For more information, see Savings from purchasing Spot Instances (p. 556).</td>
<td>5 November 2018</td>
</tr>
<tr>
<td>Console support for optimizing CPU options</td>
<td>2016-11-15</td>
<td>When you launch an instance, you can optimize the CPU options to suit specific workloads or business needs using the Amazon EC2 console. For more information, see Optimize CPU options (p. 928).</td>
<td>31 October 2018</td>
</tr>
<tr>
<td>Console support for creating a launch template from an instance</td>
<td>2016-11-15</td>
<td>You can create a launch template using an instance as the basis for a new launch template using the Amazon EC2 console. For more information, see Create a launch template (p. 743).</td>
<td>30 October 2018</td>

<tr>
<td>On-Demand Capacity Reservations</td>
<td>2016-11-15</td>
<td>You can reserve capacity for your Amazon EC2 instances in a specific Availability Zone for any duration. This allows you to create and manage capacity reservations independently from the billing discounts offered by Reserved Instances (RI). For more information, see On-Demand Capacity Reservations (p. 659).</td>
<td>25 October 2018</td>
</tr>
<tr>
<td>Bring Your Own IP Addresses (BYOIP)</td>
<td>2016-11-15</td>
<td>You can bring part or all of your public IPv4 address range from your on-premises network to your AWS account. After you bring the address range to AWS, it appears in your account as an address pool. You can create an Elastic IP address from your address pool and use it with your AWS resources. For more information, see Bring your own IP addresses (BYOIP) in Amazon EC2 (p. 1378).</td>
<td>23 October 2018</td>
</tr>
<tr>
<td>g3s.xlarge instances</td>
<td>2016-11-15</td>
<td>Expands the range of the accelerated-computing G3 instance family with the introduction of g3s.xlarge instances.</td>
<td>11 October 2018</td>
</tr>
<tr>
<td>Dedicated Host tag on create and console support</td>
<td>2016-11-15</td>
<td>You can tag your Dedicated Hosts on creation, and you can manage your Dedicated Host tags using the Amazon EC2 console. For more information, see Allocate Dedicated Hosts (p. 619).</td>
<td>08 October 2018</td>
</tr>
<tr>
<td>High memory instances</td>
<td>2016-11-15</td>
<td>These instances are purpose-built to run large in-memory databases. They offer bare metal performance with direct access to host hardware. For more information, see Memory optimized instances (p. 386).</td>
<td>27 September 2018</td>
</tr>
<tr>
<td>f1.4xlarge instances</td>
<td>2016-11-15</td>
<td>Expands the range of the accelerated-computing F1 instance family with the introduction of f1.4xlarge instances.</td>

<tr>
<td>Spread placement</td>
<td>2016-11-15</td>
<td>Spread placement groups are recommended for applications that have a small number of critical instances that should be kept separate from each other. For more information, see Spread placement groups (p. 1574).</td>
<td>29 November 2017</td>
</tr>
<tr>
<td>H1 instances</td>
<td>2016-11-15</td>
<td>H1 instances are designed for high-performance big data workloads. For more information, see Storage optimized instances (p. 416).</td>
<td>28 November 2017</td>
</tr>
<tr>
<td>M5 instances</td>
<td>2016-11-15</td>
<td>M5 instances are general purpose compute instances. They provide a balance of compute, memory, storage, and network resources.</td>
<td>28 November 2017</td>
</tr>
<tr>
<td>Spot Instance hibernation</td>
<td>2016-11-15</td>
<td>The Spot service can hibernate Spot Instances in the event of an interruption. For more information, see Hibernate interrupted Spot Instances (p. 590).</td>
<td>28 November 2017</td>
</tr>
<tr>
<td>Spot Fleet target tracking</td>
<td>2016-11-15</td>
<td>You can set up target tracking scaling policies for your Spot Fleet. For more information, see Scale Spot Fleet using a target tracking policy (p. 1202).</td>
<td>17 November 2017</td>
</tr>
<tr>
<td>Spot Fleet integrates with Elastic Load Balancing</td>
<td>2016-11-15</td>
<td>You can attach one or more load balancers to a Spot Fleet.</td>
<td>10 November 2017</td>
</tr>
<tr>
<td>X1e instances</td>
<td>2016-11-15</td>
<td>X1e instances are ideally suited for high-performance databases, in-memory databases, and other memory-intensive enterprise applications. For more information, see Memory optimized instances (p. 386).</td>
<td>28 November 2017</td>
</tr>
<tr>
<td>C5 instances</td>
<td>2016-11-15</td>
<td>C5 instances are designed for compute-heavy applications. For more information, see Compute optimized instances (p. 364).</td>
<td>6 November 2017</td>
</tr>
<tr>
<td>Merge and split Convertible Reserved Instances</td>
<td>2016-11-15</td>
<td>You can exchange (merge) two or more Convertible Reserved Instances for a new Convertible Reserved Instance. You can also use the modification process to split a Convertible Reserved Instance into smaller reservations. For more information, see Exchange Convertible Reserved Instances (p. 540).</td>
<td>6 November 2017</td>
</tr>
<tr>
<td>P3 instances</td>
<td>2016-11-15</td>
<td>P3 instances are compute-optimized GPU instances. For more information, see Linux accelerated computing instances (p. 429).</td>
<td>25 October 2017</td>
</tr>
<tr>
<td>Modify VPC tenancy</td>
<td>2016-11-15</td>
<td>You can change the instance tenancy attribute of a VPC from dedicated to default. For more information, see Change the tenancy of a VPC (p. 658).</td>
<td>16 October 2017</td>
</tr>
<tr>
<td>Per second billing</td>
<td>2016-11-15</td>
<td>Amazon EC2 charges for Linux-based usage by the second, with a one-minute minimum charge.</td>

</tr>
<tr>
<td>New g2.8xlarge instance type</td>
<td></td>
<td>The new g2.8xlarge instance is backed by four high-performance NVIDIA GPUs, making it well suited for GPU compute workloads including large scale rendering, transcoding, machine learning, and other server-side workloads that require massive parallel processing power.</td>
<td>7 April 2015</td>
</tr>
<tr>
<td>D2 instances</td>
<td></td>
<td>Dense-storage instances that are optimized for applications requiring sequential access to large amount of data on direct attached instance storage. D2 instances are designed to offer best price/performance in the dense-storage family. Powered by 2.4 GHz Intel® Xeon® E5 2676v3 (Haswell) processors, D2 instances improve on HS1 instances by providing additional compute power, more memory, and Enhanced Networking. In addition, D2 instances are available in four instance sizes with 6TB, 12TB, 24TB, and 48TB storage options. For more information, see Storage optimized instances (p. 416).</td>
<td>24 March 2015</td>
</tr>
<tr>
<td>Automatic recovery for EC2 instances</td>
<td></td>
<td>You can create an Amazon CloudWatch alarm that monitors an Amazon EC2 instance and automatically recovers the instance if it becomes impaired due to an underlying hardware failure or a problem that requires AWS involvement to repair. A recovered instance is identical to the original instance, including the instance ID, IP addresses, and all instance metadata. For more information, see Recover your instance (p. 807).</td>

<tr>
<td>C4 instances</td>
<td></td>
<td>Next-generation compute-optimized instances that provide very high CPU performance at an economical price. C4 instances are based on custom 2.9 GHz Intel® Xeon® E5-2666 v3 (Haswell) processors. With additional Turbo boost, the processor clock speed in C4 instances can reach as high as 3.5Ghz with 1 or 2 core turbo. Expanding on the capabilities of C3 compute-optimized instances, C4 instances offer customers the highest processor performance among EC2 instances. These instances are ideally suited for high-traffic web applications, ad serving, batch processing, video encoding, distributed analytics, high-energy physics, genome analysis, and computational fluid dynamics. For more information, see Compute optimized instances (p. 364).</td>
<td>11 January 2015</td>
</tr>
<tr>
<td>ClassicLink</td>
<td>2014-10-01</td>
<td>ClassicLink enables you to link your EC2-Classic instance to a VPC in your account. You can associate VPC security groups with the EC2-Classic instance, enabling communication between your EC2-Classic instance and instances in your VPC using private IP addresses.</td>
<td>7 January 2015</td>
</tr>
<tr>
<td>Spot Instance termination notices</td>
<td></td>
<td>The best way to protect against Spot Instance interruption is to architect your application to be fault tolerant. In addition, you can take advantage of Spot Instance termination notices, which provide a two-minute warning before Amazon EC2 must terminate your Spot Instance. For more information, see Spot Instance interruption notices (p. 593).</td>
<td>5 January 2015</td>
</tr>
<tr>
<td>DescribeVolumes pagination support</td>
<td>2014-09-01</td>
<td>The DescribeVolumes API call now supports the pagination of results with the MaxResults and NextToken parameters. For more information, see DescribeVolumes in the Amazon EC2 API Reference.</td>
<td>23 October 2014</td>
</tr>
<tr>
<td>T2 instances</td>
<td>2014-06-15</td>
<td>T2 instances are designed to provide moderate base performance and the capability to burst to significantly higher performance as required by your workload. They are intended for applications that need responsiveness, high performance for limited periods of time, and a low cost. For more information, see Burstable performance instances (p. 330).</td>
<td>30 June 2014</td>

<tr>
<td>Amazon EBS General Purpose SSD Volumes</td>
<td>2014-05-01</td>
<td>General Purpose SSD volumes offer cost-effective storage that is ideal for a broad range of workloads. These volumes deliver single-digit millisecond latencies, the ability to burst to 3,000 IOPS for extended periods of time, and a base performance of 3 IOPS/GiB. General Purpose SSD volumes can range in size from 1 GiB to 1 TiB. For more information, see General Purpose SSD (gp2) volumes (p. 2059).</td>
<td>16 June 2014</td>
</tr>
<tr>
<td>Amazon EBS encryption</td>
<td>2014-05-01</td>
<td>Amazon EBS encryption offers seamless encryption of EBS data volumes and snapshots, eliminating the need to build and maintain a secure key management infrastructure. EBS encryption enables data at rest security by encrypting your data using AWS managed keys. The encryption occurs on the servers that host EC2 instances, providing encryption of data as it moves between EC2 instances and EBS storage. For more information, see Amazon EBS encryption (p. 2316).</td>
<td>21 May 2014</td>
</tr>
<tr>
<td>R3 instances</td>
<td>2014-02-01</td>
<td>Memory-optimized instances with the best price point per GiB of RAM and high performance. These instances are ideally suited for relational and NoSQL databases, in-memory analytics solutions, scientific computing, and other memory-intensive applications that can benefit from the high memory per vCPU, high compute performance, and enhanced networking capabilities of R3 instances. For more information, see Amazon EC2 Instance Types.</td>
<td>9 April 2014</td>

<td>11 June 2013</td>
</tr>
<tr>
<td>New Tags page</td>
<td></td>
<td>There is a new Tags page in the Amazon EC2 console. For more information, see Tag your Amazon EC2 resources (p. 2507).</td>
<td>04 April 2013</td>
</tr>
<tr>
<td>New Amazon Linux AMI release</td>
<td></td>
<td>Amazon Linux AMI 2013.03 is released.</td>
<td>27 March 2013</td>
</tr>
<tr>
<td>Additional EBS-optimized instance types</td>
<td>2013-02-01</td>
<td>The following instance types can now be launched as EBS-optimized instances: c1.xlarge, m2.2xlarge, m3.xlarge, and m3.2xlarge. For more information, see Amazon EBS-optimized instances (p. 2339).</td>
<td>19 March 2013</td>
</tr>
<tr>
<td>Copy an AMI from one Region to another</td>
<td>2013-02-01</td>
<td>You can copy an AMI from one Region to another, enabling you to launch consistent instances in more than one AWS Region quickly and easily. For more information, see Copy an AMI (p. 209).</td>
<td>11 March 2013</td>
</tr>
<tr>
<td>Launch instances into a default VPC</td>
<td>2013-02-01</td>
<td>Your AWS account is capable of launching instances into either EC2-Classic or a VPC, or only into a VPC, on a region-by-region basis. If you can launch instances only into a VPC, we create a default VPC for you. When you launch an instance, we launch it into your default VPC, unless you create a nondefault VPC and specify it when you launch the instance.</td>
<td>11 March 2013</td>
</tr>
<tr>
<td>High-memory cluster (cr1.8xlarge) instance type</td>
<td>2012-12-01</td>
<td>Have large amounts of memory coupled with high CPU and network performance. These instances are well suited for in-memory analytics, graph analysis, and scientific computing applications.</td>
<td>21 January 2013</td>
</tr>
<tr>
<td>Feature</td>
<td>API version</td>
<td>Description</td>
<td>Release date</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>High storage (hs1.8xlarge) instance type</td>
<td>2012-12-01</td>
<td>High storage instances provide very high storage density and high sequential read and write performance per instance. They are well-suited for data warehousing, Hadoop/MapReduce, and parallel file systems.</td>
<td>20 December 2012</td>
</tr>
<tr>
<td>EBS snapshot copy</td>
<td>2012-12-01</td>
<td>You can use snapshot copies to create backups of data, to create new Amazon EBS volumes, or to create Amazon Machine Images (AMIs). For more information, see Copy an Amazon EBS snapshot (p. 2128).</td>
<td>17 December 2012</td>
</tr>
<tr>
<td>Updated EBS metrics and status checks for Provisioned IOPS SSD volumes</td>
<td>2012-10-01</td>
<td>Updated the EBS metrics to include two new metrics for Provisioned IOPS SSD volumes. For more information, see Amazon CloudWatch metrics for Amazon EBS (p. 2389). Also added new status checks for Provisioned IOPS SSD volumes. For more information, see EBS volume status checks (p. 2098).</td>
<td>20 November 2012</td>
</tr>
<tr>
<td>Linux Kernels</td>
<td></td>
<td>Updated AKI IDs; reorganized distribution kernels; updated PVOps section.</td>
<td>13 November 2012</td>
</tr>
<tr>

<tr>
<td>Medium instances, support for 64-bit on all AMIs, and a Java-based SSH Client</td>
<td>2011-12-15</td>
<td>Added support for a new instance type and 64-bit information. Added procedures for using the Java-based SSH client to connect to Linux instances.</td>
<td>7 March 2012</td>
</tr>
<tr>
<td>Reserved Instance pricing tiers</td>
<td>2011-12-15</td>
<td>Added a new section discussing how to take advantage of the discount pricing that is built into the Reserved Instance pricing tiers.</td>
<td>5 March 2012</td>
</tr>
<tr>
<td>Elastic Network Interfaces (ENIs) for EC2 instances in Amazon Virtual Private Cloud</td>
<td>2011-12-01</td>
<td>Added new section about elastic network interfaces (ENIs) for EC2 instances in a VPC. For more information, see [Elastic network interfaces](p. 1404).</td>
<td>21 December 2011</td>
</tr>
<tr>
<td>New GRU Region and AKIs</td>
<td></td>
<td>Added information about the release of new AKIs for the SA-East-1 Region. This release deprecates the AKI version 1.01. AKI version 1.02 will continue to be backward compatible.</td>
<td>14 December 2011</td>
</tr>
<tr>
<td>New offering types for Amazon EC2 Reserved Instances</td>
<td>2011-11-01</td>
<td>You can choose from a variety of Reserved Instance offerings that address your projected use of the instance.</td>
<td>01 December 2011</td>
</tr>
<tr>
<td>Amazon EC2 instance status</td>
<td>2011-11-01</td>
<td>You can view additional details about the status of your instances, including scheduled events planned by AWS that might have an impact on your instances. These operational activities include instance reboots required to apply software updates or security patches, or instance retirements required where there are hardware issues. For more information, see [Monitor the status of your instances](p. 1267).</td>
<td>16 November 2011</td>
</tr>
<tr>
<td>Amazon EC2 Cluster Compute Instance Type</td>
<td></td>
<td>Added support for Cluster Compute Eight Extra Large (cc2.8xlarge) to Amazon EC2.</td>
<td>14 November 2011</td>
</tr>
<tr>
<td>New PDX Region and AKIs</td>
<td></td>
<td>Added information about the release of new AKIs for the new US-West 2 Region.</td>
<td>8 November 2011</td>
</tr>
<tr>
<td>Spot Instances in Amazon VPC</td>
<td>2011-07-15</td>
<td>Added information about the support for Spot Instances in Amazon VPC. With this update, users can launch Spot Instances a virtual private cloud (VPC). By launching Spot Instances in a VPC, users of Spot Instances can enjoy the benefits of Amazon VPC.</td>
<td>11 October 2011</td>
</tr>
<tr>
<td>New Linux AMI release</td>
<td></td>
<td>Added information about the release of Amazon Linux AMI 2011.09. This update removes the beta tag from the Amazon Linux AMI, supports the ability to lock the repositories to a specific version, and provides for notification when updates are available to installed packages including security updates.</td>
<td>26 September 2011</td>
</tr>
<tr>
<td>Feature</td>
<td>API version</td>

<tr>
<td>Simplified VM import process for users of the CLI tools</td>
<td>2011-07-15</td>
<td>The VM Import process is simplified with the enhanced functionality of ImportInstance and ImportVolume, which now will perform the upload of the images into Amazon EC2 after creating the import task. In addition, with the introduction of ResumeImport, users can restart an incomplete upload at the point the task stopped.</td>
<td>15 September 2011</td>
</tr>
<tr>
<td>Support for importing in VHD file format</td>
<td></td>
<td>VM Import can now import virtual machine image files in VHD format. The VHD file format is compatible with the Citrix Xen and Microsoft Hyper-V virtualization platforms. With this release, VM Import now supports RAW, VHD and VMDK (VMware ESX-compatible) image formats. For more information, see the VM Import/Export User Guide.</td>
<td>24 August 2011</td>
</tr>
<tr>
<td>Update to the Amazon EC2 VM Import Connector for VMware vCenter</td>
<td></td>
<td>Added information about the 1.1 version of the Amazon EC2 VM Import Connector for VMware vCenter virtual appliance (Connector). This update includes proxy support for Internet access, better error handling, improved task progress bar accuracy, and several bug fixes.</td>
<td>27 June 2011</td>
</tr>
<tr>
<td>Enabling Linux AMI to run user-provided kernels</td>
<td></td>
<td>Added information about the AKI version change from 1.01 to 1.02. This version updates the PVGRUB to address launch failures associated with t1.micro Linux instances. For more information, see User provided kernels (p. 273).</td>
<td>20 June 2011</td>
</tr>
<tr>
<td>Spot Instances Availability Zone pricing changes</td>
<td>2011-05-15</td>
<td>Added information about the Spot Instances Availability Zone pricing feature. In this release, we've added new Availability Zone pricing options as part of the information returned when you query for Spot Instance requests and Spot price history. These additions make it easier to determine the price required to launch a Spot Instance into a particular Availability Zone.</td>
<td>26 May 2011</td>
</tr>
<tr>
<td>AWS Identity and Access Management</td>
<td></td>
<td>Added information about AWS Identity and Access Management (IAM), which enables users to specify which Amazon EC2 actions a user can use with Amazon EC2 resources in general. For more information, see Identity and access management for Amazon EC2 (p. 1935).</td>
<td>26 April 2011</td>
</tr>
<tr>
<td>Enabling Linux AMI to run user-provided kernels</td>
<td></td>
<td>Added information about enabling a Linux AMI to use PVGRUB Amazon Kernel Image (AKI) to run a user-provided kernel. For more information, see User provided kernels (p. 273).</td>
<td>26 April 2011</td>
</tr>
<tr>

<tr>
<td>Dedicated instances</td>
<td></td>
<td>Launched within your Amazon Virtual Private Cloud (Amazon VPC), Dedicated Instances are instances that are physically isolated at the host hardware level. Dedicated Instances let you take advantage of Amazon VPC and the AWS cloud, with benefits including on-demand elastic provisioning and pay only for what you use, while isolating your Amazon EC2 compute instances at the hardware level. For more information, see Dedicated Instances (p. 653).</td>
<td>27 March 2011</td>
</tr>
<tr>
<td>Reserved Instances updates to the AWS Management Console</td>
<td></td>
<td>Updates to the AWS Management Console make it easier for users to view their Reserved Instances and purchase additional Reserved Instances, including Dedicated Reserved Instances. For more information, see Reserved Instances (p. 502).</td>
<td>27 March 2011</td>
</tr>
<tr>
<td>New Amazon Linux reference AMI</td>
<td></td>
<td>The new Amazon Linux reference AMI replaces the CentOS reference AMI. Removed information about the CentOS reference AMI, including the section named Correcting Clock Drift for Cluster Instances on CentOS 5.4 AMI.</td>
<td>15 March 2011</td>
</tr>
<tr>
<td>Metadata information</td>
<td>2011-01-01</td>
<td>Added information about metadata to reflect changes in the 2011-01-01 release. For more information, see Instance metadata and user data (p. 1004) and Instance metadata categories (p. 1032).</td>
<td>11 March 2011</td>
</tr>
<tr>
<td>Amazon EC2 VM Import Connector for VMware vCenter</td>
<td></td>
<td>Added information about the Amazon EC2 VM Import Connector for VMware vCenter virtual appliance (Connector). The Connector is a plug-in for VMware vCenter that integrates with VMware vSphere Client and provides a graphical user interface that you can use to import your VMware virtual machines to Amazon EC2.</td>
<td>3 March 2011</td>
</tr>
<tr>
<td>Force volume detachment</td>
<td></td>
<td>You can now use the AWS Management Console to force the detachment of an Amazon EBS volume from an instance. For more information, see Detach an Amazon EBS volume from a Linux instance (p. 2104).</td>
<td>23 February 2011</td>
</tr>
<tr>
<td>Instance termination protection</td>
<td></td>
<td>You can now use the AWS Management Console to prevent an instance from being terminated. For more information, see Enable termination protection (p. 800).</td>
<td>23 February 2011</td>
</tr>
<tr>
<td>Correcting Clock Drift for Cluster Instances on CentOS 5.4 AMI</td>
<td></td>
<td>Added information about how to correct clock drift for cluster instances running on Amazon's CentOS 5.4 AMI.</td>
<td>25 January 2011</td>
</tr>
<tr>
