Tutorials ........................................................................................................................ 1181
Using Windows containers on AWS Fargate .............................................................. 1181
  Prerequisites ................................................................................................................ 1182
  Step 1: Create a cluster ............................................................................................... 1182
  Step 2: Register a Windows task definition ............................................................. 1183
  Step 3: Create a service with your task definition .................................................. 1184
  Step 4: View your service .......................................................................................... 1185
  Step 5: Clean Up ......................................................................................................... 1185
Creating a cluster with a Fargate Linux task using the AWS CLI .............................. 1186
  Prerequisites ................................................................................................................ 1187
  Step 1: Create a Cluster ............................................................................................. 1187
  Step 2: Register a Linux Task Definition .................................................................. 1188
  Step 3: List Task Definitions ...................................................................................... 1190
  Step 4: Create a Service ............................................................................................. 1190
  Step 5: List Services .................................................................................................... 1191
  Step 6: Describe the Running Service ...................................................................... 1191
  Step 7: Test .................................................................................................................. 1194
  Step 8: Clean Up ......................................................................................................... 1197
Creating a cluster with a Fargate Windows task using the AWS CLI .................... 1198
  Prerequisites ................................................................................................................ 1198
  Step 1: Create a Cluster ............................................................................................. 1199
  Step 2: Register a Windows Task Definition ............................................................ 1200
  Step 3: List task definitions ....................................................................................... 1201
  Step 4: Create a service ............................................................................................. 1201
  Step 5: List services .................................................................................................... 1202
  Step 6: Describe the Running Service ...................................................................... 1202
Step 7: Clean Up ........................................................................................................... 1205
Creating a cluster with an EC2 task using the AWS CLI ........................................ 1205
Prerequisites .................................................................................................................. 1206
Step 1: Create a Cluster ............................................................................................... 1206
Step 2: Launch an Instance with the Amazon ECS AMI ............................................ 1207
Step 3: List Container Instances .................................................................................. 1207
Step 4: Describe your Container Instance .................................................................... 1207
Step 5: Register a Task Definition ................................................................................ 1210
Step 6: List Task Definitions ......................................................................................... 1212
Step 7: Run a Task ........................................................................................................ 1212
Step 8: List Tasks .......................................................................................................... 1213
Step 9: Describe the Running Task ............................................................................... 1214
Using cluster auto scaling with the AWS Management Console and the Amazon ECS
console .............................................................................................................................. 1215
Prerequisites .................................................................................................................. 1215
Step 1: Create an Amazon ECS cluster ........................................................................ 1216
Step 2: Register a task definition ................................................................................. 1217
Step 3: Run a task .......................................................................................................... 1217
Step 4: Verify ................................................................................................................ 1218
Step 5: Clean up ............................................................................................................. 1219
Specifying Sensitive Data Using Secrets Manager Secrets ............................................ 1220
Prerequisites .................................................................................................................. 1220
Step 1: Create an Secrets Manager Secret ................................................................... 1220
Step 2: Update Your Task Execution IAM Role ......................................................... 1221
Step 3: Create an Amazon ECS Task Definition ......................................................... 1222
Step 4: Create an Amazon ECS Cluster ....................................................................... 1223
Step 5: Run an Amazon ECS Task ............................................................................... 1223
Step 6: Verify ................................................................................................................ 1224
Step 7: Clean Up .......................................................................................................... 1225
Creating a service using Service Discovery .................................................................... 1226
Prerequisites .................................................................................................................. 1226
Step 1: Create the Service Discovery resources in AWS Cloud Map ......................... 1226
Step 2: Create the Amazon ECS resources ................................................................. 1228
Step 3: Verify Service Discovery in AWS Cloud Map ............................................... 1230
Step 4: Clean up .......................................................................................................... 1232
Creating a service using a blue/green deployment ......................................................... 1235
Amazon Elastic Container Service

Step 6: Run a task and view the results ................................................................. 1240
Step 7: Clean up ..................................................................................................... 1248

Listening for Amazon ECS CloudWatch Events ...................................................... 1250
  Prerequisite: Set up a test cluster ...................................................................... 1250
  Step 1: Create the Lambda function .................................................................. 1250
  Step 2: Register an event rule ............................................................................ 1251
  Step 3: Create a task definition ......................................................................... 1252
  Step 4: Test your rule ......................................................................................... 1253

Sending Amazon Simple Notification Service alerts for task stopped events .......... 1253
  Prerequisite: Set up a test cluster ...................................................................... 1254
  Prerequisite: Configure permissions for Amazon SNS ...................................... 1254
  Step 1: Create and subscribe to an Amazon SNS topic ..................................... 1254
  Step 2: Register an event rule ............................................................................ 1255
  Step 3: Test your rule ......................................................................................... 1256

Concatenate multiline or stack-trace log messages .................................................. 1257

What is Amazon Elastic Container Service?

Amazon Elastic Container Service (Amazon ECS) is a fully managed container orchestration service that helps you easily deploy, manage, and scale containerized applications. As a fully managed service, Amazon ECS comes with AWS configuration and operational best practices built-in. It's integrated with both AWS and third-party tools, such as Amazon Elastic Container Registry and Docker. This integration makes it easier for teams to focus on building the applications, not the environment. You can run and scale your container workloads across AWS Regions in the cloud, and on-premises, without the complexity of managing a control plane.

Amazon ECS terminology and components

There are three layers in Amazon ECS:

- **Capacity** - The infrastructure where your containers run
- **Controller** - Deploy and manage your applications that run on the containers
- **Provisioning** - The tools that you can use to interface with the scheduler to deploy and manage your applications and containers

The following diagram shows the Amazon ECS layers.
Amazon Elastic Container Service Layers

Provisioning

Amazon Web Services Command Line Interface  Copilot  Management console  Amazon Web Services Cloud Developer Kit  Amazon Web Services Software Developer Kit

Amazon ECS scheduler

Controller

Amazon EC2 instances  Amazon Web Services Fargate  On-premises compute

Capacity options

Amazon ECS capacity

Amazon ECS capacity is the infrastructure where your containers run. The following is an overview of the capacity options:

- Amazon EC2 instances in the AWS cloud

  You choose the instance type, the number of instances, and manage the capacity.

- Serverless (AWS Fargate (Fargate)) in the AWS cloud

  Fargate is a serverless, pay-as-you-go compute engine. With Fargate you don't need to manage servers, handle capacity planning, or isolate container workloads for security.

- On-premises virtual machines (VM) or servers

  Amazon ECS Anywhere provides support for registering an external instance such as an on-premises server or virtual machine (VM), to your Amazon ECS cluster.
The capacity can be located in any of the following AWS resources:

- Availability Zones
- Local Zones
- Wavelength Zones
- AWS Regions
- AWS Outposts

Amazon ECS controller

The Amazon ECS scheduler is the software that manages your applications.

Amazon ECS provisioning

There are multiple options for provisioning Amazon ECS:

- **AWS Management Console** — Provides a web interface that you can use to access your Amazon ECS resources.
- **AWS Command Line Interface (AWS CLI)** — Provides commands for a broad set of AWS services, including Amazon ECS. It’s supported on Windows, Mac, and Linux. For more information, see [AWS Command Line Interface](#).
- **AWS SDKs** — Provides language-specific APIs and takes care of many of the connection details. These include calculating signatures, handling request retries, and error handling. For more information, see [AWS SDKs](#).
- **Copilot** — Provides an open-source tool for developers to build, release, and operate production ready containerized applications on Amazon ECS. For more information, see [Copilot](#) on the GitHub website.
- **AWS CDK** — Provides an open-source software development framework that you can use to model and provision your cloud application resources using familiar programming languages. The AWS CDK provisions your resources in a safe, repeatable manner through AWS CloudFormation.

Application lifecycle

The following diagram shows the application lifecycle and how it works with the Amazon ECS components.
You must architect your applications so that they can run on containers. A container is a standardized unit of software development that holds everything that your software application requires to run. This includes relevant code, runtime, system tools, and system libraries. Containers are created from a read-only template that's called an image. Images are typically built from a Dockerfile. A Dockerfile is a plaintext file that specifies all of the components that are included in the container. After they're built, these images are stored in a registry such as Amazon ECR where they can be downloaded from.

After you create and store your image, you create an Amazon ECS task definition. A task definition is a blueprint for your application. It is a text file in JSON format that describes the parameters and one or more containers that form your application. For example, you can use it to specify the image and parameters for the operating system, which containers to use, which ports to open for your application, and what data volumes to use with the containers in the task. The specific parameters available for your task definition depend on the needs of your specific application.
After you define your task definition, you deploy it as either a service or a task on your cluster. A *cluster* is a logical grouping of tasks or services that runs on the capacity infrastructure that is registered to a cluster.

A *task* is the instantiation of a task definition within a cluster. You can run a standalone task, or you can run a task as part of a service. You can use an Amazon ECS *service* to run and maintain your desired number of tasks simultaneously in an Amazon ECS cluster. How it works is that, if any of your tasks fail or stop for any reason, the Amazon ECS service scheduler launches another instance based on your task definition. It does this to replace it and thereby maintain your desired number of tasks in the service.

The *container agent* runs on each container instance within an Amazon ECS cluster. The agent sends information about the current running tasks and resource utilization of your containers to Amazon ECS. It starts and stops tasks whenever it receives a request from Amazon ECS.

After you deploy the task or service, you can use any of the following tools to monitor your deployment and application:

- CloudWatch
- Runtime Monitoring

General AWS resources

The following general resources can help you as you work with AWS.

- **Classes & Workshops** – Links to role-based and specialty courses, in addition to self-paced labs to help sharpen your AWS skills and gain practical experience.
- **AWS Developer Center** – Explore tutorials, download tools, and learn about AWS developer events.
- **AWS Developer Tools** – Links to developer tools, SDKs, IDE toolkits, and command line tools for developing and managing AWS applications.
- **Getting Started Resource Center** – Learn how to set up your AWS account, join the AWS community, and launch your first application.
- **Hands-On Tutorials** – Follow step-by-step tutorials to launch your first application on AWS.
- **AWS Whitepapers** – Links to a comprehensive list of technical AWS whitepapers, covering topics such as architecture, security, and economics and authored by AWS Solutions Architects or other technical experts.
- **AWS Support Center** – The hub for creating and managing your AWS Support cases. Also includes links to other helpful resources, such as forums, technical FAQs, service health status, and AWS Trusted Advisor.
- **AWS Support** – The primary webpage for information about AWS Support, a one-on-one, fast-response support channel to help you build and run applications in the cloud.
- **Contact Us** – A central contact point for inquiries concerning AWS billing, account, events, abuse, and other issues.
- **AWS Site Terms** – Detailed information about our copyright and trademark; your account, license, and site access; and other topics.
Getting started with Amazon ECS

The following guides provide an introduction to the tools available to access Amazon ECS and introductory step by step procedures to run containers. Docker basics takes you through the basic steps to create a Docker container image and upload it to an Amazon ECR private repository. The getting started guides walk you through using the AWS Copilot command line interface and the AWS Management Console to complete the common tasks to run your containers on Amazon ECS and AWS Fargate.

Contents

- Set up to use Amazon ECS
- Creating a container image for use on Amazon ECS
- Getting started with Linux containers on AWS Fargate
- Getting started with Windows on Amazon EC2

Set up to use Amazon ECS

If you’ve already signed up for Amazon Web Services (AWS) and have been using Amazon Elastic Compute Cloud (Amazon EC2), you are close to being able to use Amazon ECS. The set-up process for the two services is similar. The following guide prepares you for launching your first Amazon ECS cluster.

Complete the following tasks to get set up for Amazon ECS.

Sign up for an AWS account

If you do not have an AWS account, complete the following steps to create one.

To sign up for an AWS account

2. Follow the online instructions.

   Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.
When you sign up for an AWS account, an *AWS account root user* is created. The root user has access to all AWS services and resources in the account. As a security best practice, assign administrative access to an administrative user, and use only the root user to perform tasks that require root user access.

AWS sends you a confirmation email after the sign-up process is complete. At any time, you can view your current account activity and manage your account by going to https://aws.amazon.com/ and choosing My Account.

**Create an administrative user**

After you sign up for an AWS account, secure your AWS account root user, enable AWS IAM Identity Center, and create an administrative user so that you don't use the root user for everyday tasks.

**Secure your AWS account root user**

1. Sign in to the *AWS Management Console* as the account owner by choosing *Root user* and entering your AWS account email address. On the next page, enter your password.

   For help signing in by using root user, see Signing in as the root user in the *AWS Sign-In User Guide*.

2. Turn on multi-factor authentication (MFA) for your root user.

   For instructions, see Enable a virtual MFA device for your AWS account root user (console) in the *IAM User Guide*.

**Create an administrative user**

1. Enable IAM Identity Center.

   For instructions, see Enabling AWS IAM Identity Center in the *AWS IAM Identity Center User Guide*.

2. In IAM Identity Center, grant administrative access to an administrative user.

   For a tutorial about using the IAM Identity Center directory as your identity source, see Configure user access with the default IAM Identity Center directory in the *AWS IAM Identity Center User Guide*.
Sign in as the administrative user

- To sign in with your IAM Identity Center user, use the sign-in URL that was sent to your email address when you created the IAM Identity Center user.

  For help signing in using an IAM Identity Center user, see Signing in to the AWS access portal in the AWS Sign-In User Guide.

Create a virtual private cloud

You can use Amazon Virtual Private Cloud (Amazon VPC) to launch AWS resources into a virtual network that you've defined. We strongly suggest that you launch your container instances in a VPC.

If you have a default VPC, you can skip this section and move to the next task, Create a security group. To determine whether you have a default VPC, see Supported Platforms in the Amazon EC2 Console in the Amazon EC2 User Guide for Linux Instances. Otherwise, you can create a nondefault VPC in your account using the steps below.

⚠️ Important

If your account supports Amazon EC2 Classic in a region, then you do not have a default VPC in that region.

For information about how to create a VPC, see Create a VPC only in the Amazon VPC User Guide, and use the following table to determine what options to select.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resources to create</td>
<td>VPC only</td>
</tr>
<tr>
<td>Name</td>
<td>Optionally provide a name for your VPC.</td>
</tr>
<tr>
<td>IPv4 CIDR block</td>
<td>IPv4 CIDR manual input</td>
</tr>
<tr>
<td>Option</td>
<td>Value</td>
</tr>
<tr>
<td>-----------------</td>
<td>--------------------------------------------</td>
</tr>
<tr>
<td>The CIDR block size must have a size between /16 and /28.</td>
<td></td>
</tr>
<tr>
<td>IPv6 CIDR block</td>
<td>No IPv6 CIDR block</td>
</tr>
<tr>
<td>Tenancy</td>
<td>Default</td>
</tr>
</tbody>
</table>

For more information about Amazon VPC, see [What is Amazon VPC?](https://docs.aws.amazon.com/vpc/latest/userguide/what-is-amazon-vpc.html) in the Amazon VPC User Guide.

**Create a security group**

Security groups act as a firewall for associated container instances, controlling both inbound and outbound traffic at the container instance level. You can add rules to a security group that enable you to connect to your container instance from your IP address using SSH. You can also add rules that allow inbound and outbound HTTP and HTTPS access from anywhere. Add any rules to open ports that are required by your tasks. Container instances require external network access to communicate with the Amazon ECS service endpoint.

If you plan to launch container instances in multiple Regions, you need to create a security group in each Region. For more information, see [Regions and Availability Zones](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/regions-overview.html) in the Amazon EC2 User Guide for Linux Instances.

**Tip**

You need the public IP address of your local computer, which you can get using a service. For example, we provide the following service: [http://checkip.amazonaws.com/](http://checkip.amazonaws.com/) or [https://checkip.amazonaws.com/](https://checkip.amazonaws.com/). To locate another service that provides your IP address, use the search phrase "what is my IP address." If you are connecting through an internet service provider (ISP) or from behind a firewall without a static IP address, you must find out the range of IP addresses used by client computers.

For information about how to create a security group, see [Create a security group](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/create-security-group.html) in the Amazon EC2 User Guide for Linux Instances and use the following table to determine what options to select.
<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Region</td>
<td>The same Region in which you created your key pair.</td>
</tr>
<tr>
<td>Name</td>
<td>A name that is easy for you to remember, such as <code>ecs-instances-default-cluster</code>.</td>
</tr>
<tr>
<td>VPC</td>
<td>The default VPC (marked with &quot;(default)&quot;.</td>
</tr>
</tbody>
</table>

### Note

If your account supports Amazon EC2 Classic, select the VPC that you created in the previous task.

For information about the outbound rules to add for your use cases, see [Security group rules for different use cases](https://docs.aws.amazon.com/eucalyptus/latest/dg/security-group-rules.html) in the *Amazon EC2 User Guide for Linux Instances*.

Amazon ECS container instances do not require any inbound ports to be open. However, you might want to add an SSH rule so you can log into the container instance and examine the tasks with Docker commands. You can also add rules for HTTP and HTTPS if you want your container instance to host a task that runs a web server. Container instances do require external network access to communicate with the Amazon ECS service endpoint. Complete the following steps to add these optional security group rules.

Add the following three inbound rules to your security group. For information about how to create a security group, see [Add rules to your security group](https://docs.aws.amazon.com/eucalyptus/latest/dg/security-group-rules.html) in the *Amazon EC2 User Guide for Linux Instances*.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP rule</td>
<td>Type: HTTP</td>
</tr>
<tr>
<td>Option</td>
<td>Value</td>
</tr>
<tr>
<td>--------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>Source: Anywhere (0.0.0.0/0)</td>
<td>This option automatically adds the 0.0.0.0/0 IPv4 CIDR block as the source. This is acceptable for a short time in a test environment, but it's unsafe in production environments. In production, authorize only a specific IP address or range of addresses to access your instance.</td>
</tr>
</tbody>
</table>

**HTTPS rule**

<table>
<thead>
<tr>
<th>Type: HTTPS</th>
<th>Source: Anywhere (0.0.0.0/0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is acceptable for a short time in a test environment, but it's unsafe in production environments. In production, authorize only a specific IP address or range of addresses to access your instance.</td>
<td></td>
</tr>
<tr>
<td>Option</td>
<td>Value</td>
</tr>
<tr>
<td>---------</td>
<td>-------</td>
</tr>
</tbody>
</table>
| SSH rule | Type: SSH  
Source: Custom, specify the public IP address of your computer or network in CIDR notation. To specify an individual IP address in CIDR notation, add the routing prefix /32. For example, if your IP address is 203.0.113.25, specify 203.0.113.25/32. If your company allocates addresses from a range, specify the entire range, such as 203.0.113.0/24. |

**Important**  
For security reasons, we don't recommend that you allow SSH access from all IP addresses (0.0.0.0/0) to your instance, except for testing purposes and only for a short time.

---

**Create the credentials to connect to your EC2 instance**

For Amazon ECS, a key pair is only needed if you intend on using the EC2 launch type.
AWS uses public-key cryptography to secure the login information for your instance. A Linux instance, such as an Amazon ECS container instance, has no password to use for SSH access. You use a key pair to log in to your instance securely. You specify the name of the key pair when you launch your container instance, then provide the private key when you log in using SSH.

If you haven't created a key pair already, you can create one using the Amazon EC2 console. If you plan to launch instances in multiple regions, you'll need to create a key pair in each region. For more information about regions, see Regions and Availability Zones in the Amazon EC2 User Guide for Linux Instances.

**To create a key pair**

- Use the Amazon EC2 console to create a key pair. For more information about creating a key pair, see Create a key pair in the Amazon EC2 User Guide for Linux Instances.

For information about how to connect to your instance, see Connect to your Linux instance in the Amazon EC2 User Guide for Linux Instances.

**Install the AWS CLI**

The AWS Management Console can be used to manage all operations manually with Amazon ECS. However, you can install the AWS CLI on your local desktop or a developer box so that you can build scripts that can automate common management tasks in Amazon ECS.

To use the AWS CLI with Amazon ECS, install the latest AWS CLI version. For information about installing the AWS CLI or upgrading it to the latest version, see Installing the AWS Command Line Interface in the AWS Command Line Interface User Guide.

**Creating a container image for use on Amazon ECS**

Amazon ECS uses Docker images in task definitions to launch containers. Docker is a technology that provides the tools for you to build, run, test, and deploy distributed applications in containers. Docker provides a walkthrough on deploying containers on Amazon ECS. For more information, see Docker Compose CLI - Amazon ECS.

The purpose of the steps outlined here is to walk you through creating your first Docker image and pushing that image to Amazon ECR, which is a container registry, for use in your Amazon ECS task definitions. This walkthrough assumes that you possess a basic understanding of what Docker
Prerequisites

Before you begin, ensure the following prerequisites are met.

• Ensure you have completed the Amazon ECR setup steps. For more information, see Setting up for Amazon ECR in the Amazon Elastic Container Registry User Guide.

• Your user has the required IAM permissions to access and use the Amazon ECR service. For more information, see Amazon ECR managed policies.

• You have Docker installed. For Docker installation steps for Amazon Linux 2, see Installing Docker on AL2023. For all other operating systems, see the Docker documentation at Docker Desktop overview.

• You have the AWS CLI installed and configured. For more information, see Installing the AWS Command Line Interface in the AWS Command Line Interface User Guide.

If you don't have or need a local development environment and you prefer to use an Amazon EC2 instance to use Docker, we provide the following steps to launch an Amazon EC2 instance using Amazon Linux 2 and install Docker Engine and the Docker CLI.

Installing Docker on AL2023

Docker is available on many different operating systems, including most modern Linux distributions, like Ubuntu, and even macOS and Windows. For more information about how to install Docker on your particular operating system, go to the Docker installation guide.

You do not need a local development system to use Docker. If you are using Amazon EC2 already, you can launch an Amazon Linux 2023 instance and install Docker to get started.

If you already have Docker installed, skip to Create a Docker image.

To install Docker on an Amazon EC2 instance using an Amazon Linux 2023 AMI

1. Launch an instance with the latest Amazon Linux 2023 AMI. For more information, see Launching an instance in the Amazon EC2 User Guide for Linux Instances.

2. Connect to your instance. For more information, see Connect to Your Linux Instance in the Amazon EC2 User Guide for Linux Instances.

3. Update the installed packages and package cache on your instance.
4. Install the most recent Docker Community Edition package.

```bash
sudo yum update -y
```

5. Start the Docker service.

```bash
sudo service docker start
```

6. Add the `ec2-user` to the `docker` group so you can execute Docker commands without using `sudo`.

```bash
sudo usermod -a -G docker ec2-user
```

7. Log out and log back in again to pick up the new `docker` group permissions. You can accomplish this by closing your current SSH terminal window and reconnecting to your instance in a new one. Your new SSH session will have the appropriate `docker` group permissions.

8. Verify that the `ec2-user` can run Docker commands without `sudo`.

```bash
docker info
```

**Note**

In some cases, you may need to reboot your instance to provide permissions for the `ec2-user` to access the Docker daemon. Try rebooting your instance if you see the following error:

```shell
Cannot connect to the Docker daemon. Is the docker daemon running on this host?
```

---

**Create a Docker image**

Amazon ECS task definitions use Docker images to launch containers on the container instances in your clusters. In this section, you create a Docker image of a simple web application, and test it on
your local system or Amazon EC2 instance, and then push the image to the Amazon ECR container registry so you can use it in an Amazon ECS task definition.

**To create a Docker image of a simple web application**

1. Create a file called `Dockerfile`. A Dockerfile is a manifest that describes the base image to use for your Docker image and what you want installed and running on it. For more information about Dockerfiles, go to the [Dockerfile Reference](#).

   ```bash
touch Dockerfile
   ``

2. Edit the `Dockerfile` you just created and add the following content.

   ```bash
FROM public.ecr.aws/amazonlinux/amazonlinux:latest

# Install dependencies
RUN yum update -y && 
    yum install -y httpd

# Install apache and write hello world message
RUN echo 'Hello World!' > /var/www/html/index.html

# Configure apache
RUN echo 'mkdir -p /var/run/httpd' >> /root/run_apache.sh && 
    echo 'mkdir -p /var/lock/httpd' >> /root/run_apache.sh && 
    echo '/usr/sbin/httpd -D FOREGROUND' >> /root/run_apache.sh && 
    chmod 755 /root/run_apache.sh

EXPOSE 80

CMD /root/run_apache.sh
   ```

This Dockerfile uses the public Amazon Linux 2 image hosted on Amazon ECR Public. The `RUN` instructions update the package caches, installs some software packages for the web server, and then write the "Hello World!" content to the web servers document root. The `EXPOSE` instruction means that port 80 on the container is the one that is listening, and the `CMD` instruction starts the web server.

3. Build the Docker image from your Dockerfile.
Note
Some versions of Docker may require the full path to your Dockerfile in the following command, instead of the relative path shown below.

```
docker build -t hello-world .
```

4. List your container image.

```
docker images --filter reference=hello-world
```

Output:

<table>
<thead>
<tr>
<th>REPOSITORY</th>
<th>TAG</th>
<th>IMAGE ID</th>
<th>CREATED</th>
</tr>
</thead>
<tbody>
<tr>
<td>hello-world</td>
<td>latest</td>
<td>e9ffedc8c286</td>
<td>4 minutes ago</td>
</tr>
<tr>
<td>194MB</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. Run the newly built image. The `-p 80:80` option maps the exposed port 80 on the container to port 80 on the host system. For more information about `docker run`, go to the Docker run reference.

```
docker run -t -i -p 80:80 hello-world
```

Note
Output from the Apache web server is displayed in the terminal window. You can ignore the "Could not reliably determine the fully qualified domain name" message.

6. Open a browser and point to the server that is running Docker and hosting your container.

   - If you are using an EC2 instance, this is the Public DNS value for the server, which is the same address you use to connect to the instance with SSH. Make sure that the security group for your instance allows inbound traffic on port 80.
   - If you are running Docker locally, point your browser to http://localhost/.

Create a Docker image
• If you are using **docker-machine** on a Windows or Mac computer, find the IP address of the VirtualBox VM that is hosting Docker with the **docker-machine ip** command, substituting `machine-name` with the name of the docker machine you are using.

```
docker-machine ip machine-name
```

You should see a web page with your "Hello World!" statement.

7. Stop the Docker container by typing **Ctrl + c**.

### Push your image to Amazon Elastic Container Registry

Amazon ECR is a managed AWS Docker registry service. You can use the Docker CLI to push, pull, and manage images in your Amazon ECR repositories. For Amazon ECR product details, featured customer case studies, and FAQs, see the [Amazon Elastic Container Registry product detail pages](https://aws.amazon.com/ecz/).

#### To tag your image and push it to Amazon ECR

1. Create an Amazon ECR repository to store your `hello-world` image. Note the `repositoryUri` in the output.

   Substitute `region`, with your AWS Region, for example, `us-east-1`.

```
aws ecr create-repository --repository-name hello-repository --region region
```

Output:

```json
{
   "repository": {
      "registryId": "aws_account_id",
      "repositoryName": "hello-repository",
      "repositoryArn": "arn:aws:ecr:region:aws_account_id:repository/hello-repository",
      "createdAt": 1505337806.0,
      "repositoryUri": "aws_account_id.dkr.ecr.region.amazonaws.com/hello-repository"
   }
}
```
2. Tag the **hello-world** image with the repositoryUri value from the previous step.

   ```bash
docker tag hello-world aws_account_id.dkr.ecr.region.amazonaws.com/hello-repository
   ```

3. Run the **aws ecr get-login-password** command. Specify the registry URI you want to authenticate to. For more information, see [Registry Authentication](#) in the *Amazon Elastic Container Registry User Guide*.

   ```bash
aws ecr get-login-password --region region | docker login --username AWS --password-stdin aws_account_id.dkr.ecr.region.amazonaws.com
   ```

   **Output:**

   ```bash
Login Succeeded
   ```

   **Important**
   
   If you receive an error, install or upgrade to the latest version of the AWS CLI. For more information, see [Installing the AWS Command Line Interface](#) in the *AWS Command Line Interface User Guide*.

4. Push the image to Amazon ECR with the repositoryUri value from the earlier step.

   ```bash
docker push aws_account_id.dkr.ecr.region.amazonaws.com/hello-repository
   ```

**Clean up**

To continue on with creating an Amazon ECS task definition and launching a task with your container image, skip to the **Next steps**. When you are done experimenting with your Amazon ECR image, you can delete the repository so you are not charged for image storage.

```bash
aws ecr delete-repository --repository-name hello-repository --region region --force
```

**Next steps**

Your task definitions require a task execution role. For more information, see [Amazon ECS task execution IAM role](#).
After you have created and pushed your container image to Amazon ECR, you should consider the following next steps.

- the section called “Using the console with Linux containers on AWS Fargate”
- the section called “Using Windows containers on AWS Fargate”
- Creating a cluster with a Fargate Linux task using the AWS CLI

## Getting started with Linux containers on AWS Fargate

Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast, container management service that makes it easy to run, stop, and manage your containers. You can host your containers on a serverless infrastructure that is managed by Amazon ECS by launching your services or tasks on AWS Fargate. For more information on Fargate, see [Amazon ECS on AWS Fargate](#).

Get started with Amazon ECS on AWS Fargate by using the Fargate launch type for your tasks in the Regions where Amazon ECS supports AWS Fargate.

Complete the following steps to get started with Amazon ECS on AWS Fargate.

### Prerequisites

Before you begin, complete the steps in [Set up to use Amazon ECS](#) and that your AWS user has the permissions specified in the AdministratorAccess IAM policy example.

The console attempts to automatically create the task execution IAM role, which is required for Fargate tasks. To ensure that the console is able to create this IAM role, one of the following must be true:

- Your user has administrator access. For more information, see [Set up to use Amazon ECS](#).
- Your user has the IAM permissions to create a service role. For more information, see [Creating a Role to Delegate Permissions to an AWS Service](#).
- A user with administrator access has manually created the task execution role so that it is available on the account to be used. For more information, see [Amazon ECS task execution IAM role](#).
Important

The security group you select when creating a service with your task definition must have port 80 open for inbound traffic. Add the following inbound rule to your security group. For information about how to create a security group, see Add rules to your security group in the Amazon EC2 User Guide for Linux Instances.

- Type: HTTP
- Protocol: TCP
- Port range: 80
- Source: Anywhere (0.0.0.0/0)

Step 1: Create the cluster

Create a cluster that uses the default VPC.

Before you begin, assign the appropriate IAM permission. For more information, see the section called “Cluster examples”.

2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose Clusters.
4. On the Clusters page, choose Create cluster.
5. Under Cluster configuration, for Cluster name, enter a unique name.

   The name can contain up to 255 letters (uppercase and lowercase), numbers, and hyphens.
6. (Optional) To turn on Container Insights, expand Monitoring, and then turn on Use Container Insights.
7. (Optional) To help identify your cluster, expand Tags, and then configure your tags.

   [Add a tag] Choose Add tag and do the following:
   - For Key, enter the key name.
   - For Value, enter the key value.
[Remove a tag] Choose **Remove** to the right of the tag's Key and Value.

8. Choose **Create**.

**Step 2: Create a task definition**

A task definition is like a blueprint for your application. Each time you launch a task in Amazon ECS, you specify a task definition. The service then knows which Docker image to use for containers, how many containers to use in the task, and the resource allocation for each container.

1. In the navigation pane, choose **Task Definitions**.
2. Choose **Create new Task Definition, Create new revision with JSON**.
3. Copy and paste the following example task definition into the box and then choose **Save**.

```json
{
   "family": "sample-fargate",
   "networkMode": "awsvpc",
   "containerDefinitions": [,
       {
           "name": "fargate-app",
           "image": "public.ecr.aws/docker/library/httpd:latest",
           "portMappings": [,
               {
                   "containerPort": 80,
                   "hostPort": 80,
                   "protocol": "tcp"
               }
           ],
           "essential": true,
           "entryPoint": [,
               "sh",
               "-c"
           ],
           "command": [,
               "/bin/sh -c \"echo \'<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;}</style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1><h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon ECS.</p></div></body'></html>\" >> /usr/local/apache2/htdocs/index.html &
httpd-foreground\"
```
4. Choose **Create**.

**Step 3: Create the service**

Create a service using the task definition.

1. In the navigation pane, choose **Clusters**, and then select the cluster you created in [Step 1: Create the cluster](#).
2. From the **Services** tab, choose **Create**.
3. Under **Deployment configuration**, specify how your application is deployed.
   a. For **Task definition**, choose the task definition you created in [Step 2: Create a task definition](#).
   b. For **Service name**, enter a name for your service.
   c. For **Desired tasks**, enter 1.
4. Under **Networking**, you can create a new security group or choose an existing security group for your task. Ensure that the security group you use has the inbound rule listed under **Prerequisites**.
5. Choose **Create**.

**Step 4: View your service**

2. In the navigation pane, choose **Clusters**.
3. Choose the cluster where you ran the service.
4. In the **Services** tab, under **Service name**, choose the service you created in [Step 3: Create the service](#).
5. Choose the **Tasks** tab, and then choose the task in your service.

6. On the task page, in the **Configuration** section, under **Public IP**, choose **Open address**.

**Step 5: Clean up**

When you are finished using an Amazon ECS cluster, you should clean up the resources associated with it to avoid incurring charges for resources that you are not using.

Some Amazon ECS resources, such as tasks, services, clusters, and container instances, are cleaned up using the Amazon ECS console. Other resources, such as Amazon EC2 instances, Elastic Load Balancing load balancers, and Auto Scaling groups, must be cleaned up manually in the Amazon EC2 console or by deleting the AWS CloudFormation stack that created them.

1. In the navigation pane, choose **Clusters**.

2. On the **Clusters** page, select the cluster you created for this tutorial.

3. Choose the **Services** tab.

4. Select the service, and then choose **Delete**.

5. At the confirmation prompt, enter `delete` and then choose **Delete**.

   Wait until the service is deleted.

6. Choose **Delete Cluster**. At the confirmation prompt, enter `delete cluster-name`, and then choose **Delete**. Deleting the cluster cleans up the associated resources that were created with the cluster, including Auto Scaling groups, VPCs, or load balancers.

**Getting started with Windows on Amazon EC2**

Get started with Amazon ECS using the EC2 launch type by registering a task definition, creating a cluster, and creating a service in the console.

Complete the following steps to get started with Amazon ECS using the EC2 launch type.

**Prerequisites**

Before you begin, complete the steps in [Set up to use Amazon ECS](#) and that your AWS user has the permissions specified in the AdministratorAccess IAM policy example.
The console attempts to automatically create the task execution IAM role, which is required for Fargate tasks. To ensure that the console is able to create this IAM role, one of the following must be true:

- Your user has administrator access. For more information, see [Set up to use Amazon ECS](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/what-is-amazon-ecs.html).
- Your user has the IAM permissions to create a service role. For more information, see [Creating a Role to Delegate Permissions to an AWS Service](https://docs.aws.amazon.com/IAM/latest/userguide/quickstarts-iam-service-role.html).
- A user with administrator access has manually created the task execution role so that it is available on the account to be used. For more information, see [Amazon ECS task execution IAM role](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/task-execution-role.html).

⚠️ **Important**

The security group you select when creating a service with your task definition must have port 80 open for inbound traffic. Add the following inbound rule to your security group. For information about how to create a security group, see [Add rules to your security group](https://docs.aws.amazon.com/AWSEC2/latest/ug/guidetoec2securitygroups.html) in the [Amazon EC2 User Guide for Linux Instances](https://docs.aws.amazon.com/AWSEC2/latest/ug/guidetoec2securitygroups.html).

- Type: HTTP
- Protocol: TCP
- Port range: 80
- Source: Anywhere (0.0.0.0/0)

### Step 1: Create a cluster

An Amazon ECS cluster is a logical grouping of tasks, services, and container instances.

The following steps walk you through creating a cluster with one Amazon EC2 instance registered to it which will enable us to run a task on it. If a specific field is not mentioned, leave the default console values.

**To create a new cluster (Amazon ECS console)**

Before you begin, assign the appropriate IAM permission. For more information, see the section called “Cluster examples”.

2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose Clusters.
4. On the Clusters page, choose Create cluster.
5. Under Cluster configuration, for Cluster name, enter a unique name.
   
   The name can contain up to 255 letters (uppercase and lowercase), numbers, and hyphens.
6. (Optional) To change the VPC and subnets where your tasks and services launch, under Networking, perform any of the following operations:
   
   • To remove a subnet, under Subnets, choose X for each subnet that you want to remove.
   • To change to a VPC other than the default VPC, under VPC, choose an existing VPC, and then under Subnets, select each subnet.
7. To add Amazon EC2 instances to your cluster, expand Infrastructure, and then select Amazon EC2 instances. Next, configure the Auto Scaling group which acts as the capacity provider:
   
   a. To using an existing Auto Scaling group, from Auto Scaling group (ASG), select the group.
   b. To create a Auto Scaling group, from Auto Scaling group (ASG), select Create new group, and then provide the following details about the group:
      
      • For Operating system/Architecture, choose the Amazon ECS-optimized AMI for the Auto Scaling group instances.
      • For EC2 instance type, choose the instance type for your workloads. For more information about the different instance types, see Amazon EC2 Instances.

      Managed scaling works best if your Auto Scaling group uses the same or similar instance types.
      • For SSH key pair, choose the pair that proves your identity when you connect to the instance.
      • For Capacity, enter the minimum number and the maximum number of instances to launch in the Auto Scaling group. Amazon EC2 instances incur costs while they exist in your AWS resources. For more information, see Amazon EC2 Pricing.
8. (Optional) To turn on Container Insights, expand Monitoring, and then turn on Use Container Insights.
9. (Optional) To manage the cluster tags, expand Tags, and then perform one of the following operations:
[Add a tag] Choose Add tag and do the following:

- For Key, enter the key name.
- For Value, enter the key value.

[Remove a tag] Choose Remove to the right of the tag’s Key and Value.

10. Choose Create.

Step 2: Register a task definition

To register the sample task definition with the AWS Management Console

1. In the navigation pane, choose Task Definitions.
2. Choose Create new task definition, Create new task definition with JSON.
3. Copy and paste the following example task definition into the box, and then choose Save.

```json
{
  "containerDefinitions": [
    {
      "command": [
        "New-Item -Path C:\inetpub\wwwroot\index.html -Type file -Value '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head> <body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations! </h2> <p>Your application is now running on a container in Amazon ECS.</p>"; C:\ServiceMonitor.exe w3svc"
      ],
      "entryPoint": [
        "powershell",
        "-Command"
      ],
      "essential": true,
      "cpu": 2048,
      "memory": 4096,
      "image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-ltsc2019",
      "name": "sample_windows_app",
      "portMappings": [
        {
          "hostPort": 443,
          "containerPort": 80,
        }]
    }
  ]
}
```
4. Verify your information and choose Create.

**Step 3: Create a Service**

An Amazon ECS service helps you to run and maintain a specified number of instances of a task definition simultaneously in an Amazon ECS cluster. If any of your tasks should fail or stop for any reason, the Amazon ECS service scheduler launches another instance of your task definition to replace it in order to maintain the desired number of tasks in the service. For more information on services, see Amazon ECS services.

**To create a service**

1. In the navigation pane, choose Clusters.
2. Select the cluster you created in Step 1: Create a cluster.
3. On the Services tab, choose Create.
4. In the Environment section, do the following:
   a. For Compute options, choose Launch type.
   b. For Launch type, select EC2
5. In the Deployment configuration section, do the following:
   a. For Family, choose the task definition you created in Step 2: Register a task definition.
   b. For Service name, enter a name for your service.
   c. For Desired tasks, enter 1.
6. Review the options and choose Create.
7. Choose View service to review your service.

**Step 4: View your Service**

The service is a web-based application so you can view its containers with a web browser.

2. In the navigation pane, choose Clusters.
3. Choose the cluster where you ran the service.
4. In the Services tab, under Service name, choose the service you created in Step 3: Create a Service.
5. Choose the Tasks tab, and then choose the task in your service.
6. On the task page, in the Configuration section, under Public IP, choose Open address. The screen shot below is the expected output.

![Amazon ECS Sample App](image)

**Step 5: Clean Up**

When you are finished using an Amazon ECS cluster, you should clean up the resources associated with it to avoid incurring charges for resources that you are not using.

Some Amazon ECS resources, such as tasks, services, clusters, and container instances, are cleaned up using the Amazon ECS console. Other resources, such as Amazon EC2 instances, Elastic Load Balancing load balancers, and Auto Scaling groups, must be cleaned up manually in the Amazon EC2 console or by deleting the AWS CloudFormation stack that created them.

1. In the navigation pane, choose Clusters.
2. On the **Clusters** page, select the cluster cluster you created for this tutorial.

3. Choose the **Services** tab.

4. Select the service, and then choose **Delete**.

5. At the confirmation prompt, enter `delete` and then choose **Delete**.

   Wait until the service is deleted.

6. Choose **Delete Cluster**. At the confirmation prompt, enter `delete cluster-name`, and then choose **Delete**. Deleting the cluster cleans up the associated resources that were created with the cluster, including Auto Scaling groups, VPCs, or load balancers.
Amazon ECS developer tools overview

Whether you are part of a large enterprise or a startup, Amazon ECS offers a variety of tools that can help you to get your containers up and running quickly, regardless of your level of expertise. You can work with Amazon ECS in the following ways.

- Learn about, develop, manage and visualize your container applications and services using the AWS Management Console.
- Perform specific actions to Amazon ECS resources with automated deployments through programming or scripts using the AWS Command Line Interface, AWS SDKs or the ECS API.
- Define and manage all AWS resources in your environment with automated deployment using AWS CloudFormation.
- Use the complete AWS Copilot CLI end-to-end developer workflow to create, release, and operate container applications that comply with AWS best practices for infrastructure.
- Using your preferred programming language, define infrastructure or architecture as code with the AWS CDK.
- Containerize applications that are hosted on premises or on Amazon EC2 instances or both by using the AWS App2Container integrated portability and tooling ecosystem for containers.
- Deploy an application to Amazon ECS or test local containers with containers running in Amazon ECS using the Docker Compose file format with the Amazon ECS CLI.
- Launch containers from Docker Desktop integration with Amazon ECS using Amazon ECS in Docker Desktop.

AWS Management Console

The AWS Management Console is a browser-based interface for managing Amazon ECS resources. The console provides a visual overview of the service, making it easy to explore Amazon ECS features and functions without needing to use additional tools. Many related tutorials and walkthroughs are available that can guide you through use of the console.

For a tutorial that guides you through the console, see Getting started with Amazon ECS.

When starting out, many customers prefer using the console because it provides instant visual feedback on whether the actions they take succeed. AWS customers that are familiar with the AWS
Management Console, can easily manage related resources such as load balancers and Amazon EC2 instances.

Start with the AWS Management Console.

**AWS Command Line Interface**

The AWS Command Line Interface (AWS CLI) is a unified tool that you can use to manage your AWS services. With this one tool alone, you can both control multiple AWS services and automate these services through scripts. The Amazon ECS commands in the AWS CLI are a reflection of the Amazon ECS API.

The AWS CLI is suitable for customers who prefer and are used to scripting and interfacing with a command line tool and know exactly which actions they want to perform on their Amazon ECS resources. The AWS CLI is also helpful to customers who want to familiarize themselves with the Amazon ECS APIs. Customers can use the AWS CLI to perform a number of operations on Amazon ECS resources, including Create, Read, Update, and Delete operations, directly from the command line interface.

Use the AWS CLI if you are or want to become familiar with the Amazon ECS APIs and corresponding CLI commands and want to write automated scripts and perform specific actions on Amazon ECS resources.

**AWS CloudFormation**

[AWS CloudFormation](https://aws.amazon.com/cloudformation/) and [Terraform](https://www.terraform.io/) for Amazon ECS both provide powerful ways for you to define your infrastructure as code. You can easily track which version of your template or AWS CloudFormation stack is running at any time and rollback to a previous version if needed. You can perform infrastructure and application deployments in the same automated fashion. This flexibility and automation is what makes AWS CloudFormation and Terraform two popular formats for deploying workloads to Amazon ECS from continuous delivery pipelines.

For more information about AWS CloudFormation, see [Creating Amazon ECS resources with AWS CloudFormation](https://docs.aws.amazon.com/lambda/latest/dg/lambda-aws-cloudformation.html).
Use AWS CloudFormation or Terraform if you want to automate infrastructure deployments and applications on Amazon ECS and explicitly define and manage all of the AWS resources in your environment.

**AWS Copilot CLI**

The AWS Copilot CLI (command line interface) is a comprehensive tool that allows customers to deploy and operate applications packaged in containers and environments on Amazon ECS directly from their source code. When using AWS Copilot you can perform these operations without understanding AWS and Amazon ECS elements such as Application Load Balancers, public subnets, tasks, services, and clusters. AWS Copilot creates AWS resources on your behalf from opinionated service patterns, such as a load balanced web service or backend service, providing an immediate production environment for containerized applications. You can deploy through an AWS CodePipeline pipeline across multiple environments, accounts, or Regions, all of which can be managed within the CLI. By using AWS Copilot you can also perform operator tasks, such as viewing logs and the health of your service. AWS Copilot is an all-in-one tool that helps you more easily manage your cloud resources so that you can focus on developing and managing your applications.

For more information, see [Using the AWS Copilot command line interface](#).

Use the AWS Copilot complete end-to-end developer workflow to create, release, and operate container applications that comply with AWS best practices for infrastructure.

**AWS CDK**

The AWS Cloud Development Kit (AWS CDK) is an open source software development framework that you can use to model and provision your cloud application resources using familiar programming languages. AWS CDK provisions your resources in a safe, repeatable manner through AWS CloudFormation. Using the CDK, customers can generate their environment with fewer lines of code using the same language they used to build their application. Amazon ECS provides a module in the CDK that is named `ecs-patterns`, which creates common architectures. An available pattern is `ApplicationLoadBalancedFargateService()`. This pattern creates a cluster, task definition, and additional resources to run a load balanced Amazon ECS service on AWS Fargate.

For more information, see [Getting started with Amazon ECS using the AWS CDK](#).
Use the AWS CDK if you want to define infrastructure or architecture as code in your preferred programming language. For example, you can use the same language that you use to write your applications.

**AWS App2Container**

Sometimes enterprise customers might already have applications that are hosted on premises or on EC2 instances or both. They are interested in the portability and tooling ecosystem of containers specifically on Amazon ECS, and need to containerize first. AWS App2Container allows you to do just that. App2Container (A2C) is a command line tool for modernizing .NET and Java applications into containerized applications. A2C analyzes and builds an inventory of all applications running in virtual machines, on premises or in the cloud. After you select the application you want to containerize, A2C packages the application artifact and identified dependencies into container images. It then configures the network ports and generates the Amazon ECS task. Last, it creates a CloudFormation template that you can deploy or modify if needed.

For more information, see [Getting started with AWS App2Container](#).

Use App2Container if you have applications that are hosted on premises or on Amazon EC2 instances or both.

**Amazon ECS CLI**

The Amazon ECS CLI allows you to run your applications on Amazon ECS and AWS Fargate using the Docker Compose file format. You can quickly provision resources, push and pull images using Amazon ECR, and monitor running applications on Amazon ECS or AWS Fargate. You can also test containers running locally along with containers in the cloud within the CLI.

For more information, see [Using the Amazon ECS command line interface](#).

Use the ECS CLI if you have a Compose application and want to deploy it to Amazon ECS, or test local containers with containers running in Amazon ECS in the cloud.

**Docker Desktop integration with Amazon ECS**

AWS and Docker have collaborated to make a simplified developer experience that you can use to deploy and manage containers on Amazon ECS directly using Docker tools. You can now build and...
test your containers locally using Docker Desktop and Docker Compose, and then deploy them to Amazon ECS on Fargate. To get started with the Amazon ECS and Docker integration, download Docker Desktop and optionally sign up for a Docker ID. For more information, see [Docker Desktop](#) and [Docker ID signup](#).

Beginners to containers often start learning about containers by using Docker tools such as the Docker CLI and Docker Compose. This makes using the Docker Compose CLI plugin for Amazon ECS a natural next step in running containers on AWS after testing locally. Docker provides a walkthrough on deploying containers on Amazon ECS. For more information, see [Docker Compose CLI - Amazon ECS](#).

You can take advantage of additional Amazon ECS features, such as service discovery, load balancing and other AWS resources for use with their applications with Docker Desktop.

You can also download the Docker Compose CLI plugin for Amazon ECS directly from GitHub. For more information, see [Docker Compose CLI plugin for Amazon ECS](#) on GitHub.

**AWS SDKs**

You can also use AWS SDKs to manage Amazon ECS resources and operations from a variety of programming languages. The SDKs provide modules to help take care of tasks, including tasks in the following list.

- Cryptographically signing your service requests
- Retrying requests
- Handling error responses

For more information about the available SDKs, see [Tools for Amazon Web Services](#).

**Summary**

With the many options to choose from, you can choose the options that are best suited to you. Consider the following options.

- If you are visually oriented, you can visually create and operate containers using the AWS Management Console.
- If you prefer CLIs, consider using AWS Copilot or the AWS CLI. Alternatively, if you prefer the Docker ecosystem, you can take advantage of the functionality of ECS from within the Docker CLI.
to deploy to AWS. After these resources are deployed, you can continue managing them through
the CLI or visually through the Console.

- If you are a developer, you can use the AWS CDK to define your infrastructure in the same
language as your application. You can use the CDK and AWS Copilot to export to CloudFormation
templates where you can change granular settings, add other AWS resources, and automate
deployments through scripting or a CI/CD pipeline such as AWS CodePipeline.

The AWS CLI, SDKs, or ECS API are useful tools for automating actions on ECS resources, making
them ideal for deployment. To deploy applications using AWS CloudFormation you can use a
variety of programming languages or a simple text file to model and provision all the resources
needed for your applications. You can then deploy your application across multiple Regions and
accounts in an automated and secure manner. For example, you can define your ECS cluster,
services, task definitions, or capacity providers, as code in a file and deploy through the AWS CLI
CloudFormation commands.

To perform operations tasks, you can view and manage resources programmatically using the AWS
CLI, SDK, or ECS API. Commands like describe-tasks or list-services display the latest
metadata or a list of all resources. Similar to deployments, customers can write an automation that
includes commands such as update-service to provide corrective action upon the detection of
a resource that has stopped unexpectedly. You can also operate your services using AWS Copilot.
Commands like copilot svc logs or copilot app show provide details about each of your
microservices, or about your application as a whole.

Customers can use any of the available tooling mentioned in this document and use them in
variety of combinations. ECS tooling offers various paths to graduate from certain tools to use
others that fit your changing needs. For example, you can opt for more granular control over
resources or more automation as needed. ECS also offers a large range of tools for a wide range of
needs and levels of expertise.

**Using the AWS Copilot command line interface**

The AWS Copilot command line interface (CLI) commands simplify building, releasing, and
operating production-ready containerized applications on Amazon ECS from a local development
environment. The AWS Copilot CLI aligns with developer workflows that support modern
application best practices: from using infrastructure as code to creating a CI/CD pipeline
provisioned on behalf of a user. Use the AWS Copilot CLI as part of your everyday development and
testing cycle as an alternative to the AWS Management Console.
AWS Copilot currently supports Linux, macOS, and Windows systems. For more information about the latest version of the AWS Copilot CLI, see Releases.

**Note**

The source code for the AWS Copilot CLI is available on GitHub. The latest CLI documentation is available on the AWS Copilot website. We recommend that you submit issues and pull requests for changes that you would like to have included. However, Amazon Web Services doesn’t currently support running modified copies of AWS Copilot code. Report issues with AWS Copilot by connecting with us on Gitter or GitHub where you can open issues, provide feedback, and report bugs.

## Installing the AWS Copilot CLI

The AWS Copilot CLI can be installed on Linux or macOS systems either by using Homebrew or by manually downloading the binary. Use the following steps with your preferred installation method.

### Installing the AWS Copilot CLI using Homebrew

The following command is used to install the AWS Copilot CLI on your macOS or Linux system using Homebrew. Before installation, you should have Homebrew installed. For more information, see Homebrew.

```
brew install aws/tap/copilot-cli
```

### Manually installing the AWS Copilot CLI

As an alternative to Homebrew, you can manually install the AWS Copilot CLI on your macOS or Linux system. Use the following command for your operating system to download the binary, apply execute permissions to it, and then verify it works by listing the help menu.

**macOS**

For macOS:

```
sudo curl -Lo /usr/local/bin/copilot https://github.com/aws/copilot-cli/releases/latest/download/copilot-darwin \
    && sudo chmod +x /usr/local/bin/copilot \
    && copilot --help
```
For macOS ARM systems:

```bash
sudo curl -Lo /usr/local/bin/copilot https://github.com/aws/copilot-cli/releases/latest/download/copilot-darwin-arm64 \
    && sudo chmod +x /usr/local/bin/copilot \
    && copilot --help
```

For Linux x86 (64-bit) systems:

```bash
sudo curl -Lo /usr/local/bin/copilot https://github.com/aws/copilot-cli/releases/latest/download/copilot-linux \
    && sudo chmod +x /usr/local/bin/copilot \
    && copilot --help
```

For Linux ARM systems:

```bash
sudo curl -Lo /usr/local/bin/copilot https://github.com/aws/copilot-cli/releases/latest/download/copilot-linux-arm64 \
    && sudo chmod +x /usr/local/bin/copilot \
    && copilot --help
```

Windows

Using Powershell, run the following command:

```powershell
New-Item -Path 'C:\copilot' -ItemType directory; `
```

(Optional) Verify the manually installed AWS Copilot CLI using PGP signatures

The AWS Copilot CLI executables are cryptographically signed using PGP signatures. The PGP signatures can be used to verify the validity of the AWS Copilot CLI executable. Use the following steps to verify the signatures using the GnuPG tool.

1. Download and install GnuPG. For more information, see the [GnuPG website](https://gnupg.org/).
We recommend using Homebrew. Install Homebrew using the instructions from their website. For more information, see Homebrew. After Homebrew is installed, use the following command from your macOS terminal.

```
brew install gnupg
```

Install gpg using the package manager on your flavor of Linux.

Download the Windows simple installer from the GnuPG website and install as an Administrator. After you install GnuPG, close and reopen the Administrator PowerShell. For more information, see GnuPG Download.

2. Verify the GnuPG path is added to your environment path.

**macOS**

```
echo $PATH
```

If you do not see the GnuPG path in the output, run the following command to add it to the path.

```
PATH=$PATH:<path to GnuPG executable files>
```

**Linux**

```
echo $PATH
```

If you do not see the GnuPG path in the output, run the following command to add it to the path.

```
export PATH=$PATH:<path to GnuPG executable files>
```
Windows

Write-Output $Env:PATH

If you do not see the GnuPG path in the output, run the following command to add it to the path.

$Env:PATH += ";<path to GnuPG executable files>"

3. Create a local plain text file.

macOS

On the terminal, enter:

```
touch <public_key_filename.txt>
```

Open the file with TextEdit.

Linux

Create a text file in a text editor such as gedit. Save as public_key_filename.txt

Windows

Create a text file in a text editor such as Notepad. Save as public_key_filename.txt

4. Add the following contents of the Amazon ECS PGP public key and save the file.

```
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v2

mQINBFq1SasBEAD1iGcT1NVJ1ydfN8DqebYYe9ne3dt6jKFmKowLmm6LLGJe7HUjGtqhCWRDkN+qPpHqdArRgDZAtn2pXY5fEipHgar4CP8QgRnRMO2f1741mavr4Vg7K/KH8VH1q2uRw32/B94XLEGrbGTmWFdKuxoPcttbBqaMj3Lgn6Pe+6xVWRkChQuBoQAhjBQ+bEm0kNy0LjNgjN1nL3UMAG56t8E3LANIgGgEnpNsB1UwfW1uP0GzoTxN+6pHBjrrKIL/1v/ETU4FXpYw2zvhWNahxeNRnoYj3uycHkeliCw4kJ0+skizBg02K7oVX80c3j5+ZilhL/qDLXmUCb2az5cMM1m0o8EKX5HaNuj1KfwJXqX6NNT1c01FTr7Tw5fMNId3FanLgy/ZnIrSaqJ0L6zRSq804LN10WBVbndExk2Kt+5kFxns1BPgfPgrjshQ+KTHMa9Y8Z7yUc64B3i9F9N17FJuSsfqbdkvRlSQRbcBG9qX3rjAEhieJzVMEUNl+EgeCkxj5xuSkNU7zw2c3hQzEcrADLV+hvFJkt0z9Gm6xzbp1tnWWCz4xrIwtcEBAZqE+M1DheVd78a3gIsEaSTfQq0osYXaqQbvlNSWOoc1y/SZb

Installing the AWS Copilot CLI
The details of the Amazon ECS PGP public key for reference:

- **Key ID:** BCE9D9A42D51784F
- **Type:** RSA
- **Size:** 4096/4096
- **Expires:** Never
- **User ID:** Amazon ECS
- **Key fingerprint:** F34C 3DDA E729 26B0 79BE AEC6 BCE9 D9A4 2D51 784F

You may close the text editor.

5. Import the file with the Amazon ECS PGP public key with the following command in the terminal.
6. Download the AWS Copilot CLI signatures. The signatures are ASCII detached PGP signatures stored in files with the extension `.asc`. The signatures file has the same name as its corresponding executable, with `.asc` appended.

macOS

For macOS systems, run the following command.

```
```

Linux

For Linux x86 (64-bit) systems, run the following command.

```
```

For Linux ARM systems, run the following command.

```
sudo curl -Lo copilot.asc https://github.com/aws/copilot-cli/releases/latest/download/copilot-linux-arm64.asc
```

Windows

Using Powershell, run the following command.

```
```

7. Verify the signature with the following command.

- For macOS and Linux systems:

```
gpg --verify copilot.asc /usr/local/bin/copilot
```

- For Windows systems:
gpg --verify 'C:\copilot\copilot.asc' 'C:\copilot\copilot.exe'

Expected output:

gpg: Signature made Tue Apr  3 13:29:30 2018 PDT
    using RSA key DE3CBD61ADAF8B8E
    Good signature from "Amazon ECS <ecs-security@amazon.com>" [unknown]

gpg: WARNING: This key is not certified with a trusted signature!
    There is no indication that the signature belongs to the owner.
    Primary key fingerprint: F34C 3DDA E729 26B0 79BE  AEC6 BCE9 D9A4 2D51 784F
    Subkey fingerprint: EB3D F841 E2C9 212A 2BD4  2232 DE3C BD61 ADAF 8B8E

⚠ Important

The warning in the output is expected and is not problematic. It occurs because there is not a chain of trust between your personal PGP key (if you have one) and the Amazon ECS PGP key. For more information, see Web of trust.

8. For Windows installations, run the following command on Powershell to add AWS Copilot directory to the path.

$Env:PATH += ";<path to Copilot executable files>"

Next steps

After installation, learn how to deploy an Amazon ECS application using AWS Copilot. For more information, see Getting started with Amazon ECS using AWS Copilot.

Getting started with Amazon ECS using AWS Copilot

Get started with Amazon ECS using AWS Copilot by deploying an Amazon ECS application.

Prerequisites

Before you begin, make sure that you meet the following prerequisites:

• Set up an AWS account. For more information see Set up to use Amazon ECS.
• Install the AWS Copilot CLI. Releases currently support Linux and macOS systems. For more information, see Installing the AWS Copilot CLI.

• Install and configure the AWS CLI. For more information, see AWS Command Line Interface.

• Run aws configure to set up a default profile that the AWS Copilot CLI will use to manage your application and services.

• Install and run Docker. For more information, see Get started with Docker.

Deploy your application using one command

Make sure that you have the AWS command line tool installed and have already run aws configure before you start.

Deploy the application using the following command.

```
    git clone https://github.com/aws-samples/amazon-ecs-cli-sample-app.git demo-app && 
    cd demo-app && 
    copilot init --app demo 
    --name api 
    --type 'Load Balanced Web Service' 
    --dockerfile './Dockerfile' 
    --port 80 
    --deploy
```

Deploy your application step by step

Step 1: Configure your credentials

Run aws configure to set up a default profile that the AWS Copilot CLI uses to manage your application and services.

```bash
aws configure
```

Step 2: Clone the demo app

Clone a simple Flask application and Dockerfile.

```bash
    git clone https://github.com/aws-samples/amazon-ecs-cli-sample-app.git demo-app
```
Step 3: Set up your application

1. From within the demo-app directory, run the init command.

   For Windows users, run the init command from the folder that contains the downloaded copilot.exe file.

   copilot init

   AWS Copilot walks you through the setup of your first application and service with a series of terminal prompts, starting with next step. If you have already used AWS Copilot to deploy applications, you're prompted to choose one from a list of application names.

2. Name your application.

   What would you like to name your application? [? for help]

   Enter demo.

Step 4: Set up an ECS Service in your "demo" Application

1. You're prompted to choose a service type. You're building a simple Flask application that serves a small API.

   Which service type best represents your service's architecture? [Use arrows to move, type to filter, ? for more help]
   > Load Balanced Web Service
     Backend Service
     Scheduled Job

   Choose Load Balanced Web Service.

2. Provide a name for your service.

   What do you want to name this Load Balanced Web Service? [? for help]

   Enter api for your service name.

3. Select a Dockerfile.
Choose **Dockerfile**.

For Windows users, enter the path to the Dockerfile in the `demo-app` folder (`...\demo-app \Dockerfile`).

4. Define port.

Which port do you want customer traffic sent to? [? for help] (80)

Enter **80** or accept default.

5. You will see a log showing the application resources being created.

Creating the infrastructure to manage services under application demo.

6. After the application resources are created, deploy a test environment.

Would you like to deploy a test environment? [? for help] (y/N)

Enter **y**.

Proposing infrastructure changes for the test environment.

7. You will see a log displaying the status of your application deployment.

Note: It’s best to run this command in the root of your Git repository.

Welcome to the Copilot CLI! We’re going to walk you through some questions to help you get set up with an application on ECS. An application is a collection of containerized services that operate together.

Use existing application: **No**
Application name: **demo**
Workload type: **Load Balanced Web Service**
Service name: **api**
Dockerfile: **./Dockerfile**
no EXPOSE statements in Dockerfile ./Dockerfile
Port: 80
Ok great, we'll set up a Load Balanced Web Service named api in application demo listening on port 80.

# Created the infrastructure to manage services under application demo.

# Wrote the manifest for service api at copilot/api/manifest.yml
Your manifest contains configurations like your container size and port (:80).

# Created ECR repositories for service api.

All right, you're all set for local development.

Deploy: Yes

# Created the infrastructure for the test environment.
- Virtual private cloud on 2 availability zones to hold your services [Complete]
- Virtual private cloud on 2 availability zones to hold your services [Complete]
  - Internet gateway to connect the network to the internet [Complete]
  - Public subnets for internet facing services [Complete]
  - Private subnets for services that can't be reached from the internet [Complete]
  - Routing tables for services to talk with each other [Complete]
- ECS Cluster to hold your services [Complete]
# Linked account aws_account_id and region region to application demo.

# Created environment test in region region under application demo.

Environment test is already on the latest version v1.0.0, skip upgrade.
[+] Building 0.8s (7/7) FINISHED
=> [internal] load .dockerignore 0.1s
=> => transferring context: 2B 0.0s
=> [internal] load build definition from Dockerfile 0.0s
=> => transferring dockerfile: 37B 0.0s
Step 5: Verify your application is running

View the status of your application by using the following commands.

List all of your AWS Copilot applications.
Step 6. Learn to create a CI/CD Pipeline

Instructions can be found in the ECS Workshop detailing how to fully automate a CI/CD pipeline and git workflow using AWS Copilot.
Step 7: Clean up

Run the following command to delete and clean up all resources.

```
copilot app delete
```

Getting started with Amazon ECS using the AWS CDK

The AWS Cloud Development Kit (AWS CDK) is an Infrastructure-as-Code (IAC) framework that you can use to define AWS cloud infrastructure by using a programming language of your choosing. To define your own cloud infrastructure, you first write an app (in one of the CDK's supported languages) that contains one or more stacks. Then, you synthesize it to an AWS CloudFormation template and deploy your resources to your AWS account. Follow the steps in this topic to deploy a containerized web server with Amazon Elastic Container Service (Amazon ECS) and the AWS CDK on Fargate.

The AWS Construct Library, included with the CDK, provides modules that you can use to model the resources that AWS services provide. For popular services, the library provides curated constructs with smart defaults and best practices. One of these modules, specifically `aws-ecs-patterns`, provides high-level abstractions that you can use to define your containerized service and all the necessary supporting resources in a few lines of code.

This topic uses the `ApplicationLoadBalancedFargateService` construct. This construct deploys an Amazon ECS service on Fargate behind an application load balancer. The `aws-ecs-patterns` module also includes constructs that use a network load balancer and run on Amazon EC2.

Before starting this task, set up your AWS CDK development environment, and install the AWS CDK by running the following command. For instructions on how to set up your AWS CDK development environment, see [Getting Started With the AWS CDK - Prerequisites](#).

```
npm install -g aws-cdk
```

Note

These instructions assume you are using AWS CDK v2.
Topics

- **Step 1: Set up your AWS CDK project**
- **Step 2: Use the AWS CDK to define a containerized web server on Fargate**
- **Step 3: Test the web server**
- **Step 4: Clean up**
- **Next steps**

**Step 1: Set up your AWS CDK project**

Create a directory for your new AWS CDK app and initialize the project.

**TypeScript**

```bash
mkdir hello-ecs
cd hello-ecs
cdk init --language typescript
```

**JavaScript**

```bash
mkdir hello-ecs
cd hello-ecs
cdk init --language javascript
```

**Python**

```bash
mkdir hello-ecs
cd hello-ecs
cdk init --language python
```

After the project is started, activate the project's virtual environment and install the AWS CDK's baseline dependencies.

```bash
source .venv/bin/activate
python -m pip install -r requirements.txt
```

**Java**

```bash
mkdir hello-ecs
```
Import this Maven project to your Java IDE. For example, in Eclipse, use **File > Import > Maven > Existing Maven Projects**.

**C#**

```bash
mkdir hello-ecs
cd hello-ecs
cdk init --language csharp
```

---

**Note**

The AWS CDK application template uses the name of the project directory to generate names for source files and classes. In this example, the directory is named `hello-ecs`. If you use a different project directory name, your app won't match these instructions.

AWS CDK v2 includes stable constructs for all AWS services in a single package that's called `aws-cdk-lib`. This package is installed as a dependency when you initialize the project. When working with certain programming languages, the package is installed when you build the project for the first time. This topic covers how to use an Amazon ECS Patterns construct, which provides high-level abstractions for working with Amazon ECS. This module relies on Amazon ECS constructs and other constructs to provision the resources that your Amazon ECS application needs.

The names that you use to import these libraries into your CDK application might differ slightly depending on which programming language you use. For reference, the following are the names that are used in each supported CDK programming language.

**TypeScript**

```bash
aws-cdk-lib/aws-ecs
aws-cdk-lib/aws-ecs-patterns
```

**JavaScript**

```bash
aws-cdk-lib/aws-ecs
aws-cdk-lib/aws-ecs-patterns
```
Step 2: Use the AWS CDK to define a containerized web server on Fargate

Use the container image [amazon-ecs-sample](https://hub.docker.com/r/amazon/ecs-sample/) from DockerHub. This image contains a PHP web app that runs on Amazon Linux 2.

In the AWS CDK project that you created, edit the file that contains the stack definition to resemble one of the following examples.

**Note**

A stack is a unit of deployment. All resources must be in a stack, and all the resources that are in a stack are deployed at the same time. If a resource fails to deploy, any other resources that were already deployed are rolled back. An AWS CDK app can contain multiple stacks, and resources in one stack can refer to resources in another stack.

TypeScript

Update `lib/hello-ecs-stack.ts` so that it resembles the following.

```typescript
import * as cdk from 'aws-cdk-lib';
import { Construct } from 'constructs';
```
import * as ecs from 'aws-cdk-lib/aws-ecs';
import * as ecsp from 'aws-cdk-lib/aws-ecs-patterns';

export class HelloEcsStack extends cdk.Stack {
    constructor(scope: Construct, id: string, props?: cdk.StackProps) {
        super(scope, id, props);

        new ecsp.ApplicationLoadBalancedFargateService(this, 'MyWebServer', {
            taskImageOptions: {
                image: ecs.ContainerImage.fromRegistry('amazon/amazon-ecs-sample'),
            },
            publicLoadBalancer: true
        });
    }
}

JavaScript

Update lib/hello-ecs-stack.js so that it resembles the following.

const cdk = require('aws-cdk-lib');
const { Construct } = require('constructs');
const ecs = require('aws-cdk-lib/aws-ecs');
const ecsp = require('aws-cdk-lib/aws-ecs-patterns');

class HelloEcsStack extends cdk.Stack {
    constructor(scope = Construct, id = string, props = cdk.StackProps) {
        super(scope, id, props);

        new ecsp.ApplicationLoadBalancedFargateService(this, 'MyWebServer', {
            taskImageOptions: {
                image: ecs.ContainerImage.fromRegistry('amazon/amazon-ecs-sample'),
            },
            publicLoadBalancer: true
        });
    }
}

module.exports = { HelloEcsStack }

Python

Update hello-ecs/hello_ecs_stack.py so that it resembles the following.
import aws_cdk as cdk
from constructs import Construct

import aws_cdk.aws_ecs as ecs
import aws_cdk.aws_ecs_patterns as ecsp

class HelloEcsStack(cdk.Stack):
    def __init__(self, scope: Construct, construct_id: str, **kwargs) -> None:
        super().__init__(scope, construct_id, **kwargs)

        ecsp.ApplicationLoadBalancedFargateService(self, "MyWebServer",
            task_image_options=ecsp.ApplicationLoadBalancedTaskImageOptions(
                image=ecs.ContainerImage.from_registry("amazon/amazon-ecs-sample"),
                public_load_balancer=True
            )
        )

Java

Update src/main/java/com.myorg/HelloEcsStack.java so that it resembles the following.

package com.myorg;

import software.constructs.Construct;
import software.amazon.awscdk.Stack;
import software.amazon.awscdk.StackProps;

import software.amazon.awscdk.services.ecs.ContainerImage;
import software.amazon.awscdk.services.ecs.patterns.ApplicationLoadBalancedFargateService;
import software.amazon.awscdk.services.ecs.patterns.ApplicationLoadBalancedTaskImageOptions;

public class HelloEcsStack extends Stack {
    public HelloEcsStack(final Construct scope, final String id) {
        this(scope, id, null);
    }

    public HelloEcsStack(final Construct scope, final String id, final StackProps props) {
        super(scope, id, props);
    }

    Step 2: Use the AWS CDK to define a containerized web server on Fargate
The preceding short snippet includes the following:

- The service's logical name: MyWebServer.
- The container image that was obtained from DockerHub: amazon/amazon-ecs-sample.
• Other relevant information, such as the fact that the load balancer has a public address and is accessible from the Internet.

The AWS CDK will create all the resources that are required to deploy the web server including the following resources. These resources were omitted in this example.

• Amazon ECS cluster
• Amazon VPC and Amazon EC2 instances
• Auto Scaling group
• Application Load Balancer
• IAM roles and policies

Some automatically provisioned resources are shared by all Amazon ECS services defined in the stack.

Save the source file, then run the `cdk synth` command in your application's main directory. The AWS CDK runs the app and synthesizes an AWS CloudFormation template from it, and then displays the template. The template is an approximately 600-line YAML file. The beginning of the file is shown here. Your template might differ from this example.

```
Resources:
  MyWebServerLB3B5FD3AB:
    Type: AWS::ElasticLoadBalancingV2::LoadBalancer
    Properties:
      LoadBalancerAttributes:
        - Key: deletion_protection.enabled
          Value: "false"
      Scheme: internet-facing
      SecurityGroups:
        - Fn::GetAtt:
          - MyWebServerLBSecurityGroup01B285AA
          - GroupId
      Subnets:
        - Ref: EcsDefaultClusterMnL3mNNYNVpcPublicSubnet1Subnet3C273B99
        - Ref: EcsDefaultClusterMnL3mNNYNVpcPublicSubnet2Subnet95FF715A
      Type: application
    DependsOn:
      - EcsDefaultClusterMnL3mNNYNVpcPublicSubnet1DefaultRouteFF4E2178
```
To deploy the service in your AWS account, run the `cdk deploy` command in your application's main directory. You're asked to approve the IAM policies that the AWS CDK generated.

The deployment takes several minutes during which the AWS CDK creates several resources. The last few lines of the output from the deployment include the load balancer's public hostname and your new web server's URL. They are as follows.

```plaintext
Outputs:
```

**Step 3: Test the web server**

Copy the URL from the deployment output and paste it into your web browser. The following welcome message from the web server is displayed.
Simple PHP App

Congratulations

Your PHP application is now running on a container in Amazon ECS.
The container is running PHP version 5.4.16.

Step 4: Clean up

After you're finished with the web server, end the service using the CDK by running the `cdk destroy` command in your application's main directory. Doing this prevents you from incurring any unintended charges in the future.

Next steps

To learn more about how to develop AWS infrastructure using the AWS CDK, see the AWS CDK Developer Guide.

Creating Amazon ECS resources with AWS CloudFormation

Amazon ECS is integrated with AWS CloudFormation, a service that you can use to model and set up AWS resources with templates that you define. This way, you can spend less time creating and managing your resources and infrastructure. Using AWS CloudFormation, you can create a template that describes all the AWS resources that you want, such as specific Amazon ECS clusters. Then, AWS CloudFormation takes care of provisioning and configuring those resources for you.

When you use AWS CloudFormation, you can reuse your template to set up your Amazon ECS resources in a consistent and repeatable manner. You describe your resources one time, and then provision the same resources again across multiple AWS accounts and AWS Regions.

Amazon ECS and AWS CloudFormation templates

To provision and configure resources for Amazon ECS and related services, make sure that you're familiar with AWS CloudFormation templates. AWS CloudFormation templates are text files in the JSON or YAML format that describe the resources that you want to provision in your AWS CloudFormation stacks. If you're unfamiliar with either the JSON or YAML format, or both, you can use AWS CloudFormation Designer to get started using AWS CloudFormation templates. For more information, see What is AWS CloudFormation Designer? in the AWS CloudFormation User Guide.

Amazon ECS supports creating clusters, task definitions, services, and task sets in AWS CloudFormation. The following examples demonstrate how to create resources with these templates using the AWS CLI. You can also create these resources using the AWS CloudFormation console. For more information about how to create resources using the AWS CloudFormation console, see the AWS CloudFormation User Guide.

Example templates

Creating Amazon ECS resources using separate stacks

The following examples show how to create Amazon ECS resources by using separate stacks for each resource.
Amazon ECS task definitions

You can use the following template to create a Fargate Linux task.

**JSON**

```json
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Resources": {
        "ECSTaskDefinition": {
            "Type": "AWS::ECS::TaskDefinition",
            "Properties": {

Amazon ECS clusters

You can use the following template to create an empty cluster.

JSON

```json
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Resources": {
    "ECSCluster": {
      "Type": "AWS::ECS::Cluster",
      "Properties": {
        "ClusterName": "MyEmptyCluster"
      }
    }
  }
}
```

YAML

```yaml
AWSTemplateFormatVersion: 2010-09-09
Resources:
  ECSCluster:
```
Creating multiple Amazon ECS resources in one stack

You can use the following example template to create multiple Amazon ECS resources in one stack. The template creates an Amazon ECS cluster that's named CFNCluster. The cluster contains a Linux Fargate task definition that sets up a web server. The template also creates a service that's named cfn-service that launches and maintains the task defined by the task definition. Before you use this template, make sure that the subnet and security group IDs in the service's NetworkConfiguration all belong to the same VPC and that the security group has the necessary rules. For more information about security group rules, see Security group rules in the Amazon VPC user guide.

JSON

```json
{
    "AWSTemplateFormatVersion": "2010-09-09",
    "Resources": {
        "ECSCluster": {
            "Type": "AWS::ECS::Cluster",
            "Properties": {
                "ClusterName": "CFNCluster"
            }
        },
        "ECSTaskDefinition": {
            "Type": "AWS::ECS::TaskDefinition",
            "Properties": {
                "ContainerDefinitions": [
                    {
                        "Command": [
                            "/bin/sh -c "'echo '<html> <head> <title>Amazon ECS Sample
App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon ECS.</p> </div></body> </html>' > /usr/local/apache2/htdocs/index.html && httpd-foreground"
                    ],
                    "EntryPoint": [
                        "sh",
                        "-c"
                    ]
                }
            }
        }
    }
}
```
Example templates

```json
{
    "essential": true,
    "image": "httpd:2.4",
    "logConfiguration": {
        "logDriver": "awslogs",
        "options": {
            "awslogs-group": "/ecs/fargate-task-definition",
            "awslogs-region": "us-east-1",
            "awslogs-stream-prefix": "ecs"
        }
    },
    "name": "sample-fargate-app",
    "portMappings": [
        {

        ]
    },
    "TaskDefinition": {
        "Ref": "ECSTaskDefinition"
    }
}

YAML

AWSTemplateFormatVersion: 2010-09-09
Resources:
    ECSCluster:
        Type: 'AWS::ECS::Cluster'
        Properties:
            ClusterName: CFNCluster
    ECSTaskDefinition:
        Type: 'AWS::ECS::TaskDefinition'
        Properties:
            ContainerDefinitions:
                - Command:
                    - /bin/sh
                    - '-c'
                    - 'echo '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon ECS.</p> </div></body></html>' > /usr/local/apache2/htdocs/index.html & & httpd-foreground
            EntryPoint:
                - sh
                - '-c'
Using the AWS CLI to create resources from templates

The following command creates a stack that's named ecs-stack using a template body file that's named ecs-template-body.json. Ensure that the template body file is in the JSON or YAML
format. The location of the file is specified in the --template-body parameter. In this case, the template body file is located in the current directory.

```bash
aws cloudformation create-stack \
  --stack-name ecs-stack \
  --template-body file://ecs-template-body.json
```

To ensure that resources are created correctly, check the Amazon ECS console or alternatively use the following commands:

- The following command lists all task definitions.
  ```bash
  aws ecs list-task-definitions
  ```

- The following command lists all clusters.
  ```bash
  aws ecs list-clusters
  ```

- The following command lists all services defined in the cluster `CFNCluster`. Replace `CFNCluster` with the name of the cluster that you want to create the service in.
  ```bash
  aws ecs list-services \
    --cluster CFNCluster
  ```

**Learn more about AWS CloudFormation**

To learn more about AWS CloudFormation, see the following resources:

- [AWS CloudFormation](https://aws.amazon.com/cloudformation/)
- [AWS CloudFormation User Guide](https://docs.aws.amazon.com/cloudformation/latest/userguide/)
- [AWS CloudFormation Command Line Interface User Guide](https://docs.aws.amazon.com/cli/latest/javadoc/)

**Using the Amazon ECS command line interface**

Amazon ECS has released AWS Copilot, a command line interface (CLI) tool that simplifies building, releasing, and operating production-ready containerized applications on Amazon...
ECS from a local development environment. For more information, see Using the AWS Copilot command line interface.

The Amazon Elastic Container Service (Amazon ECS) command line interface (CLI) provides high-level commands to simplify creating, updating, and monitoring clusters and tasks from a local development environment. The Amazon ECS CLI supports Docker Compose files, a popular open-source specification for defining and running multi-container applications. Use the ECS CLI as part of your everyday development and testing cycle as an alternative to the AWS Management Console.

The latest version of the Amazon ECS CLI only supports the major versions of Docker Compose file syntax versions 1, 2, and 3. The version specified in the compose file must be the string "1", "1.0", "2", "2.0", "3", or "3.0". Docker Compose minor versions are not supported.

The source code for the Amazon ECS CLI is available on GitHub. This tool is no longer being actively developed.

Installing the Amazon ECS CLI

Amazon ECS has released AWS Copilot, a command line interface (CLI) tool that simplifies building, releasing, and operating production-ready containerized applications on Amazon ECS from a local development environment. For more information, see Using the AWS Copilot command line interface.

The following steps demonstrate how to install the Amazon ECS CLI on your macOS, Linux, or Windows system.

To install the Amazon ECS CLI

1. Download the Amazon ECS CLI binary.
   
   macOS
   
   ```shell
   ```
Linux

```
```

Windows

Open Windows PowerShell and enter the following commands.

**Note**

If you encounter permission issues, ensure that you have administrator access on Windows and you are running PowerShell as an administrator.

```
New-Item -Path 'C:\Program Files\Amazon\ECSCLI' -ItemType Directory
Invoke-WebRequest -OutFile 'C:\Program Files\Amazon\ECSCLI\ecs-cli.exe' https://amazon-ecs-cli.s3.amazonaws.com/ecs-cli-windows-amd64-latest.exe
```

2. Verify the Amazon ECS CLI using PGP signatures. The Amazon ECS CLI executables are cryptographically signed using PGP signatures. The PGP signatures can be used to verify the validity of the Amazon ECS CLI executable. Use the following steps to verify the signatures using the GnuPG tool.

a. Download and install GnuPG. For more information, see the GnuPG website.

macOS

We recommend using Homebrew. Install Homebrew using the instructions from their website. For more information, see Homebrew. After Homebrew is installed, use the following command from your macOS terminal.

```
brew install gnupg
```

Linux

Install gpg using the package manager on your flavor of Linux.
Windows

Download the Windows simple installer from the GnuPG website and install as an Administrator. After you install GnuPG, close and reopen the Administrator PowerShell.

For more information, see GnuPG Download.

b. Verify the GnuPG path is added to your environment path.

macOS

```
echo $PATH
```

If you do not see the GnuPG path in the output, run the following command to add it to the path.

```
PATH=$PATH:<path to GnuPG executable files>
```

Linux

```
echo $PATH
```

If you do not see the GnuPG path in the output, run the following command to add it to the path.

```
export PATH=$PATH:<path to GnuPG executable files>
```

Windows

```
Write-Output $Env:PATH
```

If you do not see the GnuPG path in the output, run the following command to add it to the path.

```
$Env:PATH += ";<path to GnuPG executable files>"
```

c. Create a local plain text file.
macOS

On the terminal, enter:

```
touch <public_key_filename.txt>
```

Open the file with TextEdit.

Linux

Create a text file in a text editor such as gedit. Save as `public_key_filename.txt`.

Windows

Create a text file in a text editor such as Notepad. Save as `public_key_filename.txt`.

d. Add the following contents of the Amazon ECS PGP public key and save the file.

```
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v2

mQINBFq15asBEAD1iGcT1NVJ1ydN8QebyYe9ne3dt6jQKFMkowiLmm6LGJ3e7HUjGtqhCWRDKn+qPPHqADzAtn2pXY5fEipHgar4CP8qRnRMQ2f74l4avr4Vg7/KH8VH1q2uRw32/B94xL6EgRbGTmDFkuxoPCttBqaMj3LGn6Pe+6xWRkChQuBoQAhjBQ+bEm0kNy0LhNgjN1nL3UMAG56t8E3LANIGgEnpNsb1UwFw1uPoGozoTnx6pHBJrKIL/1v/ETU4FXpYw2zvWNaMheNRnoYj3uycHkeliCrw4kj0+skizBgo2K70v8X0c3j5+zIiHl/qDiLMuC2az5cMM1m0oF8EKSXHaU9q1KfWxjQxEX6NINic01FTrT7QwD5fMNld3FanLvg/ZnIrsSaqjOL6zRSq804LO1WBVbndEx2Kr+5kFxda51BpgfPgRj5hQ+KTHMa9Y8Z7yuc64Bj1N6F9N1FJU5sfqbdkrvRlsQRbcb9g9qxX3rJAHeiJ2zVEUN1+EgeCkxj5uxSkNU7zw2c3hQZqEcrADLV+hvFJktOz9Gm6xz8q1TnWwCz4xIRWtuEBa2qE+M1DheVd78a3gsEaSTfQq0osXYaQbvnSWOocly/5ZbziHTJiLttulys9WisP2s0emeHZicVMfW61EgPrJaipgCc7kyZvFt4YywfWARAQABBtCRCBwF6b24gRUNTIDxY3Mtc2vjdXjpdHlyYW1hem9uLmVbT6JAhweEAEAACAYFA1rjzL0YAcgkJHQvRxs0TaQrg1g/+JppwPqHnv1Vpmv7lessB815UqZeD6p6uVpHd7Bs3pc3p8PV87Drs3sPlt5bV1+rkg0lw+0gZ40/ue/YbWtOAt4qY00cEo0HgcnaxlsB827QlFIFZlVtGWmh94xzm/SJkvnngml6KB3YJNnWP61A9q337/VbVVLzvmcazAMcw4BUHMNzhd0jgBCoqOpqCbpjEvUc02Bjn23eEJsS9kC70UAHYqKvnx4d9UzxF40oISF6hmQKiBoLnRrAljS4v5s3GhVHQO7ThYq0Gt+k/KMJX2CSqt7tWJ8gk1n3H3YSRerXJRnv7DsDDBwFgT6rS2QHW1TBVuoayZy5hF6ma09nHcNnvBjQADZE78Tr/QubC1LzkNSYqkpgtw7sseo2P4n1giRvDAOEFMzpVkuUr+C252Ia1HZF6ZEv+TvBvQmWY80WwxmlJiw+J6evo3N1e019UHw71jvof8zljb14bsL2c+QTJm0v7nRqZDQgCwyp7d/v2DUVVTk1j9omuLBWnJzqCQB+72LcIzJhYma+1HC4LcKQG+/f41exuItenatK
-----END PGP PUBLIC KEY BLOCK-----
```
Installing the Amazon ECS CLI
Installing the Amazon ECS CLI
The details of the Amazon ECS PGP public key for reference:

Key ID: BCE9D9A42D51784F
Type: RSA
Size: 4096/4096
Expires: Never
User ID: Amazon ECS
Key fingerprint: F34C 3DDA E729 26B0 79BE AEC6 BCE9 D9A4 2DS1 784F

You may close the text editor.

e. Import the file with the Amazon ECS PGP public key with the following command in the terminal.

```
gpg --import <public_key_filename.txt>
```

f. Download the Amazon ECS CLI signatures. The signatures are ASCII detached PGP signatures stored in files with the extension .asc. The signatures file has the same name as its corresponding executable, with .asc appended.
macOS

```
```

Linux

```
```

Windows

```
```

g. Verify the signature.

macOS and Linux

```
gpg --verify ecs-cli.asc /usr/local/bin/ecs-cli
```

Windows

```
gpg --verify ecs-cli.asc 'C:\Program Files\Amazon\ECSCLI\ecs-cli.exe'
```

Expected output:

```
gpg: Signature made Tue Apr  3 13:29:30 2018 PDT
gpg:                 using RSA key DE3CBD61ADAF8B8E
gpg: Good signature from "Amazon ECS <ecs-security@amazon.com>" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg:         There is no indication that the signature belongs to the owner.
Primary key fingerprint: F34C 3DDA E729 26B0 79BE  AEC6 BCE9 D9A4 2D51 784F
Subkey fingerprint: EB3D F841 E2C9 212A 2BD4  2232 DE3C BD61 ADAF 8B8E
```
3. Apply execute permissions to the binary.

macOS and Linux

```bash
sudo chmod +x /usr/local/bin/ecs-cli
```

Windows

Edit the environment variables and add `C:\Program Files\Amazon\ECSCLI` to the `PATH` variable field, separated from existing entries by using a semicolon. For example:

```bash
setx path "%path%;C:\Program Files\Amazon\ECSCLI"
```

Restart PowerShell so the changes go into effect.

**Note**

After the `PATH` variable is set, the Amazon ECS CLI can be used from either Windows PowerShell or the command prompt.

4. Verify that the CLI is working properly.

```bash
ecs-cli --version
```

Proceed to [Configuring the Amazon ECS CLI](#).

**Important**

You must configure the Amazon ECS CLI with your AWS credentials, an AWS Region, and an Amazon ECS cluster name before you can use it. For more information, see [Configuring the Amazon ECS CLI](#).
Configuring the Amazon ECS CLI

Amazon ECS has released AWS Copilot, a command line interface (CLI) tool that simplifies building, releasing, and operating production-ready containerized applications on Amazon ECS from a local development environment. For more information, see Using the AWS Copilot command line interface.

The Amazon ECS CLI requires some basic configuration information before you can use it, such as your AWS credentials, the AWS Region in which to create your cluster, and the name of the Amazon ECS cluster to use. Configuration information is stored in the `~/.ecs` directory on macOS and Linux systems and in `C:\Users\<username>\AppData\local\ecs` on Windows systems.

To configure the Amazon ECS CLI

1. Set up a CLI profile with the following command, substituting `profile_name` with your desired profile name, `$AWS_ACCESS_KEY_ID` and `$AWS_SECRET_ACCESS_KEY` environment variables with your AWS credentials.

   ```
   ecs-cli configure profile --profile-name profile_name --access-key $AWS_ACCESS_KEY_ID --secret-key $AWS_SECRET_ACCESS_KEY
   ```

2. Complete the configuration with the following command, substituting `launch_type` with the task launch type you want to use by default, `region_name` with your desired AWS Region, `cluster_name` with the name of an existing Amazon ECS cluster or a new cluster to use, and `configuration_name` for the name you'd like to give this configuration.

   ```
   ecs-cli configure --cluster cluster_name --default-launch-type launch_type --region region_name --config-name configuration_name
   ```

Using profiles

The Amazon ECS CLI supports the configuring of multiple sets of AWS credentials as named profiles using the `ecs-cli configure profile` command. A default profile can be set by using the `ecs-cli configure profile default` command. These profiles can then be referenced when you run Amazon ECS CLI commands that require credentials using the `--ecs-profile` flag otherwise the default profile is used.
Using cluster configurations

A cluster configuration is a set of fields that describes an Amazon ECS cluster including the name of the cluster and the region. A default cluster configuration can be set by using the `ecs-cli configure default` command. The Amazon ECS CLI supports the configuring of multiple named cluster configurations using the `--config-name` option.

Understanding the order of precedence

There are multiple methods for passing both the credentials and the region in an Amazon ECS CLI command. The following is the order of precedence for each of these.

The order of precedence for credentials is:

1. Amazon ECS CLI profile flags:
   a. Amazon ECS profile (`--ecs-profile`)
   b. AWS profile (`--aws-profile`)
2. Environment variables:
   a. ECS_PROFILE
   b. AWS_PROFILE
   c. AWS_ACCESS_KEY_ID, AWS_SECRET_ACCESS_KEY, and AWS_SESSION_TOKEN
3. ECS config-attempts to fetch credentials from the default ECS profile.
4. Default AWS profile — Attempts to use credentials (aws_access_key_id, aws_secret_access_key) or assume_role (role_arn, source_profile) from the AWS profile name.
   a. AWS_DEFAULT_PROFILE environment variable (defaults to default).
5. EC2 instance role

The order of precedence for Region is:

1. Amazon ECS CLI flags:
   a. Region flag (`--region`)
   b. Cluster config flag (`--cluster-config`)
2. ECS config-attempts to fetch the Region from the default ECS profile.
3. Environment variables—Attempts to fetch the region from the following environment variables:
4. AWS profile - attempts to use the region from the AWS profile name:
   a. AWS_PROFILE environment variable
   b. AWS_DEFAULT_PROFILE environment variable (defaults to default)
Amazon ECS on AWS Fargate

AWS Fargate is a technology that you can use with Amazon ECS to run containers without having to manage servers or clusters of Amazon EC2 instances. With AWS Fargate, you no longer have to provision, configure, or scale clusters of virtual machines to run containers. This removes the need to choose server types, decide when to scale your clusters, or optimize cluster packing.

When you run your tasks and services with the Fargate launch type, you package your application in containers, specify the CPU and memory requirements, define networking and IAM policies, and launch the application. Each Fargate task has its own isolation boundary and does not share the underlying kernel, CPU resources, memory resources, or elastic network interface with another task. You configure your task definitions for Fargate by setting the requiresCompatibilities task definition parameter to FARGATE. For more information, see Launch types.

Fargate offers platform versions for Amazon Linux 2 and Microsoft Windows 2019 Server Full and Core editions. Unless otherwise specified, the information on this page applies to all Fargate platforms.

This topic describes the different components of Fargate tasks and services, and calls out special considerations for using Fargate with Amazon ECS.

For information about the Regions that support Linux containers on Fargate, see the section called “Linux containers on AWS Fargate”.

For information about the Regions that support Windows containers on Fargate, see the section called “Windows containers on AWS Fargate”.

Fargate walkthroughs

For information about how to get started using the console, see:

- Getting started with Linux containers on AWS Fargate
- Using Windows containers on AWS Fargate

For information about how to get started using the AWS CLI, see:

- Creating a cluster with a Fargate Linux task using the AWS CLI
- Creating a cluster with a Fargate Windows task using the AWS CLI
Capacity providers

The following capacity providers are available:

- Fargate
- Fargate Spot - Run interruption tolerant Amazon ECS tasks at a discounted rate compared to the AWS Fargate price. Fargate Spot runs tasks on spare compute capacity. When AWS needs the capacity back, your tasks will be interrupted with a two-minute warning. For more information, see [AWS Fargate capacity providers](#).

You can only use Fargate Spot for Linux tasks that use the X86 architecture.

Task definitions

Tasks that use the Fargate launch type don't support all of the Amazon ECS task definition parameters that are available. Some parameters aren't supported at all, and others behave differently for Fargate tasks. For more information, see [Task CPU and memory](#).

Platform versions

AWS Fargate platform versions are used to refer to a specific runtime environment for Fargate task infrastructure. It is a combination of the kernel and container runtime versions. You select a platform version when you run a task or when you create a service to maintain a number of identical tasks.

New revisions of platform versions are released as the runtime environment evolves, for example, if there are kernel or operating system updates, new features, bug fixes, or security updates. A Fargate platform version is updated by making a new platform version revision. Each task runs on one platform version revision during its lifecycle. If you want to use the latest platform version revision, then you must start a new task. A new task that runs on Fargate always runs on the latest revision of a platform version, ensuring that tasks are always started on secure and patched infrastructure.

If a security issue is found that affects an existing platform version, AWS creates a new patched revision of the platform version and retires tasks running on the vulnerable revision. In some cases, you may be notified that your tasks on Fargate have been scheduled for retirement. For more information, see [AWS Fargate task maintenance FAQs](#).
For more information see Fargate Linux platform versions and Fargate Windows platform versions.

**Service load balancing**

Your Amazon ECS service on AWS Fargate can optionally be configured to use Elastic Load Balancing to distribute traffic evenly across the tasks in your service.

Amazon ECS services on AWS Fargate support the Application Load Balancer and Network Load Balancer load balancer types. Application Load Balancers are used to route HTTP/HTTPS (or layer 7) traffic. Network Load Balancers are used to route TCP or UDP (or layer 4) traffic. For more information, see Distribute Amazon ECS service traffic using load balancing.

When you create a target group for these services, you must choose ip as the target type, not instance. This is because tasks that use the awsvpc network mode are associated with an elastic network interface, not an Amazon EC2 instance. For more information, see Distribute Amazon ECS service traffic using load balancing.

Using a Network Load Balancer to route UDP traffic to your Amazon ECS on AWS Fargate tasks is only supported when using platform version 1.4 or later.

**Usage metrics**

You can use CloudWatch usage metrics to provide visibility into your accounts usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

AWS Fargate usage metrics correspond to AWS service quotas. You can configure alarms that alert you when your usage approaches a service quota. For more information about AWS Fargate service quotas, see AWS Fargate service quotas.

For more information about AWS Fargate usage metrics, see AWS Fargate usage metrics in the Amazon Elastic Container Service User Guide for AWS Fargate.

**Fargate Linux platform versions**

AWS Fargate platform versions are used to refer to a specific runtime environment for Fargate task infrastructure. It is a combination of the kernel and container runtime versions. You select a platform version when you run a task or when you create a service to maintain a number of identical tasks.
New revisions of platform versions are released as the runtime environment evolves, for example, if there are kernel or operating system updates, new features, bug fixes, or security updates. A Fargate platform version is updated by making a new platform version revision. Each task runs on one platform version revision during its lifecycle. If you want to use the latest platform version revision, then you must start a new task. A new task that runs on Fargate always runs on the latest revision of a platform version, ensuring that tasks are always started on secure and patched infrastructure.

If a security issue is found that affects an existing platform version, AWS creates a new patched revision of the platform version and retires tasks running on the vulnerable revision. In some cases, you may be notified that your tasks on Fargate have been scheduled for retirement. For more information, see AWS Fargate task maintenance FAQs.

**Considerations**

Consider the following when specifying a platform version:

- When specifying a platform version, you can use either a specific version number, for example 1.4.0, or LATEST.

  When the LATEST platform version is selected, 1.4.0 platform version is used.

- If you want to update the platform version for a service, create a deployment. For example, assume that you have a service that runs tasks on the Linux platform version 1.3.0. To change the service to run tasks on the Linux platform version 1.4.0, you can update your service and specify a new platform version. Your tasks are redeployed with the latest platform version and the latest platform version revision. For more information about deployments, see Amazon ECS Deployment types.

- If your service is scaled up without updating the platform version, those tasks receive the platform version that was specified on the service's current deployment. For example, assume that you have a service that runs tasks on the Linux platform version 1.3.0. If you increase the desired count of the service, the service scheduler starts the new tasks using the latest platform version revision of platform version 1.3.0.

- New tasks always run on the latest revision of a platform version, ensuring that tasks are always started on secured and patched infrastructure.

- The platform version numbers for Linux containers and Windows containers on Fargate are independent. For example, the behavior, features, and software used in platform version 1.0.0
for Windows containers on Fargate aren't comparable to those of platform version 1.0.0 for Linux containers on Fargate.

The following are the available Linux platform versions. For information about platform version deprecation, see AWS Fargate Linux platform version deprecation.

1.4.0

The following is the changelog for platform version 1.4.0.

- Beginning on November 5, 2020, any new Amazon ECS task launched on Fargate using platform version 1.4.0 will be able to use the following features:
  - When using Secrets Manager to store sensitive data, you can inject a specific JSON key or a specific version of a secret as an environment variable or in a log configuration. For more information, see Passing sensitive data to a container.
  - Specify environment variables in bulk using the environmentFiles container definition parameter. For more information, see Use task definition parameters to pass environment variables to a container.
  - Tasks run in a VPC and subnet enabled for IPv6 will be assigned both a private IPv4 address and an IPv6 address. For more information, see Fargate task networking in the Amazon Elastic Container Service User Guide for AWS Fargate.
  - The task metadata endpoint version 4 provides additional metadata about your task and container including the task launch type, the Amazon Resource Name (ARN) of the container, and the log driver and log driver options used. When querying the /stats endpoint you also receive network rate stats for your containers. For more information, see Task metadata endpoint version 4.
  - Beginning on July 30, 2020, any new Amazon ECS task launched on Fargate using platform version 1.4.0 will be able to route UDP traffic using a Network Load Balancer to their Amazon ECS on Fargate tasks. For more information, see Distribute Amazon ECS service traffic using load balancing.
  - Beginning on May 28, 2020, any new Amazon ECS task launched on Fargate using platform version 1.4.0 will have its ephemeral storage encrypted with an AES-256 encryption algorithm using an AWS owned encryption key. For more information, see Fargate task ephemeral storage and Using data volumes in tasks.
  - Added support for using Amazon EFS file system volumes for persistent task storage. For more information, see Amazon EFS volumes.
• The ephemeral task storage has been increased to a minimum of 20 GB for each task. For more information, see [Fargate task ephemeral storage](#).

• The network traffic behavior to and from tasks has been updated. Starting with platform version 1.4.0, all Fargate tasks receive a single elastic network interface (referred to as the task ENI) and all network traffic flows through that ENI within your VPC and will be visible to you through your VPC flow logs. For more information about networking for the Amazon EC2 launch type, see [Fargate Task Networking](#). For more information about networking for the Fargate launch type, see [Task networking for tasks on Fargate](#).

• Task ENIs add support for jumbo frames. Network interfaces are configured with a maximum transmission unit (MTU), which is the size of the largest payload that fits within a single frame. The larger the MTU, the more application payload can fit within a single frame, which reduces per-frame overhead and increases efficiency. Supporting jumbo frames will reduce overhead when the network path between your task and the destination supports jumbo frames, such as all traffic that remains within your VPC.

• CloudWatch Container Insights will include network performance metrics for Fargate tasks. For more information, see [Monitor Amazon ECS containers using Container Insights](#).

• Added support for the task metadata endpoint version 4 which provides additional information for your Fargate tasks, including network stats for the task and which Availability Zone the task is running in. For more information, see [Amazon ECS task metadata endpoint version 4](#) and [Amazon ECS task metadata endpoint version 4 for tasks on Fargate](#).

• Added support for the SYS_PTRACE Linux parameter in container definitions. For more information, see [Linux parameters](#).

• The Fargate container agent replaces the use of the Amazon ECS container agent for all Fargate tasks. Usually, this change does not have an effect on how your tasks run.

• The container runtime is now using Containerd instead of Docker. Most likely, this change does not have an effect on how your tasks run. You will notice that some error messages that originate with the container runtime changes from mentioning Docker to more general errors. For more information, see [Stopped tasks error codes](#) in the [Amazon Elastic Container Service User Guide for AWS Fargate](#).

• Based on Amazon Linux 2.

### 1.3.0

The following is the changelog for platform version 1.3.0.
• Beginning on Sept 30, 2019, any new Fargate task that is launched supports the awsfirelens log driver. Configure the FireLens for Amazon ECS to use task definition parameters to route logs to an AWS service or AWS Partner Network (APN) destination for log storage and analytics. For more information, see Using custom log routing.

• Added task recycling for Fargate tasks, which is the process of refreshing tasks that are a part of an Amazon ECS service. For more information, Task maintenance in the Amazon Elastic Container Service User Guide for AWS Fargate.

• Beginning on March 27, 2019, any new Fargate task that is launched can use additional task definition parameters that you use to define a proxy configuration, dependencies for container startup and shutdown as well as a per-container start and stop timeout value. For more information, see Proxy configuration, Container dependency, and Container timeouts.

• Beginning on April 2, 2019, any new Fargate task that is launched supports injecting sensitive data into your containers by storing your sensitive data in either AWS Secrets Manager secrets or AWS Systems Manager Parameter Store parameters and then referencing them in your container definition. For more information, see Passing sensitive data to a container.

• Beginning on May 1, 2019, any new Fargate task that is launched supports referencing sensitive data in the log configuration of a container using the secretOptions container definition parameter. For more information, see Passing sensitive data to a container.

• Beginning on May 1, 2019, any new Fargate task that is launched supports the splunk log driver in addition to the awslogs log driver. For more information, see Storage and logging.

• Beginning on July 9, 2019, any new Fargate tasks that is launched supports CloudWatch Container Insights. For more information, see Monitor Amazon ECS containers using Container Insights.

• Beginning on December 3, 2019, the Fargate Spot capacity provider is supported. For more information, see AWS Fargate capacity providers.

• Based on Amazon Linux 2.

**Migrating to Linux platform version 1.4.0**

Consider the following when migrating your Amazon ECS on Fargate tasks from platform version 1.0.0, 1.1.0, 1.2.0, or 1.3.0 to platform version 1.4.0. It is considered best practice to confirm your task works properly on platform version 1.4.0 prior to migrating your tasks.

• The network traffic behavior to and from tasks has been updated. Starting with platform version 1.4.0, all Amazon ECS on Fargate tasks receive a single elastic network interface (referred to as
the task ENI) and all network traffic flows through that ENI within your VPC and will be visible to you through your VPC flow logs. For more information see Task networking for tasks on Fargate.

- If you are using interface VPC endpoints, consider the following.
  - When using container images hosted with Amazon ECR, both the `com.amazonaws.region.ecr.dkr` and `com.amazonaws.region.ecr.api` Amazon ECR VPC endpoints as well as the Amazon S3 gateway endpoint are required. For more information, see Amazon ECR interface VPC endpoints (AWS PrivateLink) in the Amazon Elastic Container Registry User Guide.
  - When using a task definition that references Secrets Manager secrets to retrieve sensitive data for your containers, you must create the interface VPC endpoints for Secrets Manager. For more information, see Using Secrets Manager with VPC Endpoints in the AWS Secrets Manager User Guide.
  - When using a task definition that references Systems Manager Parameter Store parameters to retrieve sensitive data for your containers, you must create the interface VPC endpoints for Systems Manager. For more information, see Using Systems Manager with VPC endpoints in the AWS Systems Manager User Guide.
  - Ensure that the security group in the Elastic Network Interface (ENI) associated with your task has the security group rules created to allow traffic between the task and the VPC endpoints you are using.

AWS Fargate Linux platform version deprecation

This page lists Linux platform versions that AWS Fargate has deprecated or have been scheduled for deprecation. These platform versions remain available until the published deprecation date.

A force update date is provided for each platform version scheduled for deprecation. On the force update date, any service using the LATEST platform version that is pointed to a platform version that is scheduled for deprecation will be updated using the force new deployment option. When the service is updated using the force new deployment option, all tasks running on a platform version scheduled for deprecation are stopped and new tasks are launched using the platform version that the LATEST tag points to at that time. Standalone tasks or services with an explicit platform version set are not affected by the force update date.

We recommend updating your services standalone tasks to use the most recent platform version. For more information on migrating to the most recent platform version, see Migrating to Linux platform version 1.4.0.
Once a platform version reaches the *deprecation date*, the platform version will no longer be available for new tasks or services. Any standalone tasks or services which explicitly use a deprecated platform version will continue using that platform version until the tasks are stopped. After the deprecation date, a deprecated platform version will no longer receive any security updates or bug fixes.

**Changelog for deprecated AWS Fargate Linux versions**

1.2.0

The following is the changelog for platform version 1.2.0.

> **Note**
> Platform version 1.2.0 is no longer available. For information about platform version deprecation, see [AWS Fargate Linux platform version deprecation](#).

- Added support for private registry authentication using AWS Secrets Manager. For more information, see [Private registry authentication for tasks](#).

1.1.0

The following is the changelog for platform version 1.1.0.
Note

Platform version 1.1.0 is no longer available. For information about platform version deprecation, see [AWS Fargate Linux platform version deprecation](#).

- Added support for the Amazon ECS task metadata endpoint. For more information, see [Amazon ECS task metadata available for tasks on Fargate](#).
- Added support for Docker health checks in container definitions. For more information, see [Health check](#).
- Added support for Amazon ECS service discovery. For more information, see [Service discovery](#).

1.0.0

The following is the changelog for platform version 1.0.0.

Note

Platform version 1.0.0 is no longer available. For information about platform version deprecation, see [AWS Fargate Linux platform version deprecation](#).

- Based on Amazon Linux 2017.09.
- Initial release.

**Fargate Windows platform versions**

AWS Fargate platform versions are used to refer to a specific runtime environment for Fargate task infrastructure. It is a combination of the kernel and container runtime versions. You select a platform version when you run a task or when you create a service to maintain a number of identical tasks.

New revisions of platform versions are released as the runtime environment evolves, for example, if there are kernel or operating system updates, new features, bug fixes, or security updates. A Fargate platform version is updated by making a new platform version revision. Each task runs on one platform version revision during its lifecycle. If you want to use the latest platform version revision, then you must start a new task. A new task that runs on Fargate always runs on the
latest revision of a platform version, ensuring that tasks are always started on secure and patched infrastructure.

If a security issue is found that affects an existing platform version, AWS creates a new patched revision of the platform version and retires tasks running on the vulnerable revision. In some cases, you may be notified that your tasks on Fargate have been scheduled for retirement. For more information, see AWS Fargate task maintenance FAQs.

Platform version considerations

Consider the following when specifying a platform version:

- When specifying a platform version, you can use either a specific version number, for example 1.0.0, or LATEST.

  When the LATEST platform version is selected the 1.0.0 platform is used.

- New tasks always run on the latest revision of a platform version, ensuring that tasks are always started on secured and patched infrastructure.

- Microsoft Windows Server container images must be created from a specific version of Windows Server. You must select the same version of Windows Server in the platformFamily when you run a task or create a service that matches the Windows Server container image. Additionally, you can provide a matching operatingSystemFamily in the task definition to prevent tasks from being run on the wrong Windows version. For more information, see Matching container host version with container image versions on the Microsoft Learn website.

- The platform version numbers for Linux containers and Windows containers on Fargate are independent. For example, the behavior, features, and software used in platform version 1.0.0 for Windows containers on Fargate aren't comparable to those of platform version 1.0.0 for Linux containers on Fargate.

The following are the available platform versions for Windows containers.

1.0.0

The following is the changelog for platform version 1.0.0.

- Initial release for support on the following Microsoft Windows Server operating systems:
  - Windows Server 2019 Full
  - Windows Server 2019 Core
Windows containers on Fargate considerations

The following are the differences and considerations to know when you run Windows containers on AWS Fargate.

If you need to run tasks on Linux and Windows containers, then you need to create separate task definitions for each operating system.

AWS handles the operating system license management, so you do not need any additional Microsoft Windows Server licenses.

Windows containers on AWS Fargate supports the following operating systems:

- Windows Server 2019 Full
- Windows Server 2019 Core
- Windows Server 2022 Full
- Windows Server 2022 Core

Windows containers on AWS Fargate supports the awslogs driver. For more information, see the section called “Using the awslogs log driver”.

The following features are not supported on Windows containers on Fargate:

- Group managed service accounts (gMSA)
- Amazon FSx
- ENI trunking
- App Mesh service and proxy integration for tasks
- Firelens log router integration for tasks
- EFS volumes
- The following task definition parameters:
  - maxSwap
  - swappiness
• The Fargate Spot capacity provider

• Image volumes

The Dockerfile `volume` option is ignored. Instead, use bind mounts in your task definition. For more information, see [Bind mounts](#).

## AWS Fargate task maintenance FAQs

### What is Fargate task maintenance and retirement?

AWS is responsible for maintaining the underlying infrastructure for AWS Fargate. AWS determines when a platform version revision needs to be replaced with a new revision. This is known as task retirement. AWS sends a task retirement notification when a platform version revision is retired. We routinely update our supported platform versions to introduce a new revision containing updates to the Fargate runtime software and underlying dependencies such as the operating system and container runtime. Once a newer revision is made available, we retire the older revision in order to ensure all customer workloads run on the most up to date revision of the Fargate platform version. When a revision is retired, all tasks running on that revision are stopped.

Amazon ECS tasks can be categorized as either service tasks or standalone tasks. Service tasks are deployed as part of a service and controlled by the Amazon ECS schedule. For more information, see [Amazon ECS services](#). Standalone tasks are tasks started by the Amazon ECS RunTask API, either directly or by an external scheduler such as scheduled tasks (which are started by Amazon EventBridge), AWS Batch, or AWS Step Functions.

For service tasks, you do not need to take any action unless you want to replace these tasks before AWS does. When the Amazon ECS scheduler stops the tasks, it uses the minimum healthy percent and launches a new task in an attempt to maintain the desired count for the service. By default, the minimum healthy percent of a service is 100 percent, so a new task is started first before a task is stopped. Service tasks are routinely replaced in the same way when you scale the service, deploy configuration changes, or deploy task definition revisions. To prepare for the task retirement process, we recommend that you test your application behavior by simulating this scenario. You can do this by stopping an individual task in your service to test for resiliency.

For standalone task retirement, AWS stops the task on or after the task retirement date. We don’t launch a replacement task when a task is stopped. If you need these tasks to continue to run, you need to stop the running tasks and launch a replacement task before the time indicated in the
notification. Therefore, we recommend that customers monitor the state of standalone tasks and if required, implement logic to replace the stopped tasks.

When a task is stopped in any of the scenarios, you can run describe-tasks. The stoppedReason in the response is ECS is performing maintenance on the underlying infrastructure hosting the task.

**What is in the task retirement notice?**

The task retirement notifications are sent through AWS Health Dashboard as well as through an email to the registered email address and includes the following information:

- The task retirement date - The task is stopped on or after this date.
- For standalone tasks, the IDs of the tasks.
- For service tasks, the ID of the cluster where the service runs and the IDs of the service.
- The next steps you need to take.

Typically, we send one notification each for service and standalone tasks in each AWS Region. However, in certain cases you might receive more than one event for each task type, for example when there are too many tasks to be retired that will surpass limits in our notification mechanisms.

You can identify tasks scheduled for retirement in the following ways:

- The AWS Health Dashboard

  AWS Health notifications can be sent through Amazon EventBridge to archival storage such as Amazon Simple Storage Service, take automated actions such as run an AWS Lambda function, or other notification systems such as Amazon Simple Notification Service. For more information, see [Monitoring AWS Health events with Amazon EventBridge](#). For sample configuration to send notifications to Amazon Chime, Slack, or Microsoft Teams, see the [AWS Health Aware](#) repository on GitHub.

The following is a sample EventBridge event.

```json
{
  "version": "0",
  "id": "3c268027-f43c-0171-7425-1d799EXAMPLE",
  "detail-type": "AWS Health Event",
  "source": "aws.health",
  "detail": {
    "taskNames": ["task1", "task2"],
    "clusterName": "cluster1",
    "taskDefinitionArn": "arn:aws:ecs:us-east-1:123456789012:task-definition/MyTaskDefinition:1.0",
    "stopReason": "ECS is performing maintenance on the underlying infrastructure hosting the task",
    "stopTime": "2023-04-01T10:00:00Z"
  }
}
```
What is in the task retirement notice?

A software update has been deployed to Fargate which includes CVE patches or other critical patches. No action is required on your part. All new tasks launched automatically uses the latest software version. For existing tasks, your tasks need to be restarted in order for these updates to apply. Your tasks running as part of the following ECS Services will be automatically updated beginning Wed, 16 Aug 2023 23:18:51 GMT. After Wed, 16 Aug 2023 23:18:51 GMT, the ECS scheduler will gradually replace these tasks, respecting the deployment settings for your service. Typically, services should see little to no interruption during the update and no action is required. When AWS stops tasks, AWS uses the minimum healthy percent (1) and launches a new task in an attempt to maintain the desired count for the service. By default, the minimum healthy percent of a service is 100 percent, so a new task is started first before a task is stopped. Service tasks are routinely replaced in the same way when you scale the service or deploy configuration changes or deploy task definition revisions. If you would like to control the timing of this restart you can update the service before Wed, 16 Aug 2023 23:18:51 GMT, by running the update-service command from the ECS command-line interface specifying force-new-deployment for services using Rolling update deployment type. For example:

```bash
aws ecs update-service -service service_name --cluster cluster_name --force-new-deployment
```

For services using Blue/Green deployment type with AWS CodeDeploy:

Please refer to create-deployment document (2) and create new deployment using same task...
definition revision. For further details on ECS deployment types, please refer to ECS Deployment Developer Guide (1). For further details on Fargate's update process, please refer to the AWS Fargate User Guide (3). If you have any questions or concerns, please contact AWS Support (4).

(1) https://docs.aws.amazon.com/AmazonECS/latest/developerguide/deployment-types.html
(2) https://docs.aws.amazon.com/cli/latest/reference/deploy/create-deployment.html
(3) https://docs.aws.amazon.com/AmazonECS/latest/userguide/task-maintenance.html
(4) https://aws.amazon.com/support

A list of your affected resources(s) can be found in the 'Affected resources' tab in the 'Cluster/ Service' format in the AWS Health Dashboard.

• Email

An email is sent to the registered email for the AWS account ID.

Can I change the task retirement wait time?

You can configure the time that Fargate starts the task retirement. For workloads that require immediate application of the updates, choose the immediate setting (0). When you need more control, for example, when a task can only be stopped during a certain window, configure the 7 day (7), or 14 day (14) option.

We recommend that you choose a shorter waiting period in order to pick up newer platform versions revisions sooner.

Configure the wait period by running put-account-setting-default or put-account-setting as the root user or an administrative user. Use the fargateTaskRetirementWaitPeriod option for the name and the value option set to one of the following values:
- 0 - AWS sends the notification, and immediately starts to retire the affected tasks.
- 7 - AWS sends the notification, and waits 7 calendar days before starting to retire the affected tasks.
- 14 - AWS sends the notification, and waits 14 calendar days before starting to retire the affected tasks.

The default is 7 days.

For more information, see, put-account-setting-default and put-account-setting in the Amazon Elastic Container Service API Reference.

For more information, see AWS Fargate task retirement wait time.

Can I get task retirement notifications through other AWS services?

AWS sends a task retirement notification to the AWS Health Dashboard and to the primary email contact on the AWS account. The AWS Health Dashboard provides a number of integrations into other AWS services, including EventBridge. You can use EventBridge to automate the visibility of the notices (For example. forwarding the message to a ChatOps tool). For more information, see Solution overview: Capturing task retirement notifications.

Can I change a task retirement after it is scheduled?

No. The schedule is based off the task retirement wait time which has a default of 7 days. If you need more time, you can choose to configure the wait period to 14 days. For more information, see Can I change the task retirement wait time?. The change in this configuration applies to retirements that will be scheduled in the future. Currently scheduled retirements are not impacted. If you have any further concerns, contact AWS Support.

Can I control the timing of a task replacement?

For services that use rolling deployment, you update the service using update-service with the force-deployment option before the retirement start time.

The following update-service example uses the force-deployment option.

```
aws ecs update-service --service service_name \
  --cluster cluster_name \
  --force-new-deployment
```
For services that use the blue/green deployment, you need to create a new deployment in AWS CodeDeploy. For information about how to create the deployment, see `create-deployment` in the AWS Command Line Interface Reference.

**How does Amazon ECS handle tasks that are part of a service?**

Amazon ECS gradually replaces affected tasks in your service when the Fargate retirement period starts. When Amazon ECS stops a task, it uses the service's minimum healthy percent and launches a new task to maintain the desired task count for the service. A new task is started before a task is stopped because the default minimum health percent is 100. Service tasks are routinely replaced in the same way when you scale the service, deploy configuration changes, or deploy task definition revisions. For more information about the minimum healthy percent, see Deployment configuration.

**Can Amazon ECS automatically handle standalone tasks?**

No. AWS can't create a replacement task for standalone tasks which are started by RunTask, scheduled tasks (for example through EventBridge Scheduler), AWS Batch, or AWS Step Functions. Amazon ECS manages only tasks that are part of a service.

**Supported Regions for Amazon ECS on AWS Fargate**

You can use the following tables to verify the Region support for Linux containers on AWS Fargate and Windows containers on AWS Fargate.

**Linux containers on AWS Fargate**

Amazon ECS Linux containers on AWS Fargate are supported in the following AWS Regions. The supported Availability Zone IDs are noted when applicable.

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
</tr>

</table>
Architecting your solution for Amazon ECS

Before you use Amazon ECS, you need to make decisions about capacity, networking, account settings, and logging so that you can correctly configure your Amazon ECS resources.

Amazon ECS capacity

The capacity is the infrastructure where your containers run. The following are the options:

- Amazon EC2 instances
- Serverless (AWS Fargate (Fargate))
- On-premises virtual machines (VM) or servers

You specify the infrastructure when you create a cluster. You also specify the infrastructure type when you register a task definition. The task definition refers to the infrastructure as the "launch type". You also use the launch type when you run a standalone task or deploy a service. For information about the launch type options, see Amazon ECS launch types.

Networking

AWS resources are created in subnets. When you use EC2 instances, Amazon ECS launches the instances in the subnet that you specify when you create a cluster. Your tasks run in the instance subnet. For Fargate or on-premises virtual machines, you specify the subnet when you run a task or create a service.

Depending on your application, the subnet can be a private or public subnet and the subnet can be in any of the following AWS resources:

- Availability Zones
- Local Zones
- Wavelength Zones
- AWS Regions
- AWS Outposts
For more information, see Amazon ECS applications in shared subnets, Local Zones, and Wavelength Zones or Amazon Elastic Container Service on AWS Outposts.

You can have your application connect to the internet by using one of the following methods:

- A public subnet with an internet gateway

  Use public subnets when you have public applications that require large amounts of bandwidth or minimal latency. Applicable scenarios include video streaming and gaming services.

- A private subnet with a NAT gateway

  Use private subnets when you want to protect your containers from direct external access. Applicable scenarios include payment processing systems or containers storing user data and passwords.

### Accessing features

You can use your Amazon ECS account setting to access the following features:

- **Container Insights**

  CloudWatch Container Insights collects, aggregates, and summarizes metrics and logs from your containerized applications and microservices. The metrics include utilization for resources such as CPU, memory, disk, and network.

- **aws-vpc trunking**

  For certain EC2 instances types, you can have additional network interfaces (ENIs) available on newly launched container instances.

- **Tagging authorization**

  Users must have permissions for actions that create a resource, such as `ecsCreateCluster`. If tags are specified in the resource-creating action, AWS performs additional authorization on the `ecs:TagResource` action to verify if users or roles have permissions to create tags.

- **Fargate FIPS-140 compliance**

  Fargate supports the Federal Information Processing Standard (FIPS-140) which specifies the security requirements for cryptographic modules that protect sensitive information. It is the current United States and Canadian government standard, and is applicable to systems that are...
required to be compliant with Federal Information Security Management Act (FISMA) or Federal Risk and Authorization Management Program (FedRAMP).

- Fargate task retirement time changes
  
  You can configure the wait period before Fargate tasks are retired for patching.

- Dual-stack VPC
  
  Allow tasks to communicate over IPv4, IPv6, or both.

- Amazon Resource Name (ARN) format
  
  Certain features, such as tagging authorization, require a new Amazon Resource Name (ARN) format.

For more information, see Accessing Amazon ECS features through account settings.

Logging

Logging and monitoring are important aspects of maintaining the reliability, availability, and performance of Amazon ECS workloads. The following options are available:

- Amazon CloudWatch logs - route logs to Amazon CloudWatch
- FireLens for Amazon ECS - route logs to an AWS service or AWS Partner Network destination for log storage and analysis. The AWS Partner Network is a global community of partners that leverages programs, expertise, and resources to build, market, and sell customer offerings.

Amazon ECS launch types

The task definition launch type defines what capacity the task can run on, for example AWS Fargate.

After you choose the launch type, Amazon ECS verifies that the task definition parameters you configure work with the launch type.

Fargate launch type

You can use the Fargate launch type to run your containerized applications without the need of provisioning and managing the underlying infrastructure. AWS Fargate is the serverless way to host your Amazon ECS workloads.
The Fargate launch type is suitable for the following workloads:

- Large workloads that require low operational overhead
- Small workloads that have occasional burst
- Tiny workloads
- Batch workloads

For information about the Regions that support Fargate, see the section called “AWS Fargate Regions”.

The following diagram shows the general architecture.
For more information about Amazon ECS on Fargate, see Amazon ECS on AWS Fargate.
EC2 launch type

The EC2 launch type is suitable for large workloads that must be price optimized.

When considering how to model task definitions and services using the EC2 launch type, we recommend that you consider what processes must run together and how you might go about scaling each component.

As an example, suppose that an application consists of the following components:

- A frontend service that displays information on a webpage
- A backend service that provides APIs for the frontend service
- A data store

For this example, create task definitions that group the containers that are used for a common purpose together. Separate the different components into multiple and separate task definitions. The following example cluster has three container instances that are running three front-end service containers, two backend service containers, and one data store service container.

You can group related containers in a task definition, such as linked containers that must be run together. For example, add a log streaming container to your front-end service and include it in the same task definition.

After you have your task definitions, you can create services from them to maintain the availability of your desired tasks. For more information, see Creating a service using the console. In your services, you can associate containers with Elastic Load Balancing load balancers. For more information, see Distribute Amazon ECS service traffic using load balancing. When your application requirements change, you can update your services to scale the number of desired tasks up or down. Or, you can update your services to deploy newer versions of the containers in your tasks. For more information, see Updating a service using the console.
External launch type

The External launch type is used to run your containerized applications on your on-premise server or virtual machine (VM) that you register to your Amazon ECS cluster and manage remotely. For more information, see External instances (Amazon ECS Anywhere).

Amazon ECS applications in shared subnets, Local Zones, and Wavelength Zones

Amazon ECS supports workloads that use Local Zones, Wavelength Zones, and AWS Outposts for when low latency or local data processing is a requirement.

- You can use Local Zones as an extension of an AWS Region to place resources in multiple locations closer to your end users.
- You can use Wavelength Zones to build applications that deliver ultra-low latencies to 5G devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks.
• AWS Outposts brings native AWS services, infrastructure, and operating models to virtually any data center, co-location space, or on-premises facility.

⚠️ Important

Amazon ECS on AWS Fargate workloads aren't supported in Local Zones, Wavelength Zones, or on AWS Outposts at this time.

For information about the differences between Local Zones, Wavelength Zones, and AWS Outposts, see How should I think about when to use AWS Wavelength, AWS Local Zones, or AWS Outposts for applications requiring low latency or local data processing in the AWS Wavelength FAQs.

Shared subnets

You can use VPC sharing to share subnets with other AWS accounts within the same AWS Organizations.

You can use shared VPCs for the EC2 launch type with the following considerations:

• The owner of the VPC subnet must share a subnet with a participant account before that account can use it for Amazon ECS resources.

• You can't use the VPC default security group for your container instances because it belongs to the owner. Additionally, participants can't launch instances using security groups that are owned by other participants or the owner.

• In a shared subnet, the participant and the owner separately controls the security groups within each respective account. The subnet owner can see security groups that are created by the participants but cannot perform any actions on them. If the subnet owner wants to remove or modify these security groups, the participant that created the security group must take the action.

• The shared VPC owner cannot view, update or delete a cluster that a participant creates in the shared subnet. This is in addition to the VPC resources that each account has different access to. For more information, see Responsibilities and permissions for owners and participants in the Amazon VPC User Guide.

You can use shared VPCs for the Fargate launch type with the following considerations:
• The owner of the VPC subnet must share a subnet with a participant account before that account can use it for Amazon ECS resources.

• You can't create a service or run a task using the default security group for the VPC because it belongs to the owner. Additionally, participants can't create a service or run a task using security groups that are owned by other participants or the owner.

• In a shared subnet, the participant and the owner separately controls the security groups within each respective account. The subnet owner can see security groups that are created by the participants but cannot perform any actions on them. If the subnet owner wants to remove or modify these security groups, the participant that created the security group must take the action.

• The shared VPC owner cannot view, update or delete a cluster that a participant creates in the shared subnet. This is in addition to the VPC resources that each account has different access to. For more information, see Responsibilities and permissions for owners and participants in the Amazon VPC User Guide.

For more information about VPC subnet sharing, see Share your VPC with other accounts in the Amazon VPC User Guide.

Local Zones

A Local Zone is an extension of an AWS Region in close geographic proximity to your users. Local Zones have their own connections to the internet and support AWS Direct Connect. Resources that are created in a Local Zone can serve local users with low-latency communications. For more information, see AWS Local Zones.

A Local Zone is represented by a Region code followed by an identifier that indicates the location (for example, us-west-2-lax-1a).

To use a Local Zone, you must opt in to the zone. After you opt in, you must create an Amazon VPC and subnet in the Local Zone.

You can launch Amazon EC2 instances, Amazon FSx file servers, and Application Load Balancers to use for your Amazon ECS clusters and tasks.

For more information, see Local Zones in the Amazon EC2 User Guide for Linux Instances.
Wavelength Zones

You can use AWS Wavelength to build applications that deliver ultra-low latency to mobile devices and end users. Wavelength deploys standard AWS compute and storage services to the edge of telecommunication carriers' 5G networks. You can extend an Amazon Virtual Private Cloud to one or more Wavelength Zones. Then, you can use AWS resources such as Amazon EC2 instances to run applications that require ultra-low latency and a connection to AWS services in the Region.

A Wavelength Zone is an isolated Zone in the carrier location where the Wavelength infrastructure is deployed. Wavelength Zones are tied to an AWS Region. A Wavelength Zone is a logical extension of a Region, and is managed by the control plane in the Region.

A Wavelength Zone is represented by a Region code followed by an identifier that indicates the Wavelength Zone (for example, us-east-1-wl1-bos-wlz-1).

To use a Wavelength Zone, you must opt in to the Zone. After you opt in, you must create an Amazon VPC and subnet in the Wavelength Zone. Then, you can launch your Amazon EC2 instances in the Zone to use for your Amazon ECS clusters and tasks.

For more information, see Get started with AWS Wavelength in the AWS Wavelength Developer Guide.

Wavelength Zones aren't available in all AWS Regions. For information about the Regions that support Wavelength Zones, see Available Wavelength Zones in the AWS Wavelength Developer Guide.

Amazon Elastic Container Service on AWS Outposts

AWS Outposts allows native AWS services, infrastructure, and operating models in on-premises facilities. In AWS Outposts environments, you can use the same AWS APIs, tools, and infrastructure that you use in the AWS Cloud. Amazon ECS on AWS Outposts is ideal for low-latency workloads that need to be run in close proximity to on-premises data and applications. For more information about AWS Outposts, see the AWS Outposts User Guide.

Prerequisites

The following are the prerequisites for using Amazon ECS on AWS Outposts:

- You must have installed and configured an AWS Outposts in your on-premises data center.
You must have a reliable network connection between your AWS Outposts and its AWS Region.

You must have sufficient capacity of instance types available in your AWS Outposts.

All Amazon ECS container instances must have Amazon ECS container agent 1.33.0 or later.

**Limitations**

The following are the limitations of using Amazon ECS on AWS Outposts:

- Amazon Elastic Container Registry, AWS Identity and Access Management, and Network Load Balancer run in the AWS Region, not on AWS Outposts. This will increase latencies between these services and the containers.

- AWS Fargate is not available on AWS Outposts.

**Network Connectivity Considerations**

The following are network connectivity considerations for AWS Outposts:

- If network connectivity between your AWS Outposts and its AWS Region is lost, your clusters will continue to run. However, you cannot create new clusters or take new actions on existing clusters until connectivity is restored. In case of instance failures, the instance will not be automatically replaced. The CloudWatch Logs agent will be unable to update logs and event data.

- We recommend that you provide reliable, highly available, and low latency connectivity between your AWS Outposts and its AWS Region.

**Creating an Amazon ECS Cluster on an AWS Outposts**

Creating an Amazon ECS cluster on an AWS Outposts is similar to creating an Amazon ECS cluster in the AWS Cloud. When you create an Amazon ECS cluster on an AWS Outposts, you must specify a subnet associated with your AWS Outposts.

An AWS Outposts is an extension of an AWS Region, and you can extend an Amazon VPC in an account to span multiple Availability Zones and any associated AWS Outposts. When you configure your AWS Outposts, you associate a subnet with it to extend your Regional VPC environment to your on-premises facility. Instances on an AWS Outposts appear as part of your Regional VPC, similar to an Availability Zone with associated subnets.
To create an Amazon ECS cluster on an AWS Outposts with the AWS CLI, specify a security group and a subnet to associate with your AWS Outposts.

To create a subnet associated with your AWS Outposts.

```
aws ec2 create-subnet \
  --cidr-block 10.0.3.0/24 \
  --vpc-id vpc-xxxxxxx \
  --outpost-arn arn:aws:outposts:us-west-2:123456789012:outpost/op-xxxxxxxxxxxxxxxx \
  --availability-zone-id usw-az1
```

The following example creates an Amazon ECS cluster on an AWS Outposts.

1. Create a role and policy with rights on AWS Outposts.

   The `role-policy.json` file is the policy document that contains the effect and actions for resources. For information about the file format, see [PutRolePolicy](https://docs.aws.amazon.com/iam/latest/api/API_PutRolePolicy.html) in the IAM API Reference.
2. Create an IAM instance profile with rights on AWS Outposts.

aws iam create-instance-profile --instance-profile-name outpost
aws iam add-role-to-instance-profile --instance-profile-name outpost --role-name ecsRole

3. Create a VPC.

aws ec2 create-vpc --cidr-block 10.0.0.0/16

4. Create a security group for the container instances, specifying the proper CIDR range for the AWS Outposts. (This step is different for AWS Outposts.)

aws ec2 create-security-group --group-name MyOutpostSG
aws ec2 authorize-security-group-ingress --group-name MyOutpostSG --protocol tcp --port 22 --cidr 10.0.3.0/24
aws ec2 authorize-security-group-ingress --group-name MyOutpostSG --protocol tcp --port 80 --cidr 10.0.3.0/24

5. Create the Cluster.

6. Define the Amazon ECS container agent environment variables to launch the instance into the cluster created in the previous step and define any tags you want to add to help identify the cluster (for example, Outpost to indicate that the cluster is for an Outpost).

```bash
#!/bin/bash
cat << 'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=MyCluster
ECS_IMAGE_PULL_BEHAVIOR=prefer-cached
ECS_CONTAINER_INSTANCE_TAGS={"environment": "Outpost"}
EOF
```

**Note**

In order to avoid delays caused by pulling container images from Amazon ECR in the Region, use image caches. To do this, each time a task is run, configure the Amazon
ECS agent to default to using the cached image on the instance itself by setting ECS_IMAGE_PULL_BEHAVIOR to prefer-cached.

7. Create the container instance, specifying the VPC and subnet for the AWS Outposts where this instance should run and an instance type that is available on the AWS Outposts. (This step is different for AWS Outposts.)

The userdata.txt file contains the user data the instance can use to perform common automated configuration tasks and even run scripts after the instance starts. For information about the file for API calls, see Run commands on your Linux instance at launch in the Amazon EC2 User Guide for Linux Instances.

```
aws ec2 run-instances --count 1 --image-id ami-xxxxxxxx --instance-type c5.large \
   --key-name aws-outpost-key --subnet-id subnet-xxxxxxxxxxxxxxxxxx \
   --iam-instance-profile Name outpost --security-group-id sg-xxxxxx \
   --associate-public-ip-address --user-data file://userdata.txt
```

⚠ **Note**

This command is also used when adding additional instances to the cluster. Any containers deployed in the cluster will be placed on that specific AWS Outposts.

8. Register your task definition. Use the following command and substitute ecs-task.json with the name of your task definition.

```
aws ecs register-task-definition --cli-input-json file://ecs-task.json
```

9. Run the task or create the service.

Run the task

```
aws ecs run-task --cluster mycluster --count 1 --task-definition outpost-app:1
```

Create the service

```
aws ecs create-service --cluster mycluster --service-name outpost-service \
   --task-definition outpost-app:1 --desired-count 1
```
Best practices for connecting Amazon ECS applications to the internet

Most containerized applications have at least some components that need outbound access to the internet. For example, the backend for a mobile app requires outbound access to push notifications.

Amazon Virtual Private Cloud has two main methods for facilitating communication between your VPC and the internet.

**Public subnet and internet gateway**
When you use a public subnet that has a route to an internet gateway, your containerized application can run on a host inside a VPC on a public subnet. The host that runs your container is assigned a public IP address. This public IP address is routable from the internet. For more information, see Internet gateways in the Amazon VPC User Guide.

This network architecture facilitates direct communication between the host that runs your application and other hosts on the internet. The communication is bi-directional. This means that not only can you establish an outbound connection to any other host on the internet, but other hosts on the internet might also attempt to connect to your host. Therefore, you should pay close attention to your security group and firewall rules. This ensures that other hosts on the internet can't open any connections that you don't want to be opened.

For example, if your application runs on Amazon EC2, make sure that port 22 for SSH access is not open. Otherwise, your instance could receive constant SSH connection attempts from malicious bots on the internet. These bots trawl through public IP addresses. After they find an open SSH port, they attempt to brute-force passwords to try to access your instance. Because of this, many organizations limit the usage of public subnets and prefer to have most, if not all, of their resources inside of private subnets.

Using public subnets for networking is suitable for public applications that require large amounts of bandwidth or minimal latency. Applicable use cases include video streaming and gaming services.

This networking approach is supported both when you use Amazon ECS on Amazon EC2 and when you use it on AWS Fargate.

- Amazon EC2 — You can launch EC2 instances on a public subnet. Amazon ECS uses these EC2 instances as cluster capacity, and any containers that are running on the instances can use the underlying public IP address of the host for outbound networking. This applies to both the host and bridge network modes. However, the awsvpc network mode doesn't provide task ENIs with public IP addresses. Therefore, they can't make direct use of an internet gateway.

- Fargate — When you create your Amazon ECS service, specify public subnets for the networking configuration of your service, and use the Assign public IP address option. Each Fargate task is networked in the public subnet, and has its own public IP address for direct communication with the internet.
When you use a private subnet and a NAT gateway, you can run your containerized application on a host that's in a private subnet. As such, this host has a private IP address that's routable inside your VPC, but isn't routable from the internet. This means that other hosts inside the VPC can connect to the host using its private IP address, but other hosts on the internet can't make any inbound communications to the host.

With a private subnet, you can use a Network Address Translation (NAT) gateway to allow a host inside a private subnet to connect to the internet. Hosts on the internet receive an inbound connection that appears to be coming from the public IP address of the NAT gateway that's inside a public subnet. The NAT gateway is responsible for serving as a bridge between the internet and the private VPC. This configuration is often preferred for security reasons because it means that your VPC is protected from direct access by attackers on the internet. For more information, see NAT gateways in the Amazon VPC User Guide.

This private networking approach is suitable for scenarios where you want to protect your containers from direct external access. Applicable scenarios include payment processing systems or
containers storing user data and passwords. You're charged for creating and using a NAT gateway in your account. NAT gateway hourly usage and data processing rates also apply. For redundancy purposes, you should have a NAT gateway in each Availability Zone. This way, the loss in availability of a single Availability Zone doesn't compromise your outbound connectivity. Because of this, if you have a small workload, it might be more cost effective to use private subnets and NAT gateways.

This networking approach is supported both when using Amazon ECS on Amazon EC2 and when using it on AWS Fargate.

- **Amazon EC2** — You can launch EC2 instances on a private subnet. The containers that run on these EC2 hosts use the underlying hosts networking, and outbound requests go through the NAT gateway.

- **Fargate** — When you create your Amazon ECS service, specify private subnets for the networking configuration of your service, and don't use the *Assign public IP address* option. Each Fargate task is hosted in a private subnet. Its outbound traffic is routed through any NAT gateway that you have associated with that private subnet.

### Best practices for receiving inbound connections to Amazon ECS from the internet

If you run a public service, you must accept inbound traffic from the internet. For example, your public website must accept inbound HTTP requests from browsers. In such case, other hosts on the internet must also initiate an inbound connection to the host of your application.

One approach to this problem is to launch your containers on hosts that are in a public subnet with a public IP address. However, we don't recommend this for large-scale applications. For these, a better approach is to have a scalable input layer that sits between the internet and your application. For this approach, you can use any of the AWS services listed in this section as an input.

### Application Load Balancer

An Application Load Balancer functions at the application layer. It's the seventh layer of the Open Systems Interconnection (OSI) model. This makes an Application Load Balancer suitable for public HTTP services. If you have a website or an HTTP REST API, then an Application Load Balancer is a suitable load balancer for this workload. For more information, see [What is an Application Load Balancer?](#) in the *User Guide for Application Load Balancers*. 
With this architecture, you create an Application Load Balancer in a public subnet so that it has a public IP address and can receive inbound connections from the internet. When the Application Load Balancer receives an inbound connection, or more specifically an HTTP request, it opens a connection to the application using its private IP address. Then, it forwards the request over the internal connection.

An Application Load Balancer has the following advantages.

- SSL/TLS termination — An Application Load Balancer can sustain secure HTTPS communication and certificates for communications with clients. It can optionally terminate the SSL connection at the load balancer level so that you don’t have to handle certificates in your own application.
- Advanced routing — An Application Load Balancer can have multiple DNS hostnames. It also has advanced routing capabilities to send incoming HTTP requests to different destinations based on metrics such as the hostname or the path of the request. This means that you can use a single Application Load Balancer as the input for many different internal services, or even microservices on different paths of a REST API.
- gRPC support and websockets — An Application Load Balancer can handle more than just HTTP. It can also load balance gRPC and websocket based services, with HTTP/2 support.
- Security — An Application Load Balancer helps protect your application from malicious traffic. It includes features such as HTTP de sync mitigations, and is integrated with AWS Web Application Firewall (AWS WAF). AWS WAF can further filter out malicious traffic that might contain attack patterns, such as SQL injection or cross-site scripting.
Network Load Balancer

A Network Load Balancer functions at the fourth layer of the Open Systems Interconnection (OSI) model. It's suitable for non-HTTP protocols or scenarios where end-to-end encryption is necessary, but doesn’t have the same HTTP-specific features of an Application Load Balancer. Therefore, a Network Load Balancer is best suited for applications that don’t use HTTP. For more information, see What is a Network Load Balancer? in the User Guide for Network Load Balancers.

When a Network Load Balancer is used as an input, it functions similarly to an Application Load Balancer. This is because it's created in a public subnet and has a public IP address that can be accessed on the internet. The Network Load Balancer then opens a connection to the private IP address of the host running your container, and sends the packets from the public side to the private side.

Network Load Balancer features

Because the Network Load Balancer operates at a lower level of the networking stack, it doesn’t have the same set of features that Application Load Balancer does. However, it does have the following important features.
• End-to-end encryption — Because a Network Load Balancer operates at the fourth layer of the OSI model, it doesn't read the contents of packets. This makes it suitable for load balancing communications that need end-to-end encryption.

• TLS encryption — In addition to end-to-end encryption, Network Load Balancer can also terminate TLS connections. This way, your backend applications don't have to implement their own TLS.

• UDP support — Because a Network Load Balancer operates at the fourth layer of the OSI model, it's suitable for non HTTP workloads and protocols other than TCP.

Closing connections

Because the Network Load Balancer does not observe the application protocol at the higher layers of the OSI model, it cannot send closure messages to the clients in those protocols. Unlike the Application Load Balancer, those connections need to be closed by the application or you can configure the Network Load Balancer to close the fourth layer connections when a task is stopped or replaced. See the connection termination setting for Network Load Balancer target groups in the Network Load Balancer documentation.

Letting the Network Load Balancer close connections at the fourth layer can cause clients to display undesired error messages, if the client does not handle them. See the Builders Library for more information on recommended client configuration here.

The methods to close connections will vary by application, however one way is to ensure that the Network Load Balancer target deregistration delay is longer than client connection timeout. The client would timeout first and reconnect gracefully through the Network Load Balancer to the next task while the old task slowly drains all of its clients. For more information about the Network Load Balancer target deregistration delay, see the Network Load Balancer documentation.

Amazon API Gateway HTTP API

Amazon API Gateway is suitable for HTTP applications with sudden bursts in request volumes or low request volumes. For more information, see What is Amazon API Gateway? in the API Gateway Developer Guide.
The pricing model for both Application Load Balancer and Network Load Balancer include an hourly price to keep the load balancers available for accepting incoming connections at all times. In contrast, API Gateway charges for each request separately. This has the effect that, if no requests come in, there are no charges. Under high traffic loads, an Application Load Balancer or Network Load Balancer can handle a greater volume of requests at a cheaper per-request price than API Gateway. However, if you have a low number of requests overall or have periods of low traffic, then the cumulative price for using the API Gateway should be more cost effective than paying a hourly charge to maintain a load balancer that's being underutilized. The API Gateway can also cache API responses, which might result in lower backend request rates.

API Gateway functions which use a VPC link that allows the AWS managed service to connect to hosts inside the private subnet of your VPC, using its private IP address. It can detect these private IP addresses by looking at AWS Cloud Map service discovery records that are managed by Amazon ECS Service Discovery.

API Gateway supports the following features.

- The API Gateway operation is similar to a load balancer, but has additional capabilities unique to API management
- The API Gateway provides additional capabilities around client authorization, usage tiers, and request/response modification. For more information, see Amazon API Gateway features.
- The API Gateway can support edge, regional, and private API gateway endpoints. Edge endpoints are available through a managed CloudFront distribution. Regional and private endpoints are both local to a Region.
• SSL/TLS termination
• Routing different HTTP paths to different backend microservices

Besides the preceding features, API Gateway also supports using custom Lambda authorizers that you can use to protect your API from unauthorized usage. For more information, see Field Notes: Serverless Container-based APIs with Amazon ECS and Amazon API Gateway.

Accessing Amazon ECS features through account settings

You can go into Amazon ECS account settings to opt in or out of specific features. For each AWS Region, you can opt in to, or opt out of, each account setting at the account-level or for a specific user or role.

You might want to opt in or out of specific features if any of the following is relevant to you:

• A user or role can opt in or opt out specific account settings for their individual account.
• A user or role can set the default opt-in or opt-out setting for all users on the account.
• The root user or a user with administrator privileges can opt in to, or opt out of, any specific role or user on the account. If the account setting for the root user is changed, it sets the default for all the users and roles that no individual account setting was selected for.

Note
Federated users assume the account setting of the root user and can't have explicit account settings set for them separately.

The following account settings are available. You must separately opt-in and opt-out to each account setting.

Amazon Resource Names (ARNs) and IDs

Resource names: serviceLongArnFormat, taskLongArnFormat, and containerInstanceLongArnFormat

Amazon ECS is introducing a new format for Amazon Resource Names (ARNs) and resource IDs for Amazon ECS services, tasks, and container instances. The opt-in status for each resource
type determines the Amazon Resource Name (ARN) format the resource uses. You must opt in to the new ARN format to use features such as resource tagging for that resource type. For more information, see Amazon Resource Names (ARNs) and IDs.

The default is enabled.

Only resources launched after opting in receive the new ARN and resource ID format. All existing resources aren't affected. For Amazon ECS services and tasks to transition to the new ARN and resource ID formats, you must recreate the service or task. To transition a container instance to the new ARN and resource ID format, the container instance must be drained and a new container instance must be launched and registered to the cluster.

**Note**

Tasks launched by an Amazon ECS service can only receive the new ARN and resource ID format if the service was created on or after November 16, 2018, and the user who created the service has opted in to the new format for tasks.

**AWSVPC trunking**

Resource name: awsvpcTrunking

Amazon ECS supports launching container instances with increased elastic network interface (ENI) density using supported Amazon EC2 instance types. When you use these instance types and opt in to the awsvpcTrunking account setting, additional ENIs are available on newly launched container instances. You can use this configuration to place more tasks using the awsvpc network mode on each container instance. Using this feature, a c5.large instance with awsvpcTrunking enabled has an increased ENI quota of ten. The container instance has a primary network interface, and Amazon ECS creates and attaches a "trunk" network interface to the container instance. The primary network interface and the trunk network interface don't count against the ENI quota. Therefore, you can use this configuration to launch ten tasks on the container instance instead of the current two tasks. For more information, see Elastic network interface trunking.

The default is disabled.

Only resources launched after opting in receive the the increased ENI limits. All the existing resources aren't affected. To transition a container instance to the increased ENI quotas, the container instance must be drained and a new container instance registered to the cluster.
CloudWatch Container Insights

**Resource name: containerInsights**

CloudWatch Container Insights collects, aggregates, and summarizes metrics and logs from your containerized applications and microservices. The metrics include utilization for resources such as CPU, memory, disk, and network. Container Insights also provides diagnostic information, such as container restart failures, to help you isolate issues and resolve them quickly. You can also set CloudWatch alarms on metrics that Container Insights collects. For more information, see Monitor Amazon ECS containers using Container Insights.

When you opt in to the containerInsights account setting, all new clusters have Container Insights enabled by default. You can disable this setting for specific clusters when you create them. You can also change this setting by using the UpdateClusterSettings API.

For clusters that contain tasks or services using the EC2 launch type, your container instances must run version 1.29.0 or later of the Amazon ECS agent to use Container Insights. For more information, see Linux container instance management.

The default is disabled.

Dual-stack VPC IPv6

**Resource name: dualStackIPv6**

Amazon ECS supports providing tasks with an IPv6 address in addition to the primary private IPv4 address.

For tasks to receive an IPv6 address, the task must use the aws-vpc network mode, must be launched in a VPC configured for dual-stack mode, and the dualStackIPv6 account setting must be enabled. For more information about other requirements, see Using a VPC in dual-stack mode for the EC2 launch type and Using a VPC in dual-stack mode for the Fargate launch type.

⚠️ **Important**

The dualStackIPv6 account setting can only be changed using either the Amazon ECS API or the AWS CLI. For more information, see Modifying account settings.
If you had a running task using the awsvpc network mode in an IPv6 enabled subnet between the dates of October 1, 2020 and November 2, 2020, the default dualStackIPv6 account setting in the Region that the task was running in is disabled. If that condition isn't met, the default dualStackIPv6 setting in the Region is enabled.

The default is disabled.

**Fargate FIPS-140 compliance**

Resource name: fargateFIPSMode

Fargate supports the Federal Information Processing Standard (FIPS-140) which specifies the security requirements for cryptographic modules that protect sensitive information. It is the current United States and Canadian government standard, and is applicable to systems that are required to be compliant with Federal Information Security Management Act (FISMA) or Federal Risk and Authorization Management Program (FedRAMP).

The default is disabled.

You must turn on FIPS-140 compliance. For more information, see the section called “AWS Fargate FIPS-140 compliance”.

⚠️ **Important**

The fargateFIPSMode account setting can only be changed using either the Amazon ECS API or the AWS CLI. For more information, see **Modifying account settings**.

**Tag Resource Authorization**

Resource name: tagResourceAuthorization

Some Amazon ECS API actions allow you to specify tags when you create the resource.

Amazon ECS is introducing tagging authorization for resource creation. Users must have permissions for actions that create a resource, such as ecsCreateCluster. If tags are specified in the resource-creating action, AWS performs additional authorization on the ecs:TagResource action to verify if users or roles have permissions to create tags. Therefore, you must grant explicit permissions to use the ecs:TagResource action. For more information, see the section called “Tag resources during creation”.

Accessing Amazon ECS features through account settings
**Fargate task retirement waiting period**

Resource name: fargateTaskRetirementWaitPeriod

AWS is responsible for patching and maintaining the underlying infrastructure for AWS Fargate. When AWS determines that a security or infrastructure update is needed for an Amazon ECS task hosted on Fargate, the tasks need to be stopped and new tasks launched to replace them. You can configure the wait period before tasks are retired for patching. You have the option to retire the task immediately, to wait 7 calendar days, or to wait 14 calendar days.

This setting is at the account-level.

**Runtime Monitoring activation**

Resource name: guardDutyActivate

The guardDutyActivate parameter is read-only in Amazon ECS and indicates whether Runtime Monitoring is turned on or off by your security administrator in your Amazon ECS account. GuardDuty controls this account setting on your behalf. For more information, see [Protecting Amazon ECS workloads with Runtime Monitoring](#).

**Topics**

- [Modifying account settings](#)
- [Reverting to the default Amazon ECS account settings](#)
- [Account setting management using the AWS CLI](#)
Amazon Resource Names (ARNs) and IDs

When Amazon ECS resources are created, each resource is assigned a unique Amazon Resource Name (ARN) and resource identifier (ID). If you use a command line tool or the Amazon ECS API to work with Amazon ECS, resource ARNs or IDs are required for certain commands. For example, if you use the `stop-task` AWS CLI command to stop a task, you must specify the task ARN or ID in the command.

You can opt in to and opt out of the new Amazon Resource Name (ARN) and resource ID format on a per-Region basis. Currently, any new account created is opted in by default.

You can opt in or opt out of the new Amazon Resource Name (ARN) and resource ID format at any time. After you opt in, any new resources that you create use the new format.

⚠️ **Note**
A resource ID doesn't change after it's created. Therefore, opting in or out of the new format doesn't affect your existing resource IDs.

The following sections describe how ARN and resource ID formats are changing. For more information about the transition to the new formats, see [Amazon Elastic Container Service FAQ](#).

### Amazon Resource Name (ARN) format

Some resources have a user-friendly name, such as a service named `production`. In other cases, you must specify a resource using the Amazon Resource Name (ARN) format. The new ARN format for Amazon ECS tasks, services, and container instances includes the cluster name. For information about opting in to the new ARN format, see [Modifying account settings](#).

The following table shows both the current format and the new format for each resource type.

<table>
<thead>
<tr>
<th>Resource type</th>
<th>ARN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource type</td>
<td>ARN</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>Amazon ECS service</td>
<td>Current: arn:aws:ecs: region:aws_account_id :service/</td>
</tr>
<tr>
<td></td>
<td>service-name</td>
</tr>
<tr>
<td></td>
<td>cluster-name/service-name</td>
</tr>
<tr>
<td>Amazon ECS task</td>
<td>Current: arn:aws:ecs: region:aws_account_id :task/</td>
</tr>
<tr>
<td></td>
<td>task-id</td>
</tr>
<tr>
<td></td>
<td>New: arn:aws:ecs: region:aws_account_id :task/cluster-</td>
</tr>
<tr>
<td></td>
<td>name/task-id</td>
</tr>
</tbody>
</table>

**Resource ID length**

A resource ID takes the form of a unique combination of letters and numbers. New resource ID formats include shorter IDs for Amazon ECS tasks and container instances. The current resource ID format is 36 characters long. The new IDs are in a 32-character format that doesn't include any hyphens. For information about opting in to the new resource ID format, see [Modifying account settings](https://docs.aws.amazon.com/elasticcontainerservice/latest/dg/modify-account-settings.html).

**ARN and resource ID format timeline**

The timeline for the opt-in and opt-out periods for the new Amazon Resource Name (ARN) and resource ID format for Amazon ECS resources ended on April 1, 2021. By default, all accounts are opted in to the new format. All new resources created receive the new format, and you can no longer opt out.

**AWS Fargate Federal Information Processing Standard (FIPS-140) compliance**

You must turn on Federal Information Processing Standard (FIPS-140) compliance on Fargate. For more information, see [the section called “AWS Fargate FIPS-140 compliance”](https://docs.aws.amazon.com/elasticcontainerservice/latest/dg/fargate-fips-compliance.html).

Run `put-account-setting-default` with the `fargateFIPSMode` option set to `enabled`. For more information, see [put-account-setting-default](https://docs.aws.amazon.com/elasticcontainerservice/latest/dg/API_PutAccountSettingDefault.html) in the Amazon Elastic Container Service API Reference.

- You can use the following command to turn on FIPS-140 compliance.
aws ecs put-account-setting-default --name fargateFIPSMode --value enabled

Example output

```
{
    "setting": {
        "name": "fargateFIPSMode",
        "value": "enabled",
        "principalArn": "arn:aws:iam::123456789012:root",
        "type": "user"
    }
}
```

You can run `list-account-settings` to view the current FIPS-140 compliance status. Use the `effective-settings` option to view the account level settings.

aws ecs list-account-settings --effective-settings

### Tagging authorization

Amazon ECS is introducing tagging authorization for resource creation. Users must have tagging permissions for actions that create the resource, such as `ecsCreateCluster`. When you create a resource and specify tags for that resource, AWS performs additional authorization to verify that there are permissions to create tags. Therefore, you must grant explicit permissions to use the `ecs:TagResource` action. For more information, see the section called "Tag resources during creation".

In order to opt in to tagging authorization, run `put-account-setting-default` with the `tagResourceAuthorization` option set to enable. For more information, see, `put-account-setting-default` in the Amazon Elastic Container Service API Reference. You can run `list-account-settings` to view the current tagging authorization status.

- You can use the following command to enable tagging authorization.

  ```
  aws ecs put-account-setting-default --name tagResourceAuthorization --value on --region region
  ```
Example output

```json
{
    "setting": {
        "name": "tagResourceAuthorization",
        "value": "on",
        "principalArn": "arn:aws:iam::123456789012:root",
        "type": "user"
    }
}
```

After you enable tagging authorization, you must configure the appropriate permissions to allow users to tag resources on creation. For more information, see the section called “Tag resources during creation”.

You can run `list-account-settings` to view the current tagging authorization status. Use the `effective-settings` option to view the account level settings.

```
aws ecs list-account-settings --effective-settings
```

**Tagging authorization timeline**

You can confirm whether tagging authorization is active by running `list-account-settings` to view the `tagResourceAuthorization` value. When the value is on, it means that the tagging authorization is in use. For more information, see, `list-account-settings` in the *Amazon Elastic Container Service API Reference*.

The following are the important dates related to tagging authorization.

- **April 18, 2023** – Tagging authorization is introduced. All new and existing accounts must opt in to use the feature. You can opt in to start using tagging authorization. By opting in, you must grant the appropriate permissions.

- **February 9, 2024 - March 6, 2024** – All new accounts and non-impacted existing accounts have tagging authorization on be default. You can enable or disable the `tagResourceAuthorization` account setting to verify your IAM policy.

  AWS has notified impacted accounts.
To disable the feature, run `put-account-setting-default` with the `tagResourceAuthorization` option set to off.

- March 7, 2024 – If you have enabled tagging authorization, you can no longer disable the account setting.

  We recommend that you complete your IAM policy testing before this date.

- March 29, 2024 – All accounts use tagging authorization. The account-level setting will no longer be available in the Amazon ECS console or AWS CLI

### AWS Fargate task retirement wait time

AWS sends out notifications when you have Fargate tasks running on a platform version revision marked for retirement. For more information, see [AWS Fargate task maintenance FAQs](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/task-maintenance-faqs.html).

You can configure the time that Fargate starts the task retirement. For workloads that require immediate application of the updates, choose the immediate setting (0). When you need more control, for example, when a task can only be stopped during a certain window, configure the 7 day (7), or 14 day (14) option.

We recommend that you choose a shorter waiting period in order to pick up newer platform versions revisions sooner.

Configure the wait period by running `put-account-setting-default` or `put-account-setting` as the root user or an administrative user. Use the `fargateTaskRetirementWaitPeriod` option for the name and the `value` option set to one of the following values:

- 0 - AWS sends the notification, and immediately starts to retire the affected tasks.
- 7 - AWS sends the notification, and waits 7 calendar days before starting to retire the affected tasks.
- 14 - AWS sends the notification, and waits 14 calendar days before starting to retire the affected tasks.

The default is 7 days.

For more information, see [put-account-setting-default](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/put-account-setting-default.html) and [put-account-setting](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/put-account-setting.html) in the *Amazon Elastic Container Service API Reference*. 
You can run the following command to set the wait period to 14 days.

```bash
aws ecs put-account-setting-default --name fargateTaskRetirementWaitPeriod --value 14
```

Example output

```json
{
  "setting": {
    "name": "fargateTaskRetirementWaitPeriod",
    "value": "14",
    "principalArn": "arn:aws:iam::123456789012:root",
    "type": "user"
  }
}
```

You can run `list-account-settings` to view the current Fargate task retirement wait time. Use the `effective-settings` option.

```bash
aws ecs list-account-settings --effective-settings
```

**Runtime Monitoring (Amazon GuardDuty integration)**

Runtime Monitoring is an intelligent threat detection service that protects workloads running on Fargate and EC2 container instances by continuously monitoring AWS log and networking activity to identify malicious or unauthorized behavior.

The `guardDutyActivate` parameter is read-only in Amazon ECS and indicates whether Runtime Monitoring is turned on or off by your security administrator in your Amazon ECS account. GuardDuty controls this account setting on your behalf. For more information, see [Protecting Amazon ECS workloads with Runtime Monitoring](https://docs.aws.amazon.com/ecs/latest/userguide/monitoring.html).

You can run `list-account-settings` to view the current GuardDuty integration setting.

```bash
aws ecs list-account-settings
```

Example output

```json
{
  "setting": {
    "name": "guardDutyActivate",
```

[Runtime Monitoring (Amazon GuardDuty integration)]: #
Viewing account settings using the console

You can use the AWS Management Console to view your account settings.

⚠️ Important

The dualStackIPv6, fargateFIPSMode and the fargateTaskRetirementWaitPeriod account settings can only be viewed or changed using the AWS CLI.

2. In the navigation bar at the top, select the Region for which to view your account settings.
3. In the navigation page, choose Account Settings.

Modifying account settings

You can use the AWS Management Console to modify your account settings.

The guardDutyActivate parameter is read-only in Amazon ECS and indicates whether Runtime Monitoring is turned on or off by your security administrator in your Amazon ECS account. GuardDuty controls this account setting on your behalf. For more information, see Protecting Amazon ECS workloads with Runtime Monitoring.

⚠️ Important

The dualStackIPv6, fargateFIPSMode and the fargateTaskRetirementWaitPeriod account settings can only be viewed or changed using the AWS CLI.

2. In the navigation bar at the top, select the Region for which to view your account settings.
3. In the navigation page, choose Account Settings.
4. Choose Update.
5. To increase or decrease the number of tasks that you can run in the awsvpc network mode for each EC2 instance, under AWSVPC Trunking, select AWSVPC Trunking.
6. To use or stop using CloudWatch Container Insights by default for clusters, under CloudWatch Container Insights, select or clear CloudWatch Container Insights.
7. To enable or disable tagging authorization, under Resource Tagging Authorization, select or clear Resource Tagging Authorization.
8. Choose Save changes.
9. On the confirmation screen, choose Confirm to save the selection.

Reverting to the default Amazon ECS account settings

You can use the AWS Management Console to revert your Amazon ECS account settings to the default.

The Revert to account default option is only available when your account settings are no longer the default settings.

2. In the navigation bar at the top, select the Region for which to view your account settings.
3. In the navigation page, choose Account Settings.
4. Choose Update.
5. Choose Revert to account default.
6. On the confirmation screen, choose Confirm to save the selection.

Account setting management using the AWS CLI

You can manage your account settings using the Amazon ECS API, AWS CLI or SDKs. The dualStackIPv6, fargateFIPSMode and the fargateTaskRetirementWaitPeriod account settings can only be viewed or changed using those tools.

For information about the available API actions for task definitions see Account setting actions in the Amazon Elastic Container Service API Reference.
Use one of the following commands to modify the default account setting for all users or roles on your account. These changes apply to the entire AWS account unless a user or role explicitly overrides these settings for themselves.

- **put-account-setting-default** (AWS CLI)

  ```bash
  aws ecs put-account-setting-default --name serviceLongArnFormat --value enabled --region us-east-2
  ```

  You can also use this command to modify other account settings. To do this, replace the `name` parameter with the corresponding account setting.

- **Write-ECSAccountSetting** (AWS Tools for Windows PowerShell)

  ```powershell
  Write-ECSAccountSettingDefault -Name serviceLongArnFormat -Value enabled -Region us-east-1 -Force
  ```

**To modify the account settings for your user account (AWS CLI)**

Use one of the following commands to modify the account settings for your user. If you’re using these commands as the root user, changes apply to the entire AWS account unless a user or role explicitly overrides these settings for themselves.

- **put-account-setting** (AWS CLI)

  ```bash
  aws ecs put-account-setting --name serviceLongArnFormat --value enabled --region us-east-1
  ```

  You can also use this command to modify other account settings. To do this, replace the `name` parameter with the corresponding account setting.

- **Write-ECSAccountSetting** (AWS Tools for Windows PowerShell)

  ```powershell
  Write-ECSAccountSetting -Name serviceLongArnFormat -Value enabled -Force
  ```

**To modify the account settings for a specific user or role (AWS CLI)**

Use one of the following commands and specify the ARN of a user, role, or root user in the request to modify the account settings for a specific user or role.
- **put-account-setting** (AWS CLI)

```bash
aws ecs put-account-setting --name serviceLongArnFormat --value enabled --principal-arn arn:aws:iam::aws_account_id:user/principalName --region us-east-1
```

You can also use this command to modify other account settings. To do this, replace the name parameter with the corresponding account setting.

- **Write-ECSAccountSetting** (AWS Tools for Windows PowerShell)

```powershell
Write-ECSAccountSetting -Name serviceLongArnFormat -Value enabled -PrincipalArn arn:aws:iam::aws_account_id:user/principalName -Region us-east-1 -Force
```
Amazon ECS task definitions

A task definition is a blueprint for your application. It is a text file in JSON format that describes the parameters and one or more containers that form your application.

The following are some of the parameters that you can specify in a task definition:

- The launch type to use, which determines the infrastructure that your tasks are hosted on
- The Docker image to use with each container in your task
- How much CPU and memory to use with each task or each container within a task
- The memory and CPU requirements
- The operating system of the container that the task runs on
- The Docker networking mode to use for the containers in your task
- The logging configuration to use for your tasks
- Whether the task continues to run if the container finishes or fails
- The command that the container runs when it's started
- Any data volumes that are used with the containers in the task
- The IAM role that your tasks use

For a complete list of task definition parameters, see Task definition parameters.

After you create a task definition, you can run the task definition as a task or a service.

- A task is the instantiation of a task definition within a cluster. After you create a task definition for your application within Amazon ECS, you can specify the number of tasks to run on your cluster.

- An Amazon ECS service runs and maintains your desired number of tasks simultaneously in an Amazon ECS cluster. How it works is that, if any of your tasks fail or stop for any reason, the Amazon ECS service scheduler launches another instance based on your task definition. It does this to replace it and thereby maintain your desired number of tasks in the service.

Topics

- Task definition states
- Architecting your application
Task definition states

A task definition changes states when you create, deregister, or delete it. You can view the task definition state in the console, or by using DescribeTaskDefinition.

The following are the possible states for a task definition:

ACTIVE

A task definition is ACTIVE after it is registered with Amazon ECS. You can use task definitions in the ACTIVE state to run tasks, or create services.

INACTIVE

A task definition transitions from the ACTIVE state to the INACTIVE state when you deregister a task definition. You can retrieve an INACTIVE task definition by calling DescribeTaskDefinition. You cannot run new tasks or create new services with a task definition in the INACTIVE state. There is no impact on existing services or tasks.

DELETE_IN_PROGRESS

A task definition transitions from the INACTIVE state to the DELETE_IN_PROGRESS state after you submitted the task definition for deletion. After the task definition is in the DELETE_IN_PROGRESS state, Amazon ECS periodically verifies that the target task definition is not being referenced by any active tasks or deployments, and then deletes the task definition permanently. You cannot run new tasks or create new services with a task definition in the DELETE_IN_PROGRESS state. A task definition can be submitted for deletion at any moment without impacting existing tasks and services.

Task definitions that are in the DELETE_IN_PROGRESS state can be viewed in the console and you can retrieve the task definition by calling DescribeTaskDefinition.
When you delete all INACTIVE task definition revisions, the task definition name is not displayed in the console and not returned in the API. If a task definition revision is in the DELETE_IN_PROGRESS state, the task definition name is displayed in the console and returned in the API. The task definition name is retained by Amazon ECS and the revision is incremented the next time you create a task definition with that name.

If you use AWS Config to manage your task definitions, AWS Config charges you for all task definition registrations. You are only charged for deregistering the latest ACTIVE task definition. There is no charge for deleting a task definition. For more information about pricing, see AWS Config Pricing.

**Amazon ECS resources that can block a deletion**

A task definition deletion request will not complete when there are any Amazon ECS resources that depend on the task definition revision. The following resources might prevent a task definition from being deleted:

- Amazon ECS tasks - The task definition is required in order for the task to remain healthy.
- Amazon ECS deployments and task sets - The task definition is required when a scaling event is initiated for an Amazon ECS deployment or task set.

If your task definition remains in the DELETE_IN_PROGRESS state, you can use the console, or the AWS CLI to identify, and then stop the resources which block the task definition deletion.

**Task definition deletion after the blocked resource is removed**

The following rules apply after you remove the resources that block the task definition deletion:

- Amazon ECS tasks - The task definition deletion can take up to 1 hour to complete after the task is stopped.
- Amazon ECS deployments and task sets - The task definition deletion can take up to 24 hours to complete after the deployment or task set is deleted.

**Architecting your application**

You architect your application by creating a task definition for your application. The task definition contains the parameters that define information about the application, including:
• The launch type to use, which determines the infrastructure that your tasks are hosted on.

  When you use the EC2 launch type, you also choose the instance type. For some instance types, such as GPU, you need to set additional parameters. For more information, see Task definition use cases.

• The container image, which holds your application code and all the dependencies that your application code requires to run.

• The networking mode to use for the containers in your task

  The networking mode determines how your task communicates over the network.

  For tasks that run on EC2 instance, there are multiple options, but we recommend that you use the awsvpc network mode. The awsvpc network mode simplifies container networking, because you have more control over how your applications communicate with each other and other services within your VPCs.

  For tasks that run on Fargate, you can only use the awsvpc network mode.

• The logging configuration to use for your tasks.

• Any data volumes that are used with the containers in the task.

For a complete list of task definition parameters, see Task definition parameters.

Use the following guidelines when you create your task definitions:

• Use each task definition family for only one business purpose.

  If you group multiple types of application container together in the same task definition, you can’t independently scale those containers. For example, it's unlikely that both a website and an API require scaling out at the same rate. As traffic increases, there will be a different number of web containers required than API containers. If these two containers are being deployed in the same task definition, every task runs the same number of web containers and API containers.

• Match each application version with a task definition revision within a task definition family.

  Within a task definition family, consider each task definition revision as a point in time snapshot of the settings for a particular container image. This is similar to how the container is a snapshot of all the things that are needed to run a particular version of your application code.
Make sure that there's a one-to-one mapping between a version of application code, a container image tag, and a task definition revision. A typical release process involves a git commit that gets turned into a container image that's tagged with the git commit SHA. Then, that container image tag gets its own Amazon ECS task definition revision. Last, the Amazon ECS service is updated to tell it to deploy the new task definition revision.

- Use different IAM roles for each task definition family.

Define each task definition with its own IAM role. This recommendation should be done in tandem with our recommendation for providing each business component its own task definition family. By implementing both of these best practices, you can limit how much access each service has to resources in your AWS account. For example, you can give your authentication service access to connect to your passwords database. At the same time, you can also ensure that only your order service has access to the credit card payment information.

Best practices for container images

A container image is a set of instructions on how to build the container. A container image holds your application code and all the dependencies that your application code requires to run. Application dependencies include the source code packages that your application code relies on, a language runtime for interpreted languages, and binary packages that your dynamically linked code relies on.

Use the following guidelines when you design and build your container images:

- Make your container images complete by storing all application dependencies as static files inside the container image.
  
  If you change something in the container image, build a new container image with the changes.

- Run a single application process within a container.
  
  The container lifetime is as long as the application process runs. Amazon ECS replaces crashed processes and determines where to launch the replacement process. A complete image makes the overall deployment more resilient.

- Make you application handle SIGTERM.
  
  When Amazon ECS stops a task, it first sends a SIGTERM signal to the task to notify the application that it needs to finish and shut down. Amazon ECS then sends a SIGKILL message.
When applications ignore the SIGTERM, the Amazon ECS service must wait to send the SIGKILL signal to terminate the process.

You need to identify how long it takes your application to complete its work, and ensure that your applications handles the SIGTERM signal. The application's signal handling needs to stop the application from taking new work and complete the work that is in-progress, or save unfinished work to storage outside of the task when the work takes too long to complete.

- Configure containerized applications to write logs to stdout and stderr.

Decoupling log handling from your application code gives you flexibility to adjust log handling at the infrastructure level. One example of this is to change your logging system. Instead of modifying your services, and building and deploying a new container image, you can adjust the settings.

- Use tags to version your container images.

Container images are stored in a container registry. Each image in a registry is identified by a tag. There's a tag called `latest`. This tag functions as a pointer to the latest version of the application container image, similar to the HEAD in a git repository. We recommend that you use the `latest` tag only for testing purposes. As a best practice, tag container images with a unique tag for each build. We recommend that you tag your images using the git SHA for the git commit that was used to build the image.

You don’t need to build a container image for every commit. However, we recommend that you build a new container image each time you release a particular code commit to the production environment. We also recommend that you tag the image with a tag that corresponds to the git commit of the code that's inside the image. If you tagged the image with the git commit, you can more quickly find which version of the code the image is running.

We also recommend that you turn on immutable image tags in Amazon Elastic Container Registry. With this setting, you can't change the container image that a tag points at. Instead Amazon ECR enforces that a new image must be uploaded to a new tag. For more information, see Image tag mutability in the Amazon ECR User Guide.

When you architect your application to run on AWS Fargate, you must decide between deploying multiple containers into the same task definition and deploying containers separately in multiple task definitions. If the following conditions are required, we recommend deploying multiple containers into the same task definition:
• Your containers share a common lifecycle (that is, they're launched and terminated together).
• Your containers must run on the same underlying host (that is, one container references the other on a localhost port).
• You containers share resources.
• Your containers share data volumes.

If these conditions aren't required, we recommend deploying containers separately in multiple task definitions. This allows you to scale, provision, and deprovision the containers separately.

### Best practices for Amazon ECS task sizes

One of the most important choices to make when deploying containers on Amazon ECS is your container and task sizes. Your container and task sizes are both essential for scaling and capacity planning. In Amazon ECS, there are two resource metrics used for capacity: CPU and memory. CPU is measured in units of 1/1024 of a full vCPU (where 1024 units is equal to 1 whole vCPU). Memory is measured in megabytes. In your task definition, you can declare resource reservations and limits.

When you declare a reservation, you're declaring the minimum amount of resources that a task requires. Your task receives at least the amount of resources requested. Your application might be able to use more CPU or memory than the reservation that you declare. However, this is subject to any limits that you also declared. Using more than the reservation amount is known as bursting. In Amazon ECS, reservations are guaranteed. For example, if you use Amazon EC2 instances to provide capacity, Amazon ECS doesn't place a task on an instance where the reservation can't be fulfilled.

A limit is the maximum amount of CPU units or memory that your container or task can use. Any attempt to use more CPU more than this limit results in throttling. Any attempt to use more memory results in your container being stopped.

Choosing these values can be challenging. This is because the values that are the most well suited for your application greatly depend on the resource requirements of your application. Load testing your application is the key to successful resource requirement planning and better understanding your application's requirements.

### Stateless applications

For stateless applications that scale horizontally, such as an application behind a load balancer, we recommend that you first determine the amount of memory that your application consumes
when it serves requests. To do this, you can use traditional tools such as `ps` or `top`, or monitoring solutions such as CloudWatch Container Insights.

When determining a CPU reservation, consider how you want to scale your application to meet your business requirements. You can use smaller CPU reservations, such as 256 CPU units (or 1/4 vCPU), to scale out in a fine-grained way that minimizes cost. But, they might not scale fast enough to meet significant spikes in demand. You can use larger CPU reservations to scale in and out more quickly and therefore match demand spikes more quickly. However, larger CPU reservations are more costly.

**Other applications**

For applications that don't scale horizontally, such as singleton workers or database servers, available capacity and cost represent your most important considerations. You should choose the amount of memory and CPU based on what load testing indicates you need to serve traffic to meet your service-level objective. Amazon ECS ensures that the application is placed on a host that has adequate capacity.

**Task networking for tasks on Amazon EC2 instances**

The networking behavior of Amazon ECS tasks that are hosted on Amazon EC2 instances is dependent on the `network mode` that's defined in the task definition. We recommend that you use the `awsvpc` network mode unless you have a specific need to use a different network mode.

The following are the available network modes.

<table>
<thead>
<tr>
<th>Network mode</th>
<th>Linux containers on EC2</th>
<th>Windows containers on EC2</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>---------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>host</td>
<td>Yes</td>
<td>No</td>
<td>The task uses the host's network which bypasses Docker’s built-in virtual network by mapping container ports directly to the ENI of the Amazon EC2 instance that hosts the task. Dynamic port mappings can’t be used in this network mode. A container in a task definition that uses this mode must specify a specific hostPort number. A port number on a host can’t be used by multiple tasks. As a result, you can’t run multiple tasks of the same task definition on a single Amazon EC2 instance.</td>
</tr>
<tr>
<td>none</td>
<td>Yes</td>
<td>No</td>
<td>The task has no external network connectivity.</td>
</tr>
<tr>
<td>default</td>
<td>No</td>
<td>Yes</td>
<td>The task uses Docker’s built-in virtual network on Windows, which runs inside each Amazon EC2 instance that hosts the task. The built-in virtual network on Windows uses the nat Docker network driver. This is the default network mode on Windows if a network mode isn't specified in the task definition.</td>
</tr>
</tbody>
</table>

For more information about Docker networking on Linux, see [Networking overview](#) in the [Docker Documentation](#).

For more information about Docker networking on Windows, see [Windows container networking](#) in the Microsoft [Containers on Windows Documentation](#).

**Topics**
The task networking features that are provided by the `awsvpc` network mode give Amazon ECS tasks the same networking properties as Amazon EC2 instances. Using the `awsvpc` network mode simplifies container networking, because you have more control over how your applications communicate with each other and other services within your VPCs. The `awsvpc` network mode also provides greater security for your containers by allowing you to use security groups and network monitoring tools at a more granular level within your tasks. You can also use other Amazon EC2 networking features such as VPC Flow Logs to monitor traffic to and from your tasks. Additionally, containers that belong to the same task can communicate over the `localhost` interface.

The task elastic network interface (ENI) is a fully managed feature of Amazon ECS. Amazon ECS creates the ENI and attaches it to the host Amazon EC2 instance with the specified security group. The task sends and receives network traffic over the ENI in the same way that Amazon EC2 instances do with their primary network interfaces. Each task ENI is assigned a private IPv4 address by default. If your VPC is enabled for dual-stack mode and you use a subnet with an IPv6 CIDR block, the task ENI will also receive an IPv6 address. Each task can only have one ENI.

These ENIs are visible in the Amazon EC2 console for your account. Your account can't detach or modify the ENIs. This is to prevent accidental deletion of an ENI that is associated with a running task. You can view the ENI attachment information for tasks in the Amazon ECS console or with the `DescribeTasks` API operation. When the task stops or if the service is scaled down, the task ENI is detached and deleted.

When you need increased ENI density, use the `awsvpcTrunking` account setting. Amazon ECS also creates and attaches a "trunk" network interface for your container instance. The trunk network is fully managed by Amazon ECS. The trunk ENI is deleted when you either terminate or deregister your container instance from the Amazon ECS cluster. For more information about the `awsvpcTrunking` account setting, see Prerequisites.

You specify `awsvpc` in the `networkMode` parameter of the task definition. For more information, see Network mode.
Then, when you run a task or create a service, use the `networkConfiguration` parameter that includes one or more subnets to place your tasks in and one or more security groups to attach to an ENI. For more information, see [Network configuration](#). The tasks are placed on compatible Amazon EC2 instances in the same Availability Zones as those subnets, and the specified security groups are associated with the ENI that's provisioned for the task.

**Linux considerations**

Consider the following when using the Linux operating system.

- Tasks and services that use the `awsvpc` network mode require the Amazon ECS service-linked role to provide Amazon ECS with the permissions to make calls to other AWS services on your behalf. This role is created for you automatically when you create a cluster or if you create or update a service, in the AWS Management Console. For more information, see [Using service-linked roles for Amazon ECS](#). You can also create the service-linked role with the following AWS CLI command:

  ```bash
  aws iam create-service-linked-role --aws-service-name ecs.amazonaws.com
  ```

- Your Amazon EC2 Linux instance requires version 1.15.0 or later of the container agent to run tasks that use the `awsvpc` network mode. If you're using an Amazon ECS-optimized AMI, your instance needs at least version 1.15.0-4 of the `ecs-init` package as well.

- Amazon ECS populates the hostname of the task with an Amazon-provided (internal) DNS hostname when both the `enableDnsHostnames` and `enableDnsSupport` options are enabled on your VPC. If these options aren't enabled, the DNS hostname of the task is set to a random hostname. For more information about the DNS settings for a VPC, see [Using DNS with Your VPC](#) in the *Amazon VPC User Guide*.

- Each Amazon ECS task that uses the `awsvpc` network mode receives its own elastic network interface (ENI), which is attached to the Amazon EC2 instance that hosts it. There's a default quota for the number of network interfaces that can be attached to an Amazon EC2 Linux instance. The primary network interface counts as one toward that quota. For example, by default, a `c5.large` instance might have only up to three ENIs that can be attached to it. The primary network interface for the instance counts as one. You can attach an additional two ENIs to the instance. Because each task that uses the `awsvpc` network mode requires an ENI, you can typically only run two such tasks on this instance type. For more information about the default ENI limits for each instance type, see [IP addresses per network interface per instance type](#) in the *Amazon EC2 User Guide for Linux Instances*. 

Task networking for tasks on Amazon EC2 instances
• Amazon ECS supports the launch of Amazon EC2 Linux instances that use supported instance types with increased ENI density. When you opt in to the awsvpcTrunking account setting and register Amazon EC2 Linux instances that use these instance types to your cluster, these instances have higher ENI quota. Using these instances with this higher quota means that you can place more tasks on each Amazon EC2 Linux instance. To use the increased ENI density with the trunking feature, your Amazon EC2 instance must use version 1.28.1 or later of the container agent. If you’re using an Amazon ECS-optimized AMI, your instance also requires at least version 1.28.1-2 of the ecs-init package. For more information about opting in to the awsvpcTrunking account setting, see Accessing Amazon ECS features through account settings. For more information about ENI trunking, see Elastic network interface trunking.

• When hosting tasks that use the awsvpc network mode on Amazon EC2 Linux instances, your task ENIs aren't given public IP addresses. To access the internet, tasks must be launched in a private subnet that's configured to use a NAT gateway. For more information, see NAT gateways in the Amazon VPC User Guide. Inbound network access must be from within a VPC that uses the private IP address or routed through a load balancer from within the VPC. Tasks that are launched within public subnets do not have access to the internet.

• Amazon ECS recognizes only the ENIs that it attaches to your Amazon EC2 Linux instances. If you manually attached ENIs to your instances, Amazon ECS might attempt to add a task to an instance that doesn't have enough network adapters. This can result in the task timing out and moving to a deprovisioning status and then a stopped status. We recommend that you don't attach ENIs to your instances manually.

• Amazon EC2 Linux instances must be registered with the ecs.capability.task-eni capability to be considered for placement of tasks with the awsvpc network mode. Instances running version 1.15.0-4 or later of ecs-init are registered with this attribute automatically.

• The ENIs that are created and attached to your Amazon EC2 Linux instances cannot be detached manually or modified by your account. This is to prevent the accidental deletion of an ENI that is associated with a running task. To release the ENIs for a task, stop the task.

• There is a limit of 16 subnets and 5 security groups that are able to be specified in the awsVpcConfiguration when running a task or creating a service that uses the awsvpc network mode. For more information, see AwsVpcConfiguration in the Amazon Elastic Container Service API Reference.

• When a task is started with the awsvpc network mode, the Amazon ECS container agent creates an additional pause container for each task before starting the containers in the task definition. It then configures the network namespace of the pause container by running the amazon-ecs-cni-plugins CNI plugins. The agent then starts the rest of the containers in the task so that they
share the network stack of the `pause` container. This means that all containers in a task are addressable by the IP addresses of the ENI, and they can communicate with each other over the `localhost` interface.

- Services with tasks that use the `awsvpc` network mode only support Application Load Balancer and Network Load Balancer. When you create any target groups for these services, you must choose `ip` as the target type. Do not use `instance`. This is because tasks that use the `awsvpc` network mode are associated with an ENI, not with an Amazon EC2 Linux instance. For more information, see Distribute Amazon ECS service traffic using load balancing.

- If your VPC is updated to change the DHCP options set it uses, you can't apply these changes to existing tasks. Start new tasks with these changes applied to them, verify that they are working correctly, and then stop the existing tasks in order to safely change these network configurations.

## Windows considerations

The following are considerations when you use the Windows operating system:

- Container instances using the Amazon ECS optimized Windows Server 2016 AMI can't host tasks that use the `awsvpc` network mode. If you have a cluster that contains Amazon ECS optimized Windows Server 2016 AMIs and Windows AMIs that support `awsvpc` network mode, tasks that use `awsvpc` network mode aren't launched on the Windows 2016 Server instances. Rather, they're launched on instances that support `awsvpc` network mode.

- Your Amazon EC2 Windows instance requires version 1.57.1 or later of the container agent to use CloudWatch metrics for Windows containers that use the `awsvpc` network mode.

- Tasks and services that use the `awsvpc` network mode require the Amazon ECS service-linked role to provide Amazon ECS with the permissions to make calls to other AWS services on your behalf. This role is created for you automatically when you create a cluster, or if you create or update a service, in the AWS Management Console. For more information, see Using service-linked roles for Amazon ECS. You can also create the service-linked role with the following AWS CLI command.

  ```bash
  aws iam create-service-linked-role --aws-service-name ecs.amazonaws.com
  ```

- Your Amazon EC2 Windows instance requires version 1.54.0 or later of the container agent to run tasks that use the `awsvpc` network mode. When you bootstrap the instance, you must
configure the options that are required for awsvpc network mode. For more information, see the section called “Bootstrap Container Instances”.

- Amazon ECS populates the hostname of the task with an Amazon provided (internal) DNS hostname when both the enableDnsHostnames and enableDnsSupport options are enabled on your VPC. If these options aren't enabled, the DNS hostname of the task is a random hostname. For more information about the DNS settings for a VPC, see Using DNS with Your VPC in the Amazon VPC User Guide.

- Each Amazon ECS task that uses the awsvpc network mode receives its own elastic network interface (ENI), which is attached to the Amazon EC2 Windows instance that hosts it. There is a default quota for the number of network interfaces that can be attached to an Amazon EC2 Windows instance. The primary network interface counts as one toward this quota. For example, by default a c5.large instance might have only up to three ENIs attached to it. The primary network interface for the instance counts as one of those. You can attach an additional two ENIs to the instance. Because each task using the awsvpc network mode requires an ENI, you can typically only run two such tasks on this instance type. For more information about the default ENI limits for each instance type, see IP addresses per network interface per instance type in the Amazon EC2 User Guide for Windows Instances.

- When hosting tasks that use the awsvpc network mode on Amazon EC2 Windows instances, your task ENIs aren't given public IP addresses. To access the internet, launch tasks in a private subnet that's configured to use a NAT gateway. For more information, see NAT gateways in the Amazon VPC User Guide. Inbound network access must be from within the VPC that is using the private IP address or routed through a load balancer from within the VPC. Tasks that are launched within public subnets don't have access to the internet.

- Amazon ECS recognizes only the ENIs that it has attached to your Amazon EC2 Windows instance. If you manually attached ENIs to your instances, Amazon ECS might attempt to add a task to an instance that doesn't have enough network adapters. This can result in the task timing out and moving to a deprovisioning status and then a stopped status. We recommend that you don't attach ENIs to your instances manually.

- Amazon EC2 Windows instances must be registered with the ecs.capability.task-eni capability to be considered for placement of tasks with the awsvpc network mode.

- You can't manually modify or detach ENIs that are created and attached to your Amazon EC2 Windows instances. This is to prevent you from accidentally deleting an ENI that's associated with a running task. To release the ENIs for a task, stop the task.
• You can only specify up to 16 subnets and 5 security groups in `awsVpcConfiguration` when you run a task or create a service that uses the `awsvpc` network mode. For more information, see `AwsVpcConfiguration` in the `Amazon Elastic Container Service API Reference`.

• When a task is started with the `awsvpc` network mode, the Amazon ECS container agent creates an additional pause container for each task before starting the containers in the task definition. It then configures the network namespace of the pause container by running the `amazon-ecs-cni-plugins` CNI plugins. The agent then starts the rest of the containers in the task so that they share the network stack of the pause container. This means that all containers in a task are addressable by the IP addresses of the ENI, and they can communicate with each other over the localhost interface.

• Services with tasks that use the `awsvpc` network mode only support Application Load Balancer and Network Load Balancer. When you create any target groups for these services, you must choose `ip` as the target type, not `instance`. This is because tasks that use the `awsvpc` network mode are associated with an ENI, not with an Amazon EC2 Windows instance. For more information, see `Distribute Amazon ECS service traffic using load balancing`.

• If your VPC is updated to change the DHCP options set it uses, you can’t apply these changes to existing tasks. Start new tasks with these changes applied to them, verify that they are working correctly, and then stop the existing tasks in order to safely change these network configurations.

• The following are not supported when you use `awsvpc` network mode in an EC2 Windows configuration:
  • Dual-stack configuration
  • IPv6
  • ENI trunking

**Using a VPC in dual-stack mode**

When using a VPC in dual-stack mode, your tasks can communicate over IPv4, or IPv6, or both. IPv4 and IPv6 addresses are independent of each other. Therefore you must configure routing and security in your VPC separately for IPv4 and IPv6. For more information about how to configure your VPC for dual-stack mode, see `Migrating to IPv6` in the `Amazon VPC User Guide`.

If you configured your VPC with an internet gateway or an outbound-only internet gateway, you can use your VPC in dual-stack mode. By doing this, tasks that are assigned an IPv6 address can access the internet through an internet gateway or an egress-only internet gateway. NAT gateways
are optional. For more information, see Internet gateways and Egress-only internet gateways in the Amazon VPC User Guide.

Amazon ECS tasks are assigned an IPv6 address if the following conditions are met:

- The Amazon EC2 Linux instance that hosts the task is using version 1.45.0 or later of the container agent. For information about how to check the agent version your instance is using, and updating it if needed, see Updating the Amazon ECS container agent.
- The dualStackIPv6 account setting is enabled. For more information, see Accessing Amazon ECS features through account settings.
- Your task is using the awsvpc network mode.
- Your VPC and subnet are configured for IPv6. The configuration includes the network interfaces that are created in the specified subnet. For more information about how to configure your VPC for dual-stack mode, see Migrating to IPv6 and Modify the IPv6 addressing attribute for your subnet in the Amazon VPC User Guide.

**Host mode**

The host network mode is only supported for Amazon ECS tasks hosted on Amazon EC2 instances. It's not supported when using Amazon ECS on Fargate.

The host network mode is the most basic network mode that's supported in Amazon ECS. Using host mode, the networking of the container is tied directly to the underlying host that's running the container.
Assume that you're running a Node.js container with an Express application that listens on port 3000 similar to the one illustrated in the preceding diagram. When the host network mode is used, the container receives traffic on port 3000 using the IP address of the underlying host Amazon EC2 instance. We do not recommend using this mode.

There are significant drawbacks to using this network mode. You can’t run more than a single instantiation of a task on each host. This is because only the first task can bind to its required port on the Amazon EC2 instance. There's also no way to remap a container port when it's using host network mode. For example, if an application needs to listen on a particular port number, you can't remap the port number directly. Instead, you must manage any port conflicts through changing the application configuration.

There are also security implications when using the host network mode. This mode allows containers to impersonate the host, and it allows containers to connect to private loopback network services on the host.
Bridge mode

The bridge network mode is only supported for Amazon ECS tasks hosted on Amazon EC2 instances.

With bridge mode, you're using a virtual network bridge to create a layer between the host and the networking of the container. This way, you can create port mappings that remap a host port to a container port. The mappings can be either static or dynamic.

With a static port mapping, you can explicitly define which host port you want to map to a container port. Using the example above, port 80 on the host is being mapped to port 3000 on the container. To communicate to the containerized application, you send traffic to port 80 to the Amazon EC2 instance's IP address. From the containerized application's perspective it sees that inbound traffic on port 3000.
If you only want to change the traffic port, then static port mappings is suitable. However, this still has the same disadvantage as using the host network mode. You can't run more than a single instantiation of a task on each host. This is because a static port mapping only allows a single container to be mapped to port 80.

To solve this problem, consider using the bridge network mode with a dynamic port mapping as shown in the following diagram.

By not specifying a host port in the port mapping, you can have Docker choose a random, unused port from the ephemeral port range and assign it as the public host port for the container. For example, the Node.js application listening on port 3000 on the container might be assigned a random high number port such as 47760 on the Amazon EC2 host. Doing this means that you can run multiple copies of that container on the host. Moreover, each container can be assigned its own port on the host. Each copy of the container receives traffic on port 3000. However, clients that send traffic to these containers use the randomly assigned host ports.

Amazon ECS helps you to keep track of the randomly assigned ports for each task. It does this by automatically updating load balancer target groups and AWS Cloud Map service discovery to have the list of task IP addresses and ports. This makes it easier to use services operating using bridge mode with dynamic ports.
However, one disadvantage of using the bridge network mode is that it's difficult to lock down service to service communications. Because services might be assigned to any random, unused port, it's necessary to open broad port ranges between hosts. However, it's not easy to create specific rules so that a particular service can only communicate to one other specific service. The services have no specific ports to use for security group networking rules.

**Task networking for tasks on Fargate**

By default, every Amazon ECS task on Fargate is provided an elastic network interface (ENI) with a primary private IP address. When using a public subnet, you can optionally assign a public IP address to the task's ENI. If your VPC is configured for dual-stack mode and you use a subnet with an IPv6 CIDR block, your task's ENI also receives an IPv6 address. A task can only have one ENI that's associated with it at a time. Containers that belong to the same task can also communicate over the localhost interface. For more information about VPCs and subnets, see [VPCs and subnets in the Amazon VPC User Guide](#).

For a task on Fargate to pull a container image, the task must have a route to the internet. The following describes how you can verify that your task has a route to the internet.

- When using a public subnet, you can assign a public IP address to the task ENI.
- When using a private subnet, the subnet can have a NAT gateway attached.
- When using container images that are hosted in Amazon ECR, you can configure Amazon ECR to use an interface VPC endpoint and the image pull occurs over the task's private IPv4 address. For more information, see [Amazon ECR interface VPC endpoints (AWS PrivateLink)](#) in the Amazon Elastic Container Registry User Guide.

Because each task gets its own ENI, you can use networking features such as VPC Flow Logs, which you can use to monitor traffic to and from your tasks. For more information, see [VPC Flow Logs](#) in the Amazon VPC User Guide.

You can also take advantage of AWS PrivateLink. You can configure a VPC interface endpoint so that you can access Amazon ECS APIs through private IP addresses. AWS PrivateLink restricts all network traffic between your VPC and Amazon ECS to the Amazon network. You don't need an internet gateway, a NAT device, or a virtual private gateway. For more information, see [AWS PrivateLink](#) in the Amazon ECS Best Practices Guide.

For examples of how to use the NetworkConfiguration resource with AWS CloudFormation, see the section called “Creating Amazon ECS resources using separate stacks”. 
The ENIs that are created are fully managed by AWS Fargate. Moreover, there's an associated IAM policy that's used to grant permissions for Fargate. For tasks using Fargate platform version 1.4.0 or later, the task receives a single ENI (referred to as the task ENI) and all network traffic flows through that ENI within your VPC. This traffic is recorded in your VPC flow logs. For tasks that use Fargate platform version 1.3.0 and earlier, in addition to the task ENI, the task also receives a separate Fargate owned ENI, which is used for some network traffic that isn't visible in the VPC flow logs. The following table describes the network traffic behavior and the required IAM policy for each platform version.

<table>
<thead>
<tr>
<th>Action</th>
<th>Traffic flow with Linux platform version 1.3.0 and earlier</th>
<th>Traffic flow with Linux platform version 1.4.0</th>
<th>Traffic flow with Windows platform version 1.0.0</th>

### Fargate task networking considerations

Consider the following when using task networking.

- The Amazon ECS service-linked role is required to provide Amazon ECS with the permissions to make calls to other AWS services on your behalf. This role is created for you when you create a cluster or if you create or update a service in the AWS Management Console. For more information, see [Using service-linked roles for Amazon ECS](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/service-linked-roles.html). You can also create the service-linked role using the following AWS CLI command.

  ```bash
  aws iam create-service-linked-role --aws-service-name ecs.amazonaws.com
  ```

- Amazon ECS populates the hostname of the task with an Amazon provided DNS hostname when both the `enableDnsHostnames` and `enableDnsSupport` options are enabled on your VPC. If these options aren't enabled, the DNS hostname of the task is set to a random hostname. For more information about the DNS settings for a VPC, see [Using DNS with Your VPC](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/dns.html) in the *Amazon VPC User Guide*.

- You can only specify up to 16 subnets and 5 security groups for `awsVpcConfiguration`. For more information, see [AwsVpcConfiguration](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/task-vpc-settings.html) in the *Amazon Elastic Container Service API Reference*.

- You can't manually detach or modify the ENIs that are created and attached by Fargate. This is to prevent the accidental deletion of an ENI that's associated with a running task. To release the ENIs for a task, stop the task.

- If a VPC subnet is updated to change the DHCP options set it uses, you can't also apply these changes to existing tasks that use the VPC. Start new tasks, which will receive the new setting to smoothly migrate while testing the new change and then stop the old ones, if no rollback is required.
• Tasks that are launched in subnets with IPv6 CIDR blocks only receive an IPv6 address when using Fargate platform version 1.4.0 or later for Linux or 1.0.0 for Windows.

• For tasks that use platform version 1.4.0 or later for Linux or 1.0.0 for Windows, the task ENIs support jumbo frames. Network interfaces are configured with a maximum transmission unit (MTU), which is the size of the largest payload that fits within a single frame. The larger the MTU, the more application payload can fit within a single frame, which reduces per-frame overhead and increases efficiency. Supporting jumbo frames reduces overhead when the network path between your task and the destination supports jumbo frames.

• Services with tasks that use the Fargate launch type only support Application Load Balancer and Network Load Balancer. Classic Load Balancer isn't supported. When you create any target groups, you must choose ip as the target type, not instance. For more information, see Distribute Amazon ECS service traffic using load balancing.

Using a VPC in dual-stack mode

When using a VPC in dual-stack mode, your tasks can communicate over IPv4 or IPv6, or both. IPv4 and IPv6 addresses are independent of each other and you must configure routing and security in your VPC separately for IPv4 and IPv6. For more information about configuring your VPC for dual-stack mode, see Migrating to IPv6 in the Amazon VPC User Guide.

If the following conditions are met, Amazon ECS tasks on Fargate are assigned an IPv6 address:

• Your Amazon ECS dualStackIPv6 account setting is turned on (enabled) for the IAM principal launching your tasks in the Region you're launching your tasks in. This setting can only be modified using the API or AWS CLI. You have the option to turn this setting on for a specific IAM principal on your account or for your entire account by setting your account default setting. For more information, see Accessing Amazon ECS features through account settings.

• Your VPC and subnet are enabled for IPv6. For more information about how to configure your VPC for dual-stack mode, see Migrating to IPv6 in the Amazon VPC User Guide.

• Your subnet is enabled for auto-assigning IPv6 addresses. For more information about how to configure your subnet, see Modify the IPv6 addressing attribute for your subnet in the Amazon VPC User Guide.

• The task or service uses Fargate platform version 1.4.0 or later for Linux.

If you configure your VPC with an internet gateway or an outbound-only internet gateway, Amazon ECS tasks on Fargate that are assigned an IPv6 address can access the internet. NAT gateways
aren't needed. For more information, see Internet gateways and Egress-only internet gateways in the Amazon VPC User Guide.

**Fargate task ephemeral storage**

When provisioned, each Amazon ECS task hosted on Linux containers on AWS Fargate receives the following ephemeral storage for bind mounts. This can be mounted and shared among containers that use the volumes, mountPoints, and volumesFrom parameters in the task definition. This isn't supported for Windows containers on AWS Fargate.

**Fargate Linux container platform versions**

**Version 1.4.0 or later**

By default, Amazon ECS tasks that are hosted on Fargate using platform version 1.4.0 or later receive a minimum of 20 GiB of ephemeral storage. The total amount of ephemeral storage can be increased, up to a maximum of 200 GiB. You can do this by specifying the ephemeralStorage parameter in your task definition.

The pulled, compressed, and the uncompressed container image for the task is stored on the ephemeral storage. To determine the total amount of ephemeral storage your task has to use, you must subtract the amount of storage your container image uses from the total amount of ephemeral storage your task is allocated.

For tasks that use platform version 1.4.0 or later that are launched on May 28, 2020 or later, the ephemeral storage is encrypted with an AES-256 encryption algorithm. This algorithm uses an AWS owned encryption key.

For tasks that use platform version 1.4.0 or later that are launched on November 18, 2022 or later, the ephemeral storage usage is reported through the task metadata endpoint. Your applications in your tasks can query the task metadata endpoint version 4 to get their ephemeral storage reserved size and the amount used.

Additionally, the ephemeral storage reserved size and the amount used are sent to Amazon CloudWatch Container Insights if you turn on Container Insights.
Amazon Elastic Container Service

Developer Guide

Note
Fargate reserves space on disk. It is only used by Fargate. You aren't billed for it. It isn't shown in these metrics. However, you can see this additional storage in other tools such as `df`.

Version 1.3.0 or earlier

For Amazon ECS on Fargate tasks that use platform version 1.3.0 or earlier, each task receives the following ephemeral storage.

- 10 GB of Docker layer storage

  Note
  This amount includes both compressed and uncompressed container image artifacts.

- An additional 4 GB for volume mounts. This can be mounted and shared among containers that use the `volumes`, `mountPoints`, and `volumesFrom` parameters in the task definition.

Fargate Windows container platform versions

Version 1.0.0 or later

By default, Amazon ECS tasks that are hosted on Fargate using platform version 1.0.0 or later receive a minimum of 20 GiB of ephemeral storage. The total amount of ephemeral storage can be increased, up to a maximum of 200 GiB. You can do this by specifying the `ephemeralStorage` parameter in your task definition.

The pulled, compressed, and the uncompressed container image for the task is stored on the ephemeral storage. To determine the total amount of ephemeral storage that your task has to use, you must subtract the amount of storage that your container image uses from the total amount of ephemeral storage your task is allocated.

For more information, see [Bind mounts](#).

Using data volumes in tasks

Amazon ECS supports the following data volume options for containers:
Amazon EBS volumes – These volumes provide cost-effective, durable, high-performance block storage for data-intensive containerized workloads. You can configure at most 1 EBS volume for attachment to a standalone ECS task when you run the task. Or, you can configure 1 EBS volume per task for attachment to each task launched via an ECS service when you create or update the service. Amazon EBS volumes are supported for Linux tasks that are hosted on Fargate or Amazon EC2 instances. For more information, see Amazon EBS volumes.

Fargate ephemeral task storage – By default, Amazon ECS tasks that are hosted on Fargate using platform version 1.4.0 or later receive a minimum of 20 GiB of ephemeral storage. The total amount of ephemeral storage can be increased, up to a maximum of 200 GiB. You can do this by specifying the ephemeralStorage parameter in your task definition.

Amazon Elastic File System (Amazon EFS) volumes – These volumes provide simple, scalable, and persistent file storage for use with your Amazon ECS tasks. With Amazon EFS, storage capacity is elastic. It grows and shrinks automatically as you add and remove files. Your applications can have the storage that they need when they need it. Amazon EFS volumes are supported for tasks that are hosted on Fargate or Amazon EC2 instances. For more information, see Amazon EFS volumes.

Amazon FSx for Windows File Server volumes – These volumes provide fully managed Windows file servers. These file servers are backed by a Windows file system. When using FSx for Windows File Server together with Amazon ECS, you can provision your Windows tasks with persistent, distributed, shared, and static file storage. For more information, see FSx for Windows File Server volumes.

Windows containers on Fargate do not support this option.

Docker volumes – These volumes are Docker-managed volumes that are created under /var/lib/docker/volumes on the host Amazon EC2 instance. Docker volume drivers (also referred to as plugins) are used to integrate the volumes with external storage systems, such as Amazon EBS. The built-in local volume driver or a third-party volume driver can be used. Docker volumes are supported only when running tasks on Amazon EC2 instances. Windows containers support only the use of the local driver. To use Docker volumes, specify a dockerVolumeConfiguration in your task definition. For more information, see Docker volumes.

Bind mounts – These volumes consist of a file or directory on the host, such as an Amazon EC2 instance or AWS Fargate, that is mounted into a container. Bind mount host volumes are supported for tasks that are hosted on Fargate or Amazon EC2 instances. Bind mount host volumes use ephemeral storage on Fargate. The amount of ephemeral storage differs on the
various Fargate platform versions. You can request up to 200 gibibytes (GiB) of ephemeral storage on Fargate Linux platform version 1.4.0 or later. For more information, see Bind mounts.

Amazon EBS volumes

Amazon Elastic Block Store (Amazon EBS) volumes provide highly available, cost-effective, durable, high-performance block storage for data-intensive workloads. Amazon EBS volumes can be used with Amazon ECS tasks for high throughput and transaction-intensive applications. You can configure at most 1 EBS volume for attachment to a standalone ECS task when you run the task. Or, you can configure 1 EBS volume per task for attachment to each task launched via an ECS service when you create or update the service.

Amazon EBS volumes that are attached to Amazon ECS tasks are managed by ECS on your behalf, and can be encrypted with AWS Key Management Service (AWS KMS) keys to protect your data. You can either configure new, empty volumes for attachment, or you can use snapshots to load data from existing volumes.

To monitor your volume's performance, you can also use Amazon EBS Amazon CloudWatch metrics. For more information about metrics, see Amazon CloudWatch metrics for Amazon EBS in the Amazon EC2 User Guide.

For more information about Amazon EBS volumes, see Amazon EBS volumes in the Amazon EC2 User Guide.

AWS Regions and Availability Zones for Amazon EBS volumes

Amazon EBS volumes can be attached to Amazon ECS tasks in the following AWS Regions:

<table>
<thead>
<tr>
<th>Region name</th>
<th>Region code</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (N. Virginia)</td>
<td>us-east-1</td>
</tr>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
</tr>
<tr>
<td>US West (N. California)</td>
<td>us-west-1</td>
</tr>
<tr>

</tbody>
</table>
Amazon EBS volume considerations

Consider the following when using Amazon EBS volumes:

- Amazon EBS volumes are supported only for Linux tasks hosted on Fargate, and EC2 launch type tasks hosted on Nitro-based Linux instances with Amazon ECS-optimized Amazon Machine Images (AMIs).

- For tasks that are hosted on Fargate, Amazon EBS volumes are supported on platform version 1.4.0 or later (Linux). For more information, see Fargate Linux platform versions.

- For tasks that are hosted on Amazon EC2 Linux instances, Amazon EBS volumes are supported on ECS-optimized AMI 20231219 or later. For more information, see Retrieving Amazon ECS-Optimized AMI metadata.

- The magnetic (standard) Amazon EBS volume type is not supported for tasks hosted on Fargate. For more information about Amazon EBS volume types, see Amazon EBS volumes in the Amazon EC2 User Guide.

- An Amazon ECS infrastructure IAM role is required when creating a service or a standalone task that is configuring a volume at deployment. You can attach the AWS managed AmazonECSInfrastructureRolePolicyForVolumes IAM policy to the role, or you can use the managed policy as a guide to create and attach your own policy with permissions that meet your specific needs. For more information, see Amazon ECS infrastructure IAM role.

- You can attach at most one Amazon EBS volume to each Amazon ECS task, and it must be a new volume. You cannot attach an existing Amazon EBS volume to a task. However, you can configure a new Amazon EBS volume at deployment using the snapshot of an existing volume.

- You can configure Amazon EBS volumes at deployment only for services that use the rolling update deployment type and the Replica scheduling strategy.
Amazon ECS automatically adds the reserved tags AmazonECSCreated and AmazonECSManaged. If you remove these tags from the volume, Amazon ECS won't be able to manage the volume on your behalf. For more information about tagging Amazon EBS volumes, see Tagging Amazon EBS volumes. For more information about tagging Amazon ECS resources, see Tagging your Amazon ECS resources.

- Provisioning volumes from a snapshot of an Amazon EBS volume that contains partitions is not supported.
- Volumes that are attached to tasks that are managed by a service are not preserved and are always deleted upon task termination.
- You can't attach an Amazon EBS volume to an EC2 launch type task that's launched on a container instance based on the Xen system. For more information about instance types, see Instance types in the Amazon EC2 User Guide.
- You can't configure Amazon EBS volumes for attachment to Amazon ECS tasks that are running on AWS Outposts.

**Data encryption for Amazon EBS volumes**

You can use AWS Key Management Service (AWS KMS) to make and manage cryptographic keys that protect your data. Amazon EBS volumes are encrypted at rest by using AWS KMS keys. The following types of data are encrypted:

- Data stored at rest on the volume
- Disk I/O
- Snapshots created from the volume
- New volumes created from snapshots

You can configure Amazon EBS encryption by default so that all new volumes created and attached to a task are encrypted by using the KMS key that you configure for your account. For more information about Amazon EBS encryption and encryption by default, see Amazon EBS encryption in the Amazon EC2 User Guide.

Amazon EBS volumes that are attached to tasks can be encrypted by using either a default AWS managed key with the alias alias/aws/ebs, or a symmetric customer managed key. Default AWS managed keys are unique to each AWS account per AWS Region and are created automatically. To create a symmetric customer managed key, follow the steps in Creating symmetric encryption KMS keys in the AWS KMS Developer Guide.
Customer managed KMS key policy

To use your customer managed key to encrypt the EBS volume that's configured for attachment to your task, you must configure your KMS key policy to ensure that the IAM role that you use for volume configuration has the necessary permissions to use the key. The key policy must include the `kms:CreateGrant` and `kms:GenerateDataKey*` permissions. The `kms:ReEncryptTo` and `kms:ReEncryptFrom` permissions are necessary for encrypting volumes that are created using snapshots. If you want to configure and encrypt only new, empty volumes for attachment, you can exclude the `kms:ReEncryptTo` and `kms:ReEncryptFrom` permissions.

The following JSON snippet shows example key policy statements that must be attached to your KMS key policy to allow access for ECS to use the key for encrypting the EBS volume. To use the example policy statements, replace the `user input placeholders` with your own information. As always, only configure the permissions that you need.

```
{
   "Sid": "ReadOnlyPermissions",
   "Effect": "Allow",
   "Principal": { "AWS": "arn:aws:iam::111122223333:role/ecsInfrastructureRole" },
   "Action": "kms:DescribeKey",
   "Resource": "*"
},
{
   "Sid": "DataKeyGenerationForAmazonEBS",
   "Effect": "Allow",
   "Principal": { "AWS": "arn:aws:iam::111122223333:role/ecsInfrastructureRole" },
   "Action": [
      "kms:GenerateDataKey*",
      "kms:ReEncryptTo",
      "kms:ReEncryptFrom"
   ],
   "Resource": "*",
   "Condition": {
      "StringEquals": {
         "kms:CallerAccount": "aws_account_id",
         "kms:ViaService": "ec2.region.amazonaws.com"
      },
      "ForAnyValue:StringEquals": {
         "kms:EncryptionContextKeys": "aws:ebs:id"
      }
   }
}
```
For more information about key policies and permissions, see Key policies in AWS KMS and AWS KMS permissions in the AWS KMS Developer Guide. For troubleshooting issues related to key permissions, see Troubleshooting Amazon EBS volume attachment issues.

**Configuring Amazon EBS volumes at deployment**

To configure an Amazon EBS volume for attachment to your task, you must specify the mount point configuration in your task definition, name the volume, and set configuredAtLaunch to true. The following task definition JSON snippet shows the syntax for the mountPoints and volumes objects in the task definition. For more information about task definition parameters, see Task definition parameters. To use this example, replace the user input placeholders with your own information.

```json
{
    "family": "mytaskdef",
    "containerDefinitions": [
        {
            "name": "container-using-ebs",
            "image": "amazonlinux:2",
            "entryPoint": ["sh"],
            "sh": ["-c"
```
To register the task definition by using the AWS Command Line Interface (AWS CLI), save the template as a JSON file, and then use the following command. To use this example command, replace the `user input placeholders` with your own information.

```
aws ecs register-task-definition \
   --cli-input-json file://path_to_json_file/task-definition.json
```

To create and register a task definition using the AWS Management Console, see [Creating a task definition using the console](#).

After you register the task definition, you can configure the volume at deployment using the AWS Management Console, Amazon ECS APIs, or by passing an input JSON file with the following AWS CLI commands:

- `run-task` to run a standalone ECS task.
- `start-task` to run a standalone ECS task in a specific container instance. This command is not applicable for Fargate launch type tasks.
- `create-service` to create a new ECS service.
- `update-service` to update an existing service.
Configuring a volume at deployment allows you to create task definitions that aren't constrained to a volume type or specific EBS volume settings. You can then reuse your task definitions across different execution environments. For example, you can provide more throughput for your production workloads than your pre-prod environments.

The following JSON snippet shows all the parameters of an Amazon EBS volume that can be configured at deployment. To use these parameters for volume configuration, replace the user input placeholders with your own information. For more information about these parameters, see Volume configurations.

```json
"volumeConfigurations": [
  {
    "name": "ebs-volume",
    "managedEBSVolume": {
      "encrypted": true,
      "kmsKeyId": "arn:aws:kms:us-east-1:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
      "volumeType": "gp3",
      "sizeInGiB": 10,
      "snapshotId": "snap-12345",
      "iops": 3000,
      "throughput": 125,
      "tagSpecifications": [
        {
          "resourceType": "volume",
          "tags": [
            {
              "key": "key1",
              "value": "value1"
            }
          ],
          "propagateTags": "NONE"
        }
      ],
      "roleArn": "arn:aws::iam:111122223333:role/ecsInfrastructureRole",
      "terminationPolicy": {
        "deleteOnTermination": true,//can't be configured for service-managed tasks, always true
      },
      "filesystemType": "ext4"
    }
  }
]"
For a container in your task to write to the mounted Amazon EBS volume, you must run the container as a root user.

For information about how to diagnose and fix issues that you might encounter when you configure an EBS volume for attachment to a task, see Troubleshooting Amazon EBS volume attachment issues. For information about the Amazon ECS infrastructure AWS Identity and Access Management (IAM) role necessary for EBS volume attachment, see Amazon ECS infrastructure IAM role.

Configuring a volume for a standalone task

The following snippet shows the syntax for configuring Amazon EBS volumes for attachment to a standalone task. The following JSON snippet shows the syntax for configuring the `volumeType`, `sizeInGiB`, encrypted, and `kmsKeyId` settings. Save the following snippet as a JSON file. To use this example, replace the `user input placeholders` with your own information.

```json
{
    "cluster": "mycluster",
    "taskDefinition": "mytaskdef",
    "volumeConfigurations": [
      {
        "name": "datadir",
        "managedEBSVolume": {
          "volumeType": "gp3",
          "sizeInGiB": 100,
          "roleArn": "arn:aws::iam:11112222333:role/ecsInfrastructureRole",
          "encrypted": true,
          "kmsKeyId": "arn:aws:kms:region:11112222333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
        }
      }
    ]
}
```

The following command can be used to run a standalone task using a JSON input file. The configuration specified in the JSON file is used to create and attach an EBS volume to the
standalone task. To use this example, replace the user input placeholders with your own information.

```bash
aws ecs run-task \
   --cli-input-json file://path_to_json_file/task.json
```

To configure a volume for attachment to a standalone task using the AWS Management Console, see Run an application as an Amazon ECS task.

**Configuring a volume at service creation**

The following snippet shows the syntax for configuring Amazon EBS volumes for attachment to tasks managed by a service. The volumes are sourced from the snapshot by using the snapshotId. Save the following snippet as a JSON file. To use this example, replace the user input placeholders with your own information.

```json
{
   "cluster": "mycluster",
   "taskDefinition": "mytaskdef",
   "serviceName": "mysvc",
   "desiredCount": 2,
   "volumeConfigurations": [
      {
         "name": "myEbsVolume",
         "managedEBSVolume": {
            "roleArn": "arn:aws::iam:1111222333:role/ecsInfrastructureRole",
            "snapshotId": "snap-12345"
         }
      }
   ]
}
```

You can use the following command to create a service by using a JSON input file. The configuration specified in the JSON file is used to create and attach an EBS volume to each task managed by the service. To use this example command, replace the user input placeholders with your own information.

```bash
aws ecs create-service \
   --cluster mycluster \
   --service-name mysvc \
   --cli-input-json file://path_to_json_file/create-service.json
```
To configure a volume for attachment to service-managed tasks during service creation using the AWS Management Console, see [Creating a service using the console](#).

### Configuring a volume at service update

The following JSON snippet shows the syntax for updating a service that previously did not have Amazon EBS volumes configured for attachment to tasks. You must provide the ARN of a task definition with `configuredAtLaunch` set to `true`. The following JSON snippet shows the syntax for configuring the `volumeType`, `sizeInGiB`, `throughput`, and `iops`, and `filesystemType` settings of Amazon EBS volumes configured for attachment to tasks managed by a service. One volume is attached to each task in the service. To use this example, replace the [user input placeholders](#) with your own information.

```json
{
    "cluster": "mycluster",
    "taskDefinition": "mytaskdef",
    "serviceName": "mysvc",
    "desiredCount": 2,
    "volumeConfigurations": [
        {
            "name": "myEbsVolume",
            "managedEBSVolume": {
                "roleArn": "arn:aws::iam::1111222333:role/ecsInfrastructureRole",
                "volumeType": "gp3",
                "sizeInGiB": 100,
                "iops": 3000,
                "throughput": 125,
                "filesystemType": "ext4"
            }
        }
    ]
}
```

The following JSON snippet shows the syntax for updating a service to no longer utilize Amazon EBS volumes. You must provide the ARN of a task definition with `configuredAtLaunch` set to `false`, or a task definition without the `configuredAtLaunch` parameter. You must also provide an empty `volumeConfigurations` object. To use this example, replace the [user input placeholders](#) with your own information.

```json
{
    "cluster": "mycluster",
    "taskDefinition": "mytaskdef",
    "desiredCount": 2,
    "volumeConfigurations": []
}
```
You can use the following command to update a service by using a JSON input file. To use this example command, replace the user input placeholders with your own information.

```bash
aws ecs update-service \
   --cli-input-json file://path_to_json_file/update-service.json
```

To configure a volume for attachment to service-managed tasks during service update using the AWS Management Console, see Updating a service using the console.

**Amazon EBS volume termination policy**

When an Amazon ECS task terminates, Amazon ECS uses the `deleteOnTermination` value to determine whether the Amazon EBS volume that's associated with the terminated task should be deleted. By default, EBS volumes that are attached to tasks are deleted when the task is terminated. For standalone tasks, you can change this setting to instead preserve the volume upon task termination.

⚠️ **Note**

Volumes that are attached to tasks that are managed by a service are not preserved and are always deleted upon task termination.

**Tagging Amazon EBS volumes**

You can tag Amazon EBS volumes by using the `tagSpecifications` object. Using the object, you can provide your own tags and set propagation of tags from the task definition or the service, depending on whether the volume is attached to a standalone task or a task in a service. Amazon ECS automatically attaches the `AmazonECSCreated` and `AmazonECSManaged` reserved tags to an Amazon EBS volume. An additional 48 user-defined, ECS-managed, and propagated tags can be added to a volume for a total of 50 tags maximum per volume.

If you want to add Amazon ECS-managed tags to your volume, you must set `enableECSManagedTags` to `true` in your `UpdateService, CreateService, RunTask`
or StartTask call. If you turn on Amazon ECS-managed tags, Amazon ECS will tag the volume automatically with cluster and service information (aws:ecs:clusterName and aws:ecs:serviceName). For more information about tagging Amazon ECS resources, see Tagging your Amazon ECS resources.

The following JSON snippet shows the syntax for tagging each Amazon EBS volume that is attached to each task in a service with a user-defined tag and ECS-managed tags. To use this example for creating a service, replace the user input placeholders with your own information.

```
{
  "cluster": "mycluster",
  "taskDefinition": "mytaskdef",
  "serviceName": "mysvc",
  "desiredCount": 2,
  "enableECSManagedTags": true,
  "volumeConfigurations": [
    {
      "name": "datadir",
      "managedEBSVolume": {
        "volumeType": "gp3",
        "sizeInGiB": 100,
        "tagSpecifications": [
          {
            "resourceType": "volume",
            "tags": [
              {
                "key": "key1",
                "value": "value1"
              }
            ],
            "propagateTags": "NONE"
          }
        ],
        "roleArn": "arn:aws::iam:1111222333:role/ecsInfrastructureRole",
        "encrypted": true,
        "kmsKeyId": "arn:aws:kms:region:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
      }
    }
  ]
}
```
Amazon Elastic Container Service

Developer Guide

Note

You must specify a volume resource type to tag Amazon EBS volumes.

Amazon EBS volume performance for Fargate on-demand tasks

The baseline Amazon EBS volume IOPS and throughput available for a Fargate on-demand task depends on the total CPU units you request for the task. If you request 0.25, 0.5, or 1 virtual CPU unit (vCPU) for your Fargate task, we recommend that you configure a General Purpose SSD volume (gp2 or gp3) or a Hard Disk Drive (HDD) volume (st1 or sc1). If you request more than 1 vCPU for your Fargate task, the following baseline performance limits apply to an Amazon EBS volume attached to the task. You may temporarily get higher EBS performance than the following limits. However, we recommend that you plan your workload based on these limits.

<table>
<thead>
<tr>
<th>CPU units requested (in vCPUs)</th>
<th>Baseline Amazon EBS IOPS (16 KiB I/O)</th>
<th>Baseline Amazon EBS Throughput (in MiBps, 128 KiB I/O)</th>
<th>Baseline bandwidth (in Mbps)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>3,000</td>
<td>75</td>
<td>360</td>
</tr>
<tr>
<td>4</td>
<td>5,000</td>
<td>120</td>
<td>1,150</td>
</tr>
<tr>
<td>8</td>
<td>10,000</td>
<td>250</td>
<td>2,300</td>
</tr>
<tr>
<td>16</td>
<td>15,000</td>
<td>500</td>
<td>4,500</td>
</tr>
</tbody>
</table>

Note

When you configure an Amazon EBS volume for attachment to a Fargate task, the Amazon EBS performance limit for the Fargate task is shared between the task’s ephemeral storage and the attached volume.

Amazon EFS volumes

Amazon Elastic File System (Amazon EFS) provides simple, scalable file storage for use with your Amazon ECS tasks. With Amazon EFS, storage capacity is elastic. It grows and shrinks automatically.
as you add and remove files. Your applications can have the storage they need and when they need it.

You can use Amazon EFS file systems with Amazon ECS to export file system data across your fleet of container instances. That way, your tasks have access to the same persistent storage, no matter the instance on which they land. Your task definitions must reference volume mounts on the container instance to use the file system. The following sections describe how to get started using Amazon EFS with Amazon ECS.

For a tutorial, see [Using Amazon EFS file systems with Amazon ECS using the console](#).

### Amazon EFS volume considerations

Consider the following when using Amazon EFS volumes:

- For tasks that use the EC2 launch type, Amazon EFS file system support was added as a public preview with Amazon ECS-optimized AMI version 20191212 with container agent version 1.35.0. However, Amazon EFS file system support entered general availability with Amazon ECS-optimized AMI version 20200319 with container agent version 1.38.0, which contained the Amazon EFS access point and IAM authorization features. We recommend that you use Amazon ECS-optimized AMI version 20200319 or later to use these features. For more information, see [Amazon ECS-optimized AMI](#).

> **Note**
>
> If you create your own AMI, you must use container agent 1.38.0 or later, `ecs-init` version 1.38.0-1 or later, and run the following commands on your Amazon EC2 instance to enable the Amazon ECS volume plugin. The commands are dependent on whether you're using Amazon Linux 2 or Amazon Linux as your base image.
> 
> **Amazon Linux 2**
> 
> ```
> yum install amazon-efs-utils
> systemctl enable --now amazon-ecs-volume-plugin
> ```
>
> **Amazon Linux**
> 
> ```
> yum install amazon-efs-utils
> sudo shutdown -r now
> ```
• For tasks that are hosted on Fargate, Amazon EFS file systems are supported on platform version 1.4.0 or later (Linux). For more information, see [Fargate Linux platform versions](https://docs.aws.amazon.com/elasticloadbalancing/latest/app-balancers-guide/fargate-platform.html).

• When using Amazon EFS volumes for tasks that are hosted on Fargate, Fargate creates a supervisor container that's responsible for managing the Amazon EFS volume. The supervisor container uses a small amount of the task's memory. The supervisor container is visible when querying the task metadata version 4 endpoint. Additionally, it is visible in CloudWatch Container Insights as the container name `aws-fargate-supervisor`. For more information when using the Amazon EC2 launch type, see [Amazon ECS task metadata endpoint version 4](https://docs.aws.amazon.com/ecs/latest/userguide/task-metadata-endpoint.html). For more information when using the Fargate launch type, see [Amazon ECS task metadata endpoint version 4 for tasks on Fargate](https://docs.aws.amazon.com/elasticloadbalancing/latest/app-balancers-guide/fargate-task-metadata.html).

• Using Amazon EFS volumes or specifying an `EFSVolumeConfiguration` isn't supported on external instances.

• We recommend that you set the `ECS_ENGINE_TASK_CLEANUP_WAIT_DURATION` parameter in the agent configuration file to a value that is less than the default (about 1 hour). This change helps prevent EFS mount credential expiration and allows for cleanup of mounts that are not in use. For more information, see [Amazon ECS container agent configuration](https://docs.aws.amazon.com/elasticloadbalancing/latest/app-balancers-guide/fargate-container-agent.html).

**Using Amazon EFS access points**

Amazon EFS access points are application-specific entry points into an EFS file system for managing application access to shared datasets. For more information about Amazon EFS access points and how to control access to them, see [Working with Amazon EFS Access Points](https://docs.aws.amazon.com/elasticfilesystem/latest/APIReference/API_CreateAccessPoint.html) in the [Amazon Elastic File System User Guide](https://docs.aws.amazon.com/elasticfilesystem/latest/APIReference/API_CreateAccessPoint.html).

Access points can enforce a user identity, including the user's POSIX groups, for all file system requests that are made through the access point. Access points can also enforce a different root directory for the file system. This is so that clients can only access data in the specified directory or its subdirectories.

**Note**

When creating an EFS access point, specify a path on the file system to serve as the root directory. When referencing the EFS file system with an access point ID in your Amazon ECS task definition, the root directory must either be omitted or set to `/`, which enforces the path set on the EFS access point.
You can use an Amazon ECS task IAM role to enforce that specific applications use a specific access point. By combining IAM policies with access points, you can provide secure access to specific datasets for your applications. For more information about how to use task IAM roles, see Task IAM role.

**Specifying an Amazon EFS file system in your task definition**

To use Amazon EFS file system volumes for your containers, you must specify the volume and mount point configurations in your task definition. The following task definition JSON snippet shows the syntax for the volumes and mountPoints objects for a container.

```json
{
    "containerDefinitions": [
    {
        "name": "container-using-efs",
        "image": "amazonlinux:2",
        "entryPoint": ["sh", "-c"],
        "command": ["ls -la /mount/efs"],
        "mountPoints": [
            {
                "sourceVolume": "myEfsVolume",
                "containerPath": "/mount/efs",
                "readOnly": true
            }
        ]
    }
    ],
    "volumes": [
    {
        "name": "myEfsVolume",
        "efsVolumeConfiguration": {
            "fileSystemId": "fs-1234",
            "rootDirectory": "/path/to/my/data",
            "transitEncryption": "ENABLED",
            "transitEncryptionPort": integer,
            "authorizationConfig": {
                "accessPointId": "fsap-1234",
                "iam": "ENABLED"
            }
        }
    }
    ]
}
```

Using data volumes in tasks
efsVolumeConfiguration

Type: Object
Required: No

This parameter is specified when using Amazon EFS volumes.

fileSystemId

Type: String
Required: Yes

The Amazon EFS file system ID to use.

rootDirectory

Type: String
Required: No

The directory within the Amazon EFS file system to mount as the root directory inside the host. If this parameter is omitted, the root of the Amazon EFS volume is used. Specifying `/` has the same effect as omitting this parameter.

⚠️ Important

If an EFS access point is specified in the authorizationConfig, the root directory parameter must either be omitted or set to `/`, which enforces the path set on the EFS access point.

transitEncryption

Type: String

Valid values: ENABLED | DISABLED
Specifies whether to enable encryption for Amazon EFS data in transit between the Amazon ECS host and the Amazon EFS server. If Amazon EFS IAM authorization is used, transit encryption must be enabled. If this parameter is omitted, the default value of DISABLED is used. For more information, see Encrypting Data in Transit in the Amazon Elastic File System User Guide.

transitEncryptionPort
Type: Integer
Required: No
The port to use when sending encrypted data between the Amazon ECS host and the Amazon EFS server. If you don't specify a transit encryption port, it uses the port selection strategy that the Amazon EFS mount helper uses. For more information, see EFS Mount Helper in the Amazon Elastic File System User Guide.

authorizationConfig
Type: Object
Required: No
The authorization configuration details for the Amazon EFS file system.

accessPointId
Type: String
Required: No
The access point ID to use. If an access point is specified, the root directory value in the efsVolumeConfiguration must either be omitted or set to /, which enforces the path set on the EFS access point. If an access point is used, transit encryption must be enabled in the EFSVolumeConfiguration. For more information, see Working with Amazon EFS Access Points in the Amazon Elastic File System User Guide.

iam
Type: String
Valid values: ENABLED | DISABLED
Required: No
Specifies whether to use the Amazon ECS task IAM role defined in a task definition when mounting the Amazon EFS file system. If enabled, transit encryption must be enabled in the EFSVolumeConfiguration. If this parameter is omitted, the default value of DISABLED is used. For more information, see IAM Roles for Tasks.

**FSx for Windows File Server volumes**

FSx for Windows File Server provides fully managed Windows file servers, that are backed by a Windows file system. When using FSx for Windows File Server together with ECS, you can provision your Windows tasks with persistent, distributed, shared, static file storage. For more information, see What Is FSx for Windows File Server?

**Note**

EC2 instances that use the Amazon ECS-Optimized Windows Server 2016 Full AMI do not support FSx for Windows File Server ECS task volumes. You cannot use FSx for Windows File Server volumes in a Windows containers on Fargate configuration.

You can use FSx for Windows File Server to deploy Windows workloads that require access to shared external storage, highly-available Regional storage, or high-throughput storage. You can mount one or more FSx for Windows File Server file system volumes to an Amazon ECS container that runs on an Amazon ECS Windows instance. You can share FSx for Windows File Server file system volumes between multiple Amazon ECS containers within a single Amazon ECS task.

To enable the use of FSx for Windows File Server with ECS, include the FSx for Windows File Server file system ID and the related information in a task definition. This is in the following example task definition JSON snippet. Before you create and run a task definition, you need the following.

- An ECS Windows EC2 instance that's joined to a valid domain. It can be hosted by an AWS Directory Service for Microsoft Active Directory, on-premises Active Directory or self-hosted Active Directory on Amazon EC2.

- An AWS Secrets Manager secret or Systems Manager parameter that contains the credentials that are used to join the Active Directory domain and attach the FSx for Windows File Server file system. The credential values are the name and password credentials that you entered when creating the Active Directory.
The following sections describe how to get started using FSx for Windows File Server with Amazon ECS.

For a related tutorial, see Using FSx for Windows File Server file systems with Amazon ECS.

**FSx for Windows File Server volume considerations**

Consider the following when using FSx for Windows File Server volumes:

- FSx for Windows File Server with Amazon ECS only supports Windows Amazon EC2 instances. Linux Amazon EC2 instances aren't supported.
- FSx for Windows File Server with Amazon ECS doesn't support AWS Fargate.
- FSx for Windows File Server with Amazon ECS with `awsvpc` network mode requires version 1.54.0 or later of the container agent.
- The maximum number of drive letters that can be used for an Amazon ECS task is 23. Each task with an FSx for Windows File Server volume gets a drive letter assigned to it.
- By default, task resource cleanup time is three hours after the task ended. Even if no tasks use it, a file mapping that's created by a task persists for three hours. The default cleanup time can be configured by using the Amazon ECS environment variable `ECS_ENGINE_TASK_CLEANUP_WAIT_DURATION`. For more information, see [Amazon ECS container agent configuration](#).
- Tasks typically only run in the same VPC as the FSx for Windows File Server file system. However, it's possible to have cross-VPC support if there's an established network connectivity between the Amazon ECS cluster VPC and the FSx for Windows File Server file-system through VPC peering.
- You control access to an FSx for Windows File Server file system at the network level by configuring the VPC security groups. Only tasks that are hosted on EC2 instances joined to the Active Directory domain with correctly configured Active Directory security groups can access the FSx for Windows File Server file-share. If the security groups are misconfigured, ECS fails to launch the task with the following error message: unable to mount file system `fs-id`.
- FSx for Windows File Server is integrated with AWS Identity and Access Management (IAM) to control the actions that your IAM users and groups can take on specific FSx for Windows File Server resources. With client authorization, customers can define IAM roles that allow or deny access to specific FSx for Windows File Server file systems, optionally require read-only access, and optionally allow or disallow root access to the file system from the client. For more information, see [Security](#) in the Amazon FSx Windows User Guide.
Specifying an FSx for Windows File Server file system in your task definition

To use FSx for Windows File Server file system volumes for your containers, specify the volume and mount point configurations in your task definition. The following task definition JSON snippet shows the syntax for the volumes and mountPoints objects for a container.

```
{
   "containerDefinitions": [
      {
         "entryPoint": [
            "powershell",
            "-Command"
         ],
         "portMappings": [],
         "command": ["New-Item -Path C:\fsx-windows-dir\index.html -ItemType file -Value '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>It Works!</h2> <p>You are using Amazon FSx for Windows File Server file system for persistent container storage.</p>' -Force"],
         "cpu": 512,
         "memory": 256,
         "image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-ltsc2019",
         "essential": false,
         "name": "container1",
         "mountPoints": [
            {
               "sourceVolume": "fsx-windows-dir",
               "containerPath": "C:\fsx-windows-dir",
               "readOnly": false
            }
         ]
      },
      {
         "entryPoint": [
            "powershell",
            "-Command"
         ],
         "portMappings": [
            {
               "hostPort": 443,
               "protocol": "tcp",
```
"containerPort": 80
],
"command": ["Remove-Item -Recurse C:\\inetpub\\wwwroot\\* -Force; Start-Sleep -Seconds 120; Move-Item -Path C:\\fsx-windows-dir\index.html -Destination C:\\inetpub\\wwwroot\\index.html -Force; C:\\ServiceMonitor.exe w3svc"],
"mountPoints": [
{
  "sourceVolume": "fsx-windows-dir",
  "containerPath": "C:\\fsx-windows-dir",
  "readOnly": false
}
],
"cpu": 512,
"memory": 256,
"image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-ltsc2019",
"essential": true,
"name": "container2"
],

{
  "name": "fsx-windows-dir",
  "fsxWindowsFileServerVolumeConfiguration": {
    "fileSystemId": "fs-0eeb5730b2EXAMPLE",
    "authorizationConfig": {
      "domain": "example.com",
      "credentialsParameter": "arn:arn-1234"
    },
    "rootDirectory": "share"
  }
}
]}

FSxWindowsFileServerVolumeConfiguration

Type: Object

Required: No
This parameter is specified when you're using FSx for Windows File Server file system for task storage.

**fileSystemId**

*Type: String*

*Required: Yes*

The FSx for Windows File Server file system ID to use.

**rootDirectory**

*Type: String*

*Required: Yes*

The directory within the FSx for Windows File Server file system to mount as the root directory inside the host.

**authorizationConfig**

**credentialsParameter**

*Type: String*

*Required: Yes*

The authorization credential options:

- Amazon Resource Name (ARN) of an Secrets Manager secret.
- Amazon Resource Name (ARN) of an Systems Manager parameter.

**domain**

*Type: String*

*Required: Yes*

A fully qualified domain name that's hosted by an AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) directory or a self-hosted EC2 Active Directory.

**Credential storage methods**

There are two different methods of storing credentials for use with the credentials parameter.
• **AWS Secrets Manager secret**

This credential can be created in the AWS Secrets Manager console by using the *Other type of secret* category. You add a row for each key/value pair, username/admin and password/\textit{password}.

• **Systems Manager parameter**

This credential can be created in the Systems Manager parameter console by entering text in the form that's in the following example code snippet.

```json
{
    "username": "admin",
    "password": "\textit{password}"
}
```

The \texttt{credentialsParameter} in the task definition \texttt{FSxWindowsFileServerVolumeConfiguration} parameter holds either the secret ARN or the Systems Manager parameter ARN. For more information, see What is AWS Secrets Manager in the Secrets Manager User Guide and Systems Manager Parameter Store from the Systems Manager User Guide.

**Docker volumes**

When using Docker volumes, the built-in local driver or a third-party volume driver can be used. Docker volumes are managed by Docker and a directory is created in $/var/lib/docker/volumes$ on the container instance that contains the volume data.

To use Docker volumes, specify a \texttt{dockerVolumeConfiguration} in your task definition. For more information, see Using Volumes.

Some common use cases for Docker volumes are the following:

• To provide persistent data volumes for use with containers
• To share a defined data volume at different locations on different containers on the same container instance
• To define an empty, nonpersistent data volume and mount it on multiple containers within the same task
• To provide a data volume to your task that's managed by a third-party driver
Docker volume considerations

Consider the following when using Docker volumes:

- Docker volumes are only supported when using the EC2 launch type or external instances.
- Windows containers only support the use of the `local` driver.
- If a third-party driver is used, make sure it's installed and active on the container instance before the container agent is started. If the third-party driver isn't active before the agent is started, you can restart the container agent using one of the following commands:
  - For the Amazon ECS-optimized Amazon Linux 2 AMI:
    ```bash
    sudo systemctl restart ecs
    ```
  - For the Amazon ECS-optimized Amazon Linux AMI:
    ```bash
    sudo stop ecs && sudo start ecs
    ```

Specifying a Docker volume in your task definition

Before your containers can use data volumes, you must specify the volume and mount point configurations in your task definition. This section describes the volume configuration for a container. For tasks that use a Docker volume, specify a `dockerVolumeConfiguration`. For tasks that use a bind mount host volume, specify a `host` and optional `sourcePath`.

The following task definition JSON shows the syntax for the `volumes` and `mountPoints` objects for a container.

```json
{
    "containerDefinitions": [
        {
            "mountPoints": [
                {
                    "sourceVolume": "string",
                    "containerPath": "/path/to/mount_volume",
                    "readOnly": boolean
                }
            ]
        }
    ],
    "volumes": [
```
name

Type: String

Required: No

The name of the volume. Up to 255 letters (uppercase and lowercase), numbers, hyphens (-), and underscores (_) are allowed. This name is referenced in the sourceVolume parameter of the container definition mountPoints object.

dockerVolumeConfiguration

Type: `DockerVolumeConfiguration` Object

Required: No

This parameter is specified when using Docker volumes. Docker volumes are supported only when running tasks on EC2 instances. Windows containers support only the use of the `local` driver. To use bind mounts, specify a host instead.

scope

Type: String

Valid Values: task | shared

Required: No
The scope for the Docker volume, which determines its lifecycle. Docker volumes that are scoped to a task are automatically provisioned when the task starts and destroyed when the task stops. Docker volumes that are scoped as shared persist after the task stops.

**autoprovision**

Type: Boolean

Default value: false

Required: No

If this value is true, the Docker volume is created if it doesn't already exist. This field is used only if the scope is shared. If the scope is task, then this parameter must either be omitted or set to false.

**driver**

Type: String

Required: No

The Docker volume driver to use. The driver value must match the driver name provided by Docker because this name is used for task placement. If the driver was installed by using the Docker plugin CLI, use docker plugin ls to retrieve the driver name from your container instance. If the driver was installed by using another method, use Docker plugin discovery to retrieve the driver name. For more information, see Docker plugin discovery. This parameter maps to Driver in the Create a volume section of the Docker Remote API and the --driver option to docker volume create.

**driverOpts**

Type: String

Required: No

A map of Docker driver-specific options to pass through. This parameter maps to DriverOpts in the Create a volume section of the Docker Remote API and the --opt option to docker volume create.

**labels**

Type: String
Custom metadata to add to your Docker volume. This parameter maps to Labels in the Create a volume section of the Docker Remote API and the --label option to docker volume create.

mountPoints

Type: Object array

Required: No

The mount points for the data volumes in your container. This parameter maps to Volumes in the Create a container section of the Docker Remote API and the --volume option to docker run.

Windows containers can mount whole directories on the same drive as $env:ProgramData. Windows containers cannot mount directories on a different drive, and mount points cannot be used across drives.

sourceVolume

Type: String

Required: Yes, when mountPoints are used

The name of the volume to mount.

containerPath

Type: String

Required: Yes, when mountPoints are used

The path in the container where the volume will be mounted.

readOnly

Type: Boolean

Required: No

If this value is true, the container has read-only access to the volume. If this value is false, then the container can write to the volume. The default value is false.
Docker volume examples

The following are examples that show the use of Docker volumes.

To provide nonpersistent storage for a container using a Docker volume

In this example, a container uses an empty data volume that is disposed of after the task is finished. One example use case is that you might have a container that needs to access some scratch file storage location during a task. This task can be achieved using a Docker volume.

1. In the task definition volumes section, define a data volume with name and DockerVolumeConfiguration values. In this example, we specify the scope as task so the volume is deleted after the task stops and use the built-in local driver.

```
"volumes": [
  {
    "name": "scratch",
    "dockerVolumeConfiguration": {
      "scope": "task",
      "driver": "local",
      "labels": {
        "scratch": "space"
      }
    }
  }
]
```

2. In the containerDefinitions section, define a container with mountPoints values that reference the name of the defined volume and the containerPath value to mount the volume at on the container.

```
"containerDefinitions": [
  {
    "name": "container-1",
    "mountPoints": [
      {
        "sourceVolume": "scratch",
        "containerPath": "/var/scratch"
      }
    ]
  }
]
```
To provide persistent storage for a container using a Docker volume

In this example, you want a shared volume for multiple containers to use and you want it to persist after any single task that use it stopped. The built-in local driver is being used. This is so the volume is still tied to the lifecycle of the container instance.

1. In the task definition volumes section, define a data volume with name and DockerVolumeConfiguration values. In this example, specify a shared scope so the volume persists, set autoproposion to true. This is so that the volume is created for use. Then, also use the built-in local driver.

```json
"volumes": [
    {
      "name": "database",
      "dockerVolumeConfiguration": {
        "scope": "shared",
        "autoprovision": true,
        "driver": "local",
        "labels": {
          "database": "database_name"
        }
      }
    }
  ]
```

2. In the containerDefinitions section, define a container with mountPoints values that reference the name of the defined volume and the containerPath value to mount the volume at on the container.

```json
"containerDefinitions": [
  {
    "name": "container-1",
    "mountPoints": [
      {
        "sourceVolume": "database",
        "containerPath": "/var/database"
      }
    ]
  },
  {
    "name": "container-2",
    "mountPoints": [
```
To provide NFS persistent storage for a container using a Docker volume

In this example, a container uses an NFS data volume that is automatically mounted when the task starts and unmounted when the task stops. This uses the Docker built-in local driver. One example use case is that you might have a local NFS storage and need to access it from an ECS Anywhere task. This can be achieved using a Docker volume with NFS driver option.

1. In the task definition volumes section, define a data volume with name and DockerVolumeConfiguration values. In this example, specify a task scope so the volume is unmounted after the task stops. Use the local driver and configure the driverOpts with the type, device, and o options accordingly. Replace NFS_SERVER with the NFS server endpoint.

```json
"volumes": [
  {
    "name": "NFS",
    "dockerVolumeConfiguration": {
      "scope": "task",
      "driver": "local",
      "driverOpts": {
        "type": "nfs",
        "device": "/mnt/nfs",
        "o": "addr=$NFS_SERVER"
      }
    }
  }
]
```

2. In the containerDefinitions section, define a container with mountPoints values that reference the name of the defined volume and the containerPath value to mount the volume on the container.
**Bind mounts**

With bind mounts, a file or directory on a host, such as an Amazon EC2 instance, is mounted into a container. Bind mounts are supported for tasks that are hosted on both Fargate and Amazon EC2 instances. Bind mounts are tied to the lifecycle of the container that uses them. After all of the containers that use a bind mount are stopped, such as when a task is stopped, the data is removed. For tasks that are hosted on Amazon EC2 instances, the data can be tied to the lifecycle of the host Amazon EC2 instance by specifying a host and optional `sourcePath` value in your task definition. For more information, see [Using bind mounts](#) in the Docker documentation.

The following are common use cases for bind mounts.

- To provide an empty data volume to mount in one or more containers.
- To mount a host data volume in one or more containers.
- To share a data volume from a source container with other containers in the same task.
- To expose a path and its contents from a Dockerfile to one or more containers.

**Considerations when using bind mounts**

When using bind mounts, consider the following.

- For tasks that are hosted on AWS Fargate using platform version 1.4.0 or later (Linux) or 1.0.0 or later (Windows), by default they receive a minimum of 20 GiB of ephemeral storage for bind mounts. For Linux tasks, the total amount of ephemeral storage can be increased to a maximum of 200 GiB by specifying the `ephemeralStorage` parameter in your task definition.
By default, Amazon ECS Windows tasks that are hosted on Fargate using platform version 1.0.0 or later receive a minimum of 20 GiB of ephemeral storage. You can increase the total amount of ephemeral storage, up to a maximum of 200 GiB by specifying the `ephemeralStorage` parameter in your task definition.

- To expose files from a Dockerfile to a data volume when a task is run, the Amazon ECS data plane looks for a `VOLUME` directive. If the absolute path that's specified in the `VOLUME` directive is the same as the `containerPath` that's specified in the task definition, the data in the `VOLUME` directive path is copied to the data volume. In the following Dockerfile example, a file that's named `examplefile` in the `/var/log/exported` directory is written to the host and then mounted inside the container.

```bash
FROM public.ecr.aws/amazonlinux/amazonlinux:latest
RUN mkdir -p /var/log/exported
RUN touch /var/log/exported/examplefile
VOLUME ["/var/log/exported"]
```

By default, the volume permissions are set to 0755 and the owner as root. You can customize these permissions in the Dockerfile. The following example defines the owner of the directory as node.

```bash
FROM public.ecr.aws/amazonlinux/amazonlinux:latest
RUN yum install -y shadow-utils && yum clean all
RUN useradd node
RUN mkdir -p /var/log/exported && chown node:node /var/log/exported
RUN touch /var/log/exported/examplefile
USER node
VOLUME ["/var/log/exported"]
```

- For tasks that are hosted on Amazon EC2 instances, when a `host` and `sourcePath` value aren't specified, the Docker daemon manages the bind mount for you. When no containers reference this bind mount, the Amazon ECS container agent task cleanup service eventually deletes it. By default, this happens three hours after the container exits. However, you can configure this duration with the `ECS_ENGINE_TASK_CLEANUP_WAIT_DURATION` agent variable. For more information, see Amazon ECS container agent configuration. If you need this data to persist beyond the lifecycle of the container, specify a `sourcePath` value for the bind mount.
Specifying a bind mount in your task definition

For Amazon ECS tasks that are hosted on either Fargate or Amazon EC2 instances, the following task definition JSON snippet shows the syntax for the volumes, mountPoints, and ephemeralStorage objects for a task definition.

```json
{
    "family": "",
    ...
    "containerDefinitions": [
        {
            "mountPoints": [
                {
                    "containerPath": "/path/to/mount_volume",
                    "sourceVolume": "string"
                }
            ],
            "name": "string"
        }
    ],
    ...
    "volumes": [
        {
            "name": "string"
        }
    ],
    "ephemeralStorage": {
        "sizeInGiB": integer
    }
}
```

For Amazon ECS tasks that are hosted on Amazon EC2 instances, you can use the optional host parameter and a sourcePath when specifying the task volume details. When it's specified, it ties the bind mount to the lifecycle of the task rather than the container.

```json
"volumes": [
    {
        "host": {
            "sourcePath": "string"
        },
        "name": "string"
    }
]
```
The following describes each task definition parameter in more detail.

name

Type: String  
Required: No

The name of the volume. Up to 255 letters (uppercase and lowercase), numbers, hyphens (-), and underscores (_) are allowed. This name is referenced in the `sourceVolume` parameter of the container definition `mountPoints` object.

host

Required: No

The host parameter is used to tie the lifecycle of the bind mount to the host Amazon EC2 instance, rather than the task, and where it is stored. If the host parameter is empty, then the Docker daemon assigns a host path for your data volume, but the data is not guaranteed to persist after the containers associated with it stop running.

Windows containers can mount whole directories on the same drive as `$env:ProgramData`.

Note

The `sourcePath` parameter is supported only when using tasks that are hosted on Amazon EC2 instances.

sourcePath

Type: String  
Required: No

When the host parameter is used, specify a `sourcePath` to declare the path on the host Amazon EC2 instance that is presented to the container. If this parameter is empty, then the Docker daemon assigns a host path for you. If the host parameter contains a `sourcePath` file location, then the data volume persists at the specified location on the host Amazon EC2 instance until you delete it manually. If the `sourcePath` value does not exist on the host...
Amazon EC2 instance, the Docker daemon creates it. If the location does exist, the contents of the source path folder are exported.

**mountPoints**

Type: Object array
Required: No

The mount points for the data volumes in your container. This parameter maps to Volumes in the [Create a container](https://docs.docker.com/engine/reference/commandline/create/) section of the [Docker Remote API](https://docs.docker.com/api/) and the `--volume` option to `docker run`.

Windows containers can mount whole directories on the same drive as `$env:ProgramData`. Windows containers cannot mount directories on a different drive, and mount points cannot be used across drives.

**sourceVolume**

Type: String
Required: Yes, when `mountPoints` are used

The name of the volume to mount.

**containerPath**

Type: String
Required: Yes, when `mountPoints` are used

The path in the container where the volume will be mounted.

**readOnly**

Type: Boolean
Required: No

If this value is `true`, the container has read-only access to the volume. If this value is `false`, then the container can write to the volume. The default value is `false`.

**ephemeralStorage**

Type: Object
Required: No
The amount of ephemeral storage to allocate for the task. This parameter is used to expand the total amount of ephemeral storage available, beyond the default amount, for tasks hosted on AWS Fargate using platform version 1.4.0 or later (Linux) or 1.0.0 or later (Windows).

You can use the Copilot CLI, CloudFormation, the AWS SDK or the CLI to specify ephemeral storage for a bind mount.

**Bind mount examples**

The following examples cover the most common use cases for using a bind mount for your containers.

**To allocate an increased amount of ephemeral storage space for a Fargate task**

For Amazon ECS tasks that are hosted on Fargate using platform version 1.4.0 or later (Linux) or 1.0.0 (Windows), you can allocate more than the default amount of ephemeral storage for the containers in your task to use. This example can be incorporated into the other examples to allocate more ephemeral storage for your Fargate tasks.

- In the task definition, define an `ephemeralStorage` object. The `sizeInGiB` must be an integer between the values of 21 and 200 and is expressed in GiB.

```
"ephemeralStorage": {
    "sizeInGiB": integer
}
```

**To provide an empty data volume for one or more containers**

In some cases, you want to provide the containers in a task some scratch space. For example, you might have two database containers that need to access the same scratch file storage location during a task. This can be achieved using a bind mount.

1. In the task definition volumes section, define a bind mount with the name `database_scratch`.

```
"volumes": [
    {
        "name": "database_scratch"
    }
]
```
2. In the containerDefinitions section, create the database container definitions. This is so that they mount the volume.

```
"containerDefinitions": [
  {
    "name": "database1",
    "image": "my-repo/database",
    "cpu": 100,
    "memory": 100,
    "essential": true,
    "mountPoints": [
      {
        "sourceVolume": "database_scratch",
        "containerPath": "/var/scratch"
      }
    ],
  },
  {
    "name": "database2",
    "image": "my-repo/database",
    "cpu": 100,
    "memory": 100,
    "essential": true,
    "mountPoints": [
      {
        "sourceVolume": "database_scratch",
        "containerPath": "/var/scratch"
      }
    ],
  }
]
```

To expose a path and its contents in a Dockerfile to a container

In this example, you have a Dockerfile that writes data that you want to mount inside a container. This example works for tasks that are hosted on Fargate or Amazon EC2 instances.

1. Create a Dockerfile. The following example uses the public Amazon Linux 2 container image and creates a file that's named examplefile in the /var/log/exported directory that we want to mount inside the container. The VOLUME directive should specify an absolute path.
FROM public.ecr.aws/amazonlinux/amazonlinux:latest
RUN mkdir -p /var/log/exported
RUN touch /var/log/exported/examplefile
VOLUME ["/var/log/exported"]

By default, the volume permissions are set to 0755 and the owner as root. These permissions can be changed in the Dockerfile. In the following example, the owner of the /var/log/exported directory is set to node.

FROM public.ecr.aws/amazonlinux/amazonlinux:latest
RUN yum install -y shadow-utils && yum clean all
RUN useradd node
RUN mkdir -p /var/log/exported && chown node:node /var/log/exported
USER node
RUN touch /var/log/exported/examplefile
VOLUME ["/var/log/exported"]

2. In the task definition volumes section, define a volume with the name application_logs.

    "volumes": [
    {
        "name": "application_logs"
    }
    ]

3. In the containerDefinitions section, create the application container definitions. This is so they mount the storage. The containerPath value must match the absolute path that's specified in the VOLUME directive from the Dockerfile.

    "containerDefinitions": [
    {
        "name": "application1",
        "image": "my-repo/application",
        "cpu": 100,
        "memory": 100,
        "essential": true,
        "mountPoints": [
        {
            "sourceVolume": "application_logs",
            "containerPath": "/var/log/exported"
        }
        ]
To provide an empty data volume for a container that's tied to the lifecycle of the host Amazon EC2 instance

For tasks that are hosted on Amazon EC2 instances, you can use bind mounts and have the data tied to the lifecycle of the host Amazon EC2 instance. You can do this by using the host parameter and specifying a sourcePath value. Any files that exist at the sourcePath are presented to the containers at the containerPath value. Any files that are written to the containerPath value are written to the sourcePath value on the host Amazon EC2 instance.

⚠️ Important
Amazon ECS doesn't sync your storage across Amazon EC2 instances. Tasks that use persistent storage can be placed on any Amazon EC2 instance in your cluster that has available capacity. If your tasks require persistent storage after stopping and restarting, always specify the same Amazon EC2 instance at task launch time with the AWS CLI start-task command. You can also use Amazon EFS volumes for persistent storage. For more information, see Amazon EFS volumes.

1. In the task definition volumes section, define a bind mount with name and sourcePath values. In the following example, the host Amazon EC2 instance contains data at /ecs/webdata that you want to mount inside the container.
"volumes": [
  {
    "name": "webdata",
    "host": {
      "sourcePath": "/ecs/webdata"
    }
  }
]

2. In the containerDefinitions section, define a container with a mountPoints value that references the name of the bind mount and the containerPath value to mount the bind mount at on the container.

"containerDefinitions": [
  {
    "name": "web",
    "image": "nginx",
    "cpu": 99,
    "memory": 100,
    "portMappings": [
      {
        "containerPort": 80,
        "hostPort": 80
      }
    ],
    "essential": true,
    "mountPoints": [
      {
        "sourceVolume": "webdata",
        "containerPath": "/usr/share/nginx/html"
      }
    ]
  }
]

To mount a defined volume on multiple containers at different locations

You can define a data volume in a task definition and mount that volume at different locations on different containers. For example, your host container has a website data folder at /data/
webroot. You might want to mount that data volume as read-only on two different web servers that have different document roots.

1. In the task definition `volumes` section, define a data volume with the name `webroot` and the source path `/data/webroot`.

```json
"volumes": [
  {
    "name": "webroot",
    "host": {
      "sourcePath": "/data/webroot"
    }
  }
]
```

2. In the `containerDefinitions` section, define a container for each web server with `mountPoints` values that associate the `webroot` volume with the `containerPath` value pointing to the document root for that container.

```json
"containerDefinitions": [
  {
    "name": "web-server-1",
    "image": "my-repo/ubuntu-apache",
    "cpu": 100,
    "memory": 100,
    "portMappings": [
      {
        "containerPort": 80,
        "hostPort": 80
      }
    ],
    "essential": true,
    "mountPoints": [
      {
        "sourceVolume": "webroot",
        "containerPath": "/var/www/html",
        "readOnly": true
      }
    ]
  },
  {
    "name": "web-server-2",
    "image": "my-repo/ubuntu-apache",
    "cpu": 100,
    "memory": 100,
    "portMappings": [
      {
        "containerPort": 80,
        "hostPort": 80
      }
    ],
    "essential": true,
    "mountPoints": [
      {
        "sourceVolume": "webroot",
        "containerPath": "/var/www/html",
        "readOnly": true
      }
    ]
  }
]
```
"image": "my-repo/sles11-apache",
"cpu": 100,
"memory": 100,
"portMappings": [

{
  "containerPort": 8080,
  "hostPort": 8080
}
],
"essential": true,
"mountPoints": [

{
  "sourceVolume": "webroot",
  "containerPath": "/srv/www/htdocs",
  "readOnly": true
}
]
]

To mount volumes from another container using volumesFrom

For tasks hosted on Amazon EC2 instances, you can define one or more volumes on a container, and then use the volumesFrom parameter in a different container definition within the same task to mount all of the volumes from the sourceContainer at their originally defined mount points. The volumesFrom parameter applies to volumes defined in the task definition, and those that are built into the image with a Dockerfile.

1. (Optional) To share a volume that is built into an image, use the VOLUME instruction in the Dockerfile. The following example Dockerfile uses an httpd image, and then adds a volume and mounts it at dockerfile_volume in the Apache document root. It is the folder used by the httpd web server.

```
FROM httpd
VOLUME ["/usr/local/apache2/htdocs/dockerfile_volume"]
```

You can build an image with this Dockerfile and push it to a repository, such as Docker Hub, and use it in your task definition. The example my-repo/httpd_dockerfile_volume image that's used in the following steps was built with the preceding Dockerfile.
2. Create a task definition that defines your other volumes and mount points for the containers.
   In this example volumes section, you create an empty volume called empty, which the Docker daemon manages. There's also a host volume defined that's called host_etc. It exports the /etc folder on the host container instance.

```json
{
    "family": "test-volumes-from",
    "volumes": [
        {
            "name": "empty",
            "host": {}
        },
        {
            "name": "host_etc",
            "host": {
                "sourcePath": "/etc"
            }
        }
    ],
}
```

In the container definitions section, create a container that mounts the volumes defined earlier. In this example, the web container mounts the empty and host_etc volumes. This is the container that uses the image built with a volume in the Dockerfile.

```json
"containerDefinitions": [
    {
        "name": "web",
        "image": "my-repo/httpd_dockerfile_volume",
        "cpu": 100,
        "memory": 500,
        "portMappings": [
            {
                "containerPort": 80,
                "hostPort": 80
            }
        ],
        "mountPoints": [
            {
                "sourceVolume": "empty",
                "containerPath": "/usr/local/apache2/htdocs/empty_volume"
            },
        ]
    }
]```
Create another container that uses volumesFrom to mount all of the volumes that are associated with the web container. All of the volumes on the web container are likewise mounted on the busybox container. This includes the volume that’s specified in the Dockerfile that was used to build the my-repo/httpd_dockerfile_volume image.

```json
{
  "name": "busybox",
  "image": "busybox",
  "volumesFrom": [
    {
      "sourceContainer": "web"
    }
  ],
  "cpu": 100,
  "memory": 500,
  "entryPoint": [
    "sh",
    "-c"
  ],
  "command": [
    "echo $(date) > /usr/local/apache2/htdocs/empty_volume/date && echo $(date) > /usr/local/apache2/htdocs/host_etc/date && echo $(date) > /usr/local/apache2/htdocs/dockerfile_volume/date"
  ],
  "essential": false
}
```

When this task is run, the two containers mount the volumes, and the command in the busybox container writes the date and time to a file. This file is called date in each of the volume folders. The folders are then visible at the website displayed by the web container.

Using data volumes in tasks
Note

Because the busybox container runs a quick command and then exits, it must be set as "essential": false in the container definition. Otherwise, it stops the entire task when it exits.

Managing container swap space

With Amazon ECS, you can control the usage of swap memory space on your Linux-based Amazon EC2 instances at the container level. Using a per-container swap configuration, each container within a task definition can have swap enabled or disabled. For those that have it enabled, the maximum amount of swap space that's used can be limited. For example, latency-critical containers can have swap disabled. In contrast, containers with high transient memory demands can have swap turned on to reduce the chances of out-of-memory errors when the container is under load.

The swap configuration for a container is managed by the following container definition parameters.

maxSwap

The total amount of swap memory (in MiB) a container can use. This parameter is translated to the --memory- swap option to docker run where the value is the sum of the container memory plus the maxSwap value.

If a maxSwap value of 0 is specified, the container doesn't use swap. Accepted values are 0 or any positive integer. If the maxSwap parameter is omitted, the container uses the swap configuration for the container instance that it's running on. A maxSwap value must be set for the swappiness parameter to be used.

swappiness

You can use this to tune a container's memory swappiness behavior. A swappiness value of 0 causes swapping to not occur unless required. A swappiness value of 100 causes pages to be swapped aggressively. Accepted values are whole numbers between 0 and 100. If the swappiness parameter isn't specified, a default value of 60 is used. If a value isn't specified for maxSwap, this parameter is ignored. This parameter maps to the --memory-swappiness option to docker run.
In the following example, the JSON syntax is provided.

```
"containerDefinitions": [{
    ...
    "linuxParameters": {
        "maxSwap": integer,
        "swappiness": integer
    },
    ...
}]
```

**Container swap considerations**

Consider the following when you use a per-container swap configuration.

- Swap space must be enabled and allocated on the Amazon EC2 instance hosting your tasks for the containers to use. By default, the Amazon ECS optimized AMIs do not have swap enabled. You must enable swap on the instance to use this feature. For more information, see Instance Store Swap Volumes in the Amazon EC2 User Guide for Linux Instances or How do I allocate memory to work as swap space in an Amazon EC2 instance by using a swap file?

- The swap space container definition parameters are only supported for task definitions that specify the EC2 launch type. These parameters are not supported for task definitions intended only for Amazon ECS on Fargate use.

- This feature is only supported for Linux containers. Windows containers are not supported currently.

- If the maxSwap and swappiness container definition parameters are omitted from a task definition, each container has a default swappiness value of 60. Moreover, the total swap usage is limited to two times the memory reservation of the container.

- If you're using tasks on Amazon Linux 2023 the swappiness parameter isn't supported.

**Fargate considerations**

In order to use Fargate, you must configure your task definition to use the Fargate launch type. There are additional considerations when using Fargate.

**Topics**

- Task definition parameters
Task definition parameters

Tasks that use the Fargate launch type don't support all of the Amazon ECS task definition parameters that are available. Some parameters aren't supported at all, and others behave differently for Fargate tasks.

The following task definition parameters are not valid in Fargate tasks:

- disableNetworking
- dnsSearchDomains
- dnsServers
- dockerSecurityOptions
- extraHosts
- gpu
- ipcMode
- links
- placementConstraints
- privileged
- maxSwap
- swappiness

The following task definition parameters are valid in Fargate tasks, but have limitations that should be noted:

- linuxParameters – When specifying Linux-specific options that are applied to the container, for capabilities the only capability you can add is CAP_SYS_PTRACE. The devices,
sharedMemorySize, and tmpfs parameters are not supported. For more information, see Linux parameters.

• volumes – Fargate tasks only support bind mount host volumes, so the dockerVolumeConfiguration parameter is not supported. For more information, see Volumes.

• cpu - For Windows containers on AWS Fargate, the value cannot be less than 1 vCPU.

To ensure that your task definition validates for use with Fargate, you can specify the following when you register the task definition:

• In the AWS Management Console, for the Requires Compatibilities field, specify FARGATE.

• In the AWS CLI, specify the --requires-compatibilities option.

• In the Amazon ECS API, specify the requiresCompatibilities flag.

Operating Systems and architectures

When you configure a task and container definition for AWS Fargate, you must specify the Operating System that the container runs. The following Operating Systems are supported for AWS Fargate:

• Amazon Linux 2

Note

Linux containers use only the kernel and kernel configuration from the host Operating System. For example, the kernel configuration includes the sysctl system controls. A Linux container image can be made from a base image that contains the files and programs from any Linux distribution. If the CPU architecture matches, you can run containers from any Linux container image on any Operating System.

• Windows Server 2019 Full
• Windows Server 2019 Core
• Windows Server 2022 Full
• Windows Server 2022 Core
When you run Windows containers on AWS Fargate, you must have the X86_64 CPU architecture.

When you run Linux containers on AWS Fargate, you can use the X86_64 CPU architecture, or the ARM64 architecture for your ARM-based applications. For more information, see the section called “Working with 64-bit ARM workloads on Amazon ECS”.

**Task CPU and memory**

Amazon ECS task definitions for AWS Fargate require that you specify CPU and memory at the task level. Although you can also specify CPU and memory at the container level for Fargate tasks, this is optional. Most use cases are satisfied by only specifying these resources at the task level. The table below shows the valid combinations of task-level CPU and memory. You can specify memory values in the JSON file in MiB or GB. You can specify CPU values in the JSON file as an integer in CPU units or virtual CPUs (vCPUs).

<table>
<thead>
<tr>
<th>CPU value</th>
<th>Memory value</th>
<th>Operating systems supported for AWS Fargate</th>
</tr>
</thead>
<tbody>
<tr>
<td>256 (.25 vCPU)</td>
<td>512 MiB, 1 GB, 2 GB</td>
<td>Linux</td>
</tr>
<tr>
<td>512 (.5 vCPU)</td>
<td>1 GB, 2 GB, 3 GB, 4 GB</td>
<td>Linux</td>
</tr>
<tr>
<td>1024 (1 vCPU)</td>
<td>2 GB, 3 GB, 4 GB, 5 GB, 6 GB, 7 GB, 8 GB</td>
<td>Linux, Windows</td>
</tr>
<tr>
<td>2048 (2 vCPU)</td>
<td>Between 4 GB and 16 GB in 1 GB increments</td>
<td>Linux, Windows</td>
</tr>
<tr>
<td>4096 (4 vCPU)</td>
<td>Between 8 GB and 30 GB in 1 GB increments</td>
<td>Linux, Windows</td>
</tr>
<tr>
<td>8192 (8 vCPU)</td>
<td>Between 16 GB and 60 GB in 4 GB increments</td>
<td>Linux</td>
</tr>
</tbody>
</table>

**Note**

This option requires Linux platform 1.4.0 or later.
### CPU value

<table>
<thead>
<tr>
<th>Memory value</th>
<th>Operating systems supported for AWS Fargate</th>
</tr>
</thead>
<tbody>
<tr>
<td>16384 (16vCPU)</td>
<td>Linux</td>
</tr>
</tbody>
</table>

**Note**

This option requires Linux platform 1.4.0 or later.

---

### Task networking

Amazon ECS tasks for AWS Fargate require the `awsvpc` network mode, which provides each task with an elastic network interface. When you run a task or create a service with this network mode, you must specify one or more subnets to attach the network interface and one or more security groups to apply to the network interface.

If you are using public subnets, decide whether to provide a public IP address for the network interface. For a Fargate task in a public subnet to pull container images, a public IP address needs to be assigned to the task's elastic network interface, with a route to the internet or a NAT gateway that can route requests to the internet. For a Fargate task in a private subnet to pull container images, you need a NAT gateway in the subnet to route requests to the internet. When you host your container images in Amazon ECR, you can configure Amazon ECR to use an interface VPC endpoint. In this case, the task's private IPv4 address is used for the image pull. For more information about Amazon ECR interface endpoints, see [Amazon ECR interface VPC endpoints (AWS PrivateLink)](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/containers_vpc_endpoints.html) in the [Amazon Elastic Container Registry User Guide](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/containers_vpc_endpoints.html).

The following is an example of the `networkConfiguration` section for a Fargate service:

```json
"networkConfiguration": {
   "awsvpcConfiguration": {
      "assignPublicIp": "ENABLED",
      "securityGroups": [ "sg-12345678" ],
      "subnets": [ "subnet-12345678" ]
   }
}
```
Task resource limits

Amazon ECS task definitions for Linux containers on AWS Fargate support the ulimits parameter to define the resource limits to set for a container.

Amazon ECS task definitions for Windows on AWS Fargate do not support the ulimits parameter to define the resource limits to set for a container.

Amazon ECS tasks hosted on Fargate use the default resource limit values set by the operating system with the exception of the nofile resource limit parameter. The nofile resource limit sets a restriction on the number of open files that a container can use. On Fargate, the default nofile soft limit is 1024 and hard limit is 65535. You can set the values of both limits up to 1048576.

The following is an example task definition snippet that shows how to define a custom nofile limit that has been doubled:

```
"ulimits": [
  {
    "name": "nofile",
    "softLimit": 2048,
    "hardLimit": 8192
  }
]
```

For more information on the other resource limits that can be adjusted, see Resource limits.

Logging

Event logging

Amazon ECS logs the actions that it takes to EventBridge. You can use Amazon ECS events for EventBridge to receive near real-time notifications regarding the current state of your Amazon ECS clusters, services, and tasks. Additionally, you can automate actions to respond to these events. For more information, see Automate responses to Amazon ECS errors using EventBridge.

Task lifecycle logging

Tasks that run on Fargate publish timestamps to track the task through the states of the task lifecycle. You can see the timestamps in the task details in the AWS Management Console and by describing the task in the AWS CLI and SDKs. For example, you can use the timestamps to
evaluate how much time the task spent downloading the container images and decide if you should optimize the container image size, or use Seekable OCI indexes. For more information about container image practices, see Best practices for container images.

Application logging

Amazon ECS task definitions for AWS Fargate support the awslogs, splunk, and awsfirelens log drivers for the log configuration.

The awslogs log driver configures your Fargate tasks to send log information to Amazon CloudWatch Logs. The following shows a snippet of a task definition where the awslogs log driver is configured:

```json
"logConfiguration": {
   "logDriver": "awslogs",
   "options": {
      "awslogs-group": "/ecs/fargate-task-definition",
      "awslogs-region": "us-east-1",
      "awslogs-stream-prefix": "ecs"
   }
}
```

For more information about using the awslogs log driver in a task definition to send your container logs to CloudWatch Logs, see Using the awslogs log driver.

For more information about the awsfirelens log driver in a task definition, see Using custom log routing.

For more information about using the splunk log driver in a task definition, see splunk log driver.

Task storage

For Amazon ECS tasks hosted on Fargate, the following storage types are supported:

- Amazon EBS volumes provide cost-effective, durable, high-performance block storage for data-intensive containerized workloads. For more information, see Amazon EBS volumes.
- Amazon EFS volumes for persistent storage. For more information, see Amazon EFS volumes.
- Bind mounts for ephemeral storage. For more information, see Bind mounts.
Lazy loading container images using Seekable OCI (SOCI)

Amazon ECS tasks on Fargate that use Linux platform version 1.4.0 can use Seekable OCI (SOCI) to help start tasks faster. With SOCI, containers only spend a few seconds on the image pull before they can start, providing time for environment setup and application instantiation while the image is downloaded in the background. This is called lazy loading. When Fargate starts an Amazon ECS task, Fargate automatically detects if a SOCI index exists for an image in the task and starts the container without waiting for the entire image to be downloaded.

For containers that run without SOCI indexes, container images are downloaded completely before the container is started. This behavior is the same on all other platform versions of Fargate and on the Amazon ECS-optimized AMI on Amazon EC2 instances.

Seekable OCI indexes

Seekable OCI (SOCI) is an open source technology developed by AWS that can launch containers faster by lazily loading the container image. SOCI works by creating an index (SOCI Index) of the files within an existing container image. This index helps to launch containers faster, providing the capability to extract an individual file from a container image before downloading the entire image. The SOCI index must be stored as an artifact in the same repository as the image within the container registry. You should only use SOCI indices from trusted sources, as the index is the authoritative source for the contents of the image. For more information, see Introducing Seekable OCI for lazy loading container images.

Considerations

If you want Fargate to use a SOCI index to lazily load container images in a task, consider the following:

- Only tasks that run on Linux platform version 1.4.0 can use SOCI indexes. Tasks that run Windows containers on Fargate aren’t supported.
- Tasks that run on X86_64 or ARM64 CPU architecture are supported. Linux tasks with the ARM64 architecture do not support the Fargate Spot capacity provider.
- Container images in the task definition must have SOCI indexes in the same container registry as the image.
- Container images in the task definition must be stored in a compatible image registry. The following lists the compatible registries:
  - Amazon ECR private registries.
• Only container images that use gzip compression or are not compressed are supported. Container images that use zstd compression aren’t supported.

• We recommend that you try lazy loading with container images greater than 250 MiB compressed in size. You are less likely to see a reduction in the time to load smaller images.

• Because lazy loading can change how long your tasks take to start, you might need to change various timeouts like the health check grace period for Elastic Load Balancing.

• If you want to prevent a container image from being lazy loaded, delete the SOCI index from the container registry. If a container image in the task doesn't meet one of the considerations, that container image is downloaded by the default method.

Creating a Seekable OCI index

For a container image to be lazy loaded it needs a SOCI index (a metadata file) created and stored in the container image repository along side the container image. To create and push a SOCI index you can use the open source [soci-snapshotter CLI tool](https://github.com/aws-solutions/soci-snapshotter) on GitHub. Or, you can deploy the CloudFormation AWS SOCI Index Builder. This is a serverless solution that automatically creates and pushes a SOCI index when a container image is pushed to Amazon ECR. For more information about the solution and the installation steps, see [CloudFormation AWS SOCI Index Builder](https://github.com/aws-solutions/cloudformation-aws-soci-index-builder) on GitHub. The CloudFormation AWS SOCI Index Builder is a way to automate getting started with SOCI, while the open source soci tool has more flexibility around index generation and the ability to integrate index generation in your continuous integration and continuous delivery (CI/CD) pipelines.

**Note**

For the SOCI index to be created for an image, the image must exist in the containerd image store on the computer running soci-snapshotter. If the image is in the Docker image store, the image can't be found.

Verifying that a task used lazy loading

To verify that a task was lazily loaded using SOCI, check the task metadata endpoint from inside the task. When you query the task metadata endpoint version 4, there is a `Snapshotter` field in the default path for the container that you are querying from. Additionally, there are `Snapshotter` fields for each container in the `/task` path. The default value for this field is...
overlayfs, and this field is set to soci if SOCI is used. For more information, see Task metadata endpoint version 4 in the Amazon Elastic Container Service User Guide for AWS Fargate.

EC2 Windows considerations

Tasks that run on EC2 Windows instances don't support all of the Amazon ECS task definition parameters that are available. Some parameters aren't supported at all, and others behave differently.

The following task definition parameters aren't supported for Amazon EC2 Windows task definitions:

- containerDefinitions
  - disableNetworking
  - dnsServers
  - dnsSearchDomains
  - extraHosts
  - links
  - linuxParameters
  - privileged
  - readonlyRootFilesystem
  - user
  - ulimits
  - volumes
    - dockerVolumeConfiguration
  - cpu

  We recommend specifying container-level CPU for Windows containers.

- memory

  We recommend specifying container-level memory for Windows containers.

- proxyConfiguration

- ipcMode

- pidMode
The IAM roles for tasks on EC2 Windows instances features requires additional configuration, but much of this configuration is similar to configuring IAM roles for tasks on Linux container instances. For more information see the section called “Additional configuration for Windows task role”.

**Creating a task definition using the console**

To make creating task definitions as easy as possible, the Amazon ECS console has default selections for many choice.

You can create a task definition by using the console, or by editing a JSON file.

**JSON validation**

The Amazon ECS console JSON editor validates the following in the JSON file:

- The file is a valid JSON file.
- The file doesn't contain any extraneous keys.
- The file contains the `familyName` parameter.
- There is at least one entry under `containerDefinitions`.

**AWS CloudFormation stacks**

The following behavior applies to task definitions that were created in the new Amazon ECS console before January 12, 2023.

When you create a task definition, the Amazon ECS console automatically creates a CloudFormation stack that has a name that begins with `ECS-Console-V2-TaskDefinition-`. If you used the AWS CLI or an AWS SDK to deregister the task definition, then you must manually delete the task definition stack. For more information, see Deleting a stack in the AWS CloudFormation User Guide.

Task definitions created after January 12, 2023, do not have a CloudFormation stack automatically created for them.
Procedure

Amazon ECS console

2. In the navigation pane, choose Task definitions.
3. On the Create new task definition menu, choose Create new task definition.
4. For Task definition family, specify a unique name for the task definition.
5. For Launch type, choose the application environment. The console default is AWS Fargate (which is serverless). Amazon ECS uses this value to perform validation to ensure that the task definition parameters are valid for the infrastructure type.
6. For Operating system/Architecture, choose the operating system and CPU architecture for the task.

To run your task on a 64-bit ARM architecture, choose Linux/ARM64. For more information, see the section called “Runtime platform”.

To run your AWS Fargate tasks on Windows containers, choose a supported Windows operating system. For more information, see the section called “Operating Systems and architectures”.

7. For Task size, choose the CPU and memory values to reserve for the task. The CPU value is specified as vCPUs and memory is specified as GB.

For tasks hosted on Fargate, the following table shows the valid CPU and memory combinations.

<table>
<thead>
<tr>
<th>CPU value</th>
<th>Memory value</th>
<th>Operating systems supported for AWS Fargate</th>
</tr>
</thead>
<tbody>
<tr>
<td>256 (.25 vCPU)</td>
<td>512 MiB, 1 GB, 2 GB</td>
<td>Linux</td>
</tr>
<tr>
<td>512 (.5 vCPU)</td>
<td>1 GB, 2 GB, 3 GB, 4 GB</td>
<td>Linux</td>
</tr>
<tr>
<td>1024 (1 vCPU)</td>
<td>2 GB, 3 GB, 4 GB, 5 GB, 6 GB, 7 GB, 8 GB</td>
<td>Linux, Windows</td>
</tr>
</tbody>
</table>
### CPU value

<table>
<thead>
<tr>
<th>CPU value</th>
<th>Memory value</th>
<th>Operating systems supported for AWS Fargate</th>
</tr>
</thead>
<tbody>
<tr>
<td>2048 (2 vCPU)</td>
<td>Between 4 GB and 16 GB in 1 GB increments</td>
<td>Linux, Windows</td>
</tr>
<tr>
<td>4096 (4 vCPU)</td>
<td>Between 8 GB and 30 GB in 1 GB increments</td>
<td>Linux, Windows</td>
</tr>
<tr>
<td>8192 (8 vCPU)</td>
<td>Between 16 GB and 60 GB in 4 GB increments</td>
<td>Linux</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>This option requires Linux platform 1.4.0 or later.</td>
<td></td>
</tr>
<tr>
<td>16384 (16vCPU)</td>
<td>Between 32 GB and 120 GB in 8 GB increments</td>
<td>Linux</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>This option requires Linux platform 1.4.0 or later.</td>
<td></td>
</tr>
</tbody>
</table>

For tasks hosted on Amazon EC2, supported task CPU values are between 128 CPU units (0.125 vCPUs) and 10240 CPU units (10 vCPUs). To specify the memory value in GB, enter **GB** after the value. For example, to set the **Memory value** to 3GB, enter **3GB**.

**Note**

Task-level CPU and memory parameters are ignored for Windows containers.

8. For **Network mode**, choose the network mode to use. The default is **awsvpc** mode. For more information, see **Amazon ECS task networking**.
If you choose **bridge**, under **Port mappings**, for **Host port**, enter the port number on the container instance to reserve for your container.

9. **(Optional) Expand the Task roles section to configure the AWS Identity and Access Management (IAM) roles for the task:**

   a. For **Task role**, choose the IAM role to assign to the task. A task IAM role provides permissions for the containers in a task to call AWS API operations.

   b. For **Task execution role**, choose the role.

   For information about when to use a task execution role, see the section called “Task execution IAM role”. If you don’t need the role, choose **None**.

10. For each container to define in your task definition, complete the following steps.

   a. For **Name**, enter a name for the container.

   b. For **Image URI**, enter the image to use to start a container. Images in the Amazon ECR Public Gallery registry can be specified by using the Amazon ECR Public registry name only. For example, if `public.ecr.aws/ecs/amazon-ecs-agent:latest` is specified, the Amazon Linux container hosted on the Amazon ECR Public Gallery is used. For all other repositories, specify the repository by using either the `repository-url/image:tag` or `repository-url/image@digest` formats.

   c. If your image is in a private registry outside of Amazon ECR, under **Private registry**, turn on **Private registry authentication**. Then, in **Secrets Manager ARN or name**, enter the Amazon Resource Name (ARN) of the secret.

   d. For **Essential container**, if your task definition has two or more containers defined, you can specify whether the container should be considered essential. When a container is marked as **Essential**, if that container stops, then the task is stopped. Each task definition must contain at least one essential container.

   e. A port mapping allows the container to access ports on the host to send or receive traffic. Under **Port mappings**, do one of the following:

      - When you use the **awsvpc** network mode, for **Container port** and **Protocol**, choose the port mapping to use for the container.

      - When you use the **bridge** network mode, for **Container port** and **Protocol**, choose the port mapping to use for the container.
Choose Add more port mappings to specify additional container port mappings.

d. To give the container read-only access to its root file system, for Read only root file system, select Read only.

g. (Optional) To define the container-level CPU, GPU, and memory limits that are different from task-level values, under Resource allocation limits, do the following:

- For CPU, enter the number of CPU units that the Amazon ECS container agent reserves for the container.
- For GPU, enter the number of GPU units for the container instance.

An Amazon EC2 instance with GPU support has 1 GPU unit for every GPU. For more information, see the section called “Working with GPUs on Amazon ECS”.

- For Memory hard limit, enter the amount of memory, in GB, to present to the container. If the container attempts to exceed the hard limit, the container stops.
- The Docker 20.10.0 or later daemon reserves a minimum of 6 mebibytes (MiB) of memory for a container, so don't specify fewer than 6 MiB of memory for your containers.

  The Docker 19.03.13-ce or earlier daemon reserves a minimum of 4 MiB of memory for a container, so don't specify fewer than 4 MiB of memory for your containers.

- For Memory soft limit, enter the soft limit (in GB) of memory to reserve for the container.

  When system memory is under contention, Docker attempts to keep the container memory to this soft limit. If you don't specify task-level memory, you must specify a non-zero integer for one or both of Memory hard limit and Memory soft limit. If you specify both, Memory hard limit must be greater than Memory soft limit.

  This feature is not supported on Windows containers.

h. (Optional) Expand the Environment variables section to specify environment variables to inject into the container. You can specify environment variables either individually by using key-value pairs or in bulk by specifying an environment variable file that's hosted in an Amazon S3 bucket. For information about how to format an environment variable file, see Use task definition parameters to pass environment variables to a container.
i. (Optional) Select the **Use log collection** option to specify a log configuration. For each available log driver, there are log driver options to specify. The default option sends container logs to Amazon CloudWatch Logs. The other log driver options are configured by using AWS FireLens. For more information, see [Using custom log routing](#).

The following describes each container log destination in more detail.

- **Amazon CloudWatch** – Configure the task to send container logs to CloudWatch Logs. The default log driver options are provided, which create a CloudWatch log group on your behalf. To specify a different log group name, change the driver option values.

- **Export logs to Splunk** – Configure the task to send container logs to the Splunk driver that sends the logs to a remote service. You must enter the URL to your Splunk web service. The Splunk token is specified as a secret option because it can be treated as sensitive data.

- **Export logs to Amazon Data Firehose** – Configure the task to send container logs to Firehose. The default log driver options are provided, which sends log to an Firehose delivery stream. To specify a different delivery stream name, change the driver option values.

- **Export logs to Amazon Kinesis Data Streams** – Configure the task to send container logs to Kinesis Data Streams. The default log driver options are provided, which send logs to a Kinesis Data Streams stream. To specify a different stream name, change the driver option values.

- **Export logs to Amazon OpenSearch Service** – Configure the task to send container logs to an OpenSearch Service domain. The log driver options must be provided. For more information, see [Forwarding logs to an Amazon OpenSearch Service domain](#).

- **Export logs to Amazon S3** – Configure the task to send container logs to an Amazon S3 bucket. The default log driver options are provided, but you must specify a valid Amazon S3 bucket name.

j. (Optional) Configure additional container parameters.
<table>
<thead>
<tr>
<th>To configure this option</th>
<th>Do this</th>

<tr>
<td>b. For <strong>Container</strong>, choose the container.</td>
<td></td>
</tr>
<tr>
<td>c. For <strong>Condition</strong>, choose the startup dependency condition.</td>
<td></td>
</tr>
</tbody>
</table>

To add an additional dependency, choose **Add container dependency**.

k. (Optional) Choose **Add more containers** to add additional containers to the task definition.

11. (Optional) The **Storage** section is used to expand the amount of ephemeral storage for tasks hosted on Fargate. You can also use this section to add a data volume configuration for the task.

- To expand the available ephemeral storage beyond the default value of 20 gibibytes (GiB) for your Fargate tasks, for **Amount**, enter a value up to 200 GiB.

12. (Optional) To add a data volume configuration for the task definition, choose **Add volume**, and then follow these steps.

a. For **Volume name**, enter a name for the data volume. The data volume name is used when creating a container mount point.

b. For **Volume configuration**, select whether you want to configure your volume when creating the task definition or during deployment.
Note

Volumes that can be configured when creating a task definition include Bind mount, Docker, Amazon EFS, and Amazon FSx for Windows File Server. Volumes that can be configured at deployment when running a task, or when creating or updating a service include Amazon EBS.

c. For **Volume type**, select a volume type compatible with the configuration type that you selected, and then configure the volume type.
<table>
<thead>

<tr>
<td></td>
<td>• For <strong>Read only</strong>, select whether the container has read-only access to the volume.</td>
</tr>
<tr>
<td></td>
<td>b. To add additional mount points, <strong>Add mount point</strong>.</td>
</tr>
</tbody>
</table>

13. To add a volume from another container, choose **Add volume from**, and then configure the following:

   • For **Container**, choose the container.
   • For **Source**, choose the container which has the volume you want to mount.
   • For **Read only**, select whether the container has read-only access to the volume.
14. (Optional) To configure your application trace and metric collection settings by using the AWS Distro for OpenTelemetry integration, expand **Monitoring**, and then select **Use metric collection** to collect and send metrics for your tasks to either Amazon CloudWatch or Amazon Managed Service for Prometheus. When this option is selected, Amazon ECS creates an AWS Distro for OpenTelemetry container sidecar that is preconfigured to send the application metrics. For more information, see [Correlate Amazon ECS application performance using application metrics](#).

a. When **Amazon CloudWatch** is selected, your custom application metrics are routed to CloudWatch as custom metrics. For more information, see [Exporting application metrics to Amazon CloudWatch](#).

![Important](https://example.com)

**Important**

When exporting application metrics to Amazon CloudWatch, your task definition requires a task IAM role with the required permissions. For more information, see [Required IAM permissions for AWS Distro for OpenTelemetry integration with Amazon CloudWatch](#).

b. When you select **Amazon Managed Service for Prometheus (Prometheus libraries instrumentation)**, your task-level CPU, memory, network, and storage metrics and your custom application metrics are routed to Amazon Managed Service for Prometheus. For **Workspace remote write endpoint**, enter the remote write endpoint URL for your Prometheus workspace. For **Scraping target**, enter the host and port the AWS Distro for OpenTelemetry collector can use to scrape for metrics data. For more information, see [Exporting application metrics to Amazon Managed Service for Prometheus](#).

![Important](https://example.com)

**Important**

When exporting application metrics to Amazon Managed Service for Prometheus, your task definition requires a task IAM role with the required permissions. For more information, see [Required IAM permissions for AWS Distro for OpenTelemetry integration with Amazon Managed Service for Prometheus](#).

c. When you select **Amazon Managed Service for Prometheus (OpenTelemetry instrumentation)**, your task-level CPU, memory, network, and storage metrics
and your custom application metrics are routed to Amazon Managed Service for Prometheus. For **Workspace remote write endpoint**, enter the remote write endpoint URL for your Prometheus workspace. For more information, see [Exporting application metrics to Amazon Managed Service for Prometheus](https://aws.amazon.com/docs/elasticcontainercloud/exporting-prometheus-metrics/).

⚠️ **Important**

When exporting application metrics to Amazon Managed Service for Prometheus, your task definition requires a task IAM role with the required permissions. For more information, see [Required IAM permissions for AWS Distro for OpenTelemetry integration with Amazon Managed Service for Prometheus](https://docs.aws.amazon.com/elasticcontainercloud/latest/dg/prometheus-iam-permissions.html).

15. (Optional) Expand the **Tags** section to add tags, as key-value pairs, to the task definition.

   - [Add a tag] Choose **Add tag**, and then do the following:
     - For **Key**, enter the key name.
     - For **Value**, enter the key value.
   - [Remove a tag] Next to the tag, choose **Remove tag**.

16. Choose **Create** to register the task definition.

### Amazon ECS console JSON editor

2. In the navigation pane, choose **Task definitions**.
3. On the **Create new task definition** menu, choose **Create new task definition with JSON**.
4. In the JSON editor box, edit your JSON file,
   
   The JSON must pass the validation checks specified in [the section called “JSON validation”](https://docs.aws.amazon.com/elasticcontainercloud/latest/dg/prometheus-iam-permissions.html).
5. Choose **Create**.

### Updating a task definition using the console

A **task definition revision** is a copy of the current task definition with the new parameter values replacing the existing ones. All parameters that you do not modify are in the new revision.
To update a task definition, create a task definition revision. If the task definition is used in a service, you must update that service to use the updated task definition.

When you create a revision, you can modify the following container properties and environment properties.

- Container image URI
- Port mappings
- Environment variables
- Task size
- Container size
- Task role
- Task execution role
- Volumes and container mount points
- Private registry

**JSON validation**

The Amazon ECS console JSON editor validates the following in the JSON file:

- The file is a valid JSON file
- The file does not contain any extraneous keys
- The file contains the `familyName` parameter
- There is at least one entry under `containerDefinitions`

Amazon ECS console

2. From the navigation bar, choose the Region that contains your task definition.
3. In the navigation pane, choose **Task definitions**.
4. Choose the task definition.
5. Select the task definition revision, and then choose **Create new revision**, **Create new revision**.
6. On the Create new task definition revision page, make changes. For example, to change the existing container definitions (such as the container image, memory limits, or port mappings), select the container, and then make the changes.

7. Verify the information, and then choose Update.

8. If your task definition is used in a service, update your service with the updated task definition. For more information, see Updating a service using the console.

Amazon ECS console JSON editor

2. In the navigation pane, choose Task definitions.

3. Choose Create new revision, Create new revision with JSON.

4. In the JSON editor box, edit your JSON file, The JSON must pass the validation checks specified in the section called “JSON validation”.

5. Choose Create.

Deregistering a task definition revision using the console

When you no longer need a specific task definition revision in Amazon ECS, you can deregister the task definition revision so that it no longer displays in your ListTaskDefinition API calls or in the console when you want to run a task or update a service.

When you deregister a task definition revision, it is immediately marked as INACTIVE. Existing tasks and services that reference an INACTIVE task definition revision continue to run without disruption. Existing services that reference an INACTIVE task definition revision can still scale up or down by modifying the service's desired count.

You can't use an INACTIVE task definition revision to run new tasks or create new services. You also can't update an existing service to reference an INACTIVE task definition revision (even though there may be up to a 10-minute window following deregistration where these restrictions have not yet taken effect).
Note

When you deregister all revisions in a task family, the task definition family is moved to the INACTIVE list. Adding a new revision of an INACTIVE task definition moves the task definition family back to the ACTIVE list.
At this time, INACTIVE task definition revisions remain discoverable in your account indefinitely. However, this behavior is subject to change in the future. Therefore, you should not rely on INACTIVE task definition revisions persisting beyond the lifecycle of any associated tasks and services.

AWS CloudFormation stacks

The following behavior applies to task definitions that were created in the new Amazon ECS console before January 12, 2023.

When you create a task definition, the Amazon ECS console automatically creates a CloudFormation stack that has a name that begins with ECS-Console-V2-TaskDefinition-. If you used the AWS CLI or an AWS SDK to deregister the task definition, then you must manually delete the task definition stack. For more information, see Deleting a stack in the AWS CloudFormation User Guide.

Task definitions created after January 12, 2023, do not have a CloudFormation stack automatically created for them.

To deregister a new task definition (Amazon ECS console)

2. From the navigation bar, choose the region that contains your task definition.
3. In the navigation pane, choose Task definitions.
4. On the Task definitions page, choose the task definition family that contains one or more revisions that you want to deregister.
5. On the task definition Name page, select the revisions to delete, and then choose Actions, Deregister.
6. Verify the information in the Deregister window, and then choose Deregister to finish.
Deleting a task definition revision using the console

When no longer need a specific task definition revision in Amazon ECS, you can delete the task definition revision.

When you delete a task definition revision, it immediately transitions from the INACTIVE to DELETE_IN_PROGRESS. Existing tasks and services that reference a DELETE_IN_PROGRESS task definition revision continue to run without disruption.

You can't use a DELETE_IN_PROGRESS task definition revision to run new tasks or create new services. You also can't update an existing service to reference a DELETE_IN_PROGRESS task definition revision.

When you delete all INACTIVE task definition revisions, the task definition name is not displayed in the console and not returned in the API. If a task definition revision is in the DELETE_IN_PROGRESS state, the task definition name is displayed in the console and returned in the API. The task definition name is retained by Amazon ECS and the revision is incremented the next time you create a task definition with that name.

Amazon ECS resources that can block a deletion

A task definition deletion request will not complete when there are any Amazon ECS resources that depend on the task definition revision. The following resources might prevent a task definition from being deleted:

- Amazon ECS tasks - The task definition is required in order for the task to remain healthy.
- Amazon ECS deployments and task sets - The task definition is required when a scaling event is initiated for an Amazon ECS deployment or task set.

If your task definition remains in the DELETE_IN_PROGRESS state, you can use the console, or the AWS CLI to identify, and then stop the resources which block the task definition deletion.

Task definition deletion after the blocked resource is removed

The following rules apply after you remove the resources that block the task definition deletion:

- Amazon ECS tasks - The task definition deletion can take up to 1 hour to complete after the task is stopped.
• Amazon ECS deployments and task sets - The task definition deletion can take up to 24 hours to complete after the deployment or task set is deleted.

To delete task definitions (Amazon ECS console)

You must deregister a task definition revision before you delete it. For more information, see the section called “Deregistering a task definition revision using the console”.

2. From the navigation bar, choose the region that contains your task definition.
3. In the navigation pane, choose Task definitions.
4. On the Task definitions page, choose the task definition family that contains one or more revisions that you want to delete.
5. On the task definition Name page, select the revisions to delete, and then choose Actions, Delete.
6. Verify the information in the Delete confirmation box, and then choose Delete to finish.

Task definition use cases

Learn more about how to write task definitions for various AWS services and features.

Depending on your workload, there are certain task definition parameters that need to be set. Also for the EC2 launch type, you have to choose specific instances that are engineered for the workload.

Topics

• Working with GPUs on Amazon ECS
• Using video transcoding on Amazon ECS
• Using AWS Neuron on Amazon Linux 2 on Amazon ECS
• Using deep learning DL1 instances on Amazon ECS
• Working with 64-bit ARM workloads on Amazon ECS
• Using the awslogs log driver
• Using custom log routing
• Private registry authentication for tasks
• Use task definition parameters to pass environment variables to a container
• **Use a file to pass environment variables to a container**

• **Passing sensitive data to a container**

**Working with GPUs on Amazon ECS**

Amazon ECS supports workloads that use GPUs, when you create clusters with container instances that support GPUs. Amazon EC2 GPU-based container instances that use the p2, p3, p5, g3, g4, and g5 instance types provide access to NVIDIA GPUs. For more information, see [Linux Accelerated Computing Instances](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/LinuxAcceleratedComputingInstances.html) in the *Amazon EC2 User Guide for Linux Instances*.

Amazon ECS provides a GPU-optimized AMI that comes with pre-configured NVIDIA kernel drivers and a Docker GPU runtime. For more information, see [Amazon ECS-optimized AMI](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/ecs-opt-ami.html).

You can designate a number of GPUs in your task definition for task placement consideration at a container level. Amazon ECS schedules to available container instances that support GPUs and pin physical GPUs to proper containers for optimal performance.

You can retrieve the Amazon Machine Image (AMI) ID for Amazon ECS-optimized AMIs by querying the AWS Systems Manager Parameter Store API. Using this parameter, you don't need to manually look up Amazon ECS-optimized AMI IDs. For more information about the Systems Manager Parameter Store API, see [GetParameter](https://docs.aws.amazon.com/systems-manager/latest/userguide/). The user that you use must have the `ssm:GetParameter` IAM permission to retrieve the Amazon ECS-optimized AMI metadata.
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/gpu/recommended --region us-east-1

Considerations

Note

The support for g2 instance family type has been deprecated. The g2 instance family types are only supported on versions earlier than 20230906 of the Amazon ECS GPU-optimized AMI.

The p2 instance family type is only supported on versions earlier than 20230912 of the Amazon ECS GPU-optimized AMI. If you need to continue to use p2 instances, see What to do if you need a P2 instance.

In-place updates of the NVIDIA/CUDA drivers on both these instance family types will cause potential GPU workload failures.

We recommend that you consider the following before you begin working with GPUs on Amazon ECS.

- Your clusters can contain a mix of GPU and non-GPU container instances.
- You can run GPU workloads on external instances. When registering an external instance with your cluster, ensure the --enable-gpu flag is included on the installation script. For more information, see Registering an external instance to a cluster.
- You must set ECS_ENABLE_GPU_SUPPORT to true in your agent configuration file. For more information, see the section called “Container agent configuration”.
- When running a task or creating a service, you can use instance type attributes when you configure task placement constraints to determine the container instances the task is to be launched on. By doing this, you can more effectively use your resources. For more information, see How Amazon ECS places tasks on container instances.

The following example launches a task on a g4dn.xlarge container instance in your default cluster.

aws ecs run-task --cluster default --task-definition ecs-gpu-task-def --placement-constraints type=memberOf,expression="attribute:ecs.instance-type == g4dn.xlarge" --region us-east-2
For each container that has a GPU resource requirement that's specified in the container definition, Amazon ECS sets the container runtime to be the NVIDIA container runtime.

The NVIDIA container runtime requires some environment variables to be set in the container to function properly. For a list of these environment variables, see Specialized Configurations with Docker. Amazon ECS sets the NVIDIA_VISIBLE_DEVICES environment variable value to be a list of the GPU device IDs that Amazon ECS assigns to the container. For the other required environment variables, Amazon ECS doesn't set them. So, make sure that your container image sets them or they're set in the container definition.

The p5 instance type family is supported on version 20230929 and later of the Amazon ECS GPU-optimized AMI.

The g4 instance type family is supported on version 20230913 and later of the Amazon ECS GPU-optimized AMI. For more information, see Amazon ECS-optimized AMI. It's not supported in the Create Cluster workflow in the Amazon ECS console. To use these instance types, you must either use the Amazon EC2 console, AWS CLI, or API and manually register the instances to your cluster.

The p4d.24xlarge instance type only works with CUDA 11 or later.

The Amazon ECS GPU-optimized AMI has IPv6 enabled, which causes issues when using yum. This can be resolved by configuring yum to use IPv4 with the following command.

```
echo "ip_resolve=4" >> /etc/yum.conf
```

When you build a container image that doesn't use the NVIDIA/CUDA base images, you must set the NVIDIA_DRIVER_CAPABILITIES container runtime variable to one of the following values:

- utility,compute
- all

For information about how to set the variable, see Controlling the NVIDIA Container Runtime on the NVIDIA website.

GPUs are not supported on Windows containers.

Launch a GPU container instance

To use a GPU instance on Amazon ECS, you need to create a launch template, a user data file, and launch the instance.

You can then run a task that uses a task definition configured for GPU.
Use a launch template

You can create a launch template.

- Create a launch template that uses the Amazon ECS-optimized GPU AMI ID. For information about how to create a launch template, see [Create a new launch template using parameters you define](#) in the *Amazon EC2 User Guide for Linux Instances*.

Use the AMI ID from the previous step for the **Amazon Machine image**. For information about how to specify the AMI ID with the Systems Manager parameter, see [Specify a Systems Manager parameter in a launch template](#) in the *Amazon EC2 User Guide for Linux Instances*.

Add the following to the **User data** in the launch template. Replace `cluster-name` with the name of your cluster.

```bash
#!/bin/bash
echo ECS_CLUSTER=cluster-name >> /etc/ecs/ecs.config;
echo ECS_ENABLE_GPU_SUPPORT=true >> /etc/ecs/ecs.config
```

Use the AWS CLI

You can use the AWS CLI to launch the container instance.

1. Create a file that's called `userdata.toml`. This file is used for the instance user data. Replace `cluster-name` with the name of your cluster.

```bash
#!/bin/bash
echo ECS_CLUSTER=cluster-name >> /etc/ecs/ecs.config;
echo ECS_ENABLE_GPU_SUPPORT=true >> /etc/ecs/ecs.config
```

2. Run the following command to get the GPU AMI ID. You use this in the following step.

   ```bash
   aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/gpu/recommended --region us-east-1
   ```

3. Run the following command to launch the GPU instance. Remember to replace the following parameters:

   - Replace `subnet` with the ID of the private or public subnet that your instance will launch in.
   - Replace `gpu_ami` with the AMI ID from the previous step.
• Replace `t3.large` with the instance type that you want to use.

• Replace `region` with the Region code.

```
aws ec2 run-instances --key-name ecs-gpu-example \
    --subnet-id subnet \
    --image-id gpu_ami \
    --instance-type t3.large \
    --region region \
    --tag-specifications 'ResourceType=instance,Tags=[{Key=GPU,Value=example}]' \
    --user-data file://userdata.toml \
    --iam-instance-profile Name=ecsInstanceRole
```

4. Run the following command to verify that the container instance is registered to the cluster. When you run this command, remember to replace the following parameters:

• Replace `cluster` with your cluster name.

• Replace `region` with your Region code.

```
aws ecs list-container-instances --cluster cluster-name --region region
```

**Specifying GPUs in your task definition**

To use the GPUs on a container instance and the Docker GPU runtime, make sure that you designate the number of GPUs your container requires in the task definition. As containers that support GPUs are placed, the Amazon ECS container agent pins the desired number of physical GPUs to the appropriate container. The number of GPUs reserved for all containers in a task cannot exceed the number of available GPUs on the container instance the task is launched on. For more information, see [Creating a task definition using the console](#).

⚠️ **Important**

If your GPU requirements aren't specified in the task definition, the task uses the default Docker runtime.

The following shows the JSON format for the GPU requirements in a task definition:
The following example demonstrates the syntax for a Docker container that specifies a GPU requirement. This container uses two GPUs, runs the `nvidia-smi` utility, and then exits.

```json
{
  "containerDefinitions": [
    {
      "memory": 80,
      "essential": true,
      "name": "gpu",
      "image": "nvidia/cuda:11.0.3-base",
      "resourceRequirements": [
        {
          "type": "GPU",
          "value": "2"
        }
      ],
      "command": ["sh", "-c", "nvidia-smi"],
      "cpu": 100
    },
    {"family": "example-ecs-gpu"}
  ]
}
```
What to do if you need a P2 instance

If you need to use P2 instance, you can use one of the following options to continue using the instances.

You must modify the instance user data for both options. For more information see Work with instance user data in the Amazon EC2 User Guide for Linux Instances.

Use the last supported GPU-optimized AMI

You can use the 20230906 version of the GPU-optimized AMI, and add the following to the instance user data.

Replace cluster-name with the name of your cluster.

```
#!/bin/bash
echo "exclude=*nvidia* *cuda*" >> /etc/yum.conf
echo "ECS_CLUSTER=cluster-name" >> /etc/ecs/ecs.config
```

Use the latest GPU-optimized AMI, and update the user data

You can add the following to the instance user data. This uninstalls the Nvidia 535/Cuda12.2 drivers, and then installs the Nvidia 470/Cuda11.4 drivers and fixes the version.

```
#!/bin/bash
yum remove -y cuda-toolkit* nvidia-driver-latest-dkms*
tmpfile=$(mktemp)
cat >>$tmpfile <<EOF
[amzn2-nvidia]
name=Amazon Linux 2 Nvidia repository
mirrorlist=$awsproto://$amazonlinux.$awsregion.$awsdomain/$releasever/amzn2-
nvidia/latest/$basearch/mirror.list
priority=20
gpgcheck=1
x86_64/7fa2af80.pub
enabled=1
exclude=libglvnd-*
EOF
mv $tmpfile /etc/yum.repos.d/amzn2-nvidia-tmp.repo
```
Create your own P2 compatible GPU-optimized AMI

You can create your own custom Amazon ECS GPU-optimized AMI that is compatible with P2 instances, and then launch P2 instances using the AMI.

1. Run the following command to clone the `amazon-ecs-ami` repo.

   ```bash
   git clone https://github.com/aws/amazon-ecs-ami
   ```

2. Set the required Amazon ECS agent and source Amazon Linux AMI versions in `release.auto.pkrvars.hcl` or `overrides.auto.pkrvars.hcl`.

3. Run the following command to build a private P2 compatible EC2 AMI.

   ```bash
   REGION=region make al2keplergpu
   ```

4. Use the AMI with the following instance user data to connect to the Amazon ECS cluster.

   ```bash
   #!/bin/bash
   echo "ECS_CLUSTER=cluster-name" >> /etc/ecs/ecs.config
   ```

Using video transcoding on Amazon ECS

To use video transcoding workloads on Amazon ECS, register Amazon EC2 VT1 instances. After you registered these instances, you can run live and pre-rendered video transcoding workloads as tasks on Amazon ECS. Amazon EC2 VT1 instances use Xilinx U30 media transcoding cards to accelerate live and pre-rendered video transcoding workloads.
Note

For instructions on how to run video transcoding workloads in containers other than Amazon ECS, see the Xilinx documentation.

Considerations

Before you begin deploying VT1 on Amazon ECS, consider the following:

- Your clusters can contain a mix of VT1 and non-VT1 instances.
- You need a Linux application that uses Xilinx U30 media transcoding cards with accelerated AVC (H.264) and HEVC (H.265) codecs.

Important

Applications that use other codecs might not have improved performance on VT1 instances.

- Only one transcoding task can run on a U30 card. Each card has two devices that are associated with it. You can run as many transcoding tasks as there are cards for each of your VT1 instance.
- When creating a service or running a standalone task, you can use instance type attributes when configuring task placement constraints. This ensures that the task is launched on the container instance that you specify. Doing so helps ensure that you use your resources effectively and that your tasks for video transcoding workloads are on your VT1 instances. For more information, see How Amazon ECS places tasks on container instances.

In the following example, a task is run on a vt1.3xlarge instance on your default cluster.

```
aws ecs run-task \
  --cluster default \
  --task-definition vt1-3xlarge-xffmpeg-processor \
  --placement-constraints type=memberOf,expression="attribute:ecs.instance-type == vt1.3xlarge"
```

- You configure a container to use the specific U30 card available on the host container instance. You can do this by using the linuxParameters parameter and specifying the device details. For more information, see Task definition requirements.
Using a VT1 AMI

You have two options for running an AMI on Amazon EC2 for Amazon ECS container instances. The first option is to use the Xilinx official AMI on the AWS Marketplace. The second option is to build your own AMI from the sample repository.

- **Xilinx offers AMIs on the AWS Marketplace.**
- Amazon ECS provides a sample repository that you can use to build an AMI for video transcoding workloads. This AMI comes with Xilinx U30 drivers. You can find the repository that contains Packer scripts on GitHub. For more information about Packer, see the Packer documentation.

**Task definition requirements**

To run video transcoding containers on Amazon ECS, your task definition must contain a video transcoding application that uses the accelerated H.264/AVC and H.265/HEVC codecs. You can build a container image by following the steps on the Xilinx GitHub.

The task definition must be specific to the instance type. The instance types are 3xlarge, 6xlarge, and 24xlarge. You must configure a container to use specific Xilinx U30 devices that are available on the host container instance. You can do so using the `linuxParameters` parameter. The following table details the cards and device SoCs that are specific to each instance type.

<table>
<thead>
<tr>
<th>Instance Type</th>
<th>vCPUs</th>
<th>RAM (GiB)</th>
<th>U30 accelerator cards</th>
<th>Addressable XCU30 SoC devices</th>
<th>Device Paths</th>
</tr>
</thead>
<tbody>
<tr>
<td>vt1.3xlarge</td>
<td>12</td>
<td>24</td>
<td>1</td>
<td>2</td>
<td>/dev/dri/renderD128, /dev/dri/renderD129</td>
</tr>
<tr>
<td>vt1.6xlarge</td>
<td>24</td>
<td>48</td>

<td>2, /dev/dri/renderD14</td>
<td>3, /dev/dri/renderD14</td>
</tr>
</tbody>
</table>

⚠️ **Important**

If the task definition lists devices that the EC2 instance doesn't have, the task fails to run. When the task fails, the following error message appears in the stoppedReason:

`CannotStartContainerError: Error response from daemon: error gathering device information while adding custom device "/dev/dri/renderD130": no such file or directory.`

In the following example, the syntax that's used for a task definition of a Linux container on Amazon EC2 is provided. This task definition is for container images that are built following the procedure that's provided in the [Xilinx documentation](#). If you use this example, replace `image` with your own image, and copy your video files into the instance in the `/home/ec2-user` directory.
1. Create a text file that’s named `vt1-3xlarge-ffmpeg-linux.json` with the following content.

```json
{
    "family": "vt1-3xlarge-ffmpeg-processor",
    "requiresCompatibilities": ["EC2"],
    "placementConstraints": [
        {
            "type": "memberOf",
            "expression": "attribute:ecs.os-type == linux"
        },
        {
            "type": "memberOf",
            "expression": "attribute:ecs.instance-type == vt1.3xlarge"
        }
    ],
    "containerDefinitions": [
        {
            "entryPoint": ["/bin/bash", "-c"],
            "command": ["/video/ecs_ffmpeg_wrapper.sh"],
            "linuxParameters": {
                "devices": [
                    {
                        "containerPath": "/dev/dri/renderD128",
                        "hostPath": "/dev/dri/renderD128",
                        "permissions": [
                            "read",
                            "write"
                        ]
                    },
                    {
                        "containerPath": "/dev/dri/renderD129",
                        "hostPath": "/dev/dri/renderD129",
                        "permissions": [
                            "read",
                            "write"
                        ]
                    }
                ]
            }
        }
    ]
}
```
2. Register the task definition.

```
aws ecs register-task-definition --family vt1-3xlarge-xffmpeg-processor --cli-input-json file://vt1-3xlarge-xffmpeg-linux.json --region us-east-1
```

vt1.6xlarge

1. Create a text file that's named vt1-6xlarge-ffmpeg-linux.json with the following content.

```
{
    "family": "vt1-6xlarge-xffmpeg-processor",
    "requiresCompatibilities": ["EC2"],
    "placementConstraints": [
    {
        "type": "memberOf",
        "expression": "attribute:ecs.os-type == linux"
    }]
}
```
Using video transcoding on Amazon ECS

```json
{
    "type": "memberOf",
    "expression": "attribute:ecs.instance-type == vt1.6xlarge"
}
]
"containerDefinitions": [
{
    "entryPoint": [
        "/bin/bash",
        "-c"
    ],
    "command": ["/video/ecs_ffmpeg_wrapper.sh"],
    "linuxParameters": {
        "devices": [ 
            {
                "containerPath": "/dev/dri/renderD128",
                "hostPath": "/dev/dri/renderD128",
                "permissions": [ 
                    "read",
                    "write"
                ]
            },
            {
                "containerPath": "/dev/dri/renderD129",
                "hostPath": "/dev/dri/renderD129",
                "permissions": [ 
                    "read",
                    "write"
                ]
            },
            {
                "containerPath": "/dev/dri/renderD130",
                "hostPath": "/dev/dri/renderD130",
                "permissions": [ 
                    "read",
                    "write"
                ]
            },
            {
                "containerPath": "/dev/dri/renderD131",
                "hostPath": "/dev/dri/renderD131",
                "permissions": [ 
                    "read",
                    "write"
                ]
            }
        ]
    }
}
```
Using video transcoding on Amazon ECS

2. Register the task definition.

```
aws ecs register-task-definition --family vt1-6xlarge-xffmpeg-processor --cli-input-json file://vt1-6xlarge-xffmpeg-linux.json --region us-east-1
```

vt1.24xlarge

1. Create a text file that's named `vt1-24xlarge-ffmpeg-linux.json` with the following content.

```
{
    "family": "vt1-24xlarge-xffmpeg-processor",
    "requiresCompatibilities": ["EC2"],
    "placementConstraints": [
        {
            "type": "memberOf",
        }
    ]
}
```
"expression": "attribute:ecs.os-type == linux"
],
{
  "type": "memberOf",
  "expression": "attribute:ecs.instance-type == vt1.24xlarge"
}
],
"containerDefinitions": [
{
  "entryPoint": [
    "/bin/bash",
    "-c"
  ],
  "command": ["/video/ecs_ffmpeg_wrapper.sh"],
  "linuxParameters": {
    "devices": [
      {
        "containerPath": "/dev/dri/renderD128",
        "hostPath": "/dev/dri/renderD128",
        "permissions": [
          "read",
          "write"
        ]
      },
      {
        "containerPath": "/dev/dri/renderD129",
        "hostPath": "/dev/dri/renderD129",
        "permissions": [
          "read",
          "write"
        ]
      },
      {
        "containerPath": "/dev/dri/renderD130",
        "hostPath": "/dev/dri/renderD130",
        "permissions": [
          "read",
          "write"
        ]
      },
      {
        "containerPath": "/dev/dri/renderD131",
        "hostPath": "/dev/dri/renderD131",
        "permissions": [
          "read",
          "write"
        ]
      }
    ]
  }
}
Using video transcoding on Amazon ECS

```
"containerPath": "/dev/dri/renderD132",
"hostPath": "/dev/dri/renderD132",
"permissions": [
  "read",
  "write"
],
},
{
  "containerPath": "/dev/dri/renderD133",
  "hostPath": "/dev/dri/renderD133",
  "permissions": [
    "read",
    "write"
  ]
},
{
  "containerPath": "/dev/dri/renderD134",
  "hostPath": "/dev/dri/renderD134",
  "permissions": [
    "read",
    "write"
  ]
},
{
  "containerPath": "/dev/dri/renderD135",
  "hostPath": "/dev/dri/renderD135",
  "permissions": [
    "read",
    "write"
  ]
},
{
  "containerPath": "/dev/dri/renderD136",

        "read",
        "write"
    ]
},
{
    "containerPath": "/dev/dri/renderD142",
    "hostPath": "/dev/dri/renderD142",
    "permissions": [
```
Using video transcoding on Amazon ECS

2. Register the task definition.

```
```
Using AWS Neuron on Amazon Linux 2 on Amazon ECS

You can register Amazon EC2 Trn1, Amazon EC2 Inf1, and Amazon EC2 Inf2 instances to your clusters for machine learning workloads.

Amazon EC2 Trn1 instances are powered by AWS Trainium chips. These instances provide high performance and low cost training for machine learning in the cloud. You can train a machine learning inference model using a machine learning framework with AWS Neuron on a Trn1 instance. Then, you can run the model on a Inf1 instance, or an Inf2 instance to use the acceleration of the AWS Inferentia chips.

The Amazon EC2 Inf1 instances and Inf2 instances are powered by AWS Inferentia chips. They provide high performance and lowest cost inference in the cloud.

Machine learning models are deployed to containers using AWS Neuron, which is a specialized Software Developer Kit (SDK). The SDK consists of a compiler, runtime, and profiling tools that optimize the machine learning performance of AWS machine learning chips. AWS Neuron supports popular machine learning frameworks such as TensorFlow, PyTorch, and Apache MXNet.

Considerations

Before you begin deploying Neuron on Amazon ECS, consider the following:

- Your clusters can contain a mix of Trn1, Inf1, Inf2 and other instances.
- You need a Linux application in a container that uses a machine learning framework that supports AWS Neuron.

⚠️ Important

Applications that use other frameworks might not have improved performance on Trn1, Inf1, and Inf2 instances.

- Only one inference or inference-training task can run on each AWS Trainium or AWS Inferentia chip. For Inf1, each chip has 4 NeuronCores. For Trn1 and Inf2 each chip has 2 NeuronCores. You can run as many tasks as there are chips for each of your Trn1, Inf1, and Inf2 instances.
- When creating a service or running a standalone task, you can use instance type attributes when you configure task placement constraints. This ensures that the task is launched on the container instance that you specify. Doing so can help you optimize overall resource utilization.
and ensure that tasks for inference workloads are on your Trn1, Inf1, and Inf2 instances. For more information, see [How Amazon ECS places tasks on container instances](#).

In the following example, a task is run on an Inf1.xlarge instance on your default cluster.

```bash
aws ecs run-task \
  --cluster default \
  --task-definition ecs-inference-task-def \
  --placement-constraints type=memberOf,expression="attribute:ecs.instance-type == Inf1.xlarge"
```

- Neuron resource requirements can't be defined in a task definition. Instead, you configure a container to use specific AWS Trainium or AWS Inferentia chips available on the host container instance. Do this by using the `linuxParameters` parameter and specifying the device details. For more information, see [Task definition requirements](#).

### Using the Amazon ECS optimized Amazon Linux 2 (Neuron) AMI

Amazon ECS provides an Amazon ECS optimized AMI that's based on Amazon Linux 2 for AWS Trainium and AWS Inferentia workloads. It comes with the AWS Neuron drivers and runtime for Docker. This AMI makes running machine learning inference workloads easier on Amazon ECS.

We recommend using the Amazon ECS optimized Amazon Linux 2 (Neuron) AMI when launching your Amazon EC2 Trn1, Inf1, and Inf2 instances.

You can retrieve the current Amazon ECS optimized Amazon Linux 2 (Neuron) AMI using the AWS CLI with the following command.

```bash
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/inf/recommended
```

The Amazon ECS optimized Amazon Linux 2 (Neuron) AMI is supported in the following Regions:

- US East (N. Virginia)
- US East (Ohio)
- US West (N. California)
- US West (Oregon)
- Asia Pacific (Mumbai)
Task definition requirements

To deploy Neuron on Amazon ECS, your task definition must contain the container definition for a pre-built container serving the inference model for TensorFlow. It's provided by AWS Deep Learning Containers. This container contains the AWS Neuron runtime and the TensorFlow Serving application. At startup, this container fetches your model from Amazon S3, launches Neuron TensorFlow Serving with the saved model, and waits for prediction requests. In the following example, the container image has TensorFlow 1.15 and Ubuntu 18.04. A complete list of pre-built Deep Learning Containers optimized for Neuron is maintained on GitHub. For more information, see Using AWS Neuron TensorFlow Serving.

Alternatively, you can build your own Neuron sidecar container image. For more information, see Tutorial: Neuron TensorFlow Serving in the AWS Deep Learning AMI Developer Guide.

The task definition must be specific to a single instance type. You must configure a container to use specific AWS Trainium or AWS Inferentia devices that are available on the host container instance. You can do so using the linuxParameters parameter. The following table details the chips that are specific to each instance type.
<table>
<thead>
<tr>
<th>Instance Type</th>
<th>vCPUs</th>
<th>RAM (GiB)</th>
<th>AWS ML accelerator chips</th>
<th>Device Paths</th>
</tr>
</thead>
<tbody>

            "devices": ["using aws neuron on amazon linux 2 on amazon ecs"]
         }
      }
   ]
}
```
Using deep learning DL1 instances on Amazon ECS

To use deep learning workloads on Amazon ECS, register Amazon EC2 DL1 instances to your clusters. Amazon EC2 DL1 instances are powered by Gaudi accelerators from Habana Labs (an Intel company). Use the Habana SynapseAI SDK to connect to the Habana Gaudi accelerators. The SDK supports the popular machine learning frameworks, TensorFlow and PyTorch.

Considerations

Before you begin deploying DL1 on Amazon ECS, consider the following:

- Your clusters can contain a mix of DL1 and non-DL1 instances.
- When creating a service or running a standalone task, you can use instance type attributes specifically when you configure task placement constraints to ensure that your task is launched on the container instance that you specify. Doing so ensures that your resources are used effectively and that your tasks for deep learning workloads are on your DL1 instances. For more information, see How Amazon ECS places tasks on container instances.
The following example runs a task on a dl1.24xlarge instance on your default cluster.

```
aws ecs run-task \
  --cluster default \
  --task-definition ecs-dl1-task-def \
  --placement-constraints type=memberOf,expression="attribute:ecs.instance-type == dl1.24xlarge"
```

### Using a DL1 AMI

You have three options for running an AMI on Amazon EC2 DL1 instances for Amazon ECS:

- AWS Marketplace AMIs that are provided by Habana [here](#).
- Habana Deep Learning AMIs that are provided by Amazon Web Services. Because it's not included, you need to install the Amazon ECS container agent separately.
- Use Packer to build a custom AMI that's provided by the [GitHub repo](#). For more information, see the [Packer documentation](#).

### Task definition requirements

To run Habana Gaudi accelerated deep learning containers on Amazon ECS, your task definition must contain the container definition for a pre-built container that serves the deep learning model for TensorFlow or PyTorch using Habana SynapseAI that's provided by AWS Deep Learning Containers.

The following container image has TensorFlow 2.7.0 and Ubuntu 20.04. A complete list of pre-built Deep Learning Containers that's optimized for the Habana Gaudi accelerators is maintained on GitHub. For more information, see [Habana Training Containers](#).

```
763104351884.dkr.ecr.us-east-1.amazonaws.com/tensorflow-training-habana:2.7.0-hpu-py38-synapseai1.2.0-ubuntu20.04
```

The following is an example task definition for Linux containers on Amazon EC2, displaying the syntax to use. This example uses an image containing the Habana Labs System Management Interface Tool (HL-SMI) found here: [vault.habana.ai/gaudi-docker/1.1.0/ubuntu20.04/habanalabs/tensorflow-installer-tf-cpu-2.6.0:1.1.0-614](#).
Working with 64-bit ARM workloads on Amazon ECS

Amazon ECS supports using 64-bit ARM applications. You can run your applications on the platform that's powered by AWS Graviton2 processors. It's suitable for a wide variety of workloads.
This includes workloads such as application servers, micro-services, high-performance computing, CPU-based machine learning inference, video encoding, electronic design automation, gaming, open-source databases, and in-memory caches.

Considerations

Before you begin deploying task definitions that use the 64-bit ARM architecture, consider the following:

- The applications can use the Fargate or EC2 launch types.
- Linux tasks with the ARM64 architecture don't support the Fargate Spot capacity provider.
- The applications can only use the Linux operating system.
- For the Fargate type, the applications must use Fargate platform version 1.4.0 or later.
- The applications can use Fluent Bit or CloudWatch for monitoring.
- For the Fargate launch type, the following AWS Regions do not support 64-bit ARM workloads:
  - US East (N. Virginia), the us-east-1-az3 Availability Zone
- For the Amazon EC2 launch type, see the following to verify that the Region that you're in supports the instance type you want to use:
  - Amazon EC2 M6g Instances
  - Amazon EC2 T4g Instances
  - Amazon EC2 C6g Instances
  - Amazon EC2 R6gd Instances
  - Amazon EC2 X2gd Instances

You can also use the Amazon EC2 describe-instance-type-offerings command with a filter to view the instance offering for your Region.

```
aws ec2 describe-instance-type-offerings --filters Name=instance-type,Values=instance-type --region region
```

The following example checks for the M6 instance type availability in the US East (N. Virginia) (us-east-1) Region.

```
aws ec2 describe-instance-type-offerings --filters "Name=instance-type,Values=m6*" --region us-east-1
```
For more information, see `describe-instance-type-offerings` in the *Amazon EC2 Command Line Reference*.

### Specifying the ARM architecture in your task definition

To use the ARM architecture, specify `ARM64` for the `cpuArchitecture` task definition parameter.

In the following example, the ARM architecture is specified in a task definition. It's in JSON format.

```json
{
    "runtimePlatform": {
        "operatingSystemFamily": "LINUX",
        "cpuArchitecture": "ARM64"
    },
    ...
}
```

In the following example, a task definition for the ARM architecture displays "hello world."

```json
{
    "family": "arm64-testapp",
    "networkMode": "awsvpc",
    "containerDefinitions": [
        {
            "name": "arm-container",
            "image": "arm64v8/busybox",
            "cpu": 100,
            "memory": 100,
            "essential": true,
            "command": [ "echo hello world" ],
            "entryPoint": [ "sh", "-c" ]
        }
    ],
    "requiresCompatibilities": [ "FARGATE" ],
    "cpu": "256",
    "memory": "512",
    "runtimePlatform": {
        "operatingSystemFamily": "LINUX",
        "cpuArchitecture": "ARM64"
    },
    "executionRoleArn": "arn:aws:iam::123456789012:role/ecsTaskExecutionRole"
}
```
Interfaces for configuring ARM

You can configure the ARM CPU architecture for Amazon ECS task definitions using one of the following interfaces:

- Amazon ECS console
- AWS Command Line Interface (AWS CLI)
- AWS SDKs
- AWS Copilot

Using the awslogs log driver

You can configure the containers in your tasks to send log information to CloudWatch Logs. If you're using the Fargate launch type for your tasks, you can view the logs from your containers. If you're using the EC2 launch type, you can view different logs from your containers in one convenient location, and it prevents your container logs from taking up disk space on your container instances. This topic goes over how you can get started using the awslogs log driver in your task definitions.

Note

The type of information that is logged by the containers in your task depends mostly on their ENTRYPOINT command. By default, the logs that are captured show the command output that you typically might see in an interactive terminal if you ran the container locally, which are the STDOUT and STDERR I/O streams. The awslogs log driver simply passes these logs from Docker to CloudWatch Logs. For more information about how Docker logs are processed, including alternative ways to capture different file data or streams, see View logs for a container or service in the Docker documentation.

To send system logs from your Amazon ECS container instances to CloudWatch Logs, see Monitoring Log Files and CloudWatch Logs quotas in the Amazon CloudWatch Logs User Guide.
Turning on the awslogs log driver for your containers

If you're using the Fargate launch type for your tasks, you need to add the required logConfiguration parameters to your task definition to turn on the awslogs log driver. For more information, see Specifying a log configuration in your task definition.

If you're using the EC2 launch type for your tasks and want to turn on the awslogs log driver, your Amazon ECS container instances require at least version 1.9.0 of the container agent. For information about how to check your agent version and updating to the latest version, see Updating the Amazon ECS container agent.

Note

If you aren't using the Amazon ECS optimized AMI (with at least version 1.9.0-1 of the ecs-init package) for your container instances, you also need to specify that the awslogs logging driver is available on the container instance when you start the agent by using the following environment variable in your docker run statement or environment variable file. For more information, see Installing the Amazon ECS container agent.

```
ECSAVAILABLELOGGINGDRIVERS=["json-file","awslogs"]
```

Your Amazon ECS container instances also require logs:CreateLogStream and logs:PutLogEvents permission on the IAM role that you can launch your container instances with. If you created your Amazon ECS container instance role before awslogs log driver support was enabled in Amazon ECS, you might need to add this permission. The ecsTaskExecutionRole is used when it's assigned to the task and likely contains the correct permissions. For information about the task execution role, see Amazon ECS task execution IAM role. If your container instances use the managed IAM policy for container instances, your container instances likely have the correct permissions. For information about the managed IAM policy for container instances, see Amazon ECS container instance IAM role.

Creating a log group

The awslogs log driver can send log streams to an existing log group in CloudWatch Logs or create a new log group on your behalf. The AWS Management Console provides an auto-configure option, which creates a log group on your behalf using the task definition family name with ecs as the prefix. Alternatively, you can manually specify your log configuration options and specify
the awslogs-create-group option with a value of true, which creates the log groups on your behalf.

**Note**

To use the awslogs-create-group option to have your log group created, your task execution IAM role policy or EC2 instance role policy must include the logs:CreateLogGroup permission.

The following code shows how to set the awslogs-create-group option.

```json
{
  "containerDefinitions": [
    {
      "logConfiguration": {
        "logDriver": "awslogs",
        "options": {
          "awslogs-group": "firelens-container",
          "awslogs-region": "us-west-2",
          "awslogs-create-group": "true",
          "awslogs-stream-prefix": "firelens"
        }
      }
    }
  ]
}
```

**Using the auto-configuration feature to create a log group**

When you register a task definition in the Amazon ECS console, you can allow Amazon ECS to auto-configure your CloudWatch logs. Doing this causes a log group to be created on your behalf using the task definition family name with ecs as the prefix. For more information, see the section called “Creating a task definition using the console”.

**Available awslogs log driver options**

The awslogs log driver supports the following options in Amazon ECS task definitions. For more information, see CloudWatch Logs logging driver.
awslogs-create-group

Required: No

Specify whether you want the log group to be created automatically. If this option isn't specified, it defaults to false.

**Note**

Your IAM policy must include the `logs:CreateLogGroup` permission before you attempt to use `awslogs-create-group`.

awslogs-region

Required: Yes

Specify the AWS Region that the `awslogs` log driver is to send your Docker logs to. You can choose to send all of your logs from clusters in different Regions to a single region in CloudWatch Logs. This is so that they're all visible in one location. Otherwise, you can separate them by Region for more granularity. Make sure that the specified log group exists in the Region that you specify with this option.

awslogs-group

Required: Yes

Make sure to specify a log group that the `awslogs` log driver sends its log streams to. For more information, see [Creating a log group](#).

awslogs-stream-prefix

Required: Yes, when using the Fargate launch type. Optional for the EC2 launch type, required for the Fargate launch type.

Use the `awslogs-stream-prefix` option to associate a log stream with the specified prefix, the container name, and the ID of the Amazon ECS task that the container belongs to. If you specify a prefix with this option, then the log stream takes the following format.

```
prefix-name/container-name/ecs-task-id
```
If you don't specify a prefix with this option, then the log stream is named after the container ID that's assigned by the Docker daemon on the container instance. Because it's difficult to trace logs back to the container that sent them with just the Docker container ID (which is only available on the container instance), we recommend that you specify a prefix with this option.

For Amazon ECS services, you can use the service name as the prefix. Doing so, you can trace log streams to the service that the container belongs to, the name of the container that sent them, and the ID of the task that the container belongs to.

You must specify a stream-prefix for your logs to have your logs appear in the Log pane when using the Amazon ECS console.

awslogs-datetime-format

Required: No

This option defines a multiline start pattern in Python strftime format. A log message consists of a line that matches the pattern and any following lines that don't match the pattern. The matched line is the delimiter between log messages.

One example of a use case for using this format is for parsing output such as a stack dump, which might otherwise be logged in multiple entries. The correct pattern allows it to be captured in a single entry.

For more information, see awslogs-datetime-format.

You cannot configure both the awslogs-datetime-format and awslogs-multiline-pattern options.

Note

Multiline logging performs regular expression parsing and matching of all log messages. This might have a negative impact on logging performance.

awslogs-multiline-pattern

Required: No

This option defines a multiline start pattern that uses a regular expression. A log message consists of a line that matches the pattern and any following lines that don't match the pattern. The matched line is the delimiter between log messages.
For more information, see `awslogs-multiline-pattern`.

This option is ignored if `awslogs-datetime-format` is also configured.

You cannot configure both the `awslogs-datetime-format` and `awslogs-multiline-pattern` options.

Note

Multiline logging performs regular expression parsing and matching of all log messages. This might have a negative impact on logging performance.

**mode**

Required: No

Valid values: non-blocking | blocking

Default value: blocking

This option defines the delivery mode of log messages from the container to CloudWatch Logs. The delivery mode you choose affects application availability when the flow of logs from container to CloudWatch is interrupted.

If you use the default blocking mode and the flow of logs to CloudWatch is interrupted, calls from container code to write to the `stdout` and `stderr` streams will block. The logging thread of the application will block as a result. This may cause the application to become unresponsive and lead to container healthcheck failure.

If you use the non-blocking mode, the container's logs are instead stored in an in-memory intermediate buffer configured with the `max-buffer-size` option. This prevents the application from becoming unresponsive when logs cannot be sent to CloudWatch. We recommend using this mode if you want to ensure service availability and are okay with some log loss.

**max-buffer-size**

Required: No

Default value: 1m
When non-blocking mode is used, the `max-buffer-size` log option controls the size of the buffer that's used for intermediate message storage. Make sure to specify an adequate buffer size based on your application. When the buffer fills up, further logs cannot be stored. Logs that cannot be stored are lost.

**Specifying a log configuration in your task definition**

Before your containers can send logs to CloudWatch, you must specify the `awslogs` log driver for containers in your task definition. This section describes the log configuration for a container to use the `awslogs` log driver. For more information, see [Creating a task definition using the console](#).

The task definition JSON that follows has a `logConfiguration` object specified for each container. One is for the WordPress container that sends logs to a log group called `awslogs-wordpress`. The other is for a MySQL container that sends logs to a log group that's called `awslogs-mysql`. Both containers use the `awslogs-example` log stream prefix.

```json
{
    "containerDefinitions": [
        {
            "name": "wordpress",
            "links": [
                "mysql"
            ],
            "image": "wordpress",
            "essential": true,
            "portMappings": [
                {
                    "containerPort": 80,
                    "hostPort": 80
                }
            ],
            "logConfiguration": {
                "logDriver": "awslogs",
                "options": {
                    "awslogs-create-group": "true",
                    "awslogs-group": "awslogs-wordpress",
                    "awslogs-region": "us-west-2",
                    "awslogs-stream-prefix": "awslogs-example"
                }
            }
        },
        {
            "memory": 500,
        }
    ]
}
```
After you have registered a task definition with the awslogs log driver in a container definition log configuration, you can run a task or create a service with that task definition to start sending logs to CloudWatch Logs. For more information, see Run an application as an Amazon ECS task and Creating a service using the console.

Using custom log routing

You can use FireLens for Amazon ECS to use task definition parameters to route logs to an AWS service or AWS Partner Network (APN) destination for log storage and analytics. The AWS Partner Network is a global community of partners that leverages programs, expertise, and resources to build, market, and sell customer offerings. For more information see AWS Partner. FireLens works
with Fluentd and Fluent Bit. We provide the AWS for Fluent Bit image or you can use your own Fluentd or Fluent Bit image.

Considerations

Consider the following when using FireLens for Amazon ECS:

- We recommend that you add `my_service_` to the log container name so that you can easily distinguish container names in the console.
- Amazon ECS adds a start container order dependency between the application containers and the FireLens container by default. When you specify a container order between the application containers and the FireLens container, then the default start container order is overridden.
- FireLens for Amazon ECS is supported for tasks that are hosted on both AWS Fargate on Linux and Amazon EC2 on Linux. Windows containers don't support FireLens.

For information about how to configure centralized logging for Windows containers, see [Centralized logging for Windows containers on Amazon ECS using Fluent Bit](#).

- FireLens for Amazon ECS is supported in AWS CloudFormation templates. For more information, see [AWS::ECS::TaskDefinition FirelensConfiguration](#) in the [AWS CloudFormation User Guide](#).

- FireLens listens on port 24224, so to ensure that the FireLens log router isn't reachable outside of the task, you must not allow inbound traffic on port 24224 in the security group your task uses. For tasks that use the awsvpc network mode, this is the security group associated with the task. For tasks using the host network mode, this is the security group that's associated with the Amazon EC2 instance hosting the task. For tasks that use the bridge network mode, don't create any port mappings that use port 24224.

- For tasks that use the bridge network mode, the container with the FireLens configuration must start before any application containers that rely on it start. To control the start order of your containers, use dependency conditions in your task definition. For more information, see [Container dependency](#).

![Note]

If you use dependency condition parameters in container definitions with a FireLens configuration, ensure that each container has a START or HEALTHY condition requirement.
By default, FireLens adds the cluster and task definition name and the Amazon Resource Name (ARN) of the cluster as metadata keys to your stdout/stderr container logs. The following is an example of the metadata format.

```
"ecs_cluster": "cluster-name",
"ecs_task_arn": "arn:aws:ecs:region:111122223333:task/cluster-name/f2ad7dba413f45ddb4EXAMPLE",
"ecs_task_definition": "task-def-name:revision",
```

If you do not want the metadata in your logs, set enable-ecs-log-metadata to false in the firelensConfiguration section of the task definition.

```
"firelensConfiguration":{
   "type":"fluentbit",
   "options":{
      "enable-ecs-log-metadata": "false",
      "config-file-type": "file",
      "config-file-value": "/extra.conf"
   }
}
```

### Required IAM permissions

To use this feature, you must create an IAM role for your tasks that provides the permissions necessary to use any AWS services that the tasks require. For example, if a container is routing logs to Firehose, the task requires permission to call the firehose:PutRecordBatch API. For more information, see [Adding and Removing IAM Identity Permissions](#) in the [IAM User Guide](#).

The following example IAM policy adds the required permissions for routing logs to Firehose.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["firehose:PutRecordBatch"],
         "Resource": ["*"]
      }
   ]
}
```
The following example IAM policy adds the required permissions for routing logs to Amazon CloudWatch Logs.

```json
{
   "Version": "2012-10-17",
   "Statement": [{
      "Effect": "Allow",
      "Action": [
         "logs:CreateLogStream",
         "logs:CreateLogGroup",
         "logs:PutLogEvents"
      ],
      "Resource": "*"
   }]
}
```

Your task may also require the Amazon ECS task execution role under the following conditions. For more information, see [Amazon ECS task execution IAM role](#).

- If your task is hosted on Fargate and you are pulling container images from Amazon ECR or referencing sensitive data from AWS Secrets Manager in your log configuration, then you must include the task execution IAM role.

- If you are specifying a custom configuration file that's hosted in Amazon S3, your task execution IAM role must include the `s3:GetObject` permission for the configuration file and the `s3:GetBucketLocation` permission on the Amazon S3 bucket that the file is in. For more information, see [Specifying Permissions in a Policy](#) in the [Amazon Simple Storage Service User Guide](#).

The following example IAM policy adds the required permissions for retrieving a file from Amazon S3. Specify the name of your Amazon S3 bucket and configuration file name.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "s3:GetObject",
            "s3:GetBucketLocation"
         ],
         "Resource": "*"
      }
   ]
}
```
"Action": [ 
   "s3:GetObject"
 ],
"Resource": [ 
   "arn:aws:s3:::examplebucket/folder_name/config_file_name"
 ],
{
   "Effect": "Allow",
   "Action": [ 
      "s3:GetBucketLocation"
   ],
   "Resource": [ 
      "arn:aws:s3:::examplebucket"
   ]
}]
}

**Fluentd buffer limit**

When you create a task definition, you can specify the number of events that are buffered in memory by specifying the value (in bytes) in the `log-driver-buffer-limit`. For more information, see [Fluentd logging driver](https://docs.docker.com/containers/logging/fluentd/) in the Docker documentation.

Use this option when there's high throughput, because Docker might run out of buffer memory and discard buffer messages so it can add new messages. The lost logs might make it difficult to troubleshoot. Setting the buffer limit might help to prevent this issue.

The following shows the syntax for specifying the `log-driver-buffer-limit`. Replace `my_service_` with the name of your service:

```json
{
   "containerDefinitions": [ 
      {
         "essential": true,
         "image": "906394416424.dkr.ecr.us-west-2.amazonaws.com/aws-for-fluent-bit:stable",
         "name": "my_service_log_router",
         "firelensConfiguration": { 
            "type": "fluentbit"
         }
      }
   ]
}
```
Consider the following when using FireLens for Amazon ECS with the buffer limit option:

- This option is supported on the Amazon EC2 launch type and the Fargate launch type with platform version 1.4.0 or later.
- The option is only valid when `logDriver` is set to `awsfirelens`.
- The default buffer limit is 1 MiB.
- The valid values are 0 and 536870912 (512 MiB).
• The total amount of memory allocated at the task level must be greater than the amount of memory that's allocated for all the containers in addition to the memory buffer limit. The total amount of buffer memory specified must be less than 536870912 (512MiB) when you don't specify the container memory and memoryReservation values. More specifically, you can have an app container with the awsfirelens log driver and the log-driver-buffer-limit option set to 300 MiB. However, you won't be allowed to run tasks if you have more than two containers with the log-driver-buffer-limit set to 300 MiB (300 MiB * 2 > 512 MiB).

Using Fluent logger libraries or Log4j over TCP

When the awsfirelens log driver is specified in a task definition, the Amazon ECS container agent injects the following environment variables into the container:

FLUENT_HOST

The IP address that's assigned to the FireLens container.

FLUENT_PORT

The port that the Fluent Forward protocol is listening on.

You can use the FLUENT_HOST and FLUENT_PORT environment variables to log directly to the log router from code instead of going through stdout. For more information, see fluent-logger-golang on GitHub.

• the section called “AWS for Fluent Bit image”
• the section called “Specifying a FireLens configuration in a task definition”
• the section called “Filtering Fluentd and Fluent Bit logs”
• the section called “Example logging option task definitions”

AWS for Fluent Bit image

AWS provides a Fluent Bit image with plugins for both CloudWatch Logs and Firehose. We recommend using Fluent Bit as your log router because it has a lower resource utilization rate than Fluentd. For more information, see CloudWatch Logs for Fluent Bit and Amazon Kinesis Firehose for Fluent Bit.
The **AWS for Fluent Bit** image is available on Amazon ECR on both the Amazon ECR Public Gallery and in an Amazon ECR repository in most AWS Regions for high availability.

**Amazon ECR Public Gallery**

The AWS for Fluent Bit image is available on the Amazon ECR Public Gallery. This is the recommended location to download the AWS for Fluent Bit image because it's a public repository and available to be used from all AWS Regions. For more information, see [aws-for-fluent-bit](#) on the Amazon ECR Public Gallery.

**Linux**

The AWS for Fluent Bit image in the Amazon ECR Public Gallery supports Amazon Linux operating system with the ARM 64, or x86-64 architecture.

You can pull the AWS for Fluent Bit image from the Amazon ECR Public Gallery by specifying the repository URL with the desired image tag. The available image tags can be found on the **Image tags** tab on the Amazon ECR Public Gallery.

The following shows the syntax to use for the Docker CLI.

```
$ docker pull public.ecr.aws/aws-observability/aws-for-fluent-bit:tag
```

For example, you can pull the latest stable AWS for Fluent Bit image using this Docker CLI command.

```
$ docker pull public.ecr.aws/aws-observability/aws-for-fluent-bit:stable
```

---

**Note**

Unauthenticated pulls are allowed, but have a lower rate limit than authenticated pulls. To authenticate using your AWS account before pulling, use the following command.

```
aws ecr-public get-login-password --region us-east-1 | docker login --username AWS --password-stdin public.ecr.aws
```
Windows

The AWS for Fluent Bit image in the Amazon ECR Public Gallery supports the AMD64 architecture with the following operating systems:

- Windows Server 2022 Full
- Windows Server 2022 Core
- Windows Server 2019 Full
- Windows Server 2019 Core

Windows containers that are on AWS Fargate don't support FireLens.

You can pull the AWS for Fluent Bit image from the Amazon ECR Public Gallery by specifying the repository URL with the desired image tag. The available image tags can be found on the Image tags tab on the Amazon ECR Public Gallery.

The following shows the syntax to use for the Docker CLI.

```
docker pull public.ecr.aws/aws-observability/aws-for-fluent-bit:tag
```

For example, you can pull the newest stable AWS for Fluent Bit image using this Docker CLI command.

```
docker pull public.ecr.aws/aws-observability/aws-for-fluent-bit:windowsservercore-stable
```

**Note**

Unauthenticated pulls are allowed, but have a lower rate limit than authenticated pulls. To authenticate using your AWS account before pulling, use the following command.

```
aws ecr-public get-login-password --region us-east-1 | docker login --username AWS --password-stdin public.ecr.aws
```
Amazon ECR

The AWS for Fluent Bit image is available on Amazon ECR for high availability. These images are available in most AWS Regions, including AWS GovCloud (US).

Linux

The latest stable AWS for Fluent Bit image URI can be retrieved using the following command.

```
aws ssm get-parameters \
   --names /aws/service/aws-for-fluent-bit/stable \
   --region us-east-1
```

All versions of the AWS for Fluent Bit image can be listed using the following command to query the Systems Manager Parameter Store parameter.

```
aws ssm get-parameters-by-path \
   --path /aws/service/aws-for-fluent-bit \
   --region us-east-1
```

The newest stable AWS for Fluent Bit image can be referenced in an AWS CloudFormation template by referencing the Systems Manager parameter store name. The following is an example:

```
Parameters:
  FireLensImage:
      Description: Fluent Bit image for the FireLens Container
      Type: AWS::SSM::Parameter::Value<String>
      Default: /aws/service/aws-for-fluent-bit/stable
```

Windows

The latest stable AWS for Fluent Bit image URI can be retrieved using the following command.

```
aws ssm get-parameters \
   --names /aws/service/aws-for-fluent-bit/windowsservercore:stable \
   --region us-east-1
```

All versions of the AWS for Fluent Bit image can be listed using the following command to query the Systems Manager Parameter Store parameter.
The latest stable AWS for Fluent Bit image can be referenced in an AWS CloudFormation template by referencing the Systems Manager parameter store name. The following is an example:

```bash
aws ssm get-parameters-by-path \
    --path /aws/service/aws-for-fluent-bit/windowsservercore \
    --region us-east-1
```

Parameters:
- **FireLensImage**:
  - Description: Fluent Bit image for the FireLens Container
  - Type: AWS::SSM::Parameter::Value<String>
  - Default: /aws/service/aws-for-fluent-bit/windowsservercore:stable

### Specifying a FireLens configuration in a task definition

To use custom log routing with FireLens, you must specify the following in your task definition:

- A log router container that contains a FireLens configuration. We recommend that the container be marked as essential.
- One or more application containers that contain a log configuration specifying the awsfirelens log driver.
- A task IAM role Amazon Resource Name (ARN) that contains the permissions needed for the task to route the logs. For more information about permissions for an IAM task role, see [Required IAM permissions](#).

When creating a new task definition using the AWS Management Console, there is a FireLens integration section that makes it easy to add a log router container. For more information, see [Creating a task definition using the console](#).

Amazon ECS converts the log configuration and generates the Fluentd or Fluent Bit output configuration. The output configuration is mounted in the log routing container at `/fluent-bit/etc/fluent-bit.conf` for Fluent Bit and `/fluentd/etc/fluent.conf` for Fluentd.

⚠️ **Important**

FireLens listens on port 24224. Therefore, to ensure that the FireLens log router isn't reachable outside of the task, you must not allow ingress traffic on port 24224 in the
security group your task uses. For tasks that use the awsvpc network mode, this is the
security group that's associated with the task. For tasks that use the host network mode,
this is the security group that's associated with the Amazon EC2 instance hosting the task.
For tasks that use the bridge network mode, don't create any port mappings that use port
24224.

By default, Amazon ECS adds additional fields in your log entries that help identify the source of
the logs.

- **ecs_cluster** – The name of the cluster that the task is part of.
- **ecs_task_arn** – The full Amazon Resource Name (ARN) of the task that the container is part of.
- **ecs_task_definition** – The task definition name and revision that the task is using.
- **ec2_instance_id** – The Amazon EC2 instance ID that the container is hosted on. This field is
  only valid for tasks using the EC2 launch type.

You can set the `enable-ecs-log-metadata` to false if you do not want the metadata.

The following task definition example defines a log router container that uses Fluent Bit to route
its logs to CloudWatch Logs. It also defines an application container that uses a log configuration
to route logs to Amazon Data Firehose and sets the memory that's used to buffer events to the 2
MiB.

> Note
> For more example task definitions, see [Amazon ECS FireLens examples](https://github.com) on GitHub.

```json
{
  "family": "firelens-example-firehose",
  "taskRoleArn": "arn:aws:iam::123456789012:role/ecs_task_iam_role",
  "containerDefinitions": [
    {
      "essential": true,
      "image": "906394416424.dkr.ecr.us-west-2.amazonaws.com/aws-for-fluent-bit:stable",
      "name": "log_router",
      "firelensConfiguration": {
```
The key-value pairs specified as options in the `logConfiguration` object are used to generate the Fluentd or Fluent Bit output configuration. The following is a code example from a Fluent Bit output definition.

```
[OUTPUT]
  Name       firehose
  Match      app-firelens*
  region     us-west-2
  delivery_stream  my-stream
```
Specifying a custom configuration file

In addition to the auto-generated configuration file that FireLens creates on your behalf, you can also specify a custom configuration file. The configuration file format is the native format for the log router that you're using. For more information, see [Fluentd Config File Syntax](#) and [Fluent Bit Configuration File](#).

In your custom configuration file, for tasks using the `bridge` or `awsvpc` network mode, don't set a Fluentd or Fluent Bit forward input over TCP because FireLens adds it to the input configuration.

Your FireLens configuration must contain the following options to specify a custom configuration file:

config-file-type

The source location of the custom configuration file. The available options are `s3` or `file`.

Note

Tasks that are hosted on AWS Fargate only support the `file` configuration file type.

config-file-value

The source for the custom configuration file. If the `s3` config file type is used, the config file value is the full ARN of the Amazon S3 bucket and file. If the `file` config file type is used, the config file value is the full path of the configuration file that exists either in the container image or on a volume that's mounted in the container.

Important

When using a custom configuration file, you must specify a different path than the one FireLens uses. Amazon ECS reserves the `/fluent-bit/etc/fluent-bit.conf` filepath for Fluent Bit and `/fluentd/etc/fluent.conf` for Fluentd.
The following example shows the syntax required when specifying a custom configuration.

⚠️ **Important**

To specify a custom configuration file that's hosted in Amazon S3, ensure you have created a task execution IAM role with the proper permissions. For more information, see Required IAM permissions.

The following shows the syntax required when specifying a custom configuration.

```json
{
    "containerDefinitions": [
        {
            "essential": true,
            "image": "906394416424.dkr.ecr.us-west-2.amazonaws.com/aws-for-fluent-bit:stable",
            "name": "log_router",
            "firelensConfiguration": {
                "type": "fluentbit",
                "options": {
                    "config-file-type": "s3 | file",
                    "config-file-value": "arn:aws:s3:::mybucket/fluent.conf | filepath"
                }
            }
        }
    ]
}
```

⚠️ **Note**

Tasks hosted on AWS Fargate only support the file configuration file type.

**Filtering Fluentd and Fluent Bit logs**

There might be times when you want to filter what logs get sent, for example send logs that contain a specific error.

Fluentd and Fluent Bit both support filtering of logs based on their content. FireLens provides a simple method for enabling this filtering.
You can configure these in the logConfiguration options in a container definition by specifying the regular expressions to match.

The exclude-pattern key causes all logs that match its regular expression to be dropped. The include-pattern only sends logs that match the specified regular expression. You can use these keys separately or together.

The following example demonstrates how to use this filter.

```json
{
    "containerDefinitions": [
        {
            "logConfiguration": {
                "logDriver": "awsfirelens",
                "options": {
                    "@type": "cloudwatch_logs",
                    "log_group_name": "firelens-testing",
                    "auto_create_stream": "true",
                    "use_tag_as_stream": "true",
                    "region": "us-west-2",
                    "exclude-pattern": "^[a-z][aeiou].*$",
                    "include-pattern": "^.*[aeiou]$
                }
            }
        }
    ]
}
```

Example logging option task definitions

The following are some example task definitions demonstrating common custom log routing options. For more examples, see Amazon ECS FireLens examples on GitHub.

**Note**

The following logConfiguration task definition parameter shown in these examples is used to send your AWS for Fluent Bit logs to CloudWatch. AWS recommends this configuration so that you have additional information in CloudWatch to troubleshoot AWS for Fluent Bit issues.

```json
"logConfiguration": {
    "logDriver": "awslogs",
```
"options": {
    "awslogs-group": "firelens-container",
    "awslogs-region": "us-west-2",
    "awslogs-create-group": "true",
    "awslogs-stream-prefix": "firelens"
  }
},

Topics

• Forwarding logs to CloudWatch Logs
• Forwarding logs to an Amazon Data Firehose delivery stream
• Forwarding logs to an Amazon OpenSearch Service domain
• Parsing container logs that are serialized JSON
• Forwarding to an external Fluentd or Fluent Bit

Forwarding logs to CloudWatch Logs

⚠️ Note

For more examples, see Amazon ECS FireLens examples on GitHub.

The following task definition example demonstrates how to specify a log configuration that forwards logs to a CloudWatch Logs log group. For more information, see What Is Amazon CloudWatch Logs? in the Amazon CloudWatch Logs User Guide.

In the log configuration options, specify the log group name and the AWS Region it exists in. To have Fluent Bit create the log group on your behalf, specify "auto_create_group": "true", to set the fluentd-buffer-limit use log-driver-buffer-limit. You can also specify the task ID as the log stream prefix, which assists in filtering. For more information, see Fluent Bit Plugin for CloudWatch Logs.

```json
{
    "family": "firelens-example-cloudwatch",
    "taskRoleArn": "arn:aws:iam::123456789012:role/ecs_task_iam_role",
    "containerDefinitions": [
      {
```
"essential": true,
"image": "906394416424.dkr.ecr.us-west-2.amazonaws.com/aws-for-fluent-bit:latest",
"name": "log_router",
"firelensConfiguration": {
    "type": "fluentbit"
},
"logConfiguration": {
    "logDriver": "awslogs",
    "options": {
        "awslogs-group": "firelens-container",
        "awslogs-region": "us-west-2",
        "awslogs-create-group": "true",
        "awslogs-stream-prefix": "firelens"
    }
},
"memoryReservation": 50
},
{
    "essential": true,
    "image": "httpd",
    "name": "app",
    "logConfiguration": {
        "logDriver": "awsfirelens",
        "options": {
            "Name": "cloudwatch",
            "region": "us-west-2",
            "log_group_name": "firelens-blog",
            "auto_create_group": "true",
            "log_stream_prefix": "from-fluent-bit",
            "log-driver-buffer-limit": "2097152"
        }
    },
    "memoryReservation": 100
}
Forwarding logs to an Amazon Data Firehose delivery stream

Note
For more examples, see Amazon ECS FireLens examples on GitHub.

The following task definition example demonstrates how to specify a log configuration that forwards logs to an Amazon Data Firehose delivery stream. The Firehose delivery stream must already exist. For more information, see Creating an Amazon Data Firehose Delivery Stream in the Amazon Data Firehose Developer Guide.

In the log configuration options, specify the delivery stream name and the Region it exists in. For more information, see Fluent Bit Plugin for Amazon Kinesis Firehose.

```json
{
    "family": "firelens-example-firehose",
    "taskRoleArn": "arn:aws:iam::123456789012:role/ecs_task_iam_role",
    "containerDefinitions": [
        {
            "essential": true,
            "image": "906394416424.dkr.ecr.us-west-2.amazonaws.com/aws-for-fluent-bit:stable",
            "name": "log_router",
            "firelensConfiguration": {
                "type": "fluentbit"
            },
            "logConfiguration": {
                "logDriver": "awslogs",
                "options": {
                    "awslogs-group": "firelens-container",
                    "awslogs-region": "us-west-2",
                    "awslogs-create-group": "true",
                    "awslogs-stream-prefix": "firelens"
                }
            },
            "memoryReservation": 50
        },
        {
            "essential": true,
            "image": "httpd",
            "name": "app",
            "logConfiguration": {
            }
        }
    ],
    "memoryReservation": 50
}
```
Forwarding logs to an Amazon OpenSearch Service domain

Note
For more examples, see Amazon ECS FireLens examples on GitHub.

The following task definition example demonstrates how to specify a log configuration that forwards logs to an Amazon OpenSearch Service domain. The Amazon OpenSearch Service domain must already exist. For more information, see What is Amazon OpenSearch Service in the Amazon OpenSearch Service Developer Guide.

In the log configuration options, specify the log options required for OpenSearch Service integration. For more information, see Fluent Bit for Amazon OpenSearch Service.

```json
{
    "family": "firelens-example-opensearch",
    "taskRoleArn": "arn:aws:iam::123456789012:role/ecs_task_iam_role",
    "containerDefinitions": [
        {
            "essential": true,
            "image": "906394416424.dkr.ecr.us-west-2.amazonaws.com/aws-for-fluent-bit:stable",
            "name": "log_router",
            "firelensConfiguration": {
                "type": "fluentbit"
            },
            "logConfiguration": {
                "logDriver": "awslogs",
                "options": {
```
Parsing container logs that are serialized JSON

For more examples, see Amazon ECS FireLens examples on GitHub.

Beginning with AWS for Fluent Bit version 1.3, there's a JSON parser that's included in the AWS for Fluent Bit image. The following example shows how to reference the JSON parser in the FireLens configuration of your task definition.
"firelensConfiguration": {
    "type": "fluentbit",
    "options": {
        "config-file-type": "file",
        "config-file-value": "/fluent-bit/configs/parse-json.conf"
    }
},

The Fluent Bit config file parses any logs that are in JSON (for example, if the logs at your destination looked like the following without JSON parsing).

```json
{
    "source": "stdout",
    "log": "{\"requestID\": \"b5d716fca19a4252ad90e7b8ec7cc8d2\", \"requestInfo\":
    {\"ipAddress\": \"204.16.5.19\", \"path\": "/activate", \"user\": \"TheDoctor\"}},
    "container_id": "e54cccfac2b87417f71877907f67879068420042828067ae0867e60a63529d35",
    "container_name": "/ecs-demo-6-container2-a4eafbb3d4c7f1e16e00",
    "ecs_cluster": "mycluster",
    "ecs_task_arn": "arn:aws:ecs:us-east-2:01234567891011:task/mycluster/3de392df-6bfa-470b-97ed-aa6f482cd7a6",
    "ecs_task_definition": "demo:7",
    "ec2_instance_id": "i-06bc83d6c2ac2fd8"
}
```

With the JSON parsing, the log looks like the following.

```json
{
    "source": "stdout",
    "container_id": "e54cccfac2b87417f71877907f67879068420042828067ae0867e60a63529d35",
    "container_name": "/ecs-demo-6-container2-a4eafbb3d4c7f1e16e00",
    "ecs_cluster": "mycluster",
    "ecs_task_arn": "arn:aws:ecs:us-east-2:01234567891011:task/mycluster/3de392df-6bfa-470b-97ed-aa6f482cd7a6",
    "ecs_task_definition": "demo:7",
    "ec2_instance_id": "i-06bc83d6c2ac2fd8",
    "requestID": "b5d716fca19a4252ad90e7b8ec7cc8d2",
    "requestInfo": {
        "ipAddress": "204.16.5.19",
        "path": "/activate",
        "user": "TheDoctor"
    }
}
```
The serialized JSON is expanded into top level fields in the final JSON output. For more information about JSON parsing, see Parser in the Fluent Bit documentation.

**Forwarding to an external Fluentd or Fluent Bit**

**Note**
For more examples, see Amazon ECS FireLens examples on GitHub.

The following task definition example demonstrates how to specify a log configuration that forwards logs to an external Fluentd or Fluent Bit host. Specify the host and port for your environment.

```json
{
  "family": "firelens-example-forward",
  "taskRoleArn": "arn:aws:iam::123456789012:role/ecs_task_iam_role",
  "containerDefinitions": [
    {
      "essential": true,
      "image": "906394416424.dkr.ecr.us-west-2.amazonaws.com/aws-for-fluent-bit:stable",
      "name": "log_router",
      "firelensConfiguration": {
        "type": "fluentbit"
      },
      "logConfiguration": {
        "logDriver": "awslogs",
        "options": {
          "awslogs-group": "firelens-container",
          "awslogs-region": "us-west-2",
          "awslogs-create-group": "true",
          "awslogs-stream-prefix": "firelens"
        }
      },
      "memoryReservation": 50
    },
    {
      "essential": true,
      "image": "httpd",
      "name": "app",
      "logConfiguration": {
        "logDriver": "awsfirelens",
        "options": {
          "awsfirelens-host": "your-fluentd-host",
          "awsfirelens-port": 24224
        }
      }
    }
  ]
}
```
Private registry authentication for tasks

Use private registry to store your credentials in AWS Secrets Manager, and then reference them in your task definition. This provides a way to reference container images that exist in private registries outside of AWS that require authentication in your task definitions. This feature is supported by tasks hosted on Fargate, Amazon EC2 instances, and external instances using Amazon ECS Anywhere.

⚠️ Important
If your task definition references an image that's stored in Amazon ECR, this topic doesn't apply. For more information, see Using Amazon ECR Images with Amazon ECS in the Amazon Elastic Container Registry User Guide.

For tasks hosted on Amazon EC2 instances, this feature requires version 1.19.0 or later of the container agent. However, we recommend using the latest container agent version. For information about how to check your agent version and update to the latest version, see Updating the Amazon ECS container agent.

For tasks hosted on Fargate, this feature requires platform version 1.2.0 or later. For information, see Fargate Linux platform versions.

Within your container definition, specify the repositoryCredentials object with the details of the secret that you created. The secret you reference can be from a different AWS Region or a different account than the task using it.
**Note**

When using the Amazon ECS API, AWS CLI, or AWS SDK, if the secret exists in the same AWS Region as the task that you're launching then you can use either the full ARN or name of the secret. If the secret exists in a different account, the full ARN of the secret must be specified. When using the AWS Management Console, the full ARN of the secret must be specified always.

The following is a snippet of a task definition that shows the required parameters:

Substitute `private-repo` with the private repository host name and `private-image` with the image name.

```json
"containerDefinitions": [
    {
        "image": "private-repo/private-image",
        "repositoryCredentials": {
            "credentialsParameter": "arn:aws:secretsmanager:region:aws_account_id:secret:secret_name"
        }
    }
]
```

**Note**

Another method of enabling private registry authentication uses Amazon ECS container agent environment variables to authenticate to private registries. This method is only supported for tasks hosted on Amazon EC2 instances. For more information, see [Private registry authentication for container instances](#).

**To use private registry**

1. The Amazon ECS task execution role is required to use this feature. This allows the container agent to pull the container image. For more information, see [Amazon ECS task execution IAM role](#).
To provide access to the secrets that you create, add the following permissions as an inline policy to the task execution role. For more information, see Adding and Removing IAM Policies.

- `secretsmanager:GetSecretValue`
- `kms:Decrypt`—Required only if your key uses a custom KMS key and not the default key. The Amazon Resource Name (ARN) for your custom key must be added as a resource.

The following is an example inline policy that adds the permissions.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "kms:Decrypt",
            "secretsmanager:GetSecretValue"
         ],
         "Resource": [
            "arn:aws:kms:<region>:<aws_account_id>:key/key_id"
         ]
      }
   ]
}
```

2. Use AWS Secrets Manager to create a secret for your private registry credentials. For information about how to create a secret, see Create an AWS Secrets Manager secret in the AWS Secrets Manager User Guide.

Enter your private registry credentials using the following format:

```
{
   "username" : "privateRegistryUsername",
   "password" : "privateRegistryPassword"
}
```

3. Register a task definition. For more information, see the section called “Creating a task definition using the console”.

Private registry authentication for tasks
Use task definition parameters to pass environment variables to a container

⚠️ Important

We recommend storing your sensitive data in either AWS Secrets Manager secrets or AWS Systems Manager Parameter Store parameters. For more information, see [Passing sensitive data to a container](#).

Environment variables specified in the task definition are readable by all users and roles that are allowed the DescribeTaskDefinition action for the task definition.

You can pass environment variables to your containers in the following ways:

- Individually using the `environment` container definition parameter. This maps to the `--env` option to `docker run`.
- In bulk, using the `environmentFiles` container definition parameter to list one or more files that contain the environment variables. The file must be hosted in Amazon S3. This maps to the `--env-file` option to `docker run`.

The following is a snippet of a task definition showing how to specify individual environment variables.

```json
{
    "family": "",
    "containerDefinitions": [
        {
            "name": "",
            "image": "",
            ...
            "environment": [
                {
                    "name": "variable",
                    "value": "value"
                }
            ],
            ...
        }
    ],
}
```
Use a file to pass environment variables to a container

⚠️ Important

We recommend storing your sensitive data in either AWS Secrets Manager secrets or AWS Systems Manager Parameter Store parameters. For more information, see Passing sensitive data to a container.

Environment variable files are objects in Amazon S3 and all Amazon S3 security considerations apply.

You can create an environment variable file and store it in Amazon S3 to pass environment variables to your container.

By specifying environment variables in a file, you can bulk inject environment variables. Within your container definition, specify the environmentFiles object with a list of Amazon S3 buckets containing your environment variable files.

Amazon ECS doesn't enforce a size limit on the environment variables, but a large environment variables file might fill up the disk space. Each task that uses an environment variables file causes a copy of the file to be downloaded to disk. Amazon ECS removes the file as part of the task cleanup.

For information about the supported environment variables, see Advanced container definition parameters- Environment.

Considerations

Consider the following when specifying an environment variable file in a container definition.

- For Amazon ECS tasks on Amazon EC2, your container instances require that the container agent is version 1.39.0 or later to use this feature. For information about how to check your agent version and update to the latest version, see Updating the Amazon ECS container agent.

- For Amazon ECS tasks on AWS Fargate, your tasks must use platform version 1.4.0 or later (Linux) to use this feature. For more information, see Fargate Linux platform versions.
Verify that the variable is supported for the operating system platform. For more information, see the section called “Container definitions” and the section called “Other task definition parameters”.

- The file must use the `.env` file extension and UTF-8 encoding.
- There is a limit of 10 files per task definition.
- Each line in an environment file must contain an environment variable in `VARIABLE=VALUE` format. Spaces or quotation marks are included as part of the values for Amazon ECS files. Lines beginning with `#` are treated as comments and are ignored. For more information about the environment variable file syntax, see Declare default environment variables in file.

The following is the appropriate syntax.

```
#This is a comment and will be ignored
VARIABLE=VALUE
ENVIRONMENT=PRODUCTION
```

- If there are environment variables specified using the `environment` parameter in a container definition, they take precedence over the variables contained within an environment file.
- If multiple environment files are specified and they contain the same variable, they're processed in order of entry. This means that the first value of the variable is used and subsequent values of duplicate variables are ignored. We recommend that you use unique variable names.
- If an environment file is specified as a container override, it's used. Moreover, any other environment files that are specified in the container definition is ignored.

The following rules apply to the Fargate launch type:

- The file is handled like a native Docker env-file.
- There is no support for shell escape handling.
- The container entry point interprets the `VARIABLE` values.

### Required IAM permissions

The Amazon ECS task execution role is required to use this feature. This allows the container agent to pull the environment variable file from Amazon S3. For more information, see Amazon ECS task execution IAM role.

To provide access to the Amazon S3 objects that you create, manually add the following permissions as an inline policy to the task execution role. Use the `Resource` parameter to scope
the permission to the Amazon S3 buckets that contain the environment variable files. For more information, see Adding and Removing IAM Policies.

- s3:GetObject
- s3:GetBucketLocation

In the following example, the permissions are added to the inline policy.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "s3:GetObject"
         ],
         "Resource": [
            "arn:aws:s3:::examplebucket/folder_name/env_file_name"
         ]
      },
      {
         "Effect": "Allow",
         "Action": [
            "s3:GetBucketLocation"
         ],
         "Resource": [
            "arn:aws:s3:::examplebucket"
         ]
      }
   ]
}
```

Example

The following is a snippet of a task definition showing how to specify an environment variable file.

```json
{
   "family": "",
   "containerDefinitions": [
      {
         "name": "",
```
Passing sensitive data to a container

You can safely pass sensitive data, such as credentials to a database, into your container.

You can use AWS Secrets Manager or as a parameter in AWS Systems Manager Parameter Store to store the secret.

You can retrieve secrets programmatically from the application, or by using environment variables.

To start, first store the sensitive data as a secret in AWS Secrets Manager or as a parameter in AWS Systems Manager Parameter Store. Then, use one of the following ways to expose the secret to the container.

Topics

- Retrieve Secrets Manager secrets programatically
- Retrieve AWS Systems Manager Parameter Store parameters programatically
- Retrieve Secrets Manager secrets through environment variables
- Retrieving AWS Systems Manager parameters through environment variables
- Retrieve secrets for logging configuration

Retrieve Secrets Manager secrets programatically

Use Secrets Manager to protect sensitive data and rotate, manage, and retrieve database credentials, API keys, and other secrets throughout their lifecycle.
Instead of hardcoding sensitive information in plain text in your application, you can use Secrets Manager to store the sensitive data.

We recommend this method of retrieving sensitive data because if the Secrets Manager secret is subsequently updated, the application automatically retrieves the latest version of the secret.

Create a secret in Secrets Manager. After you create a Secrets Manager secret, update your application code to retrieve the secret.

**Considerations**

Review the following considerations before securing sensitive data in Secrets Manager.

- Only secrets that store text data, which are secrets created with the SecretString parameter of the `CreateSecret` API, are supported. Secrets that store binary data, which are secrets created with the SecretBinary parameter of the `CreateSecret` API are not supported.
- Use interface VPC endpoints to enhance security controls. You must create the interface VPC endpoints for Secrets Manager. For information about the VPC endpoint, see [Create VPC endpoints](https://docs.aws.amazon.com/secretsmanager/latest/userguide/create-vpc-endpoints.html) in the *AWS Secrets Manager User Guide*.
- The VPC your task uses must use DNS resolution.

**Required IAM permissions**

To use this feature, you must have the Amazon ECS task role and reference it in your task definition. For more information, see [Task IAM role](https://docs.aws.amazon.com/elasticcontainerservice/latest/dg/efi-iampolicies.html).

To provide access to the Secrets Manager secrets that you create, manually add the following permission to the task execution role. For information about how to manage permissions, see [Adding and Removing IAM identity permissions](https://docs.aws.amazon.com/IAM/latest/UserGuide/id委组织部-iam-access-control-policy-element.html) in the *IAM User Guide*.

- `secretsmanager:GetSecretValue` – Required if you are referencing a Secrets Manager secret. Adds the permission to retrieve the secret from Secrets Manager.

The following example policy adds the required permissions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
```
Create the Secrets Manager secret

You can use the Secrets Manager console to create a secret for your sensitive data. For information about how to create secrets, see Create an AWS Secrets Manager secret in the AWS Secrets Manager User Guide.

Update your application to programmatically retrieve Secrets Manager secrets

You can retrieve secrets with a call to the Secrets Manager APIs directly from your application. For information about how update your code to request the secret, see Retrieve secrets from AWS Secrets Manager in the AWS Secrets Manager User Guide.

To retrieve the sensitive data stored in the AWS Secrets Manager, see Code examples for AWS Secrets Manager using AWS SDKs in the AWS SDK Code Examples Code Library.

Retrieve AWS Systems Manager Parameter Store parameters programatically

Systems Manager Parameter Store provides secure storage and management of secrets. You can store data such as passwords, database strings, Amazon Elastic Compute Cloud (Amazon EC2) instance IDs and AMI IDs, and license codes as parameter values. You can store values as plain text or encrypted data.

Instead of hardcoding sensitive information in plain text in your application, you can use Secrets Manager to store the sensitive data.

We recommend this method of retrieving sensitive data because if the Systems Manager Parameter Store parameter is subsequently updated, the application automatically retrieves the latest version.

Create a secret in Secrets Manager. After you create a Secrets Manager secret, update your application code to retrieve the secret.
Considerations

Review the following considerations before securing sensitive data in Systems Manager Parameter Store.

- Only secrets that store text data are supported. Secrets that store binary data are not supported.
- Use interface VPC endpoints to enhance security controls.
- The VPC your task uses must use DNS resolution.

Required IAM permissions

To use this feature, you must have the Amazon ECS task role and reference it in your task definition. This allows the container agent to pull the necessary Systems Manager resources. For more information, see Task IAM role.

⚠️ Important

For tasks that use the EC2 launch type, you must use the ECS agent configuration variable ECS_ENABLE_AWSLOGS_EXECUTIONROLE_OVERRIDE=true to use this feature. You can add it to the ./etc/ecs/ecs.config file during container instance creation or you can add it to an existing instance and then restart the ECS agent. For more information, see Amazon ECS container agent configuration.

To provide access to the Systems Manager Parameter Store parameters that you create, manually add the following permissions as a policy to the task execution role. For information about how to manage permissions, see Adding and Removing IAM identity permissions in the IAM User Guide.

- ssm:GetParameters — Required if you are referencing a Systems Manager Parameter Store parameter in a task definition. Adds the permission to retrieve Systems Manager parameters.
- secretsmanager:GetSecretValue — Required if you are referencing a Secrets Manager secret either directly or if your Systems Manager Parameter Store parameter is referencing a Secrets Manager secret in a task definition. Adds the permission to retrieve the secret from Secrets Manager.
- kms:Decrypt — Required only if your secret uses a customer managed key and not the default key. The ARN for your custom key should be added as a resource. Adds the permission to decrypt the customer managed key.
The following example policy adds the required permissions:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetParameters",
                "secretsmanager:GetSecretValue",
                "kms:Decrypt"
            ],
            "Resource": [
                "arn:aws:ssm:region:aws_account_id:parameter/parameter_name",
                "arn:aws:kms:region:aws_account_id:key/key_id"
            ]
        }
    ]
}
```

Create the parameter

You can use the Systems Manager console to create a Systems Manager Parameter Store parameter for your sensitive data. For more information, see Create a Systems Manager parameter (console) or Create a Systems Manager parameter (AWS CLI) in the AWS Systems Manager User Guide.

Update your application to programmatically retrieve Systems Manager Parameter Store secrets

To retrieve the sensitive data stored in the Systems Manager Parameter Store parameter, see Code examples for Systems Manager using AWS SDKs in the AWS SDK Code Examples Code Library.

Retrieve Secrets Manager secrets through environment variables

When you inject a secret as an environment variable, you can specify the full contents of a secret, a specific JSON key within a secret, or a specific version of a secret to inject. This helps you control the sensitive data exposed to your container. For more information about secret versioning, see Key Terms and Concepts for AWS Secrets Manager in the AWS Secrets Manager User Guide.
Considerations

The following should be considered when using an environment variable to inject an Secrets Manager secret into a container.

- Sensitive data is injected into your container when the container is initially started. If the secret is subsequently updated or rotated, the container will not receive the updated value automatically. You must either launch a new task or if your task is part of a service you can update the service and use the **Force new deployment** option to force the service to launch a fresh task.

- For Amazon ECS tasks on AWS Fargate, the following should be considered:
  - To inject the full content of a secret as an environment variable or in a log configuration, you must use platform version 1.3.0 or later. For information, see [Fargate Linux platform versions](#).
  - To inject a specific JSON key or version of a secret as an environment variable or in a log configuration, you must use platform version 1.4.0 or later (Linux) or 1.0.0 (Windows). For information, see [Fargate Linux platform versions](#).

- For Amazon ECS tasks on EC2, the following should be considered:
  - To inject a secret using a specific JSON key or version of a secret, your container instance must have version 1.37.0 or later of the container agent. However, we recommend using the latest container agent version. For information about checking your agent version and updating to the latest version, see [Updating the Amazon ECS container agent](#).

  To inject the full contents of a secret as an environment variable or to inject a secret in a log configuration, your container instance must have version 1.22.0 or later of the container agent.

- Use interface VPC endpoints to enhance security controls. You must create the interface VPC endpoints for Secrets Manager. For information about the VPC endpoint, see [Create VPC endpoints](#) in the *AWS Secrets Manager User Guide*.

- For Windows tasks that are configured to use the awslogs logging driver, you must also set the ECS_ENABLE_AWSLOGS_EXECUTIONROLE_OVERRIDE environment variable on your container instance. This can be done with User Data with the following syntax:

  ```powershell
  [Environment]::SetEnvironmentVariable("ECS_ENABLE_AWSLOGS_EXECUTIONROLE_OVERRIDE", $TRUE, "Machine")
  Initialize-ECSAgent -Cluster <cluster name> -EnableTaskIAMRole -LoggingDrivers 
  ['"json-file","awslogs"]
  ```
IAM permissions

To use this feature, you must have the Amazon ECS task execution role and reference it in your task definition. For more information, see Amazon ECS task execution IAM role.

To provide access to the Secrets Manager secrets that you create, manually add the following permissions as an inline policy to the task execution role. For more information, see Adding and Removing IAM Policies.

- secretsmanager:GetSecretValue–Required if you are referencing a Secrets Manager secret. Adds the permission to retrieve the secret from Secrets Manager.
- kms:Decrypt–Required only if your secret uses a customer managed key and not the default key. The ARN for your customer managed key should be added as a resource. Adds the permission to decrypt the customer managed key.

The following example policy adds the required permissions:

```
{
   
   "Version": "2012-10-17",
   "Statement": [
   
   { "Effect": "Allow",
     "Action": [ "secretsmanager:GetSecretValue",
                 "kms:Decrypt"
               ],
                   "arn:aws:kms:region:aws_account_id:key/key_id"
                 ]
   
   }

   }
```

Create the AWS Secrets Manager secret

You can use the Secrets Manager console to create a secret for your sensitive data. For more information, see Create an AWS Secrets Manager secret in the AWS Secrets Manager User Guide.
Add the environment variable to the container definition

Within your container definition, you can specify the following:

- The secrets object containing the name of the environment variable to set in the container
- The Amazon Resource Name (ARN) of the Secrets Manager secret
- Additional parameters that contain the sensitive data to present to the container

The following example shows the full syntax that must be specified for the Secrets Manager secret.

```
```

The following section describes the additional parameters. These parameters are optional, but if you do not use them, you must include the colons : to use the default values. Examples are provided below for more context.

**json-key**

Specifies the name of the key in a key-value pair with the value that you want to set as the environment variable value. Only values in JSON format are supported. If you do not specify a JSON key, then the full contents of the secret is used.

**version-stage**

Specifies the staging label of the version of a secret that you want to use. If a version staging label is specified, you cannot specify a version ID. If no version stage is specified, the default behavior is to retrieve the secret with the AWSCURRENT staging label.

Staging labels are used to keep track of different versions of a secret when they are either updated or rotated. Each version of a secret has one or more staging labels and an ID. For more information, see [Key Terms and Concepts for AWS Secrets Manager](https://docs.aws.amazon.com/secretsmanager/latest/userguide/key-terms-concepts.html) in the [AWS Secrets Manager User Guide](https://docs.aws.amazon.com/secretsmanager/latest/userguide/).

**version-id**

Specifies the unique identifier of the version of a secret that you want to use. If a version ID is specified, you cannot specify a version staging label. If no version ID is specified, the default behavior is to retrieve the secret with the AWSCURRENT staging label.
Version IDs are used to keep track of different versions of a secret when they are either updated or rotated. Each version of a secret has an ID. For more information, see Key Terms and Concepts for AWS Secrets Manager in the AWS Secrets Manager User Guide.

Example container definitions

The following examples show ways in which you can reference Secrets Manager secrets in your container definitions.

Example referencing a full secret

The following is a snippet of a task definition showing the format when referencing the full text of a Secrets Manager secret.

```json
{
    "containerDefinitions": [{
        "secrets": [[
            "name": "environment_variable_name",
            "valueFrom": "arn:aws:secretsmanager:region:aws_account_id:secret:secret_name-AbCdEf"
        ]]
    }
}
```

To access the value of this secret from within the container you would need to call the $environment_variable_name.

Example referencing a specific key within a secret

The following shows an example output from a get-secret-value command that displays the contents of a secret along with the version staging label and version ID associated with it.

```json
{
    "Name": "appauthexample",
    "VersionId": "871d9eca-18aa-46a9-8785-981ddEXAMPLE",
    "SecretString": "{"username1": "password1","username2": "password2","username3": "password3"}",
    "VersionStages": ["AWSCURRENT"],
    "CreatedDate": 1581968848.921
}
```
Reference a specific key from the previous output in a container definition by specifying the key name at the end of the ARN.

```json
{
   "containerDefinitions": [
      {
         "secrets": [
            {
               "name": "environment_variable_name",
            }
         ]
      }
   }
}
```

Example referencing a specific secret version

The following shows an example output from a `describe-secret` command that displays the unencrypted contents of a secret along with the metadata for all versions of the secret.

```json
{
   "Name": "appauthexample",
   "Description": "Example of a secret containing application authorization data.",
   "RotationEnabled": false,
   "LastChangedDate": 1581968848.926,
   "LastAccessedDate": 1581897600.0,
   "Tags": [],
   "VersionIdsToStages": {
      "871d9eca-18aa-46a9-8785-981ddEXAMPLE": [ "AWSCURRENT" ],
      "9d4cb84b-ad69-40c0-a0ab-cead3EXAMPLE": [ "AWSPREVIOUS" ]
   }
}
```

Reference a specific version staging label from the previous output in a container definition by specifying the key name at the end of the ARN.

```json
{
}
```
Reference a specific version ID from the previous output in a container definition by specifying the key name at the end of the ARN.

Example referencing a specific key and version staging label of a secret

The following shows how to reference both a specific key within a secret and a specific version staging label.

To specify a specific key and version ID, use the following syntax.
Create a task definition that references sensitive data

You can use the Amazon ECS console to create a task definition that references a Secrets Manager secret.

2. In the navigation pane, choose Task definitions.
3. Choose Create new task definition, Create new task definition.
4. For Task definition family, specify a unique name for the task definition.
5. For each container to define in your task definition, complete the following steps.
   
a. For Name, enter a name for the container.
   
b. For Image URI, enter the image to use to start a container. Images in the Amazon ECR Public Gallery registry may be specified using the Amazon ECR Public registry name only. For example, if public.ecr.aws/ecs/amazon-ecs-agent:latest is specified, the Amazon Linux container hosted on Amazon ECR Public Gallery is used. For all other repositories, specify the repository using either the repository-url/image:tag or repository-url/image@digest formats.
   
c. For Essential container, if your task definition has two or more containers defined, you may specify whether the container should be considered essential. If a container is marked as essential, if that container stops then the task is stopped. Each task definition must contain at least one essential container.
   
d. A port mapping allows the container to access ports on the host to send or receive traffic. Under Port mappings, do one of the following:
      
      • When you use the awsvpc network mode, for Container port and Protocol, choose the port mapping to use for the container.
      
      • When you use the bridge network mode, for Container port and Protocol, choose the port mapping to use for the container. You select the bridge network mode on the
next page. After you select it, choose Previous, and then for Host port, specify the port number on the container instance to reserve for your container.

Choose Add more port mappings to specify additional container port mappings.

e. For sensitive data to inject as environment variables, under Environment, for Environment variables, complete the following fields:

i. For Key, enter the name of the environment variable to set in the container. This corresponds to the name field in the secrets section of a container definition.

ii. For Value type, choose ValueFrom. For Add value, enter the ARN of the Secrets Manager secret that contains the data to present to your container as an environment variable.

f. (Optional) Choose Add more containers to add additional containers to the task definition. Choose Next once all containers have been defined.

6. For App environment, Task size, and Container size, fill out the remaining required fields and any optional fields.

7. (Optional) Expand the Task roles, network mode section to specify the following:

- For Task role, choose the IAM role to assign to the task. A task IAM role provides permissions for the containers in a task to call AWS APIs.

8. (Optional) The Storage section is used to expand the amount of ephemeral storage for tasks hosted on Fargate as well as add a data volume configuration for the task.

- To expand the available ephemeral storage beyond the default value of 20 GiB for your Fargate tasks, for Amount, enter a value up to 200 GiB.

9. For sensitive data referenced in the log configuration for a container, under Use log collection, for Log configuration, complete the following configuration:

a. Select the log option, and then under Key, choose Add.

b. For Key, enter the name of the log configuration option to set.

c. For Value, enter the full ARN of the Secrets Manager secret that contains the data to present to your log configuration as a log option.

d. For Value type, choose ValueFrom.

10. Choose Next to review the task definition.
11. On the **Review and create** page, review each task definition section. Choose **Edit** to make changes. After the task definition is complete, choose **Create** to register the task definition.

Retrieving AWS Systems Manager parameters through environment variables

Amazon ECS enables you to inject sensitive data into your containers by storing your sensitive data in AWS Systems Manager Parameter Store parameters and then referencing them in your container definition.

**Considerations**

The following should be considered when using an environment variable to inject an AWS Systems Manager secret into a container.

- Sensitive data is injected into your container when the container is initially started. If the secret is subsequently updated or rotated, the container will not receive the updated value automatically. You must either launch a new task or if your task is part of a service you can update the service and use the **Force new deployment** option to force the service to launch a fresh task.

- For Amazon ECS tasks on AWS Fargate, the following should be considered:
  - To inject the full content of a secret as an environment variable or in a log configuration, you must use platform version 1.3.0 or later. For information, see [Fargate Linux platform versions](#).
  - To inject a specific JSON key or version of a secret as an environment variable or in a log configuration, you must use platform version 1.4.0 or later (Linux) or 1.0.0 (Windows). For information, see [Fargate Linux platform versions](#).

- For Amazon ECS tasks on EC2, the following should be considered:
  - To inject a secret using a specific JSON key or version of a secret, your container instance must have version 1.37.0 or later of the container agent. However, we recommend using the latest container agent version. For information about checking your agent version and updating to the latest version, see [Updating the Amazon ECS container agent](#).

    To inject the full contents of a secret as an environment variable or to inject a secret in a log configuration, your container instance must have version 1.22.0 or later of the container agent.

- Use interface VPC endpoints to enhance security controls. You must create the interface VPC endpoints for AWS Systems Manager. For information about the VPC endpoint, see [Create VPC endpoints](#) in the *AWS Systems Manager User Guide*. 

Passing sensitive data to a container
For Windows tasks that are configured to use the awslogs logging driver, you must also set the
ECS_ENABLE_AWSLOGS_EXECUTIONROLE_OVERRIDE environment variable on your container
instance. This can be done with User Data using the following syntax:

```powershell
[Environment]::SetEnvironmentVariable("ECS_ENABLE_AWSLOGS_EXECUTIONROLE_OVERRIDE", $TRUE, "Machine")
Initialize-ECSAgent -Cluster <cluster name> -EnableTaskIAMRole -LoggingDrivers
'"json-file","awslogs"]'
</powershell>

### IAM permissions

To use this feature, you must have the Amazon ECS task execution role and reference it in your task
definition. This allows the container agent to pull the necessary AWS Systems Manager resources.
For more information, see [Amazon ECS task execution IAM role](#).

⚠️ **Important**

For tasks that use the EC2 launch type, you must use the ECS agent configuration variable
ECS_ENABLE_AWSLOGS_EXECUTIONROLE_OVERRIDE=true to use this feature. You can
add it to the `.:/etc/ecs/ecs.config` file during container instance creation or you can
add it to an existing instance and then restart the ECS agent. For more information, see
[Amazon ECS container agent configuration](#).

To provide access to the AWS Systems Manager Parameter Store parameters that you create,
manually add the following permissions to the task execution role. For information about how to
manage permissions, see [Adding and Removing IAM identity permissions](#) in the *IAM User Guide*.

- **ssm:GetParameters** — Required if you are referencing a Systems Manager Parameter Store
  parameter in a task definition. Adds the permission to retrieve Systems Manager parameters.

- **secretsmanager:GetSecretValue** — Required if you are referencing a Secrets Manager
  secret either directly or if your Systems Manager Parameter Store parameter is referencing a
  Secrets Manager secret in a task definition. Adds the permission to retrieve the secret from
  Secrets Manager.
• `kms:Decrypt` — Required only if your secret uses a customer managed key and not the default key. The ARN for your custom key should be added as a resource. Adds the permission to decrypt the customer managed key.

The following example policy adds the required permissions:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetParameters",
        "secretsmanager:GetSecretValue",
        "kms:Decrypt"
      ],
      "Resource": [
        "arn:aws:ssm:region:aws_account_id:parameter/parameter_name",
        "arn:aws:kms:region:aws_account_id:key/key_id"
      ]
    }
  ]
}
```

**Create the AWS Systems Manager parameter**

You can use the Systems Manager console to create a Systems Manager Parameter Store parameter for your sensitive data. For more information, see [Create a Systems Manager parameter (console)](https://docs.aws.amazon.com/systemsmanager/latest/userguide/create-parameter-console.html) or [Create a Systems Manager parameter (AWS CLI)](https://docs.aws.amazon.com/systemsmanager/latest/userguide/create-parameter-cli.html) in the *AWS Systems Manager User Guide*.

**Add the environment variable to the container definition**

Within your container definition, specify secrets with the name of the environment variable to set in the container and the full ARN of the Systems Manager Parameter Store parameter containing the sensitive data to present to the container. For more information, see [secrets](https://docs.aws.amazon.com/elasticbeanstalk/latest/dg/configuring-environment-variables.html).

The following is a snippet of a task definition showing the format when referencing a Systems Manager Parameter Store parameter. If the Systems Manager Parameter Store parameter exists in the same Region as the task you are launching, then you can use either the full ARN or name of the parameter. If the parameter exists in a different Region, then specify the full ARN.
Create a task definition that references sensitive data

You can use the Amazon ECS console to create a task definition that references a Systems Manager Parameter Store parameter.

2. In the navigation pane, choose Task definitions.
3. Choose Create new task definition, Create new task definition.
4. For Task definition family, specify a unique name for the task definition.
5. For each container to define in your task definition, complete the following steps.
   a. For Name, enter a name for the container.
   b. For Image URI, enter the image to use to start a container. Images in the Amazon ECR Public Gallery registry may be specified using the Amazon ECR Public registry name only. For example, if public.ecr.aws/ecs/amazon-ecs-agent:latest is specified, the Amazon Linux container hosted on Amazon ECR Public Gallery is used. For all other repositories, specify the repository using either the repository-url/image:tag or repository-url/image@digest formats.
   c. For Essential container, if your task definition has two or more containers defined, you may specify whether the container should be considered essential. If a container is marked as essential, if that container stops then the task is stopped. Each task definition must contain at least one essential container.
   d. A port mapping allows the container to access ports on the host to send or receive traffic. Under Port mappings, do one of the following:
      - When you use the awsvpc network mode, for Container port and Protocol, choose the port mapping to use for the container.
When you use the bridge network mode, for Container port and Protocol, choose the port mapping to use for the container. You select the bridge network mode on the next page. After you select it, choose Previous, and then for Host port, specify the port number on the container instance to reserve for your container.

Choose Add more port mappings to specify additional container port mappings.

e. For sensitive data to inject as environment variables, under Environment, for Environment variables, complete the following fields:

i. For Key, enter the name of the environment variable to set in the container. This corresponds to the name field in the secrets section of a container definition.

ii. For Value type, choose ValueFrom. For Value, enter the name or full ARN of the AWS Systems Manager Parameter Store parameter that contains the data to present to your log configuration as a log option.

Note

If the Systems Manager Parameter Store parameter exists in the same Region as the task you are launching, then you can use either the full ARN or the name of the secret. If the parameter exists in a different Region, then specify the full ARN.

f. (Optional) Choose Add more containers to add additional containers to the task definition. Choose Next once all containers have been defined.

6. For App environment, Task size, and Container size, fill out the remaining required fields and any optional fields.

7. (Optional) Expand the Task roles, network mode section to specify the following:

- For Task role, choose the IAM role to assign to the task. A task IAM role provides permissions for the containers in a task to call AWS APIs.

8. (Optional) The Storage section is used to expand the amount of ephemeral storage for tasks hosted on Fargate as well as add a data volume configuration for the task.

- To expand the available ephemeral storage beyond the default value of 20 GiB for your Fargate tasks, for Amount, enter a value up to 200 GiB.
9. For sensitive data referenced in the log configuration for a container, under **Use log collection**, for **Log configuration**, complete the following configuration:

   a. Select the log option, and then under **Key**, choose **Add**.
   b. For **Key**, enter the name of the log configuration option to set.
   c. For **Value**, enter the name or full ARN of the AWS Systems Manager Parameter Store parameter that contains the data to present to your log configuration as a log option.

   **Note**
   If the Systems Manager Parameter Store parameter exists in the same Region as the task you are launching, then you can use either the full ARN or the name of the secret. If the parameter exists in a different Region, then specify the full ARN.

d. For **Value type**, choose **ValueFrom**.

10. Choose **Next** to review the task definition.

11. On the **Review and create** page, review each task definition section. Choose **Edit** to make changes. After the task definition is complete, choose **Create** to register the task definition.

**Retrieve secrets for logging configuration**

**Using Secrets Manager**

Within your container definition, when specifying a `logConfiguration` you can specify `secretOptions` with the name of the log driver option to set in the container and the full ARN of the Secrets Manager secret containing the sensitive data to present to the container.

The following is a snippet of a task definition showing the format when referencing an Secrets Manager secret.

```json
{
    "containerDefinitions": [{
        "logConfiguration": [{
            "logDriver": "splunk",
            "options": {
                "splunk-url": "https://your_splunk_instance:8088"
            },
            "secretOptions": [{
                "secret-url": 
```
Using AWS Systems Manager

You can inject sensitive data in a log configuration. Within your container definition, when specifying a `logConfiguration` you can specify `secretOptions` with the name of the log driver option to set in the container and the full ARN of the Systems Manager Parameter Store parameter containing the sensitive data to present to the container.

⚠️ Important

If the Systems Manager Parameter Store parameter exists in the same Region as the task you are launching, then you can use either the full ARN or name of the parameter. If the parameter exists in a different Region, then specify the full ARN.

The following is a snippet of a task definition showing the format when referencing a Systems Manager Parameter Store parameter.

```json
{
  "containerDefinitions": [
    {
      "logConfiguration": [
        {
          "logDriver": "fluentd",
          "options": {
            "tag": "fluentd demo"
          },
          "secretOptions": [
            {
              "name": "fluentd-address",
              "valueFrom": "arn:aws:ssm:region:aws_account_id:parameter:/parameter_name"
            }
          ]
        }
      ]
    }
  ]
}
```
Example task definitions

You can copy the examples and snippets to start creating your own task definitions.

You can copy the examples, and then paste them when you use the Configure via JSON option in the console. Make sure to customize the examples, such as using your account ID. You can include the snippets in your task definition JSON. For more information, see Creating a task definition using the console and Task definition parameters.

For more task definition examples, see AWS Sample Task Definitions on GitHub.

- Entrypoint with command
- Container dependency
- Windows sample task definitions

Webserver

The following is an example task definition using the Linux containers on Fargate launch type that sets up a web server:

```json
{
    "containerDefinitions": [
        {
            "command": ["/bin/sh -c \"echo 'html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon ECS.</p> </div></body>" > /usr/local/apache2/htdocs/index.html & & httpd-foreground"
```
The following is an example task definition using the Windows containers on Fargate launch type that sets up a web server:

```json
{
   "containerDefinitions": [
      {
         "name": "sample-fargate-app",
         "portMappings": [
            {
               "containerPort": 80,
               "hostPort": 80,
               "protocol": "tcp"
            }
         ],
         "cpu": "256",
         "executionRoleArn": "arn:aws:iam::012345678910:role/ecsTaskExecutionRole",
         "family": "fargate-task-definition",
         "memory": "512",
         "networkMode": "awsvpc",
         "runtimePlatform": {
            "operatingSystemFamily": "LINUX"
         },
         "requiresCompatibilities": ["FARGATE"]
      }
   ]
}
```
The following snippet demonstrates how to use the `splunk` log driver in a task definition that sends the logs to a remote service. The Splunk token parameter is specified as a secret option because it can be treated as sensitive data. For more information, see [Passing sensitive data to a container](#).

```json
{
    "command": ["New-Item -Path C:\inetpub\wwwroot\index.html -Type file -Value '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon ECS.</p>'; C:\ServiceMonitor.exe w3svc",
    "entryPoint": [
        "powershell",
        "-Command"
    ],
    "essential": true,
    "cpu": 2048,
    "memory": 4096,
    "image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-ltsc2019",
    "name": "sample_windows_app",
    "portMappings": [
        {
            "hostPort": 80,
            "containerPort": 80,
            "protocol": "tcp"
        }
    ],
    "memory": "4096",
    "cpu": "2048",
    "networkMode": "awsvpc",
    "family": "windows-simple-iis-2019-core",
    "executionRoleArn": "arn:aws:iam::012345678910:role/ecsTaskExecutionRole",
    "runtimePlatform": {"operatingSystemFamily": "WINDOWS_SERVER_2019_CORE"},
    "requiresCompatibilities": ["FARGATE"]
}
```
"logConfiguration": {
    "logDriver": "splunk",
    "options": {
        "splunk-url": "https://cloud.splunk.com:8080",
        "tag": "tag_name",
    },
    "secretOptions": [{
        "name": "splunk-token",
        "valueFrom": "arn:aws:secretsmanager:region:aws_account_id:secret:splunk-token-KnrBkD"
    }]
},

**fluentd log driver**

The following snippet demonstrates how to use the fluentd log driver in a task definition that sends the logs to a remote service. The `fluentd-address` value is specified as a secret option as it may be treated as sensitive data. For more information, see [Passing sensitive data to a container](#).

"containerDefinitions": [{
    "logConfiguration": {
        "logDriver": "fluentd",
        "options": {
            "tag": "fluentd demo"
        },
        "secretOptions": [{
            "name": "fluentd-address",
            "valueFrom": "arn:aws:secretsmanager:region:aws_account_id:secret:fluentd-address-KnrBkD"
        }]
    },
    "entryPoint": [],
    "portMappings": [{
        "hostPort": 80,
        "protocol": "tcp",
        "containerPort": 80
    },
    {
        "hostPort": 24224,
        "protocol": "tcp",
        "containerPort": 24224
    }]
}],

**fluentd log driver**
gelf log driver

The following snippet demonstrates how to use the gelf log driver in a task definition that sends the logs to a remote host running Logstash that takes Gelf logs as an input. For more information, see logConfiguration.

```
"containerDefinitions": [{
 "logConfiguration": {
  "logDriver": "gelf",
  "options": {
   "gelf-address": "udp://logstash-service-address:5000",
   "tag": "gelf task demo"
  }
 },
 "entryPoint": [],
 "portMappings": [{
  "hostPort": 5000,
  "protocol": "udp",
  "containerPort": 5000
 },
 { "hostPort": 5000,
  "protocol": "tcp",
  "containerPort": 5000
 }
],
]
```

Workloads on external instances

When registering an Amazon ECS task definition, use the requiresCompatibilities parameter and specify EXTERNAL which validates that the task definition is compatible to use when running Amazon ECS workloads on your external instances. If you use the console for registering a task definition, you must use the JSON editor. For more information, see Creating a task definition using the console.

⚠️ Important

If your tasks require a task execution IAM role, make sure that it's specified in the task definition.
When you deploy your workload, use the EXTERNAL launch type when creating your service or running your standalone task.

The following is an example task definition.

Linux

```json
{
    "requiresCompatibilities": ["EXTERNAL"],
    "containerDefinitions": [{
        "name": "nginx",
        "image": "public.ecr.aws/nginx/nginx:latest",
        "memory": 256,
        "cpu": 256,
        "essential": true,
        "portMappings": [{
            "containerPort": 80,
            "hostPort": 8080,
            "protocol": "tcp"
        }]
    }],
    "networkMode": "bridge",
    "family": "nginx"
}
```

Windows

```json
{
    "requiresCompatibilities": ["EXTERNAL"],
    "containerDefinitions": [{
        "name": "windows-container",
        "image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-ltsc2019",
        "memory": 256,
        "cpu": 512,
        "essential": true,
        "portMappings": [{
            "containerPort": 80,
            "hostPort": 8080,
            "protocol": "tcp"
        }]
    }]
}
```
Amazon ECR image and task definition IAM role

The following snippet uses an Amazon ECR image called `aws-nodejs-sample` with the v1 tag from the 123456789012.dkr.ecr.us-west-2.amazonaws.com registry. The container in this task inherits IAM permissions from the arn:aws:iam::123456789012:role/AmazonECSTaskS3BucketRole role. For more information, see Task IAM role.

```json
{
    "containerDefinitions": [
        {
            "name": "sample-app",
            "memory": 200,
            "cpu": 10,
            "essential": true
        }
    ],
    "family": "example_task_3",
    "taskRoleArn": "arn:aws:iam::123456789012:role/AmazonECSTaskS3BucketRole"
}
```

Entrypoint with command

The following snippet demonstrates the syntax for a Docker container that uses an entry point and a command argument. This container pings google.com four times and then exits.

```json
{
    "containerDefinitions": [
        {
            "memory": 32,
            "essential": true,
            "entryPoint": ["ping"],
            "name": "alpine_ping",
            "readonlyRootFilesystem": true,
            "command": ["ping", "google.com"]
        }
    ]
}
```
Container dependency

This snippet demonstrates the syntax for a task definition with multiple containers where container dependency is specified. In the following task definition, the envoy container must reach a healthy status, determined by the required container health check parameters, before the app container will start. For more information, see Container dependency.

```json
{
    "family": "appmesh-gateway",
    "runtimePlatform": {
        "operatingSystemFamily": "LINUX"
    },
    "proxyConfiguration": {
        "type": "APPMESH",
        "containerName": "envoy",
        "properties": [
            {
                "name": "IgnoredUID",
                "value": "1337"
            },
            {
                "name": "ProxyIngressPort",
                "value": "15000"
            },
            {
                "name": "ProxyEgressPort",
                "value": "15001"
            },
            {
                "name": "AppPorts",
                "value": "9080"
            }
        ]
    }
}
```
"name": "EgressIgnoredIPs",
"value": "169.254.170.2,169.254.169.254"
]
},
"containerDefinitions": [
{
"name": "app",
"image": "application_image",
"portMappings": [
{
"containerPort": 9080,
"hostPort": 9080,
"protocol": "tcp"
}
],
"essential": true,
"dependsOn": [
{

Windows sample task definitions

The following is a sample task definition to help you get started with Windows containers on Amazon ECS.

Example Amazon ECS Console Sample Application for Windows

The following task definition is the Amazon ECS console sample application that is produced in the first-run wizard for Amazon ECS; it has been ported to use the microsoft/iis Windows container image.

```json
{
  "family": "windows-simple-iis",
  "containerDefinitions": [
    {
      "name": "windows_sample_app",
      "image": "mcr.microsoft.com/windows/servercore/iis",

"memory": "1024",
"cpu": "1024"
}
```
Amazon ECS clusters and capacity

An Amazon ECS cluster is a logical grouping of tasks or services. In addition to tasks and services, a cluster consists of the following resources:

- The infrastructure capacity which can be a combination of the following:
  - Amazon EC2 instances in the AWS cloud
  - Serverless (AWS Fargate (Fargate)) in the AWS cloud
  - On-premises virtual machines (VM) or servers
- The network (VPC and subnet) where your tasks and services run

When you use Amazon EC2 instances for the capacity, the subnet can be in Availability Zones, Local Zones, Wavelength Zones or AWS Outposts.

- An optional namespace

  The namespace is used for service-to-service communication with Service Connect.

- A monitoring option

  CloudWatch Container Insights comes at an additional cost and is a fully managed service. It automatically collects, aggregates, and summarizes Amazon ECS metrics and logs.

Capacity provider concepts

Capacity providers consist of the following components.

Capacity provider

A capacity provider defines the cluster capacity that Amazon ECS scales up and down of the infrastructure you specify. You must first associate the capacity provider with a cluster before you use the capacity provider.

You use a capacity provider in a capacity provider strategy to determine the infrastructure that a task runs on. Every task must have a capacity provider strategy, a launch type, or use the default capacity provider strategy that's associated with the selected cluster. You must reference the capacity provider strategy and not the capacity provider. If a task uses a launch type, the capacity it uses isn't counted by any capacity providers in the cluster.
For AWS Fargate, the capacity providers are a FARGATE and a FARGATE_SPOT capacity provider which AWS creates. You associate the capacity provider with your cluster, and then add them to a capacity provider strategy.

For Amazon ECS on Amazon EC2 users, a capacity provider consists of a capacity provider name, an Auto Scaling group. A capacity provider also consists of all of the settings for managed scaling and managed termination protection. When you turn on managed scaling, Amazon ECS scales Auto Scaling groups in and out on your behalf.

Default capacity provider strategy

You can associate a default capacity provider strategy with an Amazon ECS cluster. After you do this, Amazon ECS uses a default capacity provider strategy when you create service or run a standalone task in the cluster and don't specify a launch type or custom capacity provider. We recommend that you define a default capacity provider strategy for each cluster.

Capacity provider strategy

A capacity provider strategy consists of one or more capacity providers. You can specify an optional base and weight value for finer control. A capacity provider strategy is part of the configuration of a cluster, service, or task. However, you can't create re-useable capacity provider strategies. The capacity provider strategy of each cluster, service, or task capacity provider strategy is independent.

If the default capacity provider strategy for a cluster doesn't meet your capacity requirements, specify a custom capacity provider strategy when creating a service or running a standalone task.

⚠️ Important

When you set a launch type instead of a capacity provider strategy on tasks in clusters where the capacity is managed by capacity providers, those tasks aren't counted for capacity provider scaling actions.

Only capacity providers that are both already associated with a cluster and have an ACTIVE or UPDATING status can be used in a capacity provider strategy. You can associate a capacity provider with a cluster when you create a cluster.
In a capacity provider strategy, the optional *base* value designates how many tasks, at a minimum, run on a specified capacity provider. Only one capacity provider in a capacity provider strategy can have a base defined.

The *weight* value determines the relative percentage of the total number of launched tasks that use the specified capacity provider. Consider the following example. You have a strategy that contains two capacity providers, and both have a weight of 1. When the base percentage is reached, the tasks are split evenly across the two capacity providers. Using that same logic, suppose that you specify a weight of 1 for `capacityProviderA` and a weight of 4 for `capacityProviderB`. Then, for every one task that's run using `capacityProviderA`, there are four tasks that use `capacityProviderB`.

**Amazon ECS capacity providers**

Amazon ECS capacity providers manage the scaling of infrastructure for tasks in your clusters. Each cluster can have one or more capacity providers and an optional capacity provider strategy. The capacity provider strategy determines how the tasks are spread across the cluster's capacity providers. When you run a standalone task or create a service, you either use the cluster's default capacity provider strategy or a capacity provider strategy that overrides the default one.

Capacity providers are available for tasks that run on Fargate or on Amazon EC2 instances. You cannot use capacity providers for tasks that run on external container instances (Amazon ECS Anywhere).

**Capacity provider types**

For Amazon ECS workloads that are hosted on Fargate, the following predefined capacity providers are available:

- Fargate
- Fargate Spot

For Amazon ECS workloads that are hosted on Amazon EC2 instances, you must create and maintain a capacity provider that consists of the following components:

- A name
- An Auto Scaling group
• The settings for managed scaling and managed termination protection.

You can create the Auto Scaling group when you create the cluster, or you can create the group before the cluster, and then specify the group name when you create the cluster.

**Capacity provider considerations**

Consider the following when using capacity providers:

• A capacity provider must be associated with a cluster before being specified in a capacity provider strategy.

• When you specify a capacity provider strategy, the number of capacity providers that you can specify is limited to 20.

• You can't update a service using an Auto Scaling group capacity provider to use a Fargate capacity provider. The opposite is also the case.

• In a capacity provider strategy, if no weight value is specified for a capacity provider in the console, then the default value of 1 is used. If using the API or AWS CLI, the default value of 0 is used.

• When multiple capacity providers are specified within a capacity provider strategy, at least one of the capacity providers must have a weight value that's greater than zero. Moreover, any capacity providers with a weight of zero aren't used to place tasks. If you specify multiple capacity providers in a strategy with all the same weight of zero, then any RunTask or CreateService actions using the capacity provider strategy fail.

• In a capacity provider strategy, only one capacity provider can have a defined base value. If no base value is specified, the default value of zero is used.

• A cluster can contain a mix of both Auto Scaling group capacity providers and Fargate capacity providers. However, a capacity provider strategy can only contain Auto Scaling group or Fargate capacity providers, but not both.

• A cluster can contain a mix of services and standalone tasks that use both capacity providers and launch types. A service can be updated to use a capacity provider strategy rather than a launch type. However, you must force a new deployment when doing so.

• When you use managed termination protection, you must also use managed scaling. Otherwise, managed termination protection doesn't work.

**Topics**
AWS Fargate capacity providers

With Amazon ECS on AWS Fargate capacity providers, you can use both Fargate and Fargate Spot capacity with your Amazon ECS tasks.

With Fargate Spot, you can run interruption tolerant Amazon ECS tasks at a rate that's discounted compared to the Fargate price. Fargate Spot runs tasks on spare compute capacity. When AWS needs the capacity back, your tasks are interrupted with a two-minute warning.

Fargate capacity provider considerations

Consider the following when using Fargate capacity providers:

- Windows containers on Fargate don't support the Fargate Spot capacity provider.
- Linux tasks with the ARM64 architecture don't support the Fargate Spot capacity provider. Fargate Spot only supports Linux tasks with the X86_64 architecture.
- You don't need to create Fargate and Fargate Spot capacity providers. They're available to all accounts. To use them, all you need to do is associate them with a cluster.
- To associate Fargate and Fargate Spot capacity providers to a cluster, you must use the Amazon ECS API or AWS CLI. You cannot associate them using the console.
- The Fargate and Fargate Spot capacity providers are reserved and can't be deleted. However, you can disassociate them from a cluster using the PutClusterCapacityProviders API operation.
- You can associate a capacity provider with an existing cluster using the PutClusterCapacityProviders API operation.
- If you use Fargate Spot, your task must use platform version 1.3.0 or later (for Linux). For more information, see Fargate Linux platform versions.
- When tasks that use the Fargate and Fargate Spot capacity providers are stopped, the task state change event is sent to Amazon EventBridge. The stopped reason describes the cause. For more information, see Amazon ECS task state change events.
- A cluster can contain a mix of Fargate and Auto Scaling group capacity providers. However, a capacity provider strategy can only contain either Fargate or Auto Scaling group capacity.
providers, but not both. For more information, see Auto Scaling Group Capacity Providers in the Amazon Elastic Container Service Developer Guide.

### Handling Fargate Spot termination notices

Understand that the following consequences because Spot capacity might not be available all the time.

- During periods of extremely high demand, Fargate Spot capacity might be unavailable. This can cause Fargate Spot tasks to be delayed. In these events, Amazon ECS services retry launching tasks until the required capacity becomes available. Fargate doesn't replace Spot capacity with on-demand capacity.

- When tasks using Fargate Spot capacity are stopped due to a Spot interruption, a two-minute warning is sent before a task is stopped. The warning is sent as a task state change event to Amazon EventBridge and as a SIGTERM signal to the running task. If you use Fargate Spot as part of a service, then in this scenario the service scheduler receives the interruption signal and attempts to launch additional tasks on Fargate Spot if there's capacity available. A service with only one task is interrupted until capacity is available. For more information about a graceful shutdown, see Graceful shutdowns with ECS.

To ensure that your containers exit gracefully before the task stops, you can configure the following:

- A stopTimeout value of 120 seconds or less can be specified in the container definition that the task is using. The default stopTimeout value is 30 seconds. You can specify a longer stopTimeout value to give yourself more time between the moment that the task state change event is received and the point in time when the container is forcefully stopped. For more information, see Container timeouts.

- The SIGTERM signal must be received from within the container to perform any cleanup actions. Failure to process this signal results in the task receiving a SIGKILL signal after the configured stopTimeout and may result in data loss or corruption.

The following is a snippet of a task state change event. This snippet displays the stopped reason and stop code for a Fargate Spot interruption.

```json
{
}
```
The following is an event pattern that's used to create an EventBridge rule for Amazon ECS task state change events. You can optionally specify a cluster in the detail field. Doing so means that you will receive task state change events for that cluster. For more information, see Creating an EventBridge Rule in the Amazon EventBridge User Guide.
Amazon EC2 Auto Scaling group capacity providers

When you use Amazon EC2 instances for your capacity, you use Auto Scaling groups to manage the Amazon EC2 instances registered to their clusters. Auto Scaling helps you ensure that you have the correct number of Amazon EC2 instances available to handle the load for your application.

You can use the managed scaling feature to have Amazon ECS manage the scale-in and scale-out actions of the Auto Scaling group (managed scaling) or you can manage the scaling actions yourself. For more information, see Amazon ECS cluster auto scaling.

Auto Scaling group capacity providers considerations

Consider the following when using Auto Scaling group capacity providers in the console:

- We recommend that you create a new empty Auto Scaling group to use with a capacity provider rather than using an existing one. If you use an existing Auto Scaling group, any Amazon EC2 instances that are associated with the group that were already running and registered to an Amazon ECS cluster before the Auto Scaling group being used to create a capacity provider might not be properly registered with the capacity provider. This might cause issues when using the capacity provider in a capacity provider strategy. Use DescribeContainerInstances to confirm whether a container instance is associated with a capacity provider or not.

  Note
  
  To create an empty Auto Scaling group, set the desired count to zero. After you created the capacity provider and associated it with a cluster, you can then scale it out. When you use the Amazon ECS console Create Cluster with the Amazon EC2 instances option under Infrastructure, Amazon ECS creates an Amazon EC2 Auto Scaling launch configuration and Auto Scaling group on your behalf as part of the AWS CloudFormation stack. They are prefixed with EC2ContainerService-<ClusterName>, which make them easy to identify. You can use the Auto Scaling group as a capacity provider for that cluster.

- An Auto Scaling group must have a MaxSize greater than zero to scale out.
- The Auto Scaling group can't have instance weighting settings. Instance weighting isn't supported when used with an Amazon ECS capacity provider.
- If the Auto Scaling group can't scale out to accommodate the number of tasks run, the tasks fails to transition beyond the PROVISIONING state.
• Don't modify the scaling policy resource associated with your Auto Scaling groups that are managed by capacity providers.

• When you use managed termination protection, you must also use managed scaling. Otherwise, managed termination protection won't work.

• When managed scaling is turned on, the Auto Scaling group capacity provider creates a scaling policy resource to manage the scaling of your Auto Scaling group. You can identify these resources by the ECSManaged prefix.

When you use managed termination protection, Amazon ECS only terminates EC2 instances that don't have any running Amazon ECS tasks.

• If managed termination protection is turned on when you create a capacity provider, the Auto Scaling group and each Amazon EC2 instance in the Auto Scaling group must have instance protection from scale in turned on. For more information, see Instance Protection in the AWS Auto Scaling User Guide.

• You can add a warm pool to your Auto Scaling group. A warm pool is a group of pre-initialized Amazon EC2 instances that are ready to be included in the cluster whenever your application needs to scale out. For more information about warm pools, see Using a warm pool for your Auto Scaling group.

• If managed scaling is turned on when you create a capacity provider, the Auto Scaling group desired count can be set to 0. When managed scaling is turned on, Amazon ECS manages the scale-in and scale-out actions of the Auto Scaling group.

• Managed instance draining is turned on by default when you create a capacity provider. We recommend you use this feature to enable graceful termination of Amazon EC2 instances without disrupting your workloads.

For more information about creating an Amazon EC2 Auto Scaling launch template, see Launch Templates in the Amazon EC2 Auto Scaling User Guide. For more information about creating an Amazon EC2 Auto Scaling group, see Auto Scaling groups in the Amazon EC2 Auto Scaling User Guide.

Using a warm pool for your Auto Scaling group

Amazon ECS supports Amazon EC2 Auto Scaling warm pools. A warm pool is a group of pre-initialized Amazon EC2 instances ready to be placed into service. Whenever your application needs to scale out, Amazon EC2 Auto Scaling uses the pre-initialized instances from the warm pool rather
than launching cold instances, allows for any final initialization process to run, and then places the instance into service.

To learn more about warm pools and how to add a warm pool to your Auto Scaling group, see [Warm pools for Amazon EC2 Auto Scaling](https://docs.aws.amazon.com/autoscaling/ec2/userguide/warm-pools.html) in the Amazon EC2 Auto Scaling User Guide.

When you create or update a warm pool for an Auto Scaling group for Amazon ECS, you cannot set the option that returns instances to the warm pool on scale in (ReuseOnScaleIn). For more information, see `put-warm-pool` in the [AWS Command Line Interface Reference](https://docs.aws.amazon.com/cli/latest/reference/ecs/put-warm-pool.html).

To use warm pools with your Amazon ECS cluster, set the `ECS_WARM_POOLS_CHECK` agent configuration variable to `true` in the **User data** field of your Amazon EC2 Auto Scaling group launch template. The following shows an example of how the agent configuration variable can be specified in the **User data** field of an Amazon EC2 launch template.

```bash
#!/bin/bash
cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=MyCluster
ECS_WARM_POOLS_CHECK=true
EOF
```

The `ECS_WARM_POOLS_CHECK` variable is only supported on agent versions 1.59.0 and later. For more information about the variable, see [Amazon ECS container agent configuration](https://docs.aws.amazon.com/ecs/latest/userguide/agent-configuration.html).

## Amazon ECS cluster auto scaling

Amazon ECS can manage the scaling of Amazon EC2 instances that are registered to your cluster. This is referred to as Amazon ECS **cluster auto scaling**. This is done by using an Amazon ECS Auto Scaling group capacity provider with `managed scaling` turned on. When you use an Auto Scaling group capacity provider with managed scaling turned on, you set a target percentage (the `targetCapacity`) for the utilization of the instances in this Auto Scaling group. Amazon ECS creates two custom CloudWatch metrics and a target tracking scaling policy that attaches to your Auto Scaling group. Amazon ECS then manages the scale-in and scale-out actions of the Auto Scaling group based on the resource utilization that your tasks use from this capacity provider. For more information about Auto Scaling group capacity providers, see [the section called “Amazon EC2 Auto Scaling group capacity providers”](https://docs.aws.amazon.com/autoscaling/ec2/userguide/autoscaling-capacity-providers.html).
Amazon ECS cluster auto scaling is only supported with Auto Scaling group capacity providers. For Amazon ECS workloads that are hosted on AWS Fargate, see the section called “AWS Fargate capacity providers”.

The following is your workflow to use Amazon ECS cluster auto scaling. For more information, see the section called “Turn on cluster auto scaling”.

1. Create an Auto Scaling group.
2. Create a capacity provider that uses that Auto Scaling group.
3. Turn on managed scaling for the capacity provider.
4. Associate the capacity provider with a cluster.
5. Run a task or create a service with a capacity provider strategy that uses the capacity provider.

   The capacity provider strategy determines how the tasks are spread across the cluster’s capacity providers. When you run a standalone task or create a service, you either use the cluster’s default capacity provider strategy or a capacity provider strategy that overrides the default one.

6. (Optional) Create a default capacity provider strategy for the cluster.

As of May 27, 2022, Amazon ECS no longer creates an AWS Auto Scaling scaling plan for newly created capacity providers. Instead, Amazon ECS uses the target tracking scaling policy attached to the Auto Scaling group to perform dynamic scaling based on your target capacity specification. For more information, see Amazon EC2 Auto Scaling group capacity providers.

With this new release, you can use an existing Auto Scaling group with a scaling policy for use when creating a new capacity provider. We don't recommend that you modify the ECS managed scaling policy or plan resources. However, when creating new capacity provider resources, if you have customized tooling that made modifications to the AWS Auto Scaling scaling plan, do one of the following:

- (Recommended) Update your capacity provider to modify the Amazon ECS managed scaling settings. For more information, see UpdateCapacityProvider.
- Update the scaling policy associated with your Auto Scaling group to modify the target tracking configuration used. For more information, see PutScalingPolicy.
Considerations

Consider the following when using cluster auto scaling:

- Don't change or manage the desired capacity for the Auto Scaling group that's associated with a capacity provider with any scaling policies other than the one Amazon ECS manages.

- Amazon ECS uses the AWSServiceRoleForECS service-linked IAM role for the permissions that it requires to call AWS Auto Scaling on your behalf. For more information about using and creating Amazon ECS service-linked IAM roles, see Using service-linked roles for Amazon ECS.

- When using capacity providers with Auto Scaling groups, the user, group, or role that creates the capacity providers requires the autoscaling:CreateOrUpdateTags permission. This is because Amazon ECS adds a tag to the Auto Scaling group when it associates it with the capacity provider.

⚠️ Important

Make sure any tooling that you use doesn't remove the AmazonECSManaged tag from the Auto Scaling group. If this tag is removed, Amazon ECS can't manage the scaling.

- Cluster auto scaling doesn't modify the MinimumCapacity or MaximumCapacity for the group. For the group to scale out, the value for MaximumCapacity must be greater than zero.

- When Auto Scaling (managed scaling) is turned on, a capacity provider can only be connected to one cluster at the same time. If your capacity provider has managed scaling turned off, you can associate it with multiple clusters.

- When managed scaling is turned off, the capacity provider doesn't scale in or scale out. You can use a capacity provider strategy to balance your tasks between capacity providers.

- The binpack strategy is the most efficient strategy in terms of capacity.

- When the target capacity is less than 100%, the placement strategy needs to use the binpack strategy without the spread strategy having a higher order than the binpack strategy. This prevents the capacity provider from scaling out until each task has a dedicated instance or the limit is reached.

Consider the following when you use the console:

- By default, the Amazon ECS managed scaling feature is on. For more information, see Managed scale-out behavior.
• By default, *managed termination protection* is off. For more information, see the next section *the section called “Managed termination protection”*.  

• By default, Auto Scaling instance scale-in protection is off. For more information, see *Using instance scale-in protection* in the *Amazon EC2 Auto Scaling User Guide*.  

• The Auto Scaling group that's used with your capacity provider can't use instance weighting settings. Instance weighting isn't supported when used together with an Amazon ECS capacity provider.

### Cluster auto scaling overview

For each Auto Scaling group capacity provider that's associated with a cluster, Amazon ECS creates and manages the following resources:

• A low metric value CloudWatch alarm  
• A high metric value CloudWatch alarm  
• A target tracking scaling policy

![Note]

Amazon ECS creates the target tracking scaling policy and attaches it to the Auto Scaling group. To update the target tracking scaling policy, update the capacity provider managed scaling settings, rather than updating the scaling policy directly.

When you turn off managed scaling or disassociate the capacity provider from a cluster, Amazon ECS removes both CloudWatch metrics and the target tracking scaling policy resources.

Amazon ECS uses the following metrics to determine what actions to take:

**CapacityProviderReservation**

The percent of container instances in use for a specific capacity provider. Amazon ECS generates this metric.

Amazon ECS sets the *CapacityProviderReservation* value to a number between 0-100. Amazon ECS uses the following formula to represent the ratio of how much capacity remains in the Auto Scaling group. Then, Amazon ECS publishes the metric to CloudWatch. For more
information about how the metric is calculated, see Deep Dive on Amazon ECS Cluster Auto Scaling

\[
\text{CapacityProviderReservation} = \frac{\text{(number of instances needed)}}{\text{(number of running instances)}} \times 100
\]

DesiredCapacity

The amount of capacity for the Auto Scaling group.

Amazon ECS performs the cluster auto scaling process for each capacity provider that's associated with your clusters. Amazon ECS performs the process every minute.

Amazon ECS publishes the CapacityProviderReservation metric to CloudWatch in the AWS/ECS/ManagedScaling namespace. The CapacityProviderReservation metric causes one of the following actions to occur:

**The CapacityProviderReservation value equals targetCapacity**

The Auto Scaling group doesn't need to scale in or scale out. The target utilization percentage has been reached.

**The CapacityProviderReservation value is greater than targetCapacity**

There are more tasks using a higher percentage of the capacity than your targetCapacity percentage. The increased value of the CapacityProviderReservation metric causes the associated CloudWatch alarm to act. This alarm updates the DesiredCapacity value for the Auto Scaling group. The Auto Scaling group uses this value to launch EC2 instances, and then register them with the cluster.

When the targetCapacity is the default value of 100%, the new tasks are in the PENDING state during the scale-out because there is no available capacity on the instances to run the tasks. After the new instances register with ECS, these tasks will start on the new instances.

**The CapacityProviderReservation value is less than targetCapacity**

There are less tasks using a lower percentage of the capacity than your targetCapacity percentage and there is at least one instance that can be terminated. The decreased value of the CapacityProviderReservation metric causes the associated CloudWatch alarm to act. This alarm updates the DesiredCapacity value for the Auto Scaling group. The Auto Scaling
group uses this value to terminate EC2 container instances, and then deregister them from the cluster.

The Auto Scaling group follows the group termination policy to determine which instances it terminates first during scale-in events. Additionally it avoids instances with the instance scale-in protection setting turned on. Cluster auto scaling can manage which instances have the instance scale-in protection setting if you turn on managed termination protection. For more information about managed termination protection, see Managed termination protection. For more information about how Auto Scaling groups terminate instances, see Control which Auto Scaling instances terminate during scale in in the Amazon EC2 Auto Scaling User Guide.

Managed termination protection

Important
You must turn on Auto Scaling instance scale-in protection on the Auto Scaling group to use the managed termination protection feature of cluster auto scaling.

Amazon ECS cluster auto scaling scales in the Auto Scaling group when the CapacityProviderReservation value is less than targetCapacity percentage that you set. Cluster auto scaling can control which instances are terminated if you turn on managed termination protection. When you use managed termination protection, Amazon ECS only terminates EC2 instances that don't have any running Amazon ECS tasks. Tasks that are run by a service that uses the DAEMON scheduling strategy are ignored and an instance can be terminated by cluster auto scaling even when the instance is running these tasks. This is because all of the instances in the cluster are running these tasks.

When you use managed termination protection, Amazon ECS first turns on the instance scale-in protection option for the EC2 instances in the Auto Scaling group. Then, Amazon ECS places the tasks on the instances. When all non-daemon tasks are stopped on an instance, Amazon ECS initiates the scale-in process and turns off scale-in protection for the EC2 instance. The Auto Scaling group can then terminate the instance.

Auto Scaling instance scale-in protection controls which EC2 instances can be terminated by Auto Scaling. Instances with the scale-in feature turned on can't be terminated during the scale-in process. For more information about Auto Scaling instance scale-in protection, see Using instance scale-in protection in the Amazon EC2 Auto Scaling User Guide.
You can set the targetCapacity percentage so that you have spare capacity. This helps future tasks launch more quickly because the Auto Scaling group does not have to launch more instances. Amazon ECS uses the target capacity value to manage the CloudWatch metric that the service creates to facilitate cluster auto scaling. Amazon ECS manages the CloudWatch metric. This way, the Auto Scaling group is treated as a steady state so that no scaling action is required. The values can be from 0-100%. For example, to configure Amazon ECS to keep 10% free capacity on top of that used by Amazon ECS tasks, set the target capacity value to 90%. Consider the following when setting the targetCapacity value on a capacity provider.

- A targetCapacity value of less than 100% represents the amount of free capacity (Amazon EC2 instances) that need to be present in the cluster. Free capacity means that there are no running tasks.

- Placement constraints such as Availability Zones, without additional binpack forces Amazon ECS to eventually run one task for each instance, which might not be the desired behavior. To prevent this behavior, don't use the spread strategy together with the binpack strategy.

Consider the following when using managed termination protection with the console:

- By default, managed termination protection is turned off for new capacity providers that you create.

- The console doesn't turn on the instance scale-in protection of the selected Auto Scaling group. By default, Auto Scaling instance scale-in protection is off. You must turn on Auto Scaling instance scale-in protection on the Auto Scaling group to use managed termination protection. If you don't turn on scale-in protection, then turning on managed termination protection can lead to undesirable behavior. For example, you may have instances stuck in draining state. For more information, see Using instance scale-in protection in the Amazon EC2 Auto Scaling User Guide.

- When you use termination protection with a capacity provider, don't perform any manual actions, like detaching the instance, on the Auto Scaling group associated with the capacity provider. Manual actions can break the scale-in operation of the capacity provider. If you detach an instance from the Auto Scaling group, you need to also deregister the detached instance from the Amazon ECS cluster.
Managed scale-out behavior

When you have Auto Scaling group capacity providers that use managed scaling, Amazon ECS estimates the optimal number of instances to add to your cluster and uses the value to determine how many instances to request. The following describes the scale-out behavior in more detail.

1. Amazon ECS selects a capacity provider for each task by following the capacity provider strategy from the service, from the standalone task, or from the cluster default. Amazon ECS follows the rest of these steps for a single capacity provider.

   Tasks without a capacity provider strategy are ignored by capacity providers. A pending task that doesn't have a capacity provider strategy won't cause any capacity provider to scale out. Tasks or services can't set a capacity provider strategy if that task or service sets a launch type.

2. Group all of the provisioning tasks for this capacity provider so that each group has the same exact resource requirements.

3. When you use multiple instance types in an Auto Scaling group, the instance types in the Auto Scaling group are sorted by their parameters. These parameters include vCPU, memory, elastic network interfaces (ENIs), ports, and GPUs. The smallest and the largest instance types for each parameter are selected. For more information about how to choose the instance type, see Characterizing your application in the Amazon ECS Best Practices Guide.

   Important
   If a group of tasks have resource requirements that are greater than the smallest instance type in the Auto Scaling group, then that group of tasks can't run with this capacity provider. The capacity provider doesn't scale the Auto Scaling group. The tasks remain in the PENDING state.

   To prevent tasks from staying in the PENDING state, we recommend that you create separate Auto Scaling groups and capacity providers for different minimum resource requirements. When you run tasks or create services, only add capacity providers to the capacity provider strategy that can run the task on the smallest instance type in the Auto Scaling group. For other parameters, you can use placement constraints.

4. For each group of tasks, Amazon ECS calculates the number of instances that are required to run the unplaced tasks. This calculation uses a binpack strategy. This strategy accounts for the vCPU, memory, elastic network interfaces (ENI), ports, and GPUs requirements of the tasks. It also accounts for the resource availability of the Amazon EC2 instances. The values for the
largest instance types are treated as the maximum calculated instance count. The values for the smallest instance type are used as protection. If the smallest instance type can't run at least one instance of the task, the calculation considers the task as not compatible. As a result, the task is excluded from scale-out calculation. When all the tasks aren't compatible with the smallest instance type, cluster auto scaling stops and the CapacityProviderReservation value remains at the targetCapacity value.

5. Amazon ECS publishes the CapacityProviderReservation metric to CloudWatch with respect to the minimumScalingStepSize if either of the following is the case. Either, the maximum calculated instance count is less than the minimum scaling step size. Or, the lower value of either the maximumScalingStepSize or the maximum calculated instance count.

6. CloudWatch alarms use the CapacityProviderReservation metric for capacity providers. When the CapacityProviderReservation metric is greater than the targetCapacity value, alarms also increase the DesiredCapacity of the Auto Scaling group. The targetCapacity value is a capacity provider setting that's sent to the CloudWatch alarm during the cluster auto scaling activation phase.

   You can set the targetCapacity when you create the Auto Scaling group, or modify the value after the group is created. The default is 100%.

7. The Auto Scaling group launches additional EC2 instances. To prevent over-provisioning, Auto Scaling makes sure that recently launched EC2 instance capacity is stabilized before it launches new instances. Auto Scaling checks if all existing instances have passed the instanceWarmupPeriod (now minus the instance launch time). The scale-out is blocked for instances that are within the instanceWarmupPeriod.

   The default number of seconds for a newly launched instance to warm up is 300.

For more information, see Deep dive on Amazon ECS cluster auto scaling.

**Scale-out considerations**

Consider the following for the scale-out process:

1. Although there are multiple placement constraints, we recommend that you only use the distinctInstance task placement constraint. This prevents the scale-out process from stopping because you're using a placement constraint that's not compatible with the sampled instances.
2. Managed scaling works best if your Auto Scaling group uses the same or similar instance types. For more information, see Managed scale-out behavior.

3. When a scale-out process is required and there are no currently running container instances, Amazon ECS always scales-out to two instances initially, and then performs additional scale-out or scale-in processes. Any additional scale-out waits for the instance warmup period. For scale-in processes, Amazon ECS waits 15 minutes after a scale-out process before starting scale-in processes at all times.

4. The second scale-out step needs to wait until the instanceWarmupPeriod expires, which might affect the overall scale limit. If you need to reduce this time, make sure that instanceWarmupPeriod is large enough for the EC2 instance to launch and start the Amazon ECS agent (which prevents over provisioning).

5. Cluster auto scaling supports Launch Configuration, Launch Templates, and multiple instance types in the capacity provider Auto Scaling group. You can also use attribute-based instance type selection without multiple instances types.

6. When using an Auto Scaling group with On-Demand instances and multiple instance types or Spot Instances, place the larger instance types higher in the priority list and don't specify a weight. Specifying a weight isn't supported at this time. For more information, see Auto Scaling groups with multiple instance types in the AWS Auto Scaling User Guide.

7. Amazon ECS then launch either the minimumScalingStepSize, if the maximum calculated instance count is less than the minimum scaling step size, or the lower of either the maximumScalingStepSize or the maximum calculated instance count value.

8. If an Amazon ECS service or the run-task API launches a task and the capacity provider container instances don't have enough resources to start the task, then Amazon ECS limits the number of tasks with this status for each cluster and prevents any tasks from exceeding this limit. For more information, see Service quotas.

Managed scale-in behavior

Amazon ECS monitors container instances for each capacity provider within a cluster. When a container instance isn't running any tasks, the container instance is considered empty and Amazon ECS starts the scale-in process. The following describes the scale-in behavior in more detail:

1. Amazon ECS calculates the number of container instances that are empty. A container instance is considered empty even when daemon tasks are running.
2. Amazon ECS sets the `CapacityProviderReservation` value to a number between 0-100 that uses the following formula to represent the ratio of how big the Auto Scaling group needs to be relative to how big it actually is, expressed as a percentage. Then, Amazon ECS publishes the metric to CloudWatch. For more information about how the metric is calculated, see [Deep Dive on Amazon ECS Cluster Auto Scaling](#)

\[
\text{CapacityProviderReservation} = \frac{\text{(number of instances needed)}}{\text{(number of running instances)}} \times 100
\]

3. The `CapacityProviderReservation` metric generates a CloudWatch alarm. This alarm updates the `DesiredCapacity` value for the Auto Scaling group. Then, one of the following actions occurs:

- If you don’t use capacity provider managed termination, the Auto Scaling group selects EC2 instances using the Auto Scaling group termination policy and terminates the instances until the number of EC2 instances reaches the `DesiredCapacity`. The container instances are then deregistered from the cluster.

- If all the container instances use managed termination protection, Amazon ECS removes the scale-in protection on the container instances that are empty. The Auto Scaling group will then be able to terminate the EC2 instances. The container instances are then deregistered from the cluster.

**Scale-in considerations**

Consider the following for the scale-in process:

- When there are no running non-daemon tasks, Amazon ECS container instances are considered available for scale in.

- CloudWatch scale-in alarms require 15 data points (15 minutes) before the scale-in process for the Auto Scaling group starts. After the scale-in process starts until Amazon ECS needs to reduce the number of registered container instances, the Auto Scaling group sets the `DesiredCapacity` value to be greater than one instance and less than 50% each minute.

- When Amazon ECS requests a scale-out (when `CapacityProviderReservation` is greater than 100) while a scale-in process is in progress, the scale-in process is stopped and starts from the beginning if required.
Update on the way Amazon ECS creates resources for cluster auto scaling

As of May 27, 2022, Amazon ECS changed how it manages the resources that facilitate cluster auto scaling. To simplify the experience, Amazon ECS no longer requires an AWS Auto Scaling scaling plan when you turn on managed scaling for an Auto Scaling group capacity provider.

⚠️ Important
This change has no functional impact on your cluster auto scaling workflows and no pricing or performance impact.

Capacity providers created before May 27, 2022

Capacity providers that were created before May 27, 2022, and that use AWS Auto Scaling scaling plans continue to function as before.

Review the following considerations:

- We don't recommend that you update or delete the ECS-managed AWS Auto Scaling scaling plan or the scaling policy resources that are associated with your capacity providers.
- You can access the scaling plan resource for clusters on the Auto Scaling console and by the `describe-clusters` with attachments. For more information, see the API documentation [DescribeClusters](#).
- You can't add scaling policies to the Auto Scaling group that functions as the cluster capacity provider.
- The number of Auto Scaling plans for each account is limited. For more information, see [Quotas for your scaling plans](#) in the Amazon EC2 Auto Scaling User Guide.

Capacity providers created on or after May 27, 2022

As of May 27, 2022, Amazon ECS no longer creates an AWS Auto Scaling scaling plan for newly created capacity providers. Instead, Amazon ECS uses the target tracking scaling policy attached to the Auto Scaling group to perform dynamic scaling based on your target capacity specification. For more information, see [Amazon EC2 Auto Scaling group capacity providers](#).
With this new release, you can use an existing Auto Scaling group with a scaling policy for use when creating a new capacity provider. We don't recommend that you modify the ECS managed scaling policy or plan resources. However, when creating new capacity provider resources, if you have customized tooling that made modifications to the AWS Auto Scaling scaling plan, do one of the following:

- (Recommended) Update your capacity provider to modify the Amazon ECS managed scaling settings. For more information, see UpdateCapacityProvider.
- Update the scaling policy associated with your Auto Scaling group to modify the target tracking configuration used. For more information, see PutScalingPolicy.

Turn on cluster auto scaling

You can use the AWS CLI to turn on cluster auto scaling.

Before you begin, create an Auto Scaling group and a capacity provider. For more information, see the section called “Amazon EC2 Auto Scaling group capacity providers”.

Associate the capacity provider with the cluster

Use the following steps to associate the capacity provider with the cluster.

1. Use the put-cluster-capacity-providers command to associate one or more capacity providers with the cluster.

   To add the AWS Fargate capacity providers, include the FARGATE and FARGATE_SPOT capacity providers in the request. For more information, see put-cluster-capacity-providers in the AWS CLI Command Reference.

   ```
   aws ecs put-cluster-capacity-providers \
   --cluster ClusterName \
   --capacity-providers CapacityProviderName FARGATE FARGATE_SPOT \
   --default-capacity-provider-strategy capacityProvider=CapacityProvider,weight=1
   ```

   To add an Auto Scaling group for the EC2 launch type, include the Auto Scaling group name in the request. For more information, see put-cluster-capacity-providers in the AWS CLI Command Reference.

   ```
   aws ecs put-cluster-capacity-providers \
   ```
2. Use the describe-clusters command to verify that the association was successful. For more information, see `describe-clusters` in the `AWS CLI Command Reference`.

```
aws ecs describe-clusters
  --cluster ClusterName \
  --include ATTACHMENTS
```

**Turn on managed scaling for the capacity provider**

Use the following steps to turn on managed scaling for the capacity provider.

- Use the `update-capacity-provider` command to turn on managed auto scaling for the capacity provider. For more information, see `update-capacity-provider` in the `AWS CLI Command Reference`.

```
aws ecs update-capacity-provider
  --capacity-providers CapacityProviderName \
  --auto-scaling-group-provider managedScaling=ENABLED
```

**Turn off cluster auto scaling**

You can use the AWS CLI to turn off cluster auto scaling.

To turn off cluster auto scaling for a cluster, you can either disassociate the capacity provider with managed scaling turned on from the cluster or by updating the capacity provider to turn off managed scaling.

**Disassociate the capacity provider with the cluster**

Use the following steps to disassociate a capacity provider with a cluster.

1. Use the `put-cluster-capacity-providers` command to disassociate the Auto Scaling group capacity provider with the cluster. The cluster can keep the association with the AWS Fargate capacity providers. For more information, see `put-cluster-capacity-providers` in the `AWS CLI Command Reference`.

```
--cluster ClusterName \
--capacity-providers CapacityProviderName \
--default-capacity-provider-strategy capacityProvider=CapacityProvider,weight=1
```
Use the put-cluster-capacity-providers command to disassociate the Auto Scaling group capacity provider with the cluster. For more information, see put-cluster-capacity-providers in the AWS CLI Command Reference.

aws ecs put-cluster-capacity-providers \\ 
--cluster \ClusterName\\ 
--capacity-providers FARGATE FARGATE_SPOT \\ 
--default-capacity-provider-strategy '[]'

2. Use the describe-clusters command to verify that the disassociation was successful. For more information, see describe-clusters in the AWS CLI Command Reference.

aws ecs describe-clusters \\ 
--cluster \ClusterName\\ 
--include ATTACHMENTS

**Turn off managed scaling for the capacity provider**

Use the following steps to turn off managed scaling for the capacity provider.

- Use the update-capacity-provider command to turn off managed auto scaling for the capacity provider. For more information, see update-capacity-provider in the AWS CLI Command Reference.

aws ecs update-capacity-provider \\ 
--capacity-providers \CapacityProviderName\\ 
--auto-scaling-group-provider managedScaling=DISABLED

**Cluster management**

The following are general concepts about Amazon ECS clusters.
• Amazon ECS creates a default cluster. You can create additional clusters in an account to keep your resources separate.

• Clusters are AWS Region specific.

• The following are the possible states that a cluster can be in.

ACTIVE

The cluster is ready to accept tasks and, if applicable, you can register container instances with the cluster.

PROVISIONING

The cluster has capacity providers associated with it and the resources needed for the capacity provider are being created.

DEPROVISIONING

The cluster has capacity providers associated with it and the resources needed for the capacity provider are being deleted.

FAILED

The cluster has capacity providers associated with it and the resources needed for the capacity provider have failed to create.

INACTIVE

The cluster has been deleted. Clusters with an INACTIVE status may remain discoverable in your account for a period of time. However, this behavior is subject to change in the future, so make sure you do not rely on INACTIVE clusters persisting.

• A cluster can contain a mix of tasks that are hosted on AWS Fargate, Amazon EC2 instances, or external instances. Tasks can run on Fargate or EC2 infrastructure as a launch type or a capacity provider strategy. If you use EC2 as a launch type, ECS doesn't track and scale the capacity of Amazon EC2 Auto Scaling groups. For more information about launch types, see Amazon ECS launch types.

• A cluster can contain a mix of both Auto Scaling group capacity providers and Fargate capacity providers. However, when you specify a capacity provider strategy, they may only contain one or the other but not both. For more information, see Amazon ECS capacity providers.

• For tasks that use the EC2 launch type or Auto Scaling group capacity providers, clusters can contain multiple different container instance types. However, each container instance can only be registered to one cluster at a time.
• Custom IAM policies may be created to allow or restrict user access to specific clusters. For more information, see the Cluster examples section in Identity-based policy examples for Amazon Elastic Container Service.

• Clusters with Fargate tasks can be scaled using Service Auto Scaling. For more information, see Automatically scale your Amazon ECS service.

• *You can configure a default Service Connect namespace for a cluster. After you set a default Service Connect namespace, any new services created in the cluster can be added as client services in the namespace by turning on Service Connect. No additional configuration is required. For more information, see Service Connect*.

• If you use EC2 instances, the cluster capacity can be located in any of the following AWS resources:

  For information about how to use these resources with Amazon ECS see Amazon ECS applications in shared subnets, Local Zones, and Wavelength Zones.

  • Availability Zones
  • Local Zones
  • Wavelength Zones
  • AWS Outposts

Creating a cluster for the Fargate and External launch type using the console

You can create an Amazon ECS cluster using the Amazon ECS console. Before you begin, be sure that you've completed the steps in Set up to use Amazon ECS and assign the appropriate IAM permission. For more information, see the section called “Cluster examples”. The Amazon ECS console provides a simple way to create the resources that are needed by an Amazon ECS cluster by creating a AWS CloudFormation stack.

To make the cluster creation process as easy as possible, the console has default selections for many choices which we describe below. There are also help panels available for most of the sections in the console which provide further context.

• Creates a default namespace in AWS Cloud Map that is the same name as the cluster. A namespace allows services that you create in the cluster to connect to the other services in the namespace without additional configuration.
For more information, see Interconnecting services.

You can modify the following options:

- Change the default namespace associated with the cluster.

  A namespace allows services that you create in the cluster can connect to the other services in the namespace without additional configuration. The default namespace is the same as the cluster name. For more information, see Interconnecting services.

- Configure the cluster for external instances

- Turn on Container Insights.

  CloudWatch Container Insights collects, aggregates, and summarizes metrics and logs from your containerized applications and microservices. Container Insights also provides diagnostic information, such as container restart failures, that you use to isolate issues and resolve them quickly. For more information, see the section called “Monitor Amazon ECS containers using Container Insights”.

- Add tags to help you identify your cluster.

**To create a new cluster (Amazon ECS console)**

2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose Clusters.
4. On the Clusters page, choose Create cluster.
5. Under **Cluster configuration**, configure the following:
   - For **Cluster name**, enter a unique name.
     
     The name can contain up to 255 letters (uppercase and lowercase), numbers, and hyphens.
   - (Optional) To have the namespace used for Service Connect be different from the cluster name, for **Namespace**, enter a unique name.
6. (Optional) Use external instances (Amazon ECS Anywhere) for your capacity. Expand **Infrastructure**, clear **AWS Fargate (serverless)**, and then select **External instances using ECS Anywhere**.
7. (Optional) To turn on Container Insights, expand **Monitoring**, and then turn on **Use Container Insights**.

8. (Optional) To help identify your cluster, expand **Tags**, and then configure your tags.

   [Add a tag] Choose **Add tag** and do the following:
   
   • For **Key**, enter the key name.
   
   • For **Value**, enter the key value.

   [Remove a tag] Choose **Remove** to the right of the tag’s Key and Value.

9. Choose **Create**.

**Next steps**

If you are using external instances, you must register the instances with the cluster. For more information, see [Registering an external instance to a cluster](#).

After you create the cluster, you can create task definitions for your applications and then run them as standalone tasks, or as part of a service. For more information, see the following:

- [Amazon ECS task definitions](#)
- [Run an application as an Amazon ECS task](#)
- [Creating a service using the console](#)

**Creating a cluster for the Amazon EC2 launch type using the console**

You can create an Amazon ECS cluster using the console. Before you begin, be sure that you've completed the steps in [Set up to use Amazon ECS](#) and assign the appropriate IAM permission. For more information, see [the section called “Cluster examples”](#). The Amazon ECS console provides a simple way to create the resources that are needed by an Amazon ECS cluster by creating a **AWS CloudFormation stack**.

To make the cluster creation process as easy as possible, the console has default selections for many choices which we describe below. There are also help panels available for most of the sections in the console which provide further context.
You can register Amazon EC2 instances when you create the cluster or register additional instances with the cluster after it has been created.

You can modify the following default options:

- Change the subnets where your instances launch
- Change the security groups used to control traffic to the container instances
- Change the default namespace associated with the cluster.

A namespace allows services that you create in the cluster can connect to the other services in the namespace without additional configuration. The default namespace is the same as the cluster name. For more information, see Interconnecting services.

- Turn on Container Insights.

CloudWatch Container Insights collects, aggregates, and summarizes metrics and logs from your containerized applications and microservices. Container Insights also provides diagnostic information, such as container restart failures, that you use to isolate issues and resolve them quickly. For more information, see the section called “Monitor Amazon ECS containers using Container Insights”.

- Add tags to help you identify your cluster.

**Auto Scaling group options**

When you use Amazon EC2 instances, you must specify an Auto Scaling group to manage the infrastructure that your tasks and services run on.

When you choose to create a new Auto Scaling group, it is automatically configured for the following behavior:

- Amazon ECS manages the scale-in and scale-out actions of the Auto Scaling group.
- Amazon ECS will not prevent Amazon EC2 instances that contain tasks and that are in an Auto Scaling group from being terminated during a scale-in action. For more information, see Instance Protection in the AWS Auto Scaling User Guide.

You configure the following Auto Scaling group properties which determine the type and number of instances to launch for the group:

- The Amazon ECS-optimized AMI.
• The instance type.
• The SSH key pair that proves your identity when you connect to the instance. For information about how to create SSH keys, see Amazon EC2 key pairs and Linux instances in the Amazon EC2 User Guide for Linux Instances.
• The minimum number of instances to launch for the Auto Scaling group.
• The maximum number of instances that are started for the Auto Scaling group.

In order for the group to scale out, the maximum must be greater than 0.

Amazon ECS creates an Amazon EC2 Auto Scaling launch template and Auto Scaling group on your behalf as part of the AWS CloudFormation stack. The values that you specified for the AMI, the instance types, and the SSH key pair are part of the launch template. The templates are prefixed with EC2ContainerService-<ClusterName>, which makes them easy to identify. The Auto Scaling groups are prefixed with <ClusterName>-ECS-Infra-ECSAutoScalingGroup.

Instances launched for the Auto Scaling group use the launch template.

**Networking options**

By default instances are launched into the default subnets for the Region. The security groups, which control the traffic to your container instances, currently associated with the subnets are used. You can changed the subnets and security groups for the instances.

You can choose an existing subnet. You can either use an existing security group, or create a new one, When you create a new security group, you need to specify at least one inbound rule.

The inbound rules determine what traffic can reach your container instances and include the following properties:

• The protocol to allow
• The range of ports to allow
• The inbound traffic (source)

To allow inbound traffic from a specific address or CIDR block, use **Custom** for **Source** with the allowed CIDR.

To allow inbound traffic from all destinations, use **Anywhere** for **Source**. This automatically adds the 0.0.0.0/0 IPv4 CIDR block and ::/0 IPv6 CIDR block.
To allow inbound traffic from your local computer, use Source group for Source. This automatically adds the current IP address of your local computer as the allowed source.

To create a new cluster (Amazon ECS console)

Before you begin, assign the appropriate IAM permission. For more information, see the section called “Cluster examples”.

2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose Clusters.
4. On the Clusters page, choose Create cluster.
5. Under Cluster configuration, configure the following:

   • For Cluster name, enter a unique name.
     The name can contain up to 255 letters (uppercase and lowercase), numbers, and hyphens.
   • (Optional) To have the namespace used for Service Connect be different from the cluster name, for Namespace, enter a unique name.

6. Add Amazon EC2 instances to your cluster, expand Infrastructure, clear AWS Fargate (serverless), and then select Amazon EC2 instances. Next, configure the Auto Scaling group which acts as the capacity provider:

   a. To using an existing Auto Scaling group, from Auto Scaling group (ASG), select the group.
   b. To create a Auto Scaling group, from Auto Scaling group (ASG), select Create new group, and then provide the following details about the group:

      • For Provisioning model, choose whether to use On-demand instances or Spot Instances.
      • If you choose to use Spot Instances, for Allocation Strategy, choose what Spot capacity pools (instance types and Availability Zones) are used for the instances.

      For most workloads, you can choose Price capacity optimized.

      For more information, see Allocation strategies for Spot Instances in the Amazon EC2 User Guide for Linux Instances.
      • For Operating system/Architecture, choose the Amazon ECS-optimized AMI for the Auto Scaling group instances.
• For **EC2 instance type**, choose the instance type for your workloads.

Managed scaling works best if your Auto Scaling group uses the same or similar instance types.

• For **EC2 instance role**, choose an existing container instance role, or you can create a new one.

For more information, see [Amazon ECS container instance IAM role](#).

• For **Capacity**, enter the minimum number and the maximum number of instances to launch in the Auto Scaling group.

• For **SSH key pair**, choose the pair that proves your identity when you connect to the instance.

• To allow for larger image and storage, for **Root EBS volume size**, enter the value in GiB.

7. (Optional) To change the VPC and subnets, under **Networking for Amazon EC2 instances**, perform any of the following operations:

• To remove a subnet, under **Subnets**, choose X for each subnet that you want to remove.

• To change to a VPC other than the default VPC, under **VPC**, choose an existing **VPC**, and then under **Subnets**, choose the subnets.

• Choose the security groups. Under **Security group**, choose one of the following options:
  
  • To use an existing security group, choose **Use an existing security group**, and then choose the security group.

  • To create a security group, choose **Create a new security group**. Then, choose **Add rule** for each inbound rule.

  For information about inbound rules, see [Networking options](#).

• To automatically assign public IP addresses to your Amazon EC2 container instances, for **Auto-assign public IP**, choose one of the following options:

  • **Use subnet setting** – Assign a public IP address to the instances when the subnet that the instances launch in are a public subnet.

  • **Turn on** – Assign a public IP address to the instances.

8. (Optional) To turn on Container Insights, expand **Monitoring**, and then turn on **Use Container Insights**.

9. (Optional)
If you use Runtime Monitoring with the manual option and you want to have this cluster monitored by GuardDuty, choose Add tag and do the following:

- For **Key**, enter `guardDutyRuntimeMonitoringManaged`
- For **Value**, enter `true`.

10. (Optional) To manage the cluster tags, expand Tags, and then perform one of the following operations:

    [Add a tag] Choose Add tag and do the following:
    - For **Key**, enter the key name.
    - For **Value**, enter the key value.

    [Remove a tag] Choose Remove to the right of the tag's Key and Value.

11. Choose **Create**.

**Next steps**

After you create the cluster, you can create task definitions for your applications and then run them as standalone tasks, or as part of a service. For more information, see the following:

- Amazon ECS task definitions
- Run an application as an Amazon ECS task
- Creating a service using the console

**Updating a cluster using the console**

You can modify the following cluster properties:

- Set a default capacity provider

Each cluster can have one or more capacity providers and an optional capacity provider strategy. The capacity provider strategy determines how the tasks are spread across the cluster's capacity providers. When you run a standalone task or create a service, you either use the cluster's default capacity provider strategy or a capacity provider strategy that overrides the default one.
Capacity providers are an alternative to launch types. For more information, see Capacity provider concepts.

- Turn on Container Insights.

CloudWatch Container Insights collects, aggregates, and summarizes metrics and logs from your containerized applications and microservices. Container Insights also provides diagnostic information, such as container restart failures, that you use to isolate issues and resolve them quickly. For more information, see the section called “Monitor Amazon ECS containers using Container Insights”.

- Add tags to help you identify your clusters.

To update the cluster (Amazon ECS console)

2. In the navigation pane, choose Clusters.
3. On the Clusters page, choose the cluster.
5. To set the default capacity provider, under Default capacity provider strategy, choose Add more.
   a. For Capacity provider, choose the capacity provider.
   b. (Optional) For Base, enter the minimum number of tasks that run on the capacity provider.
       You can only set a Base value for one capacity provider.
   c. (Optional) For Weight, enter the relative percentage of the total number of launched tasks
      that use the specified capacity provider.
   d. (Optional) Repeat the steps for any additional capacity providers.
6. To turn on or off Container Insights, expand Monitoring, and then turn on Use Container Insights.
7. To help identify your cluster, expand Tags, and then configure your tags.

   [Add a tag] Choose Add tag and do the following:
   a. For Key, enter the key name.
   b. For Value, enter the key value.
[Remove a tag] Choose Remove to the right of the tag's Key and Value.

8. Choose Update.

Deleting a cluster using the console

If you are finished using a cluster, you can delete it. After you delete the cluster, it transitions to the INACTIVE state. Clusters with an INACTIVE status may remain discoverable in your account for a period of time. However, this behavior is subject to change in the future, so you should not rely on INACTIVE clusters persisting.

Before you delete a cluster, you must perform the following operations:

- Delete all services in the cluster. For more information, see the section called “Deleting a service”.
- Stop all currently running tasks. For more information, see the section called “Stop an Amazon ECS task”.
- Deregister all registered container instances in the cluster. For more information, see the section called “Deregister a container instance”.
- Delete the namespace. For more information, see Deleting namespaces in the AWS Cloud Map Developer Guide.

To delete a cluster (Amazon ECS console)

2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose Clusters.
4. On the Clusters page, select the cluster to delete.
5. In the upper-right of the page, choose Delete Cluster.

A message is displayed when you did not delete all the resources associated with the cluster.
6. In the confirmation box, enter delete cluster name.
Creating a capacity provider for a cluster using the console

After the cluster creation completes, you can create a new capacity provider (Auto Scaling group) for the EC2 launch type.

Before you create the capacity provider, you need to create an Auto Scaling group. For more information, see Auto Scaling groups in the Amazon EC2 Auto Scaling User Guide.

To create a capacity provider for the cluster (Amazon ECS console)

2. In the navigation pane, choose Clusters.
3. On the Clusters page, choose the cluster.
4. On the Cluster : name page, choose Infrastructure, and then choose Create.
5. On the Create capacity providers page, configure the following options.
   a. Under Basic details, for Capacity provider name, enter a unique capacity provider name.
   b. Under Auto Scaling group, for Use an existing Auto Scaling group, choose the Auto Scaling group.
   c. (Optional) To configure a scaling policy, under Scaling policies, configure the following options.
      • To have Amazon ECS manage the scale-in and scale-out actions, select Turn on managed scaling.
      • To prevent EC2 instance with running Amazon ECS tasks from being terminated, select Turn on scaling protection.
      • For Set target capacity, enter the target value for the CloudWatch metric used in the Amazon ECS-managed target tracking scaling policy.
6. Choose Create.

Updating a capacity provider for a cluster using the console

When you use an Auto Scaling group as a capacity provider, you can modify the group's scaling policy.
To update a capacity provider for the cluster (Amazon ECS console)

2. In the navigation pane, choose Clusters.
3. On the Clusters page, choose the cluster.
4. On the Cluster : name page, choose Infrastructure, and then choose Update.
5. On the Create capacity providers page, configure the following options.
   - Under Auto Scaling group, under Scaling policies, configure the following options.
     - To have Amazon ECS manage the scale-in and scale-out actions, select Turn on managed scaling.
     - To prevent EC2 instances with running Amazon ECS tasks from being terminated, select Turn on scaling protection.
     - For Set target capacity, enter the target value for the CloudWatch metric used in the Amazon ECS-managed target tracking scaling policy.
6. Choose Update.

Deleting a capacity provider for a cluster using the console

If you are finished using an Auto Scaling group capacity provider, you can delete it. After the group is deleted, the Auto Scaling group capacity provider will transition to the INACTIVE state. Capacity providers with an INACTIVE status may remain discoverable in your account for a period of time. However, this behavior is subject to change in the future, so you should not rely on INACTIVE capacity providers persisting. Before the Auto Scaling group capacity provider is deleted, the capacity provider must be removed from the capacity provider strategy from all services. You can use the UpdateService API or the update service workflow in the Amazon ECS console to remove a capacity provider from a service’s capacity provider strategy. Use the force new deployment option to ensure that any tasks using the Amazon EC2 instance capacity provided by the capacity provider are transitioned to use the capacity from the remaining capacity providers.

To delete a capacity provider for the cluster (Amazon ECS console)

2. In the navigation pane, choose Clusters.
3. On the Clusters page, choose the cluster.
4. On the **Cluster : name** page, choose **Infrastructure**, the Auto Scaling group, and then choose **Delete**.

5. In the confirmation box, enter **delete Auto Scaling group name**

6. Choose **Delete**.

**Capacity creation**

An Amazon ECS container instance is an Amazon EC2 instance that is running the Amazon ECS container agent and has been registered into an Amazon ECS cluster. When you run tasks with Amazon ECS using the EC2 launch type, External launch type or an Auto Scaling group capacity provider, your tasks are placed on your active container instances. You are responsible for the container instance management and maintenance.

Amazon ECS provides the Amazon ECS-optimized AMIs that are preconfigured with the requirements and recommendations to run your container workloads. We recommend that you use the Amazon ECS-optimized Amazon Linux 2023 AMI for your Amazon EC2 instances unless your application requires Amazon EC2 GPU-based instances, a specific operating system or a Docker version that is not yet available in that AMI. For information about the the Amazon Linux 2 and Amazon Linux 2023 instances, see [Comparing Amazon Linux 2 and Amazon Linux 2023](#) in the [Amazon Linux 2023 User Guide](#).

Although you can create your own Amazon EC2 instance AMI that meets the basic specifications needed to run your containerized workloads on Amazon ECS, the Amazon ECS-optimized AMIs are preconfigured and tested on Amazon ECS by AWS engineers. It is the simplest way for you to get started and to get your containers running on AWS quickly.

You can run either Linux or Windows on your container instances. You can choose the instance type based on your application requirements such as CPU architecture, network throughput, and architecture. As a general rule, the CPU and memory must be large enough to hold at least one replica of the task that you want to run. You can launch more tasks at the same time with larger instances. You can scale out in a more fine-grained way to save costs with smaller instances. You don't need to choose a single Amazon EC2 instance type that to fit all the applications in your cluster. You can create multiple Auto Scaling Groups with different instance types to fit all the applications. For more information, see [Amazon EC2 Instances](#).

To determine which instance types you can use, start by eliminating the instance types or instance families that don't meet the specific requirements of your application. For example, if your
application requires a GPU, you can exclude any instance types that don't have a GPU. However, you should also consider other requirements, too. For example, consider the CPU architecture, network throughput, and if instance storage is a requirement. Next, examine the amount of CPU and memory provided by each instance type. As a general rule, the CPU and memory must be large enough to hold at least one replica of the task that you want to run.

You can choose from the instance types that are compatible with your application. With larger instances, you can launch more tasks at the same time. And, with smaller instances, you can scale out in a more fine-grained way to save costs. You don't need to choose a single Amazon EC2 instance type that fits all the applications in your cluster. Instead, you can create multiple Auto Scaling Groups. Each group can have a different instance type. Then, you can create an Amazon EC2 Capacity Provider for each one of these groups. Last, in the Capacity Provider strategy of your service and task, you can select the Capacity Provider that best suits its needs. For more information, see Amazon EC2 Instances.

Use the following guidelines for networking your instances:

- We recommend launching your container instances inside a VPC, because Amazon VPC delivers more control over your network and offers more extensive configuration capabilities. For more information, see Amazon EC2 and Amazon Virtual Private Cloud in the Amazon EC2 User Guide for Linux Instances.

- If any of the containers associated with your tasks require external connectivity, you can map their network ports to ports on the host Amazon ECS container instance so they are reachable from the internet. Your container instance security group must allow inbound access to the ports you want to expose. For more information, see Create a Security Group in the Amazon VPC Getting Started Guide.

- Container instances need access to communicate with the Amazon ECS service endpoint. This can be through an interface VPC endpoint or through your container instances having public IP addresses.

For more information about interface VPC endpoints, see Amazon ECS interface VPC endpoints (AWS PrivateLink).

If you do not have an interface VPC endpoint configured and your container instances do not have public IP addresses, then they must use network address translation (NAT) to provide this access. For more information, see NAT gateways in the Amazon VPC User Guide and HTTP proxy configuration for Linux container instances in this guide. For more information, see the section called “Create a virtual private cloud“.
Spot Instances

Spot capacity can provide significant cost savings over on-demand instances. Spot capacity is excess capacity that's priced significantly lower than on-demand or reserved capacity. Spot capacity is suitable for batch processing and machine-learning workloads, and development and staging environments. More generally, it's suitable for any workload that tolerates temporary downtime.

Understand that the following consequences because Spot capacity might not be available all the time.

- During periods of extremely high demand, Spot capacity might be unavailable. This can cause Amazon EC2 Spot instance launches to be delayed. In these events, Amazon ECS services retry launching tasks, and Amazon EC2 Auto Scaling groups also retry launching instances, until the required capacity becomes available. Amazon EC2 doesn't replace Spot capacity with on-demand capacity.

- When the overall demand for capacity increases, Spot instances and tasks might be terminated with only a two-minute warning. After the warning is sent, tasks should begin an orderly shutdown if necessary before the instance is fully terminated. This helps minimize the possibility of errors. For more information about a graceful shutdown, see Graceful shutdowns with ECS.

To help minimize Spot capacity shortages, consider the following recommendations:

- Use multiple Regions and Availability Zones - Spot capacity varies by Region and Availability Zone. You can improve Spot availability by running your workloads in multiple Regions and Availability Zones. If possible, specify subnets in all the Availability Zones in the Regions where you run your tasks and instances.

- Use multiple Amazon EC2 instance types - When you use Mixed Instance Policies with Amazon EC2 Auto Scaling, multiple instance types are launched into your Auto Scaling Group. This ensures that a request for Spot capacity can be fulfilled when needed. To maximize reliability and minimize complexity, use instance types with roughly the same amount of CPU and memory in your Mixed Instances Policy. These instances can be from a different generation, or variants of the same base instance type. Note that they might come with additional features that you might not require. An example of such a list could include m4.large, m5.large, m5a.large, m5d.large, m5n.large, m5dn.large, and m5ad.large. For more information, see Auto Scaling groups with multiple instance types and purchase options in the Amazon EC2 Auto Scaling User Guide.

- Use the capacity-optimized Spot allocation strategy - With Amazon EC2 Spot, you can choose between the capacity- and cost-optimized allocation strategies. If you choose the capacity-
optimized strategy when launching a new instance, Amazon EC2 Spot selects the instance type with the greatest availability in the selected Availability Zone. This helps reduce the possibility that the instance is terminated soon after it launches.

**Linux Spot Instance draining**

Amazon EC2 terminates, stops, or hibernates your Spot Instance when the Spot price exceeds the maximum price for your request or capacity is no longer available. Amazon EC2 provides a Spot Instance two-minute interruption notice for terminate and stop actions. It does not provide the two-minute notice for the hibernate action. If Amazon ECS Spot Instance draining is enabled on the instance, ECS receives the Spot Instance interruption notice and places the instance in DRAINING status.

⚠️ **Important**

Amazon ECS does not receive a notice from Amazon EC2 when instances are removed by Auto Scaling Capacity Rebalancing. For more information, see [Amazon EC2 Auto Scaling Capacity Rebalancing](#).

When a container instance is set to DRAINING, Amazon ECS prevents new tasks from being scheduled for placement on the container instance. Service tasks on the draining container instance that are in the PENDING state are stopped immediately. If there are container instances in the cluster that are available, replacement service tasks are started on them.

Spot Instance draining is turned off by default and must be manually enabled. To enable Spot Instance draining for a new container instance, when launching the container instance add the following script into the User data field, replacing `MyCluster` with the name of the cluster to register the container instance to.

```
#!/bin/bash
cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=MyCluster
ECS_ENABLE_SPOT_INSTANCE_DRAINING=true
EOF
```

For more information, see [Launching an Amazon ECS Linux container instance](#).
To turn on Spot Instance draining for an existing container instance

1. Connect to the Spot Instance over SSH.
2. Edit the `/etc/ecs/ecs.config` file and add the following:

   ```
   ECS_ENABLE_SPOT_INSTANCE_DRAINING=true
   ```

3. Restart the `ecs` service.
   - For the Amazon ECS-optimized Amazon Linux 2 AMI:
     ```
     sudo systemctl restart ecs
     ```
   - For the Amazon ECS-optimized Amazon Linux AMI:
     ```
     sudo stop ecs && sudo start ecs
     ```

4. (Optional) You can verify that the agent is running and see some information about your new container instance by querying the agent introspection API operation. For more information, see the section called “Container introspection”.

   ```
   curl http://localhost:51678/v1/metadata
   ```

Windows Spot Instance draining

Amazon EC2 terminates, stops, or hibernates your Spot Instance when the Spot price exceeds the maximum price for your request or capacity is no longer available. Amazon EC2 provides a Spot Instance interruption notice, which gives the instance a two-minute warning before it is interrupted. If Amazon ECS Spot Instance draining is enabled on the instance, ECS receives the Spot Instance interruption notice and places the instance in DRAINING status.

⚠️ Important

Amazon ECS monitors for the Spot Instance interruption notices that have the terminate and stop instance-actions. If you specified either the hibernate instance interruption behavior when requesting your Spot Instances or Spot Fleet, then Amazon ECS Spot Instance draining is not supported for those instances.
When a container instance is set to DRAINING, Amazon ECS prevents new tasks from being scheduled for placement on the container instance. Service tasks on the draining container instance that are in the PENDING state are stopped immediately. If there are container instances in the cluster that are available, replacement service tasks are started on them.

You must set the ECS_ENABLE_SPOT_INSTANCE_DRAINING parameter before you start the container agent. Use the following commands to manually turn on Spot Instance draining. Substitute my-cluster with the name of your cluster.

```bash
[Environment]::SetEnvironmentVariable("ECS_ENABLE_SPOT_INSTANCE_DRAINING", "true", "Machine")

# Initialize the agent
Initialize-ECSAgent -Cluster my-cluster
```

For more information, see the section called “Launching a container instance”.

### Linux instances

You can use EC2 instances with the following Linux operating systems to run your applications:

- **Amazon Linux**: This is a general purpose operating system.
- **Bottlerocket**: Bottlerocket is a Linux based open-source operating system that is purpose built by AWS for running containers on virtual machines or bare metal hosts. The Amazon ECS-optimized Bottlerocket AMI is secure and only includes the minimum number of packages that's required to run containers. This improves resource usage, reduces security attack surface, and helps lower management overhead. For information about the security features and guidance, see [Security Features](#) and [Security Guidance](#) on the GitHub website.

Amazon ECS provides the Amazon ECS-optimized AMIs that are preconfigured with the requirements and recommendations to run your container workloads. We recommend that you use the Amazon ECS-optimized Amazon Linux 2023 AMI for your Amazon EC2 instances unless your application requires Amazon EC2 GPU-based instances, a specific operating system or a Docker version that is not yet available in that AMI. For information about the the Amazon Linux 2 and Amazon Linux 2023 instances, see [Comparing Amazon Linux 2 and Amazon Linux 2023](#) in the Amazon Linux 2023 User Guide.

Although you can create your own Amazon EC2 instance AMI that meets the basic specifications needed to run your containerized workloads on Amazon ECS, the Amazon ECS-optimized AMIs are
preconfigured and tested on Amazon ECS by AWS engineers. It is the simplest way for you to get started and to get your containers running on AWS quickly.

An Amazon ECS container instance specification consists of the following components:

**Required**

- A Linux distribution running at least version 3.10 of the Linux kernel.
- The Amazon ECS container agent (preferably the latest version). For more information, see [Updating the Amazon ECS container agent](#).
- A Docker daemon running at least version 1.9.0, and any Docker runtime dependencies. For more information, see [Check runtime dependencies](#) in the Docker documentation.

**Note**

For the best experience, we recommend the Docker version that ships with and is tested with the corresponding Amazon ECS container agent version that you are using.

**Recommended**

- An initialization and nanny process to run and monitor the Amazon ECS container agent. The Amazon ECS-optimized AMIs use the `ecs-init` RPM to manage the agent. For more information, see the [ecs-init project](#) on GitHub.

**Topics**

- [Amazon ECS-optimized AMI](#)
- [Amazon ECS-optimized Bottlerocket AMIs](#)
- [Installing the Amazon ECS container agent](#)

**Amazon ECS-optimized AMI**

Amazon ECS provides the Amazon ECS-optimized AMIs that are preconfigured with the requirements and recommendations to run your container workloads. We recommend that you use the Amazon ECS-optimized Amazon Linux 2023 AMI for your Amazon EC2 instances unless your application requires Amazon EC2 GPU-based instances, a specific operating system or a Docker version that is not yet available in that AMI. For information about the the Amazon Linux 2 and
Amazon Linux 2023 instances, see Comparing Amazon Linux 2 and Amazon Linux 2023 in the Amazon Linux 2023 User Guide. Launching your container instances from the most recent Amazon ECS-Optimized AMI ensures that you receive the current security updates and container agent version. For information about how to launch an instance, see Launching an Amazon ECS Linux container instance.

The Linux variants of the Amazon ECS-optimized AMI use the Amazon Linux 2 AMI as their base. The Amazon Linux 2 AMI release notes are available as well. For more information, see Amazon Linux 2 release notes.

We recommend that you use an AMI with Linux kernel 5.10 because Linux kernel 4.14 reached end-of-life on January 10, 2024.

The following variants of the Amazon ECS-optimized AMI are available for your Amazon EC2 instances.

<table>
<thead>
<tr>
<th>Operating system</th>
<th>AMI</th>
<th>Description</th>
<th>Storage configuration</th>
</tr>

Amazon ECS provides a changelog for the Linux variant of the Amazon ECS-optimized AMI on GitHub. For more information, see [Changelog](#).

The Linux variants of the Amazon ECS-optimized AMI use the Amazon Linux 2 AMI or Amazon Linux 2023 AMI as their base. You can retrieve the Amazon Linux 2 source AMI name or the Amazon Linux 2023 AMI name for each variant by querying the Systems Manager Parameter Store API. For more information, see [Retrieving Amazon ECS-Optimized AMI metadata](#). The Amazon Linux 2 AMI

Linux instances
release notes are available as well. For more information, see Amazon Linux 2 release notes. The Amazon Linux 2023 release notes are available as well. For more information see, Amazon Linux 2023 release notes.

The following pages provide additional information about the changes:

- Source AMI release notes on GitHub
- Docker Engine release notes in the Docker documentation
- NVIDIA Driver Documentation in the NVIDIA documentation
- Amazon ECS Agent changelog on GitHub

The source code for the ecs-init application and the scripts and configuration for packaging the agent are now part of the agent repository. For older versions of ecs-init and packaging, see Amazon ecs-init changelog on GitHub

Retrieving Amazon ECS-Optimized AMI metadata

You can programatically retrieve the Amazon ECS-optimized AMI metadata. The metadata includes the AMI name, Amazon ECS container agent version, and Amazon ECS runtime version which includes the Docker version.

The AMI ID, image name, operating system, container agent version, source image name, and runtime version for each variant of the Amazon ECS-optimized AMIs can be programatically retrieved by querying the Systems Manager Parameter Store API. For more information about the Systems Manager Parameter Store API, see GetParameters and GetParametersByPath.

⚠️ Note

Your administrative user must have the following IAM permissions to retrieve the Amazon ECS-optimized AMI metadata. These permissions have been added to the AmazonECS_FullAccess IAM policy.

- ssm:GetParameters
- ssm:GetParameter
- ssm:GetParametersByPath
Systems Manager Parameter Store parameter format

The following is the format of the parameter name for each Amazon ECS-optimized AMI variant.

**Linux Amazon ECS-optimized AMIs**

- Amazon Linux 2023 AMI metadata:
  
  /aws/service/ecs/optimized-ami/amazon-linux-2023/<version>

- Amazon Linux 2023 (arm64) AMI metadata:
  
  /aws/service/ecs/optimized-ami/amazon-linux-2023/arm64/<version>

- Amazon Linux 2023 (Neuron) AMI metadata:
  
  /aws/service/ecs/optimized-ami/amazon-linux-2023/inf/<version>

- Amazon Linux 2 AMI metadata:
  
  /aws/service/ecs/optimized-ami/amazon-linux-2/<version>

- Amazon Linux 2 kernel 5.10 AMI metadata:
  
  /aws/service/ecs/optimized-ami/amazon-linux-2/kernel-5.10/<version>

- Amazon Linux 2 (arm64) AMI metadata:
  
  /aws/service/ecs/optimized-ami/amazon-linux-2/arm64/<version>

- Amazon Linux 2 kernel 5.10 (arm64) AMI metadata:
  
  /aws/service/ecs/optimized-ami/amazon-linux-2/kernel-5.10/arm64/<version>

- Amazon ECS GPU-optimized kernel 5.10 AMI metadata:
  
  /aws/service/ecs/optimized-ami/amazon-linux-2/kernel-5.10/gpu/<version>

- Amazon Linux 2 (GPU) AMI metadata:
  
  /aws/service/ecs/optimized-ami/amazon-linux-2/gpu/<version>
• Amazon ECS optimized Amazon Linux 2 (Neuron) kernel 5.10 AMI metadata:

/aws/service/ecs/optimized-ami/amazon-linux-2/kernel-5.10/inf/<version>

• Amazon Linux 2 (Neuron) AMI metadata:

/aws/service/ecs/optimized-ami/amazon-linux-2/inf/<version>

The following parameter name format retrieves the image ID of the latest stable Amazon ECS-optimized Amazon Linux 2 AMI by using the sub-parameter image_id.

/aws/service/ecs/optimized-ami/amazon-linux-2/recommended/image_id

The following parameter name format retrieves the metadata of a specific Amazon ECS-optimized AMI version by specifying the AMI name.

• Amazon ECS-optimized Amazon Linux 2 AMI metadata:

/aws/service/ecs/optimized-ami/amazon-linux-2/amzn2-ami-ecs-hvm-2.0.20181112-x86_64-ebs

Note

All versions of the Amazon ECS-optimized Amazon Linux 2 AMI are available for retrieval. Only Amazon ECS-optimized AMI versions amzn-ami-2017.09.1-amazon-ecs-optimized (Linux) and later can be retrieved.

Examples

The following examples show ways in which you can retrieve the metadata for each Amazon ECS-optimized AMI variant.

Retrieving the metadata of the latest stable Amazon ECS-optimized AMI

You can retrieve the latest stable Amazon ECS-optimized AMI using the AWS CLI with the following AWS CLI commands.
Linux Amazon ECS-optimized AMIs

- For the Amazon ECS-optimized Amazon Linux 2023 AMIs:

  ```
  aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2023/recommended --region us-east-1
  ```

- For the Amazon ECS-optimized Amazon Linux 2023 (arm64) AMIs:

  ```
  aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2023/arm64/recommended --region us-east-1
  ```

- For the Amazon ECS-optimized Amazon Linux 2 kernel 5.10 AMIs:

  ```
  aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/kernel-5.10/recommended --region us-east-1
  ```

- For the Amazon ECS-optimized Amazon Linux 2 AMIs:

  ```
  aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/recommended --region us-east-1
  ```

- For the Amazon ECS-optimized Amazon Linux 2 kernel 5.10 (arm64) AMIs:

  ```
  aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/kernel-5.10/arm64/recommended --region us-east-1
  ```

- For the Amazon ECS-optimized Amazon Linux 2 (arm64) AMIs:

  ```
  aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/arm64/recommended --region us-east-1
  ```

- For the Amazon ECS GPU-optimized kernel 5.10 AMIs:

  ```
  aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/kernel-5.10/gpu/recommended --region us-east-1
  ```

- For the Amazon ECS GPU-optimized AMIs:

  ```
  aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/gpu/recommended --region us-east-1
  ```
For the Amazon ECS optimized Amazon Linux 2 (Neuron) kernel 5.10 AMIs:

```bash
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/kernel-5.10/inf/recommended --region us-east-1
```

For the Amazon ECS optimized Amazon Linux 2 (Neuron) AMIs:

```bash
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/inf/recommended --region us-east-1
```

Retrieving the image ID of the latest recommended Amazon ECS-optimized Amazon Linux 2023 AMI

You can retrieve the image ID of the latest recommended Amazon ECS-optimized Amazon Linux 2023 AMI ID by using the sub-parameter `image_id`.

```bash
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2023/recommended/image_id --region us-east-1
```

To retrieve the `image_id` value only, you can query the specific parameter value; for example:

```bash
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2023/recommended/image_id --region us-east-1 --query "Parameters[0].Value"
```

Retrieving the metadata of a specific Amazon ECS-optimized Amazon Linux 2 AMI version

Retrieve the metadata of a specific Amazon ECS-optimized Amazon Linux AMI version using the AWS CLI with the following AWS CLI command. Replace the AMI name with the name of the Amazon ECS-optimized Amazon Linux AMI to retrieve.

```bash
aws ssm get-parameters --names /aws/service/ecs/optimized-ami/amazon-linux-2/amzn2-ami-ecs-hvm-2.0.20200928-x86_64-ebs --region us-east-1
```

Retrieving the Amazon ECS-optimized Amazon Linux 2 kernel 5.10 AMI metadata using the Systems Manager GetParametersByPath API

Retrieve the Amazon ECS-optimized Amazon Linux 2 AMI metadata with the Systems Manager GetParametersByPath API using the AWS CLI with the following command.
Retrieving the image ID of the latest recommended Amazon ECS-optimized Amazon Linux 2 kernel 5.10 AMI

You can retrieve the image ID of the latest recommended Amazon ECS-optimized Amazon Linux 2 kernel 5.10 AMI ID by using the sub-parameter image_id.

To retrieve the image_id value only, you can query the specific parameter value; for example:

Using the latest recommended Amazon ECS-optimized AMI in an AWS CloudFormation template

You can reference the latest recommended Amazon ECS-optimized AMI in an AWS CloudFormation template by referencing the Systems Manager parameter store name.

Linux example

Amazon ECS-optimized Linux AMI build script

Amazon ECS has open-sourced the build scripts that are used to build the Linux variants of the Amazon ECS-optimized AMI. These build scripts are now available on GitHub. For more information, see amazon-ecs-ami on GitHub.

The build scripts repository includes a HashiCorp packer template and build scripts to generate each of the Linux variants of the Amazon ECS-optimized AMI. These scripts are the source of truth for Amazon ECS-optimized AMI builds, so you can follow the GitHub repository to monitor changes.
to our AMIs. For example, perhaps you want your own AMI to use the same version of Docker that the Amazon ECS team uses for the official AMI.

For more information, see the Amazon ECS AMI repository at [aws/amazon-ecs-ami](https://github.com/aws/amazon-ecs-ami) on GitHub.

**To build an Amazon ECS-optimized Linux AMI**

1. **Clone the aws/amazon-ecs-ami GitHub repo.**
   
   ```bash
   git clone https://github.com/aws/amazon-ecs-ami.git
   ```

2. **Add an environment variable for the AWS Region to use when creating the AMI. Replace the `us-west-2` value with the Region to use.**
   
   ```bash
   export REGION=us-west-2
   ```

3. **A Makefile is provided to build the AMI. From the root directory of the cloned repository, use one of the following commands, corresponding to the Linux variant of the Amazon ECS-optimized AMI you want to build.**

   - **Amazon ECS-optimized Amazon Linux 2 AMI**
     
     ```bash
     make al2
     ```
   
   - **Amazon ECS-optimized Amazon Linux 2 (arm64) AMI**
     
     ```bash
     make al2arm
     ```
   
   - **Amazon ECS GPU-optimized AMI**
     
     ```bash
     make al2gpu
     ```
   
   - **Amazon ECS optimized Amazon Linux 2 (Neuron) AMI**
     
     ```bash
     make al2inf
     ```
   
   - **Amazon ECS-optimized Amazon Linux 2023 AMI**
     
     ```bash
     make al2023
     ```
   
   - **Amazon ECS-optimized Amazon Linux 2023 (arm64) AMI**
     
     ```bash
     make al2023arm
     ```
Amazon ECS-optimized Bottlerocket AMIs

Bottlerocket is a Linux based open-source operating system that is purpose built by AWS for running containers on virtual machines or bare metal hosts. The Amazon ECS-optimized Bottlerocket AMI is secure and only includes the minimum number of packages that's required to run containers. This improves resource usage, reduces security attack surface, and helps lower management overhead. The Bottlerocket AMI is also integrated with Amazon ECS to help reduce the operational overhead involved in updating container instances in a cluster.

Bottlerocket differs from Amazon Linux in the following ways:

- Bottlerocket doesn't include a package manager, and its software can only be run as containers. Updates to Bottlerocket are both applied and can be rolled back in a single step, which reduces the likelihood of update errors.
- The primary mechanism to manage Bottlerocket hosts is with a container scheduler. Unlike Amazon Linux, logging into individual Bottlerocket instances is intended to be an infrequent operation for advanced debugging and troubleshooting purposes only.

For more information about Bottlerocket, see the [documentation](https://github.com) and [releases](https://github.com) on GitHub.

There are variants of the Amazon ECS-optimized Bottlerocket AMI for kernel 6.1 and kernel 5.10.

The following variants use kernel 6.1:

- aws-ecs-2
- aws-ecs-2-nvidia

The following variants use kernel 5.1.10:

- aws-ecs-1
- aws-ecs-1-nvidia
For more information about the aws-ecs-1-nvidia variant, see [Announcing NVIDIA GPU support for Bottlerocket on Amazon ECS](https://aws.amazon.com/boto3/).

**Considerations**

Consider the following when using a Bottlerocket AMI with Amazon ECS.

- Bottlerocket supports Amazon EC2 instances with x86_64 and arm64 processors. The Bottlerocket AMI isn't recommended for use with Amazon EC2 instances with an Inferentia chip.
- Bottlerocket images don't include an SSH server or a shell. However, you can use out-of-band management tools to gain SSH administrator access and perform bootstrapping. For more information, see these sections in the [bottlerocket README.md](https://github.com/bottlerocketlabs/bottlerocket) on GitHub:
  - Exploration
  - Admin container
- By default, Bottlerocket has a control container that's enabled. This container runs the [AWS Systems Manager agent](https://docs.aws.amazon.com/systems-manager/latest/userguide/sysmgmt-agent.html) that you can use to run commands or start shell sessions on Amazon EC2 Bottlerocket instances. For more information, see [Setting up Session Manager](https://docs.aws.amazon.com/systems-manager/latest/userguide/session-manager-getting-started.html) in the [AWS Systems Manager User Guide](https://docs.aws.amazon.com/systems-manager/latest/userguide/sysmgmt-session-manager.html).
- Bottlerocket is optimized for container workloads and has a focus on security. Bottlerocket doesn't include a package manager and is immutable. For information about the security features and guidance, see [Security Features](https://github.com/bottlerocketlabs/bottlerocket/blob/main/README.md#security-features) and [Security Guidance](https://github.com/bottlerocketlabs/bottlerocket/blob/main/README.md#security-guidance) on GitHub.
- The awsvpc network mode is supported for Bottlerocket AMI version 1.1.0 or later.
- App Mesh in a task definition is supported for Bottlerocket AMI version 1.15.0 or later.
- The initProcessEnabled task definition parameter is supported for Bottlerocket AMI version 1.19.0 or later.
- The Bottlerocket AMIs also don't support the following services and features:
  - ECS Anywhere
  - Service Connect
  - Amazon EFS in encrypted mode and awsvpc network mode
  - Elastic Inference Accelerator
Retrieving an Amazon ECS-optimized Bottlerocket AMI

You can retrieve the Amazon Machine Image (AMI) ID for Amazon ECS-optimized AMIs by querying the AWS Systems Manager Parameter Store API. Using this parameter, you don't need to manually look up Amazon ECS-optimized AMI IDs. For more information about the Systems Manager Parameter Store API, see GetParameter. The user that you use must have the ssm:GetParameter IAM permission to retrieve the Amazon ECS-optimized AMI metadata.

Retrieving the `aws-ecs-2` Bottlerocket AMI variant

You can retrieve the latest stable `aws-ecs-2` Bottlerocket AMI variant by AWS Region and architecture with the AWS CLI or the AWS Management Console.

- **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon ECS-optimized Bottlerocket AMI with the following AWS CLI command by using the subparameter `image_id`. Replace the `region` with the Region code that you want the AMI ID for. For information about the supported AWS Regions, see Finding an AMI on GitHub. To retrieve a version other than the latest, replace `latest` with the version number.

  - For the 64-bit (x86_64) architecture:
    
    ```
    aws ssm get-parameter --region us-east-2 --name "/aws/service/bottlerocket/aws-ecs-2/x86_64/latest/image_id" --query Parameter.Value --output text
    ```

  - For the 64-bit Arm (arm64) architecture:
    
    ```
    aws ssm get-parameter --region us-east-2 --name "/aws/service/bottlerocket/aws-ecs-2/arm64/latest/image_id" --query Parameter.Value --output text
    ```

- **AWS Management Console** – You can query for the recommended Amazon ECS-optimized AMI ID using a URL in the AWS Management Console. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, replace `region` with the Region code that you want the AMI ID for. For information about the supported AWS Regions, see Finding an AMI on GitHub.

  - For the 64-bit (x86_64) architecture:
    
    ```
    ```

  - For the 64-bit Arm (arm64) architecture:
Retrieving the `aws-ecs-2-nvidia` Bottlerocket AMI variant

You can retrieve the latest stable `aws-ecs-2-nvidia` Bottlerocket AMI variant by Region and architecture with the AWS CLI or the AWS Management Console.

- **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon ECS-optimized Bottlerocket AMI with the following AWS CLI command by using the subparameter `image_id`. Replace the `region` with the Region code that you want the AMI ID for. For information about the supported AWS Regions, see [Finding an AMI](#) on GitHub. To retrieve a version other than the latest, replace `latest` with the version number.
  - For the 64-bit (x86_64) architecture:
    ```bash
    aws ssm get-parameter --region us-east-1 --name "/aws/service/bottlerocket/aws-ecs-2-nvidia/x86_64/latest/image_id" --query Parameter.Value --output text
    ```
  - For the 64 bit Arm (arm64) architecture:
    ```bash
    aws ssm get-parameter --region us-east-1 --name "/aws/service/bottlerocket/aws-ecs-2-nvidia/arm64/latest/image_id" --query Parameter.Value --output text
    ```

- **AWS Management Console** – You can query for the recommended Amazon ECS optimized AMI ID using a URL in the AWS Management Console. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, replace `region` with the Region code that you want the AMI ID for. For information about the supported AWS Regions, see [Finding an AMI](#) on GitHub.
  - For the 64 bit (x86_64) architecture:
    ```bash
    ```
  - For the 64 bit Arm (arm64) architecture:
    ```bash
    ```
Retrieving the `aws-ecs-1` Bottlerocket AMI variant

You can retrieve the latest stable `aws-ecs-1` Bottlerocket AMI variant by AWS Region and architecture with the AWS CLI or the AWS Management Console.

- **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon ECS-optimized Bottlerocket AMI with the following AWS CLI command by using the subparameter `image_id`. Replace the `region` with the Region code that you want the AMI ID for. For information about the supported AWS Regions, see Finding an AMI on GitHub. To retrieve a version other than the latest, replace `latest` with the version number.

  - For the 64-bit (x86_64) architecture:
    ```bash
    aws ssm get-parameter --region us-east-1 --name "/aws/service/bottlerocket/aws-ecs-1/x86_64/latest/image_id" --query Parameter.Value --output text
    ```

  - For the 64-bit Arm (arm64) architecture:
    ```bash
    aws ssm get-parameter --region us-east-1 --name "/aws/service/bottlerocket/aws-ecs-1/arm64/latest/image_id" --query Parameter.Value --output text
    ```

- **AWS Management Console** – You can query for the recommended Amazon ECS-optimized AMI ID using a URL in the AWS Management Console. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, replace `region` with the Region code that you want the AMI ID for. For information about the supported AWS Regions, see Finding an AMI on GitHub.

  - For the 64-bit (x86_64) architecture:
    ```bash
    ```

  - For the 64-bit Arm (arm64) architecture:
    ```bash
    ```

Retrieving the `aws-ecs-1-nvidia` Bottlerocket AMI variant

You can retrieve the latest stable `aws-ecs-1-nvidia` Bottlerocket AMI variant by Region and architecture with the AWS CLI or the AWS Management Console.
• **AWS CLI** – You can retrieve the image ID of the latest recommended Amazon ECS-optimized Bottlerocket AMI with the following AWS CLI command by using the subparameter `image_id`. Replace the `region` with the Region code that you want the AMI ID for. For information about the supported AWS Regions, see Finding an AMI on GitHub. To retrieve a version other than the latest, replace `latest` with the version number.

For the 64-bit (x86_64) architecture:

```bash
aws ssm get-parameter --region us-east-1 --name "/aws/service/bottlerocket/aws-ecs-1-nvidia/x86_64/latest/image_id" --query Parameter.Value --output text
```

For the 64 bit Arm (arm64) architecture:

```bash
aws ssm get-parameter --region us-east-1 --name "/aws/service/bottlerocket/aws-ecs-1-nvidia/arm64/latest/image_id" --query Parameter.Value --output text
```

• **AWS Management Console** – You can query for the recommended Amazon ECS optimized AMI ID using a URL in the AWS Management Console. The URL opens the Amazon EC2 Systems Manager console with the value of the ID for the parameter. In the following URL, replace `region` with the Region code that you want the AMI ID for. For information about the supported AWS Regions, see Finding an AMI on GitHub.

For the 64 bit (x86_64) architecture:

For the 64 bit Arm (arm64) architecture:

**Next steps**

For a detailed walkthrough of how to get started with the Bottlerocket operating system on Amazon ECS, see Using a Bottlerocket AMI with Amazon ECS on GitHub and Getting started with Bottlerocket and Amazon ECS on the AWS blog site.

For information about how to launch a Bottlerocket instance, see Launching a Bottlerocket instance.
Launching a Bottlerocket instance

You can launch a Bottlerocket instance so that you can run your container workloads.

You can use the AWS CLI to launch the Bottlerocket instance.

1. Create a file that’s called `userdata.toml`. This file is used for the instance user data. Replace `cluster-name` with the name of your cluster.

   ```toml
   [settings.ecs]
   cluster = "cluster-name"
   ```

2. Use one of the commands that are included in the section called “Retrieving an Amazon ECS-optimized Bottlerocket AMI” to get the Bottlerocket AMI ID. You use this in the following step.

3. Run the following command to launch the Bottlerocket instance. Remember to replace the following parameters:

   - Replace `subnet` with the ID of the private or public subnet that your instance will launch in.
   - Replace `bottlerocket_ami` with the AMI ID from the previous step.
   - Replace `t3.large` with the instance type that you want to use.
   - Replace `region` with the Region code.

   ```bash
   aws ec2 run-instances --key-name ecs-bottlerocket-example \
   --subnet-id subnet \
   --image-id bottlerocket_ami \
   --instance-type t3.large \
   --region region \
   --tag-specifications 'ResourceType=instance,Tags=[{Key=bottlerocket,Value=example}]' \
   --user-data file://userdata.toml \
   --iam-instance-profile Name=ecsInstanceRole
   ```

4. Run the following command to verify that the container instance is registered to the cluster. When you run this command, remember to replace the following parameters:

   - Replace `cluster` with your cluster name.
   - Replace `region` with your Region code.
For a detailed walkthrough of how to get started with the Bottlerocket operating system on Amazon ECS, see Using a Bottlerocket AMI with Amazon ECS on GitHub and Getting started with Bottlerocket and Amazon ECS on the AWS blog site.

Installing the Amazon ECS container agent

If your container instance was not launched using an Amazon ECS-optimized AMI, you can install the Amazon ECS container agent manually using one of the following procedures. The Amazon ECS container agent is included in the Amazon ECS-optimized AMIs and does not require installation.

- For Amazon Linux 2 instances, you can install the agent using the `amazon-linux-extras` command. For more information, see Installing the Amazon ECS container agent on an Amazon Linux 2 EC2 instance.

- For Amazon Linux AMIs instances, you can install the agent using the Amazon YUM repo. For more information, see Installing the Amazon ECS container agent on an Amazon Linux EC2 instance.

- For non-Amazon Linux instances, you can either download the agent from one of the regional S3 buckets or from Amazon Elastic Container Registry Public. If you download from one of the regional S3 buckets, you can optionally verify the validity of the container agent file using the PGP signature. For more information, see Installing the Amazon ECS container agent on a non-Amazon Linux EC2 instance.

**Note**

The systemd units for both Amazon ECS and Docker services have a directive to wait for cloud-init to finish before starting both services. The cloud-init process is not considered finished until your Amazon EC2 user data has finished running. Therefore, starting Amazon ECS or Docker via Amazon EC2 user data may cause a deadlock. To start the container agent using Amazon EC2 user data you can use `systemctl enable --now --no-block ecs.service`.
Installing the Amazon ECS container agent on an Amazon Linux 2 EC2 instance

To install the Amazon ECS container agent on an Amazon Linux 2 EC2 instance using the `amazon-linux-extras` command, use the following steps.

1. Launch an Amazon Linux 2 EC2 instance with an IAM role that allows access to Amazon ECS. For more information, see Amazon ECS container instance IAM role.
2. Connect to your instance.
3. Disable the `docker` Amazon Linux extra repository. The `ecs` Amazon Linux extra repository ships with its own version of Docker, so the `docker` extra must be turned off to avoid any potential future conflicts. This ensures that you are always using the Docker version that Amazon ECS intends for you to use with a particular version of the container agent.

```
[ec2-user ~]$ sudo amazon-linux-extras disable docker
```

4. Install and enable the `ecs` Amazon Linux extra repository.

```
[ec2-user ~]$ sudo amazon-linux-extras install -y ecs; sudo systemctl enable --now ecs
```

5. (Optional) You can verify that the agent is running and see some information about your new container instance with the agent introspection API. For more information, see the section called “Container introspection”.

```
[ec2-user ~]$ curl -s http://localhost:51678/v1/metadata | python -mjson.tool
```

**Note**

If you get no response, ensure that you associated the Amazon ECS container instance IAM role when launching the instance. For more information, see Amazon ECS container instance IAM role.

Installing the Amazon ECS container agent on an Amazon Linux EC2 instance

To install the Amazon ECS container agent on an Amazon Linux EC2 instance using the Amazon YUM repo, use the following steps.
To install the Amazon ECS container agent on an Amazon Linux EC2 instance

1. Launch an Amazon Linux EC2 instance with an IAM role that allows access to Amazon ECS. For more information, see Amazon ECS container instance IAM role.

2. Connect to your instance.

3. Install the ecs-init package. For more information about ecs-init, see the source code on GitHub.

   ```
   [ec2-user ~]$ sudo yum install -y ecs-init
   ```

4. Start the Docker daemon.

   ```
   [ec2-user ~]$ sudo service docker start
   ```

   Output:

   ```
   Starting cgconfig service: [  OK  ]
   Starting docker: [  OK  ]
   ```

5. Start the ecs-init upstart job.

   ```
   [ec2-user ~]$ sudo service ecs start
   ```

   Output:

   ```
   ecs start/running, process 2804
   ```

6. (Optional) You can verify that the agent is running and see some information about your new container instance with the agent introspection API. For more information, see the section called “Container introspection”.

   ```
   [ec2-user ~]$ curl -s http://localhost:51678/v1/metadata | python -mjson.tool
   ```

Installing the Amazon ECS container agent on a non-Amazon Linux EC2 instance

To install the Amazon ECS container agent on a non-Amazon Linux EC2 instance, you can download the agent from one of the regional S3 buckets and install it.
### Note

When using a non-Amazon Linux AMI, your Amazon EC2 instance requires `cgroupfs` support for the `cgroup` driver in order for the Amazon ECS agent to support task level resource limits. For more information, see Amazon ECS agent on GitHub.

The latest Amazon ECS container agent files, by Region, for each system architecture are listed below for reference.

**To install the Amazon ECS container agent on an Amazon EC2 instance using a non-Amazon Linux AMI**

1. Launch an Amazon EC2 instance with an IAM role that allows access to Amazon ECS. For more information, see [Amazon ECS container instance IAM role](#).
2. Connect to your instance.
3. Install the latest version of Docker on your instance.
4. Check your Docker version to verify that your system meets the minimum version requirement.

### Note

The minimum Docker version for reliable metrics is Docker version v20.10.13 and newer, which is included in Amazon ECS-optimized AMI 20220607 and newer. Amazon ECS agent versions 1.20.0 and newer have deprecated support for Docker versions older than 1.9.0.

```bash
docker --version
```

5. Download the appropriate Amazon ECS agent file for your operating system and system architecture and install it.
For deb architectures:

```
ubuntu:~$ sudo dpkg -i amazon-ecs-init-latest.amd64.deb
```

For rpm architectures:

```
fedora:~$ sudo yum localinstall -y amazon-ecs-init-latest.x86_64.rpm
```

6. Edit the `/lib/systemd/system/ecs.service` file and add the following line at the end of the `[Unit]` section.

```
After=cloud-final.service
```

7. (Optional) To register the instance with a cluster other than the default cluster, edit the `/etc/ecs/ecs.config` file and add the following contents. The following example specifies the MyCluster cluster.

```
ECS_CLUSTER=MyCluster
```

For more information about these and other agent runtime options, see Amazon ECS container agent configuration.

⚠️ **Note**

You can optionally store your agent environment variables in Amazon S3 (which can be downloaded to your container instances at launch time using Amazon EC2 user data). This is recommended for sensitive information such as authentication credentials for private repositories. For more information, see Storing container instance configuration in Amazon S3 and Private registry authentication for tasks.

8. Start the `ecs` service.

```
ubuntu:~$ sudo systemctl start ecs
```
Running the Amazon ECS agent with host network mode

When running the Amazon ECS container agent, `ecs-init` will create the container agent container with the host network mode. This is the only supported network mode for the container agent container.

This allows you to block access to the Amazon EC2 instance metadata service endpoint (http://169.254.169.254) for the containers started by the container agent. This ensures that containers cannot access IAM role credentials from the container instance profile and enforces that tasks use only the IAM task role credentials. For more information, see Task IAM role.

This also makes it so the container agent doesn't contend for connections and network traffic on the `docker0` bridge.

Windows instances

An Amazon ECS container instance is an Amazon EC2 instance that is running the Amazon ECS container agent and has been registered into an Amazon ECS cluster. When you run tasks with Amazon ECS using the EC2 launch type or an AutoScaling group capacity provider, your tasks are placed on your active container instances.

Note

Tasks using the Fargate launch type are deployed onto infrastructure managed by AWS, so this topic does not apply.

Topics

- Amazon ECS-optimized AMI
- Building your own Amazon ECS-optimized Windows AMI

Amazon ECS-optimized AMI

The Amazon ECS-optimized AMIs are preconfigured with the necessary components that you need to run Amazon ECS workloads. Although you can create your own container instance AMI that meets the basic specifications needed to run your containerized workloads on Amazon ECS, the Amazon ECS-optimized AMIs are preconfigured and tested on Amazon ECS by AWS engineers. It is the simplest way for you to get started and to get your containers running on AWS quickly.
The Amazon ECS-optimized AMI metadata, including the AMI name, Amazon ECS container agent version, and Amazon ECS runtime version which includes the Docker version, for each variant can be retrieved programmatically. For more information, see the section called “Retrieving Amazon ECS-Optimized AMI metadata“.

You can subscribe to the Windows AMI Amazon SNS topics to be notified when a new AMI is released or an AMI version is marked private. For more information, see Subscribing to Amazon ECS-optimized AMI update notifications.

⚠️ Important

All ECS-optimized AMI variants produced after August will be migrating from Docker EE (Mirantis) to Docker CE (Moby project).

To ensure that customers have the latest security updates by default, Amazon ECS maintains at least the last three Windows Amazon ECS-optimized AMIs. After releasing new Windows Amazon ECS-optimized AMIs, Amazon ECS makes the Windows Amazon ECS-optimized AMIs that are older private. If there is a private AMI that you need access to, let us know by filing a ticket with Cloud Support.

Amazon ECS-optimized AMI variants

The following Windows Server variants of the Amazon ECS-optimized AMI are available for your Amazon EC2 instances.

⚠️ Important

All ECS-optimized AMI variants produced after August will be migrating from Docker EE (Mirantis) to Docker CE (Moby project).

- Amazon ECS-optimized Windows Server 2022 Full AMI
- Amazon ECS-optimized Windows Server 2022 Core AMI
- Amazon ECS-optimized Windows Server 2019 Full AMI
- Amazon ECS-optimized Windows Server 2019 Core AMI
- Amazon ECS-optimized Windows Server 2016 Full AMI
- Amazon ECS-optimized Windows Server 20H2 Core AMI
Important

On August 9, 2022, the Amazon ECS-optimized Windows Server 20H2 Core AMI reached its end of support date. No new versions of this AMI will be released. For more information, see Windows Server release information.

Windows Server 2022, Windows Server 2019, and Windows Server 2016 are Long-Term Servicing Channel (LTSC) releases. Windows Server 20H2 is a Semi-Annual Channel (SAC) release. For more information, see Windows Server release information.

Windows container caveats

Here are some things you should know about Amazon EC2 Windows containers and Amazon ECS.

- Windows containers can't run on Linux container instances, and the opposite is also the case. For better task placement for Windows and Linux tasks, keep Windows and Linux container instances in separate clusters and only place Windows tasks on Windows clusters. You can ensure that Windows task definitions are only placed on Windows instances by setting the following placement constraint: memberOf(ecs.os-type=='windows').

- Windows containers are supported for tasks that use the EC2 and Fargate launch types.

- Windows containers and container instances can't support all the task definition parameters that are available for Linux containers and container instances. For some parameters, they aren't supported at all, and others behave differently on Windows than they do on Linux. For more information, see EC2 Windows considerations.

- For the IAM roles for tasks feature, you need to configure your Windows container instances to allow the feature at launch. Your containers must run some provided PowerShell code when they use the feature. For more information, see Additional configuration for Windows IAM roles for tasks.

- The IAM roles for tasks feature uses a credential proxy to provide credentials to the containers. This credential proxy occupies port 80 on the container instance, so if you use IAM roles for tasks, port 80 is not available for tasks. For web service containers, you can use an Application Load Balancer and dynamic port mapping to provide standard HTTP port 80 connections to your containers. For more information, see Distribute Amazon ECS service traffic using load balancing.

- The Windows Server Docker images are large (9 GiB). So, your Windows container instances require more storage space than Linux container instances.
To run a Windows container on a Windows Server, the container's base image OS version must match that of the host. For more information, see Windows container version compatibility on the Microsoft documentation website. If your cluster runs multiple Windows versions, you can ensure that a task is placed on an EC2 instance running on the same version by using the placement constraint: `memberOf(attribute:ecs.os-family == WINDOWS_SERVER_<OS_Release>_FULL or CORE)`. For more information, see the section called “Retrieving Amazon ECS-Optimized AMI metadata”.

**Retrieving Amazon ECS-Optimized AMI metadata**

The AMI ID, image name, operating system, container agent version, and runtime version for each variant of the Amazon ECS-optimized AMIs can be programmatically retrieved by querying the Systems Manager Parameter Store API. For more information about the Systems Manager Parameter Store API, see GetParameters and GetParametersByPath.

**Note**

Your administrative user must have the following IAM permissions to retrieve the Amazon ECS-optimized AMI metadata. These permissions have been added to the AmazonECS_FullAccess IAM policy.

- ssm:GetParameters
- ssm:GetParameter
- ssm:GetParametersByPath

**Systems Manager Parameter Store parameter format**

**Note**

The following Systems Manager Parameter Store API parameters are deprecated and should not be used to retrieve the latest Windows AMIs:

- /aws/service/ecs/optimized-ami/windows_server/2016/english/full/recommended/image_id
- /aws/service/ecs/optimized-ami/windows_server/2019/english/full/recommended/image_id
The following is the format of the parameter name for each Amazon ECS-optimized AMI variant.

- Windows Server 2022 Full AMI metadata:
  /aws/service/ami-windows-latest/Windows_Server-2022-English-Full-ECS_Optimized

- Windows Server 2022 Core AMI metadata:
  /aws/service/ami-windows-latest/Windows_Server-2022-English-Core-ECS_Optimized

- Windows Server 2019 Full AMI metadata:

- Windows Server 2019 Core AMI metadata:

- Windows Server 2016 Full AMI metadata:
  /aws/service/ami-windows-latest/Windows_Server-2016-English-Full-ECS_Optimized

The following parameter name format retrieves the metadata of the latest stable Windows Server 2019 Full AMI:

```
```

The following is an example of the JSON object that is returned for the parameter value.

```
{
   "Parameters": [
      {
         "Name": "/aws/service/ami-windows-latest/Windows_Server-2019-English-Full-ECS_Optimized",
         "Type": "String",
         "Value": "{\"image_name\":\"Windows_Server-2019-English-Full-ECS_Optimized-2023.06.13\",\"image_id\":\"ami-0debc1fb48e4ae16\",\"ecs_runtime_version\":\"Docker (CE) version 20.10.21\",\"ecs_agent_version\":\"1.72.0\"}",
         "Version": 58,
```
Each of the fields in the output above are available to be queried as sub-parameters. Construct the parameter path for a sub-parameter by appending the sub-parameter name to the path for the selected AMI. The following sub-parameters are available:

- `schema_version`
- `image_id`
- `image_name`
- `os`
- `ecs_agent_version`
- `ecs_runtime_version`

**Examples**

The following examples show ways in which you can retrieve the metadata for each Amazon ECS-optimized AMI variant.

**Retrieving the metadata of the latest stable Amazon ECS-optimized AMI**

You can retrieve the latest stable Amazon ECS-optimized AMI using the AWS CLI with the following AWS CLI commands.

- **For the Amazon ECS-optimized Windows Server 2022 Full AMI:**
  
  ```
  ```

- **For the Amazon ECS-optimized Windows Server 2022 Core AMI:**
  
  ```
  aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2022-English-Core-ECS_Optimized --region us-east-1
  ```
• For the Amazon ECS-optimized Windows Server 2019 Full AMI:

```bash
```

• For the Amazon ECS-optimized Windows Server 2019 Core AMI:

```bash
```

• For the Amazon ECS-optimized Windows Server 2016 Full AMI:

```bash
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2016-English-Full-ECS_Optimized --region us-east-1
```

Using the latest recommended Amazon ECS-optimized AMI in an AWS CloudFormation template

You can reference the latest recommended Amazon ECS-optimized AMI in an AWS CloudFormation template by referencing the Systems Manager parameter store name.

Parameters:

- **LatestECSOptimizedAMI:**
  - Description: AMI ID
  - Type: AWS::SSM::Parameter::Value<AWS::EC2::Image::Id>

Subscribing to Amazon ECS-optimized AMI update notifications

AWS provides two Amazon SNS topic ARNs for notifications related to the Windows Server AMIs. One topic sends update notifications when new Windows Server AMIs are released. The other topic sends notifications when previously released Windows Server AMIs are made private. While these topics are not specific to the Amazon ECS-optimized Windows AMIs, because the Amazon ECS-optimized Windows AMIs follow the same release schedule, you can use these notifications for an indication for when new Amazon ECS-optimized Windows AMIs are updated. For more information on subscribing to Windows AMI notifications, see [Subscribing to Windows AMI notifications](#) in the *Amazon EC2 User Guide for Windows Instances*.
Note

Your user, or the role attached to your user must have the `sns::subscribe` IAM permission to subscribe to an Amazon SNS topic.

Amazon ECS-optimized AMI versions

View the current and previous versions of the Amazon ECS-optimized AMIs and their corresponding versions of the Amazon ECS container agent, Docker, and the `ecs-init` package.

The Amazon ECS-optimized AMI metadata, including the AMI ID, for each variant can be retrieved programatically. For more information, see the section called “Retrieving Amazon ECS-Optimized AMI metadata”.

Windows Amazon ECS-optimized AMIs versions

The following tabs display a list of Windows Amazon ECS-optimized AMIs versions.

Note

For details on referencing the Systems Manager Parameter Store parameter in an AWS CloudFormation template, see Using the latest recommended Amazon ECS-optimized AMI in an AWS CloudFormation template.

Important

To ensure that customers have the latest security updates by default, Amazon ECS maintains at least the last three Windows Amazon ECS-optimized AMIs. After releasing new Windows Amazon ECS-optimized AMIs, Amazon ECS makes the Windows Amazon ECS-optimized AMIs that are older private. If there is a private AMI that you need access to, let us know by filing a ticket with Cloud Support.

Windows Server 2022 Full AMI versions

The table below lists the current and previous versions of the Amazon ECS-optimized Windows Server 2022 Full AMI and their corresponding versions of the Amazon ECS container agent and Docker.
<table>

Use the following AWS CLI Amazon ECS-optimized Windows Server 2016 Full AMI.

```
aws ssm get-parameters --names /aws/service/ami-windows-latest/Windows_Server-2016-English-Full-ECS_Optimized
```

**Building your own Amazon ECS-optimized Windows AMI**

Use EC2 Image Builder to build your own custom Amazon ECS-optimized Windows AMI. This makes it easy to use a Windows AMI with your own license on Amazon ECS. Amazon ECS provides a managed Image Builder component which provides the system configuration needed to run Windows instances to host your containers. Each Amazon ECS managed component includes a specific container agent and Docker version. You can customize your image to use either the latest
Amazon ECS managed component, or if an older container agent or Docker version is needed, you can specify a different component.

For a full walkthrough of using EC2 Image Builder, see Getting started with EC2 Image Builder in the EC2 Image Builder User Guide.

When building your own Amazon ECS-optimized Windows AMI using EC2 Image Builder, you create an image recipe. Your image recipe must meet the following requirements:

- **The Source image** should be based on Windows Server 2016 Full, Windows Server 2019 Core, Windows Server 2019 Full, Windows Server 2022 Core, or Windows Server 2022 Full. Any other Windows operating system is not supported and may not be compatible with the component.

- **When specifying the Build components**, the ecs-optimized-ami-windows component is required. The update-windows component is recommended, which ensures the image contains the latest security updates.

  To specify a different component version, expand the **Versioning options** menu and specify the component version you want to use. For more information, see Listing the ecs-optimized-ami-windows component versions.

**Listing the ecs-optimized-ami-windows component versions**

When creating an EC2 Image Builder recipe and specifying the ecs-optimized-ami-windows component, you can either use the default option or you can specify a specific component version. To determine what component versions are available, along with the Amazon ECS container agent and Docker versions contained within the component, you can use the AWS Management Console.

Windows instances
To list the available `ecs-optimized-ami-windows` component versions

2. On the navigation bar, select the Region that are building your image in.
3. In the navigation pane, under the Saved configurations menu, choose Components.
4. On the Components page, in the search bar type `ecs-optimized-ami-windows` and pull down the qualification menu and select Quick start (Amazon-managed).
5. Use the Description column to determine the component version with the Amazon ECS container agent and Docker version your image requires.

External instances (Amazon ECS Anywhere)

Amazon ECS Anywhere provides support for registering an external instance such as an on-premises server or virtual machine (VM), to your Amazon ECS cluster. External instances are optimized for running applications that generate outbound traffic or process data. If your application requires inbound traffic, the lack of Elastic Load Balancing support makes running these workloads less efficient. Amazon ECS added a new EXTERNAL launch type that you can use to create services or run tasks on your external instances.

The following provides a high-level system architecture overview of Amazon ECS Anywhere.
Topics

- Supported operating systems and system architectures
- Considerations
- Registering an external instance to a cluster
- Deregistering an external instance
- Updating the AWS Systems Manager Agent and Amazon ECS container agent on an external instance

Supported operating systems and system architectures

The following is the list of supported operating systems and system architectures.

- Amazon Linux 2
- CentOS 7
- CentOS Stream 8
- RHEL 7, RHEL 8 — Neither Docker or RHEL's open package repositories support installing Docker natively on RHEL. You must ensure that Docker is installed before you run the install script that's described in this document.
- Fedora 32, Fedora 33
- openSUSE Tumbleweed
- Ubuntu 18, Ubuntu 20, Ubuntu 22
- Debian 10

⚠️ Important

Debian 9 Long Term Support (LTS support) ended on June 30, 2022 and is no longer supported by Amazon ECS Anywhere.

- SUSE Enterprise Server 15
- The x86_64 and ARM64 CPU architectures are supported.
- The following Windows operating system versions are supported:
  - Windows Server 2022
  - Windows Server 2019
Considerations

Before you start using external instances, be aware of the following considerations.

- You can register an external instance to one cluster at a time. For instructions on how to register an external instance with a different cluster, see Deregistering an external instance.
- Your external instances require an IAM role that allows them to communicate with AWS APIs. For more information, see ECS Anywhere IAM role.
- Your external instances should not have a preconfigured instance credential chain defined locally as this will interfere with the registration script.
- To send container logs to CloudWatch Logs, make sure that you create and specify a task execution IAM role in your task definition.
- When an external instance is registered to a cluster, the ecs.capability.external attribute is associated with the instance. This attribute identifies the instance as an external instance. You can add custom attributes to your external instances to use as a task placement constraint. For more information, see Custom attributes.
- You can add resource tags to your external instance. For more information, see Tagging an external container instance.
- ECS Exec is supported on external instances. For more information, see Monitor Amazon ECS containers with ECS Exec.
- The following are additional considerations that are specific to networking with your external instances. For more information, see Networking with ECS Anywhere.
  - Service load balancing isn't supported.
  - Service discovery isn't supported.
  - Tasks that run on external instances must use the bridge, host, or none network modes. The awsvpc network mode isn't supported.
  - There are Amazon ECS service domains in each AWS Region. These service domains must be allowed to send traffic to your external instances.
  - The SSM Agent installed on your external instance maintains IAM credentials that are rotated every 30 minutes using a hardware fingerprint. If your external instance loses connection to AWS, the SSM Agent automatically refreshes the credentials after the connection is re-
Networking with ECS Anywhere

Amazon ECS external instances are optimized for running applications that generate outbound traffic or process data. If your application requires inbound traffic, such as a web service, the lack of Elastic Load Balancing support makes running these workloads less efficient because there isn't support for placing these workloads behind a load balancer.

The following are additional considerations that are specific to networking with your external instances.

- Service load balancing isn't supported.
- Service discovery isn't supported.
• Linux tasks that run on external instances must use the bridge, host, or none network modes. The awsvpc network mode isn't supported.

For more information about each network mode, see Choosing a network mode in the Amazon ECS Best Practices Guide.

• Windows tasks that run on external instances must use the default network mode.

• There are Amazon ECS service domains in each Region and must be allowed to send traffic to your external instances.

• The SSM Agent installed on your external instance maintains IAM credentials that are rotated every 30 minutes using a hardware fingerprint. If your external instance loses connection to AWS, the SSM Agent automatically refreshes the credentials after the connection is re-established. For more information, see Validating on-premises servers and virtual machines using a hardware fingerprint in the AWS Systems Manager User Guide.

The following domains are used for communication between the Amazon ECS service and the Amazon ECS agent that's installed on your external instance. Make sure that traffic is allowed and that DNS resolution works. For each endpoint, region represents the Region identifier for an AWS Region that's supported by Amazon ECS, such as us-east-2 for the US East (Ohio) Region. The endpoints for all Regions that you use should be allowed. For the ecs-a and ecs-t endpoints, you should include an asterisk (for example, ecs-a-*)..

• ecs-a-*.region.amazonaws.com — This endpoint is used when managing tasks.
• ecs-t-*.region.amazonaws.com — This endpoint is used to manage task and container metrics.
• ecs.region.amazonaws.com — This is the service endpoint for Amazon ECS.
• ssm.region.amazonaws.com — This is the service endpoint for AWS Systems Manager.
• ec2messages.region.amazonaws.com — This is the service endpoint that AWS Systems Manager uses to communicate between the Systems Manager agent and the Systems Manager service in the cloud.
• ssmmessages.region.amazonaws.com — This is the service endpoint that is required to create and delete session channels with the Session Manager service in the cloud.

• If your tasks require communication with any other AWS services, make sure that those service endpoints are allowed. Example applications include using Amazon ECR to pull container images or using CloudWatch for CloudWatch Logs. For more information, see Service endpoints in the AWS General Reference.
Amazon FSx for Windows File Server with ECS Anywhere

In order to use the Amazon FSx for Windows File Server with Amazon ECS external instances you must establish a connection between your on-premises data center and the AWS Cloud. For information about the options for connecting your network to your VPC, see Amazon Virtual Private Cloud Connectivity Options.

gMSA with ECS Anywhere

The following use cases are supported for ECS Anywhere.

- The Active Directory is in the AWS Cloud - For this configuration, you create a connection between your on-premises network and the AWS Cloud using an AWS Direct Connect connection. For information about how to create the connection, see Amazon Virtual Private Cloud Connectivity Options. You create an Active Directory in the AWS Cloud. For information about how to get started with AWS Directory Service, see Setting up AWS Directory Service in the AWS Directory Service Administration Guide. You can then join your external instances to the domain using the AWS Direct Connect connection. For information about working with gMSA with Amazon ECS, see the section called “Using gMSAs for Windows Containers on Amazon EC2”.

- The Active Directory is in the on-premises data center. - For this configuration, you join your external instances to the on-premises Active Directory. You then use the locally available credentials when you run the Amazon ECS tasks.

Registering an external instance to a cluster

For each external instance you register with an Amazon ECS cluster, it must have the SSM Agent, the Amazon ECS container agent, and Docker installed. To register the external instance to an Amazon ECS cluster, it must first be registered as an AWS Systems Manager managed instance. You can create the installation script in a few clicks on the Amazon ECS console. The installation script includes an Systems Manager activation key and commands to install each of the required agents and Docker. The installation script must be run on your on-premises server or VM to complete the installation and registration steps.

Note

Before registering your Linux external instance with the cluster, create the /etc/ecs/ecs.config file on your external instance and add any container agent configuration
parameters that you want. You can't do this after registering the external instance to a cluster. For more information, see Amazon ECS container agent configuration.

AWS Management Console

2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose Clusters.
4. On the Clusters page, choose a cluster to register your external instance to.
5. On the Cluster : name page, choose the Infrastructure tab.
6. On the Register external instances page, complete the following steps.
   a. For Activation key duration (in days), enter the number of days that the activation key remains active for. After the number of days you entered pass, the key no longer works when registering an external instance.
   b. For Number of instances, enter the number of external instances that you want to register to your cluster with the activation key.
   c. For Instance role, choose the IAM role to associate with your external instances. If a role wasn't already created, choose Create new role to have Amazon ECS create a role on your behalf. For more information about what IAM permissions are required for your external instances, see ECS Anywhere IAM role.
   d. Copy the registration command. This command should be run on each external instance you want to register to the cluster.
   e. Choose Close.

AWS CLI for Linux operating systems

1. Create an Systems Manager activation pair. This is used for Systems Manager managed instance activation. The output includes an ActivationId and ActivationCode. You
use these in a later step. Make sure that you specify the ECS Anywhere IAM role that you created. For more information, see [ECS Anywhere IAM role](#).

```bash
aws ssm create-activation --iam-role ecsAnywhereRole | tee ssm-activation.json
```

2. On your on-premises server or virtual machine (VM), download the installation script.

```bash
```

3. (Optional) On your on-premises server or virtual machine (VM), use the following steps to verify the installation script using the script signature file.

   a. Download and install GnuPG. For more information about GNUpg, see the [GnuPG website](#). For Linux systems, install gpg using the package manager on your flavor of Linux.

   b. Retrieve the Amazon ECS PGP public key.

   ```bash
gpg --keyserver hkp://keys.gnupg.net:80 --recv BCE9D9A42D51784F
   ```

   c. Download the installation script signature. The signature is an ascii detached PGP signature stored in a file with the .asc extension.

   ```bash
   ```

   d. Verify the installation script file using the key.

   ```bash
gpg --verify /tmp/ecs-anywhere-install.sh.asc /tmp/ecs-anywhere-install.sh
   ```

   The following is the expected output.

   ```
gpg: Signature made Tue 25 May 2021 07:16:29 PM UTC
gpg: using RSA key 50DECCC4710E61AF
gpg: Good signature from "Amazon ECS <ecs-security@amazon.com>" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg: There is no indication that the signature belongs to the owner.
Primary key fingerprint: F34C 3DDA E729 26B0 79BE AEC6 BCE9 D9A4 2D51 784F
Subkey fingerprint: D64B B6F9 0CF3 77E9 B5FB 346F 50DE CCC4 710E 61AF
```
4. On your on-premises server or virtual machine (VM), run the installation script. Specify the cluster name, Region, and the Systems Manager activation ID and activation code from the first step.

```bash
sudo bash /tmp/ecs-anywhere-install.sh \
  --region $REGION \
  --cluster $CLUSTER_NAME \
  --activation-id $ACTIVATION_ID \
  --activation-code $ACTIVATION_CODE
```

For an on-premises server or virtual machine (VM) that has the NVIDIA driver installed for GPU workloads, you must add the `--enable-gpu` flag to the installation script. When this flag is specified, the install script verifies that the NVIDIA driver is running and then adds the required configuration variables to run your Amazon ECS tasks. For more information about running GPU workloads and specifying GPU requirements in a task definition, see [Specifying GPUs in your task definition](#).

```bash
sudo bash /tmp/ecs-anywhere-install.sh \
  --region $REGION \
  --cluster $CLUSTER_NAME \
  --activation-id $ACTIVATION_ID \
  --activation-code $ACTIVATION_CODE \
  --enable-gpu
```

Use the following steps to register an existing external instance with a different cluster.

**To register an existing external instance with a different cluster**

1. Stop the Amazon ECS container agent.

   ```bash
   sudo systemctl stop ecs.service
   ```

2. Edit the `/etc/ecs/ecs.config` file and on the ECS_CLUSTER line, ensure the cluster name matches the name of the cluster to register the external instance with.

3. Remove the existing Amazon ECS agent data.

   ```bash
   sudo rm /var/lib/ecs/data/agent.db
   ```

4. Start the Amazon ECS container agent.
AWS CLI for Windows operating systems

1. Create an Systems Manager activation pair. This is used for Systems Manager managed instance activation. The output includes an ActivationId and ActivationCode. You use these in a later step. Make sure that you specify the ECS Anywhere IAM role that you created. For more information, see [ECS Anywhere IAM role](#).

   ```bash
   aws ssm create-activation --iam-role ecsAnywhereRole | tee ssm-activation.json
   ```

2. On your on-premises server or virtual machine (VM), download the installation script.

   ```powershell
   ```

3. (Optional) The Powershell script is signed by Amazon and therefore, Windows automatically performs the certificate validation on the same. You do not need to perform any manual validation.

   To manually verify the certificate, right-click on the file, navigate to properties and use the Digital Signatures tab to obtain more details.

   This option is only available when the host has the certificate in the certificate store.

   The verification should return information similar to the following:

   ```powershell
   # Verification (PowerShell)
   Get-AuthenticodeSignature -FilePath .\ecs-anywhere-install.ps1
   
   SignerCertificate                  Status       Path
   ------------------                ------       ----
   EXAMPLECERTIFICATE                Valid       ecs-anywhere-install.ps1
   
   Subject : CN="Amazon Web Services, Inc.",...
   ```
4. On your on-premises server or virtual machine (VM), run the installation script. Specify the cluster name, Region, and the Systems Manager activation ID and activation code from the first step.

\ecs-anywhere-install.ps1 -Region $Region -Cluster $Cluster -ActivationID $ActivationID -ActivationCode $ActivationCode

5. Verify the Amazon ECS container agent is running.

Get-Service AmazonECS

<table>
<thead>
<tr>
<th>Status</th>
<th>Name</th>
<th>DisplayName</th>
</tr>
</thead>
<tbody>
<tr>
<td>Running</td>
<td>AmazonECS</td>
<td>Amazon ECS</td>
</tr>
</tbody>
</table>

Use the following steps to register an existing external instance with a different cluster.

**To register an existing external instance with a different cluster**

1. Stop the Amazon ECS container agent.

Stop-Service AmazonECS

2. Modify the ECS_cluster parameter so that the cluster name matches the name of the cluster to register the external instance with.

[Environment]::SetEnvironmentVariable("ECS_CLUSTER", $ECSCluster, [System.EnvironmentVariableTarget]::Machine)

3. Remove the existing Amazon ECS agent data.

Remove-Item -Recurse -Force $env:ProgramData\Amazon\ECS\data\*

4. Start the Amazon ECS container agent.

Start-Service AmazonECS

The AWS CLI can be used to create a Systems Manager activation before running the installation script to complete the external instance registration process.
Deregistering an external instance

We recommend that, after you finish using an external instance, you deregister the instance from both Amazon ECS and AWS Systems Manager. Following deregistration, the external instance is no longer able to accept new tasks.

If you have tasks that are running on the container instance when you deregister it, the tasks remain running until they stop through some other means. However, these tasks are no longer monitored or accounted for by Amazon ECS. If these tasks on your external instance are part of an Amazon ECS service, then the service scheduler starts another copy of that task, on a different instance, if possible.

To register an external instance to a new cluster, after the external instance has been deregistered from both Amazon ECS and Systems Manager, you can clean up the remaining AWS resources on the instance and register it with a new cluster.

AWS Management Console

2. From the navigation bar, choose the Region where your external instance is registered.
3. In the navigation pane, choose Clusters and select the cluster that hosts the external instance.
4. On the Cluster: name page, choose the Infrastructure tab.
5. Under Container instances, select the external instance ID to deregister. You're redirected to the container instance detail page.
7. Review the deregistration message. Select Deregister from AWS Systems Manager to also deregister the external instance as a Systems Manager managed instance. Choose Deregister.

Note

You can deregister the external instance as a Systems Manager managed instance in the Systems Manager console. For instructions, see Deregistering managed instances in the AWS Systems Manager User Guide.

8. After you deregister the instance, clean up AWS resources on your on-premises server or VM.
<table>
<thead>

|                  | .\ecs-anywhere-ins tall.ps1 -Uninstall |

**AWS CLI**

1. You need the instance ID and the container instance ARN to deregister the container instance. If you do not have these values, run the following commands:

Run the following command to get the instance ID.

You use the instance ID (instanceID) to get the container instance ARN (containerInstanceARN).
instanceId=$(aws ssm describe-instance-information --region "{{ region }}" | jq ".InstanceInformationList[] |select(.IPAddress="{{ IPv4 Address }}") | .InstanceId" | tr -d''

Run the following commands.

You use the containerInstanceArn as a parameter in the command to deregister the instance (deregister-container-instance).

instances=$(aws ecs list-container-instances --cluster "{{ cluster }}" --region "{{ region }}" | jq -c '.containerInstanceArns')
containerInstanceArn=$(aws ecs describe-container-instances --cluster "{{ cluster }}" --region "{{ region }}" --container-instances $instances | jq ".containerInstances[] | select(.ec2InstanceId="{{ instanceId }}") | .containerInstanceArn" | tr -d '"')

2. Run the following command to drain the instance.

aws ecs update-container-instances-state --cluster "{{ cluster }}" --region "{{ region }}" --container-instances "{{ containerInstanceArn }}" --status DRAINING

3. After the container instance finishes draining, run the following command to deregister the instance.

aws ecs deregister-container-instance --cluster "{{ cluster }}" --region "{{ region }}" --container-instance "{{ containerInstanceArn }}"

4. Run the following command to remove the container instance from SSM.

aws ssm deregister-managed-instance --region "{{ region }}" --instance-id "{{ instanceId }}"

5. After you deregister the instance, clean up AWS resources on your on-premises server or VM.

**Updating the AWS Systems Manager Agent and Amazon ECS container agent on an external instance**

Your on-premises server or VM must run both the AWS Systems Manager Agent (SSM Agent) and the Amazon ECS container agent when running Amazon ECS workloads. AWS releases new versions of these agents when any capabilities are added or updated. If your external instances are using an earlier version of either agent, you can update them using the following procedures.

**Updating the SSM Agent on an external instance**

AWS Systems Manager recommends that you automate the process of updating the SSM Agent on your instances. They provide several methods to automate updates. For more information, see [Automating updates to SSM Agent](#) in the [AWS Systems Manager User Guide](#).

**Updating the Amazon ECS agent on an external instance**

On your external instances, the Amazon ECS container agent is updated by upgrading the `ecs-init` package. Updating the Amazon ECS agent doesn't interrupt the running tasks or services.
Amazon ECS provides the `ecs-init` package and signature file in an Amazon S3 bucket in each Region. Beginning with `ecs-init` version 1.52.1-1, Amazon ECS provides separate `ecs-init` packages for use depending on the operating system and system architecture your external instance uses.

Use the following table to determine the `ecs-init` package that you should download based on the operating system and system architecture your external instance uses.

**Note**

You can determine which operating system and system architecture that your external instance uses by using the following commands.

```
cat /etc/os-release
uname -m
```

<table>
<thead>
<tr>
<th>Operating systems (architecture)</th>
<th>ecs-init package</th>
</tr>
</thead>
<tbody>
<tr>

## Operating systems (architecture) | ecs-init package
---|---
Ubuntu 20 (x86_64) |  
Debian 9 (aarch64) |  
Debian 10 (aarch64) |  
Ubuntu 18 (aarch64) |  
Ubuntu 20 (aarch64) |  

Follow these steps to update the Amazon ECS agent.

### To update the Amazon ECS agent

1. Confirm the Amazon ECS agent version that you're running.

   ```
curl -s 127.0.0.1:51678/v1/metadata | python3 -mjson.tool
   ```

2. Download the `ecs-init` package for your operating system and system architecture. Amazon ECS provides the `ecs-init` package file in an Amazon S3 bucket in each Region. Make sure that you replace the `<region>` identifier in the command with the Region name (for example, `us-west-2`) that you're geographically closest to.

   **amazon-ecs-init-latest.x86_64.rpm**

   ```
   ```

   **amazon-ecs-init-latest.aarch64.rpm**

   ```
   ```

   **amazon-ecs-init-latest.amd64.deb**

   ```
   ```
amazon-ecs-init-latest.arm64.deb

```bash
```

3. (Optional) Verify the validity of the `ecs-init` package file using the PGP signature.

   a. Download and install GnuPG. For more information about GNUpg, see the [GnuPG website](#).
   For Linux systems, install `gpg` using the package manager on your flavor of Linux.

   b. Retrieve the Amazon ECS PGP public key.

   ```bash
gpg --keyserver hkp://keys.gnupg.net:80 --recv BCE9D9A42D51784F
```

   c. Download the `ecs-init` package signature. The signature is an ASCII detached PGP signature that's stored in a file with the `.asc` extension. Amazon ECS provides the signature file in an Amazon S3 bucket in each Region. Make sure that you replace the `<region>` identifier in the command with the Region name (for example, `us-west-2`) that you're geographically closest to.

   **amazon-ecs-init-latest.x86_64.rpm**

   ```bash
```

   **amazon-ecs-init-latest.aarch64.rpm**

   ```bash
```

   **amazon-ecs-init-latest.amd64.deb**

   ```bash
```

   **amazon-ecs-init-latest.arm64.deb**

   ```bash
```
d. Verify the `ecs-init` package file using the key.

For the **rpm** packages

```
gpg --verify amazon-ecs-init.rpm.asc ./amazon-ecs-init.rpm
```

For the **deb** packages

```
gpg --verify amazon-ecs-init.deb.asc ./amazon-ecs-init.deb
```

The following is the expected output.

```
gpg: Signature made Fri 14 May 2021 09:31:36 PM UTC
gpg:                using RSA key 50DECCC4710E61AF
gpg: Good signature from "Amazon ECS <ecs-security@amazon.com>" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg: Primary key fingerprint: F34C 3DDA E729 26B0 79BE  AEC6 BCE9 D9A4 2D51 784F
      Subkey fingerprint: D64B B6F9 0CF3 77E9 B5FB  346F 50DE CCC4 710E 61AF
```

4. Install the `ecs-init` package.

For the **rpm** package on CentOS 7, CentOS 8, and RHEL 7

```
sudo yum install -y ./amazon-ecs-init.rpm
```

For the **rpm** package on SUSE Enterprise Server 15

```
sudo zypper install -y --allow-unsigned-rpm ./amazon-ecs-init.rpm
```

For the **deb** package

```
sudo dpkg -i ./amazon-ecs-init.deb
```

5. Restart the `ecs` service.

```
sudo systemctl restart ecs
```

6. Verify the Amazon ECS agent version was updated.
Capacity management

AWS manages your Fargate capacity, but you are responsible for managing your EC2 instances and external instances.

Management includes security patching as well as updating the container instances so that you have access to the latest Amazon ECS features.

In addition to container agent management, there is additional instance management that might be required depending on your configuration. This includes:

- Launching a container instance
- Bootstrapping a container instance
- Starting a task at launch
- Using ENI trunking
- Managing memory
- Managing your container instance remotely
- Using an HTTP proxy for both the container agent and the Docker daemon
- Updating the container agent
- Deregistering the container instance
- Managed instance draining

Topics

- Amazon ECS Linux container agent
- Linux container instance management
- Windows container instance management
- Amazon ECS managed instance draining

For more information on Fargate capacity providers and Amazon EC2 Auto Scaling group capacity providers, see Capacity providers.
Amazon ECS Linux container agent

Each Amazon ECS container agent version supports a different feature set and provides bug fixes from previous versions. When possible, we always recommend using the latest version of the Amazon ECS container agent. To update your container agent to the latest version, see Updating the Amazon ECS container agent.

To see which features and enhancements are included with each agent release, see https://github.com/aws/amazon-ecs-agent/releases.

⚠️ Important

The minimum Docker version for reliable metrics is Docker version v20.10.13 and newer, which is included in Amazon ECS-optimized AMI 20220607 and newer. Amazon ECS agent versions 1.20.0 and newer have deprecated support for Docker versions older than 1.9.0.

Lifecycle

When the Amazon ECS container agent registers an Amazon EC2 instance to your cluster, the Amazon EC2 instance reports its status as ACTIVE and its agent connection status as TRUE. This container instance can accept run task requests.

If you stop (not terminate) a container instance, the status remains ACTIVE, but the agent connection status transitions to FALSE within a few minutes. Any tasks that were running on the container instance stop. If you start the container instance again, the container agent reconnects with the Amazon ECS service, and you are able to run tasks on the instance again.

⚠️ Important

If you stop and start a container instance, or reboot that instance, some older versions of the Amazon ECS container agent register the instance again without deregistering the original container instance ID. In this case, Amazon ECS lists more container instances in your cluster than you actually have. (If you have duplicate container instance IDs for the same Amazon EC2 instance ID, you can safely deregister the duplicates that are listed as ACTIVE with an agent connection status of FALSE.) This issue is fixed in the current version.
of the Amazon ECS container agent. For more information about updating to the current version, see Updating the Amazon ECS container agent.

If you change the status of a container instance to DRAINING, new tasks are not placed on the container instance. Any service tasks running on the container instance are removed, if possible, so that you can perform system updates. For more information, see Container instance draining.

If you deregister or terminate a container instance, the container instance status changes to INACTIVE immediately, and the container instance is no longer reported when you list your container instances. However, you can still describe the container instance for one hour following termination. After one hour, the instance description is no longer available.

⚠️ Important

You can drain the instances manually, or build an Auto Scaling group lifecycle hook to set the instance status to DRAINING. See Amazon EC2 Auto Scaling lifecycle hooks for more information about Auto Scaling lifecycle hooks.

Amazon ECS-optimized AMI

The Linux variants of the Amazon ECS-optimized AMI use the Amazon Linux 2 AMI as their base. The Amazon Linux 2 source AMI name for each variant can be retrieved by querying the Systems Manager Parameter Store API. For more information, see Retrieving Amazon ECS-Optimized AMI metadata. When you launch our container instances from the most recent Amazon ECS-optimized Amazon Linux 2 AMI you receive the current container agent version. To launch a container instance with the latest Amazon ECS-optimized Amazon Linux 2 AMI, see Launching an Amazon ECS Linux container instance.

Using other Linux Operating Systems

To install the latest version of the Amazon ECS container agent on another operating system, see Installing the Amazon ECS container agent. The table in Amazon ECS-optimized AMI shows the Docker version that is tested on Amazon Linux 2 for each agent version.

Additional information

The following pages provide additional information about the changes:

Container agent versions
Amazon ECS container agent configuration

The Amazon ECS container agent supports a number of configuration options, most of which should be set through environment variables. The following environment variables are available, and all of them are optional.

If your container instance was launched with a Linux variant of the Amazon ECS-optimized AMI, you can set these environment variables in the `/etc/ecs/ecs.config` file and then restart the agent. You can also write these configuration variables to your container instances with Amazon EC2 user data at launch time. For more information, see Bootstrapping container instances with Amazon EC2 user data.

If your container instance was launched with a Windows variant of the Amazon ECS-optimized AMI, you can set these environment variables with the PowerShell SetEnvironmentVariable command and then restart the agent. For more information, see Run commands on your Windows instance at launch in the Amazon EC2 User Guide for Windows Instances and the section called “Bootstrap Container Instances”.

If you are manually starting the Amazon ECS container agent (for non Amazon ECS-optimized AMIs), you can use these environment variables in the `docker run` command that you use to start the agent. Use these variables with the syntax `--env=VARIABLE_NAME=VARIABLE_VALUE`. For sensitive information, such as authentication credentials for private repositories, you should store your agent environment variables in a file and pass them all at one time with the `--env-file path_to_env_file` option. You can use the following commands to add the variables.

```
sudo systemctl stop ecs
sudo vi /etc/ecs/ecs.config
# And add the environment variables with VARIABLE_NAME=VARIABLE_VALUE format.
sudo systemctl start ecs
```
Available Parameters

For information about the available Amazon ECS container agent configuration parameters, see Amazon ECS Container Agent on GitHub.

Storing container instance configuration in Amazon S3

Amazon ECS container agent configuration is controlled with the environment variables described in the previous section. Linux variants of the Amazon ECS-optimized AMI look for these variables in /etc/ecs/ecs.config when the container agent starts and configure the agent accordingly. Certain innocuous environment variables, such as ECS_CLUSTER, can be passed to the container instance at launch through Amazon EC2 user data and written to this file without consequence. However, other sensitive information, such as your AWS credentials or the ECS_ENGINE_AUTH_DATA variable, should never be passed to an instance in user data or written to /etc/ecs/ecs.config in a way that would allow them to show up in a .bash_history file.

Storing configuration information in a private bucket in Amazon S3 and granting read-only access to your container instance IAM role is a secure and convenient way to allow container instance configuration at launch. You can store a copy of your ecs.config file in a private bucket. You can then use Amazon EC2 user data to install the AWS CLI and copy your configuration information to /etc/ecs/ecs.config when the instance launches.

To allow Amazon S3 read-only access for your container instance role

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles and select the IAM role to use for your container instances. This role is likely titled ecsInstanceRole. For more information, see Amazon ECS container instance IAM role.
4. To narrow the policy results, on the Attach Policy page, for Filter, type S3.
5. Select the box to the left of the AmazonS3ReadOnlyAccess policy and choose Attach Policy.

To store an ecs.config file in Amazon S3

1. Create an ecs.config file with valid Amazon ECS agent configuration variables using the following format. This example configures private registry authentication. For more information, see Private registry authentication for tasks.
ECS_ENGINE_AUTH_TYPE=dockerconfig
ECS_ENGINE_AUTH_DATA="{"https://index.docker.io/v1/":
{"auth":"zq212MzEXAMPLE7o6T25Dk0i","email":"email@example.com"}}"

Note
For a full list of available Amazon ECS agent configuration variables, see Amazon ECS Container Agent on GitHub.

2. To store your configuration file, create a private bucket in Amazon S3. For more information, see Create a Bucket in the Amazon Simple Storage Service User Guide.

3. Upload the ecs.config file to your S3 bucket. For more information, see Add an Object to a Bucket in the Amazon Simple Storage Service User Guide.

To load an ecs.config file from Amazon S3 at launch

1. Complete the earlier procedures in this section to allow read-only Amazon S3 access to your container instances and store an ecs.config file in a private S3 bucket.

2. Launch new container instances by following the steps in Launching an Amazon ECS Linux container instance. In Step 6.g, use the following example script that installs the AWS CLI and copies your configuration file to /etc/ecs/ecs.config.

```
#!/bin/bash
yum install -y aws-cli
aws s3 cp s3://your_bucket_name/ecs.config /etc/ecs/ecs.config
```

Private registry authentication for container instances

The Amazon ECS container agent can authenticate with private registries, using basic authentication. When you enable private registry authentication, you can use private Docker images in your task definitions. This feature is only supported by tasks using the EC2 launch type.

Another method of enabling private registry authentication uses AWS Secrets Manager to store your private registry credentials securely and then reference them in your container definition. This allows your tasks to use images from private repositories. This method supports tasks using
either the EC2 or Fargate launch types. For more information, see Private registry authentication for tasks.

The Amazon ECS container agent looks for two environment variables when it launches:

- **ECS_ENGINE_AUTH_TYPE**, which specifies the type of authentication data that is being sent.
- **ECS_ENGINE_AUTH_DATA**, which contains the actual authentication credentials.

Linux variants of the Amazon ECS-optimized AMI scan the `/etc/ecs/ecs.config` file for these variables when the container instance launches, and each time the service is started (with the `sudo start ecs` command). AMIs that are not Amazon ECS-optimized should store these environment variables in a file and pass them with the `--env-file` option to the `docker run` command that starts the container agent.

⚠️ Important

We do not recommend that you inject these authentication environment variables at instance launch with Amazon EC2 user data or pass them with the `--env` option to the `docker run` command. These methods are not appropriate for sensitive data, such as authentication credentials. For information about safely adding authentication credentials to your container instances, see Storing container instance configuration in Amazon S3.

### Authentication formats

There are two available formats for private registry authentication, `dockercfg` and `docker`.

**dockercfg authentication format**

The `dockercfg` format uses the authentication information stored in the configuration file that is created when you run the `docker login` command. You can create this file by running `docker login` on your local system and entering your registry user name, password, and email address. You can also log in to a container instance and run the command there. Depending on your Docker version, this file is saved as either `~/.dockercfg` or `~/.docker/config.json`.

```bash
cat ~/.docker/config.json
```

Output:
Important

Newer versions of Docker create a configuration file as shown above with an outer `auths` object. The Amazon ECS agent only supports `dockerconfig` authentication data that is in the below format, without the `auths` object. If you have the `jq` utility installed, you can extract this data with the following command: 

```
cat ~/.docker/config.json | jq .auths
```

Output:

```
{
  "https://index.docker.io/v1/": {
    "auth": "zq212MzEXAMPLE7o6T25Dk0i",
    "email": "email@example.com"
  }
}
```

In the above example, the following environment variables should be added to the environment variable file (`/etc/ecs/ecs.config` for the Amazon ECS-optimized AMI) that the Amazon ECS container agent loads at runtime. If you are not using an Amazon ECS-optimized AMI and you are starting the agent manually with `docker run`, specify the environment variable file with the `--env-file` option when you start the agent.

```
ECS_ENGINE_AUTH_TYPE=dockerconfig
ECS_ENGINE_AUTH_DATA="https://index.docker.io/v1/":{
  "auth": "zq212MzEXAMPLE7o6T25Dk0i",
  "email": "email@example.com"
}
```

You can configure multiple private registries with the following syntax:
ECS_ENGINE_AUTH_TYPE=dockercfg
ECS_ENGINE_AUTH_DATA="repo.example-01.com":
{"auth":"zq212MzEXAMPLE7o6T25Dk0i","email":"email@example-01.com"},
"repo.example-02.com":
{"auth":"FQ172MzEXAMPLEoF7225DU0j","email":"email@example-02.com"}

**docker authentication format**

The docker format uses a JSON representation of the registry server that the agent should authenticate with. It also includes the authentication parameters required by that registry (such as user name, password, and the email address for that account). For a Docker Hub account, the JSON representation looks like the following:

```json
{
    "https://index.docker.io/v1/": {
        "username": "my_name",
        "password": "my_password",
        "email": "email@example.com"
    }
}
```

In this example, the following environment variables should be added to the environment variable file (/etc/ecs/ecs.config for the Amazon ECS-optimized AMI) that the Amazon ECS container agent loads at runtime. If you are not using an Amazon ECS-optimized AMI, and you are starting the agent manually with `docker run`, specify the environment variable file with the `--env-file path_to_env_file` option when you start the agent.

ECS_ENGINE_AUTH_TYPE=docker
ECS_ENGINE_AUTH_DATA="https://index.docker.io/v1/":
{"username": "my_name","password": "my_password","email": "email@example.com"}

You can configure multiple private registries with the following syntax:

ECS_ENGINE_AUTH_TYPE=docker
ECS_ENGINE_AUTH_DATA="repo.example-01.com":
{"username": "my_name","password": "my_password","email": "email@example-01.com"},
"repo.example-02.com":
{"username": "another_name","password": "another_password","email": "email@example-02.com"}

**Turning on private registries**

Use the following procedure to turn on private registries for your container instances.
To enable private registries in the Amazon ECS-optimized AMI

1. Log in to your container instance using SSH.

2. Open the /etc/ecs/ecs.config file and add the ECS_ENGINE_AUTH_TYPE and ECS_ENGINE_AUTH_DATA values for your registry and account:

   ```bash
   sudo vi /etc/ecs/ecs.config
   ```

   This example authenticates a Docker Hub user account:

   ```bash
   ECS_ENGINE_AUTH_TYPE=docker
   ECS_ENGINE_AUTH_DATA={"https://index.docker.io/v1/":
   {"username": "my_name", "password": "my_password", "email": "email@example.com"}}
   ```

3. Check to see if your agent uses the ECS_DATADIR environment variable to save its state:

   ```bash
docker inspect ecs-agent | grep ECS_DATADIR
   ```

   Output:

   ```bash
   "ECS_DATADIR=/data",
   ```

   **Important**

   If the previous command does not return the ECS_DATADIR environment variable, you must stop any tasks running on this container instance before stopping the agent. Newer agents with the ECS_DATADIR environment variable save their state and you can stop and start them while tasks are running without issues. For more information, see [Updating the Amazon ECS container agent](#).

4. Stop the ecs service:

   ```bash
   sudo stop ecs
   ```

   Output:

   ```bash
   ecs stop/waiting
   ```
5. Restart the `ecs` service.

   - For the Amazon ECS-optimized Amazon Linux 2 AMI:
     
     `sudo systemctl restart ecs`

   - For the Amazon ECS-optimized Amazon Linux AMI:
     
     `sudo stop ecs && sudo start ecs`

6. (Optional) You can verify that the agent is running and see some information about your new container instance by querying the agent introspection API operation. For more information, see the section called “Container introspection”.

   `curl http://localhost:51678/v1/metadata`

**Automated task and image cleanup**

Each time a task is placed on a container instance, the Amazon ECS container agent checks to see if the images referenced in the task are the most recent of the specified tag in the repository. If not, the default behavior allows the agent to pull the images from their respective repositories. If you frequently update the images in your tasks and services, your container instance storage can quickly fill up with Docker images that you are no longer using and may never use again. For example, you may use a continuous integration and continuous deployment (CI/CD) pipeline.

**Note**

The Amazon ECS agent image pull behavior can be customized using the `ECS_IMAGE_PULL_BEHAVIOR` parameter. For more information, see Amazon ECS container agent configuration.

Likewise, containers that belong to stopped tasks can also consume container instance storage with log information, data volumes, and other artifacts. These artifacts are useful for debugging containers that have stopped unexpectedly, but most of this storage can be safely freed up after a period of time.
By default, the Amazon ECS container agent automatically cleans up stopped tasks and Docker images that are not being used by any tasks on your container instances.

Note

The automated image cleanup feature requires at least version 1.13.0 of the Amazon ECS container agent. To update your agent to the latest version, see Updating the Amazon ECS container agent.

Tunable parameters

The following agent configuration variables are available to tune your automated task and image cleanup experience. For more information about how to set these variables on your container instances, see Amazon ECS container agent configuration.

ECS_ENGINE_TASK_CLEANUP_WAIT_DURATION

This variable specifies the time to wait before removing any containers that belong to stopped tasks. The image cleanup process cannot delete an image as long as there is a container that references it. After images are not referenced by any containers (either stopped or running), the image becomes a candidate for cleanup. By default, this parameter is set to 3 hours, but you can reduce this period to as low as 1 second if you need to for your application. The parameter is ignored if you set the value less than 1 second.

ECS_DISABLE_IMAGE_CLEANUP

If you set this variable to true, then automated image cleanup is turned off on your container instance and no images are automatically removed.

ECS_IMAGE_CLEANUP_INTERVAL

This variable specifies how frequently the automated image cleanup process should check for images to delete. The default is every 30 minutes but you can reduce this period to as low as 10 minutes to remove images more frequently.

ECS_IMAGE_MINIMUM_CLEANUP_AGE

This variable specifies the minimum amount of time between when an image was pulled and when it may become a candidate for removal. This is used to prevent cleaning up images that have just been pulled. The default is 1 hour.
ECS_NUM_IMAGES_DELETE_PER_CYCLE

This variable specifies how many images may be removed during a single cleanup cycle. The default is 5 and the minimum is 1.

Cleanup workflow

When the Amazon ECS container agent is running and automated image cleanup is not turned off, the agent checks for Docker images that are not referenced by running or stopped containers at a frequency determined by the ECS_IMAGE_CLEANUP_INTERVAL variable. If unused images are found and they are older than the minimum cleanup time specified by the ECS_IMAGE_MINIMUM_CLEANUP_AGE variable, the agent removes up to the maximum number of images that are specified with the ECS_NUM_IMAGES_DELETE_PER_CYCLE variable. The least-recently referenced images are deleted first. After the images are removed, the agent waits until the next interval and repeats the process again.

Adding an attribute to an Amazon ECS container instance

You can add custom attributes at instance registration time using the container agent or manually, using the AWS Management Console. For information about the available Amazon ECS container agent configuration parameters, see Amazon ECS Container Agent on GitHub.

To add custom attributes using the console

2. In the navigation pane, choose Clusters, and then choose the cluster.
3. Choose Infrastructure.
4. Choose the container instance, and then choose Attributes.
5. Choose Add custom attribute.
6. For Attribute name and Value, enter a name and a value for the attribute, and then choose Submit.

Repeat for each attribute that you want to add.

Adding custom attributes using the AWS CLI

The following examples demonstrate how to add custom attributes using the put-attributes command.
Example: Single Attribute
The following example adds the custom attribute "stack=prod" to the specified container instance in the default cluster.

```
aws ecs put-attributes --attributes name=stack,value=prod,targetId=arn
```

Example: Multiple Attributes
The following example adds the custom attributes "stack=prod" and "project=a" to the specified container instance in the default cluster.

```
aws ecs put-attributes --attributes name=stack,value=prod,targetId=arn
name=project,value=a,targetId=arn
```

Filtering by attribute using the console
You can apply a filter for your container instances, allowing you to see custom attributes.

Filter container instances by attribute using the console
2. In the navigation pane, choose Clusters, and then choose the cluster.
3. Choose Infrastructure,
4. Choose the container instance.
5. Using the Filter custom attributes by key or value text field, enter the attributes you want to filter by. The format must be AttributeName:AttributeValue.

Filter container instances by attribute using the AWS CLI
The following examples demonstrate how to filter container instances by attribute using the list-container-instances command. For more information about the filter syntax, see Create expressions to define container instances for Amazon ECS tasks.

Example: Built-in attribute
The following example uses built-in attributes to list the g2.2xlarge instances.

```
aws ecs list-container-instances --filter "attribute:ecs.instance-type == g2.2xlarge"
```
Example: Custom attribute

The following example lists the instances with the custom attribute "stack=prod".

```
aws ecs list-container-instances --filter "attribute:stack == prod"
```

Example: Exclude an attribute value

The following example lists the instances with the custom attribute "stack" unless the attribute value is "prod".

```
aws ecs list-container-instances --filter "attribute:stack != prod"
```

Example: Multiple attribute values

The following example uses built-in attributes to list the instances of type t2.small or t2.medium.

```
aws ecs list-container-instances --filter "attribute:ecs.instance-type in [t2.small, t2.medium]"
```

Example: Multiple attributes

The following example uses built-in attributes to list the T2 instances in the us-east-1a Availability Zone.

```
aws ecs list-container-instances --filter "attribute:ecs.instance-type =~ t2.* and attribute:ecs.availability-zone == us-east-1a"
```

Linux container instance management

Linux container instance management includes:

- Launching a container instance
- Bootstrapping a container instance
- Starting a task at launch
- Using ENI trunking
- Managing memory
- Managing your container instance remotely
• Using an HTTP proxy for both the container agent and the Docker daemon
• Updating the container agent

Each Amazon ECS container agent version supports a different feature set and provides bug fixes from previous versions. When possible, we always recommend using the latest version of the Amazon ECS container agent. To update your container agent to the latest version, see Updating the Amazon ECS container agent.

To see which features and enhancements are included with each agent release, see https://github.com/aws/amazon-ecs-agent/releases.

⚠️ Important
The minimum Docker version for reliable metrics is Docker version v20.10.13 and newer, which is included in Amazon ECS-optimized AMI 20220607 and newer. Amazon ECS agent versions 1.20.0 and newer have deprecated support for Docker versions older than 1.9.0.

Launching an Amazon ECS Linux container instance

Your Amazon ECS container instances are created using the Amazon EC2 console. Before you begin, be sure that you've completed the steps in Set up to use Amazon ECS.

You can launch an instance by various methods including the Amazon EC2 console, AWS CLI, and SDK. The procedure on this page covers the launch wizard in the Amazon EC2 console. For information about the other methods for launching an instance, see Launch your instance in the Amazon EC2 User Guide for Linux Instances.

For more information about the launch wizard, see Launch an instance using the new launch instance wizard in the Amazon EC2 User Guide for Linux Instances.

New Amazon EC2 launch instance wizard

You can use the new Amazon EC2 wizard to launch an instance. The launch instance wizard specifies the launch parameters that are required for launching an instance. You can use the following list for the parameters and leave the parameters not listed as the default. The following instructions take you through each parameter group.

Parameters for instance configuration
• **Initiate instance launch**

• **Name and tags**

• **Application and OS Images (Amazon Machine Image)**

• **Instance type**

• **Key pair (login)**

• **Network settings**

• **Configure storage**

• **Advanced details**

**Initiate instance launch**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, US East (Ohio)). Select a Region in which to launch the instance.
3. From the Amazon EC2 console dashboard, choose **Launch instance**.

**Name and tags**

The instance name is a tag, where the key is **Name**, and the value is the name that you specify. You can tag the instance, the volumes, and elastic graphics. For Spot Instances, you can tag the Spot Instance request only.

Specifying an instance name and additional tags is optional.

- For **Name**, enter a descriptive name for the instance. If you don't specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.
- To add additional tags, choose **Add additional tags**. Choose **Add tag**, and then enter a key and value, and select the resource type to tag. Choose **Add tag** again for each additional tag to add.

**Application and OS Images (Amazon Machine Image)**

An Amazon Machine Image (AMI) contains the information required to create an instance. For example, an AMI might contain the software that's required to act as a web server, such as Apache, and your website.

Use the **Search** bar to find a suitable Amazon ECS-optimized AMI published by AWS.
1. Enter one of the following terms in the Search bar.
   - ami-ecs
   - The Value of an Amazon ECS-optimized AMI.

   For the latest Amazon ECS-optimized AMIs and their values, see Linux Amazon ECS-optimized AMI.

2. Press Enter.

3. On the Choose an Amazon Machine Image (AMI) page, select the AWS Marketplace AMIs tab.

4. From the left Refine results pane, select Amazon Web Services as the Publisher.

5. Choose Select on the row of the AMI that you want to use.

   Alternatively, choose Cancel (at top right) to return to the launch instance wizard without choosing an AMI. A default AMI will be selected. Ensure that the AMI meets the requirements outlined in Linux instances.

### Instance type

The instance type defines the hardware configuration and size of the instance. Larger instance types have more CPU and memory. For more information, see Instance types.

- For Instance type, select the instance type for the instance.

   The instance type that you select determines the resources available for your tasks to run on.

### Key pair (login)

For Key pair name, choose an existing key pair, or choose Create new key pair to create a new one.

⚠️ **Important**

If you choose the Proceed without key pair (Not recommended) option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

### Network settings

Configure the network settings, as necessary.
• **Networking platform**: Choose Virtual Private Cloud (VPC), and then specify the subnet in the Network interfaces section.

• **VPC**: Select an existing VPC in which to create the security group.

• **Subnet**: You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone, or Outpost.

To launch the instance in an Availability Zone, select the subnet in which to launch your instance. To create a new subnet, choose **Create new subnet** to go to the Amazon VPC console. When you are done, return to the launch instance wizard and choose the Refresh icon to load your subnet in the list.

To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

To launch an instance in an Outpost, select a subnet in a VPC that you associated with the Outpost.

• **Auto-assign Public IP**: If your instance should be accessible from the internet, verify that the **Auto-assign Public IP** field is set to **Enable**. If not, set this field to **Disable**.

**Note**

Container instances need access to communicate with the Amazon ECS service endpoint. This can be through an interface VPC endpoint or through your container instances having public IP addresses.

For more information about interface VPC endpoints, see [Amazon ECS interface VPC endpoints (AWS PrivateLink)](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/Amazon-VPC-ECS.html).

If you do not have an interface VPC endpoint configured and your container instances do not have public IP addresses, then they must use network address translation (NAT) to provide this access. For more information, see [NAT gateways](https://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/Amazon-VPC-NAT-gateway.html) in the Amazon VPC User Guide and [HTTP proxy configuration for Linux container instances](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/using-lc-instance-configuration.html) in this guide.

• **Firewall (security groups)**: Use a security group to define firewall rules for your container instance. These rules specify which incoming network traffic is delivered to your container instance. All other traffic is ignored.

  • To select an existing security group, choose **Select existing security group**, and select the security group that you created in [Set up to use Amazon ECS](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/using-lc-instance-configuration.html).
Configure storage

The AMI you selected includes one or more volumes of storage, including the root volume. You can specify additional volumes to attach to the instance.

You can use the Simple view.

- **Storage type**: Configure the storage for your container instance.

  If you are using the Amazon ECS-optimized Amazon Linux 2 AMI, your instance has a single 30 GiB volume configured, which is shared between the operating system and Docker.

  If you are using the Amazon ECS-optimized AMI, your instance has two volumes configured. The Root volume is for the operating system's use, and the second Amazon EBS volume (attached to /dev/xvdcz) is for Docker's use.

  You can optionally increase or decrease the volume sizes for your instance to meet your application needs.

Advanced details

For Advanced details, expand the section to view the fields and specify any additional parameters for the instance.

- **Purchasing option**: Choose Request Spot Instances to request Spot Instances. You also need to set the other fields related to Spot Instances. For more information, see Spot Instance Requests.

  ![Note](https://example.com)

  If you are using Spot Instances and see a Not available message, you may need to choose a different instance type.

- **IAM instance profile**: Select your container instance IAM role. This is usually named ecsInstanceRole.
Important

If you do not launch your container instance with the proper IAM permissions, your Amazon ECS agent cannot connect to your cluster. For more information, see Amazon ECS container instance IAM role.

(Optional) User data: Configure your Amazon ECS container instance with user data, such as the agent environment variables from Amazon ECS container agent configuration. Amazon EC2 user data scripts are executed only one time, when the instance is first launched. The following are common examples of what user data is used for:

- By default, your container instance launches into your default cluster. To launch into a non-default cluster, choose the Advanced Details list. Then, paste the following script into the User data field, replacing your_cluster_name with the name of your cluster.

```bash
#!/bin/bash
echo ECS_CLUSTER=your_cluster_name >> /etc/ecs/ecs.config
```

- If you have an ecs.config file in Amazon S3 and have enabled Amazon S3 read-only access to your container instance role, choose the Advanced Details list. Then, paste the following script into the User data field, replacing your_bucket_name with the name of your bucket to install the AWS CLI and write your configuration file at launch time.

```bash
#!/bin/bash
yum install -y aws-cli
aws s3 cp s3://your_bucket_name/ecs.config /etc/ecs/ecs.config
```

- Specify tags for your container instance using the ECS_CONTAINER_INSTANCE_TAGS configuration parameter. This creates tags that are associated with Amazon ECS only, they cannot be listed using the Amazon EC2 API.

Note

For more information about this configuration, see Storing container instance configuration in Amazon S3.
Important

If you launch your container instances using an Amazon EC2 Auto Scaling group, then you should use the ECS_CONTAINER_INSTANCE_TAGS agent configuration parameter to add tags. This is due to the way in which tags are added to Amazon EC2 instances that are launched using Auto Scaling groups.

```bash
#!/bin/bash

cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=
ECS_CONTAINER_INSTANCE_TAGS={"tag_key": "tag_value"}
EOF
```

- Specify tags for your container instance and then use the ECS_CONTAINER_INSTANCE_PROPAGATE_TAGS_FROM configuration parameter to propagate them from Amazon EC2 to Amazon ECS.

The following is an example of a user data script that would propagate the tags associated with a container instance, as well as register the container instance with a cluster named your_cluster_name:

```bash
#!/bin/bash

cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=
ECS_CONTAINER_INSTANCE_PROPAGATE_TAGS_FROM=ec2_instance
EOF
```

For more information, see Bootstrapping container instances with Amazon EC2 user data.

Old Amazon EC2 launch instance wizard

To launch a container instance

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. From the navigation bar, select the Region to use.
3. From the EC2 Dashboard, choose Launch instance.
4. On the **Choose an Amazon Machine Image (AMI)** page, complete the following steps:

   a. Choose **AWS Marketplace**.

   b. Choose an AMI for your container instance. You can search for one of the Amazon ECS-optimized AMIs, for example the **Amazon ECS-Optimized Amazon Linux 2 AMI**. If you do not choose an Amazon ECS-optimized AMI, you must follow the procedures in **Installing the Amazon ECS container agent**.

   For more information on the latest Amazon ECS-optimized AMIs, see [Amazon ECS-optimized AMI](#).

5. On the **Choose an Instance Type** page, you can select the hardware configuration of your instance. The `t2.micro` instance type is selected by default. The instance type that you select determines the resources available for your tasks to run on.

   Choose **Next: Configure Instance Details** when you are done.

6. On the **Configure Instance Details** page, complete the following steps:

   a. Set the **Number of instances** field depending on how many container instances you want to add to your cluster.

   b. (Optional) To use Spot Instances, for **Purchasing option**, select the check box next to **Request Spot Instances**. You also need to set the other fields related to Spot Instances.

   For more information, see [Spot Instance Requests](#).

   - **Note**
     
     If you are using Spot Instances and see a **Not available** message, you may need to choose a different instance type.

   c. For **Network**, choose the VPC into which to launch your container instance.

   d. For **Subnet**, choose a subnet to use, or keep the default option to choose the default subnet in any Availability Zone.

   e. Set the **Auto-assign Public IP** field depending on whether you want your instance to be accessible from the public internet. If your instance should be accessible from the internet, verify that the **Auto-assign Public IP** field is set to **Enable**. If not, set this field to **Disable**.
Note

Container instances need access to communicate with the Amazon ECS service endpoint. This can be through an interface VPC endpoint or through your container instances having public IP addresses.

For more information about interface VPC endpoints, see Amazon ECS interface VPC endpoints (AWS PrivateLink).

If you do not have an interface VPC endpoint configured and your container instances do not have public IP addresses, then they must use network address translation (NAT) to provide this access. For more information, see NAT gateways in the Amazon VPC User Guide and HTTP proxy configuration for Linux container instances in this guide. For more information, see the section called “Create a virtual private cloud”.

f. Select your container instance IAM role. This is usually named ecsInstanceRole.

Important

If you do not launch your container instance with the proper IAM permissions, your Amazon ECS agent cannot connect to your cluster. For more information, see Amazon ECS container instance IAM role.

g. (Optional) Configure your Amazon ECS container instance with user data, such as the agent environment variables from Amazon ECS container agent configuration. Amazon EC2 user data scripts are executed only one time, when the instance is first launched. The following are common examples of what user data is used for:

- By default, your container instance launches into your default cluster. To launch into a non-default cluster, choose the Advanced Details list. Then, paste the following script into the User data field, replacing your_cluster_name with the name of your cluster.

```
#!/bin/bash
echo ECS_CLUSTER=your_cluster_name >> /etc/ecs/ecs.config
```

- If you have an ecs.config file in Amazon S3 and have enabled Amazon S3 read-only access to your container instance role, choose the Advanced Details list. Then, paste the

```
following script into the **User data** field, replacing `your_bucket_name` with the name of your bucket to install the AWS CLI and write your configuration file at launch time.

**Note**

For more information about this configuration, see [Storing container instance configuration in Amazon S3](https://docs.aws.amazon.com/lambda/latest/dg/configuration-s3.html).

```bash
#!/bin/bash
yum install -y aws-cli
aws s3 cp s3://your_bucket_name/ecs.config /etc/ecs/ecs.config
```

- Specify tags for your container instance using the `ECS_CONTAINER_INSTANCE_TAGS` configuration parameter. This creates tags that are associated with Amazon ECS only, they cannot be listed using the Amazon EC2 API.

**Important**

If you launch your container instances using an Amazon EC2 Auto Scaling group, then you should use the `ECS_CONTAINER_INSTANCE_TAGS` agent configuration parameter to add tags. This is due to the way in which tags are added to Amazon EC2 instances that are launched using Auto Scaling groups.

```bash
#!/bin/bash
cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=your_cluster_name
ECS_CONTAINER_INSTANCE_TAGS="{ "tag_key": "tag_value" }"
EOF
```

- Specify tags for your container instance and then use the `ECS_CONTAINER_INSTANCE_PROPAGATE_TAGS_FROM` configuration parameter to propagate them from Amazon EC2 to Amazon ECS.

The following is an example of a user data script that would propagate the tags associated with a container instance, as well as register the container instance with a cluster named `your_cluster_name`:

```bash
#!/bin/bash
```
#!/bin/bash
cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=
ECS_CONTAINER_INSTANCE_PROPAGATE_TAGS_FROM=ec2_instance
EOF

For more information, see [Bootstrapping container instances with Amazon EC2 user data](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/bootstrap-container-instance.html).

h. Choose **Next: Add Storage**.

7. On the **Add Storage** page, configure the storage for your container instance.

   If you are using the Amazon ECS-optimized Amazon Linux 2 AMI, your instance has a single 30 GiB volume configured, which is shared between the operating system and Docker.

   If you are using the Amazon ECS-optimized AMI, your instance has two volumes configured. The **Root** volume is for the operating system's use, and the second Amazon EBS volume (attached to /dev/xvdcz) is for Docker's use.

   You can optionally increase or decrease the volume sizes for your instance to meet your application needs.

   When done configuring your volumes, choose **Next: Add Tags**.

8. On the **Add Tags** page, specify tags by providing key and value combinations for the container instance. Choose **Add another tag** to add more than one tag to your container instance. For more information resource tags, see [Amazon ECS resource tagging](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/resource-tags.html).

   Choose **Next: Configure Security Group** when you are done.

9. On the **Configure Security Group** page, use a security group to define firewall rules for your container instance. These rules specify which incoming network traffic is delivered to your container instance. All other traffic is ignored. Select or create a security group as follows, and then choose **Review and Launch**.

10. On the **Review Instance Launch** page, under **Security Groups**, you see that the wizard created and selected a security group for you. Instead, select the security group that you created in **Set up to use Amazon ECS** using the following steps:

   a. Choose **Edit security groups**.
b. On the **Configure Security Group** page, select the **Select an existing security group** option.

c. Select the security group you created for your container instance from the list of existing security groups, and choose **Review and Launch**.

11. On the **Review Instance Launch** page, choose **Launch**.

12. In the **Select an existing key pair or create a new key pair** dialog box, choose **Choose an existing key pair**, then select the key pair that you created when getting set up.

   When you are ready, select the acknowledgment field, and then choose **Launch Instances**.

13. A confirmation page lets you know that your instance is launching. Choose **View Instances** to close the confirmation page and return to the console.

14. On the **Instances** screen, you can view the status of your instance. It takes a short time for an instance to launch. When you launch an instance, its initial state is **pending**. After the instance starts, its state changes to **running**, and it receives a public DNS name. If the **Public DNS** column is hidden, choose **Show/Hide, Public DNS**.

### Using Spot Instances

A Spot Instance is an unused Amazon EC2 instance that is available for less than the On-Demand price. Because Spot Instances enable you to request unused EC2 instances at steep discounts, you can lower your Amazon EC2 costs significantly. The hourly price for a Spot Instance is called a Spot price. The Spot price of each instance type in each Availability Zone is set by Amazon EC2, and adjusted gradually based on the long-term supply of and demand for Spot Instances. For more information, see [Spot Instances](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/spot-instances.html) in the *Amazon EC2 User Guide for Linux Instances*.

You can register Spot Instances to your Amazon ECS clusters. For more information, see [Launching an Amazon ECS Linux container instance](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/configure-and-launch-an-instance.html).

### Spot Instance draining

Amazon EC2 terminates, stops, or hibernates your Spot Instance when the Spot price exceeds the maximum price for your request or capacity is no longer available. Amazon EC2 provides a Spot Instance two-minute interruption notice for terminate and stop actions. It does not provide the two-minute notice for the hibernate action. If Amazon ECS Spot Instance draining is enabled on the instance, ECS receives the Spot Instance interruption notice and places the instance in **DRAINING** status.
**Important**

Amazon ECS does not receive a notice from Amazon EC2 when instances are removed by Auto Scaling Capacity Rebalancing. For more information, see [Amazon EC2 Auto Scaling Capacity Rebalancing](https://docs.aws.amazon.com/elastic-cloud-frontdoor/latest/ef-userguide/autoscaling.html).

When a container instance is set to DRAINING, Amazon ECS prevents new tasks from being scheduled for placement on the container instance. Service tasks on the draining container instance that are in the PENDING state are stopped immediately. If there are container instances in the cluster that are available, replacement service tasks are started on them.

Spot Instance draining is turned off by default and must be manually enabled. To enable Spot Instance draining for a new container instance, when launching the container instance add the following script into the **User data** field, replacing `MyCluster` with the name of the cluster to register the container instance to.

```bash
#!/bin/bash
cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=MyCluster
ECS_ENABLE_SPOT_INSTANCE_DRAINING=true
EOF
```

For more information, see [Launching an Amazon ECS Linux container instance](https://docs.aws.amazon.com/elastic-cloud-frontdoor/latest/ef-userguide/launching.html).

**To turn on Spot Instance draining for an existing container instance**

1. Connect to the Spot Instance over SSH.
2. Edit the `/etc/ecs/ecs.config` file and add the following:

   ```bash
   ECS_ENABLE_SPOT_INSTANCE_DRAINING=true
   ```

3. Restart the `ecs` service.
   - For the Amazon ECS-optimized Amazon Linux 2 AMI:
     ```bash
     sudo systemctl restart ecs
     ```
   - For the Amazon ECS-optimized Amazon Linux AMI:
4. (Optional) You can verify that the agent is running and see some information about your new container instance by querying the agent introspection API operation. For more information, see the section called “Container introspection”.

```
curl http://localhost:51678/v1/metadata
```

## Container instance draining

There might be times when you need to remove a container instance from your cluster; for example, to perform system updates, update the Docker daemon, or to scale down the cluster capacity. Amazon ECS provides the ability to transition a container instance to a DRAINING status. This is referred to as *container instance draining*. When a container instance is set to DRAINING, Amazon ECS prevents new tasks from being scheduled for placement on the container instance.

### Draining behavior for services

Any tasks that are part of a service that are in a PENDING state are stopped immediately. If there is available container instance capacity in the cluster, the service scheduler will start replacement tasks. If there isn't enough container instance capacity, a service event message will be sent indicating the issue.

Tasks that are part of a service on the container instance that are in a RUNNING state are transitioned to a STOPPED state. The service scheduler attempts to replace the tasks according to the service's deployment type and deployment configuration parameters, `minimumHealthyPercent` and `maximumPercent`. For more information, see Amazon ECS Deployment types and Service definition parameters.

- If `minimumHealthyPercent` is below 100%, the scheduler can ignore `desiredCount` temporarily during task replacement. For example, `desiredCount` is four tasks, a minimum of 50% allows the scheduler to stop two existing tasks before starting two new tasks. If the minimum is 100%, the service scheduler can't remove existing tasks until the replacement tasks are considered healthy. If tasks for services that do not use a load balancer are in the RUNNING state, they are considered healthy. Tasks for services that use a load balancer are considered healthy if they are in the RUNNING state and the container instance they are hosted on is reported as healthy by the load balancer.
Important

If you use Spot Instances and minimumHealthyPercent is greater than or equal to 100%, then the service will not have enough time to replace the task before the Spot Instance terminates.

- The maximumPercent parameter represents an upper limit on the number of running tasks during task replacement, which allows you to define the replacement batch size. For example, if desiredCount of four tasks, a maximum of 200% starts four new tasks before stopping the four tasks to be drained (provided that the cluster resources required to do this are available). If the maximum is 100%, then replacement tasks can't start until the draining tasks have stopped.

Important

If both minimumHealthyPercent and maximumPercent are 100%, then the service can't remove existing tasks, and also cannot start replacement tasks. This prevents successful container instance draining and prevents making new deployments.

Draining behavior for standalone tasks

Any standalone tasks in the PENDING or RUNNING state are unaffected; you must wait for them to stop on their own or stop them manually. The container instance will remain in DRAINING status.

A container instance has completed draining when all tasks running on the instance transition to a STOPPED state. The container instance remains in a DRAINING state until it is activated again or deleted. You can verify the state of the tasks on the container instance by using the ListTasks operation with the containerInstance parameter to get a list of tasks on the instance followed by a DescribeTasks operation with the Amazon Resource Name (ARN) or ID of each task to verify the task state.

When you are ready for the container instance to start hosting tasks again, you change the state of the container instance from DRAINING to ACTIVE. The Amazon ECS service scheduler will then consider the container instance for task placement again.
Draining container instances

The following steps can be used to set a container instance to draining using the new AWS Management Console.

You can also use the UpdateContainerInstancesState API action or the update-container-instances-state command to change the status of a container instance to DRAINING.

AWS Management Console

2. In the navigation pane, choose Clusters.
3. On the Clusters page, choose a cluster that hosts your instances.
4. On the Cluster : name page, choose the Infrastructure tab. Then, under Container instances select the check box for each container instance you want to drain.
5. Choose Actions, Drain.

Bootstrapping container instances with Amazon EC2 user data

When you launch an Amazon EC2 instance, you have the option of passing user data to the instance. The data can be used to perform common automated configuration tasks and even run scripts when the instance boots. For Amazon ECS, the most common use cases for user data are to pass configuration information to the Docker daemon and the Amazon ECS container agent.

You can pass multiple types of user data to Amazon EC2, including cloud boothooks, shell scripts, and cloud-init directives. For more information about these and other format types, see the Cloud-Init documentation.

You can pass this user data when using the Amazon EC2 launch wizard. For more information, see Launching an Amazon ECS Linux container instance.

Topics

- Amazon ECS container agent
- Docker daemon
Amazon ECS container agent

The Linux variants of the Amazon ECS-optimized AMI look for agent configuration data in the `/etc/ecs/ecs.config` file when the container agent starts. You can specify this configuration data at launch with Amazon EC2 user data. For more information about available Amazon ECS container agent configuration variables, see Amazon ECS container agent configuration.

To set only a single agent configuration variable, such as the cluster name, use `echo` to copy the variable to the configuration file:

```bash
#!/bin/bash
echo "ECS_CLUSTER=MyCluster" >> /etc/ecs/ecs.config
```

If you have multiple variables to write to `/etc/ecs/ecs.config`, use the following heredoc format. This format writes everything between the lines beginning with `cat` and `EOF` to the configuration file.

```bash
#!/bin/bash

cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=MyCluster
ECS_ENGINE_AUTH_TYPE=docker
ECS_ENGINE_AUTH_DATA="\nhttps://index.docker.io/v1/":\n\n"username":"my_name","password":"my_password","email":"email@example.com\n"
ECS_LOGLEVEL=debug
ECS_WARM_POOLS_CHECK=true
EOF
```

To set custom instance attributes, set the `ECS_INSTANCE_ATTRIBUTES` environment variable.

```bash
#!/bin/bash

cat <<'EOF' >> ec.config
ECS_INSTANCE_ATTRIBUTES="\nenvtype":"prod\n"
EOF
```

Docker daemon

You can specify Docker daemon configuration information with Amazon EC2 user data. For more information about configuration options, see the Docker daemon documentation.
In the example below, the custom options are added to the Docker daemon configuration file, `/etc/docker/daemon.json` which is then specified in the user data when the instance is launched.

```bash
#!/bin/bash
cat <<EOF >/etc/docker/daemon.json
{"debug": true}
EOF
systemctl restart docker --no-block
```

In the example below, the custom options are added to the Docker daemon configuration file, `/etc/docker/daemon.json` which is then specified in the user data when the instance is launched. This example shows how to disable the docker-proxy in the Docker daemon config file.

```bash
#!/bin/bash
cat <<EOF >/etc/docker/daemon.json
{"userland-proxy": false}
EOF
systemctl restart docker --no-block
```

**Starting a task at container instance launch time**

Depending on your application architecture design, you may need to run a specific container on every container instance to deal with operations or security concerns such as monitoring, security, metrics, service discovery, or logging.

To do this, you can configure your container instances to call the `docker run` command with the user data script at launch, or in some init system such as Upstart or `systemd`. While this method works, it has some disadvantages because Amazon ECS has no knowledge of the container and cannot monitor the CPU, memory, ports, or any other resources used. To ensure that Amazon ECS can properly account for all task resources, create a task definition for the container to run on your container instances. Then, use Amazon ECS to place the task at launch time with Amazon EC2 user data.

The Amazon EC2 user data script in the following procedure uses the Amazon ECS introspection API to identify the container instance. Then, it uses the AWS CLI and the `start-task` command to run a specified task on itself during startup.
To start a task at container instance launch time

1. If you have not done so already, create a task definition with the container you want to run on your container instance at launch by following the procedures in Creating a task definition using the console.

2. Modify your ecsInstanceRole IAM role to add permissions for the StartTask API operation. For more information, see Amazon ECS container instance IAM role.
   b. In the navigation pane, choose Roles.
   c. Choose the ecsInstanceRole. If the role does not exist, use the procedure in Amazon ECS container instance IAM role to create the role and return to this procedure. If the role does exist, select the role to view the attached policies.
   d. In the Permissions tab, choose Add inline policy.
   e. For Service, choose Choose a service, Elastic Container Service.
   f. For Actions, type StartTask in the search field, and then select StartTask.
   g. For Resources, select All resources, and then choose Review policy.
   h. On the Review policy page, enter a name for your policy, such as ecs-start-task and choose Create policy.

3. Launch one or more container instances using the Amazon ECS-optimized Amazon Linux 2 AMI by following the procedure in Launching an Amazon ECS Linux container instance, but in Step 6.g copy and paste the MIME multi-part user data script below into the User data field. Substitute your_cluster_name with the cluster for the container instance to register into and my_task_def with the task definition to run on the instance at launch.

Note

The MIME multi-part content below uses a shell script to set configuration values and install packages. It also uses a systemd job to start the task after the ecs service is running and the introspection API is available.
#!/bin/bash

# Specify the cluster that the container instance should register into
cluster=your_cluster_name

# Write the cluster configuration variable to the ecs.config file
# (add any other configuration variables here also)
echo ECS_CLUSTER=$cluster >> /etc/ecs/ecs.config

START_TASK_SCRIPT_FILE="/etc/ecs/ecs-start-task.sh"
cat << 'EOF' > ${START_TASK_SCRIPT_FILE}
exec 2>>/var/log/ecs/ecs-start-task.log
set -x

# Install prerequisite tools
yum install -y jq aws-cli

# Wait for the ECS service to be responsive
until curl -s http://localhost:51678/v1/metadata
do
    sleep 1
done

# Grab the container instance ARN and AWS Region from instance metadata
instance_arn=$(curl -s http://localhost:51678/v1/metadata | jq -r '.ContainerInstanceArn' | awk -F/ '{print $NF}')
cluster=$(curl -s http://localhost:51678/v1/metadata | jq -r '.Cluster' | awk -F/ '{print $NF}')
region=$(curl -s http://localhost:51678/v1/metadata | jq -r '.ContainerInstanceArn' | awk -F: '{print $4}')

# Specify the task definition to run at launch
task_definition=my_task_def

# Run the AWS CLI start-task command to start your task on this container instance
aws ecs start-task --cluster $cluster --task-definition $task_definition --container-instances $instance_arn --started-by $instance_arn --region $region

EOF

# Write systemd unit file
UNIT="ecs-start-task.service"
cat << EOF > /etc/systemd/system/${UNIT}
[Unit]
EOF
4. Verify that your container instances launch into the correct cluster and that your tasks have started.

   b. From the navigation bar, choose the Region that your cluster is in.

   c. In the navigation pane, choose Clusters and select the cluster that hosts your container instances.

   d. On the Cluster page, choose Tasks, and then choose your tasks.

      Each container instance you launched should have your task running on it.

      If you do not see your tasks, you can log in to your container instances with SSH and check the /var/log/ecs/ecs-start-task.log file for debugging information.

Elastic network interface trunking

Note

This feature is not available on Fargate.
Each Amazon ECS task that uses the awsvpc network mode receives its own elastic network interface (ENI), which is attached to the container instance that hosts it. There is a default limit to the number of network interfaces that can be attached to an Amazon EC2 instance, and the primary network interface counts as one. For example, by default a c5.large instance may have up to three ENIs attached to it. The primary network interface for the instance counts as one, so you can attach an additional two ENIs to the instance. Because each task using the awsvpc network mode requires an ENI, you can typically only run two such tasks on this instance type.

Amazon ECS supports launching container instances with increased ENI density using supported Amazon EC2 instance types. When you use these instance types and enable the awsvpcTrunking account setting, additional ENIs are available on newly launched container instances. This configuration allows you to place more tasks using the awsvpc network mode on each container instance. For information about the awsvpcTrunking account setting, see Accessing Amazon ECS features through account settings.

Using this feature, a c5.large instance with awsvpcTrunking enabled has an increased ENI limit of twelve. The container instance will have the primary network interface and Amazon ECS creates and attaches a "trunk" network interface to the container instance. So this configuration allows you to launch ten tasks on the container instance instead of the current two tasks.

The trunk network interface is fully managed by Amazon ECS and is deleted when you either terminate or deregister your container instance from the cluster. For more information, see Task networking for tasks on Amazon EC2 instances.

Considerations

There are several things to consider when using the ENI trunking feature.

- Only Linux variants of the Amazon ECS-optimized AMI, or other Amazon Linux variants with version 1.28.1 or later of the container agent and version 1.28.1-2 or later of the ecs-init package, support the increased ENI limits. If you use the latest Linux variant of the Amazon ECS-optimized AMI, these requirements will be met. Windows containers are not supported at this time.
- Only new Amazon EC2 instances launched after enabling awsvpcTrunking receive the increased ENI limits and the trunk network interface. Previously launched instances do not receive these features regardless of the actions taken.
- Amazon EC2 instances must have resource-based IPv4 DNS requests turned off. To disable this option, ensure the Enable resource-based IPv4 (A record) DNS requests option is deselected.
when creating a new instance using the Amazon EC2 console. To disable this option using the AWS CLI, use the following command.

```
aws ec2 modify-private-dns-name-options --instance-id i-xxxxxxx --no-enable-resource-name-dns-a-record --no-dry-run
```

- Amazon EC2 instances in shared subnets are not supported. They will fail to register to a cluster if they are used.

- Your Amazon ECS tasks must use the awsvpc network mode and the EC2 launch type. Tasks using the Fargate launch type always received a dedicated ENI regardless of how many are launched, so this feature is not needed.

- Your Amazon ECS tasks must be launched in the same Amazon VPC as your container instance. Your tasks will fail to start with an attribute error if they are not within the same VPC.

- When launching a new container instance, the instance transitions to a REGISTERING status while the trunk elastic network interface is provisioned for the instance. If the registration fails, the instance transitions to a REGISTRATION_FAILED status. You can troubleshoot a failed registration by describing the container instance to view the statusReason field which describes the reason for the failure. The container instance then can be manually deregistered or terminated. Once the container instance is successfully deregistered or terminated, Amazon ECS will delete the trunk ENI.

**Note**

Amazon ECS emits container instance state change events which you can monitor for instances that transition to a REGISTRATION_FAILED state. For more information, see Amazon ECS container instance state change events.

- Once the container instance is terminated, the instance transitions to a DEREGISTERING status while the trunk elastic network interface is deprovisioned. The instance then transitions to an INACTIVE status.

- If a container instance in a public subnet with the increased ENI limits is stopped and then restarted, the instance loses its public IP address, and the container agent loses its connection.

- When you enable awsvpcTrunking, container instances receive an additional ENI that uses the VPC's default security group, and is managed by Amazon ECS.
Prerequisites

Before you launch a container instance with the increased ENI limits, the following prerequisites must be completed.

- The service-linked role for Amazon ECS must be created. The Amazon ECS service-linked role provides Amazon ECS with the permissions to make calls to other AWS services on your behalf. This role is created for you automatically when you create a cluster, or if you create or update a service in the AWS Management Console. For more information, see Using service-linked roles for Amazon ECS. You can also create the service-linked role with the following AWS CLI command.

  ```
  aws iam create-service-linked-role --aws-service-name ecs.amazonaws.com
  ```

- Your account or container instance IAM role must enable the awsvpcTrunking account setting. We recommend that you create 2 container instance roles (ecsInstanceRole). You can then enable the awsvpcTrunking account setting for one role and use that role for tasks that require ENI trunking. For information about the container instance role, see Amazon ECS container instance IAM role.

After the prerequisites are met, you can launch a new container instance using one of the supported Amazon EC2 instance types, and the instance will have the increased ENI limits. For a list of supported instance types, see Supported Amazon EC2 instance types. The container instance must have version 1.28.1 or later of the container agent and version 1.28.1-2 or later of the ecs-init package. If you use the latest Linux variant of the Amazon ECS-optimized AMI, these requirements will be met. For more information, see Launching an Amazon ECS Linux container instance.

⚠️ Important

Amazon EC2 instances must have resource-based IPv4 DNS requests turned off. To disable this option, ensure the Enable resource-based IPV4 (A record) DNS requests option is deselected when creating a new instance using the Amazon EC2 console. To disable this option using the AWS CLI, use the following command.

```
aws ec2 modify-private-dns-name-options --instance-id i-xxxxxxx --no-enable-resource-name-dns-a-record --no-dry-run
```
To view your container instances with increased ENI limits with the AWS CLI

Each container instance has a default network interface, referred to as a trunk network interface. Use the following command to list your container instances with increased ENI limits by querying for the `ecs.awsvpc-trunk-id` attribute, which indicates it has a trunk network interface.

- **list-attributes** (AWS CLI)

  ```
  aws ecs list-attributes \\n  --target-type container-instance \\n  --attribute-name ecs.awsvpc-trunk-id \\n  --cluster cluster_name \\n  --region us-east-1
  ```

- **Get-ECSAttributeList** (AWS Tools for Windows PowerShell)

  ```
  Get-ECSAttributeList -TargetType container-instance -AttributeName ecs.awsvpc-trunk-id -Region us-east-1
  ```

**Supported Amazon EC2 instance types**

The following shows the supported Amazon EC2 instance types and how many tasks using the awsvpc network mode can be launched on each instance type before and after enabling the awsvpcTrunking account setting. For the elastic network interface (ENI) limits on each instance type, add one to the current task limit, as the primary network interface counts against the limit, and add two to the new task limit, as both the primary network interface and the trunk network interface count again the limit.

⚠️ **Important**

Although other instance types are supported in the same instance family, the a1.metal, c5.metal, c5a.8xlarge, c5ad.8xlarge, c5d.metal, m5.metal, p3dn.24xlarge, r5.metal, r5.8xlarge, and r5d.metal instance types are not supported. The c5n, d3, d3en, g3, g3s, g4dn, i3, i3en, inf1, m5dn, m5n, m5zn, mac1, r5b, r5n, r5dn, u-12tb1, u-6tb1, u-9tb1, and z1d instance families are not supported.

### Container instance memory management

When the Amazon ECS container agent registers a container instance into a cluster, the agent must determine how much memory the container instance has available to reserve for your tasks. Because of platform memory overhead and memory occupied by the system kernel, this number is different than the installed memory amount that is advertised for Amazon EC2 instances. For example, an m4.large instance has 8 GiB of installed memory. However, this does not always translate to exactly 8192 MiB of memory available for tasks when the container instance registers.

The Amazon ECS container agent provides a configuration variable called `ECS_RESERVED_MEMORY`, which you can use to remove a specified number of MiB of memory from the pool that is allocated to your tasks. This effectively reserves that memory for critical system processes.

If you occupy all of the memory on a container instance with your tasks, then it is possible that your tasks will contend with critical system processes for memory and possibly start a system failure.

For example, if you specify `ECS_RESERVED_MEMORY=256` in your container agent configuration file, then the agent registers the total memory minus 256 MiB for that instance, and 256 MiB of memory could not be allocated by ECS tasks. For more information about agent configuration variables and how to set them, see [Amazon ECS container agent configuration](#) and [Bootstrapping container instances with Amazon EC2 user data](#).

If you specify 8192 MiB for the task, and none of your container instances have 8192 MiB or greater of memory available to satisfy this requirement, then the task cannot be placed in your cluster. If you are using a managed compute environment, then AWS Batch must launch a larger instance type to accommodate the request.

You should also reserve some memory for the Amazon ECS container agent and other critical system processes on your container instances, so that your task's containers do not contend for the same memory and possibly starts a system failure.

<table>

Linux container instance management
The Amazon ECS container agent uses the Docker ReadMemInfo() function to query the total memory available to the operating system. Both Linux and Windows provide command line utilities to determine the total memory.

**Example - Determine Linux total memory**

The `free` command returns the total memory that is recognized by the operating system.

```bash
$ free -b
```

Example output for an `m4.large` instance running the Amazon ECS-optimized Amazon Linux AMI.

```
total       used       free     shared    buffers     cached
Mem: 8373026816 348180480 8024846336      90112   25534464  205418496
-/+ buffers/cache: 117227520 8255799296
```

This instance has 8373026816 bytes of total memory, which translates to 7985 MiB available for tasks.

**Example - Determine Windows total memory**

The `wmic` command returns the total memory that is recognized by the operating system.

```bash
C:\> wmic ComputerSystem get TotalPhysicalMemory
```

Example output for an `m4.large` instance running the Amazon ECS-optimized Windows Server AMI.

```
TotalPhysicalMemory
8589524992
```

This instance has 8589524992 bytes of total memory, which translates to 8191 MiB available for tasks.

**Viewing container instance memory**

You can view how much memory a container instance registers with in the Amazon ECS console (or with the `DescribeContainerInstances` API operation). If you are trying to maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type, you
can observe the memory available for that container instance and then assign your tasks that much memory.

**To view container instance memory**

2. In the navigation pane, choose **Clusters**, and then choose the cluster that hosts your container instance.
3. Choose **Infrastructure**, and then under Container instances, choose a container instance.
4. The **Resources** section shows the registered and available memory for the container instance.

   The **Registered** memory value is what the container instance; registered with Amazon ECS when it was first launched, and the **Available** memory value is what has not already been allocated to tasks.

**Manage container instances remotely using AWS Systems Manager**

You can use the Run Command capability in AWS Systems Manager (Systems Manager) to securely and remotely manage the configuration of your Amazon ECS container instances. Run Command provides a simple way to perform common administrative tasks without logging on locally to the instance. You can manage configuration changes across your clusters by simultaneously executing commands on multiple container instances. Run Command reports the status and results of each command.

Here are some examples of the types of tasks you can perform with Run Command:

- Install or uninstall packages.
- Perform security updates.
- Clean up Docker images.
- Stop or start services.
- View system resources.
- View log files.
- Perform file operations.

For more information about Run Command, see **AWS Systems Manager Run Command** in the **AWS Systems Manager User Guide**.
Run Command IAM policy

Before you can send commands to your container instances with Run Command, you must attach an IAM policy that allows ecsInstanceRole to have access to the Systems Manager APIs. The following procedure describes how to attach the Systems Manager managed policies to your container instance role so that instances launched with this role can use Run Command.

To attach the Systems Manager policies to your ecsInstanceRole

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles.
3. Choose ecsInstanceRole. If the role does not exist, follow the procedures in Amazon ECS container instance IAM role to create the role.
4. Choose the Permissions tab.
5. Choose Attach policies.
6. To narrow the available policies to attach, for Filter, type SSM.
7. In the list of policies, select the box next AmazonSSMManagedInstanceCore. Use this policy to provide the minimum permissions that are necessary to use Systems Manager.
   For information about other policies you can provide for Systems Manager operations, see Create an IAM Instance Profile for Systems Manager in the AWS Systems Manager User Guide.
8. Choose Attach Policy.

Using Run Command

After you attach Systems Manager managed policies to your ecsInstanceRole and verify that AWS Systems Manager Agent (SSM Agent) is installed on your container instances, you can start using Run Command to send commands to your container instances. For information about running commands and shell scripts on your instances and viewing the resulting output, see Running Commands Using Systems Manager Run Command and Run Command Walkthroughs in the AWS Systems Manager User Guide.
Example: To update container instance software with Run Command

A common use case for Run Command is to update the instance software on your entire fleet of container instances at one time.

1. **Attach Systems Manager managed policies to your ecsInstanceRole.**
2. Verify that SSM Agent is installed on your container instances. For more information, see [Manually install SSM Agent on EC2 instances for Linux](https://docs.aws.amazon.com/systems-manager/latest/userguide/extend-manually.html).
4. In the left navigation pane, choose Run Command, and then choose Run command.
5. For Command document, choose AWS-RunShellScript.
6. In the Commands section, enter the command or commands to send to your container instances. In this example, the following command updates the instance software:

   ```
   $ yum update -y
   ```
7. In the Target instances section, select the boxes next to the container instances where you want to run the update command.
8. Choose Run to send the command to the specified instances.
9. (Optional) Choose the refresh icon to monitor the command status.
10. (Optional) In Targets and output, choose the button next to the instance ID, and then choose View output.

HTTP proxy configuration for Linux container instances

You can configure your Amazon ECS container instances to use an HTTP proxy for both the Amazon ECS container agent and the Docker daemon. This is useful if your container instances do not have external network access through an Amazon VPC internet gateway, NAT gateway, or instance.

To configure your Amazon ECS Linux container instance to use an HTTP proxy, set the following variables in the relevant files at launch time (with Amazon EC2 user data). You could also manually edit the configuration file and restart the agent afterwards.
/etc/ecs/ecs.config (Amazon Linux 2 and AmazonLinux AMI)

HTTP_PROXY=10.0.0.131:3128

Set this value to the hostname (or IP address) and port number of an HTTP proxy to use for the Amazon ECS agent to connect to the internet. For example, your container instances may not have external network access through an Amazon VPC internet gateway, NAT gateway, or instance.

NO_PROXY=169.254.169.254,169.254.170.2,/var/run/docker.sock

Set this value to 169.254.169.254,169.254.170.2,/var/run/docker.sock to filter EC2 instance metadata, IAM roles for tasks, and Docker daemon traffic from the proxy.

/etc/systemd/system/ecs.service.d/http-proxy.conf (Amazon Linux 2 only)

Environment="HTTP_PROXY=10.0.0.131:3128/"

Set this value to the hostname (or IP address) and port number of an HTTP proxy to use for ecs-init to connect to the internet. For example, your container instances may not have external network access through an Amazon VPC internet gateway, NAT gateway, or instance.

Environment="NO_PROXY=169.254.169.254,169.254.170.2,/var/run/docker.sock"

Set this value to 169.254.169.254,169.254.170.2,/var/run/docker.sock to filter EC2 instance metadata, IAM roles for tasks, and Docker daemon traffic from the proxy.

/etc/init/ecs.override (Amazon Linux AMI only)

env HTTP_PROXY=10.0.0.131:3128

Set this value to the hostname (or IP address) and port number of an HTTP proxy to use for ecs-init to connect to the internet. For example, your container instances may not have external network access through an Amazon VPC internet gateway, NAT gateway, or instance.

env NO_PROXY=169.254.169.254,169.254.170.2,/var/run/docker.sock

Set this value to 169.254.169.254,169.254.170.2,/var/run/docker.sock to filter EC2 instance metadata, IAM roles for tasks, and Docker daemon traffic from the proxy.
/etc/systemd/system/docker.service.d/http-proxy.conf (Amazon Linux 2 only)

    Environment="HTTP_PROXY=http://10.0.0.131:3128"

    Set this value to the hostname (or IP address) and port number of an HTTP proxy to use for
the Docker daemon to connect to the internet. For example, your container instances may
not have external network access through an Amazon VPC internet gateway, NAT gateway,
or instance.

    Environment="NO_PROXY=169.254.169.254"

    Set this value to 169.254.169.254 to filter EC2 instance metadata from the proxy.

/etc/sysconfig/docker (Amazon Linux AMI and Amazon Linux 2 only)

    export HTTP_PROXY=http://10.0.0.131:3128

    Set this value to the hostname (or IP address) and port number of an HTTP proxy to use for
the Docker daemon to connect to the internet. For example, your container instances may
not have external network access through an Amazon VPC internet gateway, NAT gateway,
or instance.

    export NO_PROXY=169.254.169.254,169.254.170.2

    Set this value to 169.254.169.254 to filter EC2 instance metadata from the proxy.

Setting these environment variables in the above files only affects the Amazon ECS container
agent, ecs-init, and the Docker daemon. They do not configure any other services (such as yum)
to use the proxy.

**Example Amazon Linux HTTP proxy user data script**

The example user data cloud-boothook script below configures the Amazon ECS container agent,
ecs-init, the Docker daemon, and yum to use an HTTP proxy that you specify. You can also
specify a cluster into which the container instance registers itself.

To use this script when you launch a container instance, follow the steps in *Launching an Amazon
ECS Linux container instance*, and in *Step 6.g*. Then, copy and paste the cloud-boothook script
below into the **User data** field (be sure to substitute the red example values with your own proxy
and cluster information).
Note

The user data script below only supports Amazon Linux 2 and Amazon Linux AMI variants of the Amazon ECS-optimized AMI.

```bash
#cloud-boothook
# Configure Yum, the Docker daemon, and the ECS agent to use an HTTP proxy

# Specify proxy host, port number, and ECS cluster name to use
PROXY_HOST=10.0.0.131
PROXY_PORT=3128
CLUSTER_NAME=proxy-test

if grep -q 'Amazon Linux release 2' /etc/system-release; then

## Updating the Amazon ECS container agent

Occasionally, you may need to update the Amazon ECS container agent to pick up bug fixes and new features. Updating the Amazon ECS container agent does not interrupt running tasks or services on the container instance. The process for updating the agent differs depending on whether your container instance was launched with an Amazon ECS-optimized AMI or another operating system.

### Note

Agent updates do not apply to Windows container instances. We recommend that you launch new container instances to update the agent version in your Windows clusters.

### Topics

- [Checking the Amazon ECS container agent version](#)
- [Updating the Amazon ECS container agent on an Amazon ECS-optimized AMI](#)
- [Manually updating the Amazon ECS container agent (for non-Amazon ECS-Optimized AMIs)](#)

### Checking the Amazon ECS container agent version

You can check the version of the container agent that is running on your container instances to see if you need to update it. The container instance view in the Amazon ECS console provides the agent version. Use the following procedure to check your agent version.
Amazon ECS console

2. From the navigation bar, choose the Region where your external instance is registered.
3. In the navigation pane, choose Clusters and select the cluster that hosts the external instance.
4. On the Cluster : name page, choose the Infrastructure tab.
5. Under Container instances, note the Agent version column for your container instances. If the container instance does not contain the latest version of the container agent, the console alerts you with a message and flags the outdated agent version.

If your agent version is outdated, you can update your container agent with the following procedures:

- If your container instance is running an Amazon ECS-optimized AMI, see Updating the Amazon ECS container agent on an Amazon ECS-optimized AMI.
- If your container instance is not running an Amazon ECS-optimized AMI, see Manually updating the Amazon ECS container agent (for non-Amazon ECS-Optimized AMIs).

⚠️ Important
To update the Amazon ECS agent version from versions before v1.0.0 on your Amazon ECS-optimized AMI, we recommend that you terminate your current container instance and launch a new instance with the most recent AMI version. Any container instances that use a preview version should be retired and replaced with the most recent AMI. For more information, see Launching an Amazon ECS Linux container instance.

Amazon ECS container agent introspection API

You can also use the to check the agent Amazon ECS container agent introspection API version from the container instance itself. For more information, see Amazon ECS container introspection.
To check if your Amazon ECS container agent is running the latest version with the introspection API

1. Log in to your container instance via SSH.
2. Query the introspection API.

```
[ec2-user ~]$ curl -s 127.0.0.1:51678/v1/metadata | python -mjson.tool
```

**Note**

The introspection API added Version information in the version v1.0.0 of the Amazon ECS container agent. If Version is not present when querying the introspection API, or the introspection API is not present in your agent at all, then the version you are running is v0.0.3 or earlier. You should update your version.

Updating the Amazon ECS container agent on an Amazon ECS-optimized AMI

If you are using an Amazon ECS-optimized AMI, you have several options to get the latest version of the Amazon ECS container agent (shown in order of recommendation):

- Terminate the container instance and launch the latest version of the Amazon ECS-optimized Amazon Linux 2 AMI (either manually or by updating your Auto Scaling launch configuration with the latest AMI). This provides a fresh container instance with the most current tested and validated versions of Amazon Linux, Docker, ecs-init, and the Amazon ECS container agent. For more information, see Amazon ECS-optimized AMI.

- Connect to the instance with SSH and update the ecs-init package (and its dependencies) to the latest version. This operation provides the most current tested and validated versions of Docker and ecs-init that are available in the Amazon Linux repositories and the latest version of the Amazon ECS container agent. For more information, see To update the ecs-init package on an Amazon ECS-optimized AMI.

- Update the container agent with the UpdateContainerAgent API operation, either through the console or with the AWS CLI or AWS SDKs. For more information, see Updating the Amazon ECS container agent with the UpdateContainerAgent API operation.
Note
Agent updates do not apply to Windows container instances. We recommend that you launch new container instances to update the agent version in your Windows clusters.

To update the ecs-init package on an Amazon ECS-optimized AMI

1. Log in to your container instance via SSH.
2. Update the ecs-init package with the following command.

   ```
   sudo yum update -y ecs-init
   ```

Note
The ecs-init package and the Amazon ECS container agent are updated immediately. However, newer versions of Docker are not loaded until the Docker daemon is restarted. Restart either by rebooting the instance, or by running the following commands on your instance:

- Amazon ECS-optimized Amazon Linux 2 AMI:

  ```
  sudo systemctl restart docker
  ```

- Amazon ECS-optimized Amazon Linux AMI:

  ```
  sudo service docker restart && sudo start ecs
  ```

Updating the Amazon ECS container agent with the UpdateContainerAgent API operation

⚠️ Important
The UpdateContainerAgent API is only supported on Linux variants of the Amazon ECS-optimized AMI, with the exception of the Amazon ECS-optimized Amazon Linux 2 (arm64) AMI. For container instances using the Amazon ECS-optimized Amazon Linux 2 (arm64) AMI, update the ecs-init package to update the agent. For container instances that are running other operating systems, see [Manually updating the Amazon ECS container agent](#).
If you are using Windows container instances, we recommend that you launch new container instances to update the agent version in your Windows clusters.

The UpdateContainerAgent API process begins when you request an agent update, either through the console or with the AWS CLI or AWS SDKs. Amazon ECS checks your current agent version against the latest available agent version, and if an update is possible, the update process progresses as shown in the flow chart below. If an update is not available, for example, if the agent is already running the most recent version, then a NoUpdateAvailableException is returned.

The stages in the update process shown above are as follows:

**PENDING**

An agent update is available, and the update process has started.

**STAGING**

The agent has begun downloading the agent update. If the agent cannot download the update, or if the contents of the update are incorrect or corrupted, then the agent sends a notification of the failure and the update transitions to the **FAILED** state.

**STAGED**

The agent download has completed and the agent contents have been verified.
UPDATING

The `ecs-init` service is restarted and it picks up the new agent version. If the agent is for some reason unable to restart, the update transitions to the `FAILED` state; otherwise, the agent signals Amazon ECS that the update is complete.

Note

Agent updates do not apply to Windows container instances. We recommend that you launch new container instances to update the agent version in your Windows clusters.

To update the Amazon ECS container agent on an Amazon ECS-optimized AMI in the console

2. From the navigation bar, choose the Region where your external instance is registered.
3. In the navigation pane, choose **Clusters** and select the cluster.
4. On the **Cluster : name** page, choose the **Infrastructure** tab.
5. Under **Container instances**, select the instances to update, and then choose **Actions, Update agent**.

Manually updating the Amazon ECS container agent (for non-Amazon ECS-Optimized AMIs)

To manually update the Amazon ECS container agent (for non-Amazon ECS-optimized AMIs)

Note

Agent updates do not apply to Windows container instances. We recommend that you launch new container instances to update the agent version in your Windows clusters.

1. Log in to your container instance via SSH.
2. Check to see if your agent uses the `ECS_DATADIR` environment variable to save its state.

```
ubuntu:~$ docker inspect ecs-agent | grep ECS_DATADIR
```

Output:
"ECS_DATADIR=/data",

⚠️ **Important**

If the previous command does not return the ECS_DATADIR environment variable, you must stop any tasks running on this container instance before updating your agent. Newer agents with the ECS_DATADIR environment variable save their state and you can update them while tasks are running without issues.

3. Stop the Amazon ECS container agent.

   ```bash
   ubuntu:~$ docker stop ecs-agent
   ```

4. Delete the agent container.

   ```bash
   ubuntu:~$ docker rm ecs-agent
   ```

5. Ensure that the /etc/ecs directory and the Amazon ECS container agent configuration file exist at /etc/ecs/ecs.config.

   ```bash
   ubuntu:~$ sudo mkdir -p /etc/ecs && sudo touch /etc/ecs/ecs.config
   ```

6. Edit the /etc/ecs/ecs.config file and ensure that it contains at least the following variable declarations. If you do not want your container instance to register with the default cluster, specify your cluster name as the value for ECS_CLUSTER.

   ```
   ECS_DATADIR=/data
   ECS_ENABLE_TASK_IAM_ROLE=true
   ECS_ENABLE_TASK_IAM_ROLE_NETWORK_HOST=true
   ECS_LOGFILE=/log/ecs-agent.log
   ECS_AVAILABLE_LOGGING_DRIVERS=["json-file","awslogs"]
   ECS_LOGLEVEL=info
   ECS_CLUSTER=default
   ```

   For more information about these and other agent runtime options, see [Amazon ECS container agent configuration](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/agent-architecture.html#agent-variables).

---

**Linux container instance management**

585
Note
You can optionally store your agent environment variables in Amazon S3 (which can be downloaded to your container instances at launch time using Amazon EC2 user data). This is recommended for sensitive information such as authentication credentials for private repositories. For more information, see Storing container instance configuration in Amazon S3 and Private registry authentication for tasks.

7. Pull the latest Amazon ECS container agent image from Amazon Elastic Container Registry Public.

```
ubuntu:~$ docker pull public.ecr.aws/ecs/amazon-ecs-agent:latest
```

Output:

```
Pulling repository amazon/amazon-ecs-agent
a5a56a5e13dc: Download complete
511136ea3c5a: Download complete
9950b5d678a1: Download complete
c48ddcf21b63: Download complete
Status: Image is up to date for amazon/amazon-ecs-agent:latest
```

8. Run the latest Amazon ECS container agent on your container instance.

Note
Use Docker restart policies or a process manager (such as upstart or systemd) to treat the container agent as a service or a daemon and ensure that it is restarted after exiting. For more information, see Automatically start containers and Restart policies in the Docker documentation. The Amazon ECS-optimized AMI uses the ecs-init RPM for this purpose, and you can view the source code for this RPM on GitHub.

The following example of the agent run command is broken into separate lines to show each option. For more information about these and other agent runtime options, see Amazon ECS container agent configuration.
Important

Operating systems with SELinux enabled require the --privileged option in your `docker run` command. In addition, for SELinux-enabled container instances, we recommend that you add the :Z option to the /log and /data volume mounts. However, the host mounts for these volumes must exist before you run the command or you receive a no such file or directory error. Take the following action if you experience difficulty running the Amazon ECS agent on an SELinux-enabled container instance:

- Create the host volume mount points on your container instance.

  ```
  ubuntu:~$ sudo mkdir -p /var/log/ecs /var/lib/ecs/data
  ```

- Add the --privileged option to the `docker run` command below.

- Append the :Z option to the /log and /data container volume mounts (for example, --volume=/var/log/ecs:/log:Z) to the `docker run` command below.

  ```
  ubuntu:~$ sudo docker run --name ecs-agent \
  --detach=true \ 
  --restart=on-failure:10 \ 
  --volume=/var/run:/var/run \ 
  --volume=/var/log/ecs:/log \ 
  --volume=/var/lib/ecs/data:/data \ 
  --volume=/etc/ecs:/etc/ecs \ 
  --volume=/etc/ecs:/etc/ecs/pki \ 
  --net=host \ 
  --env-file=/etc/ecs/ecs.config \ 
  amazon/amazon-ecs-agent:latest
  ```

Note

If you receive an Error response from daemon: Cannot start container message, you can delete the failed container with the `sudo docker rm ecs-agent` command and try running the agent again.
Windows container instance management

Windows container instance management includes:

- Launching a container instance
- Bootstrapping a container instance
- Connecting to your container instance
- Using an HTTP proxy for both the container agent and the Docker daemon
- Deregistering a container instance

Agent updates do not apply to Windows container instances. We recommend that you launch new container instances to update the agent version in your Windows clusters.

Launching an Amazon ECS Windows container instance

Your Amazon ECS container instances are created using the Amazon EC2 console. Before you begin, be sure that you've completed the steps in Set up to use Amazon ECS.

For more information about the launch wizard, see Launch an instance using the new launch instance wizard in the Amazon EC2 User Guide for Windows Instances.

New Amazon EC2 launch instance wizard

You can use the new Amazon EC2 wizard to launch an instance. You can use the following list for the parameters and leave the parameters not listed as the default. The following instructions take you through each parameter group.

Parameters for instance configuration

- Initiate instance launch
- Name and tags
- Application and OS Images (Amazon Machine Image)
- Instance type
- Key pair (login)
- Network settings
- Configure storage
Initiate instance launch

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. In the navigation bar at the top of the screen, the current AWS Region is displayed (for example, US East (Ohio)). Select a Region in which to launch the instance. This choice is important because some Amazon EC2 resources can be shared between Regions, while others can't.
3. From the Amazon EC2 console dashboard, choose Launch instance.

Name and tags

The instance name is a tag, where the key is Name, and the value is the name that you specify. You can tag the instance, the volumes, and elastic graphics. For Spot Instances, you can tag the Spot Instance request only.

Specifying an instance name and additional tags is optional.

• For Name, enter a descriptive name for the instance. If you don’t specify a name, the instance can be identified by its ID, which is automatically generated when you launch the instance.
• To add additional tags, choose Add additional tags. Choose Add tag, and then enter a key and value, and select the resource type to tag. Choose Add tag again for each additional tag to add.

Application and OS Images (Amazon Machine Image)

An Amazon Machine Image (AMI) contains the information required to create an instance. For example, an AMI might contain the software that's required to act as a web server, such as Apache, and your website.

For the latest Amazon ECS-optimized AMIs and their values, see Windows Amazon ECS-optimized AMI.

Use the Search bar to find a suitable Amazon ECS-optimized AMI published by AWS.

1. Based on your requirements, enter one of the following AMIs in the Search bar and press Enter.
   • Windows_Server-2022-English-Full-ECS_Optimized
2. On the **Choose an Amazon Machine Image (AMI)** page, select the **Community AMIs** tab.

3. From the list that appears, choose a Microsoft-verified AMI with the most recent publish date and click **Select**.

**Instance type**

The instance type defines the hardware configuration and size of the instance. Larger instance types have more CPU and memory. For more information, see [Instance types](#).

For **Instance type**, select the instance type for the instance.

The instance type that you select determines the resources available for your tasks to run on.

**Key pair (login)**

For **Key pair name**, choose an existing key pair, or choose **Create new key pair** to create a new one.

⚠️ **Important**

If you choose the **Proceed without key pair (Not recommended)** option, you won't be able to connect to the instance unless you choose an AMI that is configured to allow users another way to log in.

**Network settings**

Configure the network settings, as necessary.

- **Networking platform**: Choose **Virtual Private Cloud (VPC)**, and then specify the subnet in the **Network interfaces** section.
- **VPC**: Select an existing VPC in which to create the security group.
- **Subnet**: You can launch an instance in a subnet associated with an Availability Zone, Local Zone, Wavelength Zone, or Outpost.
To launch the instance in an Availability Zone, select the subnet in which to launch your instance. To create a new subnet, choose **Create new subnet** to go to the Amazon VPC console. When you are done, return to the launch instance wizard and choose the Refresh icon to load your subnet in the list.

To launch the instance in a Local Zone, select a subnet that you created in the Local Zone.

To launch an instance in an Outpost, select a subnet in a VPC that you associated with the Outpost.

- **Auto-assign Public IP**: If your instance should be accessible from the internet, verify that the **Auto-assign Public IP** field is set to **Enable**. If not, set this field to **Disable**.

### Note

Container instances need access to communicate with the Amazon ECS service endpoint. This can be through an interface VPC endpoint or through your container instances having public IP addresses.

For more information about interface VPC endpoints, see [Amazon ECS interface VPC endpoints (AWS PrivateLink)](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/vpc-endpoints.html)

If you do not have an interface VPC endpoint configured and your container instances do not have public IP addresses, then they must use network address translation (NAT) to provide this access. For more information, see [NAT gateways](https://docs.aws.amazon.com/vpc/latest/userguide/nat.html) in the [Amazon VPC User Guide](https://docs.aws.amazon.com/vpc/latest/userguide/index.html) and [HTTP proxy configuration for Linux container instances](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/http-proxy.html) in this guide.

- **Firewall (security groups)**: Use a security group to define firewall rules for your container instance. These rules specify which incoming network traffic is delivered to your container instance. All other traffic is ignored.

  - To select an existing security group, choose **Select existing security group**, and select the security group that you created in [Set up to use Amazon ECS](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/vpc-subnets.html).

### Configure storage

The AMI you selected includes one or more volumes of storage, including the root volume. You can specify additional volumes to attach to the instance.

You can use the **Simple** view.
• **Storage type:** Configure the storage for your container instance.

If you are using the Amazon ECS-optimized Amazon Linux 2 AMI, your instance has a single 30 GiB volume configured, which is shared between the operating system and Docker.

If you are using the Amazon ECS-optimized AMI, your instance has two volumes configured. The **Root** volume is for the operating system's use, and the second Amazon EBS volume (attached to `/dev/xvdcz`) is for Docker's use.

You can optionally increase or decrease the volume sizes for your instance to meet your application needs.

**Advanced details**

For **Advanced details**, expand the section to view the fields and specify any additional parameters for the instance.

• **Purchasing option:** Choose **Request Spot Instances** to request Spot Instances. You also need to set the other fields related to Spot Instances. For more information, see **Spot Instance Requests**.

⚠️ **Note**

If you are using Spot Instances and see a **Not available** message, you may need to choose a different instance type.

• **IAM instance profile:** Select your container instance IAM role. This is usually named `ecsInstanceRole`.

⚠️ **Important**

If you do not launch your container instance with the proper IAM permissions, your Amazon ECS agent cannot connect to your cluster. For more information, see **Amazon ECS container instance IAM role**.

• (Optional) **User data:** Configure your Amazon ECS container instance with user data, such as the agent environment variables from **Amazon ECS container agent configuration**. Amazon EC2 user
data scripts are executed only one time, when the instance is first launched. The following are common examples of what user data is used for:

- **By default, your container instance launches into your default cluster. To launch into a non-default cluster, choose the **Advanced Details** list. Then, paste the following script into the **User data** field, replacing `your_cluster_name` with the name of your cluster.

  ```powershell
  Import-Module ECSTools
  Initialize-ECSAgent -Cluster your_cluster_name -EnableTaskIAMRole -EnableTaskENI -AwsvpcBlockIMDS -AwsvpcAdditionalLocalRoutes '["ip-address"]'
  </powershell>

The **EnableTaskIAMRole** turns on the Task IAM roles feature for the tasks.

In addition, the following options are available when you use the awsvpc network mode.

- **EnableTaskENI**: This flag turns on task networking and is required when you use the awsvpc network mode.
- **AwsvpcBlockIMDS**: This optional flag blocks IMDS access for the task containers running in the awsvpc network mode.
- **AwsvpcAdditionalLocalRoutes**: This optional flag allows you to have additional routes in the task namespace.

Replace `ip-address` with the IP Address for the additional routes, for example `172.31.42.23/32`.

**Old Amazon EC2 launch instance wizard**

**To launch a container instance**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. From the navigation bar, select the Region to use.
3. From the **EC2 Dashboard**, choose **Launch instance**.
4. On the **Choose an Amazon Machine Image (AMI)** page, complete the following steps:

   a. Choose **AWS Marketplace**.
b. Choose an AMI for your container instance. You can search for one of the Amazon ECS-optimized AMIs, for example Windows_2019_Full_ECS_Optimized. If you do not choose an Amazon ECS-optimized AMI, you must follow the procedures in Installing the Amazon ECS container agent.

5. On the Choose an Instance Type page, you can select the hardware configuration of your instance. The t2.micro instance type is selected by default. The instance type that you select determines the resources available for your tasks to run on.

Choose Next: Configure Instance Details when you are done.

6. On the Configure Instance Details page, complete the following steps:

   a. Set the Number of instances field depending on how many container instances you want to add to your cluster.

   b. (Optional) To use Spot Instances, for Purchasing option, select the check box next to Request Spot Instances. You also need to set the other fields related to Spot Instances. For more information, see Spot Instance Requests.

   Note
   
   If you are using Spot Instances and see a Not available message, you may need to choose a different instance type.

   c. For Network, choose the VPC into which to launch your container instance.

   d. For Subnet, choose a subnet to use, or keep the default option to choose the default subnet in any Availability Zone.

   e. Set the Auto-assign Public IP field depending on whether you want your instance to be accessible from the public internet. If your instance should be accessible from the internet, verify that the Auto-assign Public IP field is set to Enable. If not, set this field to Disable.

   Note
   
   Container instances need access to communicate with the Amazon ECS service endpoint. This can be through an interface VPC endpoint or through your container instances having public IP addresses.
   For more information about interface VPC endpoints, see Amazon ECS interface VPC endpoints (AWS PrivateLink).
If you do not have an interface VPC endpoint configured and your container instances do not have public IP addresses, then they must use network address translation (NAT) to provide this access. For more information, see NAT gateways in the Amazon VPC User Guide and HTTP proxy configuration for Linux container instances in this guide. For more information, see the section called “Create a virtual private cloud”.

f. Select your container instance IAM role. This is usually named ecsInstanceRole.

**Important**

If you do not launch your container instance with the proper IAM permissions, your Amazon ECS agent cannot connect to your cluster. For more information, see Amazon ECS container instance IAM role.

g. Configure your Amazon ECS container instance with user data, such as the agent environment variables from Amazon ECS container agent configuration. Amazon EC2 user data scripts are executed only one time, when the instance is first launched. The following are common examples of what user data is used for:

- By default, your container instance launches into your default cluster. To launch into a non-default cluster, choose the Advanced Details list. Then, paste the following script into the User data field, replacing your_cluster_name with the name of your cluster.

The EnableTaskIAMRole turns on the Task IAM roles feature for the tasks.

In addition, the following options are available when you use the awsvpc network mode.

- EnableTaskENI: This flag turns on task networking and is required when you use the awsvpc network mode.

- AwsvpcBlockIMDS: This optional flag blocks IMDS access for the task containers running in the awsvpc network mode.

- AwsvpcAdditionalLocalRoutes: This optional flag allows you to have additional routes in the task namespace.

Replace ip-address with the IP Address for the additional routes, for example 172.31.42.23/32.
h. Choose **Next: Add Storage**.

7. On the **Add Storage** page, configure the storage for your container instance.

   You can optionally increase or decrease the volume sizes for your instance to meet your application needs.

   When done configuring your volumes, choose **Next: Add Tags**.

8. On the **Add Tags** page, specify tags by providing key and value combinations for the container instance. Choose **Add another tag** to add more than one tag to your container instance. For more information resource tags, see [Amazon ECS resource tagging](#).

   Choose **Next: Configure Security Group** when you are done.

9. On the **Configure Security Group** page, use a security group to define firewall rules for your container instance. These rules specify which incoming network traffic is delivered to your container instance. All other traffic is ignored. Select or create a security group as follows, and then choose **Review and Launch**.

10. On the **Review Instance Launch** page, under **Security Groups**, you see that the wizard created and selected a security group for you. Instead, select the security group that you created in **Set up to use Amazon ECS** using the following steps:

    a. Choose **Edit security groups**.

    b. On the **Configure Security Group** page, select the **Select an existing security group** option.

    c. Select the security group you created for your container instance from the list of existing security groups, and choose **Review and Launch**.

11. On the **Review Instance Launch** page, choose **Launch**.

12. In the **Select an existing key pair or create a new key pair** dialog box, choose **Choose an existing key pair**, then select the key pair that you created when getting set up.

    When you are ready, select the acknowledgment field, and then choose **Launch Instances**.
13. A confirmation page lets you know that your instance is launching. Choose View Instances to close the confirmation page and return to the console.

14. On the **Instances** screen, you can view the status of your instance. It takes a short time for an instance to launch. When you launch an instance, its initial state is pending. After the instance starts, its state changes to running, and it receives a public DNS name. If the **Public DNS** column is hidden, choose **Show/Hide, Public DNS**.

**Using Spot Instances**

A Spot Instance is an unused Amazon EC2 instance that is available for less than the On-Demand price. Because Spot Instances allow you to request unused EC2 instances at steep discounts, you can lower your Amazon EC2 costs significantly. The hourly price for a Spot Instance is called a Spot price. The Spot price of each instance type in each Availability Zone is set by Amazon EC2, and adjusted gradually based on the long-term supply of and demand for Spot Instances. For more information, see [Spot Instances](#) in the Amazon EC2 User Guide for Windows Instances.

You can register Spot Instances to your Amazon ECS clusters. For more information, see [Launching an Amazon ECS Linux container instance](#).

**Spot Instance draining**

Amazon EC2 terminates, stops, or hibernates your Spot Instance when the Spot price exceeds the maximum price for your request or capacity is no longer available. Amazon EC2 provides a Spot Instance interruption notice, which gives the instance a two-minute warning before it is interrupted. If Amazon ECS Spot Instance draining is enabled on the instance, ECS receives the Spot Instance interruption notice and places the instance in DRAINING status.

**Important**

Amazon ECS monitors for the Spot Instance interruption notices that have the terminate and stop instance-actions. If you specified either the hibernate instance interruption behavior when requesting your Spot Instances or Spot Fleet, then Amazon ECS Spot Instance draining is not supported for those instances.

When a container instance is set to DRAINING, Amazon ECS prevents new tasks from being scheduled for placement on the container instance. Service tasks on the draining container
instance that are in the PENDING state are stopped immediately. If there are container instances in the cluster that are available, replacement service tasks are started on them.

You must set the `ECS_ENABLE_SPOT_INSTANCE_DRAINING` parameter before you start the container agent. Use the following commands to manually turn on Spot Instance draining. Substitute `my-cluster` with the name of your cluster.

```powershell
[Environment]::SetEnvironmentVariable("ECS_ENABLE_SPOT_INSTANCE_DRAINING", "true", "Machine")

# Initialize the agent
Initialize-ECSAgent -Cluster my-cluster
```

For more information, see the section called “Launching a container instance”.

**Bootstrapping Windows container instances with Amazon EC2 user data**

When you launch an Amazon ECS container instance, you have the option of passing user data to the instance. The data can be used to perform common automated configuration tasks and run scripts when the instance boots. For Amazon ECS, the most common use cases for user data are to pass configuration information to the Docker daemon and the Amazon ECS container agent.

You can pass multiple types of user data to Amazon EC2, including cloud boothooks, shell scripts, and `cloud-init` directives. For more information about these and other format types, see the `Cloud-Init documentation`.

You can pass this user data when using the Amazon EC2 launch wizard. For more information, see `Launching an Amazon ECS Linux container instance`.

**Topics**

- Default Windows user data
- Windows agent installation user data
- Windows IAM roles for tasks

**Default Windows user data**

This example user data script shows the default user data that your Windows container instances receive if you use the console. The script below does the following:
- Sets the cluster name to the name you entered.
- Sets the IAM roles for tasks.
- Sets json-file and awslogs as the available logging drivers.

In addition, the following options are available when you use the awsvpc network mode.

- EnableTaskENI: This flag turns on task networking and is required when you use the awsvpc network mode.
- AwsvpcBlockIMDS: This optional flag blocks IMDS access for the task containers running in awsvpc network mode.
- AwsvpcAdditionalLocalRoutes: This optional flag allows you to have additional routes.

Replace ip-address with the IP Address for the additional routes, for example 172.31.42.23/32.

You can use this script for your own container instances (provided that they are launched from the Amazon ECS-optimized Windows Server AMI).

Replace the -Cluster cluster-name line to specify your own cluster name.

```powershell
Initialize-ECSAgent -Cluster cluster-name -EnableTaskIAMRole -LoggingDrivers ['"json-file","awslogs"'] -EnableTaskENI -AwsvpcBlockIMDS -AwsvpcAdditionalLocalRoutes ['"ip-address"]
```

For Windows tasks that are configured to use the awslogs logging driver, you must also set the ECS_ENABLE_AWSLOGS_EXECUTIONROLE_OVERRIDE environment variable on your container instance. Use the following syntax.

Replace the -Cluster cluster-name line to specify your own cluster name.

```powershell
[Environment]::SetEnvironmentVariable("ECS_ENABLE_AWSLOGS_EXECUTIONROLE_OVERRIDE", $TRUE, "Machine")
Initialize-ECSAgent -Cluster cluster-name -EnableTaskIAMRole -LoggingDrivers ['"json-file","awslogs"]
```

Windows container instance management
Windows agent installation user data

This example user data script installs the Amazon ECS container agent on an instance launched with a Windows_Server-2016-English-Full-Containers AMI. It has been adapted from the agent installation instructions on the Amazon ECS Container Agent GitHub repository README page.

Note

This script is shared for example purposes. It is much easier to get started with Windows containers by using the Amazon ECS-optimized Windows Server AMI. For more information, see Creating a cluster for the Fargate and External launch type using the console.

You can use this script for your own container instances (provided that they are launched with a version of the Windows_Server-2016-English-Full-Containers AMI). Be sure to replace the windows line to specify your own cluster name (if you are not using a cluster called windows).

```powershell
# Set up directories the agent uses
New-Item -Type directory -Path ${env:ProgramFiles}\Amazon\ECS -Force
New-Item -Type directory -Path ${env:ProgramData}\Amazon\ECS -Force
New-Item -Type directory -Path ${env:ProgramData}\Amazon\ECS\data -Force
# Set up configuration
$ecsExeDir = "${env:ProgramFiles}\Amazon\ECS"
[Environment]::SetEnvironmentVariable("ECS_CLUSTER", "windows", "Machine")
[Environment]::SetEnvironmentVariable("ECS_LOGFILE", "${env:ProgramData}\Amazon\ECS\log\ecs-agent.log", "Machine")
[Environment]::SetEnvironmentVariable("ECS_DATADIR", "${env:ProgramData}\Amazon\ECS\data", "Machine")
# Download the agent
$agentVersion = "latest"
$zipFile = "${env:TEMP}\ecs-agent.zip"
Invoke-RestMethod -OutFile $zipFile -Uri $agentZipUri
# Put the executables in the executable directory.
Expand-Archive -Path $zipFile -DestinationPath $ecsExeDir -Force
Set-Location $ecsExeDir
# Set $EnableTaskIAMRoles to $true to enable task IAM roles
# Note that enabling IAM roles will make port 80 unavailable for tasks.
[bool]$EnableTaskIAMRoles = $false
if ($EnableTaskIAMRoles) {
```
    Invoke-Expression ($($HostSetupScript.Content)}
}
# Install the agent service
New-Service -Name "AmazonECS" `
    -BinaryPathName "$ecsExeDir\amazon-ecs-agent.exe -windows-service" `
    -DisplayName "Amazon ECS" `
    -Description "Amazon ECS service runs the Amazon ECS agent" `
    -DependsOn Docker `
    -StartupType Manual
sc.exe failure AmazonECS reset=300 actions=restart/5000/restart/30000/restart/60000
sc.exe failureflag AmazonECS 1
Start-Service AmazonECS
</powershell>

Windows IAM roles for tasks

See the following Windows examples regarding bootstrapping IAM task roles.

- [Additional configuration for Windows IAM roles for tasks](#)
- [IAM roles for task container bootstrap script](#)

Connect to your container Windows instance

You can connect to your Windows instances to perform basic administrative tasks, such as installing or updating software or accessing diagnostic logs. To connect to your instance using Remote Desktop Protocol (RDP), your Windows instance must meet the following prerequisites.

- Amazon EC2 instances created from most Windows AMIs allow you to connect using Remote Desktop Protocol (RDP). RDP allows you to connect to and use your instance in the same way you use a computer sitting in front of you. It is available on most editions of Windows and available for Mac OS.
- Your Windows instance must have been launched with a valid Amazon EC2 key pair. Amazon EC2 instances have no password, you use a key pair for access over RDP. If you did not specify a key pair when you launched your instance, there is no way to connect to the instance. For more information, see [the section called “Launching a container instance”](#).
- Ensure that the security group associated with your instance allows incoming RDP traffic (port 3389) from your IP address. The default security group doesn't allow incoming RDP traffic by
For more information, see Authorize inbound traffic for your Windows instances in the Amazon EC2 User Guide for Windows Instances.

1. Find the public IP or DNS address for your container instance.
   b. In the navigation pane, choose Clusters and select the cluster that hosts the instance.
   c. On the Cluster: name page, choose the Infrastructure tab.
   d. Under Container instances, select the instance ID.
   e. On the Instances page, record the Public IP or Public DNS for your instance.
2. Find the default username for your container instance AMI.
3. You can connect to your instance by using RDP. For more information, see Connect to your Windows instance using RDP in the Amazon EC2 User Guide for Windows Instances.

HTTP proxy configuration for Windows container instances

You can configure your Amazon ECS container instances to use an HTTP proxy for both the Amazon ECS container agent and the Docker daemon. This is useful if your container instances do not have external network access through an Amazon VPC internet gateway, NAT gateway, or instance.

To configure your Amazon ECS Windows container instance to use an HTTP proxy, set the following variables at launch time (with Amazon EC2 user data).

Set HTTP_PROXY to the hostname (or IP address) and port number of an HTTP proxy to use for the Amazon ECS agent to connect to the internet. For example, your container instances may not have external network access through an Amazon VPC internet gateway, NAT gateway, or instance.

[Environment]::SetEnvironmentVariable("NO_PROXY", "169.254.169.254,169.254.170.2,\.\pipe\docker_engine", "Machine")

Set NO_PROXY to 169.254.169.254,169.254.170.2,\.\pipe\docker_engine to filter EC2 instance metadata, IAM roles for tasks, and Docker daemon traffic from the proxy.
Example Windows HTTP proxy user data script

The example user data PowerShell script below configures the Amazon ECS container agent and the Docker daemon to use an HTTP proxy that you specify. You can also specify a cluster into which the container instance registers itself.

To use this script when you launch a container instance, follow the steps in the section called “Launching a container instance”. Just copy and paste the PowerShell script below into the User data field (be sure to substitute the red example values with your own proxy and cluster information).

> Note
> The -EnableTaskIAMRole option is required to enable IAM roles for tasks. For more information, see Additional configuration for Windows IAM roles for tasks.

```powershell
Import-Module ECSTools

$proxy = "http://proxy.mydomain:port"
[Environment]::SetEnvironmentVariable("HTTP_PROXY", $proxy, "Machine")
[Environment]::SetEnvironmentVariable("NO_PROXY", "169.254.169.254,169.254.170.2,\.
\pipe\docker_engine", "Machine")

Restart-Service Docker
Initialize-ECSAgent -Cluster MyCluster -EnableTaskIAMRole
</powershell>

Deregister an Amazon EC2 backed container instance

> Important
> This topic is for container instances created in Amazon EC2 only. For more information about deregistering external instances, see Deregistering an external instance.

When you are finished with an Amazon EC2 backed container instance, you should deregister it from your cluster. Following deregistration, the container instance is no longer able to accept new tasks.
If you have tasks running on the container instance when you deregister it, these tasks remain running until you terminate the instance or the tasks stop through some other means. However, these tasks are orphaned which means they are no longer monitored or accounted for by Amazon ECS. If an orphaned task on your container instance is part of an Amazon ECS service, then the service scheduler starts another copy of that task, on a different container instance, if possible. Any containers in orphaned service tasks that are registered with an Application Load Balancer target group are deregistered. They begin connection draining according to the settings on the load balancer or target group. If an orphaned tasks is using the `awsvpc` network mode, their elastic network interfaces are deleted.

If you intend to use the container instance for some other purpose after deregistration, you should stop all of the tasks running on the container instance before deregistration. This stops any orphaned tasks from consuming resources.

When deregistering a container instance, be aware of the following considerations.

- Because each container instance has unique state information, they should not be deregistered from one cluster and re-registered into another. To relocate container instance resources, we recommend that you terminate container instances from one cluster and launch new container instances in the new cluster. For more information, see [Terminate your instance](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/terminate-instance.html) in the *Amazon EC2 User Guide for Linux Instances* and [Launching an Amazon ECS Linux container instance](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/launch-container-instance.html).

- If the container instance is managed by an Auto Scaling group or a AWS CloudFormation stack, terminate the instance by updating the Auto Scaling group or AWS CloudFormation stack. Otherwise, the Auto Scaling group or AWS CloudFormation will create a new instance after you terminate it.

- If you terminate a running container instance with a connected Amazon ECS container agent, the agent automatically deregisters the instance from your cluster. Stopped container instances or instances with disconnected agents are not automatically deregistered when terminated.

- Deregistering a container instance removes the instance from a cluster, but it does not terminate the Amazon EC2 instance. If you are finished using the instance, be sure to terminate it to stop billing. For more information, see [Terminate your instance](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/terminate-instance.html) in the *Amazon EC2 User Guide for Linux Instances*.

2. From the navigation bar, choose the Region where your external instance is registered.
3. In the navigation pane, choose **Clusters** and select the cluster that hosts the instance.
4. On the **Cluster : name** page, choose the **Infrastructure** tab.

5. Under **Container instances**, select the instance ID to deregister. You're redirected to the container instance detail page.

6. On the **Container Instance : id** page, choose **Deregister**.

7. On the confirmation screen, choose **Deregister**.

8. If you are finished with the container instance, terminate the underlying Amazon EC2 instance. For more information, see [Terminate Your Instance](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/how-to-manage-timeline.html) in the *Amazon EC2 User Guide for Linux Instances*.

### Amazon ECS managed instance draining

Managed instance draining facilitates graceful termination of Amazon EC2 instances. This allows your workloads to stop safely and be rescheduled to non-terminating instances. Infrastructure maintenance and updates are performed without worrying about disruption to workloads. By using managed instance draining, you simplify your infrastructure management workflows that require replacement of Amazon EC2 instances while you ensure resilience and availability of your applications.

Amazon ECS managed instance draining works with Auto Scaling group instance replacements. Based on instance refresh and maximum instance lifetime, customers can ensure that they stay compliant with the latest OS and security mandates for their capacity.

Managed instance draining can only be used with Amazon ECS capacity providers and is enabled when creating or updating your Auto Scaling group capacity providers using the Amazon ECS console, AWS CLI, or SDK.

The following events are covered by Amazon ECS managed instance draining.

- **Auto Scaling group instance refresh** - Use instance refresh to perform rolling replacement of your Amazon EC2 instances in your Auto Scaling group instead of manually doing it in batches. This is especially useful when you need to replace a large number of instances. An instance refresh is initiated through the Amazon EC2 console or the `StartInstanceRefresh` API. Make sure you select `Replace` for Scale-in protection when calling `StartInstanceRefresh` if you're using managed termination protection.

- **Maximum instance lifetime** - You can define a maximum lifetime when it comes to replacing Auto Scaling group instances. This is helpful for scheduling replacement instances based on internal security policies or compliance.
• Auto Scaling group scale-in - Based on scaling policies and scheduled scaling actions, Auto Scaling group supports automatic scaling of instances. By using Auto Scaling group with Amazon ECS capacity providers, which facilitate cluster-autoscaling, you can scale-in Auto Scaling group instances when no tasks are running in them.

• **Auto Scaling group health checks** - Auto Scaling group supports many health checks to manage termination of unhealthy instances.

• **AWS CloudFormation stack updates** - You can add an UpdatePolicy attribute to your AWS CloudFormation to perform rolling updates when group changes.

• **Spot capacity rebalancing** - Auto Scaling group tries to proactively replace Spot instances that have a higher risk of interruption based on Amazon EC2 capacity rebalance notice. The Auto Scaling group terminates the old instance when the replacement is launched and healthy. Amazon ECS-managed instance draining drains the Spot instance that's terminating just like it drains a non-Spot instance.

• **Spot interruption** - Spot instances are terminated with a two minute notice. Amazon ECS-managed instance draining puts the instance in draining state in response.

**Amazon EC2 Auto Scaling lifecycle hooks with managed instance draining**

Auto Scaling group lifecycle hooks enable customer to create solutions that are triggered by certain events in the instance lifecycle and perform a custom action when that certain event occurs. An Auto Scaling group allows for up to 50 hooks. Multiple termination hooks can exist and are executed in parallel, and Auto Scaling group waits for all hooks to finish before terminating an instance.

In addition to the Amazon ECS-managed hook termination, you can also configure your own lifecycle termination hooks. Lifecycle hooks have a default action, and we recommend setting continue as the default to ensure other hooks, such as the Amazon ECS-managed hook, aren't impacted by any errors from custom hooks.

If you've already configured an Auto Scaling group termination lifecycle hook and also enabled Amazon ECS-managed instance draining, both lifecycle hooks will execute. The relative timings, however, are not guaranteed. Lifecycle hooks have a default action setting to specify the action to take when timeout elapses. In case of failures we recommend using continue as the default result in your custom hook. This ensures other hooks, particularly the Amazon ECS-managed hooks, aren't impacted by any errors in your custom lifecycle hook. The alternative result of abandon causes all other hooks to be skipped and should be avoided.
Tasks and managed instance draining

Amazon ECS managed instance draining uses the existing draining feature found in container instances. The container instance draining feature performs replacement and stops for replica tasks that belong to an Amazon ECS service. A standalone task, like one invoked by RunTask, that is in the pending or running state will remain unaffected. You'll have to wait for these to either complete or stop them manually. The container instance remains in the draining state until either all tasks are stopped or 48 hours has passed. Daemon tasks are the last to stop after all replica tasks have stopped.

Managed instance draining and managed termination protection

Since Amazon ECS managed instance draining facilitates graceful draining of Amazon EC2 instances, it keeps your applications from being disrupted by any termination events. Managed instance draining facilitates graceful shutdown of Amazon ECS service tasks for instances being scaled-in, even if managed termination is disabled.

The following table summarizes the behavior for different combinations of managed termination and managed draining.

<table>
<thead>
<tr>
<th>Managed termination</th>
<th>Managed draining</th>
<th>Outcome</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled</td>
<td>Enabled</td>
<td>Amazon ECS protects Amazon EC2 instances that are running tasks from being terminated by scale-in events. Any instances undergoin</td>
</tr>
<tr>
<td>Managed termination</td>
<td>Managed draining</td>
<td>Outcome</td>
</tr>
<tr>
<td>---------------------</td>
<td>------------------</td>
<td>---------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Terminated, such as those that don't have termination protection set, have received Spot interruption, or are forced by instance refresh are gracefully drained.</td>
</tr>
<tr>
<td>Managed termination</td>
<td>Managed draining</td>
<td>Outcome</td>
</tr>
<tr>
<td>---------------------</td>
<td>------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Disabled</td>
<td>Enabled</td>
<td>Amazon ECS don't protect Amazon EC2 instances running tasks from being scaled-in. However, any instances that are being terminated are gracefully drained.</td>
</tr>
</tbody>
</table>
Amazon Elastic Container Service

**Outcome**

Amazon ECS protects Amazon EC2 instances that are running tasks from being terminate by scale-in events. However, instances can still get terminate by Spot interruption or forced instance refresh, or if they aren't running any tasks. Amazon ECS doesn't perform graceful draining.

<table>
<thead>
<tr>
<th>Managed termination</th>
<th>Managed draining</th>
<th>Outcome</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled</td>
<td>Disabled</td>
<td></td>
</tr>
</tbody>
</table>

---

Amazon ECS managed instance draining
<table>
<thead>
<tr>
<th>Managed termination</th>
<th>Managed draining</th>
<th>Outcome</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disabled</td>
<td>Disabled</td>
<td>Amazon EC2 instances can be scaled-in or terminated at any time, even if they are running Amazon ECS tasks. Amazon ECS will launch replacement service tasks after they stop.</td>
</tr>
</tbody>
</table>

**Managed instance draining and Spot instance draining**

With Amazon ECS Spot instance draining, you can set an environment variable `ECS_ENABLE_SPOT_INSTANCE_DRAINING` on the Amazon ECS Agent which enables Amazon ECS to place an instance in the draining status in response to the two-minute Spot interruption.
Amazon ECS managed instance draining facilitates graceful shutdown of Amazon EC2 instances undergoing termination due to many reasons, not just Spot interruption. For instance, you can use Amazon EC2 Auto Scaling capacity rebalancing to proactively replace Spot instances at elevated risk of interruption, and managed instance draining performs graceful shutdown of Spot instances being replaced. When you use managed instance draining, you don't need to enable Spot instance draining separately, so ECS_ENABLE_SPOT_INSTANCE_DRAINING in ASG user data is redundant.

**Amazon ECS managed instance draining troubleshooting**

Amazon ECS managed instance draining events are published to Amazon EventBridge, and Amazon ECS creates an EventBridge managed rule in your account’s default bus to support managed instance draining. You can filter these events to other AWS services like Lambda, Amazon SNS, and Amazon SQS to monitor and troubleshoot.

- Amazon EC2 Auto Scaling sends an event to EventBridge when a lifecycle hook is invoked.
- Spot interruption notices are published to EventBridge.
- Amazon ECS generates error messages that are retrievable on the Amazon ECS console and API if there are any failures when provisioning managed instance draining resources.
- EventBridge has retry mechanisms built in as mitigations for temporary failures.

**Using Amazon ECS managed instance draining**

You enable managed instance draining when you create or update your Auto Scaling group capacity providers using the Amazon ECS console and AWS CLI.

**Note**

Managed instance draining is enabled by default when you create a capacity provider.

The following are examples using the AWS CLI for creating a capacity provider with managed instance draining enabled and enabling managed instance draining for a cluster's existing capacity provider.

**Create a capacity provider with managed instance draining enabled**

To create a capacity provider with managed instance draining enabled, use the `create-capacity-provider` command.
Enable managed instance draining for a cluster's existing capacity provider

Enable managed instance draining for a cluster's existing capacity provider uses the update-capacity-provider command. You see that managedDraining currently says DISABLED and updateStatus says UPDATE_IN_PROGRESS.

```
aws ecs update-capacity-provider
```
--name cp-draining \
--auto-scaling-group-provider '{
  "managedDraining": "ENABLED"
} 

Response:

{
  "capacityProvider": {
    "capacityProviderArn": "cp-draining-arn",
    "name": "cp-draining",
    "status": "ACTIVE",
    "autoScalingGroupProvider": {
      "autoScalingGroupArn": "asg-draining-arn",
      "managedScaling": {
        "status": "ENABLED",
        "targetCapacity": 100,
        "minimumScalingStepSize": 1,
        "maximumScalingStepSize": 1,
        "instanceWarmupPeriod": 300
      },
      "managedTerminationProtection": "DISABLED",
      "managedDraining": "DISABLED" // before update
    },
    "updateStatus": "UPDATE_IN_PROGRESS", // in progress and need describe again to find out the result
    "tags": []
  }
}

Use the describe-clusters command and include ATTACHMENTS. The status of the managed instance draining attachment is PRECREATED, and the overall attachmentsStatus is UPDATING.

aws ecs describe-clusters --clusters cluster-name --include ATTACHMENTS

Response:

{
  "clusters": [
    {
      "managedInstanceDrainingAttachment": {
        "status": "PRECREATED",
        "attachmentsStatus": "UPDATING"
      }
    }
  ]
}
When the update is finished, use `describe-capacity-providers`, and you see managedDraining is now ENABLED.

```bash
aws ecs describe-capacity-providers --capacity-providers cp-draining
```

Response:

```json
{
  "capacityProviders": [
    {
      "id": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
      "type": "managed_draining",
      "status": "PRECREATED",
      "details": [
        {
          "name": "capacityProviderName",
          "value": "cp-draining"
        },
        {
          "name": "autoScalingLifecycleHookName",
          "value": "ecs-managed-draining-termination-hook"
        }
      ]
    },
    ...
  ],
  "attachmentsStatus": "UPDATING"
}
"failures": []
}
"capacityProviderArn": "cp-draining-arn",
"name": "cp-draining",
"status": "ACTIVE",

    "maximumScalingStepSize": 1,
    "instanceWarmupPeriod": 300
  },
  "managedTerminationProtection": "DISABLED",
  "managedDraining": "ENABLED" // successfully update
},
"updateStatus": "UPDATE_COMPLETE",
"tags": []}
Scheduling your containers on Amazon ECS

Amazon Elastic Container Service (Amazon ECS) is a shared state, optimistic concurrency system that provides flexible scheduling capabilities for your containerized workloads. The Amazon ECS schedulers use the same cluster state information as the Amazon ECS API to make appropriate placement decisions.

Amazon ECS provides a service scheduler for long-running tasks and applications. It also provides the ability to run standalone tasks or scheduled tasks for batch jobs or single run tasks. You can specify the task placement strategies and constraints for running tasks that best meet your needs. For example, you can specify whether tasks run across multiple Availability Zones or within a single Availability Zone. And, optionally, you can integrate tasks with your own custom or third-party schedulers.

Service scheduler

The service scheduler is suitable for long running stateless services and applications. The service scheduler ensures that the scheduling strategy that you specify is followed and reschedules tasks when a task fails. For example, if the underlying infrastructure fails, the service scheduler can reschedule tasks.

The service scheduler also replaces tasks determined to be unhealthy after a container health check or a load balancer target group health check fails. This replacement depends on the maximumPercent and desiredCount service definition parameters. If a task is marked unhealthy, the service scheduler will first start a replacement task. If the replacement task has a health status of HEALTHY, the service scheduler stops the unhealthy task. If the replacement task has a health status of UNHEALTHY, the scheduler will stop either the unhealthy replacement task or the existing unhealthy task to get the total task count to equal desiredCount. If the maximumPercent parameter limits the scheduler from starting a replacement task first, the scheduler will stop an unhealthy task one at a time at random to free up capacity, and then start a replacement task. The start and stop process continues until all unhealthy tasks are replaced with healthy tasks. Once all unhealthy tasks have been replaced and only healthy tasks are running, if the total task count exceeds the desiredCount, healthy tasks are stopped at random until the total task count equals desiredCount. For more information about maximumPercent and desiredCount, see Service definition parameters.
Note

This behavior does not apply to tasks run and maintained by services that use the *rolling update* deployment type. During a rolling update, the service scheduler first stops unhealthy tasks and then starts replacement tasks.

There are two service scheduler strategies available:

- **REPLICA**—The replica scheduling strategy places and maintains the desired number of tasks across your cluster. By default, the service scheduler spreads tasks across Availability Zones. You can use task placement strategies and constraints to customize task placement decisions. For more information, see [Replica](#).

- **DAEMON**—The daemon scheduling strategy deploys exactly one task on each active container instance that meets all of the task placement constraints that you specify in your cluster. When using this strategy, there is no need to specify a desired number of tasks, a task placement strategy, or use Service Auto Scaling policies. For more information, see [Daemon](#).

Note

Fargate tasks do not support the DAEMON scheduling strategy.

The service scheduler optionally also makes sure that tasks are registered against an Elastic Load Balancing load balancer. You can update your services that are maintained by the service scheduler. This might include deploying a new task definition or changing the number of desired tasks that are running. By default, the service scheduler spreads tasks across multiple Availability Zones. However, you can use task placement strategies and constraints to customize task placement decisions. For more information, see [Amazon ECS services](#).

**Standalone tasks**

You can run a standalone task when you have processes such as batch jobs that perform work and then stop. For example, you can have a process call RunTask when work comes into a queue. The task pulls work from the queue, performs the work, and then exits. Using RunTask, you can allow the default task placement strategy to distribute tasks randomly across your cluster. This minimizes the chances that a single instance gets a disproportionate number of tasks. Alternatively, you can
use RunTask to customize how the scheduler places tasks using task placement strategies and constraints.

**Custom schedulers**

With Amazon ECS, you can create your own schedulers or use third-party schedulers. For more information, see [How to create a custom scheduler for Amazon ECS](#). Custom schedulers use the StartTask API operation to place tasks on specific container instances within your cluster.

ℹ️ **Note**

Custom schedulers are only compatible with tasks hosted on EC2 instances. If you use Amazon ECS on Fargate, the StartTask API doesn't work.

**Amazon ECS task lifecycle**

When a task is started, either manually or as part of a service, it can pass through several states before it finishes on its own or is stopped manually. Some tasks are meant to run as batch jobs that naturally progress through from PENDING to RUNNING to STOPPED. Other tasks, which can be part of a service, are meant to continue running indefinitely, or to be scaled up and down as needed.

When task status changes are requested, such as stopping a task or updating the desired count of a service to scale it up or down, the Amazon ECS container agent tracks these changes as the last known status (lastStatus) of the task and the desired status (desiredStatus) of the task. Both the last known status and desired status of a task can be seen either in the console or by describing the task with the API or AWS CLI.

The flow chart below shows the task lifecycle flow.
**Lifecycle states**

The following are descriptions of each of the task lifecycle states.

**PROVISIONING**

Amazon ECS has to perform additional steps before the task is launched. For example, for tasks that use the awsvpc network mode, the elastic network interface needs to be provisioned.

**PENDING**

This is a transition state where Amazon ECS is waiting on the container agent to take further action. A task stays in the pending state until there are available resources for the task.
ACTIVATING

This is a transition state where Amazon ECS has to perform additional steps after the task is launched but before the task can transition to the RUNNING state. For example, for tasks that have service discovery configured, the service discovery resources must be created. For tasks that are part of a service that's configured to use multiple Elastic Load Balancing target groups, the target group registration occurs during this state.

RUNNING

The task is successfully running.

DEACTIVATING

This is a transition state where Amazon ECS has to perform additional steps before the task is stopped. For example, for tasks that are part of a service that's configured to use multiple Elastic Load Balancing target groups, the target group deregistration occurs during this state.

STOPPING

This is a transition state where Amazon ECS is waiting on the container agent to take further action.

For Linux containers, the container agent will send the SIGTERM signal to notify the application needs to finish and shut down, and then the sends a SIGKILL after waiting the StopTimeout duration set in the task definition.

DEPROVISIONING

Amazon ECS has to perform additional steps after the task has stopped but before the task transitions to the STOPPED state. For example, for tasks that use the awsvpc network mode, the elastic network interface needs to be detached and deleted.

STOPPED

The task has been successfully stopped.

DELETED

This is a transition state when a task stops. This state is not displayed in the console, but is displayed in describe-tasks.
How Amazon ECS places tasks on container instances

You can use task placement to configure Amazon ECS to place your tasks on container instances that meet certain criteria, for example an Availability Zone or instance type.

The following are task placement components:

- Task placement strategy - The algorithm for selecting container instances for task placement or tasks for termination. For example, Amazon ECS can select container instances at random, or it can select container instances such that tasks are distributed evenly across a group of instances.
- Task group - A group of related tasks, for example database tasks.
- Task placement constraint - These are rules that must be met in order to place a task on a container instance. If the contraint is not met, the task is not placed and remains in the PENDING state. For example, you can use a constraint to place tasks only on a particular instance type.

Amazon ECS has different algorithms for the launch types.

EC2 launch type

For tasks that use the EC2 launch type, Amazon ECS must determine where to place the task based on the requirements specified in the task definition, such as CPU and memory. Similarly, when you scale down the task count, Amazon ECS must determine which tasks to terminate. You can apply task placement strategies and constraints to customize how Amazon ECS places and terminates tasks.

The default task placement strategies depend on whether you run tasks manually (standalone tasks) or within a service. For tasks running as part of an Amazon ECS service, the task placement strategy is spread using the attribute:ecs.availability-zone. There isn't a default task placement constraint for tasks in services. For more information, see Scheduling your containers on Amazon ECS.

Note

Task placement strategies are a best effort. Amazon ECS still attempts to place tasks even when the most optimal placement option is unavailable. However, task placement constraints are binding, and they can prevent task placement.
You can use task placement strategies and constraints together. For example, you can use a task placement strategy and a task placement constraint to distribute tasks across Availability Zones and bin pack tasks based on memory within each Availability Zone, but only for G2 instances.

When Amazon ECS places tasks, it uses the following process to select container instances:

1. Identify the container instances that satisfy the CPU, GPU, memory, and port requirements in the task definition.
2. Identify the container instances that satisfy the task placement constraints.
3. Identify the container instances that satisfy the task placement strategies.
4. Select the container instances for task placement.

**Fargate launch type**

Task placement strategies and constraints aren't supported for tasks using the Fargate launch type. Fargate will try its best to spread tasks across accessible Availability Zones. If the capacity provider includes both Fargate and Fargate Spot, the spread behavior is independent for each capacity provider.

**Use strategies to define Amazon ECS task placement**

For tasks that use the EC2 launch type, Amazon ECS must determine where to place the task based on the requirements specified in the task definition, such as CPU and memory. Similarly, when you scale down the task count, Amazon ECS must determine which tasks to terminate. You can apply task placement strategies and constraints to customize how Amazon ECS places and terminates tasks.

The default task placement strategies depend on whether you run tasks manually (standalone tasks) or within a service. For tasks running as part of an Amazon ECS service, the task placement strategy is spread using the attribute:ecs.availability-zone. There isn't a default task placement constraint for tasks in services. For more information, see [Scheduling your containers on Amazon ECS](#).
**Note**

Task placement strategies are a best effort. Amazon ECS still attempts to place tasks even when the most optimal placement option is unavailable. However, task placement constraints are binding, and they can prevent task placement.

You can use task placement strategies and constraints together. For example, you can use a task placement strategy and a task placement constraint to distribute tasks across Availability Zones and bin pack tasks based on memory within each Availability Zone, but only for G2 instances.

When Amazon ECS places tasks, it uses the following process to select container instances:

1. Identify the container instances that satisfy the CPU, GPU, memory, and port requirements in the task definition.
2. Identify the container instances that satisfy the task placement constraints.
3. Identify the container instances that satisfy the task placement strategies.
4. Select the container instances for task placement.

You specify task placement strategies in the service definition, or task definition using the `placementStrategy` parameter.

```
"placementStrategy": [ 
    {
        "field": "The field to apply the placement strategy against",
        "type": "The placement strategy to use"
    }
]
```

You can specify the strategies when you run a task (RunTask), create a new service (CreateService), or update an existing service (UpdateService).

The following table describes the available types and fields.

<table>
<thead>
<tr>
<th>type</th>
<th>Valid field values</th>
</tr>
</thead>
<tbody>
<tr>
<td>binpack</td>
<td>• cpu</td>
</tr>
<tr>
<td></td>
<td>• memory</td>
</tr>
</tbody>
</table>
### Valid field values

<table>
<thead>
<tr>
<th>type</th>
<th>Valid field values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tasks are placed on container instances so as to leave the least amount of unused CPU or memory. This strategy minimizes the number of container instances in use.</td>
<td>Not used</td>
</tr>
<tr>
<td>When this strategy is used and a scale-in action is taken, Amazon ECS terminates tasks. It does this based on the amount of resources that are left on the container instance after the task is terminated. The container instance that has the most available resources left after task termination has that task terminated.</td>
<td></td>
</tr>
<tr>
<td>random</td>
<td>Tasks are placed randomly.</td>
</tr>
</tbody>
</table>
Tasks are placed evenly based on the specified value. Service tasks are spread based on the tasks from that service. Standalone tasks are spread based on the tasks from the same task group. For more information about task groups, see Group related Amazon ECS tasks.

When the spread strategy is used and a scale-in action is taken, Amazon ECS selects tasks to terminate that maintain a balance across Availability Zones. Within an Availability Zone, tasks are selected at random.

The task placement strategies can be updated for existing services as well. For more information, see How Amazon ECS places tasks on container instances.

You can create a task placement strategy that uses multiple strategies by creating arrays of strategies in the order that you want them performed. For example, if you want to spread tasks across Availability Zones and then bin pack tasks based on memory within each Availability Zone, specify the Availability Zone strategy followed by the memory strategy. For example strategies, see Example Amazon ECS task placement strategies.

### Example Amazon ECS task placement strategies

You can specify task placement strategies with the following actions: [CreateService](#), [UpdateService](#), and [RunTask](#).
Examples

- Distribute tasks evenly across Availability Zones
- Distribute tasks evenly across all instances
- Bin pack tasks based on memory
- Place tasks randomly
- Distribute tasks evenly across Availability Zones and then distributes tasks evenly across the instances within each Availability Zone
- Distribute tasks evenly across Availability Zones and then bin pack tasks based on memory within each Availability Zone
- Distribute tasks evenly across instances and then bin pack tasks based on memory

Distribute tasks evenly across Availability Zones

The following strategy distributes tasks evenly across Availability Zones.

```json
"placementStrategy": [
  {
    "field": "attribute:ecs.availability-zone",
    "type": "spread"
  }
]
```

Distribute tasks evenly across all instances

The following strategy distributes tasks evenly across all instances.

```json
"placementStrategy": [
  {
    "field": "instanceId",
    "type": "spread"
  }
]
```

Bin pack tasks based on memory

The following strategy bin packs tasks based on memory.

```json
"placementStrategy": [
  {
```

Use strategies to define task placement
Use strategies to define task placement

Place tasks randomly

The following strategy places tasks randomly.

```
"placementStrategy": [
  {
    "type": "random"
  }
]
```

Distribute tasks evenly across Availability Zones and then distributes tasks evenly across the instances within each Availability Zone

The following strategy distributes tasks evenly across Availability Zones and then distributes tasks evenly across the instances within each Availability Zone.

```
"placementStrategy": [
  {
    "field": "attribute:ecs.availability-zone",
    "type": "spread"
  },
  {
    "field": "instanceId",
    "type": "spread"
  }
]
```

Distribute tasks evenly across Availability Zones and then bin pack tasks based on memory within each Availability Zone

The following strategy distributes tasks evenly across Availability Zones and then bin packs tasks based on memory within each Availability Zone.

```
"placementStrategy": [
  {
    "field": "attribute:ecs.availability-zone",
    "type": "spread"
  }
]
```
Distribute tasks evenly across instances and then bin pack tasks based on memory

The following strategy distributes tasks evenly across evenly across all instances and then bin packs tasks based on memory within each instance.

```json
"placementStrategy": [
{
  "field": "instanceId",
  "type": "spread"
},
{
  "field": "memory",
  "type": "binpack"
}
]
```

Group related Amazon ECS tasks

You can identify a set of related tasks and place them in a task group. All tasks with the same task group name are considered as a set when using the `spread` task placement strategy. For example, suppose that you're running different applications in one cluster, such as databases and web servers. To ensure that your databases are balanced across Availability Zones, add them to a task group named `databases` and then use the `spread` task placement strategy. For more information, see [Use strategies to define Amazon ECS task placement](#).

Task groups can also be used as a task placement constraint. When you specify a task group in the `memberOf` constraint, tasks are only sent to container instances that run tasks in the specified task group. For an example, see [Example Amazon ECS task placement constraints](#).

By default, standalone tasks use the task definition family name (for example, `family:my-task-definition`) as the task group name if a custom task group name isn't specified. Tasks launched as part of a service use the service name as the task group name and can't be changed.

The following requirements for the task group apply.
Define which container instances Amazon ECS uses for tasks

A task placement constraint is a rule about a container instance that Amazon ECS uses to determine if the task is allowed to run on the instance. At least one container instance must match the constraint. If there are no instances that match the constraint, the task remains in a PENDING state. When you create a new service or update an existing one, you can specify task placement constraints for the service's tasks.

You can specify task placement constraints in the service definition, task definition, or task using the `placementConstraint` parameter.

```
"placementConstraint": [
  {
    "expression": "The expression that defines the task placement constraints",
    "type": "The placement constraint type to use"
  }
]
```

The following table describes how to use the parameters.

<table>
<thead>
<tr>
<th>Constraint type</th>
<th>Can be specified when</th>
</tr>
</thead>
<tbody>
<tr>
<td>distinctInstance</td>
<td>• Running a task <a href="#">RunTask</a></td>
</tr>
<tr>
<td>Place each task on a different container instance.</td>
<td>• Creating a new service <a href="#">CreateService</a>,</td>
</tr>
</tbody>
</table>

⚠️ **Important**

We recommend that customers looking for strong isolation for their tasks use Fargate. Fargate
<table>
<thead>
<tr>
<th>Constraint type</th>
<th>Can be specified when</th>
</tr>
</thead>
<tbody>
<tr>
<td>runs each task in a hardware virtualization environment. This ensures that these containerized workloads do not share network interfaces, Fargate ephemeral storage, CPU, or memory with other tasks. For more information, see <a href="#">Security Overview of AWS Fargate</a>.</td>
<td></td>
</tr>
</tbody>
</table>
| memberOf | • Running a task [RunTask](#)  
• Creating a new service [CreateService](#) 
• Creating a new task definition [RegisterTaskDefinition](#) 
• Creating a new revision of a task definition [RegisterTaskDefinition](#) 
• Updating a service [UpdateService](#) |

When you use the memberOf constraint type, you can create an expression using the cluster query language which defines the container instances where Amazon ECS can place tasks. The expression is a way for you to group your container instances by attributes. The expression goes in the expression parameter of placementConstraint.
Amazon ECS container instance attributes

You can add custom metadata to your container instances, known as attributes. Each attribute has a name and an optional string value. You can use the built-in attributes provided by Amazon ECS or define custom attributes.

The following sections contain sample built-in, optional, and custom attributes.

**Built-in attributes**

Amazon ECS automatically applies the following attributes to your container instances.

- **ecs.ami-id**
  
  The ID of the AMI used to launch the instance. An example value for this attribute is ami-1234abcd.

- **ecs.availability-zone**
  
  The Availability Zone for the instance. An example value for this attribute is us-east-1a.

- **ecs.instance-type**
  
  The instance type for the instance. An example value for this attribute is g2.2xlarge.

- **ecs.os-type**
  
  The operating system for the instance. The possible values for this attribute are linux and windows.

- **ecs.os-family**
  
  The operating system version for the instance. For Linux instances, the valid value is LINUX. For Windows instances, ECS sets the value in the WINDOWS_SERVER_<OS_Release>_<FULL or CORE> format. The valid values are WINDOWS_SERVER_2022_FULL, WINDOWS_SERVER_2022_CORE, WINDOWS_SERVER_20H2_CORE, WINDOWS_SERVER_20H1_CORE, WINDOWS_SERVER_2019_FULL, WINDOWS_SERVER_2019_CORE, and WINDOWS_SERVER_2016_FULL.

  This is important for Windows containers and Windows containers on AWS Fargate because the OS version of every Windows container must match that of the host. If the Windows version of the container image is different than the host, the container doesn't start. For more information, see [Windows container version compatibility](#) on the Microsoft documentation website.
If your cluster runs multiple Windows versions, you can ensure that a task is placed on an EC2 instance running on the same version by using the placement constraint: memberOf(attribute:ecs.os-family == WINDOWS_SERVER_<OS_Release>_(<FULL or CORE>). For more information, see the section called “Retrieving Amazon ECS-Optimized AMI metadata”.

ecs.cpu-architecture

The CPU architecture for the instance. Example values for this attribute are x86_64 and arm64.

ecs.vpc-id

The VPC the instance was launched into. An example value for this attribute is vpc-1234abcd.

ecs.subnet-id

The subnet the instance is using. An example value for this attribute is subnet-1234abcd.

Optional attributes

Amazon ECS may add the following attributes to your container instances.

ecs.awsvpc-trunk-id

If this attribute exists, the instance has a trunk network interface. For more information, see Elastic network interface trunking.

ecs.outpost-arn

If this attribute exists, it contains the Amazon Resource Name (ARN) of the Outpost. For more information, see the section called “Amazon Elastic Container Service on AWS Outposts”.

ecs.capability.external

If this attribute exists, the instance is identified as an external instance. For more information, see External instances (Amazon ECS Anywhere).

Custom attributes

You can apply custom attributes to your container instances. For example, you can define an attribute with the name "stack" and a value of "prod".

When specifying custom attributes, you must consider the following.
• The name must contain between 1 and 128 characters and name may contain letters (uppercase and lowercase), numbers, hyphens, underscores, forward slashes, backslashes, or periods.
• The value must contain between 1 and 128 characters and may contain letters (uppercase and lowercase), numbers, hyphens, underscores, periods, at signs (@), forward slashes, backslashes, colons, or spaces. The value can't contain any leading or trailing whitespace.

Create expressions to define container instances for Amazon ECS tasks

Cluster queries are expressions that allow you to group objects. For example, you can group container instances by attributes such as Availability Zone, instance type, or custom metadata. For more information, see Amazon ECS container instance attributes.

After you have defined a group of container instances, you can customize Amazon ECS to place tasks on container instances based on group. For more information, see Run an application as an Amazon ECS task, and Creating a service using the console. You can also apply a group filter when listing container instances. For more information, see Filtering by attribute using the console.

Expression syntax

Expressions have the following syntax:

```
subject operator [argument]
```

**Subject**

The attribute or field to be evaluated.

agentConnected

Select container instances by their Amazon ECS container agent connection status. You can use this filter to search for instances with container agents that are disconnected.

Valid operators: equals (==), not_equality (!=), in, not_in (liin), matches (=~), not_matches (!~)

agentVersion

Select container instances by their Amazon ECS container agent version. You can use this filter to find instances that are running outdated versions of the Amazon ECS container agent.

Valid operators: equals (==), not_equality (!=), greater_than (>) greater_than_equal (>=), less_than (<), less_than_equal (<=)
attribute:attribute-name

Select container instances by attribute. For more information, see Amazon ECS container instance attributes.

ec2InstanceId

Select container instances by their Amazon EC2 instance ID.

Valid operators: equals (==), not_equals (!=), in, not_in (iin), matches (=~), not_matches (!~)

registeredAt

Select container instances by their container instance registration date. You can use this filter to find newly registered instances or instances that are very old.

Valid operators: equals (==), not_equals (!=), greater_than (>), greater_than_equal (>=), less_than (<), less_than_equal (<=)

runningTasksCount

Select container instances by number of running tasks. You can use this filter to find instances that are empty or near empty (few tasks running on them).

Valid operators: equals (==), not_equals (!=), greater_than (>), greater_than_equal (>=), less_than (<), less_than_equal (<=)

task:group

Select container instances by task group. For more information, see Group related Amazon ECS tasks.

Operator

The comparison operator. The following operators are supported.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>==, equals</td>
<td>String equality</td>
</tr>
<tr>
<td>!=, not_equal</td>
<td>String inequality</td>
</tr>
</tbody>
</table>

Define which container instances are used for tasks
### Operator Description

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;, greater_than</td>
<td>Greater than</td>
</tr>
<tr>
<td>&gt;=, greater_than_equal</td>
<td>Greater than or equal to</td>
</tr>
<tr>
<td>&lt;, less_than</td>
<td>Less than</td>
</tr>
<tr>
<td>&lt;=, less_than_equal</td>
<td>Less than or equal to</td>
</tr>
<tr>
<td>exists</td>
<td>Subject exists</td>
</tr>
<tr>
<td>!exists, not_exists</td>
<td>Subject doesn't exist</td>
</tr>
<tr>
<td>in</td>
<td>Value in argument list</td>
</tr>
<tr>
<td>!in, not_in</td>
<td>Value not in argument list</td>
</tr>
<tr>
<td>=~, matches</td>
<td>Pattern match</td>
</tr>
<tr>
<td>!~, not_matches</td>
<td>Pattern mismatch</td>
</tr>
</tbody>
</table>

#### Note

A single expression can't contain parentheses. However, parentheses can be used to specify precedence in compound expressions.

#### Argument

For many operators, the argument is a literal value.

The `in` and `not_in` operators expect an argument list as the argument. You specify an argument list as follows:

```
[argument1, argument2, ..., argumentN]
```

The `matches` and `not_matches` operators expect an argument that conforms to the Java regular expression syntax. For more information, see [java.util.regex.Pattern](https://docs.oracle.com/javase/7/docs/api/java/util/regex/Pattern.html).
Compound expressions

You can combine expressions using the following Boolean operators:

- `&&`, and
- `||`, or
- `!`, not

You can specify precedence using parentheses:

```
(expression1 or expression2) and expression3
```

Example expressions

The following are example expressions.

Example: String Equality

The following expression selects instances with the specified instance type.

```
attribute:ecs.instance-type == t2.small
```

Example: Argument List

The following expression selects instances in the us-east-1a or us-east-1b Availability Zone.

```
attribute:ecs.availability-zone in [us-east-1a, us-east-1b]
```

Example: Compound Expression

The following expression selects G2 instances that aren't in the us-east-1d Availability Zone.

```
attribute:ecs.instance-type =~ g2.* and attribute:ecs.availability-zone != us-east-1d
```

Example: Task Affinity

The following expression selects instances that are hosting tasks in the `service:production` group.
Example: Task Anti-Affinity

The following expression selects instances that aren't hosting tasks in the database group.

```
not(task:group == database)
```

Example: Running task count

The following expression selects instances that are only running one task.

```
runningTasksCount == 1
```

Example: Amazon ECS container agent version

The following expression selects instances that are running a container agent version below 1.14.5.

```
agentVersion < 1.14.5
```

Example: Instance registration time

The following expression selects instances that were registered before February 13, 2018.

```
registeredAt < 2018-02-13
```

Example: Amazon EC2 instance ID

The following expression selects instances with the following Amazon EC2 instance IDs.

```
ec2InstanceId in ['i-abcd1234', 'i-wxyx7890']
```

Example Amazon ECS task placement constraints

The following are task placement constraint examples.

This example uses the `memberOf` constraint to place tasks on t2 instances. It can be specified with the following actions: [CreateService](#), [UpdateService](#), [RegisterTaskDefinition](#), and [RunTask](#).
"placementConstraints": [
  {
    "expression": "attribute:ecs.instance-type =~ t2.*",
    "type": "memberOf"
  }
]

The example uses the `memberOf` constraint to place replica tasks on instances with tasks in the daemon service `daemon-service` task group, respecting any task placement strategies that are also specified. This constraint ensures that the daemon service tasks get placed on the EC2 instance prior to the replica service tasks.

Replace `daemon-service` with the name of the daemon service.

"placementConstraints": [
  {
    "expression": "task:group == service:daemon-service",
    "type": "memberOf"
  }
]

The example uses the `memberOf` constraint to place tasks on instances with other tasks in the databases task group, respecting any task placement strategies that are also specified. For more information about task groups, see Group related Amazon ECS tasks. It can be specified with the following actions: CreateService, UpdateService, RegisterTaskDefinition, and RunTask.

"placementConstraints": [
  {
    "expression": "task:group == databases",
    "type": "memberOf"
  }
]

The `distinctInstance` constraint places each task in the group on a different instance. It can be specified with the following actions: CreateService, UpdateService, and RunTask.

"placementConstraints": [
  {
    "type": "distinctInstance"
  }
]
Amazon ECS standalone tasks

You can run your application as a task when you have an application that performs some work, and then stops, for example a batch process. If you want to run a task one time, you can use the console, AWS CLI, APIs, or SDKs.

If you need to run your application on a rate-based, cron-based, or one-time schedule, you can create schedule using EventBridge Scheduler.

Task workflow

When you launch Amazon ECS tasks (standalone tasks or by Amazon ECS services), a task is created and initially moved to the PROVISIONING state. When a task is in the PROVISIONING state, neither the task nor the containers exist because Amazon ECS needs to find compute capacity for placing the task.

Amazon ECS selects the appropriate compute capacity for your task based on your launch type or capacity provider configuration. You can use capacity providers and capacity provider strategies with both the Fargate and Amazon EC2 launch types. With Fargate, you don't have to think about provisioning, configuring, and scaling of your cluster capacity. Fargate takes care of all infrastructure management for your tasks. For the EC2 launch type, you can either manage your cluster capacity by registering Amazon EC2 instances to your cluster, or you can use cluster auto scaling to simplify your compute capacity management. Cluster auto scaling takes care of dynamically scaling your cluster capacity, so that you can focus on running tasks. Amazon ECS determines where to place the task based on the requirements you specify in the task definition, such as CPU and memory, as well your placement constraints and strategies. For more information, see, How Amazon ECS places tasks on container instances.

After finding the capacity for placing your task, Amazon ECS provisions the necessary attachments (for example, Elastic Network Interfaces (ENIs) for tasks in awsvpc mode). It uses the Amazon ECS container agent to pull your container images, and then start your containers. After the provisioning completes and the relevant containers have launched, Amazon ECS moves the task into RUNNING state.

Topics

- Best practices for improving Amazon ECS task launch time
• Run an application as an Amazon ECS task
• Run Amazon ECS tasks on schedules using Amazon EventBridge Scheduler
• Stop an Amazon ECS task

Best practices for improving Amazon ECS task launch time

In order to speed up your task launches, consider the following recommendations.

• Cache container images and binpack instances

If you use the EC2 launch type you can configure the Amazon ECS container agent pull behavior to ECS_IMAGE_PULL_BEHAVIOR: prefer-cached. The image is pulled remotely if there is no cached image. Otherwise, the cached image on the instance is used. Automated image cleanup is turned off for the container to ensure that the cached image isn't removed. This reduces image pull-time for subsequent launches. The effect of caching is even greater when you have a high task density in your container instances, which you can configure using the binpack placement strategy. Caching container images is especially beneficial for windows-based workloads which usually have large (tens of GBs) container image sizes. When using the binpack placement strategy, you can also consider using Elastic Network Interface (ENI) trunking to place more tasks with the awsvpc network mode on each container instance. ENI trunking increases the number of tasks you can run on awsvpc mode. For example, a c5.large instance that may support running only 2 tasks concurrently, can run up to 10 tasks with ENI trunking.

• Choose an optimal network mode

Although there are many instances where awsvpc network mode is ideal, this network mode can inherently increase task launch latency, because for each task in awsvpc mode, Amazon ECS workflows need to provision and attach an ENI by invoking Amazon EC2 APIs which adds an overhead of several seconds to your task launches. By contrast, a key advantage of using awsvpc network mode is that each task has a security group to allow or deny traffic. This means you have greater flexibility to control communications between tasks and services at a more granular level. If the deployment speed is your priority, you can consider using bridge mode to speed up task launches. For more information, see the section called “AWSVPC mode”.

• Track your task launch lifecycle to find optimization opportunities

It is often difficult to know the amount of time it takes for your application to start-up. Launching your container image, running start-up scripts, and other configurations during
application start-up can take a surprising amount of time. You can use the Task metadata endpoint to post metrics to track application start-up time from ContainerStartTime to when your application is ready to serve traffic. With this data, you can understand how your application is contributing to the total launch time, and find areas where you can reduce unnecessary application-specific overhead and optimize your container images. For more information, see Retrieve Amazon ECS metadata.

- **Choose an optimal instance type (when using the EC2 launch type)**

Choosing the correct instance type is based on the resource reservation (for example, CPU, memory) that you configure on your task. Therefore, when sizing the instance, you can calculate how many tasks can be placed on a single instance. A simple example of a well-placed task, is hosting 4 tasks requiring 0.5 vCPU and 2GB of memory reservations in an m5.large instance (supporting 2 vCPU and 8 GB memory). The reservations of this task definition take full advantage of the instance’s resources.

**Run an application as an Amazon ECS task**

You can create a task for a one-time process using the AWS Management Console.

**To create a standalone task (AWS Management Console)**

2. The Amazon ECS console allows you to create a standalone task from either your cluster detail page or from the task definition revision list. Use the following steps to create your standalone task depending on the resource page you choose.

<table>
<thead>
<tr>
<th>To start a service from</th>
<th>Steps</th>
</tr>
</thead>
</table>
| a cluster detail page... | a. On the Clusters page, select the cluster to create the service in.  
  b. From the Tasks tab, choose Run new task. |
| a task definition revision page... | a. On the Task definitions page, choose the task definition family to |
### To start a service from

<table>
<thead>
<tr>
<th></th>
<th>Steps</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>display the revisions for that family.</td>
</tr>
<tr>
<td>b.</td>
<td>Select the revision you want to use.</td>
</tr>
<tr>
<td>c.</td>
<td>From the <strong>Deploy</strong> menu, choose <strong>Run task</strong>.</td>
</tr>
</tbody>
</table>

3. (Optional) The **Compute configuration (advanced)** section is where you choose how your tasks will be distributed. You can use either a **Capacity provider strategy** or a **Launch type**.

To use a capacity provider strategy, you must configure your capacity providers at the cluster level. For more information, see Amazon ECS capacity providers. If you haven't configured your cluster to use a capacity provider, use a launch type instead.

<table>
<thead>
<tr>
<th>Distribution method</th>
<th>Steps</th>
</tr>
</thead>
</table>
| Capacity provider strategy | a. In the **Compute options** section, select **Capacity provider strategy**.  
|                       | b. Choose a strategy:  
|                       | • To use the cluster's default capacity provider strategy, choose **Use cluster default**.  
|                       | • If your cluster doesn't have a default capacity provider strategy, or to use a custom strategy, choose **Use custom**, **Add capacity provider strategy** and define your custom capacity provider strategy by specifying a **Base**, |
### Distribution method

| Capacity provider, and Weight. |

### Note

To use a capacity provider in a strategy, the capacity provider must be associated with the cluster. For more information about capacity provider strategies, see [Amazon ECS capacity providers](https://docs.aws.amazon.com/ecs/latest/userguide/capacity-providers.html).

### Launch type

<table>
<thead>
<tr>
<th>Launch type</th>
<th>a. In the <strong>Compute options</strong> section, select <strong>Launch type</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>b. For <strong>Launch type</strong>, choose a launch type.</td>
</tr>
<tr>
<td></td>
<td>c. (Optional) When the Fargate launch type is specified, for <strong>Platform version</strong>, specify the platform version to use. If a platform version isn't specified, the LATEST platform version is used.</td>
</tr>
</tbody>
</table>

4. For **Application type**, choose **Task**.

5. For **Task definition**, choose the task definition family and revision.
Important

The console validates the selection to ensure that the selected task definition family and revision are compatible with the defined compute configuration.

6. For **Desired tasks**, enter the number of tasks to launch.

7. If your task definition uses the `awsvpc` network mode, expand **Networking**. Use the following steps to specify a custom configuration.

   a. For **VPC**, select the VPC to use.

   b. For **Subnets**, select one or more subnets in the VPC that the task scheduler considers when placing your tasks.

   Important

   Only private subnets are supported for the `awsvpc` network mode. Tasks do not receive public IP addresses. Therefore, a NAT gateway is required for outbound internet access, and inbound internet traffic is routed through a load balancer.

   c. For **Security group**, you can either choose an existing security group or create a new one. To use an existing security group, choose the security group and move to the next step. To create a new security group, choose **Create a new security group**. You must specify a security group name, description, and then add one or more inbound rules for the security group.

   d. For **Public IP**, choose whether to auto-assign a public IP address to the elastic network interface (ENI) of the task.

     AWS Fargate tasks can be assigned a public IP address when run in a public subnet so they have a route to the internet. For more information, see **Fargate task networking** in the *Amazon Elastic Container Service User Guide for AWS Fargate*.

8. If your task uses a data volume that's compatible with configuration at deployment, you can configure the volume by expanding **Volume**.

The volume name and volume type are configured when creating a task definition revision and can't be changed when you run a standalone task. To update the volume name and type, you must create a new task definition revision and run a task by using the new revision.
<table>
<thead>

</tbody>
</table>

k. (Optional) Under **Tags**, you can add tags to your Amazon EBS volume by either propagating tags from the task definition or by providing your own tags.

If you want to propagate tags from the task definition, choose **Task definition** for **Propagate tags from**. If you choose **Do not propagate**, or if you don't choose a value, the tags aren't propagated.

If you want to provide your own tags, choose **Add tag** and then provide the key and value for each tag you add.

For more information about tagging Amazon EBS volumes, see [Tagging Amazon EBS volumes](https://docs.aws.amazon.com/elasticbeanstalk/latest/dg/configuring-volumes.html).

9. (Optional) To use a task placement strategy other than the default, expand **Task Placement**, and then choose from the following options.
For more information, see How Amazon ECS places tasks on container instances.

- **AZ Balanced Spread** – Distribute tasks across Availability Zones and across container instances in the Availability Zone.
- **AZ Balanced BinPack** – Distribute tasks across Availability Zones and across container instances with the least available memory.
- **BinPack** – Distribute tasks based on the least available amount of CPU or memory.
- **One Task Per Host** – Place, at most, one task from the service on each container instance.
- **Custom** – Define your own task placement strategy.

If you chose **Custom**, define the algorithm for placing tasks and the rules that are considered during task placement.

- Under **Strategy**, for **Type** and **Field**, choose the algorithm and the entity to use for the algorithm.

  You can enter a maximum of 5 strategies.

- Under **Constraint**, for **Type** and **Expression**, choose the rule and attribute for the constraint.

  For example, to set the constraint to place tasks on T2 instances, for the **Expression**, enter `attribute:ecs.instance-type =~ t2.*`.

  You can enter a maximum of 10 constraints.

10. (Optional) To override the task IAM role, or task execution role that is defined in your task definition, expand **Task overrides**, and then complete the following steps:

   a. For **Task role**, choose an IAM role for this task. For more information, see Task IAM role.

      Only roles with the `ecs-tasks.amazonaws.com` trust relationship are displayed. For instructions on how to create an IAM role for your tasks, see Creating an IAM role and policy for your tasks.

   b. For **Task execution role**, choose a task execution role. For more information, see Amazon ECS task execution IAM role.

11. (Optional) To override the container commands and environment variables, expand **Container Overrides**, and then expand the container.
• To send a command to the container other than the task definition command, for Command override, enter the Docker command.

For more information about the Docker run command, see Docker Run reference in the Docker Reference Manual.

• To add an environment variable, choose Add Environment Variable. For Key, enter the name of your environment variable. For Value, enter a string value for your environment value (without the surrounding double quotation marks (" ")).

AWS surrounds the strings with double quotation marks (" ") and passes the string to the container in the following format:

```
MY_ENV_VAR="This variable contains a string."
```

12. (Optional) To help identify your task, expand the Tags section, and then configure your tags.

To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the task definition tags, select Turn on Amazon ECS managed tags, and then select Task definitions.

Add or remove a tag.

  • [Add a tag] Choose Add tag, and then do the following:
    • For Key, enter the key name.
    • For Value, enter the key value.
  • [Remove a tag] Next to the tag, choose Remove tag.

13. Choose Create.

Run Amazon ECS tasks on schedules using Amazon EventBridge Scheduler

EventBridge Scheduler is a serverless scheduler that allows you to create, run, and manage tasks from one central, managed service. It provides one-time and recurring scheduling functionality independent of event buses and rules. EventBridge Scheduler is highly customizable, and offers improved scalability over EventBridge scheduled rules, with a wider set of target API operations.
and AWS services. EventBridge Scheduler provides the following schedules which you can configure for your tasks in the EventBridge Scheduler console:

- Rate-based
- Cron-based

  You can configure cron-based schedules in any time zone.

- One-time schedules

  You can configure one-time schedules in any time zone.

You can schedule your Amazon ECS using Amazon EventBridge Scheduler.

Although you can create a scheduled task in the Amazon ECS console, currently the EventBridge Scheduler console provides more functionality.

Complete the following steps before you schedule a task:

1. Use the VPC console to get the subnet IDs where the tasks run and the security group IDs for the subnets. For more information, see View your subnets, and View your security groups in the Amazon VPC User Guide.

2. Configure the EventBridge Scheduler execution role. For more information, see Set up the execution role in the Amazon EventBridge Scheduler User Guide.

To create a new schedule using the console

2. On the Schedules page, choose Create schedule.

3. On the Specify schedule detail page, in the Schedule name and description section, do the following:

   a. For Schedule name, enter a name for your schedule. For example, MyTestSchedule.

   b. (Optional) For Description, enter a description for your schedule. For example, TestSchedule.

   c. For Schedule group, choose a schedule group from the dropdown list. If you don't have a group, choose default. To create a schedule group, choose create your own schedule.
You use schedule groups to add tags to groups of schedules.

4. Choose your schedule options.

<table>
<thead>
<tr>
<th>Occurrence</th>
<th>Do this...</th>
</tr>
</thead>
</table>
| **One-time schedule** | For **Date and time**, do the following:  
• Enter a valid date in YYYY/MM/DD format.  
• Enter a timestamp in 24-hour hh:mm format.  
• For **Timezone**, choose the timezone. |

| Recurring schedule | a. For **Schedule type**, do one of the following:  
• To use a cron expression to define the schedule, choose **Cron-based schedule** and enter the cron expression.  
• To use a rate expression to define the schedule, choose **Rate-based schedule** and enter the rate expression.  

For more information about cron and rate expressions, see **Schedule types on EventBridge Scheduler** in the **Amazon** Run Amazon ECS tasks on schedules using Amazon EventBridge Scheduler
<table>
<thead>
<tr>
<th>Occurrence</th>

</tr>
<tr>
<td>b. For <strong>Flexible time window</strong>, choose <strong>Off</strong> to turn off the option, or choose one of the pre-defined time windows. For example, if you choose <strong>15 minutes</strong> and you set a recurring schedule to invoke its target once every hour, the schedule runs within 15 minutes after the start of every hour.</td>
<td></td>
</tr>
</tbody>
</table>

5. (Optional) If you chose **Recurring schedule** in the previous step, in the **Timeframe** section, do the following:

a. For **Timezone**, choose a timezone.

b. For **Start date and time**, enter a valid date in **YYYY/MM/DD** format, and then specify a timestamp in **24-hour hh:mm** format.

c. For **End date and time**, enter a valid date in **YYYY/MM/DD** format, and then specify a timestamp in **24-hour hh:mm** format.

6. Choose **Next**.

7. On the **Select target** page, do the following:

a. Choose **All APIs**, and then in the search box enter **ECS**.

b. Select **Amazon ECS**.

c. In the search box, enter **RunTask**, and then choose **RunTask**.

d. For **ECS cluster**, choose the cluster.

e. For **ECS task**, choose the task definition to use for the task.

f. To use a launch type, expand **Compute options**, and then select **Launch type**. Then, choose the launch type.
When the Fargate launch type is specified, for **Platform version**, enter the platform version to use. If there is no platform specified, the LATEST platform version is used.

g. For **Subnets**, enter the subnet IDs to run the task in.

h. For **Security groups**, enter the security group IDs for the subnet.

i. (Optional) To use a task placement strategy other than the default, expand **Placement constraint**, and then enter the constraints.

For more information, see [How Amazon ECS places tasks on container instances](#).

j. (Optional) To help identify your tasks, under **Tags** configure your tags.

To have Amazon ECS automatically tag all newly launched tasks with the task definition tags, select **Enable Amazon ECS managed tags**.

8. Choose **Next**.

9. On the **Settings** page, do the following:

   a. To turn on the schedule, under **Schedule state**, toggle **Enable schedule**.

   b. To configure a retry policy for your schedule, under **Retry policy and dead-letter queue (DLQ)**, do the following:

      - Toggle **Retry**.

      - For **Maximum retention time of event**, enter the maximum **hour(s)** and **min(s)** that EventBridge Scheduler must keep an unprocessed event.

      - The maximum time is 24 hours.

      - For **Maximum retries**, enter the maximum number of times EventBridge Scheduler retries the schedule if the target returns an error.

        The maximum value is 185 retries.

With retry policies, if a schedule fails to invoke its target, EventBridge Scheduler re-runs the schedule. If configured, you must set the maximum retention time and retries for the schedule.

c. Choose where EventBridge Scheduler stores undelivered events.
<table>
<thead>
<tr>
<th>Dead-letter queue (DLQ) option</th>
<th>Do this...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Don't store</td>
<td>Choose None.</td>
</tr>
</tbody>
</table>
| Store the event in the same AWS account where you're creating the schedule | a. Choose **Select an Amazon SQS queue in my AWS account as a DLQ.**  
  b. Choose the Amazon Resource Name (ARN) of the Amazon SQS queue. |
| Store the event in a different AWS account from where you're creating the schedule | a. Choose **Specify an Amazon SQS queue in other AWS accounts as a DLQ.**  
  b. Enter the Amazon Resource Name (ARN) of the Amazon SQS queue. |

d. To use a customer managed key to encrypt your target input, under **Encryption**, choose **Customize encryption settings (advanced)**.

If you choose this option, enter an existing KMS key ARN or choose **Create an AWS KMS key** to navigate to the AWS KMS console. For more information about how EventBridge Scheduler encrypts your data at rest, see **Encryption at rest** in the *Amazon EventBridge Scheduler User Guide*.

e. For **Permissions**, choose **Use existing role**, then select the role.

To have EventBridge Scheduler create a new execution role for you, choose **Create new role for this schedule**. Then, enter a name for **Role name**. If you choose this option, EventBridge Scheduler attaches the required permissions necessary for your templated target to the role.

10. Choose **Next**.
11. In the **Review and create schedule** page, review the details of your schedule. In each section, choose **Edit** to go back to that step and edit its details.

12. Choose **Create schedule**.

You can view a list of your new and existing schedules on the **Schedules** page. Under the **Status** column, verify that your new schedule is **Enabled**.

**Next steps**

You can use the EventBridge Scheduler console or the AWS CLI to manage the schedule. For more information, see [Managing a schedule](#) in the *Amazon EventBridge Scheduler User Guide*.

**Stop an Amazon ECS task**

If you no longer need to keep a standalone task running, you can stop the task. The Amazon ECS console makes it easy to stop one or more tasks.

If you want to stop a service, see [Deleting a service using the console](#).

**To stop a standalone task (AWS Management Console)**

2. In the navigation pane, choose **Clusters**.
3. On the **Clusters** page, choose the cluster to navigate to the cluster details page.
4. On the cluster detail page, choose the **Tasks** tab.
5. You can filter tasks by launch type using the **Filter launch type** list.

<table>
<thead>
<tr>

Amazon ECS services

You can use an Amazon ECS service to run and maintain a specified number of instances of a task definition simultaneously in an Amazon ECS cluster. If one of your tasks fails or stops, the Amazon ECS service scheduler launches another instance of your task definition to replace it. This helps maintain your desired number of tasks in the service.

You can also optionally run your service behind a load balancer. The load balancer distributes traffic across the tasks that are associated with the service.

Service scheduler concepts

We recommend that you use the service scheduler for long running stateless services and applications. The service scheduler ensures that the scheduling strategy that you specify is
followed and reschedules tasks when a task fails. For example, if the underlying infrastructure fails, the service scheduler reschedules a task. You can use task placement strategies and constraints to customize how the scheduler places and terminates tasks. If a task in a service stops, the scheduler launches a new task to replace it. This process continues until your service reaches your desired number of tasks based on the scheduling strategy that the service uses. The scheduling strategy of the service is also referred to as the service type.

The service scheduler also replaces tasks determined to be unhealthy after a container health check or a load balancer target group health check fails. This replacement depends on the maximumPercent and desiredCount service definition parameters. If a task is marked unhealthy, the service scheduler will first start a replacement task. If the replacement task has a health status of HEALTHY, the service scheduler stops the unhealthy task. If the replacement task has a health status of UNHEALTHY, the scheduler will stop either the unhealthy replacement task or the existing unhealthy task to get the total task count to equal desiredCount. If the maximumPercent parameter limits the scheduler from starting a replacement task first, the scheduler will stop an unhealthy task one at a time at random to free up capacity, and then start a replacement task. The start and stop process continues until all unhealthy tasks are replaced with healthy tasks. Once all unhealthy tasks have been replaced and only healthy tasks are running, if the total task count exceeds the desiredCount, healthy tasks are stopped at random until the total task count equals desiredCount. For more information about maximumPercent and desiredCount, see Service definition parameters.

Note

This behavior does not apply to tasks run and maintained by services that use the rolling update deployment type. During a rolling update, the service scheduler first stops unhealthy tasks and then starts replacement tasks.

The service scheduler includes logic that throttles how often tasks are restarted if tasks repeatedly fail to start. If a task is stopped without having entered a RUNNING state, the service scheduler starts to slow down the launch attempts and sends out a service event message. This behavior prevents unnecessary resources from being used for failed tasks before you can resolve the issue. After the service is updated, the service scheduler resumes normal scheduling behavior. For more information, see Amazon ECS service throttle logic and Service event messages.

There are two service scheduler strategies available:
• **REPLICA**—The replica scheduling strategy places and maintains the desired number of tasks across your cluster. By default, the service scheduler spreads tasks across Availability Zones. You can use task placement strategies and constraints to customize task placement decisions. For more information, see [Replica](#).

• **DAEMON**—The daemon scheduling strategy deploys exactly one task on each active container instance that meets all of the task placement constraints that you specify in your cluster. When using this strategy, there is no need to specify a desired number of tasks, a task placement strategy, or use Service Auto Scaling policies. For more information, see [Daemon](#).

> **Note**
> Fargate tasks do not support the DAEMON scheduling strategy.

### Daemon

The *daemon* scheduling strategy deploys exactly one task on each active container instance that meets all of the task placement constraints specified in your cluster. The service scheduler also evaluates the task placement constraints for running tasks, and stops tasks that don’t meet the placement constraints. When using this strategy, you don’t need to specify a desired number of tasks, a task placement strategy, or use Service Auto Scaling policies.

Amazon ECS reserves container instance compute resources including CPU, memory, and network interfaces for the daemon tasks. When you launch a daemon service on a cluster with other replica services, Amazon ECS prioritizes the daemon task. This means that the daemon task is the first task to launch on the instances and the last task to stop. This strategy ensures that resources aren’t used by pending replica tasks and are available for the daemon tasks.

The daemon service scheduler doesn’t place any tasks on instances that have a DRAINING status. If a container instance transitions to a DRAINING status, the daemon tasks on it are stopped. The service scheduler ensures that daemon tasks are the last to stop after all replica tasks are stopped. The service scheduler also monitors when new container instances are added to your cluster and adds the daemon tasks to them.

If a deployment configuration is specified, the maximum percent parameter must be 100. The default value for a daemon service for `maximumPercent` is 200%. The default value for a daemon service for `minimumHealthyPercent` is 0%.
You must restart the service when you change the placement constraints for the daemon service. Amazon ECS dynamically updates the resources that are reserved on qualifying instances for the daemon task. For existing instances, the scheduler tries to place the task on the instance.

A new deployment starts when there is a change to the task size or container resource reservation in the task definition. Amazon ECS picks up the updated CPU and memory reservations for the daemon, and then blocks that capacity for the daemon task.

If there are insufficient resources for either of the above cases, the following happens:

- The task placement fails.
- A CloudWatch event is generated.
- Amazon ECS continues to try and schedule the task on the instance by waiting for resources to become available.
- Amazon ECS frees up any reserved instances that no longer meet the placement constraint criteria and stops the corresponding daemon tasks.

The daemon scheduling strategy can be used in the following cases:

- Running application containers
- Running support containers for logging, monitoring and tracing tasks

Tasks using the Fargate launch type or the CODE_DEPLOY or EXTERNAL deployment controller types don't support the daemon scheduling strategy.

When the service scheduler stops running tasks, it attempts to maintain balance across the Availability Zones in your cluster. The scheduler uses the following logic:

- If a placement strategy is defined, use that strategy to select which tasks to terminate. For example, if a service has an Availability Zone spread strategy defined, a task is selected that leaves the remaining tasks with the best spread.
- If no placement strategy is defined, use the following logic to maintain balance across the Availability Zones in your cluster:
  - Sort the valid container instances. Give priority to instances that have the largest number of running tasks for this service in their respective Availability Zone. For example, if zone A has one running service task and zones B and C each have two running service task, container instances in either zone B or C are considered optimal for termination.
• Stop the task on a container instance in an optimal Availability Zone based on the previous steps. Favoring container instances with the largest number of running tasks for this service.

Replica

The replica scheduling strategy places and maintains the desired number of tasks in your cluster.

For a service that runs tasks on Fargate, when the service scheduler launches new tasks or stops running tasks, the service scheduler uses a best attempt to maintain a balance across Availability Zones. You don't need to specify task placement strategies or constraints.

When you create a service that runs tasks on EC2 instances, you can optionally specify task placement strategies and constraints to customize task placement decisions. If no task placement strategies or constraints are specified, then by default the service scheduler spreads the tasks across Availability Zones. The service scheduler uses the following logic:

• Determines which of the container instances in your cluster can support your service's task definition (for example, required CPU, memory, ports, and container instance attributes).

• Determines which container instances satisfy any placement constraints that are defined for the service.

• When you have a replica service that depends on a daemon service (for example, a daemon log router task that needs to be running before tasks can use logging), create a task placement constraint that ensures that the daemon service tasks get placed on the EC2 instance prior to the replica service tasks. For more information, see Example Amazon ECS task placement constraints.

• When there's a defined placement strategy, use that strategy to select an instance from the remaining candidates.

• When there's no defined placement strategy, use the following logic to balance tasks across the Availability Zones in your cluster:

  • Sorts the valid container instances. Gives priority to instances that have the fewest number of running tasks for this service in their respective Availability Zone. For example, if zone A has one running service task and zones B and C each have zero, valid container instances in either zone B or C are considered optimal for placement.

  • Places the new service task on a valid container instance in an optimal Availability Zone based on the previous steps. Favors container instances with the fewest number of running tasks for this service.
Additional service concepts

- You can optionally run your service behind a load balancer. For more information, see Distribute Amazon ECS service traffic using load balancing.

- You can optionally specify a deployment configuration for your service. A deployment is initiated by updating the task definition of a service. During a deployment, the service scheduler uses the minimum healthy percent and maximum percent parameters to determine the deployment strategy. For more information, see Service definition parameters.

- You can optionally configure your service to use Amazon ECS service discovery. Service discovery uses the AWS Cloud Map autonaming APIs to manage DNS entries for your service's tasks. This makes them discoverable from within your VPC. For more information, see Service discovery.

- When you delete a service, if there are still running tasks that require cleanup, the service moves from an ACTIVE to a DRAINING status, and the service is no longer visible in the console or in the ListServices API operation. After all tasks transition to either a STOPPING or STOPPED status, the service moves from a DRAINING to INACTIVE status. You can view services in the DRAINING or INACTIVE status by using the DescribeServices API operation. However, in the future, INACTIVE services might be cleaned up and purged from Amazon ECS record keeping, and DescribeServices calls on those services return a ServiceNotFoundException error.

- The bake time is a period of time after a new service version has scaled out and the old service version has scaled in, during which Amazon ECS continues to monitor the alarm associated with the deployment. Amazon ECS computes this time period based on the alarm configuration associated with the deployment.

  The bake time applies only when you use CloudWatch alarms to detect deployment failures. For more information, see the section called “Failure detection methods”.

Best Practices for improving Amazon ECS deployment times

When you use the rolling update deployment option, you can modify parameters to speed up your deployments.

When you choose the rolling update deployment type, the Amazon ECS service scheduler replaces any currently running tasks with new tasks whenever a new service deployment is started. The deployment configuration determines the specific number of tasks that Amazon ECS adds to or removes from the service during a rolling update. The following is an overview of the deployment process:
1. The scheduler starts your application.
2. The scheduler then decides if your application is ready for traffic.
3. When you scale down or create a new version of the application, the scheduler decides whether your application is safe to stop. At the same time, it must maintain the availability of the application during the rolling update deployment.

The strategy of maintaining task availability can cause deployments to take longer than you expect.

To speed up deployment times, modify the default load balancer, Amazon ECS agent, service and task definition options.

**Load balancer health check parameters for faster Amazon ECS deployment times**

Load balancers route requests only to the healthy targets in the Availability Zones for the load balancer. Each load balancer checks the health of each target, using the health check settings for the target groups with which the target is registered. After your target is registered, it must pass one health check to be considered healthy. The following diagram describes the load balancer health check process. The load balancer periodically sends health checks to the Amazon ECS container. The Amazon ECS agent monitors and waits for the load balancer to report on the container health. It does this before it considers the container to be in a healthy status.
Two Elastic Load Balancing health check parameters affect deployment speed:

- **Health check interval**: Determines the approximate amount of time, in seconds, between health checks of an individual container. By default, the load balancer checks every 30 seconds.

  This parameter is named:
  
  - HealthCheckIntervalSeconds in the Elastic Load Balancing API
  - **Interval** on the Amazon EC2 console

- **Healthy threshold count**: Determines the number of consecutive health check successes required before considering an unhealthy container healthy. By default, the load balancer requires five passing health checks before it reports that the target container is healthy.

  This parameter is named:
  
  - HealthyThresholdCount in the Elastic Load Balancing API
  - **Healthy threshold** on the Amazon EC2 console

With the default settings, the total time to determine the health of a container is two minutes and 30 seconds (30 seconds * 5 = 150 seconds).
You can speed up the health-check process if your service starts up and stabilizes in under 10 seconds. To speed up the process, reduce the number of health checks and the interval between the checks.

- HealthCheckIntervalSeconds (Elastic Load Balancing API name) or **Interval** (Amazon EC2 console name): 5
- HealthyThresholdCount (Elastic Load Balancing API name) or **Healthy threshold** (Amazon EC2 console name): 2

With this setting, the health-check process takes 10 seconds compared to the default of two minutes and 30 seconds.

For more information about the Elastic Load Balancing health check parameters, see [Health checks for your target groups](https://docs.aws.amazon.com/elasticloadbalancing/latest/application/target-groups.html) in the *Elastic Load Balancing User Guide*.

**Load balancer connection draining parameters for faster Amazon ECS deployment times**

To allow for optimization, clients maintain a keep alive connection to the container service. This is so that subsequent requests from that client can reuse the existing connection. When you want to stop traffic to a container, you notify the load balancer. When you tell the load balancer to stop traffic to the container, it periodically checks to see if the client closed the keep alive connection. The Amazon ECS agent monitors the load balancer, and waits for the load balancer to report that the keep alive connection is closed (the target is in an UNUSED state).
The amount of time that the load balancer waits to move the target to the UNUSED state is the deregistration delay. You can configure the following load balancer parameter to speed up your deployments.

- `deregistration_delay.timeout_seconds`: 300 (default)

When you have a service with a response time that's under one second, set the parameter to the following value to have the load balancer only wait 5 seconds before it breaks the connection between the client and the back-end service:

- `deregistration_delay.timeout_seconds`: 5

**Note**

Do not set the value to 5 seconds when you have a service with long-lived requests, such as slow file uploads or streaming connections.
SIGTERM responsiveness

Amazon ECS first sends a SIGTERM signal to the task to notify the application needs to finish and shut down. Then, Amazon ECS sends a SIGKILL message. When applications ignore the SIGTERM, the Amazon ECS service must wait to send the SIGKILL signal to terminate the process.

The following diagram shows how Amazon ECS terminates a task.

The amount of time that Amazon ECS waits to send the SIGKILL message is determined by the following Amazon ECS agent option:

- **ECS_CONTAINER_STOP_TIMEOUT**: 30 (default)

  For more information about the container agent parameter, see [Amazon ECS Container Agent](https://github.com) on GitHub.

To speed up the waiting period, set the Amazon ECS agent parameter to the following value:
Note

If your application takes more than 1 second, multiply the value by 2 and use that number as the value.

- **ECS_CONTAINER_STOP_TIMEOUT:** 2

In this case, the Amazon ECS waits 2 seconds for the container to shut down, and then Amazon ECS sends a SIGKILL message when the application didn't stop.

You can also modify the application code to trap the SIGTERM signal and react to it. The following is example in JavaScript:

```javascript
process.on('SIGTERM', function() {
  server.close();
});
```

This code causes the HTTP server to stop listening for any new requests, finish answering any in-flight requests, and then the Node.js process terminates. This is because its event loop has nothing left to do. Given this, if it takes the process only 500 ms to finish its in-flight requests, it terminates early without having to wait out the stop timeout and get sent a SIGKILL.

**Container images pull behavior for faster Amazon ECS deployments**

The time that it takes a container to start up varies, based on the underlying container image. For example, a fatter image (full versions of Debian, Ubuntu, and Amazon1/2) might take longer to start up because there are a more services that run in the containers compared to their respective slim versions (Debian-slim, Ubuntu-slim, and Amazon-slim) or smaller base images (Alpine).

**Fargate launch types**

Fargate does not cache images, and therefore the whole image is pulled from the registry when a task runs. We recommend the following for images used for Fargate tasks:

- Use a larger task size with additional vCPUs.

  The larger task size can help reduce the time that is required to extract the image when a task launches.
- Use a smaller base image.
- Have the repository that stores the image in the same Region as the task.

**Windows AMIs on Fargate launch types**

Fargate Windows AMIs cache the most recent month's, and the previous month's, servercore base image provided by Microsoft. These images match the KB/Build number patches updated each Patch Tuesday. For example, on 8/8/2023 Microsoft released KB5029247 (17763.4737) for Windows Server 2019. The previous month KB on 7/11/2023 was KB5028168 (17763.4645). So for the platforms WINDOWS_SERVER_2019_CORE and WINDOWS_SERVER_2019_FULL the following container images were cached:

- mcr.microsoft.com/windows/servercore:ltsc2019
- mcr.microsoft.com/windows/servercore:10.0.17763.4737
- mcr.microsoft.com/windows/servercore:10.0.17763.4645

Additionally, on 8/8/2023 Microsoft released KB5029250 (20348.1906) for Windows Server 2022. The previous months KB on 7/11/2023 was KB5028171 (20348.1850). So for the platforms WINDOWS_SERVER_2022_CORE and WINDOWS_SERVER_2022_FULL the following container images were cached:

- mcr.microsoft.com/windows/servercore:ltsc2022
- mcr.microsoft.com/windows/servercore:10.0.20348.1906
- mcr.microsoft.com/windows/servercore:10.0.20348.1850

**Amazon EC2 launch types**

When the Amazon ECS agent starts a task, it pulls the Docker image from its remote registry, and then caches a local copy. When you use a new image tag for each release of your application, this behavior is unnecessary.
The ECS_IMAGE_PULL_BEHAVIOR agent parameter determines the image pull behavior and has the following values:

- **ECS_IMAGE_PULL_BEHAVIOR**: default
  The image will be pulled remotely. If the pull fails, the cached image in the instance is used.
- **ECS_IMAGE_PULL_BEHAVIOR**: always
  The image will be pulled remotely. If the pull fails, the task fails.

To speed up deployment, set the Amazon ECS agent parameter to one of the following values:

- **ECS_IMAGE_PULL_BEHAVIOR**: once
  The image is pulled remotely only if it wasn't pulled by a previous task on the same container instance or if the cached image was removed by the automated image cleanup process. Otherwise, the cached image on the instance is used. This ensures that no unnecessary image pulls are attempted.
- **ECS_IMAGE_PULL_BEHAVIOR**: prefer-cached
The image is pulled remotely if there is no cached image. Otherwise, the cached image on the instance is used. Automated image cleanup is turned off for the container to ensure that the cached image isn't removed.

Setting the ECS_IMAGE_PULL_BEHAVIOR parameter to either of the preceding values can save time because the Amazon ECS agent uses the existing downloaded image. For larger Docker images, the download time might take 10-20 seconds to pull over the network.

**Amazon ECS service parameters for faster Amazon ECS deployments**

To ensure that there's no application downtime, the deployment process is as follows:

1. Start the new application containers while keeping the existing containers running.
2. Check that the new containers are healthy.
3. Stop the old containers.

Depending on your deployment configuration and the amount of free, unreserved space in your cluster it may take multiple rounds of this to complete replace all old tasks with new tasks.

There are two ECS service configuration options that you can use to modify the number:

- **minimumHealthyPercent**: 100% (default)
  
  The lower limit on the number of tasks for your service that must remain in the **RUNNING** state during a deployment. This is a percentage of the desiredCount rounded up to the nearest integer. This parameter allows you to deploy without using additional cluster capacity.

- **maximumPercent**: 200% (default)
  
  The upper limit on the number of tasks for your service that are allowed in the **RUNNING** or **PENDING** state during a deployment. This is a percentage of the desiredCount rounded down to the nearest integer.

Consider the following service that has six tan tasks, deployed in a cluster that has room for eight tasks total. The default Amazon ECS service configuration options don't allow the deployment to go below 100% of the six desired tasks.
The deployment process is as follows:

1. The goal is to replace the tan tasks with the blue tasks.
2. The scheduler starts two new blue tasks because the default settings require that there are six running tasks.
3. The scheduler stops two of the tan tasks because there will be a total of six tasks (four tan and two blue).
4. The scheduler starts two additional blue tasks.
5. The scheduler shuts down two of the tan tasks.
6. The scheduler starts two additional blue tasks.
7. The scheduler shuts down the last two tan tasks.

In the above example, if you use the default values for the options, there is a 2.5 minute wait for each new task that starts. Additionally, the load balancer might have to wait 5 minutes for the old task to stop.

You can speed up the deployment by setting the `minimumHealthyPercent` value to 50%.
Consider the following service that has six tan tasks, deployed in a cluster that has room for eight tasks total.

The deployment process is as follows:

1. The goal is to replace the tan tasks with the blue tasks.
2. The scheduler stops three of the tan tasks. There are still three tan tasks running which meets the `minimumHealthyPercent` value.
3. The scheduler starts five blue tasks.
4. The scheduler stops the remaining three tan tasks.
5. The scheduler starts the final blue tasks.

You could also add additional free space so that you can run additional tasks.
The deployment process is as follows:

1. The goal is to replace the tan tasks with the blue tasks.
2. The scheduler stops three of the tan tasks
3. The scheduler starts six blue tasks
4. The scheduler stops the three tan tasks.

Use the following values for the Amazon ECS service configuration options when your tasks are idle for some time and don't have a high utilization rate.

- minimumHealthyPercent: 50%
- maximumPercent: 200%

Creating a service using the console

You can create a service using the console.

Consider the following when you use the console:

- There are two compute options that distribute your tasks.
  - A capacity provider strategy causes Amazon ECS to distribute your tasks in one or across multiple capacity providers.
  - A launch type causes Amazon ECS to launch our tasks directly on either Fargate or on the Amazon EC2 instances registered to your clusters.

- Task definitions that use the awsvpc network mode or services configured to use a load balancer must have a networking configuration. By default, the console selects the default Amazon VPC along with all subnets and the default security group within the default Amazon VPC.

- The default the task placement strategy distributes tasks evenly across Availability Zones.

- When you use the Launch Type for your service deployment, by default the service starts in the subnets in your cluster VPC.

- For the capacity provider strategy, the console selects a compute option by default. The following describes the order that the console uses to select a default:
  - If your cluster has a default capacity provider strategy defined, it is selected.
• If your cluster doesn't have a default capacity provider strategy defined but you do have the Fargate capacity providers added to the cluster, a custom capacity provider strategy that uses the FARGATE capacity provider is selected.

• If your cluster doesn't have a default capacity provider strategy defined but you do have one or more Auto Scaling group capacity providers added to the cluster, the Use custom (Advanced) option is selected and you need to manually define the strategy.

• If your cluster doesn't have a default capacity provider strategy defined and no capacity providers added to the cluster, the Fargate launch type is selected.

• The default Deployment failure detection default options are to use the Amazon ECS deployment circuit breaker option with the Rollback on failures option.

For more information, see Deployment circuit breaker.

• If you want to use the blue/green deployment option, determine how CodeDeploy moves the applications. The following options are available:

  • CodeDeployDefault.ECSAllAtOnce: Shifts all traffic to the updated Amazon ECS container at once

  • CodeDeployDefault.ECSLinear10PercentEvery1Minutes: Shifts 10 percent of traffic every minute until all traffic is shifted.

  • CodeDeployDefault.ECSLinear10PercentEvery3Minutes: Shifts 10 percent of traffic every 3 minutes until all traffic is shifted.

  • CodeDeployDefault.ECSCanary10Percent5Minutes: Shifts 10 percent of traffic in the first increment. The remaining 90 percent is deployed five minutes later.

  • CodeDeployDefault.ECSCanary10Percent15Minutes: Shifts 10 percent of traffic in the first increment. The remaining 90 percent is deployed 15 minutes later.

• If you need an application to connect to other applications that run in Amazon ECS, determine the option that fits your architecture. For more information, see Interconnecting services.

• You must use AWS CloudFormation or the AWS Command Line Interface to deploy a service that uses any of the following parameters:

  • Tracking policy with a custom metric

  • Update Service – You cannot update the awsvpc network configuration and the health check grace period.

For information about how to create a service using the AWS CLI, see create-service in the AWS Command Line Interface Reference.
Quickly create a service

You can use the console to quickly create and deploy a service. The service has the following configuration:

- Deploys in the VPC and subnets associated with your cluster
- Deploys one task
- Uses the rolling deployment
- Uses the capacity provider strategy with your default capacity provider
- Uses the deployment circuit breaker to detect failures and sets the option to automatically roll back the deployment on failure

To deploy a service using the default parameters follow these steps.

**To create a service (Amazon ECS console)**

2. In the navigation page, choose Clusters.
3. On the Clusters page, choose the cluster to create the service in.
4. From the Services tab, choose Create.
5. Under Deployment configuration, specify how your application is deployed.
   a. For Application type, choose Service.
   b. For Task definition, choose the task definition family and revision to use.
   c. For Service name, enter a name for your service.
   d. For Desired tasks, enter the number of tasks to launch and maintain in the service.
6. (Optional) To help identify your service and tasks, expand the Tags section, and then configure your tags.

To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the task definition tags, select Turn on Amazon ECS managed tags, and then select Task definitions.
To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the service tags, select **Turn on Amazon ECS managed tags**, and then select **Service**.

Add or remove a tag.

- **[Add a tag]** Choose **Add tag**, and then do the following:
  - For **Key**, enter the key name.
  - For **Value**, enter the key value.
- **[Remove a tag]** Next to the tag, choose **Remove tag**.

**Create a service using defined parameters**

To create a service by using defined parameters, follow these steps.

**To create a service (Amazon ECS console)**

2. Determine the resource from where you launch the service.

<table>
<thead>
<tr>
<th>To start a service from</th>
<th>Steps</th>
</tr>
</thead>
</table>
| Clusters               | a. On the **Clusters** page, select the cluster to create the service in.  
  b. From the **Services** tab, choose **Create**. |
| Launch type            | a. On the **Task definitions** page, select the option button next to the task definition.  
  b. On the **Deploy** menu, choose **Create service**. |

3. **(Optional)** Choose how your tasks are distributed across your cluster infrastructure. Expand **Compute configuration**, and then choose your option.
<table>
<thead>
<tr>
<th><strong>Distribution method</strong></th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

**Launch type**

a. In the Compute options section, select **Launch type**.

b. For **Launch type**, choose a launch type.

c. (Optional) When the Fargate launch type is specified, for **Platform version**, specify the platform version to use. If a platform version isn't specified, the LATEST platform version is used.

4. To specify how your service is deployed, go to the **Deployment configuration** section, and then choose your options.

   a. For **Application type**, leave the choice as **Service**.

   b. For **Task definition** and **Revision**, choose the task definition family and revision to use.

   c. For **Service name**, enter a name for your service.

   d. For **Service type**, choose the service scheduling strategy.

      - To have the scheduler deploy exactly one task on each active container instance that meets all of the task placement constraints, choose **Daemon**.

      - To have the scheduler place and maintain the desired number of tasks in your cluster, choose **Replica**.

   For more information, see the section called “Service scheduler concepts”.

   e. If you chose **Replica**, for **Desired tasks**, enter the number of tasks to launch and maintain in the service.
f. Determine the deployment type for your service. Expand **Deployment options**, and then specify the following parameters.

<table>
<thead>
<tr>
<th>Deployment type</th>
<th>Steps</th>
</tr>
</thead>
</table>
| Rolling update  | a. For **Min running tasks**, enter the lower limit on the number of tasks in the service that must remain in the RUNNING state during a deployment, as a percentage of the desired number of tasks (rounded up to the nearest integer). For more information, see [Deployment configuration](#).  
b. For **Max running tasks**, enter the upper limit on the number of tasks in the service that are allowed in the RUNNING or PENDING state during a deployment, as a percentage of the desired number of tasks (rounded down to the nearest integer). |
### Blue/green deployment

- **Steps**

  **a.** For **Deployment configuration**, choose how CodeDeploy routes production traffic to your replacement task set during a deployment.

  **b.** For **Service role for CodeDeploy**, choose the IAM role the service uses to make API requests to authorized AWS services.

**g.** To configure how Amazon ECS detects and handles deployment failures, expand **Deployment failure detection**, and then choose your options.

  **i.** To stop a deployment when the tasks cannot start, select **Use the Amazon ECS deployment circuit breaker**.

  To have the software automatically roll back the deployment to the last completed deployment state when the deployment circuit breaker sets the deployment to a failed state, select **Rollback on failures**.

  **ii.** To stop a deployment based on application metrics, select **Use CloudWatch alarm(s)**. Then, from **CloudWatch alarm name**, choose the alarms. To create a new alarm, go to the CloudWatch console.

  To have the software automatically roll back the deployment to the last completed deployment state when a CloudWatch alarm sets the deployment to a failed state, select **Rollback on failures**.

**5.** (Optional) To configure service Auto Scaling, expand **Service auto scaling**, and then specify the following parameters.

  **a.** To use service auto scaling, select **Service auto scaling**.
b. For **Minimum number of tasks**, enter the lower limit of the number of tasks for service auto scaling to use. The desired count will not go below this count.

c. For **Maximum number of tasks**, enter the upper limit of the number of tasks for service auto scaling to use. The desired count will not go above this count.

d. Choose the policy type. Under **Scaling policy type**, choose one of the following options.
<table>
<thead>
<tr>
<th>To use this policy type...</th>
<th>Do this...</th>
</tr>
</thead>
</table>
| Target tracking          | a. For **Scaling policy type**, choose **Target tracking**.  
b. For **Policy name**, enter the name of the policy.  
c. For **ECS service metric**, select one of the following metrics.  
  • **ECSServiceAverageCPUUtilization** – Average CPU utilization of the service.  
  • **ECSServiceAverageMemoryUtilization** – Average memory utilization of the service.  
  • **ALBRequestCountPerTarget** – Number of requests completed per target in an Application Load Balancer target group.  
d. For **Target value**, enter the value the service maintains for the selected metric.  
e. For **Scale-out cooldown period**, enter the amount of time, in seconds, after a scale-out activity (add tasks) that the scaling policy |
<table>
<thead>
<tr>
<th><strong>To use this policy type...</strong></th>
<th><strong>Do this...</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>blocks scale-in activities and limits how many tasks can be scale out at a time.</td>
</tr>
<tr>
<td>f.</td>
<td>For <em>Scale-in cooldown period</em>, enter the amount of time, in seconds, after a scale-in activity (remove tasks) that must pass before another scale-in activity can start.</td>
</tr>
<tr>
<td>g.</td>
<td>To prevent the policy from performing a scale-in activity, select <strong>Turn off scale-in</strong>.</td>
</tr>
<tr>
<td>h.</td>
<td>• (Optional) Select <strong>Turn off scale-in</strong> if you want your scaling policy to scale out for increased traffic but don’t need it to scale in when traffic decreases.</td>
</tr>
<tr>
<td>To use this policy type...</td>
<td>Do this...</td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------</td>
</tr>
</tbody>
</table>
| Step scaling              | a. For **Scaling policy type**, choose **Step scaling**.  
  b. For **Policy name**, enter the policy name.  
  c. For **Alarm name**, enter a unique name for the alarm.  
  d. For **Amazon ECS service metric**, choose the metric to use for the alarm.  
  e. For **Statistic**, choose the alarm statistic.  
  f. For **Period**, choose the period for the alarm.  
  g. For **Alarm condition**, choose how to compare the selected metric to the defined threshold.  
  h. For **Threshold to compare metrics** and **Evaluation period to initiate alarm**, enter the threshold used for the alarm and how long to evaluate the threshold.  
  i. Under **Scaling actions**, do the following:  
    - For **Action**, select whether to add, remove, or set a specific desired count for your service. |
<table>
<thead>
<tr>
<th>To use this policy type...</th>
<th>Do this...</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• If you chose to add or remove tasks, for <strong>Value</strong>, enter the number of tasks (or percent of existing tasks) to add or remove when the scaling action is initiated. If you chose to set the desired count, enter the number of tasks. For <strong>Type</strong>, select whether the <strong>Value</strong> is an integer or a percent value of the existing desired count.</td>
</tr>
<tr>
<td></td>
<td>• For <strong>Lower bound</strong> and <strong>Upper bound</strong>, enter the lower boundary and upper boundary of your step scaling adjustment. By default, the lower bound for an add policy is the alarm threshold and the upper bound is positive (+) infinity. By default, the upper bound for a remove policy is the alarm threshold and</td>
</tr>
<tr>
<td>To use this policy type...</td>
<td>Do this...</td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------</td>
</tr>
<tr>
<td></td>
<td>the lower bound is negative (-) infinity.</td>
</tr>
<tr>
<td></td>
<td>• (Optional) Add additional scaling options. Choose Add new scaling action, and then repeat the Scaling actions steps.</td>
</tr>
<tr>
<td></td>
<td>• For Cooldown period, enter the amount of time, in seconds, to wait for a previous scaling activity to take effect. For an add policy, this is the time after a scale-out activity that the scaling policy blocks scale-in activities and limits how many tasks can be scale out at a time. For a remove policy, this is the time after a scale-in activity that must pass before another scale-in activity can start.</td>
</tr>
</tbody>
</table>

6. (Optional) To use Service Connect, select Turn on Service Connect, and then specify the following:

   a. Under Service Connect configuration, specify the client mode.
• If your service runs a network client application that only needs to connect to other services in the namespace, choose **Client side only**.

• If your service runs a network or web service application and needs to provide endpoints for this service, and connects to other services in the namespace, choose **Client and server**.

b. To use a namespace that is not the default cluster namespace, for **Namespace**, choose the service namespace.

c. (Optional) Select the **Use log collection** option to specify a log configuration. For each available log driver, there are log driver options to specify. The default option sends container logs to CloudWatch Logs. The other log driver options are configured using AWS FireLens. For more information, see **Using custom log routing**.

The following describes each container log destination in more detail.

• **Amazon CloudWatch** – Configure the task to send container logs to CloudWatch Logs. The default log driver options are provided, which create a CloudWatch log group on your behalf. To specify a different log group name, change the driver option values.

• **Amazon Data Firehose** – Configure the task to send container logs to Firehose. The default log driver options are provided, which send logs to a Firehose delivery stream. To specify a different delivery stream name, change the driver option values.

• **Amazon Kinesis Data Streams** – Configure the task to send container logs to Kinesis Data Streams. The default log driver options are provided, which send logs to a Kinesis Data Streams stream. To specify a different stream name, change the driver option values.

• **Amazon OpenSearch Service** – Configure the task to send container logs to an OpenSearch Service domain. The log driver options must be provided. For more information, see [Forwarding logs to an Amazon OpenSearch Service domain](#).

• **Amazon S3** – Configure the task to send container logs to an Amazon S3 bucket. The default log driver options are provided, but you must specify a valid Amazon S3 bucket name.

7. To have Amazon ECS perform periodic container-level health checks, select **Enable Amazon ECS task health propagation**.

8. Configure your DNS records.
For **DNS record type**, select the DNS record type to create for your service. Amazon ECS service discovery only supports **A** and **SRV** records, depending on the network mode that your task definition specifies. For more information about these record types, see [Supported DNS Record Types](https://docs.aws.amazon.com/AmazonRoute53/latest/DeveloperGuide/SupportedDNSRecordTypes.html) in the *Amazon Route 53 Developer Guide*.

- If the task definition that your service task specifies uses the `bridge` or `host` network mode, only type **SRV** records are supported. Choose a container name and port combination to associate with the record.

- If the task definition that your service task specifies uses the `awsvpc` network mode, select either the **A** or **SRV** record type. If you choose **A**, skip to the next step. If you choose **SRV**, specify either the port that the service can be found on or a container name and port combination to associate with the record.

For **TTL**, enter the time in seconds how long a record set is cached by DNS resolvers and by web browsers.

9. **(Optional)** To configure a load balancer for your service, expand **Load balancing**.

Choose the load balancer.

<table>
<thead>
<tr>
<th>To use this load balancer</th>
<th>Do this</th>
</tr>
</thead>
</table>
| Application Load Balancer | a. For **Load balancer type**, select **Application Load Balancer**.  
b. Choose **Create a new load balancer** to create a new Application Load Balancer or **Use an existing load balancer** to select an existing Application Load Balancer.  
c. For **Load balancer name**, enter a unique name. |
<table>
<thead>
<tr>
<th>To use this load balancer</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>d. For <strong>Choose container to load balance</strong>, choose the container that hosts the service.</td>
<td></td>
</tr>
<tr>
<td>e. For <strong>Listener</strong>, enter a port and protocol for the Application Load Balancer to listen for connection requests on. By default, the load balancer will be configured to use port 80 and HTTP.</td>
<td></td>
</tr>
<tr>
<td>f. For <strong>Target group name</strong>, enter a name and a protocol for the target group that the Application Load Balancer routes requests to. By default, the target group routes requests to the first container defined in your task definition.</td>
<td></td>
</tr>
<tr>
<td>g. For <strong>Deggregation delay</strong>, enter the number of seconds for the load balancer to change the target state to UNUSED. The default is 300 seconds.</td>
<td></td>
</tr>
<tr>
<td>h. For <strong>Health check path</strong>, enter an existing path within your container where the Application Load Balancer periodically checks.</td>
<td></td>
</tr>
<tr>
<td>To use this load balancer</td>
<td>Do this</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------</td>
</tr>
<tr>
<td></td>
<td>lly sends requests to verify the connection health between the Application Load Balancer and the container. The default is the root directory (/).</td>
</tr>
<tr>
<td></td>
<td>i. For <strong>Health check grace period</strong>, enter the amount of time (in seconds) that the service scheduler should ignore unhealthy Elastic Load Balancing target health checks.</td>
</tr>
<tr>
<td>To use this load balancer</td>
<td>Do this</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| **Network Load Balancer** | a. For Load balancer type, select **Network Load Balancer**.  
b. For Load Balancer, choose an existing Network Load Balancer.  
c. For Choose container to load balance, choose the container that hosts the service.  
d. For Target group name, enter a name and a protocol for the target group that the Network Load Balancer routes requests to. By default, the target group routes requests to the first container defined in your task definition.  
e. For Degregistration delay, enter the number of seconds for the load balancer to change the target state to UNUSED. The default is 300 seconds.  
f. For Health check path, enter an existing path within your container where the Network Load Balancer periodically sends requests to verify
### To use this load balancer

<table>
<thead>
<tr>

</tr>
</thead>
</table>
| the connection health between the Application Load Balancer and the container. The default is the root directory (\`).

#### g. For Health check grace period, enter the amount of time (in seconds) that the service scheduler should ignore unhealthy Elastic Load Balancing target health checks.

### 10. (Optional) To use a task placement strategy other than the default, expand **Task Placement**, and then choose from the following options.

For more information, see [How Amazon ECS places tasks on container instances](#).

- **AZ Balanced Spread** – Distribute tasks across Availability Zones and across container instances in the Availability Zone.

- **AZ Balanced BinPack** – Distribute tasks across Availability Zones and across container instances with the least available memory.

- **BinPack** – Distribute tasks based on the least available amount of CPU or memory.

- **One Task Per Host** – Place, at most, one task from the service on each container instance.

- **Custom** – Define your own task placement strategy.

If you chose **Custom**, define the algorithm for placing tasks and the rules that are considered during task placement.

- Under **Strategy**, for **Type** and **Field**, choose the algorithm and the entity to use for the algorithm.

  You can enter a maximum of 5 strategies.

- Under **Constraint**, for **Type** and **Expression**, choose the rule and attribute for the constraint.
For example, to set the constraint to place tasks on T2 instances, for the Expression, enter `attribute:ecs.instance-type =~ t2.*`.

You can enter a maximum of 10 constraints.

11. If your task definition uses the awsvpc network mode, expand Networking. Use the following steps to specify a custom configuration.

   a. For VPC, select the VPC to use.
   b. For Subnets, select one or more subnets in the VPC that the task scheduler considers when placing your tasks.

   **Important**
   Only private subnets are supported for the awsvpc network mode. Tasks don't receive public IP addresses. Therefore, a NAT gateway is required for outbound internet access, and inbound internet traffic is routed through a load balancer.

   c. For Security group, you can either select an existing security group or create a new one. To use an existing security group, select the security group and move to the next step. To create a new security group, choose **Create a new security group**. You must specify a security group name, description, and then add one or more inbound rules for the security group.

12. (Optional) To configure a load balancer for your service, expand Load balancing.

   Choose the load balancer.

<table>
<thead>
<tr>
<th>To use this load balancer</th>

13. (Optional) To use a task placement strategy other than the default, expand **Task Placement**, and then choose from the following options.

For more information, see [How Amazon ECS places tasks on container instances](#).

- **AZ Balanced Spread** – Distribute tasks across Availability Zones and across container instances in the Availability Zone.
- **AZ Balanced BinPack** – Distribute tasks across Availability Zones and across container instances with the least available memory.
- **BinPack** – Distribute tasks based on the least available amount of CPU or memory.
- **One Task Per Host** – Place, at most, one task from the service on each container instance.
- **Custom** – Define your own task placement strategy.

If you chose **Custom**, define the algorithm for placing tasks and the rules that are considered during task placement.

- Under **Strategy**, for **Type** and **Field**, choose the algorithm and the entity to use for the algorithm.

  You can enter a maximum of 5 strategies.

- Under **Constraint**, for **Type** and **Expression**, choose the rule and attribute for the constraint.

  For example, to set the constraint to place tasks on T2 instances, for the **Expression**, enter `attribute:ecs.instance-type =~ t2.*`.

  You can enter a maximum of 10 constraints.

14. If your task uses a data volume that’s compatible with configuration at deployment, you can configure the volume by expanding **Volume**.
The volume name and volume type are configured when you create a task definition revision and can't be changed when creating a service. To update the volume name and type, you must create a new task definition revision and create a service by using the new revision.
<table>

<tr>
<td></td>
<td>If you want to propagate tags from the task definition, choose <strong>Task definition</strong> for <strong>Propagate tags from</strong>. If you want to propagate tags from the service, choose <strong>Service</strong> for <strong>Propagate tags from</strong>. If you choose <strong>Do not propagate</strong>, or if you don't choose a value, the tags aren't propagated. If you want to provide your own tags, choose <strong>Add tag</strong> and then provide the key and value for each tag you add. For more information about tagging Amazon EBS volumes, see <a href="https://docs.aws.amazon.com/AmazonEBS/latest/UserGuide/EBS-Tagging.html">Tagging Amazon EBS volumes</a>.</td>
</tr>
</tbody>
</table>

15. (Optional) To help identify your service and tasks, expand the **Tags** section, and then configure your tags.

   To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the task definition tags, select **Turn on Amazon ECS managed tags**, and then for **Propagate tags from**, choose **Task definitions**.

   To have Amazon ECS automatically tag all newly launched tasks with the cluster name and the service tags, select **Turn on Amazon ECS managed tags**, and then for **Propagate tags from**, choose **Service**.
Add or remove a tag.

- [Add a tag] Choose **Add tag**, and then do the following:
  - For **Key**, enter the key name.
  - For **Value**, enter the key value.
- [Remove a tag] Next to the tag, choose **Remove tag**.

**Updating a service using the console**

You can update an Amazon ECS service using the Amazon ECS console. The current service configuration is pre-populated. You can update the task definition, desired task count, capacity provider strategy, platform version, and deployment configuration; or any combination of these.

For information about how to update the blue/green deployment configuration, see [Updating a blue/green deployment configuration using the console](#).

Consider the following when you use the console:

If you want to temporarily stop your service, set **Desired tasks** to 0. Then, when you are ready to start the service, update the service with the original **Desired tasks** count.

Consider the following when you use the console:

- You must use the AWS Command Line Interface to update a service that uses any of the following parameters:
  - **Blue/green deployments**
  - **Service Discovery** – You can only view your Service Discovery configuration.
  - **Tracking policy with a custom metric**
  - **Update Service** – You cannot update the aws vpc network configuration and the health check grace period.

For information about how to update a service using the AWS CLI, see [update-service](#) in the **AWS Command Line Interface Reference**.

- If you are changing the ports used by containers in a task definition, you might need to update the security groups for the container instances to work with the updated ports.
- Amazon ECS does not automatically update the security groups associated with Elastic Load Balancing load balancers or Amazon ECS container instances.
• If your service uses a load balancer, the load balancer configuration defined for your service when it was created cannot be changed using the console. You can instead use the AWS CLI or SDK to modify the load balancer configuration. For information about how to modify the configuration, see UpdateService in the Amazon Elastic Container Service API Reference.

• If you update the task definition for the service, the container name and container port that are specified in the load balancer configuration must remain in the task definition.

You can update an existing service to change some of the service configuration parameters, such as the number of tasks that are maintained by a service, which task definition is used by the tasks, or if your tasks are using the Fargate launch type, you can change the platform version your service uses. A service using a Linux platform version cannot be updated to use a Windows platform version and vice versa. If you have an application that needs more capacity, you can scale up your service. If you have unused capacity to scale down, you can reduce the number of desired tasks in your service and free up resources.

If you want to use an updated container image for your tasks, you can create a new task definition revision with that image and deploy it to your service by using the force new deployment option in the console.

The service scheduler uses the minimum healthy percent and maximum percent parameters (in the deployment configuration for the service) to determine the deployment strategy.

If a service is using the rolling update (ECS) deployment type, the **minimum healthy percent** represents a lower limit on the number of tasks in a service that must remain in the RUNNING state during a deployment, as a percentage of the desired number of tasks (rounded up to the nearest integer). The parameter also applies while any container instances are in the DRAINING state if the service contains tasks using the EC2 launch type. Use this parameter to deploy without using additional cluster capacity. For example, if your service has a desired number of four tasks and a minimum healthy percent of 50 percent, the scheduler may stop two existing tasks to free up cluster capacity before starting two new tasks. Tasks for services that do not use a load balancer are considered healthy if they are in the RUNNING state. Tasks for services that do use a load balancer are considered healthy if they are in the RUNNING state and they are reported as healthy by the load balancer. The default value for minimum healthy percent is 100 percent.

If a service is using the rolling update (ECS) deployment type, the **maximum percent** parameter represents an upper limit on the number of tasks in a service that are allowed in the PENDING, RUNNING, or STOPPING state during a deployment, as a percentage of the desired number of tasks (rounded down to the nearest integer). The parameter also applies while any container
instances are in the DRAINING state if the service contains tasks using the EC2 launch type. Use this parameter to define the deployment batch size. For example, if your service has a desired number of four tasks and a maximum percent value of 200 percent, the scheduler may start four new tasks before stopping the four older tasks. That is provided that the cluster resources required to do this are available. The default value for the maximum percent is 200 percent.

When the service scheduler replaces a task during an update, the service first removes the task from the load balancer (if used) and waits for the connections to drain. Then, the equivalent of `docker stop` is issued to the containers running in the task. This results in a SIGTERM signal and a 30-second timeout, after which SIGKILL is sent and the containers are forcibly stopped. If the container handles the SIGTERM signal gracefully and exits within 30 seconds from receiving it, no SIGKILL signal is sent. The service scheduler starts and stops tasks as defined by your minimum healthy percent and maximum percent settings.

The service scheduler also replaces tasks determined to be unhealthy after a container health check or a load balancer target group health check fails. This replacement depends on the `maximumPercent` and `desiredCount` service definition parameters. If a task is marked unhealthy, the service scheduler will first start a replacement task. If the replacement task has a health status of HEALTHY, the service scheduler stops the unhealthy task. If the replacement task has a health status of UNHEALTHY, the scheduler will stop either the unhealthy replacement task or the existing unhealthy task to get the total task count to equal desiredCount. If the `maximumPercent` parameter limits the scheduler from starting a replacement task first, the scheduler will stop an unhealthy task one at a time at random to free up capacity, and then start a replacement task. The start and stop process continues until all unhealthy tasks are replaced with healthy tasks. Once all unhealthy tasks have been replaced and only healthy tasks are running, if the total task count exceeds the `desiredCount`, healthy tasks are stopped at random until the total task count equals `desiredCount`. For more information about `maximumPercent` and `desiredCount`, see Service definition parameters.

**Note**

This behavior does not apply to tasks run and maintained by services that use the *rolling update* deployment type. During a rolling update, the service scheduler first stops unhealthy tasks and then starts replacement tasks.
Important

If you are changing the ports used by containers in a task definition, you may need to update the security groups for the container instances to work with the updated ports. If you update the task definition for the service, the container name and container port that were specified when the service was created must remain in the task definition. Amazon ECS does not automatically update the security groups associated with Elastic Load Balancing load balancers or Amazon ECS container instances.

To update a service (Amazon ECS console)

2. On the Clusters page, choose the cluster.
3. On the cluster details page, in the Services section, select the check box next to the service, and then choose Update.
4. To have your service start a new deployment, select Force new deployment.
5. For Task definition, choose the task definition family and revision.

Important

The console validates that the selected task definition family and revision are compatible with the defined compute configuration. If you receive a warning, verify both your task definition compatibility and the compute configuration that you selected.

6. For Desired tasks, enter the number of tasks that you want to run for the service.
7. For Min running tasks, enter the lower limit on the number of tasks in the service that must remain in the RUNNING state during a deployment, as a percentage of the desired number of tasks (rounded up to the nearest integer). For more information, see Deployment configuration.
8. For Max running tasks, enter the upper limit on the number of tasks in the service that are allowed in the RUNNING or PENDING state during a deployment, as a percentage of the desired number of tasks (rounded down to the nearest integer).
9. To configure how Amazon ECS detects and handles deployment failures, expand Deployment failure detection, and then choose your options.
a. To stop a deployment when the tasks cannot start, select **Use the Amazon ECS deployment circuit breaker**.

To have the software automatically roll back the deployment to the last completed deployment state when the deployment circuit breaker sets the deployment to a failed state, select **Rollback on failures**.

b. To stop a deployment based on application metrics, select **Use CloudWatch alarm(s)**. Then, from **CloudWatch alarm name**, choose the alarms. To create a new alarm, go to the CloudWatch console.

To have the software automatically roll back the deployment to the last completed deployment state when a CloudWatch alarm sets the deployment to a failed state, select **Rollback on failures**.

10. To change the compute options, expand **Compute configuration**, and then do the following:

a. For services on AWS Fargate, for **Platform version**, choose the new version.

b. For services that use a capacity provider strategy, for **Capacity provider strategy**, do the following:

   - To add an additional capacity provider, choose **Add more**. Then, for **Capacity provider**, choose the capacity provider.
   - To remove a capacity provider, to the right of the capacity provider, choose **Remove**.

A service that's using an Auto Scaling group capacity provider can't be updated to use a Fargate capacity provider. A service that's using a Fargate capacity provider can't be updated to use an Auto Scaling group capacity provider.

11. (Optional) To configure service Auto Scaling, expand **Service auto scaling**, and then specify the following parameters.

a. To use service auto scaling, select **Service auto scaling**.

b. For **Minimum number of tasks**, enter the lower limit of the number of tasks for service auto scaling to use. The desired count will not go below this count.

c. For **Maximum number of tasks**, enter the upper limit of the number of tasks for service auto scaling to use. The desired count will not go above this count.

d. Choose the policy type. Under **Scaling policy type**, choose one of the following options.
<table>

**g. For Infrastructure role,** choose an IAM role with the necessary permissions that allow Amazon ECS to manage Amazon EBS volumes for tasks. You can attach the AmazonECSInfrastructureRolePolicyForVolumes managed policy to the role, or you can use the policy as a guide to create and attach an your own policy with permissions that meet your specific needs. For more information about the necessary permissions, see Amazon ECS infrastructure IAM role.

**h. For Encryption,** choose Default if you want to use the Amazon EBS encryption by default settings. If your account...
<table>
<thead>
<tr>
<th>To configure this volume type</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>has <strong>Encryption by default</strong> configured, the volume will be encrypted with the AWS Key Management Service (AWS KMS) key that's specified in the setting. If you choose <strong>Default</strong> and Amazon EBS default encryption isn't turned on, the volume will be unencrypted.</td>
<td></td>
</tr>
</tbody>
</table>

If you choose **Custom**, you can specify an AWS KMS key of your choice for volume encryption.

If you choose **None**, the volume will be unencrypted unless you have encryption by default configured, or if you create a volume from an encrypted snapshot.

i. If you've chosen **Custom** for **Encryption**, you must specify the AWS KMS key that you want to use. For **KMS key**, choose an AWS KMS key or enter a key ARN. If you choose to encrypt your volume by using a symmetric customer managed key,
To configure this volume type | Do this
--- | ---
| | make sure that you have the right permissions defined in your AWS KMS key policy. For more information, see Data encryption for Amazon EBS volumes.

j. (Optional) Under Tags, you can add tags to your Amazon EBS volume by either propagating tags from the task definition or service, or by providing your own tags.

If you want to propagate tags from the task definition, choose Task definition for Propagate tags from. If you want to propagate tags from the service, choose Service for Propagate tags from. If you choose Do not propagate, or if you don't choose a value, the tags aren't propagated.

If you want to provide your own tags, choose Add tag and then provide the key and value for each tag you add.
To configure this volume type | Do this
--- | ---
|  | For more information about tagging Amazon EBS volumes, see Tagging Amazon EBS volumes.

14. (Optional) To help identify your service, expand the Tags section, and then configure your tags.

- [Add a tag] Choose Add tag, and do the following:
  - For Key, enter the key name.
  - For Value, enter the key value.
- [Remove a tag] Next to the tag, choose Remove tag.

15. Choose Update.

### Updating a blue/green deployment configuration using the console

You can update a blue/green deployment configuration using the Amazon ECS console. The current blue/green deployment configuration is pre-populated. You can update the following blue/green deployment options:

- Deployment group name - The CodeDeploy deployment settings
- Application name - The CodeDeploy deployment group
- Deployment configuration - How CodeDeploy routes production traffic to your replacement task set during a deployment
- Test listener on the load balancer - CodeDeploy uses the test listener to route your test traffic to the replacement task set during a deployment

You must configure the new option before you update the configuration.

**To update a blue/green deployment configuration (Amazon ECS console)**

2. On the Clusters page, select the cluster.
3. On the Cluster overview page, select the service, and then choose Update.
4. Expand **Deployment options - Powered by CodeDeploy**, and then choose which options to update:

- To modify the CodeDeploy deployment group, for **Application name**, choose the deployment group.
- To modify the CodeDeploy deployment settings, for **Deployment group name**, choose the group.
- To modify how CodeDeploy routes production traffic to your replacement task set during a deployment, for **Deployment configuration**, choose the option.

5. Select the deployment lifecycle event hooks and the associated Lambda functions to run as part of the new revision of the service deployment. The available lifecycle hooks are:

- **BeforeInstall** – Use this deployment lifecycle event hook to invoke a Lambda function before the replacement task set is created. The result of the Lambda function at this lifecycle event does not initiate a rollback.
- **AfterInstall** – Use this deployment lifecycle event hook to invoke a Lambda function after the replacement task set is created. The result of the Lambda function at this lifecycle event can initiate a rollback.
- **BeforeAllowTraffic** – Use this deployment lifecycle event hook to invoke a Lambda function before the production traffic has been rerouted to the replacement task set. The result of the Lambda function at this lifecycle event can initiate a rollback.
- **AfterAllowTraffic** – Use this deployment lifecycle event hook to invoke a Lambda function after the production traffic has been rerouted to the replacement task set. The result of the Lambda function at this lifecycle event can initiate a rollback.

6. To modify the test listener, expand **Load balancing**, and then for **Test listener for CodeDeploy deployment**, choose the test listener.

7. Choose **Update**.

**Deleting a service using the console**

You can delete an Amazon ECS service using the console. The service is automatically scaled down to zero before it is deleted. Load balancer resources or service discovery resources associated with the service are not affected by the service deletion. To delete your Elastic Load Balancing resources, see one of the following topics, depending on your load balancer type: [Delete an Application Load Balancer](#) or [Delete a Network Load Balancer](#).
When you delete a service, if there are still running tasks that require cleanup, the service status moves from ACTIVE to DRAINING, and the service is no longer visible in the console or in the ListServices API operation. After all tasks have transitioned to either STOPPING or STOPPED status, the service status moves from DRAINING to INACTIVE. Services in the DRAINING or INACTIVE status can still be viewed with the DescribeServices API operation.

⚠️ Important

If you attempt to create a new service with the same name as an existing service in either ACTIVE or DRAINING status, you receive an error.

To delete a service (Amazon ECS console)

2. On the Clusters page, select the cluster for the service.
3. On the Clusters page, choose the cluster.
4. On the Cluster: name page, choose the Services tab.
5. Select the services, and then choose Delete.
6. To delete a service even if it wasn't scaled down to zero tasks, select Force delete service.
7. At the confirmation prompt, enter delete, and then choose Delete.

Amazon ECS Deployment types

An Amazon ECS deployment type determines the deployment strategy that your service uses. There are three deployment types: rolling update, blue/green, and external.

You can view information about the service deployment type on the service details page, or by using the describe-services API. For more information, see DescribeServices in the Amazon Elastic Container Service API Reference.

Topics

- Rolling update
- Blue/Green deployment with CodeDeploy
- Use a third-party controller for Amazon ECS external deployments
Rolling update

When you create a service which uses the rolling update (ECS) deployment type, the Amazon ECS service scheduler replaces the currently running tasks with new tasks. The number of tasks that Amazon ECS adds or removes from the service during a rolling update is controlled by the service deployment configuration. The deployment configuration consists of the following:

- The `minimumHealthyPercent` represents the lower limit on the number of tasks that should be running for a service during a deployment or when a container instance is draining, as a percent of the desired number of tasks for the service. This value is rounded up. For example, if the minimum healthy percent is 50 and the desired task count is four, then the scheduler can stop two existing tasks before starting two new tasks. Likewise, if the minimum healthy percent is 75% and the desired task count is two, then the scheduler can't stop any tasks due to the resulting value also being two.

- The `maximumPercent` represents the upper limit on the number of tasks that should be running for a service during a deployment or when a container instance is draining, as a percent of the desired number of tasks for a service. This value is rounded down. For example, if the maximum percent is 200 and the desired task count is four, then the scheduler can start four new tasks before stopping four existing tasks. Likewise, if the maximum percent is 125 and the desired task count is three, the scheduler can't start any tasks due to the resulting value also being three.

⚠️ **Important**

When setting a minimum healthy percent or a maximum percent, you should ensure that the scheduler can stop or start at least one task when a deployment is initiated. If your service has a deployment that is stuck due to an invalid deployment configuration, a service event message will be sent. For more information, see service (service-name) was unable to stop or start tasks during a deployment because of the service deployment configuration. Update the minimumHealthyPercent or maximumPercent value and try again.

A rolling deployment uses the deployment circuit breaker to determine if the tasks reach a steady state. The deployment circuit breaker can optionally roll back a deployment on failure.
Failure detection methods

The are two methods which provide a way to quickly identify when a deployment has failed, and then to optionally roll back the failure to the last working deployment.

- the section called “Deployment circuit breaker”
- the section called “CloudWatch alarms”

The methods can be used separately or together. When both methods are use, the deployment is set to failed as soon as the failure criteria for either failure method is met.

Use the following guidelines to help determine which method to use:

- Circuit breaker - Use this method when you want to stop a deployment when the tasks can't start.
- CloudWatch alarms - Use this method when you want to stop a deployment based on application metrics.

For information about the Amazon ECS deployment process best practices, see Task deployment in the Amazon ECS Best Practices Guide.

Deployment circuit breaker

The deployment circuit breaker is the rolling update mechanism that determines if the tasks reach a steady state. The deployment circuit breaker has an option that will automatically roll back a failed deployment to the deployment that is in the COMPLETED state.

When a service deployment changes state, Amazon ECS sends a service deployment state change event to EventBridge. This provides a programmatic way to monitor the status of your service deployments. For more information, see Amazon ECS service deployment state change events. We recommend that you create and monitor an EventBridge rule with an eventName of SERVICE_DEPLOYMENT_FAILED so that you can take manual action to start your deployment. For more information, see Creating an EventBridge Rule in the Amazon EventBridge User Guide.

When the deployment circuit breaker determines that a deployment failed, it looks for the most recent deployment that is in a COMPLETED state. This is the deployment that it uses as the rollback deployment. When the rollback starts, the deployment changes from a COMPLETED to IN_PROGRESS. This means that the deployment is not eligible for another rollback until it reaches
the a COMPLETED state. When the deployment circuit breaker does not find a deployment that is in a COMPLETED state, the circuit breaker does not launch new tasks and the deployment is stalled.

When you create a service, the scheduler keeps track of the tasks that failed to launch in two stages.

- Stage 1 - The scheduler monitors the tasks to see if they transition into the RUNNING state.
  - Success - The deployment has a chance of transitioning to the COMPLETED state because there is more than one task that transitioned to the RUNNING state. The failure criteria is skipped and the circuit breaker moves to stage 2.
  - Failure - There are consecutive tasks that did not transition to the RUNNING state and the deployment might transition to the FAILED state.

- Stage 2 - The deployment enters this stage when there is at least one task in the RUNNING state. The circuit breaker checks the health checks for the tasks in the current deployment being evaluated. The validated health checks are Elastic Load Balancing, AWS Cloud Map service health checks, and container health checks.
  - Success - There is at least one task in the running state with health checks that have passed.
  - Failure - The tasks that are replaced because of health check failures have reached the failure threshold.

Consider the following when you use the deployment circuit breaker method on a service. EventBridge generates the rule.

- The DescribeServices response provides insight into the state of a deployment, the rolloutState and rolloutStateReason. When a new deployment is started, the rollout state begins in an IN_PROGRESS state. When the service reaches a steady state, the rollout state transitions to COMPLETED. If the service fails to reach a steady state and circuit breaker is turned on, the deployment will transition to a FAILED state. A deployment in a FAILED state doesn't launch any new tasks.

- In addition to the service deployment state change events Amazon ECS sends for deployments that have started and have completed, Amazon ECS also sends an event when a deployment with circuit breaker turned on fails. These events provide details about why a deployment failed or if a deployment was started because of a rollback. For more information, see Amazon ECS service deployment state change events.
• If a new deployment is started because a previous deployment failed and a rollback occurred, the `reason` field of the service deployment state change event indicates the deployment was started because of a rollback.

• The deployment circuit breaker is only supported for Amazon ECS services that use the rolling update (ECS) deployment controller.

• You must use the Amazon ECS console, or the AWS CLI when you use the deployment circuit breaker with the CloudWatch option. For more information, see [the section called “Create a service using defined parameters”](https://docs.aws.amazon.com/elasticcontainers/v2../../../../DeveloperGuide/ecs-cli-deployment-circuit-breaker.html) and `create-service` in the [AWS Command Line Interface Reference](https://docs.aws.amazon.com/elasticcontainers/v2/ecs-reference/). The following `create-service` AWS CLI example shows how to create a Linux service when the deployment circuit breaker is used with the rollback option.

```bash
aws ecs create-service \
   --service-name MyService \
   --deployment-controller type=ECS \
   --desired-count 3 \
   --deployment-configuration "deploymentCircuitBreaker={enable=true,rollback=true}" \
   --task-definition sample-fargate:1 \
   --launch-type FARGATE \
   --platform-family LINUX \
   --platform-version 1.4.0 \
   --network-configuration "awsvpcConfiguration={subnets=[subnet-12344321],securityGroups=[sg-12344321],assignPublicIp=ENABLED}"
```

Example:

Deployment 1 is in a COMPLETED state.

Deployment 2 cannot start, so the circuit breaker rolls back to Deployment 1. Deployment 1 transitions to the IN_PROGRESS state.

Deployment 3 starts and there is no deployment in the COMPLETED state, so Deployment 3 cannot roll back, or launch tasks.

**Failure threshold**

The deployment circuit breaker calculates the threshold value, and then uses the value to determine when to move the deployment to a FAILED state.
The deployment circuit breaker has a minimum threshold of 3 and a maximum threshold of 200, and uses the values in the following formula to determine the deployment failure.

\[
\text{Minimum threshold} \leq 0.5 \times \text{desired task count} \Rightarrow \text{maximum threshold}
\]

When the result of the calculation is greater than the minimum of 3, but smaller than the maximum of 200, the failure threshold is set to the calculated threshold (rounded up).

\[3 \leq 0.5 \times 1 \Rightarrow 200\]

**Note**
You cannot change either of the threshold values.

There are two stages for the deployment status check.

1. The deployment circuit breaker monitors tasks that are part of the deployment and checks for tasks that are in the **RUNNING** state. The scheduler ignores the failure criteria when a task in the current deployment is in the **RUNNING** state and proceeds to the next stage. When tasks fail to reach in the **RUNNING** state, the deployment circuit breaker increases the failure count by one. When the failure count equals the threshold, the deployment is marked as **FAILED**.

2. This stage is entered when there are one or more tasks in the **RUNNING** state. The deployment circuit breaker performs health checks on the following resources for the tasks in the current deployment:
   - Elastic Load Balancing load balancers
   - AWS Cloud Map service
   - Amazon ECS container health checks

   When a health check fails for the task, the deployment circuit breaker increases the failure count by one. When the failure count equals the threshold, the deployment is marked as **FAILED**.

The following table provides some examples.

<table>
<thead>
<tr>
<th>Desired task count</th>
<th>Calculation</th>
<th>Threshold</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3 \leq 0.5 \times 1 \Rightarrow 200</td>
<td>3 (the calculated value is less than the minimum)</td>
</tr>
<tr>
<td>Desired task count</td>
<td>Calculation</td>
<td>Threshold</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------</td>
<td>-----------</td>
</tr>
<tr>
<td>25</td>
<td>3 &lt;= 0.5 * 25 =&gt; 200</td>
<td>13 (the value is rounded up)</td>
</tr>
<tr>
<td>400</td>
<td>3 &lt;= 0.5 * 400 =&gt; 200</td>
<td>200</td>
</tr>
<tr>
<td>800</td>
<td>3 &lt;= 0.5 * 800 =&gt; 200</td>
<td>200 (the calculated value is greater than the maximum)</td>
</tr>
</tbody>
</table>

For example, when the threshold is 3, the circuit breaker starts with the failure count set at 0. When a task fails to reach the RUNNING state, the deployment circuit breaker increases the failure count by one. When the failure count equals 3, the deployment is marked as FAILED.

For additional examples about how to use the rollback option, see Announcing Amazon ECS deployment circuit breaker.

**CloudWatch alarms**

You can configure Amazon ECS to set the deployment to failed when it detects that a specified CloudWatch alarm has gone into the ALARM state.

You can optionally set the configuration to roll back a failed deployment to the last completed deployment.

The following create-service AWS CLI example shows how to create a Linux service when the deployment alarms are used with the rollback option.

```bash
aws ecs create-service \
  --service-name MyService \ 
  --deployment-controller type=ECS \ 
  --desired-count 3 \ 
  --deployment-configuration "alarms={alarmNames=[alarm1Name,alarm2Name],enable=true,rollback=true}" \ 
  --task-definition sample-fargate:1 \ 
  --launch-type FARGATE \ 
  --platform-family LINUX \ 
  --platform-version 1.4.0 \ 
  --network-configuration "awsvpcConfiguration={subnets=[subnet-12344321],securityGroups=[sg-12344321],assignPublicIp=ENABLED}" \ 
```

Deployment types
Consider the following when you use the Amazon CloudWatch alarms method on a service.

- The `deploymentConfiguration` request parameter now contains the `alarms` data type. You can specify the alarm names, whether to use the method, and whether to initiate a rollback when the alarms indicate a deployment failure. For more information, see `CreateService` in the Amazon Elastic Container Service API Reference.

- The `DescribeServices` response provides insight into the state of a deployment, the `rolloutState` and `rolloutStateReason`. When a new deployment starts, the rollout state begins in an `IN_PROGRESS` state. When the service reaches a steady state and the bake time is complete, the rollout state transitions to `COMPLETED`. If the service fails to reach a steady state and the alarm has gone into the `ALARM` state, the deployment will transition to a `FAILED` state. A deployment in a `FAILED` state won't launch any new tasks.

- In addition to the service deployment state change events Amazon ECS sends for deployments that have started and have completed, Amazon ECS also sends an event when a deployment that uses alarms fails. These events provide details about why a deployment failed or if a deployment was started because of a rollback. For more information, see Amazon ECS service deployment state change events.

- If a new deployment is started because a previous deployment failed and rollback was turned on, the `reason` field of the service deployment state change event will indicate the deployment was started because of a rollback.

- If you use the deployment circuit breaker and the Amazon CloudWatch alarms to detect failures, either one can initiate a deployment failure as soon as the criteria for either method is met. A rollback occurs when you use the rollback option for the method that initiated the deployment failure.

- The Amazon CloudWatch alarms is only supported for Amazon ECS services that use the rolling update (ECS) deployment controller.

- You can configure this option by using the Amazon ECS console, or the AWS CLI. For more information, see the section called “Create a service using defined parameters” and `create-service` in the AWS Command Line Interface Reference.

- You might notice that the deployment status remains `IN_PROGRESS` for a prolonged amount of time. The reason for this is that Amazon ECS does not change the status until it has deleted the active deployment, and this does not happen until after the bake time. Depending on your alarm configuration, the deployment might appear to take several minutes longer than it does when you don't use alarms (even though the new primary task set is scaled up and the old deployment
is scaled down). If you use CloudFormation timeouts, consider increasing the timeouts. For more information, see Creating wait conditions in a template in the AWS CloudFormation User Guide.

- Amazon ECS calls DescribeAlarms to poll the alarms. The calls to DescribeAlarms count toward the CloudWatch service quotas associated with your account. If you have other AWS services that call DescribeAlarms, there might be an impact on Amazon ECS to poll the alarms. For example, if another service makes enough DescribeAlarms calls to reach the quota, that service is throttled and Amazon ECS is also throttled and unable to poll alarms. If an alarm is generated during the throttling period, Amazon ECS might miss the alarm and the roll back might not occur. There is no other impact on the deployment. For more information on CloudWatch service quotas, see CloudWatch service quotas in the CloudWatch User Guide.

- If an alarm is in the ALARM state at the beginning of a deployment, Amazon ECS will not monitor alarms for the duration of that deployment (Amazon ECS ignores the alarm configuration). This behavior address the case where you want to start a new deployment to fix an initial deployment failure.

**Recommended alarms**

We recommend that you use the following alarm metrics:

- If you use an Application Load Balancer, use the HTTPCode_ELB_5XX_Count and HTTPCode_ELB_4XX_Count Application Load Balancer metrics. These metrics check for HTTP spikes. For more information about the Application Load Balancer metrics, see CloudWatch metrics for your Application Load Balancer in the User Guide for Application Load Balancers.

- If you have an existing application, use the CPUUtilization and MemoryUtilization metrics. These metrics check for the percentage of CPU and memory that the cluster or service uses. For more information, see the section called “Considerations”.

- If you use Amazon Simple Queue Service queues in your tasks, use ApproximateNumberOfMessagesNotVisible Amazon SQS metric. This metric checks for number of messages in the queue that are delayed and not available for reading immediately. For more information about Amazon SQS metrics, see Available CloudWatch metrics for Amazon SQS in the Amazon Simple Queue Service Developer Guide.

**Blue/Green deployment with CodeDeploy**

The blue/green deployment type uses the blue/green deployment model controlled by CodeDeploy. Use this deployment type to verify a new deployment of a service before sending
production traffic to it. For more information, see What Is CodeDeploy in the AWS CodeDeploy User Guide.

There are three ways traffic can shift during a blue/green deployment:

- **Canary** — Traffic is shifted in two increments. You can choose from predefined canary options that specify the percentage of traffic shifted to your updated task set in the first increment and the interval, in minutes, before the remaining traffic is shifted in the second increment.

- **Linear** — Traffic is shifted in equal increments with an equal number of minutes between each increment. You can choose from predefined linear options that specify the percentage of traffic shifted in each increment and the number of minutes between each increment.

- **All-at-once** — All traffic is shifted from the original task set to the updated task set all at once.

The following are components of CodeDeploy that Amazon ECS uses when a service uses the blue/green deployment type:

**CodeDeploy application**

A collection of CodeDeploy resources. This consists of one or more deployment groups.

**CodeDeploy deployment group**

The deployment settings. This consists of the following:

- Amazon ECS cluster and service
- Load balancer target group and listener information
- Deployment roll back strategy
- Traffic rerouting settings
- Original revision termination settings
- Deployment configuration
- CloudWatch alarms configuration that can be set up to stop deployments
- SNS or CloudWatch Events settings for notifications

For more information, see Working with Deployment Groups in the AWS CodeDeploy User Guide.

**CodeDeploy deployment configuration**

Specifies how CodeDeploy routes production traffic to your replacement task set during a deployment. The following pre-defined linear and canary deployment configuration are
Amazon Elastic Container Service
available. You can also create custom defined linear and canary deployments as well. For more information, see Working with Deployment Configurations in the AWS CodeDeploy User Guide.

- **CodeDeployDefault.ECSAllAtOnce**: Shifts all traffic to the updated Amazon ECS container at once
- **CodeDeployDefault.ECSLinear10PercentEvery1Minutes**: Shifts 10 percent of traffic every minute until all traffic is shifted.
- **CodeDeployDefault.ECSLinear10PercentEvery3Minutes**: Shifts 10 percent of traffic every 3 minutes until all traffic is shifted.
- **CodeDeployDefault.ECSCanary10Percent5Minutes**: Shifts 10 percent of traffic in the first increment. The remaining 90 percent is deployed five minutes later.
- **CodeDeployDefault.ECSCanary10Percent15Minutes**: Shifts 10 percent of traffic in the first increment. The remaining 90 percent is deployed 15 minutes later.

**Revision**

A revision is the CodeDeploy application specification file (AppSpec file). In the AppSpec file, you specify the full ARN of the task definition and the container and port of your replacement task set where traffic is to be routed when a new deployment is created. The container name must be one of the container names referenced in your task definition. If the network configuration or platform version has been updated in the service definition, you must also specify those details in the AppSpec file. You can also specify the Lambda functions to run during the deployment lifecycle events. The Lambda functions allow you to run tests and return metrics during the deployment. For more information, see AppSpec File Reference in the AWS CodeDeploy User Guide.

**Blue/Green Deployment Considerations**

Consider the following when using the blue/green deployment type:

- When an Amazon ECS service using the blue/green deployment type is initially created, an Amazon ECS task set is created.
- You must configure the service to use either an Application Load Balancer or Network Load Balancer. The following are the load balancer requirements:
  - You must add a production listener to the load balancer, which is used to route production traffic.
• An optional test listener can be added to the load balancer, which is used to route test traffic. If you specify a test listener, CodeDeploy routes your test traffic to the replacement task set during a deployment.

• Both the production and test listeners must belong to the same load balancer.

• You must define a target group for the load balancer. The target group routes traffic to the original task set in a service through the production listener.

• When a Network Load Balancer is used, only the CodeDeployDefault.ECSAllAtOnce deployment configuration is supported.

• For services configured to use service auto scaling and the blue/green deployment type, auto scaling is not blocked during a deployment but the deployment may fail under some circumstances. The following describes this behavior in more detail.

• If a service is scaling and a deployment starts, the green task set is created and CodeDeploy will wait up to an hour for the green task set to reach steady state and won't shift any traffic until it does.

• If a service is in the process of a blue/green deployment and a scaling event occurs, traffic will continue to shift for 5 minutes. If the service doesn't reach steady state within 5 minutes, CodeDeploy will stop the deployment and mark it as failed.

• If a service is in the process of a blue/green deployment and a scaling event occurs, the desired task count might be set to an unexpected value. This is caused by auto scaling considering the running task count as current capacity, which is twice the appropriate number of tasks being used in the desired task count calculation.

• Tasks using the Fargate launch type or the CODE_DEPLOY deployment controller types don't support the DAEMON scheduling strategy.

• When you initially create a CodeDeploy application and deployment group, you must specify the following:

  • You must define two target groups for the load balancer. One target group should be the initial target group defined for the load balancer when the Amazon ECS service was created. The second target group's only requirement is that it can't be associated with a different load balancer than the one the service uses.

• When you create a CodeDeploy deployment for an Amazon ECS service, CodeDeploy creates a replacement task set (or green task set) in the deployment. If you added a test listener to the load balancer, CodeDeploy routes your test traffic to the replacement task set. This is when you can run any validation tests. Then CodeDeploy reroutes the production traffic from the original task
set to the replacement task set according to the traffic rerouting settings for the deployment group.

Blue/green deployment required IAM permissions

Amazon ECS blue/green deployments are made possible by a combination of the Amazon ECS and CodeDeploy APIs. Users must have the appropriate permissions for these services before they can use Amazon ECS blue/green deployments in the AWS Management Console or with the AWS CLI or SDKs.

In addition to the standard IAM permissions for creating and updating services, Amazon ECS requires the following permissions. These permissions have been added to the AmazonECS_FullAccess IAM policy. For more information, see AmazonECS_FullAccess.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "codedeploy:CreateApplication",
        "codedeploy:CreateDeployment",
        "codedeploy:CreateDeploymentGroup",
        "codedeploy:GetApplication",
        "codedeploy:GetDeployment",
        "codedeploy:GetDeploymentGroup",
        "codedeploy:GetDeploymentTarget",
        "codedeploy:ListApplications",
        "codedeploy:ListDeploymentGroups",
        "codedeploy:ListDeployments",
        "codedeploy:StopDeployment",
        "codedeploy:GetDeploymentTarget",
        "codedeploy:ListDeploymentTargets",
        "codedeploy:GetDeploymentConfig",
        "codedeploy:GetApplicationRevision",
        "codedeploy:RegisterApplicationRevision",
        "codedeploy:BatchGetApplicationRevisions",
        "codedeploy:BatchGetDeploymentGroups",
        "codedeploy:BatchGetDeployments",
        "codedeploy:BatchGetApplications",
        "codedeploy:ListApplicationRevisions",
        "codedeploy:ListDeploymentConfigs",
        "codedeploy:ContinueDeployment",
      ]
    }
  ]
}
```
Note

In addition to the standard Amazon ECS permissions required to run tasks and services, users also require `iam:PassRole` permissions to use IAM roles for tasks.

CodeDeploy needs permissions to call Amazon ECS APIs, modify your Elastic Load Balancing, invoke Lambda functions, and describe CloudWatch alarms, as well as permissions to modify your service's desired count on your behalf. Before creating an Amazon ECS service that uses the blue/green deployment type, you must create an IAM role (ecsCodeDeployRole). For more information, see [Amazon ECS CodeDeploy IAM Role](#).

The Create service example and Update service example IAM policy examples show the permissions that are required for users to use Amazon ECS blue/green deployments on the AWS Management Console.

### Use a third-party controller for Amazon ECS external deployments

The external deployment type allows you to use any third-party deployment controller for full control over the deployment process for an Amazon ECS service. The details for your service are managed by either the service management API actions (CreateService, UpdateService, and DeleteService) or the task set management API actions (CreateTaskSet, UpdateTaskSet, UpdateServicePrimaryTaskSet, and DeleteTaskSet). Each API action manages a subset of the service definition parameters.

The UpdateService API action updates the desired count and health check grace period parameters for a service. If the launch type, platform version, load balancer details, network configuration, or task definition need to be updated, you must create a new task set.

The UpdateTaskSet API action updates only the scale parameter for a task set.
The UpdateServicePrimaryTaskSet API action modifies which task set in a service is the primary task set. When you call the DescribeServices API action, it returns all fields specified for a primary task set. If the primary task set for a service is updated, any task set parameter values that exist on the new primary task set that differ from the old primary task set in a service are updated to the new value when a new primary task set is defined. If no primary task set is defined for a service, when describing the service, the task set fields are null.

**External deployment considerations**

Consider the following when using the external deployment type:

- The supported load balancer types are either an Application Load Balancer or a Network Load Balancer.
- The Fargate launch type or EXTERNAL deployment controller types don't support the DAEMON scheduling strategy.

**External deployment workflow**

The following is the basic workflow to managing an external deployment on Amazon ECS.

**To manage an Amazon ECS service using an external deployment controller**

1. Create an Amazon ECS service. The only required parameter is the service name. You can specify the following parameters when creating a service using an external deployment controller. All other service parameters are specified when creating a task set within the service.

   **serviceName**

   Type: String

   Required: Yes

   The name of your service. Up to 255 letters (uppercase and lowercase), numbers, hyphens, and underscores are allowed. Service names must be unique within a cluster, but you can have similarly named services in multiple clusters within a Region or across multiple Regions.
desiredCount

The number of instantiations of the specified task set task definition to place and keep running within the service.

deploymentConfiguration

Optional deployment parameters that control how many tasks run during a deployment and the ordering of stopping and starting tasks. For more information, see deploymentConfiguration.

tags

Type: Array of objects

Required: No

The metadata that you apply to the service to help you categorize and organize them. Each tag consists of a key and an optional value, both of which you define. When a service is deleted, the tags are deleted as well. A maximum of 50 tags can be applied to the service. For more information, see Amazon ECS resource tagging.

deploymentConfiguration

Type: String

Required: No

One part of a key-value pair that make up a tag. A key is a general label that acts like a category for more specific tag values.

deploymentConfiguration

Type: String

Length Constraints: Minimum length of 0. Maximum length of 256.

Required: No

The optional part of a key-value pair that make up a tag. A value acts as a descriptor within a tag category (key).
enableECSManagedTags

Specifies whether to use Amazon ECS managed tags for the tasks within the service. For more information, see Tagging your resources for billing.

propagateTags

Type: String

Valid values: TASK_DEFINITION | SERVICE

Required: No

Specifies whether to copy the tags from the task definition or the service to the tasks in the service. If no value is specified, the tags are not copied. Tags can only be copied to the tasks within the service during service creation. To add tags to a task after service creation or task creation, use the TagResource API action.

healthCheckGracePeriodSeconds

Type: Integer

Required: No

The period of time, in seconds, that the Amazon ECS service scheduler should ignore unhealthy Elastic Load Balancing target health checks, container health checks, and Route 53 health checks after a task enters a RUNNING state. This is only valid if your service is configured to use a load balancer. If your service has a load balancer defined and you do not specify a health check grace period value, the default value of 0 is used.

If your service's tasks take a while to start and respond to health checks, you can specify a health check grace period of up to 2,147,483,647 seconds during which the ECS service scheduler ignores the health check status. This grace period can prevent the ECS service scheduler from marking tasks as unhealthy and stopping them before they have time to come up.

If you do not use an Elastic Load Balancing, we recommend that you use the startPeriod in the task definition health check parameters. For more information, see Health check.
schedulingStrategy

The scheduling strategy to use. Services using an external deployment controller support only the REPLICA scheduling strategy. For more information, see Service scheduler concepts.

placementConstraints

An array of placement constraint objects to use for tasks in your service. You can specify a maximum of 10 constraints per task (this limit includes constraints in the task definition and those specified at run time). If you are using the Fargate launch type, task placement constraints aren't supported.

placementStrategy

The placement strategy objects to use for tasks in your service. You can specify a maximum of four strategy rules per service.

The following is an example service definition for creating a service using an external deployment controller.

```json
{
    "cluster": 
    "serviceName": 
    "desiredCount": 0,
    "role": 
    "deploymentConfiguration": { 
        "maximumPercent": 0,
        "minimumHealthyPercent": 0
    },
    "placementConstraints": [
    {
        "type": "distinctInstance",
        "expression": ""
    }
    ],
    "placementStrategy": [
    {
        "type": "binpack",
        "field": ""
    }
    ],
```
2. Create an initial task set. The task set contains the following details about your service:

   taskDefinition

   The task definition for the tasks in the task set to use.

   launchType

   Type: String
   Valid values: EC2 | FARGATE | EXTERNAL
   Required: No

   The launch type on which to run your service. If a launch type is not specified, the default capacityProviderStrategy is used by default. For more information, see Amazon ECS launch types.

   If a launchType is specified, the capacityProviderStrategy parameter must be omitted.

   platformVersion

   Type: String
   Required: No
The platform version on which your tasks in the service are running. A platform version is only specified for tasks using the Fargate launch type. If one is not specified, the latest version (LATEST) is used by default.

AWS Fargate platform versions are used to refer to a specific runtime environment for the Fargate task infrastructure. When specifying the LATEST platform version when running a task or creating a service, you get the most current platform version available for your tasks. When you scale up your service, those tasks receive the platform version that was specified on the service's current deployment. For more information, see Fargate Linux platform versions.

**Note**
Platform versions are not specified for tasks using the EC2 launch type.

**loadBalancers**

A load balancer object representing the load balancer to use with your service. When using an external deployment controller, only Application Load Balancers and Network Load Balancers are supported. If you're using an Application Load Balancer, only one Application Load Balancer target group is allowed per task set.

The following snippet shows an example `loadBalancers` object to use.

```
"loadBalancers": [
    {
        "targetGroupArn": "",
        "containerName": "",
        "containerPort": 0
    }
]
```

**Note**
When specifying a `loadBalancer` object, you must specify a `targetGroupArn` and omit the `loadBalancerName` parameters.
networkConfiguration

The network configuration for the service. This parameter is required for task definitions that use the awsvpc network mode to receive their own elastic network interface, and it's not supported for other network modes. For more information about networking for the Amazon EC2 launch type, see Fargate Task Networking. For more information about networking for the Fargate launch type, see Task networking for tasks on Fargate.

serviceRegistries

The details of the service discovery registries to assign to this service. For more information, see Service discovery.

scale

A floating-point percentage of the desired number of tasks to place and keep running in the task set. The value is specified as a percent total of a service's desiredCount. Accepted values are numbers between 0 and 100.

The following is a JSON example for creating a task set for an external deployment controller.

```json
{
    "service": "",
    "cluster": "",
    "externalId": "",
    "taskDefinition": "",
    "networkConfiguration": {
        "awsvpcConfiguration": {
            "subnets": [""],
            "securityGroups": [""],
            "assignPublicIp": "DISABLED"
        }
    },
    "loadBalancers": [
        {
            "targetGroupArn": "",
            "containerName": ""
        }
    ]
}
```
3. When service changes are needed, use the UpdateService, UpdateTaskSet, or CreateTaskSet API action depending on which parameters you're updating. If you created a task set, use the scale parameter for each task set in a service to determine how many tasks to keep running in the service. For example, if you have a service that contains tasksetA and you create a tasksetB, you might test the validity of tasksetB before wanting to transition production traffic to it. You could set the scale for both task sets to 100, and when you were ready to transition all production traffic to tasksetB, you could update the scale for tasksetA to 0 to scale it down.

**Distribute Amazon ECS service traffic using load balancing**

Your Amazon ECS service can optionally be configured to use Elastic Load Balancing to distribute traffic evenly across the tasks in your service.
Amazon ECS services hosted on AWS Fargate support the Application Load Balancer and Network Load Balancer load balancer types. Application Load Balancers are used to route HTTP/HTTPS (or layer 7) traffic. Network Load Balancers are used to route TCP or UDP (or layer 4) traffic.

Application Load Balancers offer several features that make them attractive for use with Amazon ECS services:

- Each service can serve traffic from multiple load balancers and expose multiple load balanced ports by specifying multiple target groups.
- They are supported by tasks hosted on both Fargate and EC2 instances.
- Application Load Balancers allow containers to use dynamic host port mapping (so that multiple tasks from the same service are allowed per container instance).
- Application Load Balancers support path-based routing and priority rules (so that multiple services can use the same listener port on a single Application Load Balancer).

We recommend that you use Application Load Balancers for your Amazon ECS services so that you can take advantage of these latest features, unless your service requires a feature that is only available with Network Load Balancers. For more information about Elastic Load Balancing and the differences between the load balancer types, see the Elastic Load Balancing User Guide.

With your load balancer, you pay only for what you use. For more information, see Elastic Load Balancing pricing.

- Registering multiple target groups with a service
Use an Application Load Balancer for Amazon ECS

An Application Load Balancer makes routing decisions at the application layer (HTTP/HTTPS), supports path-based routing, and can route requests to one or more ports on each container instance in your cluster. Application Load Balancers support dynamic host port mapping. For example, if your task’s container definition specifies port 80 for an NGINX container port, and port 0 for the host port, then the host port is dynamically chosen from the ephemeral port range of the container instance (such as 32768 to 61000 on the latest Amazon ECS-optimized AMI). When the task is launched, the NGINX container is registered with the Application Load Balancer as an instance ID and port combination, and traffic is distributed to the instance ID and port corresponding to that container. This dynamic mapping allows you to have multiple tasks from a single service on the same container instance. For more information, see the User Guide for Application Load Balancers.

Application Load Balancer considerations

The following considerations are specific to Amazon ECS services using Application Load Balancers or Network Load Balancers:

- Amazon ECS requires the service-linked IAM role which provides the permissions needed to register and deregister targets with your load balancer when tasks are created and stopped. For more information, see Using service-linked roles for Amazon ECS.
- For services that use an Application Load Balancer or Network Load Balancer, you cannot attach more than five target groups to a service.
• For services with tasks using the `awsvpc` network mode, when you create a target group for your service, you must choose `ip` as the target type, not `instance`. This is because tasks that use the `awsvpc` network mode are associated with an elastic network interface, not an Amazon EC2 instance.

• If your service uses an Application Load Balancer and requires access to multiple load balanced ports, such as port 80 and port 443 for an HTTP/HTTPS service, you can configure two listeners. One listener is responsible for HTTPS that forwards the request to the service, and another listener that is responsible for redirecting HTTP requests to the appropriate HTTPS port. For more information, see Create a listener to your Application Load Balancer in the User Guide for Application Load Balancers.

• Your load balancer subnet configuration must include all Availability Zones that your container instances reside in.

• After you create a service, the load balancer configuration can't be changed from the AWS Management Console. You can use the AWS Copilot, AWS CloudFormation, AWS CLI or SDK to modify the load balancer configuration for the ECS rolling deployment controller only, not AWS CodeDeploy blue/green or external. When you add, update, or remove a load balancer configuration, Amazon ECS starts a new deployment with the updated Elastic Load Balancing configuration. This causes tasks to register to and deregister from load balancers. We recommend that you verify this on a test environment before you update the Elastic Load Balancing configuration. For information about how to modify the configuration, see UpdateService in the Amazon Elastic Container Service API Reference.

• If a service task fails the load balancer health check criteria, the task is stopped and restarted. This process continues until your service reaches the number of desired running tasks.

• When you use a Network Load Balancer configured with IP addresses as targets and Client IP Preservation disabled, requests are seen as coming from the Network Load Balancers private IP address. This means that services behind an Network Load Balancer are effectively open to the world as soon as you allow incoming requests and health checks in the target security group.

• Using a Network Load Balancer to route UDP traffic to your Amazon ECS tasks on Fargate require the task to use platform version 1.4.0 (Linux) or 1.0.0 (Windows).

• Minimize errors in your client applications by setting the `StopTimeout` in the task definition longer than the target group deregistration delay, which should be longer than your client connection timeout. See the Builders Library for more information on recommended client configuration [here](#).
Also, the Network Load Balancer target group attribute for connection termination closes all remaining connections after the deregistration time. This can cause clients to display undesired error messages, if the client does not handle them.

- If you are experiencing problems with your load balancer-enabled services, see Troubleshooting service load balancers.
- Your tasks and load balancer (Application Load Balancer or Network Load Balancer) must be in the same VPC.
- The Network Load Balancer client IP address preservation is also compatible with Fargate targets.
- Use a unique target group for each service.

Using the same target group for multiple services might lead to issues during service deployments.

For information about how to create an Application Load Balancer, see Create an Application Load Balancer in Application Load Balancers

Use a Network Load Balancer for Amazon ECS

A Network Load Balancer makes routing decisions at the transport layer (TCP/SSL). It can handle millions of requests per second. After the load balancer receives a connection, it selects a target from the target group for the default rule using a flow hash routing algorithm. It attempts to open a TCP connection to the selected target on the port specified in the listener configuration. It forwards the request without modifying the headers. Network Load Balancers support dynamic host port mapping. For example, if your task's container definition specifies port 80 for an NGINX container port, and port 0 for the host port, then the host port is dynamically chosen from the ephemeral port range of the container instance (such as 32768 to 61000 on the latest Amazon ECS-optimized AMI). When the task is launched, the NGINX container is registered with the Network Load Balancer as an instance ID and port combination, and traffic is distributed to the instance ID and port corresponding to that container. This dynamic mapping allows you to have multiple tasks from a single service on the same container instance. For more information, see the User Guide for Network Load Balancers.
Network Load Balancer considerations

The following considerations are specific to Amazon ECS services using Application Load Balancers or Network Load Balancers:

- Amazon ECS requires the service-linked IAM role which provides the permissions needed to register and deregister targets with your load balancer when tasks are created and stopped. For more information, see [Using service-linked roles for Amazon ECS](#).

- For services that use an Application Load Balancer or Network Load Balancer, you cannot attach more than five target groups to a service.

- For services with tasks using the `awsvpc` network mode, when you create a target group for your service, you must choose `ip` as the target type, not `instance`. This is because tasks that use the `awsvpc` network mode are associated with an elastic network interface, not an Amazon EC2 instance.

- If your service uses an Application Load Balancer and requires access to multiple load balanced ports, such as port 80 and port 443 for an HTTP/HTTPS service, you can configure two listeners. One listener is responsible for HTTPS that forwards the request to the service, and another listener that is responsible for redirecting HTTP requests to the appropriate HTTPS port. For more information, see [Create a listener to your Application Load Balancer](#) in the User Guide for Application Load Balancers.

- Your load balancer subnet configuration must include all Availability Zones that your container instances reside in.
• After you create a service, the load balancer configuration can't be changed from the AWS Management Console. You can use the AWS Copilot, AWS CloudFormation, AWS CLI or SDK to modify the load balancer configuration for the ECS rolling deployment controller only, not AWS CodeDeploy blue/green or external. When you add, update, or remove a load balancer configuration, Amazon ECS starts a new deployment with the updated Elastic Load Balancing configuration. This causes tasks to register to and deregister from load balancers. We recommend that you verify this on a test environment before you update the Elastic Load Balancing configuration. For information about how to modify the configuration, see UpdateService in the Amazon Elastic Container Service API Reference.

• If a service task fails the load balancer health check criteria, the task is stopped and restarted. This process continues until your service reaches the number of desired running tasks.

• When you use a Network Load Balancer configured with IP addresses as targets and Client IP Preservation disabled, requests are seen as coming from the Network Load Balancers private IP address. This means that services behind an Network Load Balancer are effectively open to the world as soon as you allow incoming requests and health checks in the target security group.

• Using a Network Load Balancer to route UDP traffic to your Amazon ECS tasks on Fargate require the task to use platform version 1.4.0 (Linux) or 1.0.0 (Windows).

• Minimize errors in your client applications by setting the StopTimeout in the task definition longer than the target group deregistration delay, which should be longer than your client connection timeout. See the Builders Library for more information on recommended client configuration here.

Also, the Network Load Balancer target group attribute for connection termination closes all remaining connections after the deregistration time. This can cause clients to display undesired error messages, if the client does not handle them.

• If you are experiencing problems with your load balancer-enabled services, see Troubleshooting service load balancers.

• Your tasks and load balancer (Application Load Balancer or Network Load Balancer) must be in the same VPC.

• The Network Load Balancer client IP address preservation is also compatible with Fargate targets.

• Use a unique target group for each service.

Using the same target group for multiple services might lead to issues during service deployments.
For information about how to create a Network Load Balancer, see Create a Network Load Balancer in Network Load Balancers

⚠️ **Important**

If your service’s task definition uses the `awsvpc` network mode (which is required for the Fargate launch type), you must choose `ip` as the target type, not `instance`. This is because tasks that use the `awsvpc` network mode are associated with an elastic network interface, not an Amazon EC2 instance.

You cannot register instances by instance ID if they have the following instance types: C1, CC1, CC2, CG1, CG2, CR1, G1, G2, HI1, HS1, M1, M2, M3, and T1. You can register instances of these types by IP address.

---

**Registering multiple target groups with a service**

Your Amazon ECS service can serve traffic from multiple load balancers and expose multiple load balanced ports when you specify multiple target groups in a service definition.

To create a service specifying multiple target groups, you must create the service using the Amazon ECS API, SDK, AWS CLI, or an AWS CloudFormation template. After the service is created, you can view the service and the target groups registered to it with the AWS Management Console. You must use `UpdateService` to modify the load balancer configuration of an existing service.

Multiple target groups can be specified in a service definition using the following format. For the full syntax of a service definition, see Service definition template.

```json
"loadBalancers": [
  {
    "targetGroupArn": "arn:aws:elasticloadbalancing:region:123456789012:targetgroup/target_group_name_1/1234567890123456",
    "containerName": "container_name",
    "containerPort": container_port
  },
  {
    "targetGroupArn": "arn:aws:elasticloadbalancing:region:123456789012:targetgroup/target_group_name_2/6543210987654321",
    "containerName": "container_name",
    "containerPort": container_port
  }
]
```
Multiple target group considerations

The following should be considered when you specify multiple target groups in a service definition.

- For services that use an Application Load Balancer or Network Load Balancer, you cannot attach more than five target groups to a service.
- Specifying multiple target groups in a service definition is only supported under the following conditions:
  - The service must use either an Application Load Balancer or Network Load Balancer.
  - The service must use the rolling update (ECS) deployment controller type.
- Specifying multiple target groups is supported for services containing tasks using both the Fargate and EC2 launch types.
- When creating a service that specifies multiple target groups, the Amazon ECS service-linked role must be created. The role is created by omitting the `role` parameter in API requests, or the `Role` property in AWS CloudFormation. For more information, see Using service-linked roles for Amazon ECS.

Example service definitions

Following are a few example use cases for specifying multiple target groups in a service definition. For the full syntax of a service definition, see Service definition template.

Example: Having separate load balancers for internal and external traffic

In the following use case, a service uses two separate load balancers, one for internal traffic and a second for internet-facing traffic, for the same container and port.

```json
"loadBalancers": [
  // Internal ELB
  {
    "targetGroupArn": "arn:aws:elasticloadbalancing:region:123456789012:targetgroup/target_group_name_1/1234567890123456",
    "containerName": "nginx",
    "containerPort": 8080
  },
]"
Example: Exposing multiple ports from the same container

In the following use case, a service uses one load balancer but exposes multiple ports from the same container. For example, a Jenkins container might expose port 8080 for the Jenkins web interface and port 50000 for the API.

Example: Exposing ports from multiple containers

In the following use case, a service uses one load balancer and two target groups to expose ports from separate containers.
Automatically scale your Amazon ECS service

Automatic scaling is the ability to increase or decrease the desired count of tasks in your Amazon ECS service automatically. Amazon ECS leverages the Application Auto Scaling service to provide this functionality. For more information, see the Application Auto Scaling User Guide.

Amazon ECS publishes CloudWatch metrics with your service's average CPU and memory usage. For more information, see Service utilization. You can use these and other CloudWatch metrics to scale out your service (add more tasks) to deal with high demand at peak times, and to scale in your service (run fewer tasks) to reduce costs during periods of low utilization.

Amazon ECS Service Auto Scaling supports the following types of automatic scaling:

- **Scale your Amazon ECS service using a target metric value**— Increase or decrease the number of tasks that your service runs based on a target value for a specific metric. This is similar to the way that your thermostat maintains the temperature of your home. You select temperature and the thermostat does the rest.
- **Scale your Amazon ECS service using predefined increments based on CloudWatch alarms**— Increase or decrease the number of tasks that your service runs based on a set of scaling adjustments, known as step adjustments, that vary based on the size of the alarm breach.
- **Scale your Amazon ECS service using a schedule**— Increase or decrease the number of tasks that your service runs based on the date and time.

Considerations

When using scaling policies, consider the following:
• Amazon ECS sends metrics in 1-minute intervals to CloudWatch. Metrics are not available until the clusters and services send the metrics to CloudWatch, and you cannot create CloudWatch alarms for metrics that do not exist.

• The scaling policies support a cooldown period. This is the number of seconds to wait for a previous scaling activity to take effect.

• For scale-out events, the intention is to continuously (but not excessively) scale out. After Service Auto Scaling successfully scales out using a scaling policy, it starts to calculate the cooldown time. The scaling policy won't increase the desired capacity again unless either a larger scale out is initiated or the cooldown period ends. While the scale-out cooldown period is in effect, the capacity added by the initiating scale-out activity is calculated as part of the desired capacity for the next scale-out activity.

• For scale-in events, the intention is to scale in conservatively to protect your application's availability, so scale-in activities are blocked until the cooldown period has expired. However, if another alarm initiates a scale-out activity during the scale-in cooldown period, Service Auto Scaling scales out the target immediately. In this case, the scale-in cooldown period stops and doesn't complete.

• The service scheduler respects the desired count at all times, but as long as you have active scaling policies and alarms on a service, Service Auto Scaling could change a desired count that was manually set by you.

• If a service's desired count is set below its minimum capacity value, and an alarm initiates a scale-out activity, Service Auto Scaling scales the desired count up to the minimum capacity value and then continues to scale out as required, based on the scaling policy associated with the alarm. However, a scale-in activity does not adjust the desired count, because it is already below the minimum capacity value.

• If a service's desired count is set above its maximum capacity value, and an alarm initiates a scale-in activity, Service Auto Scaling scales the desired count out to the maximum capacity value and then continues to scale in as required, based on the scaling policy associated with the alarm. However, a scale-out activity does not adjust the desired count, because it is already above the maximum capacity value.

• During scaling activities, the actual running task count in a service is the value that Service Auto Scaling uses as its starting point, as opposed to the desired count. This is what processing capacity is supposed to be. This prevents excessive (runaway) scaling that might not be satisfied, for example, if there aren't enough container instance resources to place the additional tasks. If the container instance capacity is available later, the pending scaling activity may succeed, and then further scaling activities can continue after the cooldown period.
• If you want your task count to scale to zero when there's no work to be done, set a minimum capacity of 0. With target tracking scaling policies, when actual capacity is 0 and the metric indicates that there is workload demand, Service Auto Scaling waits for one data point to be sent before scaling out. In this case, it scales out by the minimum possible amount as a starting point and then resumes scaling based on the actual running task count.

• Application Auto Scaling turns off scale-in processes while Amazon ECS deployments are in progress. However, scale-out processes continue to occur, unless suspended, during a deployment. For more information, see Service auto scaling and deployments.

• You have several Application Auto Scaling options for Amazon ECS tasks. Target tracking is the easiest mode to use. With it, all you need to do is set a target value for a metric, such as CPU average utilization. Then, the auto scaler automatically manages the number of tasks that are needed to attain that value. With step scaling you can more quickly react to changes in demand, because you define the specific thresholds for your scaling metrics, and how many tasks to add or remove when the thresholds are crossed. And, more importantly, you can react very quickly to changes in demand by minimizing the amount of time a threshold alarm is in breach.

**Best practices for Amazon ECS service auto scaling**

An Amazon ECS service is a managed collection of tasks. Each service has an associated task definition, a desired task count, and an optional placement strategy. Amazon ECS service auto scaling is implemented through the Application Auto Scaling service. Application Auto Scaling uses CloudWatch metrics as the source for scaling metrics. It also uses CloudWatch alarms to set thresholds on when to scale your service in or out. You provide the thresholds for scaling, either by setting a metric target, referred to as **target tracking scaling**, or by specifying thresholds, referred to as **step scaling**. After Application Auto Scaling is configured, it continually calculates the appropriate desired task count for the service. It also notifies Amazon ECS when the desired task count should change, either by scaling it out or scaling it in.

To use service auto scaling effectively, you must choose an appropriate scaling metric.

An application should be scaled out if demand is forecasted to be greater than the current capacity. Conversely, an application can be scaled in to conserve costs when resources exceed demand.

**Identify a metric**

To scale effectively, it's critical to identify a metric that indicates utilization or saturation. This metric must exhibit the following properties to be useful for scaling.
• The metric must be correlated with demand. When resources are held steady, but demand changes, the metric value must also change. The metric should increase or decrease when demand increases or decreases.

• The metric value must scale in proportion to capacity. When demand holds constant, adding more resources must result in a proportional change in the metric value. So, doubling the number of tasks should cause the metric to decrease by 50%.

The best way to identify a utilization metric is through load testing in a pre-production environment such as a staging environment. Commercial and open-source load testing solutions are widely available. These solutions typically can either generate synthetic load or simulate real user traffic.

To start the process of load testing, build dashboards for your application’s utilization metrics. These metrics include CPU utilization, memory utilization, I/O operations, I/O queue depth, and network throughput. You can collect these metrics with a service such as Container Insights. For more information, see Monitor Amazon ECS containers using Container Insights. During this process, make sure that you collect and plot metrics for your application’s response times or work completion rates.

Start with a small request or job insertion rate. Keep this rate steady for several minutes to allow your application to warm up. Then, slowly increase the rate and hold it steady for a few minutes. Repeat this cycle, increasing the rate each time until your application’s response or completion times are too slow to meet your service-level objectives (SLOs).

While load testing, examine each of the utilization metrics. The metrics that increase along with the load are the top candidates to serve as your best utilization metrics.

Next, identify the resource that reaches saturation. At the same time, also examine the utilization metrics to see which one flattens out at a high level first, or reaches a peak and then crashes your application first. For example, if CPU utilization increases from 0% to 70-80% as you add load, then stays at that level after even more load is added, then it’s safe to say that the CPU is saturated. Depending on the CPU architecture, it might never reach 100%. For example, assume that memory utilization increases as you add load, and then your application suddenly crashes when it reaches the task or Amazon EC2 instance memory limit. In this situation, it’s likely the case that memory has been fully consumed. Multiple resources might be consumed by your application. Therefore, choose the metric that represents the resource that depletes first.
Last, try load testing again after doubling the number of tasks or Amazon EC2 instances. Assume that the key metric increases, or decreases, at half the rate as before. If this is the case, then the metric is proportional to capacity. This is a good utilization metric for auto scaling.

Now consider this hypothetical scenario. Suppose that you load test an application and find that the CPU utilization eventually reaches 80% at 100 requests per second. When more load is added, it doesn't make CPU utilization raise anymore. However, it does make your application respond more slowly. Then, you run the load test again, doubling the number of tasks but holding the rate at its previous peak value. If you find the average CPU utilization falls to about 40%, then average CPU utilization is a good candidate for a scaling metric. On the other hand, if CPU utilization remains at 80% after increasing the number of tasks, then average CPU utilization isn't a good scaling metric. In that case, more research is needed to find a suitable metric.

**Common application models and scaling properties**

Software of all kinds are run on AWS. Many workloads are homegrown, whereas others are based on popular open-source software. Regardless of where they originate, we have observed some common design patterns for services. How to scale effectively depends in large part on the pattern.

**The efficient CPU-bound server**

The efficient CPU-bound server utilizes almost no resources other than CPU and network throughput. Each request can be handled by the application alone. Requests don't depend on other services such as databases. The application can handle hundreds of thousands of concurrent requests, and can efficiently utilize multiple CPUs to do so. Each request is either serviced by a dedicated thread with low memory overhead, or there's an asynchronous event loop that runs on each CPU that services requests. Each replica of the application is equally capable of handling a request. The only resource that might be depleted before CPU is network bandwidth. In CPU bound-services, memory utilization, even at peak throughput, is a fraction of the resources available.

This type of application is suitable for CPU-based auto scaling. The application enjoys maximum flexibility in terms of scaling. It can be scaled vertically by providing larger Amazon EC2 instances or Fargate vCPUs to it. And, it can also be scaled horizontally by adding more replicas. Adding more replicas, or doubling the instance size, cuts the average CPU utilization relative to capacity by half.

If you’re using Amazon EC2 capacity for this application, consider placing it on compute-optimized instances such as the c5 or c6g family.
The efficient memory-bound server

The efficient memory-bound server allocates a significant amount of memory per request. At maximum concurrency, but not necessarily throughput, memory is depleted before the CPU resources are depleted. Memory associated with a request is freed when the request ends. Additional requests can be accepted as long as there is available memory.

This type of application is suitable for memory-based auto scaling. The application enjoys maximum flexibility in terms of scaling. It can be scaled both vertically by providing larger Amazon EC2 or Fargate memory resources to it. And, it can also be scaled horizontally by adding more replicas. Adding more replicas, or doubling the instance size, can cut the average memory utilization relative to capacity by half.

If you're using Amazon EC2 capacity for this application, consider placing it on memory-optimized instances such as the r5 or r6g family.

Some memory-bound applications don't free the memory that's associated with a request when it ends, so that a reduction in concurrency doesn't result in a reduction in the memory used. For this, we don't recommend that you use memory-based scaling.

The worker-based server

The worker-based server processes one request for each individual worker thread one after another. The worker threads can be lightweight threads, such as POSIX threads. They can also be heavier-weight threads, such as UNIX processes. No matter which thread they are, there's always a maximum concurrency that the application can support. Usually the concurrency limit is set proportionally to the memory resources that are available. If the concurrency limit is reached, additional requests are placed into a backlog queue. If the backlog queue overflows, additional incoming requests are immediately rejected. Common applications that fit this pattern include Apache web server and Gunicorn.

Request concurrency is usually the best metric for scaling this application. Because there's a concurrency limit for each replica, it's important to scale out before the average limit is reached.

The best way to obtain request concurrency metrics is to have your application report them to CloudWatch. Each replica of your application can publish the number of concurrent requests as a custom metric at a high frequency. We recommend that the frequency is set to be at least once every minute. After several reports are collected, you can use the average concurrency as a scaling metric. This metric is calculated by taking the total concurrency and dividing it by the number
of replicas. For example, if total concurrency is 1000 and the number of replicas is 10, then the average concurrency is 100.

If your application is behind an Application Load Balancer, you can also use the ActiveConnectionCount metric for the load balancer as a factor in the scaling metric. The ActiveConnectionCount metric must be divided by the number of replicas to obtain an average value. The average value must be used for scaling, as opposed to the raw count value.

For this design to work best, the standard deviation of response latency should be small at low request rates. We recommend that, during periods of low demand, most requests are answered within a short time, and there isn't a lot of requests that take significantly longer than average time to respond. The average response time should be close to the 95th percentile response time. Otherwise, queue overflows might occur as result. This leads to errors. We recommend that you provide additional replicas where necessary to mitigate the risk of overflow.

**The waiting server**

The waiting server does some processing for each request, but it is highly dependent on one or more downstream services to function. Container applications often make heavy use of downstream services like databases and other API services. It can take some time for these services to respond, particularly in high capacity or high concurrency scenarios. This is because these applications tend to use few CPU resources and utilize their maximum concurrency in terms of available memory.

The waiting service is suitable either in the memory-bound server pattern or the worker-based server pattern, depending on how the application is designed. If the application's concurrency is limited only by memory, then average memory utilization should be used as a scaling metric. If the application's concurrency is based on a worker limit, then average concurrency should be used as a scaling metric.

**The Java-based server**

If your Java-based server is CPU-bound and scales proportionally to CPU resources, then it might be suitable for the efficient CPU-bound server pattern. If that is the case, average CPU utilization might be appropriate as a scaling metric. However, many Java applications aren't CPU-bound, making them challenging to scale.

For the best performance, we recommend that you allocate as much memory as possible to the Java Virtual Machine (JVM) heap. Recent versions of the JVM, including Java 8 update 191 or later,
automatically set the heap size as large as possible to fit within the container. This means that, in
Java, memory utilization is rarely proportional to application utilization. As the request rate and
concurrency increases, memory utilization remains constant. Because of this, we don't recommend
scaling Java-based servers based on memory utilization. Instead, we typically recommend scaling
on CPU utilization.

In some cases, Java-based servers encounter heap exhaustion before exhausting CPU. If your
application is prone to heap exhaustion at high concurrency, then average connections are the best
scaling metric. If your application is prone to heap exhaustion at high throughput, then average
request rate is the best scaling metric.

Servers that use other garbage-collected runtimes

Many server applications are based on runtimes that perform garbage collection such as .NET
and Ruby. These server applications might fit into one of the patterns described earlier. However,
as with Java, we don't recommend scaling these applications based on memory, because their
observed average memory utilization is often uncorrelated with throughput or concurrency.

For these applications, we recommend that you scale on CPU utilization if the application is CPU
bound. Otherwise, we recommend that you scale on average throughput or average concurrency,
based on your load testing results.

Job processors

Many workloads involve asynchronous job processing. They include applications that don't receive
requests in real time, but instead subscribe to a work queue to receive jobs. For these types
of applications, the proper scaling metric is almost always queue depth. Queue growth is an
indication that pending work outstrips processing capacity, whereas an empty queue indicates that
there's more capacity than work to do.

AWS messaging services, such as Amazon SQS and Amazon Kinesis Data Streams,
provide CloudWatch metrics that can be used for scaling. For Amazon SQS,
ApproximateNumberOfMessagesVisible is the best metric. For Kinesis Data Streams, consider
using the MillisBehindLatest metric, published by the Kinesis Client Library (KCL). This metric
should be averaged across all consumers before using it for scaling.

Service auto scaling and deployments

Application Auto Scaling turns off scale-in processes while Amazon ECS deployments are in
progress. However, scale-out processes continue to occur, unless suspended, during a deployment.
If you want to suspend scale-out processes while deployments are in progress, take the following steps.

1. Call the `describe-scalable-targets` command, specifying the resource ID of the service associated with the scalable target in Application Auto Scaling (Example: `service/default/sample-webapp`). Record the output. You will need it when you call the next command.

2. Call the `register-scalable-target` command, specifying the resource ID, namespace, and scalable dimension. Specify `true` for both `DynamicScalingInSuspended` and `DynamicScalingOutSuspended`.

3. After deployment is complete, you can call the `register-scalable-target` command to resume scaling.

For more information, see [Suspending and resuming scaling for Application Auto Scaling](#).

**Scale your Amazon ECS service using a target metric value**

With target tracking scaling policies, you select a metric and set a target value. Amazon ECS Service Auto Scaling creates and manages the CloudWatch alarms that control the scaling policy and calculates the scaling adjustment based on the metric and the target value. The scaling policy adds or removes service tasks as required to keep the metric at, or close to, the specified target value. In addition to keeping the metric close to the target value, a target tracking scaling policy also adjusts to the fluctuations in the metric due to a fluctuating load pattern and minimizes rapid fluctuations in the number of tasks running in your service.

**Considerations**

Consider the following when using target tracking policies:

- A target tracking scaling policy assumes that it should perform scale out when the specified metric is above the target value. You cannot use a target tracking scaling policy to scale out when the specified metric is below the target value.

- A target tracking scaling policy does not perform scaling when the specified metric has insufficient data. It does not perform scale in because it does not interpret insufficient data as low utilization.

- You may see gaps between the target value and the actual metric data points. This is because Service Auto Scaling always acts conservatively by rounding up or down when it determines how much capacity to add or remove. This prevents it from adding insufficient capacity or removing too much capacity.
• To ensure application availability, the service scales out proportionally to the metric as fast as it can, but scales in more gradually.

• Application Auto Scaling turns off scale-in processes while Amazon ECS deployments are in progress. However, scale-out processes continue to occur, unless suspended, during a deployment. For more information, see Service auto scaling and deployments.

• You can have multiple target tracking scaling policies for an Amazon ECS service, provided that each of them uses a different metric. The intention of Service Auto Scaling is to always prioritize availability, so its behavior differs depending on whether the target tracking policies are ready for scale out or scale in. It will scale out the service if any of the target tracking policies are ready for scale out, but will scale in only if all of the target tracking policies (with the scale-in portion turned on) are ready to scale in.

• Do not edit or delete the CloudWatch alarms that Service Auto Scaling manages for a target tracking scaling policy. Service Auto Scaling deletes the alarms automatically when you delete the scaling policy.

• The ALBRequestCountPerTarget metric for target tracking scaling policies is not supported for the blue/green deployment type.

For more information about target tracking scaling policies, see Target tracking scaling policies in the Application Auto Scaling User Guide.

To configure target scaling policies for your Amazon ECS service using the Amazon ECS console

1. In addition to the standard IAM permissions for creating and updating services, you need additional permissions. For more information, see IAM permissions required for service auto scaling.

2. You can configure a scaling policy when you create or update a service. For more information, see one of the following:
   • Create a service using defined parameters— Create a new service
   • Updating a service using the console— Update an existing service

To configure target scaling policies for your Amazon ECS service using the AWS CLI

1. In addition to the standard IAM permissions for creating and updating services, you need additional permissions. For more information, see IAM permissions required for service auto scaling.
2. Register your Amazon ECS service as a scalable target using the `register-scalable-target` command.

3. Create a scaling policy using the `put-scaling-policy` command.

**Scale your Amazon ECS service using predefined increments based on CloudWatch alarms**

With step scaling policies, you specify CloudWatch alarms that initiate the scaling process. For example, if you want to scale out when CPU utilization reaches a certain level, create an alarm using the `CPUUtilization` metric provided. When you create a step scaling policy, you must specify one of the following scaling adjustment types:

- **Add** – Increase the number of tasks by a specified number of capacity units or a specified percentage of the current capacity.
- **Remove** – Decrease the number of tasks by a specified number of capacity units or a specified percentage of the current capacity.
- **Set to** - Set the number of tasks to the specified number of capacity units.

For example, suppose that the target capacity and fulfilled capacity are 10 and the scaling policy adds 1. When the alarm is breached, the automatic scaling process adds 1 to 10 to get 11, so Amazon ECS launches 1 task for the service.

We strongly recommend that you use target tracking scaling policies to scale on metrics like average CPU utilization or average request count per target. Metrics that decrease when capacity increases and increase when capacity decreases can be used to proportionally scale out or in the number of tasks using target tracking. This helps ensure that Service Auto Scaling follows the demand curve for your applications closely.

For an overview of step scaling policies and how they work, see Step scaling policies in the Application Auto Scaling User Guide. After you read this introduction, see the following sections to learn how to configure step scaling for Amazon ECS using the console and AWS Command Line Interface.
To configure step scaling policies for your Amazon ECS service using the Amazon ECS console

1. In addition to the standard IAM permissions for creating and updating services, you need additional permissions. For more information, see IAM permissions required for service auto scaling.

2. You can configure a scaling policy when you create or update a service. For more information, see one of the following:
   - Create a service using defined parameters — Create a new service
   - Updating a service using the console — Update an existing service

To configure step scaling policies for your Amazon ECS service using the AWS CLI

1. In addition to the standard IAM permissions for creating and updating services, you need additional permissions. For more information, see IAM permissions required for service auto scaling.

2. Register your Amazon ECS service as a scalable target using the register-scalable-target command.

3. Create a scaling policy using the put-scaling-policy command.

4. Create an alarm that initiates the scaling policy using the put-metric-alarm command.

Scale your Amazon ECS service using a schedule

With scheduled scaling, you can set up automatic scaling for your application based on predictable load changes by creating scheduled actions that increase or decrease capacity at specific times. This allows you to scale your application proactively to match predictable load changes.

These scheduled scaling actions allow you to optimize costs and performance. Your application has sufficient capacity to handle the mid-week traffic peak, but does not over-provision unneeded capacity at other times.

You can use scheduled scaling and scaling policies together to get the benefits of proactive and reactive approaches to scaling. After a scheduled scaling action runs, the scaling policy can continue to make decisions about whether to further scale capacity. This helps you ensure that you have sufficient capacity to handle the load for your application. While your application scales to match demand, current capacity must fall within the minimum and maximum capacity that was set by your scheduled action.
You can configure schedule scaling using the AWS CLI. For more information about scheduled scaling, see *Scheduled Scaling* in the *Application Auto Scaling User Guide*.

**Interconnecting services**

Applications that run in Amazon ECS tasks often need to receive connections from the internet or to connect to other applications that run in Amazon ECS services. If you need external connections from the internet, we recommend using Elastic Load Balancing. For more information about integrated load balancing, see *the section called “Distribute Amazon ECS service traffic using load balancing”*.  

**Choosing an interconnection method**

If you need an application to connect to other applications that run in Amazon ECS services, Amazon ECS provides the following ways to do this without a load balancer:

- **Amazon ECS Service Connect**

  We recommend Service Connect, which provides Amazon ECS configuration for service discovery, connectivity, and traffic monitoring. With Service Connect, your applications can use short names and standard ports to connect to Amazon ECS services in the same cluster, other clusters, including across VPCs in the same AWS Region.

  When you use Service Connect, Amazon ECS manages all of the parts of service discovery: creating the names that can be discovered, dynamically managing entries for each task as the tasks start and stop, running an agent in each task that is configured to discover the names. Your application can look up the names by using the standard functionality for DNS names and making connections. If your application does this already, you don't need to modify your application to use Service Connect.

  You provide the complete configuration inside each service and task definition. Amazon ECS manages changes to this configuration in each service deployment, to ensure that all tasks in a deployment behave in the same way. For example, a common problem with DNS as service discovery is controlling a migration. If you change a DNS name to point to the new replacement IP addresses, it might take the maximum TTL time before all the clients begin using the new service. With Service Connect, the client deployment updates the configuration by replacing the client tasks. You can configure the deployment circuit breaker and other deployment configuration to affect Service Connect changes in the same way as any other deployment.

  For more information, see *Service Connect*.  

• **Amazon ECS service discovery**

Another approach for service-to-service communication is direct communication using service discovery. In this approach, you can use the AWS Cloud Map service discovery integration with Amazon ECS. Using service discovery, Amazon ECS syncs the list of launched tasks to AWS Cloud Map, which maintains a DNS hostname that resolves to the internal IP addresses of one or more tasks from that particular service. Other services in the Amazon VPC can use this DNS hostname to send traffic directly to another container using its internal IP address.

This approach to service-to-service communication provides low latency. There are no extra components between the containers. Traffic travels directly from one container to the other container.

This approach is suitable when using the `aws-vpc` network mode, where each task has its own unique IP address. Most software only supports the use of DNS A records, which resolve directly to IP addresses. When using the `aws-vpc` network mode, the IP address for each task are an A record. However, if you're using `bridge` network mode, multiple containers could be sharing the same IP address. Additionally, dynamic port mappings cause the containers to be randomly assigned port numbers on that single IP address. At this point, an A record is no longer be enough for service discovery. You must also use an SRV record. This type of record can keep track of both IP addresses and port numbers but requires that you configure applications appropriately. Some prebuilt applications that you use might not support SRV records.

Another advantage of the `aws-vpc` network mode is that you have a unique security group for each service. You can configure this security group to allow incoming connections from only the specific upstream services that need to talk to that service.

The main disadvantage of direct service-to-service communication using service discovery is that you must implement extra logic to have retries and deal with connection failures. DNS records have a time-to-live (TTL) period that controls how long they are cached for. It takes some time for the DNS record to be updated and for the cache to expire so that your applications can pick up the latest version of the DNS record. So, your application might end up resolving the DNS record to point at another container that's no longer there. Your application needs to handle retries and have logic to ignore bad backends.

For more information, see [Service discovery](#)
Network mode compatibility table

The following table covers the compatibility between these options and the task network modes. In the table, "client" refers to the application that's making the connections from inside an Amazon ECS task.

<table>
<thead>
<tr>
<th>Interconnection Options</th>
<th>Bridged</th>
<th>awsvpc</th>
<th>Host</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service discovery</td>
<td>yes, but requires clients be aware of SRV records in DNS without hostPort.</td>

<td>yes, but requires clients be aware of SRV records in DNS without hostPort.</td>
</tr>
<tr>
<td>Service Connect</td>
<td>yes</td>
<td>yes</td>
<td>no</td>
</tr>
</tbody>
</table>

Service Connect

Amazon ECS Service Connect provides management of service-to-service communication as Amazon ECS configuration. It does this by building both service discovery and a service mesh in Amazon ECS. This provides the complete configuration inside each Amazon ECS service that you manage by service deployments, a unified way to refer to your services within namespaces that doesn't depend on the Amazon VPC DNS configuration, and standardized metrics and logs to monitor all of your applications on Amazon ECS. Amazon ECS Service Connect only interconnects Amazon ECS services.

The following diagram shows an example Service Connect network with 2 subnets in the VPC and 2 services. A client service that runs WordPress with 1 task in each subnet. A server service that runs MySQL with 1 task in each subnet. Both services are highly available and resilient to task and Availability Zone issues because each service runs multiple tasks that are spread out over 2 subnets. The solid arrows show a connection from WordPress to MySQL. For example, a `mysql --host=mysql` CLI command that is run from inside the WordPress container in the task with the IP address 172.31.16.1. The command uses the short name `mysql` on the default port for MySQL. This name and port connects to the Service Connect proxy in the same task. The proxy in the WordPress task uses round-robin load balancing and any previous failure information in outlier detection to pick which MySQL task to connect to. As shown by the solid arrows in the diagram, the proxy connects to the second proxy in the MySQL task with the IP Address 172.31.16.2. The
second proxy connects to the local MySQL server in the same task. Both proxies report connection performance that is visible in graphs in the Amazon ECS and Amazon CloudWatch consoles so that you can get performance metrics from all kinds of applications in the same way.

**Overview of steps to configure Service Connect**

Follow these steps to configure Service Connect for a group of related services.

⚠️ **Important**

- Amazon ECS Service Connect creates AWS Cloud Map services in your account. Modifying these AWS Cloud Map resources by manually registering/deregistering instances, changing instance attributes, or deleting a service may lead to unexpected behaviour for your application traffic or subsequent deployments.
- Amazon ECS Service Connect doesn’t support links in the task definition.
1. Add port names to the port mappings in your task definitions. Additionally, you can identify the layer 7 protocol of the application, to get additional metrics.

2. Create an ECS cluster with a AWS Cloud Map namespace or create the namespace separately. For simple organization, create an Amazon ECS cluster with the name that you want for the namespace and specify the identical name for the namespace. In this case, Amazon ECS creates a new HTTP namespace with the necessary configuration. Amazon ECS Service Connect doesn't use or create DNS hosted zones in Amazon Route 53.

3. Configure services to create Service Connect endpoints within the namespace.

4. Deploy services to create the endpoints. Amazon ECS adds a Service Connect proxy container to each task, and creates the Service Connect endpoints in AWS Cloud Map. This container isn't configured in the task definition, and the task definition can be reused without modification to create multiple services in the same namespace or in multiple namespaces.

5. Deploy client apps as services to connect to the endpoints. Amazon ECS connects them to the Service Connect endpoints through the Service Connect proxy in each task.

   Applications only use the proxy to connect to Service Connect endpoints. There is no additional configuration to use the proxy. The proxy performs round-robin load balancing, outlier detection, and retries. For more information about the proxy, see Service Connect proxy.

6. Monitor traffic through the Service Connect proxy in Amazon CloudWatch.

**Regions with Service Connect**

Amazon ECS Service Connect is available in the following AWS Regions:

<table>
<thead>
<tr>
<th>Region Name</th>
<th>Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>US East (Ohio)</td>
<td>us-east-2</td>
</tr>
<tr>
<td>US East (N. Virginia)</td>

### Service Connect concepts

The Service Connect feature creates a virtual network of related services. The same service configuration can be used across multiple different namespaces to run independent yet identical sets of applications. Service Connect defines the proxy container in the Amazon ECS service. This way, the same task definition can be used to run identical applications in different namespaces with different Service Connect configurations. Each task that the Amazon ECS service makes runs a proxy container in the task.

Service Connect is suitable for connections between Amazon ECS services within the same namespace. For the following applications, you need to use an additional interconnection method to connect to an Amazon ECS service that is configured with Service Connect:

- Amazon ECS tasks that are configured in other namespaces
- Amazon ECS tasks that aren't configured for Service Connect
- Other applications outside of Amazon ECS

These applications can connect through the Service Connect proxy but can't resolve Service Connect endpoint names.

For these applications to resolve the IP addresses of Amazon ECS tasks, you need to use another interconnection method. For a list of interconnection methods, see [Choosing an interconnection method](#).
Service Connect terminology

The following terms are used with Service Connect.

port name

The Amazon ECS task definition configuration that assigns a name to a particular port mapping. This configuration is only used by Amazon ECS Service Connect.

client alias

The Amazon ECS service configuration that assigns the port number that is used in the endpoint. Additionally, the client alias can assign the DNS name of the endpoint, overriding the discovery name. If a discovery name isn't provided in the Amazon ECS service, the client alias name overrides the port name as the endpoint name. For endpoint examples, see the definition of endpoint. Multiple client aliases can be assigned to an Amazon ECS service. This configuration is only used by Amazon ECS Service Connect.

discovery name

The optional, intermediate name that you can create for a specified port from the task definition. This name is used to create a AWS Cloud Map service. If this name isn't provided, the port name from the task definition is used. Multiple discovery names can be assigned to a specific port an Amazon ECS service. This configuration is only used by Amazon ECS Service Connect.

AWS Cloud Map service names must be unique within a namespace. Because of this limitation, you can have only one Service Connect configuration without a discovery name for a particular task definition in each namespace.

endpoint

The URL to connect to an API or website. The URL contains the protocol, a DNS name, and the port. For more information about endpoints in general, see endpoint in the AWS glossary in the Amazon Web Services General Reference.

Service Connect creates endpoints that connect to Amazon ECS services and configures the tasks in Amazon ECS services to connect to the endpoints. The URL contains the protocol, a DNS name, and the port. You select the protocol and port name in the task definition, as the port must match the application that is inside the container image. In the service, you select each port by name and can assign the DNS name. If you don't specify a DNS name in the Amazon ECS service configuration, the port name from the task definition is used by default. For
example, a Service Connect endpoint could be http://blog:80, grpc://checkout:8080, or http://_db.production.internal:99.

**Service Connect service**

The configuration of a single endpoint in an Amazon ECS service. This is a part of the Service Connect configuration, consisting of a single row in the Service Connect and discovery name configuration in the console, or one object in the services list in the JSON configuration of an Amazon ECS service. This configuration is only used by Amazon ECS Service Connect.

For more information, see [ServiceConnectService](https://docs.aws.amazon.com/elasticcontainerservice/latest/dg/service-connect.html) in the Amazon Elastic Container Service API Reference.

**namespace**

The short name or full Amazon Resource Name (ARN) of the AWS Cloud Map namespace for use with Service Connect. The namespace must be in the same AWS Region as the Amazon ECS service and cluster. The type of namespace in AWS Cloud Map doesn't affect Service Connect.

Service Connect uses the AWS Cloud Map namespace as a logical grouping of Amazon ECS tasks that talk to one another. Each Amazon ECS service can belong to only one namespace. The services within a namespace can be spread across different Amazon ECS clusters within the same AWS Region in the same AWS account. Because each cluster can run tasks of every operating system, CPU architecture, VPC, and EC2, Fargate, and External types, you can freely organize your services by any criteria that you choose.

**client service**

An Amazon ECS service that runs a network client application. This service must have a namespace configured. Each task in the service can discover and connect to all of the endpoints in the namespace through a Service Connect proxy container.

If any of your containers in the task need to connect to an endpoint from a service in a namespace, choose a client service. If a frontend, reverse proxy, or load balancer application receives external traffic through other methods such as from Elastic Load Balancing, it could use this type of Service Connect configuration.

**client-server service**

An Amazon ECS service that runs a network or web service application. This service must have a namespace and at least one endpoint configured. Each task in the service is reachable by using the endpoints. The Service Connect proxy container listens on the endpoint name and port to direct traffic to the app containers in the task.
If any of the containers expose and listen on a port for network traffic, choose a client-server service. These applications don't need to connect to other client-server services in the same namespace, but the client configuration is configured. A backend, middleware, business tier, or most microservices would use this type of Service Connect configuration. If you want a frontend, reverse proxy, or load balancer application to receive traffic from other services configured with Service Connect in the same namespace, these services should use this type of Service Connect configuration.

**Cluster configuration**

You can set a default namespace for Service Connect when you create the cluster or by updating the cluster. If you specify a namespace name that doesn't exist in the same AWS Region and account, a new HTTP namespace is created.

If you create a cluster and specify a default Service Connect namespace, the cluster waits in the PROVISIONING status while Amazon ECS creates the namespace. You can see an attachment in the status of the cluster that shows the status of the namespace. Attachments aren't displayed by default in the AWS CLI, you must add --include ATTACHMENTS to see them.

**Service Connect service configuration**

Service Connect is designed to require the minimum configuration. You need to set a name for each port mapping that you would like to use with Service Connect in the task definition. In the service, you need to turn on Service Connect and select a namespace to make a client service. To make a client-server service, you need to add a single Service Connect service configuration that matches the name of one of the port mappings. Amazon ECS reuses the port number and port name from the task definition to define the Service Connect service and endpoint. To override those values, you can use the other parameters Discovery, DNS, and Port in the console, or discoveryName and clientAliases, respectively in the Amazon ECS API.

The following example shows each kind of Service Connect configuration being used together in the same Amazon ECS service. Shell comments are provided, however note that the JSON configuration used to Amazon ECS services doesn't support comments.

```
{
    
    serviceConnectConfiguration: {
        enabled: true,
    
```
namespace: "internal",
# config for client services can end here, only these two parameters are
required.
services: [{
    portName: "http"
}, # minimal client - server service config can end here. portName must match
the "name" parameter of a port mapping in the task definition. {
    discoveryName: "http-second"
    # name the discoveryName to avoid a Task def port name collision with
the minimal config in the same Cloud Map namespace
    portName: "http"
},
{
    clientAliases: [{
        dnsName: "db",
        port: 81
    }] # use when the port in Task def is not the port that client apps
use. Client apps can use http://db:81 to connect
    discoveryName: "http-three"
    portName: "http"
},
{
    clientAliases: [{
        dnsName: "db.app",
        port: 81
    }] # use when the port in Task def is not the port that client apps
use. duplicates are fine as long as the discoveryName is different.
    discoveryName: "http-four"
    portName: "http",
    ingressPortOverride: 99 # If App should also accept traffic directly on
Task def port.
}
}

**Deployment order**

When you use Amazon ECS Service Connect, you configure each Amazon ECS service either to
run a server application that receives network requests (client-server service) or to run a client
application that makes the requests (client service).
When you prepare to start using Service Connect, start with a client-server service. You can add a Service Connect configuration to a new service or an existing service. After you edit and update an Amazon ECS service to add a Service Connect configuration, Amazon ECS creates a Service Connect endpoint in the namespace. Additionally, Amazon ECS creates a new deployment in the service to replace the tasks that are currently running.

Existing tasks and other applications can continue to connect to existing endpoints, and external applications. If a client-server service adds tasks by scaling out, new connections from clients will be balanced between all of the tasks immediately. If a client-server service is updated, new connections from clients will be balanced between the tasks of the new version immediately.

Existing tasks can't resolve and connect to the new endpoint. Only new Amazon ECS tasks that have a Service Connect configuration in the same namespace and that start running after this deployment can resolve and connect to this endpoint. For example, an Amazon ECS service that runs a client application must be redeployed to connect to a new database server endpoint. Start the client deployment after the deployment completes for the server.

This means that the operator of the client application determines when the configuration of their app changes, even though the operator of the server application can change their configuration at any time. The list of endpoints in the namespace can change every time that any Amazon ECS service in the namespace is deployed, but existing tasks and replacement tasks continue to behave the same as they did after the most recent deployment.

Consider the following examples.

First, assume that you are creating an application that is available to the public internet in a single AWS CloudFormation template and single AWS CloudFormation stack. The public discovery and reachability should be created last by AWS CloudFormation, including the frontend client service. The services need to be created in this order to prevent an time period when the frontend client service is running and available the public, but a backend isn't. This eliminates error messages from being sent to the public during that time period. In AWS CloudFormation, you must use the dependsOn to indicate to AWS CloudFormation that multiple Amazon ECS services can't be made in parallel or simultaneously. You should add the dependsOn to the frontend client service for each backend client-server service that the client tasks connect to.

Second, assume that a frontend service exists without Service Connect configuration. The tasks are connecting to an existing backend service. Add a client-server Service Connect configuration to the backend service first, using the same name in the DNS or clientAlias that the frontend uses. This creates a new deployment, so all the deployment rollback detection or AWS Management
Console, AWS CLI, AWS SDKs and other methods to roll back and revert the backend service to the previous deployment and configuration. If you are satisfied with the performance and behavior of the backend service, add a client or client-server Service Connect configuration to the frontend service. Only the tasks in the new deployment use the Service Connect proxy that is added to those new tasks. If you have issues with this configuration, you can roll back and revert to your previous configuration by using the deployment rollback detection or AWS Management Console, AWS CLI, AWS SDKs and other methods to roll back and revert the backend service to the previous deployment and configuration. If you use another service discovery system that is based on DNS instead of Service Connect, any frontend or client applications begin using new endpoints and changed endpoint configuration after the local DNS cache expires, commonly taking multiple hours.

**Networking**

In the default configuration, the Service Connect proxy listens on the `containerPort` from the port mapping in the task definition. You need rules in your security group to allow incoming (ingress) traffic to this port from the VPC CIDRs, or specifically from subnets where clients will run. Even if you set a port number in the Service Connect service configuration, this doesn't change the port for the client-server service that the Service Connect proxy listens on. When you set this port number, Amazon ECS changes the port of the endpoint that the client services connect to, on the Service Connect proxy inside those tasks. The proxy in the client service connects to the proxy in the client-server service using the `containerPort`.

If you want to change the port that the Service Connect proxy listens on, change the `ingressPortOverride` in the Service Connect configuration of the client-server service. If you change this port number, you must allow inbound traffic on this port in the Amazon VPC security group that is used by traffic to this service.

Traffic that your applications send to Amazon ECS services configured for Service Connect require that the Amazon VPC and subnets have route table rules and network ACL rules that allow the `containerPort` and `ingressPortOverride` port numbers that you are using.

You can send traffic between VPCs with Service Connect. You must consider the same requirements for the route table rules, network ACLs, and security groups as they apply to both VPCs.

For example, two clusters create tasks in different VPCs. A service in each cluster is configured to use the same namespace. The applications in these two services can resolve every endpoint in the namespace without any VPC DNS configuration. However, the proxies can't connect unless
the VPC peering, VPC or subnet route tables, and VPC network ACLs allow the traffic on the containerPort and ingressPortOverride port numbers you are using.

For tasks that use the bridge networking mode, you must create a security group with an inbound rule that allows traffic on the upper dynamic port range. Then, assign the security group to all the EC2 instances in the Service Connect cluster.

**Service Connect proxy**

If you create or update an Amazon ECS service with Service Connect configuration, Amazon ECS adds a new container to each new task as it is started. This pattern of using a separate container is called a sidecar. This container isn't present in the task definition and you can't configure it. Amazon ECS manages the configuration of this container in the Amazon ECS service. Because of this, you can reuse the same task definitions between multiple Amazon ECS services, namespaces, and you can run tasks without Service Connect also.

**Proxy resources**

- The task CPU and memory limits are the only parameters that you need to configure for this container in the task definition. The only parameter you need to configure for this container in the Amazon ECS service is the log configuration, which you'll find in the Service Connect configuration. For more information about Service Connect configuration, see [Service Connect service configuration](#).

- The task definition must set the task memory limit to use Service Connect. The additional CPU and memory in the task limits that you don't allocate in the container limits in your other containers are used by the Service Connect proxy container and other containers that don't set container limits.

- We recommend adding 256 CPU units and at least 64 MiB of memory to your task CPU and memory for the Service Connect proxy container. On AWS Fargate, the lowest amount of memory that you can set is 512 MiB of memory. On Amazon EC2, task memory is optional, but it is required for Service Connect.

- If you expect tasks in this service to receive more than 500 requests per second at their peak load, we recommend adding 512 CPU units to your task CPU in this task definition for the Service Connect proxy container.

- If you expect to create more than 100 Service Connect services in the namespace or 2000 tasks in total across all Amazon ECS services within the namespace, we recommend adding 128 MiB of memory to your task memory for the Service Connect proxy container. You should do this in every task definition that is used by all of the Amazon ECS services in the namespace.
Proxy configuration

Your applications connect to the proxy in the sidecar container in the same task as the application is in. Amazon ECS configures the task and containers so that applications only connect to the proxy if the application is connecting to the endpoint names in the same namespace. All other traffic doesn't use the proxy. The other traffic includes IP addresses in the same VPC, AWS service endpoints, and external traffic.

Load balancing

Service Connect configures the proxy to use the round-robin strategy for load balancing between the tasks in a Service Connect endpoint. The local proxy that is in the task where the connection comes from, picks one of the tasks in the client-server service that provides the endpoint.

For example, consider a task that runs WordPress in an Amazon ECS service that is configured as a client service in a namespace called local. There is another service with 2 tasks that run the MySQL database. This service is configured to provide an endpoint called mysql through Service Connect in the same namespace. In the WordPress task, the WordPress application connects to the database using the endpoint name. Because of the Service Connect configuration, connections to this name go to the proxy that runs in a sidecar container in the same task. Then, the proxy can connect to either of the MySQL tasks using the round-robin strategy.

Load balancing strategies: round-robin

Outlier detection

This feature uses data that the proxy has about prior failed connections to avoid sending new connections to the hosts that had the failed connections. Service Connect configures the outlier detection feature of the proxy to provide passive health checks.

For example, consider a task that runs WordPress in an Amazon ECS service that is configured as a client service in a namespace called local. There is another service with 2 tasks that run the MySQL database. This service is configured to provide an endpoint called mysql through Service Connect in the same namespace. In the WordPress task, the WordPress application connects to the proxy that runs in a sidecar container in the same task. The proxy can connect to either of the MySQL tasks. If the proxy made multiple connections to a specific MySQL task, and 5 or more of the connections failed in the last 30 seconds, then the proxy avoids that MySQL task for 30 to 300 seconds.
Retries

Service Connect configures the proxy to retry connection that pass through the proxy and fail, and the second attempt avoids using the host from the previous connection. This ensures that each connection through Service Connect doesn't fail for one-off reasons.

Number of retries: 2

Timeout

Service Connect configures the proxy to wait a maximum time for your client-server applications to respond. The default timeout value is 15 seconds, but it can be updated.

Optional parameters:

idleTimeout - The amount of time in seconds a connection will stay active while idle. A value of 0 disables idleTimeout.

The idleTimeout default for HTTP/HTTP2/GRPC is 5 minutes.

The idleTimeout default for TCP is 1 hour.

perRequestTimeout - The amount of time waiting for the upstream to respond with a complete response per request. A value of 0 disables perRequestTimeout. Can only be set when the appProtocol for application container is HTTP/HTTP2/GRPC. The default is 15 seconds.

Note

If idleTimeout is set to a time that is less than perRequestTimeout, the connection will close when the idleTimeout is reached and not the perRequestTimeout.

Service Connect considerations

- Windows containers aren't supported with Service Connect.
- Tasks that run in Fargate must use the Fargate Linux platform version 1.4.0 or higher to use Service Connect.
- The ECS agent version on the container instance must be 1.67.2 or higher.
- Container instances must run the Amazon ECS-optimized Amazon Linux 2023 AMI version 20230428 or later, or Amazon ECS-optimized Amazon Linux 2 AMI version 2.0.20221115 to use Service Connect. These versions have the Service Connect agent in addition to the Amazon
ECS container agent. For more information about the Service Connect agent, see Amazon ECS Service Connect Agent on GitHub.

- Container instances must have the ecs:Poll permission for the resource arn:aws:ecs:region:0123456789012:task-set/cluster/*. If you are using the ecsInstanceRole, you don't need to add additional permissions. The AmazonEC2ContainerServiceforEC2Role managed policy has the necessary permissions. For more information, see Amazon ECS container instance IAM role.

- External container instance for Amazon ECS Anywhere aren't supported with Service Connect.

- Only services that use rolling deployments are supported with Service Connect. Services that use the blue/green and external deployment types aren't supported.

- Task definitions must set the task memory limit to use Service Connect. For more information, see Service Connect proxy.

- Task definitions that set container memory limits for all containers instead of setting the task memory limit aren't supported.

You can set container memory limits on your containers, but you must set the task memory limit to a number greater than the sum of the container memory limits. The additional CPU and memory in the task limits that aren't allocated in the container limits are used by the Service Connect proxy container and other containers that don't set container limits. For more information, see Service Connect proxy.

- You can configure Service Connect in a service to use any AWS Cloud Map namespace in the same AWS Region in the same AWS account.

- Each Amazon ECS service can belong to only one namespace.

- Only the tasks that Amazon ECS services create are supported. Standalone tasks can't be configured for Service Connect.

- All endpoints must be unique within a namespace.

- All discovery names must be unique within a namespace.

- Existing services must be redeployed before the applications in them can resolve new endpoints. New endpoints that are added to the namespace after the most recent deployment won't be added to the task configuration. For more information, see the section called “Deployment order”.

- You can create a namespace when creating a new cluster. Amazon ECS Service Connect doesn't delete namespaces when clusters are deleted. You must delete namespaces directly in AWS Cloud Map if you are done using them.
• Service Connect doesn't support HTTP 1.0.

• Application Load Balancer traffic defaults to routing through the Service Connect agent in awsvpc network mode. If you want non-service traffic to bypass the Service Connect agent, use the `ingressPortOverride` parameter in your Service Connect service configuration.

**Service Connect console experience**

To create a new namespace, either create a new Amazon ECS cluster using the Amazon ECS console and specify a namespace name to create, or use the AWS Cloud Map console. Amazon ECS Service Connect can use any *instance discovery* type of AWS Cloud Map namespace. We recommend the *API calls* type to make the minimum amount of additional resources. To create a new Amazon ECS cluster and namespace in the Amazon ECS console, see [Creating a cluster for the Fargate and External launch type using the console](#).

Every AWS Cloud Map namespace in this AWS account in the selected AWS Region is displayed in the **Namespaces** in the Amazon ECS console.

To delete a namespace, use the AWS Cloud Map console. A namespace must be empty before it can be deleted.

To create a new Amazon ECS task definition, or register a new revision to an existing task definition and use Service Connect, see [Creating a task definition using the console](#).

To create a new Amazon ECS service that uses Service Connect, see [Creating a service using the console](#).

**Service Connect pricing**

Amazon ECS Service Connect pricing depends on whether you use AWS Fargate or Amazon EC2 infrastructure to host your containerized workloads. When using Amazon ECS on AWS Outposts, the pricing follows the same model that's used when you use Amazon EC2 directly. For more information, see [Amazon ECS Pricing](#).

AWS Cloud Map usage is completely free, when it's consumed through Amazon ECS Service Connect.

**TLS with Service Connect**

Amazon ECS Service Connect supports automatic traffic encryption with Transport Layer Security (TLS) certificates for Amazon ECS services. When you point your Amazon ECS services toward an
AWS Private Certificate Authority (AWS Private CA), Amazon ECS automatically provisions TLS certificates to encrypt traffic between your Amazon ECS Service Connect services. Amazon ECS generates, rotates, and distributes TLS certificates used for traffic encryption.

Automatic traffic encryption with Amazon ECS Service Connect uses industry-leading encryption capabilities to secure your inter-service communication that helps you meet your security requirements. It supports AWS Private Certificate Authority TLS certificates with 256-bit ECDSA and 2048-bit RSA encryption. By default, TLS 1.3 is supported, but TLS 1.0 - 1.2 are not supported. You also have full control over private certificates and signing keys to help you meet compliance requirements.

Note

Only inbound and outbound traffic passing though the Amazon ECS Service Connect Agent is encrypted.

AWS Private Certificate Authority certificates and Service Connect

AWS Private Certificate Authority modes for Service Connect

AWS Private Certificate Authority can run in two modes: general purpose and short-lived.

- General purpose - Certificates that can be configured with any expiration date.
- Short-lived - Certificates with a maximum validity of seven days.

While Amazon ECS supports both modes, we recommend using short-lived certificates. By default, certificates rotate every five days, and running in short-lived mode offers significant cost savings over general purpose.

Service Connect doesn't support certificate revocation and instead leverages short-lived certificates with frequent certificate rotation. You have the authority to modify the rotation frequency, disable, or delete the secrets using managed rotation in Secrets Manager, but doing so can come with the following possible consequences.

- Shorter Rotation Frequency - A shorter rotation frequency incurs higher costs due to AWS Private CA, AWS KMS and Secrets Manager, and Auto Scaling experiencing an increased workload for rotation.
• Longer Rotation Frequency - Your applications’ communications fail if the rotation frequency exceeds **seven** days.

• Deletion of Secret - Deleting the secret results in rotation failure and impacts customer application communications.

In the event of your secret rotation failing, a RotationFailed event is published in **AWS CloudTrail**. You can also set up a **CloudWatch Alarm** for RotationFailed.

**Subordinate Certificate Authorities**

You can bring any AWS Private CA, root or subordinate, to Amazon ECS Service Connect TLS to issue end-entity certificates for the services. The provided issuer is treated as the signer and root of trust everywhere. You can issue end-entity certificates for different parts of your application from different subordinate CAs. When using the AWS CLI, provide the Amazon Resource Name (ARN) of the CA to establish the trust chain.

**On-premises Certificate Authorities**

To use your on-premises CA, you create and configure a subordinate CA in AWS Private Certificate Authority. This ensures all TLS certificates issued for your Amazon ECS workloads share the trust chain with the workloads you run on premises and are able to securely connect.

⚠️ **Important**

Please add the **required** tag AmazonECSManaged : true in your AWS Private CA.

**AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity IAM policy**

Amazon ECS provides a new managed resource trust policy that outlines the set of permissions required for issuing certificates. For more information about this new policy, see **AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity** in the **AWS managed policies for Amazon ECS**.

**Service Connect and AWS Key Management Service**

You can use **AWS Key Management Service** to encrypt and decrypt your Service Connect resources. AWS KMS is a service managed by AWS where you can make and manage cryptographic keys that protect your data.
When using AWS KMS with Service Connect, you can either choose to use an AWS owned key that AWS manages for you, or you can choose an existing AWS KMS key. You can also create a new AWS KMS key to use.

Providing your own encryption key

You can provide your own key materials, or you can use an external key store through AWS Key Management Service. Import your own key into AWS KMS, and then specify the Amazon Resource Name (ARN) of that key in Amazon ECS Service Connect.

The following is an example AWS KMS policy. Replace the red values with your own.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "id",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::111122223333:role/role-name"
            },
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:GenerateDataKey",
                "kms:GenerateDataKeyPair"
            ],
            "Resource": "*"
        }
    ]
}
```

For more information about key policies, see Creating a key policy in the AWS Key Management Service Developer Guide.

**Note**

Service Connect supports only symmetric encryption AWS KMS keys. You can’t use any other type of AWS KMS key to encrypt your Service Connect resources. For help determining whether a AWS KMS key is a symmetric encryption key, see Identifying symmetric and asymmetric AWS KMS keys.
For more information on AWS Key Management Service symmetric encryption keys, see Symmetric encryption AWS KMS keys in the AWS Key Management Service Developer Guide.

Enable TLS with Service Connect

You enable traffic encryption when you create or update a Service Connect service.

To enable traffic encryption for a service in an existing namespace using the AWS Management Console

1. Choose the **Namespace** with the **Service** you’d like to enable traffic encryption for.
2. Choose the **Service** you’d like to enable traffic encryption for.
3. Choose **Update Service** in the top right corner and scroll down to the Service Connect section.
4. Choose **Turn on traffic encryption** under your service information to enable TLS.
5. For **Service Connect TLS role**, choose an existing role or to create a new one.
6. For **Signer certificate authority**, choose an existing certificate authority or to create a new one.
7. For **Choose an AWS KMS key**, choose an AWS owned and managed key or you can choose a different key. You can also choose to create a new one.

For an example of using the AWS CLI to configure TLS for your service, see Tutorial: Using Service Connect in Fargate with the AWS CLI.

Verify TLS is enabled

Service Connect initiates TLS at the Service Connect agent and terminates it at the destination agent. As a result, the application code never sees TLS interactions. In order to verify that TLS is enabled, you can use the following steps.

1. Ensure your application image has the openssl CLI.
2. Enable **ECS Exec** on your services to connect to your tasks via SSM. Alternately, you can spin up an Amazon EC2 instance in the same Amazon VPC as the service.
3. Retrieve the IP and port of a task from a service that you want to verify. For example, if your *redis* service has TLS turned on, you can retrieve its task IP by navigating to AWS Cloud Map, finding the service, and looking at the IP and port of one instance.
4. Log on to any of your Amazon ECS tasks using `execute-command` like in the following example. Alternately, log on to the Amazon EC2 instance created in **Step 2**.

```bash
$ aws ecs execute-command --cluster cluster-name \
   --task < TASK_ID> \
   --container app \
   --interactive \
   --command "/bin/sh"
```

**Note**
Calling the DNS name directly does not reveal the certificate.

5. In the connected shell, use the `openssl` CLI to verify and view the certificate attached to the task.

Example:

```bash
openssl s_client -connect 10.0.147.43:6379 < /dev/null 2> /dev/null \
| openssl x509 -noout -text
```

Example response:

```
Certificate:
  Data:
    Version: 3 (0x2)
    Serial Number:
      <serial-number>
    Signature Algorithm: ecdsa-with-SHA256
    Issuer: <issuer>
    Validity
      Not Before: Jan 23 21:38:12 2024 GMT
```
Service Connect parameters

The following parameters have extra fields when using Service Connect.

<table>
<thead>
<tr>
<th>Parameter location</th>
<th>App type</th>
<th>Description</th>
<th>Required?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task definition</td>
<td>Client</td>
<td>There are no changes available for Service Connect in client task definitions.</td>
<td>N/A</td>
</tr>
<tr>
<td>Task definition</td>
<td>Client-server</td>
<td>Servers must add name fields to ports in the portMappings of containers. For more information, see portMappings.</td>
<td>Yes</td>
</tr>
<tr>
<td>Parameter location</td>
<td>App type</td>

</tr>
</tbody>
</table>
Using Service Connect in Fargate with the AWS CLI

The following tutorial shows how to create an Amazon ECS service with a Fargate task that uses Service Connect with the AWS CLI.

Amazon ECS supports the Service Connect feature in the AWS Regions listed in Regions with Service Connect.

Prerequisites

This tutorial assumes that the following prerequisites have been completed:

- The latest version of the AWS CLI is installed and configured. For more information, see Installing the AWS Command Line Interface.
- The steps in Set up to use Amazon ECS have been completed.
- Your AWS user has the required permissions specified in the AmazonECS_FullAccess IAM policy example.
- You have a VPC, subnet, route table, and security group created to use. For more information, see the section called “Create a virtual private cloud“.
- You have a task execution role with the name ecsTaskExecutionRole and the AmazonECSTaskExecutionRolePolicy managed policy is attached to the role. This role allows Fargate to write the NGINX application logs and Service Connect proxy logs to Amazon CloudWatch Logs. For more information, see Creating the task execution (ecsTaskExecutionRole) role.

Step 1: Create the Amazon ECS cluster

Use the following steps to create your Amazon ECS cluster and namespace.

To create the Amazon ECS cluster and AWS Cloud Map namespace

1. Create an Amazon ECS cluster named tutorial to use. The parameter --service-connect-defaults sets the default namespace of the cluster. In the example output, a AWS Cloud Map namespace of the name service-connect doesn't exist in this account and AWS Region, so the namespace is created by Amazon ECS. The namespace is made in AWS Cloud Map in the account, and is visible with all of the other namespaces, so use a name that indicates the purpose.
aws ecs create-cluster --cluster-name tutorial --service-connect-defaults namespace=service-connect

Output:

{
  "cluster": {
    "clusterName": "tutorial",
    "serviceConnectDefaults": {
    },
    "status": "PROVISIONING",
    "registeredContainerInstancesCount": 0,
    "runningTasksCount": 0,
    "pendingTasksCount": 0,
    "activeServicesCount": 0,
    "statistics": [],
    "tags": [],
    "settings": [
      {
        "name": "containerInsights",
        "value": "disabled"
      }
    ],
    "capacityProviders": [],
    "defaultCapacityProviderStrategy": [],
    "attachments": [
      {
        "id": "a1b2c3d4-5678-90ab-cdef-EXAMPLE11111",
        "type": "sc",
        "status": "ATTACHING",
        "details": []
      }
    ],
    "attachmentsStatus": "UPDATE_IN_PROGRESS"
  }
}

2. Verify that the cluster is created:
aws ecs describe-clusters --clusters tutorial

Output:

```json
{
   "clusters": [
      {
         "clusterName": "tutorial",
         "serviceConnectDefaults": {
         },
         "status": "ACTIVE",
         "registeredContainerInstancesCount": 0,
         "runningTasksCount": 0,
         "pendingTasksCount": 0,
         "activeServicesCount": 0,
         "statistics": [],
         "tags": [],
         "settings": [],
         "capacityProviders": [],
         "defaultCapacityProviderStrategy": []
      }
   ],
   "failures": []
}
```

3. **(Optional)** Verify that the namespace is created in AWS Cloud Map. You can use the AWS Management Console or the normal AWS CLI configuration as this is created in AWS Cloud Map.

For example, use the AWS CLI:

```
aws servicediscovery --region us-west-2 getNamespace --id ns-EXAMPLE
```

Output:

```json
{
   "Namespace": {
```
Step 2: Create the Amazon ECS service for the server

The Service Connect feature is intended for interconnecting multiple applications on Amazon ECS. At least one of those applications needs to provide a web service to connect to. In this step, you create:

- The task definition that uses the unmodified official NGINX container image and includes Service Connect configuration.
- The Amazon ECS service definition that configures Service Connect to provide service discovery and service mesh proxying for traffic to this service. The configuration reuses the default namespace from the cluster configuration to reduce the amount of service configuration that you make for each service.
- The Amazon ECS service. It runs one task using the task definition, and inserts an additional container for the Service Connect proxy. The proxy listens on the port from the container port mapping of the task definition. In a client application running in Amazon ECS, the proxy in the client task listens for outbound connections to the task definition port name, service discovery name or service client alias name, and the port number from the client alias.
To create the web service with Amazon ECS Service Connect

1. Register a task definition that's compatible with Fargate and uses the `awsvpc` network mode. Follow these steps:

   a. Create a file that's named `service-connect-nginx.json` with the contents of the following task definition.

      This task definition configures Service Connect by adding `name` and `appProtocol` parameters to the port mapping. The port name makes this port more identifiable in the service configuration when multiple ports are used. The port name is also used by default as the discoverable name for use by other applications in the namespace.

      The task definition contains the task IAM role because the service has ECS Exec enabled.

      **Important**

      This task definition uses a `logConfiguration` to send the nginx output from `stdout` and `stderr` to Amazon CloudWatch Logs. This task execution role doesn't have the extra permissions required to make the CloudWatch Logs log group. Create the log group in CloudWatch Logs using the AWS Management Console or AWS CLI. If you don't want to send the nginx logs to CloudWatch Logs you can remove the `logConfiguration`. Replace the AWS account id in the execution role with your AWS account id.

```json
{
  "family": "service-connect-nginx",
  "executionRoleArn": "arn:aws:iam::123456789012:role/ecsTaskExecutionRole",
  "taskRoleArn": "arn:aws:iam::123456789012:role/ecsTaskRole",
  "networkMode": "awsvpc",
  "containerDefinitions": [
    {
      "name": "webserver",
      "image": "public.ecr.aws/docker/library/nginx:latest",
      "cpu": 100,
      "portMappings": [
        {
          "name": "nginx",
```
Interconnecting services

b. Register the task definition using the service-connect-nginx.json file:

```bash
aws ecs register-task-definition --cli-input-json file://service-connect-nginx.json
```

2. Create an ECS service by following these steps:

   a. Create a file that's named service-connect-nginx-service.json with the contents of the Amazon ECS service that you're creating. This example uses the task definition that was created in the previous step. An awsvpcConfiguration is required because the example task definition uses the awsvpc network mode.

   When you create the ECS service, specify the Fargate launch type, and the LATEST platform version that supports Service Connect. The securityGroups and subnets must belong to a VPC that has the requirements for using Amazon ECS. You can obtain the security group and subnet IDs from the Amazon VPC Console.

   This service configures Service Connect by adding the serviceConnectConfiguration parameter. The namespace is not required because the cluster has a default namespace configured. Client applications running in ECS in the namespace connect to this service by using the portName and the port in the clientAliases. For example, this service
is reachable using http://nginx:80/, as nginx provides a welcome page in the root location /. External applications that are not running in Amazon ECS or are not in the same namespace can reach this application through the Service Connect proxy by using the IP address of the task and the port number from the task definition. For your tls configuration, add the certificate arn for your awsPcaAuthorityArn, your kmsKey, and roleArn of your IAM role.

This service uses a logConfiguration to send the service connect proxy output from stdout and stderr to Amazon CloudWatch Logs. This task execution role doesn't have the extra permissions required to make the CloudWatch Logs log group. Create the log group in CloudWatch Logs using the AWS Management Console or AWS CLI. We recommend that you create this log group and store the proxy logs in CloudWatch Logs. If you don't want to send the proxy logs to CloudWatch Logs you can remove the logConfiguration.

```json
{
    "cluster": "tutorial",
    "deploymentConfiguration": {
        "maximumPercent": 200,
        "minimumHealthyPercent": 0
    },
    "deploymentController": {
        "type": "ECS"
    },
    "desiredCount": 1,
    "enableECSManagedTags": true,
    "enableExecuteCommand": true,
    "launchType": "FARGATE",
    "networkConfiguration": {
        "awsvpcConfiguration": {
            "assignPublicIp": "ENABLED",
            "securityGroups": [
                "sg-EXAMPLE"
            ],
            "subnets": [
                "subnet-EXAMPLE",
                "subnet-EXAMPLE",
                "subnet-EXAMPLE"
            ]
        }
    }
}
```
b. Create an ECS service using the `service-connect-nginx-service.json` file:

```
aws ecs create-service --cluster tutorial --cli-input-json file://service-connect-nginx-service.json
```

Output:

The serviceConnectConfiguration that you provided appears inside the first deployment of the output. As you make changes to the ECS service in ways that need to make changes to tasks, a new deployment is created by Amazon ECS.

**Step 3: Verify that you can connect**

To verify that Service Connect is configured and working, follow these steps to connect to the web service from an external application. Then, see the additional metrics in CloudWatch that are created by the Service Connect proxy.
To connect to the web service from an external application

- Connect to the task IP address and container port using the task IP address

  Use the AWS CLI to get the task ID, using the `aws ecs list-tasks --cluster tutorial`.

  If your subnets and security group permit traffic from the public internet on the port from the task definition, you can connect to the public IP from your computer. The public IP isn't available from `describe-tasks` however, so the steps involve going to the Amazon EC2 AWS Management Console or AWS CLI to get the details of the elastic network interface.

  In this example, an Amazon EC2 instance in the same VPC uses the private IP of the task. The application is nginx, but the `server: envoy` header shows that the Service Connect proxy is used. The Service Connect proxy is listening on the container port from the task definition.

```
$ curl -v 10.0.19.50:80/
*   Trying 10.0.19.50:80...
* Connected to 10.0.19.50 (10.0.19.50) port 80 (#0)
> GET / HTTP/1.1
> Host: 10.0.19.50
> User-Agent: curl/7.79.1
> Accept: */*
> *
* Mark bundle as not supporting multiuse

Interconnecting services
**To view Service Connect metrics**

The Service Connect proxy creates application (HTTP, HTTP2, gRPC, or TCP connection) metrics in CloudWatch metrics. When you use the CloudWatch console, see the additional metric dimensions of **DiscoveryName**, (**DiscoveryName, ServiceName, ClusterName**), **TargetDiscoveryName**, and (**TargetDiscoveryName, ServiceName, ClusterName**) under the ECS namespace. For more information about these metrics and the dimensions, see [Available metrics and dimensions for Amazon ECS](#).

**Service discovery**

Your Amazon ECS service can optionally be configured to use Amazon ECS service discovery. Service discovery uses AWS Cloud Map API actions to manage HTTP and DNS namespaces for your Amazon ECS services. For more information, see [What Is AWS Cloud Map?](#) in the *AWS Cloud Map Developer Guide*.

Service discovery is available in the following AWS Regions:

**Service Discovery concepts**

Service discovery consists of the following components:

- **Service discovery namespace**: A logical group of service discovery services that share the same domain name, such as example.com. This is the domain name where you want to route traffic to. You can create a namespace with a call to the aws servicediscovery create-private-dns-namespace command or in the Amazon ECS console. You can use the aws servicediscovery list-namespaces command to view the summary information about the namespaces that were created by the current account. For more information about the service discovery commands, see [create-private-dns-namespace](#) and [list-namespaces](#) in the [AWS Cloud Map (service discovery) AWS CLI Reference Guide](#).
• **Service discovery service**: Exists within the service discovery namespace and consists of the service name and DNS configuration for the namespace. It provides the following core component:

  • **Service registry**: Allows you to look up a service via DNS or AWS Cloud Map API actions and get back one or more available endpoints that can be used to connect to the service.

• **Service discovery instance**: Exists within the service discovery service and consists of the attributes associated with each Amazon ECS service in the service directory.

• **Instance attributes**: The following metadata is added as custom attributes for each Amazon ECS service that is configured to use service discovery:
  
  • **AWS_INSTANCE_IPV4** – For an A record, the IPv4 address that Route 53 returns in response to DNS queries and AWS Cloud Map returns when discovering instance details, for example, 192.0.2.44.
  
  • **AWS_INSTANCE_PORT** – The port value associated with the service discovery service.
  
  • **AVAILABILITY_ZONE** – The Availability Zone into which the task was launched. For tasks using the EC2 launch type, this is the Availability Zone in which the container instance exists. For tasks using the Fargate launch type, this is the Availability Zone in which the elastic network interface exists.
  
  • **REGION** – The Region in which the task exists.
  
  • **ECS_SERVICE_NAME** – The name of the Amazon ECS service to which the task belongs.
  
  • **ECS_CLUSTER_NAME** – The name of the Amazon ECS cluster to which the task belongs.
  
  • **EC2_INSTANCE_ID** – The ID of the container instance the task was placed on. This custom attribute is not added if the task is using the Fargate launch type.
  
  • **ECS_TASK_DEFINITION_FAMILY** – The task definition family that the task is using.
  
  • **ECS_TASK_SET_EXTERNAL_ID** – If a task set is created for an external deployment and is associated with a service discovery registry, then the ECS_TASK_SET_EXTERNAL_ID attribute will contain the external ID of the task set.

• **Amazon ECS health checks**: Amazon ECS performs periodic container-level health checks. If an endpoint does not pass the health check, it is removed from DNS routing and marked as unhealthy.

**Service discovery considerations**

The following should be considered when using service discovery:

**Interconnecting services**
Service discovery is supported for tasks on Fargate that use platform version 1.1.0 or later. For more information, see Fargate Linux platform versions.

Services configured to use service discovery have a limit of 1,000 tasks per service. This is due to a Route 53 service quota.

The Create Service workflow in the Amazon ECS console only supports registering services into private DNS namespaces. When an AWS Cloud Map private DNS namespace is created, a Route 53 private hosted zone will be created automatically.

The VPC DNS attributes must be configured for successful DNS resolution. For information about how to configure the attributes, see DNS support in your VPC in the Amazon VPC User Guide.

The DNS records created for a service discovery service always register with the private IP address for the task, rather than the public IP address, even when public namespaces are used.

Service discovery requires that tasks specify either the awsvpc, bridge, or host network mode (none is not supported).

If the service task definition uses the awsvpc network mode, you can create any combination of A or SRV records for each service task. If you use SRV records, a port is required.

If the service task definition uses the bridge or host network mode, the SRV record is the only supported DNS record type. Create a SRV record for each service task. The SRV record must specify a container name and container port combination from the task definition.

DNS records for a service discovery service can be queried within your VPC. They use the following format: <service discovery service name>.<service discovery namespace>.

When doing a DNS query on the service name, A records return a set of IP addresses that correspond to your tasks. SRV records return a set of IP addresses and ports for each task.

If you have eight or fewer healthy records, Route 53 responds to all DNS queries with all of the healthy records.

When all records are unhealthy, Route 53 responds to DNS queries with up to eight unhealthy records.

You can configure service discovery for a service that's behind a load balancer, but service discovery traffic is always routed to the task and not the load balancer.

Service discovery doesn't support the use of Classic Load Balancers.

We recommend you use container-level health checks managed by Amazon ECS for your service discovery service.
• **HealthCheckCustomConfig**—Amazon ECS manages health checks on your behalf. Amazon ECS uses information from container and health checks, and your task state, to update the health with AWS Cloud Map. This is specified using the `--health-check-custom-config` parameter when creating your service discovery service. For more information, see `HealthCheckCustomConfig` in the *AWS Cloud Map API Reference*.

• The AWS Cloud Map resources created when service discovery is used must be cleaned up manually.

• Tasks and instances are registered as UNHEALTHY until the container health checks return a value. If the health checks pass, the status is updated to HEALTHY. If the container health checks fail, the service discovery instance is deregistered.

**Service discovery pricing**

Customers using Amazon ECS service discovery are charged for Route 53 resources and AWS Cloud Map discovery API operations. This involves costs for creating the Route 53 hosted zones and queries to the service registry. For more information, see [AWS Cloud Map Pricing](https://aws.amazon.com/cloud-map/pricing) in the *AWS Cloud Map Developer Guide*.

Amazon ECS performs container level health checks and exposes them to AWS Cloud Map custom health check API operations. This is currently made available to customers at no extra cost. If you configure additional network health checks for publicly exposed tasks, you're charged for those health checks.

**Protect your Amazon ECS tasks from being terminated by scale-in events**

You can use Amazon ECS task scale-in protection to protect your tasks from being terminated by scale-in events from either [Service Auto Scaling](https://docs.aws.amazon.com/autoscaling/ec2/userguide/scale-in-events.html) or deployments.

Certain applications require a mechanism to safeguard mission-critical tasks from termination by scale-in events during times of low utilization or during service deployments. For example:

• You have a queue-processing asynchronous application such as a video transcoding job where some tasks need to run for hours even when cumulative service utilization is low.

• You have a gaming application that runs game servers as Amazon ECS tasks that need to continue running even if all users have logged-out to reduce start-up latency of a server reboot.
When you deploy a new code version, you need tasks to continue running because it would be expensive to reprocess.

To protect tasks that belong to your service from terminating in a scale-in event, set the protectionEnabled attribute to true. By default, tasks are protected for 2 hours. You can customize the protection period by using the expiresInMinutes attribute. You can protect your tasks for a minimum of 1 minute and up to a maximum of 2880 minutes (48 hours).

After a task finishes its requisite work, you can set the protectionEnabled attribute to false, allowing the task to be terminated by subsequent scale-in events.

**Task scale-in protection mechanisms**

You can set and get task scale-in protection using either the Amazon ECS container agent endpoint or the Amazon ECS API.

- **Amazon ECS container agent endpoint**

  We recommend using the Amazon ECS container agent endpoint for tasks that can self-determine the need to be protected. Use this approach for queue-based or job-processing workloads.

  When a container starts processing work, for example by consuming an SQS message, you can set the ProtectionEnabled attribute through the task scale-in protection endpoint path $ECS_AGENT_URI/task-protection/v1/state from within the container. Amazon ECS will not terminate this task during scale-in events. After your task finishes its work, you can clear the ProtectionEnabled attribute using the same endpoint, making the task eligible for termination during subsequent scale-in events.

  For more information about the Amazon ECS container agent endpoint, see [Amazon ECS task scale-in protection endpoint](#).

- **Amazon ECS API**

  You can use the Amazon ECS API to set and retrieve task scale-in protection if your application has a component that tracks the status of active tasks. Use UpdateTaskProtection to mark one or more tasks as protected. Use GetTaskProtection to retrieve the protection status.

  An example of this approach would be if your application is hosting game server sessions as Amazon ECS tasks. When a user logs in to a session on the server (task), you can mark the task as...
protected. After the user logs out, you can either clear the protection specifically for this task or periodically clear protection for similar tasks that no longer have active sessions, depending on your requirement to keep idle servers.

For more information, see `UpdateTaskProtection` and `GetTaskProtection` in the *Amazon Elastic Container Service API Reference*.

You can combine both approaches. For example, use the Amazon ECS agent endpoint to set task protection from within a container and use the Amazon ECS API to remove task protection from your external controller service.

**Considerations**

Consider the following points before using task scale-in protection:

- We recommend using the Amazon ECS container agent endpoint because the Amazon ECS agent has built-in retry mechanisms and a simpler interface.
- You can reset the task scale-in protection expiration period by calling `UpdateTaskProtection` for a task that already has protection turned on.
- Determine how long a task would need to complete its requisite work and set the `expiresInMinutes` property accordingly. If you set the protection expiration longer than necessary, then you will incur costs and face delays in the deployment of new tasks.
- Task scale-in protection is supported on Amazon ECS container agent 1.65.0 or later.

You can add support for this feature on Amazon EC2 instances using older versions of the Amazon ECS container agent by updating the agent to the latest version. For more information, see [Updating the Amazon ECS container agent](#).

- Deployment considerations:
  - If the service uses a rolling update, new tasks will be created but tasks running older version will not be terminated until `protectionEnabled` is cleared or expires. You can adjust the `maximumPercentage` parameter in deployment configuration to a value that allows new tasks to be created when old tasks are protected.
  - If a blue/green update is applied, the blue deployment with protected tasks will not be removed if tasks have `protectionEnabled`. Traffic will be diverted to the new tasks that come up and older tasks will only be removed when `protectionEnabled` is cleared or expires. Depending on the timeout of the CodeDeploy or CloudFormation updates, the deployment may timeout and the older Blue tasks may still be present.
• If you use CloudFormation, the update-stack has a 3 hour timeout. Therefore, if you set your task protection for longer than 3 hours, then your CloudFormation deployment may result in failure and rollback.

During the time your old tasks are protected, the CloudFormation stack shows UPDATE_IN_PROGRESS. If task scale-in protection is removed or expires within the 3 hour window, your deployment will succeed and move to the UPDATE_COMPLETE status. If the deployment is stuck in UPDATE_IN_PROGRESS for more than 3 hours, it will fail and show UPDATE_FAILED state, and will then be rolled back to old task set.

• Amazon ECS sends service events when protected tasks keep a deployment (rolling or blue/green) from reaching the steady state, so that you can take remedial actions. While trying to update the protection status of a task, if you receive a DEPLOYMENT_BLOCKED error message, it means the service has more protected tasks than the desired count of tasks for the service. To resolve this error, do one the following:
  • Wait for the current task protection to expire. Then set task protection.
  • Determine which tasks can be stopped. Then use UpdateTaskProtection with the protectionEnabled option set to false for these tasks.
  • Increase the desired task count of the service to more than the number of protected tasks.

IAM permissions required for task scale-in protection

The ask must have the Amazon ECS task role with the following permissions:

• ecs:GetTaskProtection: Allows the Amazon ECS container agent to call GetTaskProtection.

• ecs:UpdateTaskProtection: Allows the Amazon ECS container agent to call UpdateTaskProtection.

Amazon ECS task scale-in protection endpoint

The Amazon ECS container agent automatically injects the ECS_AGENT_URI environment variable into the containers of Amazon ECS tasks to provide a method to interact with the container agent API endpoint.

We recommend using the Amazon ECS container agent endpoint for tasks that can self-determine the need to be protected.
When a container starts processing work, you can set the `protectionEnabled` attribute using the task scale-in protection endpoint path `$ECS_AGENT_URI/task-protection/v1/state` from within the container.

Use a PUT request to this URI from within a container to set task scale-in protection. A GET request to this URI returns the current protection status of a task.

**Task scale-in protection request parameters**

You can set task scale-in protection using the `${ECS_AGENT_URI}/task-protection/v1/state` endpoint with the following request parameters.

**ProtectionEnabled**

Specify `true` to mark a task for protection. Specify `false` to remove protection and make the task eligible for termination.

  - Type: Boolean
  - Required: Yes

**ExpiresInMinutes**

The number of minutes the task is protected. You can specify a minimum of 1 minute to up to 2,880 minutes (48 hours). During this time period, your task will not be terminated by scale-in events from service Auto Scaling or deployments. After this time period lapses, the `protectionEnabled` parameter is set to `false`.

  - If you don't specify the time, then the task is automatically protected for 120 minutes (2 hours).

  - Type: Integer
  - Required: No

The following examples show how to set task protection with different durations.

**Example of how to protect a task with the default time period**

This example shows how to protect a task with the default time period of 2 hours.

```bash
curl --request PUT --header 'Content-Type: application/json' ${ECS_AGENT_URI}/task-protection/v1/state --data '{"ProtectionEnabled":true}'
```
Example of how to protect a task for 60 minutes

This example shows how to protect a task for 60 minutes using the expiresInMinutes parameter.

```
curl --request PUT --header 'Content-Type: application/json' ${ECS_AGENT_URI}/task-protection/v1/state --data '{"ProtectionEnabled":true,"ExpiresInMinutes":60}'
```

Example of how to protect a task for 24 hours

This example shows how to protect a task for 24 hours using the expiresInMinutes parameter.

```
curl --request PUT --header 'Content-Type: application/json' ${ECS_AGENT_URI}/task-protection/v1/state --data '{"ProtectionEnabled":true,"ExpiresInMinutes":1440}'
```

The PUT request returns the following response.

```
{
   "protection": {
      "ExpirationDate": "2023-12-20T21:57:44.837Z",
      "ProtectionEnabled": true,
      "TaskArn": "arn:aws:ecs:us-west-2:111122223333:task/1234567890abcdef0"
   }
}
```

Task scale-in protection response parameters

The following information is returned from the task scale-in protection endpoint ${ECS_AGENT_URI}/task-protection/v1/state in the JSON response.

ExpirationDate

   The epoch time when protection for the task will expire. If the task is not protected, this value is null.

ProtectionEnabled

   The protection status of the task. If scale-in protection is enabled for a task, the value is true. Otherwise, it is false.

TaskArn

   The full Amazon Resource Name (ARN) of the task that the container belongs to.
The following example shows the details returned for a protected task.

```bash
curl --request GET ${ECS_AGENT_URI}/task-protection/v1/state
```

```
{
  "protection":{
    "ExpirationDate": "2023-12-20T21:57:44Z",
    "ProtectionEnabled": true,
    "TaskArn": "arn:aws:ecs:us-west-2:111122223333:task/1234567890abcdef0"
  }
}
```

The following information is returned when a failure occurs.

**Arn**

The full Amazon Resource Name (ARN) of the task.

**Detail**

The details related to the failure.

**Reason**

The reason for the failure.

The following example shows the details returned for a task that is not protected.

```
{
  "failure":{
    "Arn": "arn:aws:ecs:us-west-2:111122223333:task/1234567890abcdef0",
    "Detail": null,
    "Reason": "TASK_NOT_VALID"
  }
}
```

The following information is returned when an exception occurs.

**requestID**

The AWS request ID for the Amazon ECS API call that results in an exception.
Arn

The full Amazon Resource Name (ARN) of the task or service.

Code

The error code.

Message

The error message.

**Note**

If a RequestError or RequestTimeout error appears, it is likely that it's a networking issue. Try using VPC endpoints for Amazon ECS.

The following example shows the details returned when an error occurs.

```json
{
   "requestID":"12345-abc-6789-0123-abc",
   "error":{
      "Arn":"arn:aws:ecs:us-west-2:555555555555:task/my-cluster-name/1234567890abcdef0",
      "Code":"AccessDeniedException",
      "Message":"User: arn:aws:sts::444455556666:assumed-role/my-ecs-task-role/1234567890abcdef0 is not authorized to perform: ecs:GetTaskProtection on resource: arn:aws:ecs:us-west-2:555555555555:task/test/1234567890abcdef0 because no identity-based policy allows the ecs:GetTaskProtection action"
   }
}
```

The following error appears if the Amazon ECS agent is unable to get a response from the Amazon ECS endpoint for reasons such as network issues or the Amazon ECS control plane is down.

```json
{
   "error": {
      "Arn": "arn:aws:ecs:us-west-2:555555555555:task/my-cluster-name/1234567890abcdef0",
      "Code": "RequestCanceled",
      "Message": "Timed out calling Amazon ECS Task Protection API"
   }
}
```
The following error appears when the Amazon ECS agent gets a throttling exception from Amazon ECS.

```json
{
  "requestID": "12345-abc-6789-0123-abc",
  "error": {
    "Arn": "arn:aws:ecs:us-west-2:555555555555:task/my-cluster-name/1234567890abcdef0",
    "Code": "ThrottlingException",
    "Message": "Rate exceeded"
  }
}
```

**Amazon ECS service throttle logic**

The Amazon ECS service scheduler includes logic that throttles how often service tasks are launched if they repeatedly fail to start.

If tasks for a service repeatedly fail to enter the **RUNNING** state (progressing directly from a **PENDING** to a **STOPPED** status), then the time between subsequent restart attempts is incrementally increased up to a maximum of 27 minutes. This maximum period is subject to change in the future. This behavior reduces the effect that failing tasks have on your Amazon ECS cluster resources or Fargate infrastructure costs. If your service initiates the throttle logic, you receive the following **service event message**:

```
(service service-name) is unable to consistently start tasks successfully.
```

Amazon ECS doesn't ever stop a failing service from retrying. It also doesn't attempt to modify it in any way other than increasing the time between restarts. The service throttle logic doesn't provide any user-tunable parameters.

If you update your service to use a new task definition, your service returns to a normal, non-throttled state immediately. For more information, see [Updating a service using the console](#).

The following are some common causes that initiate this logic. We recommend that you take manual action to address the issue:

- A lack of resources to host your task with, such as ports, memory, or CPU units in your cluster. In this case, you also see the **insufficient resource service event message**.
• The Amazon ECS container agent can't pull your task Docker image. This might be because a bad container image name, image, or tag, or a lack of private registry authentication or permissions. In this case, you also see CannotPullContainerError in your stopped task errors.

• Insufficient disk space on your container instance to create the container. In this case, you also see CannotCreateContainerError in your stopped task errors. For more information, see CannotCreateContainerError: API error (500): devmapper.

⚠️ **Important**

Tasks that are stopped after they reach the RUNNING state don't start the throttle logic or the associated service event message. For example, assume that failed Elastic Load Balancing health checks for a service cause a task to be flagged as unhealthy, and Amazon ECS deregisters it and stops the task. At this point, the tasks aren't throttled. Even if a task’s container command immediately exits with a non-zero exit code, the task already moved to the RUNNING state. Tasks that fail immediately because command errors don't cause the throttle or the service event message.
Amazon ECS resource tagging

To help you manage your Amazon ECS resources, you can optionally assign your own metadata to each resource using tags. Each tag consists of a key and an optional value.

You can use tags to categorize your Amazon ECS resources in different ways, for example, by purpose, owner, or environment. This is useful when you have many resources of the same type. You can quickly identify a specific resource based on the tags that you assigned to it. For example, you can define a set of tags for your account's Amazon ECS container instances. This helps you track each instance's owner and stack level.

You can use tags for your Cost and Usage reports. You can use these reports to analyze the cost and usage of your Amazon ECS resources. For more information, see the section called “Usage Reports”.

⚠️ Warning

There are many APIs that return tag keys and their values. Denying access to DescribeTags doesn't automatically deny access to tags returned by other APIs. As a best practice, we recommend that you do not include sensitive data in your tags.

We recommend that you devise a set of tag keys that meets your needs for each resource type. You can use a consistent set of tag keys for easier management of your resources. You can search and filter the resources based on the tags you add.

Tags don't have any semantic meaning to Amazon ECS and are interpreted strictly as a string of characters. You can edit tag keys and values, and you can remove tags from a resource at any time. You can set the value of a tag to an empty string, but you can't set the value of a tag to null. If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the earlier value. When you delete a resource, any tags for the resource are also deleted.

If you use AWS Identity and Access Management (IAM), you can control which users in your AWS account have permission to manage tags.

How resources are tagged

There are multiple ways that Amazon ECS tasks, services, task definitions, and clusters are tagged:
- A user manually tags a resource by using the AWS Management Console, Amazon ECS API, the AWS CLI, or an AWS SDK.

- A user creates a service or runs a standalone task and selects the Amazon ECS-managed tags option.

Amazon ECS automatically tags all newly launched tasks. For more information, see the section called “Amazon ECS-managed tags”.

- A user creates a resource using the console. The console automatically tags the resources.

These tags are returned in the AWS CLI, and AWS SDK responses and are displayed in the console. You cannot modify or delete these tags.

For information about the added tags, see the Tags automatically added by the console column in the Tagging support for Amazon ECS resources table.

If you specify tags when you create a resource and the tags can't be applied, Amazon ECS rolls back the creation process. This ensures that resources are either created with tags or not created at all, and that no resources are left untagged at any time. By tagging resources while they're being created, you can eliminate the need to run custom tagging scripts after resource creation.

The following table describes the Amazon ECS resources that support tagging.

### Tagging support for Amazon ECS resources

<table>
<thead>
<tr>
<th>Resource</th>
<th>Supports tags</th>
<th>Supports tag propagation</th>
<th>Tags automatically added by the console</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon ECS tasks</td>
<td>Yes</td>
<td>Yes, from the task definition.</td>
<td>Key: <code>aws:ecs:clusterName</code> Value: <code>cluster-name</code></td>

</tbody>
</table>
### Tagging resources on creation

The following resources support tagging on creation using the Amazon ECS API, AWS CLI, or AWS SDK:

- Amazon ECS tasks
- Amazon ECS services
- Amazon ECS task definition
- Amazon ECS task sets
- Amazon ECS clusters
- Amazon ECS container instances
- Amazon ECS capacity providers

<table>
<thead>
<tr>
<th>Resource</th>
<th>Supports tags</th>
<th>Supports tag propagation</th>
<th>Tags automatically added by the console</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon ECS container instances</td>
<td>Yes</td>
<td>Yes, from the Amazon EC2 instance. For more information, see Adding tags to an Amazon EC2 container instance.</td>
<td>N/A</td>
</tr>
<tr>
<td>Amazon ECS External instances</td>
<td>Yes</td>
<td>No</td>
<td>N/A</td>
</tr>
<tr>
<td>Amazon ECS capacity provider</td>
<td>Yes. You cannot tag the predefined FARGATE and FARGATE_SPOT capacity providers.</td>
<td>No</td>
<td>N/A</td>
</tr>
</tbody>
</table>
Amazon ECS has the option to use tagging authorization for resource creation. When the AWS account is configured for tagging authorization, users must have permissions for actions that create the resource, such as `ecsCreateCluster`. If you specify tags in the resource-creating action, AWS performs additional authorization to verify if users or roles have permissions to create tags. Therefore, you must grant explicit permissions to use the `ecs:TagResource` action. For more information, see the section called “Tag resources during creation”. For information about how to configure the option, see the section called “Tagging authorization”.

**Restrictions**

The following restrictions apply to tags:

- A maximum of 50 tags can be associated with a resource.
- Tag keys can't be repeated for one resource. Each tag key must be unique, and can only have one value.
- Keys can be up to 128 characters long in UTF-8.
- Values can be up to 256 characters long in UTF-8.
- If multiple AWS services and resources use your tagging schema, limit the types of characters you use. Some services might have restrictions on allowed characters. Generally, allowed characters are letters, numbers, spaces, and the following characters: + - . _ : / @.
- Tag keys and values are case sensitive.
- You can't use `aws:`, `AWS:`, or any upper or lowercase combination of such as a prefix for either keys or values. These are reserved only for AWS use. You can't edit or delete tag keys or values with this prefix. Tags with this prefix don't count against your tags-per-resource limit.

**Amazon ECS-managed tags**

When you use Amazon ECS-managed tags, Amazon ECS automatically tags all newly launched tasks and any Amazon EBS volumes attached to the tasks with the cluster information and either the user-added task definition tags or the service tags. The following describes the added tags:

- Standalone tasks – a tag with a *Key* as `aws:ecs:clusterName` and a *Value* set to the cluster name. All task definition tags that were added by users. An Amazon EBS volume attached to a standalone task will receive the tag with a *Key* as `aws:ecs:clusterName` and a *Value* set to the cluster name. For more information about Amazon EBS volume tagging, see [Tagging Amazon EBS volumes](#).
Tasks that are part of a service – a tag with a Key as `aws:ecs:clusterName` and a Value set to the cluster name. A tag with a Key as `aws:ecs:serviceName` and a Value set to the service name. Tags from one of the following resources:

- Task definitions – All task definition tags that were added by users.
- Services – All service tags that were added by users.

An Amazon EBS volume attached to a task that is part of a service will receive a tag with a Key as `aws:ecs:clusterName` and a Value set to the cluster name, and a tag with a Key as `aws:ecs:serviceName` and a Value set to the service name. For more information about Amazon EBS volume tagging, see [Tagging Amazon EBS volumes](#).

The following options are required for this feature:

- You must opt in to the new Amazon Resource Name (ARN) and resource identifier (ID) formats. For more information, see [Amazon Resource Names (ARNs) and IDs](#).
- When you use the APIs to create a service or run a task, you must set `enableECSManagedTags` to `true` for `run-task` and `create-service`. For more information, see [create-service](#) and [run-task](#) in the [AWS Command Line Interface API Reference](#).
- Amazon ECS uses managed tags to determine when some features are enabled, for example cluster Auto Scaling. We recommend that you do not manually modify tags so that the Amazon ECS can effectively manage the features.

**Tagging your resources for billing**

AWS provides a reporting tool called Cost Explorer that you can use to analyze the cost and usage of your Amazon ECS resources.

You can use Cost Explorer to view charts of your usage and costs. You can view data from the last 13 months, and forecast how much you're likely to spend for the next three months. You can use Cost Explorer to see patterns in how much you spend on AWS resources over time. For example, you can use it to identify areas that need further inquiry and see trends that you can use to understand your costs. You also can specify time ranges for the data, and view time data by day or by month.

You can use Amazon ECS-managed tags or user-added tags for your Cost and Usage Report. For more information, see [Amazon ECS usage reports](#).
To see the cost of your combined resources, you can organize your billing information based on resources that have the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information about setting up a cost allocation report with tags, see The Monthly Cost Allocation Report in the AWS Billing User Guide.

Additionally, you can turn on Split Cost Allocation Data to get task-level CPU and memory usage data in your Cost and Usage Reports. For more information, see Task-level Cost and Usage Reports.

### Note

If you've turned on reporting, it can take up to 24 hours before the data for the current month is available for viewing.

---

## Working with tags using the console

You can use the Amazon ECS console, you can manage the tags that are associated with new or existing tasks, services, task definitions, clusters, or container instances.

When you select a resource-specific page in the Amazon ECS console, it displays a list of those resources. For example, if you select Clusters from the navigation pane, the console displays a list of Amazon ECS clusters. When you select a resource from one of these lists (for example, a specific cluster) that supports tags, you can view and manage its tags on the Tags tab.

### Warning

As a best practice, we recommend that you do not include sensitive data in your tags.

---

### Contents

- Adding tags on an individual resource during launch
- Managing individual resource tags

---

## Adding tags on an individual resource during launch

You can use the following resources to specify tags when you create the resource.
### Managing individual resource tags

You can add or delete tags that are associated with your clusters, services, tasks, and task definitions directly from the resource's page. For information about tagging your container instances, see [Adding tags to an Amazon EC2 container instance](#).
Warning
Do not add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including billing. Tags are not intended to be used for private or sensitive data.

To modify a tag for an individual resource

2. From the navigation bar, select the AWS Region to use.
3. In the navigation pane, select a resource type (for example, Clusters).
4. Select the resource from the resource list, choose the Tags tab, and then choose Manage tags.
5. Configure your tags.

[Add a tag] Choose Add tag, and then do the following:

- For Key, enter the key name.
- For Value, enter the key value.

[Remove a tag] Choose Remove to the right of the tag’s Key and Value.
6. Choose Save.

Adding tags to an Amazon EC2 container instance

You can associate tags with your container instances using one of the following methods:

- Method 1 – When creating the container instance using the Amazon EC2 API, CLI, or console, specify tags by passing user data to the instance using the container agent configuration parameter ECS_CONTAINER_INSTANCE_TAGS. This creates tags that are associated with the container instance in Amazon ECS only, they cannot be listed using the Amazon EC2 API. For more information, see Bootstrapping container instances with Amazon EC2 user data.
**Important**

If you launch your container instances using an Amazon EC2 Auto Scaling group, then you should use the ECS_CONTAINER_INSTANCE_TAGS agent configuration parameter to add tags. This is due to the way in which tags are added to Amazon EC2 instances that are launched using Auto Scaling groups.

The following is an example of a user data script that associates tags with your container instance:

```
#!/bin/bash

ECS_CLUSTER=MyCluster
ECS_CONTAINER_INSTANCE_TAGS={"tag_key": "tag_value"}

EOF
```

- **Method 2** – When you create your container instance using the Amazon EC2 API, CLI, or console, first specify tags using the TagSpecification.N parameter. Then, pass user data to the instance by using the container agent configuration parameter ECS_CONTAINER_INSTANCE_PROPAGATE_TAGS_FROM. Doing so propagates them from Amazon EC2 to Amazon ECS.

The following is an example of a user data script that propagates the tags that are associated with an Amazon EC2 instance, and registers the instance with a cluster that's named MyCluster.

```
#!/bin/bash

ECS_CLUSTER=MyCluster
ECS_CONTAINER_INSTANCE_PROPAGATE_TAGS_FROM=ec2_instance

EOF
```

To provide access to allow container instance tags to propagate from Amazon EC2 to Amazon ECS, manually add the following permissions as an inline policy to the Amazon ECS container instance IAM role. For more information, see [Adding and Removing IAM Policies](#).

- ec2:DescribeTags

The following is an example policy that's used to add these permissions.
Tagging an external container instance

You can associate tags with your external container instances by using one of the following methods.

- **Method 1** – Before running the installation script to register your external instance with your cluster, create or edit the Amazon ECS container agent configuration file at `/etc/ecs/ecs.config` and add the `ECS_CONTAINER_INSTANCE_TAGS` container agent configuration parameter. This creates tags that are associated with the external instance.

  The following is example syntax.

  ```
  ECS_CONTAINER_INSTANCE_TAGS={"tag_key": "tag_value"}
  ```

- **Method 2** – After your external instance is registered to your cluster, you can use the AWS Management Console to add tags. For more information, see [Managing individual resource tags](#).

**Working with tags using the CLI or API**

You can use the AWS Command Line Interface or API to tag your Amazon ECS resources.

Use the following to add, update, list, and delete the tags for your resources. The corresponding documentation provides examples.
### Warning

Don't add personally identifiable information (PII) or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including billing. Tags aren't intended to be used for private or sensitive data.

---

### Tagging support for Amazon ECS resources

<table>
<thead>
<tr>
<th>Task</th>
<th>AWS CLI</th>
<th>API action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add or overwrite one or more tags.</td>
<td><code>tag-resource</code></td>
<td><code>TagResource</code></td>
</tr>
<tr>
<td>Delete one or more tags.</td>
<td><code>untag-resource</code></td>
<td><code>UntagResource</code></td>
</tr>
</tbody>
</table>

You can use some resource-creating actions to specify tags when you create the resource. The following actions support tagging on creation.

You must have the `ecsTagResource` permission. For more information, see [Grant permission to tag resources on creation](#).

<table>
<thead>
<tr>
<th>Task</th>
<th>AWS CLI</th>
<th>AWS Tools for Windows PowerShell</th>
<th>API Action</th>
</tr>

</tr>
<tr>
<td>Register a task definition.</td>
<td><code>register-task-definition</code></td>
<td><code>Register-ECSTaskDefinition</code></td>
<td><code>RegisterTaskDefinition</code></td>
</tr>
</tbody>
</table>
### Amazon Elastic Container Service

**Task** | **AWS CLI** | **AWS Tools for Windows PowerShell** | **API Action**
---|---|---|---
Create a cluster. | `create-cluster` | `New-ECSCluster` | `CreateCluster`
Run one or more container instances. | `run-instances` | `New-EC2Instance` | `RunInstances`

### Amazon ECS usage reports

AWS provides a reporting tool called Cost Explorer that you can use to analyze the cost and usage of your Amazon ECS resources.

You can use Cost Explorer to view charts of your usage and costs. You can view data from the last 13 months, and forecast how much you're likely to spend for the next three months. You can use Cost Explorer to see patterns in how much you spend on AWS resources over time. For example, you can use it to identify areas that need further inquiry and see trends that you can use to understand your costs. You also can specify time ranges for the data, and view time data by day or by month.

The metering data in your Cost and Usage Report shows usage across all of your Amazon ECS tasks. The metering data includes CPU usage as `vCPU-Hours` and memory usage as `GB-Hours` for each task that was run. How that data is presented depends on the launch type of the task.

For tasks using the Fargate launch type, the `lineItem/Operation` column shows `FargateTask` and you will see the cost associated with each task.

For tasks that use the EC2 launch type, the `lineItem/Operation` column shows `ECSTask-EC2` and the tasks don't have a direct cost associated with them. The metering data that's shown in the report, such as memory usage, represents the total resources that the task reserved over the billing period that you specify. You can use this data to determine the cost of your underlying cluster of Amazon EC2 instances. The cost and usage data for your Amazon EC2 instances are listed separately under the Amazon EC2 service.

You can also use the Amazon ECS managed tags to identify the service or cluster that each task belongs to. For more information, see [Tagging your resources for billing](#).
Important

The metering data is only viewable for tasks that are launched on or after November 16, 2018. Tasks that are launched before this date don't show metering data.

The following is an example of some of the fields that you can use to sort cost allocation data in Cost Explorer.

- Cluster name
- Service name
- Resource tags
- Launch type
- AWS Region
- Usage type

For more information about creating an AWS Cost and Usage Report, see AWS Cost and Usage Report in the AWS Billing User Guide.

Task-level Cost and Usage Reports

AWS Cost Management can provide CPU and memory usage data in the AWS Cost and Usage Report for each task on Amazon ECS, including tasks on Fargate and tasks on EC2. This data is called Split Cost Allocation Data. You can use this data to analyze costs and usage for applications. Additionally, you can split and allocate the costs to individual business units and teams with cost allocation tags and cost categories. For more information about Split Cost Allocation Data, see Understanding split cost allocation data in the AWS Cost and Usage Report User Guide.

You can opt in to task-level Split Cost Allocation Data for the account in the AWS Cost Management Console. If you have a management (payer) account, you can opt in from the payer account to apply this configuration to every linked account.

After you set up Split Cost Allocation Data, there will be additional columns under the splitLineItem header in the report. For more information see Split line item details in the AWS Cost and Usage Report User Guide.

For tasks on EC2, this data splits the cost of the EC2 instance based on the resource usage or reservations and the remaining resources on the instance.
Prerequisites

- To use *Split Cost Allocation Data*, you must create a report, and select *Split cost allocation data*. For more information, see [Creating Cost and Usage Reports](#) in the AWS Cost and Usage Report User Guide.

- The minimum Docker version for reliable metrics is Docker version v20.10.13 and newer, which is included in Amazon ECS-optimized AMI 20220607 and newer.

- Ensure that the Amazon ECS agent has the `ECS_DISABLE_METRICS` configuration set to `false`. When this setting is `false`, the Amazon ECS agent sends metrics to Amazon CloudWatch. On Linux, this setting is `false` by default and metrics are sent to CloudWatch. On Windows, this setting is `true` by default, so you must change the setting to `false` to send the metrics to CloudWatch for AWS Cost Management to use. For more information about ECS agent configuration, see [Amazon ECS container agent configuration](#).

**Note**
AWS Cost Management calculates the *Split Cost Allocation Data* with the task CPU and memory usage. AWS Cost Management can use the task CPU and memory reservation instead of the usage, if the usage is unavailable. If you see the CUR is using the reservations, check that your container instances meet the prerequisites and the task resource usage metrics appear in CloudWatch.

Setting up Task-level Cost and Usage Reports

You can turn on *Split Cost Allocation Data* for ECS in the Cost Management Console, AWS Command Line Interface, or the AWS SDKs.

Use the following for *Split Cost Allocation Data*.

2. Include the data in a new or existing report.

3. View the report. You can use the Billing and Cost Management console or view the report files in Amazon Simple Storage Service.
Monitoring Amazon ECS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon ECS and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. Before you start monitoring Amazon ECS, create a monitoring plan that includes answers to the following questions:

• What are your monitoring goals?
• What resources will you monitor?
• How often will you monitor these resources?
• What monitoring tools will you use?
• Who will perform the monitoring tasks?
• Who should be notified when something goes wrong?

The metrics made available depend on the launch type of the tasks and services in your clusters. If you are using the Fargate launch type for your services, then CPU and memory utilization metrics are provided to assist in the monitoring of your services. For the Amazon EC2 launch type, you own and need to monitor the EC2 instances that make your underlying infrastructure. Additional CPU and memory reservation and utilization metrics are made available at the cluster, service, and task.

The next step is to establish a baseline for normal Amazon ECS performance in your environment, by measuring performance at various times and under different load conditions. As you monitor Amazon ECS, store historical monitoring data so that you can compare it with current performance data, identify normal performance patterns and performance anomalies, and devise methods to address issues.

To establish a baseline you should, at a minimum, monitor the following items:

• The CPU and memory reservation and utilization metrics for your Amazon ECS clusters
• The CPU and memory utilization metrics for your Amazon ECS services

For more information, see Viewing Amazon ECS metrics.

Topics
• Best practices for monitoring Amazon ECS

Best practices for monitoring Amazon ECS

Use the following best practices for monitoring Amazon ECS.

• Make monitoring a priority to head off small problems before they become big ones
• Create a monitoring plan that includes answers to the following question
  • What are your monitoring goals?
  • What resources will you monitor?
  • How often will you monitor these resources?
  • What monitoring tools will you use?
  • Who will perform the monitoring tasks?
  • Who should be notified when something goes wrong?
• Automate monitoring as much as possible.
• Check the Amazon ECS log files. For more information, see Amazon ECS log file locations.
Monitoring tools for Amazon ECS

AWS provides various tools that you can use to monitor Amazon ECS. You can configure some of these tools to do the monitoring for you, while some of the tools require manual intervention. We recommend that you automate monitoring tasks as much as possible.

Automated monitoring tools

You can use the following automated monitoring tools to watch Amazon ECS and report when something is wrong:

- Amazon CloudWatch alarms – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see Monitor Amazon ECS using CloudWatch.

  For services with tasks that use the Fargate launch type, you can use CloudWatch alarms to scale in and scale out the tasks in your service based on CloudWatch metrics, such as CPU and memory utilization. For more information, see Automatically scale your Amazon ECS service.

  For clusters with tasks or services using the EC2 launch type, you can use CloudWatch alarms to scale in and scale out the container instances based on CloudWatch metrics, such as cluster memory reservation.

  For your container instances that were launched with the Amazon ECS-optimized Amazon Linux AMI, you can use CloudWatch Logs to view different logs from your container instances in one convenient location. You must install the CloudWatch agent on your container instances. For more information, see Download and configure the CloudWatch agent using the command line in the Amazon CloudWatch User Guide. You must also add the ECS-CloudWatchLogs policy to the ecsInstanceRole role. For more information, see Required permissions for monitoring container instances.

- Amazon CloudWatch Logs – Monitor, store, and access the log files from the containers in your Amazon ECS tasks by specifying the awslogs log driver in your task definitions. For more information, see Using the awslogs log driver.
You can also monitor, store, and access the operating system and Amazon ECS container agent log files from your Amazon ECS container instances. This method for accessing logs can be used for containers using the EC2 launch type.

- Amazon CloudWatch Events – Match events and route them to one or more target functions or streams to make changes, capture state information, and take corrective action. For more information, see Automate responses to Amazon ECS errors using EventBridge in this guide and What Is Amazon CloudWatch Events? in the Amazon CloudWatch Events User Guide.

- Container Insights – Collect, aggregate, and summarize metrics and logs from your containerized applications and microservices. Container Insights collects data as performance log events using embedded metric format. These performance log events are entries that use a structured JSON schema that allow high-cardinality data to be ingested and stored at scale. From this data, CloudWatch creates aggregated metrics at the cluster, task, and service level as CloudWatch metrics. The metrics that Container Insights collects are available in CloudWatch automatic dashboards, and are also viewable in the Metrics section of the CloudWatch console.

- AWS CloudTrail log monitoring – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log processing applications in Java, and validate that your log files have not changed after delivery by CloudTrail. For more information, see Log Amazon ECS API calls using AWS CloudTrail in this guide, and Working with CloudTrail Log Files in the AWS CloudTrail User Guide.

- Runtime Monitoring – Detect threats for clusters and containers within your AWS environment. Runtime Monitoring uses a GuardDuty security agent that adds runtime visibility into individual Amazon ECS workloads, for example, file access, process execution, and network connections.

**Manual monitoring tools**

Another important part of monitoring Amazon ECS involves manually monitoring those items that the CloudWatch alarms don't cover. The CloudWatch, Trusted Advisor, and other AWS console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on your container instances and the containers in your tasks.

- Amazon ECS console:
  - Cluster metrics for the EC2 launch type
  - Service metrics
  - Service health status
• Service deployment events

• CloudWatch home page:
  • Current alarms and status
  • Graphs of alarms and resources
  • Service health status

In addition, you can use CloudWatch to do the following:

• Create [customized dashboards](#) to monitor the services you care about.

• Graph metric data to troubleshoot issues and discover trends.

• Search and browse all your AWS resource metrics.

• Create and edit alarms to be notified of problems.

• Container health check - These are commands that run locally on a container and validate application health and availability. You configure these per container in your task definition.

• AWS Trusted Advisor can help you monitor your AWS resources to improve performance, reliability, security, and cost effectiveness. Four Trusted Advisor checks are available to all users; more than 50 checks are available to users with a Business or Enterprise support plan. For more information, see [AWS Trusted Advisor](#).

  Trusted Advisor has these checks that relate to Amazon ECS:

  • A fault tolerance which indicates that you have a service running in a single Availability Zone.
  • A fault tolerance which indicates that you have not used the spread placement strategy for multiple Availability Zones.

• AWS Compute Optimizer is a service that analyzes the configuration and utilization metrics of your AWS resources. It reports whether your resources are optimal, and generates optimization recommendations to reduce the cost and improve the performance of your workloads.

  For more information, see [AWS Compute Optimizer recommendations for Amazon ECS](#).

**Monitor Amazon ECS using CloudWatch**

You can monitor your Amazon ECS resources using Amazon CloudWatch, which collects and processes raw data from Amazon ECS into readable, near real-time metrics. These statistics are recorded for a period of two weeks so that you can access historical information and gain a better perspective on how your clusters or services are performing. Amazon ECS metric data is
automatically sent to CloudWatch in 1-minute periods. For more information about CloudWatch, see the Amazon CloudWatch User Guide.

Amazon ECS provides free metrics for clusters and services. For an additional cost, you can turn on Amazon ECS CloudWatch Container Insights for your cluster for per-task metrics, including CPU, memory, and EBS filesystem utilization. For more information about Container Insights, see Monitor Amazon ECS containers using Container Insights.

Considerations

The following should be considered when using Amazon ECS CloudWatch metrics.

- Any Amazon ECS service hosted on Fargate has CloudWatch CPU and memory utilization metrics automatically, so you don't need to take any manual steps.

- For any Amazon ECS task or service hosted on Amazon EC2 instances, the Amazon EC2 instance requires version 1.4.0 or later (Linux) or 1.0.0 or later (Windows) of the container agent for CloudWatch metrics to be generated. However, we recommend using the latest container agent version. For information about checking your agent version and updating to the latest version, see Updating the Amazon ECS container agent.

- The minimum Docker version for reliable CloudWatch metrics is Docker version 20.10.13 and newer.

- Your Amazon EC2 instances also require the ecs:StartTelemetrySession permission on the IAM role that you launch your Amazon EC2 instances with. If you created your Amazon ECS container instance IAM role before CloudWatch metrics were available for Amazon ECS, you might need to add this permission. For information about the container instance IAM role and attaching the managed IAM policy for container instances, see Amazon ECS container instance IAM role.

- You can disable CloudWatch metrics collection on your Amazon EC2 instances by setting ECS_DISABLE_METRICS=true in your Amazon ECS container agent configuration. For more information, see Amazon ECS container agent configuration.

Available metrics and dimensions for Amazon ECS

Amazon ECS provides free CloudWatch metrics you can use to monitor your resources.
A metric represents a time-ordered set of data points that are published to CloudWatch. The infrastructure your Amazon ECS tasks are hosted on in your clusters determines which metrics are available.

CloudWatch metrics have namespaces, dimensions, and statistics. Namespaces are used to isolate metrics. The Amazon ECS namespace is `AWS/ECS`.

Dimensions which are name/value pairs that are part of the metric identity. Dimensions are like categories for the metrics. Dimensions for Amazon ECS include `ClusterName`, and `ServiceName`.

*Statistics* are metric data aggregations over specified periods of time. CloudWatch provides statistics based on the metric data points provided by your custom data or provided by other services in AWS to CloudWatch. Aggregations are made using the namespace, metric name, dimensions, and the data point unit of measure, within the time period you specify.

Amazon ECS sends the following metrics to CloudWatch every minute. When Amazon ECS collects metrics, it collects multiple data points every minute. It then aggregates them to one data point before sending the data to CloudWatch. So in CloudWatch, one sample count is actually the aggregate of multiple data points during one minute.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Average</td>
<td>The value of <strong>Sum / SampleCount</strong> during the specified period. By comparing this statistic with the <strong>Minimum</strong> and <strong>Maximum</strong>, you can determine the full scope of a metric and how close the average use is to the <strong>Minimum</strong> and <strong>Maximum</strong>. This comparison helps you to know when to increase or decrease your resources as needed.</td>
</tr>
<tr>
<td>Maximum</td>
<td>The highest value observed during the specified period. You can use this value to determine high volumes of activity for your application.</td>
</tr>
<tr>
<td>Minimum</td>
<td>The lowest value observed during the specified period. You can use this value to determine low volumes of activity for your application.</td>
</tr>
<tr>
<td>SampleCount</td>
<td>The count (number) of data points used for the statistical calculation.</td>
</tr>
<tr>
<td>Sum</td>
<td>All values submitted for the matching metric added together. This statistic can be useful for determining the total volume of a metric.</td>
</tr>
</tbody>
</table>

• Cluster utilization
• Service utilization
• Service RUNNING task count

Amazon ECS metrics

Amazon ECS provides free CloudWatch metrics you can use to monitor your resources. The CPU and memory reservation and the CPU, memory, and EBS filesystem utilization across your cluster as a whole, and the CPU, memory, and EBS filesystem utilization on the services in your clusters can be measured using these metrics. For your GPU workloads, you can measure your GPU reservation across your cluster.

The infrastructure your Amazon ECS tasks are hosted on in your clusters determines which metrics are available. For tasks hosted on Fargate infrastructure, Amazon ECS provides CPU, memory, and EBS filesystem utilization metrics are provided to assist in the monitoring of your services. For tasks hosted on EC2 instances, Amazon ECS provides CPU, memory, and GPU reservation metrics and CPU and memory utilization metrics at the cluster and service level. You need to monitor the Amazon EC2 instances that make your underlying infrastructure separately. For more information about monitoring your Amazon EC2 instances, see Monitoring Amazon EC2 in the Amazon EC2 User Guide for Linux Instances.

The AWS/ECS namespace in CloudWatch includes the following metrics.

CPUReservation

The percentage of CPU units that are reserved in the cluster or service.

The CPU reservation (filtered by ClusterName) is measured as the total CPU units that are reserved by Amazon ECS tasks on the cluster, divided by the total CPU units for all of the Amazon EC2 instances registered in the cluster. Only Amazon EC2 instances in ACTIVE or DRAINING status will affect CPU reservation metrics. The metric is only supported for tasks hosted on an Amazon EC2 instance.
Reason to use: You can use this alarm to determine when to scale-out or add additional capacity.

Recommended value: We recommend that you set this metric to 90%. We do not recommend that you use this alarm when you have EC2 capacity providers with managed scaling turned on, or you have Fargate capacity providers. In these cases, Amazon ECS manages scaling on your behalf.

Valid dimensions: ClusterName.

Useful statistics: Average, Minimum, Maximum

Unit: Percent.

CPUUtilization

The percentage of CPU units that is used by the cluster or service.

The cluster-level CPU utilization (filtered by ClusterName) is measured as the total CPU units that are in use by Amazon ECS tasks on the cluster, divided by the total CPU units for all of the Amazon EC2 instances registered in the cluster. Only Amazon EC2 instances in ACTIVE or DRAINING status will affect CPU reservation metrics. The cluster-level metric is only supported for tasks hosted on an Amazon EC2 instance.

The service-level CPU utilization (filtered by ClusterName, ServiceName) is measured as the total CPU units in use by the tasks that belong to the service, divided by the total number of CPU units that are reserved for the tasks that belong to the service. The service-level metric is supported for tasks hosted on Amazon EC2 instances and Fargate.

Reason to use: You can use this metric to determine when to add more CPU for your instances or tasks so that there are no resource bottleneck or application performance problems.

Recommended value: Even though the service-level metric might exceed 100% utilization, we recommend that you set the threshold to 90-95%. This can help to avoid an impact to other services. We recommend that you update your task definitions to reflect the actual usage to prevent future issues with services.

Valid dimensions: ClusterName, ServiceName.

Useful statistics: Average, Minimum, Maximum

Unit: Percent.
MemoryReservation

The percentage of memory that is reserved by running tasks in the cluster.

Cluster memory reservation is measured as the total memory that is reserved by Amazon ECS tasks on the cluster, divided by the total amount of memory for all of the Amazon EC2 instances registered in the cluster. This metric can only be filtered by ClusterName. Only Amazon EC2 instances in ACTIVE or DRAINING status will affect memory reservation metrics. The cluster level memory reservation metric is only supported for tasks hosted on an Amazon EC2 instance.

**Note**

When calculating memory utilization, if MemoryReservation is specified, it's used in the calculation instead of total memory.

Reason to use: You can use this metric to determine when to scale out the cluster. Reaching the total memory units for the cluster can cause the cluster to be unable to launch new tasks.

Recommended value: We recommend that you set this metric to 90%. We do not recommend that you use this alarm when you have EC2 capacity providers with managed scaling turned on, or you have Fargate capacity providers. In these cases, Amazon ECS manages scaling on your behalf.

Valid dimensions: ClusterName.

Useful statistics: Average, Minimum, Maximum

Unit: Percent.

MemoryUtilization

The percentage of memory in use by the cluster or service.

The cluster-level memory utilization (filtered by ClusterName) is measured as the total memory in use by Amazon ECS tasks on the cluster, divided by the total memory for all of the Amazon EC2 instances registered in the cluster. Only Amazon EC2 instances in ACTIVE or DRAINING status will affect memory utilization metrics. The cluster-level metric is only supported for tasks hosted on an Amazon EC2 instance.
The service-level memory utilization (filtered by ClusterName, ServiceName) is measured as the total memory in use by the tasks that belong to the service, divided by the total memory reserved for the tasks that belong to the service. The service-level metric is supported for tasks hosted on Amazon EC2 instances and Fargate.

Reason to use: You can use this metric to determine when to add more memory for your instances or tasks so that there are no resource bottleneck or application performance problems.

Recommended value: We recommend that you set the threshold to 90-95%. This can help to avoid an impact to other services. We recommend that you update your task definitions to reflect the actual usage to prevent future issues with services.

Valid dimensions: ClusterName, ServiceName.

Useful statistics: Average, Minimum, Maximum

Unit: Percent.

EBSFilesystemUtilization

The percentage of the Amazon EBS filesystem that is used by tasks in a service.

The service level EBS filesystem utilization metric (filtered by ClusterName, ServiceName) is measured as the total amount of the EBS filesystem in use by the tasks that belong to the service, divided by the total amount of EBS filesystem storage that is allocated for all tasks that belong to the service. The service level EBS filesystem utilization metric is only available for tasks hosted on Amazon EC2 instances (using container agent version 1.79.0) and Fargate (using platform version 1.4.0) that have an EBS volume attached.

Note
For tasks hosted on Fargate, there is space on the disk that is only used by Fargate. There is no cost associated with the space Fargate uses, but you will see this additional storage using tools like df.

Valid dimensions: ClusterName, ServiceName.

Useful statistics: Average, Minimum, Maximum
GPUReservation

The percentage of total available GPUs that are reserved by running tasks in the cluster.

The cluster level GPU reservation metric is measured as the number of GPUs reserved by Amazon ECS tasks on the cluster, divided by the total number of GPUs that was available on all of the Amazon EC2 instances with GPUs registered in the cluster. Only Amazon EC2 instances in ACTIVE or DRAINING status will affect GPU reservation metrics.

Valid dimensions: ClusterName.

Useful statistics: Average, Minimum, Maximum

All statistics: Average, Minimum, Maximum, Sum, Sample Count.

Unit: Percent.

ActiveConnectionCount

The total number of concurrent connections active from clients to the Amazon ECS Service Connect proxies that run in tasks that share the selected DiscoveryName.

This metric is only available if you have configured Amazon ECS Service Connect.

Valid dimensions: DiscoveryName and DiscoveryName, ServiceName, ClusterName.

Useful statistics: Average, Minimum, Maximum, Sum.

Unit: Count.

NewConnectionCount

The total number of new connections established from clients to the Amazon ECS Service Connect proxies that run in tasks that share the selected DiscoveryName.

This metric is only available if you have configured Amazon ECS Service Connect.

Valid dimensions: DiscoveryName and DiscoveryName, ServiceName, ClusterName.

Useful statistics: Average, Minimum, Maximum, Sum.
Unit: Count.

ProcessedBytes

The total number of bytes of inbound traffic processed by the Service Connect proxies.

This metric is only available if you have configured Amazon ECS Service Connect.

Valid dimensions: DiscoveryName and DiscoveryName, ServiceName, ClusterName.

Useful statistics: Average, Minimum, Maximum, Sum.

Unit: Bytes.

RequestCount

The number of inbound traffic requests processed by the Service Connect proxies.

This metric is only available if you have configured Amazon ECS Service Connect.

Valid dimensions: DiscoveryName and DiscoveryName, ServiceName, ClusterName.

Useful statistics: Average, Minimum, Maximum, Sum.

Unit: Count.

GrpcRequestCount

The number of gRPC inbound traffic requests processed by the Service Connect proxies.

This metric is only available if you have configured Amazon ECS Service Connect and the appProtocol is GRPC in the port mapping in the task definition.

Valid dimensions: DiscoveryName and DiscoveryName, ServiceName, ClusterName.

Useful statistics: Average, Minimum, Maximum, Sum.

Unit: Count.

HTTPCode_Target_2XX_Count

The number of HTTP response codes with numbers 200 to 299 generated by the applications in these tasks. These tasks are the targets. This metric only counts the responses sent to the Service Connect proxies by the applications in these tasks, not responses sent directly.
This metric is only available if you have configured Amazon ECS Service Connect and the appProtocol is HTTP or HTTP2 in the port mapping in the task definition.

Valid dimensions: TargetDiscoveryName and TargetDiscoveryName, ServiceName, ClusterName.

Useful statistics: Average, Minimum, Maximum, Sum.

Unit: Count.

HTTPCode_Target_3XX_Count

The number of HTTP response codes with numbers 300 to 399 generated by the applications in these tasks. These tasks are the targets. This metric only counts the responses sent to the Service Connect proxies by the applications in these tasks, not responses sent directly.

This metric is only available if you have configured Amazon ECS Service Connect and the appProtocol is HTTP or HTTP2 in the port mapping in the task definition.

Valid dimensions: TargetDiscoveryName and TargetDiscoveryName, ServiceName, ClusterName.

Useful statistics: Average, Minimum, Maximum, Sum.

Unit: Count.

HTTPCode_Target_4XX_Count

The number of HTTP response codes with numbers 400 to 499 generated by the applications in these tasks. These tasks are the targets. This metric only counts the responses sent to the Service Connect proxies by the applications in these tasks, not responses sent directly.

This metric is only available if you have configured Amazon ECS Service Connect and the appProtocol is HTTP or HTTP2 in the port mapping in the task definition.

Valid dimensions: TargetDiscoveryName and TargetDiscoveryName, ServiceName, ClusterName.

Useful statistics: Average, Minimum, Maximum, Sum.

Unit: Count.
HTTPCode_Target_5XX_Count

The number of HTTP response codes with numbers 500 to 599 generated by the applications in these tasks. These tasks are the targets. This metric only counts the responses sent to the Service Connect proxies by the applications in these tasks, not responses sent directly.

This metric is only available if you have configured Amazon ECS Service Connect and the appProtocol is HTTP or HTTP2 in the port mapping in the task definition.

Reason to use: You can use this metric to detect a high server-side error count for a service.

Recommended value: We recommend that you initially set the value to 5% of your average traffic. You can use the RequestCount metric to find the average traffic. You might need adjust the value so that the alarm is not too sensitive.

Useful statistics: Average, Minimum, Maximum, Sum.

Unit: Count.

RequestCountPerTarget

The average number of requests received by each target that share the selected DiscoveryName.

This metric is only available if you have configured Amazon ECS Service Connect.

Valid dimensions: TargetDiscoveryName and TargetDiscoveryName, ServiceName, ClusterName.

Useful statistics: Average.

Unit: Count.

TargetProcessedBytes

The total number of bytes processed by the Service Connect proxies.

This metric is only available if you have configured Amazon ECS Service Connect.

Valid dimensions: TargetDiscoveryName and TargetDiscoveryName, ServiceName, ClusterName.

Useful statistics: Average, Minimum, Maximum, Sum.
TargetResponseTime

The latency of the application request processing. The time elapsed, in milliseconds, after the request reached the Service Connect proxy in the target task until a response from the target application is received back to the proxy.

This metric is only available if you have configured Amazon ECS Service Connect.

Reason to use: You can use this metric to detect a high service response time. You can then look at other metrics such as CPUUtilization to determine if the service has enough resources.

Recommended value: Review the critical response time and historical behavior of the metric to determine a value.

Valid dimensions: TargetDiscoveryName and TargetDiscoveryName, ServiceName, ClusterName.

Useful statistics: Average, Minimum, Maximum.

All statistics: Average, Minimum, Maximum, Sum, Sample Count.

Unit: Milliseconds.

ClientTLSNegotiationErrorCount

The total number of times the TLS connection failed. This metric is only used when TLS is enabled.

This metric is only available if you have configured Amazon ECS Service Connect.

Valid dimensions: DiscoveryName and DiscoveryName, ServiceName, ClusterName.

Useful statistics: Average, Minimum, Maximum, Sum.

Unit: Count.

TargetTLSNegotiationErrorCount

The total number of times the TLS connection failed due to missing client certificates, failed AWS Private CA verifications, or failed SAN verifications. This metric is only used when TLS is enabled.
This metric is only available if you have configured Amazon ECS Service Connect.

Valid dimensions: ServiceName, ClusterName, TargetDiscoveryName and TargetDiscoveryName.

Useful statistics: Average, Minimum, Maximum, Sum.

Unit: Count.

**Dimensions for Amazon ECS metrics**

Amazon ECS metrics use the AWS/ECS namespace and provide metrics for the following dimensions. Amazon ECS only sends metrics for resources that have tasks in the RUNNING state. For example, if you have a cluster with one service in it but that service has no tasks in a RUNNING state, there will be no metrics sent to CloudWatch. If you have two services and one of them has running tasks and the other doesn't, only the metrics for the service with running tasks would be sent.

**ClusterName**

This dimension filters the data that you request for all resources in a specified cluster. All Amazon ECS metrics are filtered by ClusterName.

**ServiceName**

This dimension filters the data that you request for all resources in a specified service within a specified cluster.

**DiscoveryName**

This dimension filters the data that you request for traffic metrics to a specified Service Connect discovery name across all Amazon ECS clusters.

Note that a specific port in a running container can have multiple discovery names.

**DiscoveryName, ServiceName, ClusterName**

This dimension filters the data that you request for traffic metrics to a specified Service Connect discovery name across tasks that have this discovery name and that are created by this service in this cluster.

Use this dimension to see the inbound traffic metrics for a specific service, if you have reused the same discovery name in multiple services in different namespaces.
Note that a specific port in a running container can have multiple discovery names.

**TargetDiscoveryName**

This dimension filters the data that you request for traffic metrics to a specified Service Connect discovery name across all Amazon ECS clusters.

Different from `DiscoveryName`, these traffic metrics only measure inbound traffic to this `DiscoveryName` that come from other Amazon ECS tasks that have a Service Connect configuration in this namespace. This includes tasks made by services with either a client-only or client-server Service Connect configuration.

Note that a specific port in a running container can have multiple discovery names.

**TargetDiscoveryName, ServiceName, ClusterName**

This dimension filters the data that you request for traffic metrics to a specified Service Connect discovery name but only counts traffic from tasks created by this service in this cluster.

Use this dimension to see the inbound traffic metrics that come from a specific client in another service.

Different from `DiscoveryName, ServiceName, ClusterName`, these traffic metrics only measure inbound traffic to this `DiscoveryName` that come from other Amazon ECS tasks that have a Service Connect configuration in this namespace. This includes tasks made by services with either a client-only or client-server Service Connect configuration.

Note that a specific port in a running container can have multiple discovery names.

**Cluster reservation metrics**

Cluster reservation metrics are measured as the percentage of CPU, memory, and GPUs that are reserved by all Amazon ECS tasks on a cluster when compared to the aggregate CPU, memory, and GPUs that were registered for each active container instance in the cluster. Only container instances in ACTIVE or DRAINING status will affect cluster reservation metrics. This metric is used only on clusters with tasks or services hosted on EC2 instances. It's not supported on clusters with tasks hosted on AWS Fargate.

\[
\text{Cluster CPU reservation} = \frac{\text{(Total CPU units reserved by tasks in cluster)}}{\text{Total CPU units available for tasks in cluster}}} \times 100
\]
When you run a task in a cluster, Amazon ECS parses its task definition and reserves the aggregate CPU units, MiB of memory, and GPUs that are specified in its container definitions. Each minute, Amazon ECS calculates the number of CPU units, MiB of memory, and GPUs that are currently reserved for each task that is running in the cluster. The total amount of CPU, memory, and GPUs reserved for all tasks running on the cluster is calculated, and those numbers are reported to CloudWatch as a percentage of the total registered resources for the cluster. If you specify a soft limit (memoryReservation) in the task definition, it's used to calculate the amount of reserved memory. Otherwise, the hard limit (memory) is used. The total MiB of memory reserved by tasks in a cluster also includes temporary file system (tmpfs) volume size and sharedMemorySize if defined in the task definition. For more information about hard and soft limits, shared memory size, and tmpfs volume size, see Task Definition Parameters.

For example, a cluster has two active container instances registered: a c4.4xlarge instance and a c4.large instance. The c4.4xlarge instance registers into the cluster with 16,384 CPU units and 30,158 MiB of memory. The c4.large instance registers with 2,048 CPU units and 3,768 MiB of memory. The aggregate resources of this cluster are 18,432 CPU units and 33,926 MiB of memory.

If a task definition reserves 1,024 CPU units and 2,048 MiB of memory, and ten tasks are started with this task definition on this cluster (and no other tasks are currently running), a total of 10,240 CPU units and 20,480 MiB of memory are reserved. This is reported to CloudWatch as 55% CPU reservation and 60% memory reservation for the cluster.

The following illustration shows the total registered CPU units in a cluster and what their reservation and utilization means to existing tasks and new task placement. The lower (Reserved,
used) and center (Reserved, not used) blocks represent the total CPU units that are reserved for
the existing tasks that are running on the cluster, or the CPUReservation CloudWatch metric.
The lower block represents the reserved CPU units that the running tasks are actually using on the
cluster, or the CPUUtilization CloudWatch metric. The upper block represents CPU units that
are not reserved by existing tasks; these CPU units are available for new task placement. Existing
tasks can use these unreserved CPU units as well, if their need for CPU resources increases. For
more information, see the cpu task definition parameter documentation.

Cluster utilization

The cluster utilization metrics are available for CPU, memory, and, when there is an EBS volume
attached to your tasks, EBS filesystem utilization. These metrics are only available for clusters with
tasks or services hosted on Amazon EC2 instances. They’re not supported on clusters with tasks
hosted on AWS Fargate.

Cluster level CPU and memory utilization

The CPU and memory utilization is measured as the percentage of CPU and memory that is used
by all tasks on a cluster when compared to the aggregate CPU and memory that was registered for
each active Amazon EC2 instances registered to the cluster. Only Amazon EC2 instances in ACTIVE
or DRAINING status will affect cluster utilization metrics.
Cluster CPU utilization = \[
\frac{\text{Total CPU units used by tasks in cluster} \times 100}{\text{Total CPU units registered by container instances in cluster}}
\]

Cluster memory utilization = \[
\frac{\text{Total MiB of memory used by tasks in cluster} \times 100}{\text{Total MiB of memory registered by container instances in cluster}}
\]

Each minute, the Amazon ECS container agent on each Amazon EC2 instance calculates the number of CPU units and MiB of memory that is currently being used for each task that is running on that Amazon EC2 instance, and this information is reported back to Amazon ECS. The total amount of CPU and memory used for all tasks running on the cluster is calculated, and those numbers are reported to CloudWatch as a percentage of the total registered resources for the cluster.

For example, a cluster has two active Amazon EC2 instances registered, a c4.4xlarge instance and a c4.large instance. The c4.4xlarge instance registers into the cluster with 16,384 CPU units and 30,158 MiB of memory. The c4.large instance registers with 2,048 CPU units and 3,768 MiB of memory. The aggregate resources of this cluster are 18,432 CPU units and 33,926 MiB of memory.

If ten tasks are running on this cluster and each task consumes 1,024 CPU units and 2,048 MiB of memory, a total of 10,240 CPU units and 20,480 MiB of memory are used on the cluster. This is reported to CloudWatch as 55% CPU utilization and 60% memory utilization for the cluster.

**Cluster level EBS filesystem utilization**

The cluster level EBS filesystem utilization metric is measured as the total amount of the EBS filesystem in use by the tasks running on the cluster, divided by the total amount of EBS filesystem storage that was allocated for all of the tasks in the cluster.

Cluster EBS filesystem utilization = \[
\frac{\text{Total GB of EBS filesystem used by tasks in cluster} \times 100}{\text{Total GB of EBS filesystem allocated for cluster}}
\]
Service utilization

The service utilization metrics are available for CPU, memory, and, when there is an EBS volume attached to your tasks, EBS filesystem utilization. The service level metrics are supported for services with tasks hosted on both Amazon EC2 instances and Fargate.

Service level CPU and memory utilization

The CPU and memory utilization is measured as the percentage of CPU and memory that is used by the Amazon ECS tasks that belong to a service on a cluster when compared to the CPU and memory that is specified in the service's task definition.

\[
\text{Service CPU utilization} = \frac{\text{(Total CPU units used by tasks in service)} \times 100}{\text{(Total CPU units specified in task definition)} \times \text{(number of tasks in service)}}
\]

\[
\text{Service memory utilization} = \frac{\text{(Total MiB of memory used by tasks in service)} \times 100}{\text{(Total MiB of memory specified in task definition)} \times \text{(number of tasks in service)}}
\]

Each minute, the Amazon ECS container agent calculates the number of CPU units and MiB of memory that are currently being used for each task owned by the service, and this information is reported back to Amazon ECS. The total amount of CPU and memory used for all tasks owned by the service that are running on the cluster is calculated, and those numbers are reported to CloudWatch as a percentage of the total resources that are specified for the service in the service's task definition. If you specify a soft limit (memoryReservation), it's used to calculate the amount of reserved memory. Otherwise, the hard limit (memory) is used. For more information about hard and soft limits, see Task size.

For example, the task definition for a service specifies a total of 512 CPU units and 1,024 MiB of memory (with the hard limit memory parameter) for all of its containers. The service has a desired
count of 1 running task, the service is running on a cluster with 1 `c4.large` container instance (with 2,048 CPU units and 3,768 MiB of total memory), and there are no other tasks running on the cluster. Although the task specifies 512 CPU units, because it is the only running task on a container instance with 2,048 CPU units, it can use up to four times the specified amount (2,048 / 512). However, the specified memory of 1,024 MiB is a hard limit and it can't be exceeded, so in this case, service memory utilization can't exceed 100%.

If the previous example used the soft limit `memoryReservation` instead of the hard limit `memory` parameter, the service's tasks could use more than the specified 1,024 MiB of memory as needed. In this case, the service's memory utilization could exceed 100%.

If your application has a sudden spike in memory utilization for a short amount of time, you will not see the service memory utilization increasing because Amazon ECS collects multiple data points every minute, and then aggregates them to one data point that is sent to CloudWatch.

If this task is performing CPU-intensive work during a period and using all 2,048 of the available CPU units and 512 MiB of memory, the service reports 400% CPU utilization and 50% memory utilization. If the task is idle and using 128 CPU units and 128 MiB of memory, the service reports 25% CPU utilization and 12.5% memory utilization.

**Note**

In this example, the CPU utilization will only go above 100% when the CPU units are defined at the container level. If you define CPU units at the task level, the utilization will not go above the defined task-level limit.

### Service level EBS filesystem utilization

The service level EBS filesystem utilization is measured as the total amount of the EBS filesystem in use by the tasks that belong to the service, divided by the total amount of EBS filesystem storage that is allocated for all tasks that belong to the service.

\[
\text{Service EBS filesystem utilization} = \frac{\text{Total GB of EBS filesystem used by tasks in the service} \times 100}{\text{Total GB of EBS filesystem allocated to tasks in the service}}
\]
Service RUNNING task count

You can use CloudWatch metrics to view the number of tasks in your services that are in the RUNNING state. For example, you can set a CloudWatch alarm for this metric to alert you if the number of running tasks in your service falls below a specified value.

Service RUNNING task count in Amazon ECS CloudWatch Container Insights

A "Number of Running Tasks" (RunningTaskCount) metric is available per cluster and per service when you use Amazon ECS CloudWatch Container Insights. You can use Container Insights for all new clusters created by opting in to the containerInsights account setting, on individual clusters by turning on the cluster settings during cluster creation, or on existing clusters by using the UpdateClusterSettings API. Metrics collected by CloudWatch Container Insights are charged as custom metrics. For more information about CloudWatch pricing, see CloudWatch Pricing.

To view this metric, see Amazon ECS Container Insights Metrics in the Amazon CloudWatch User Guide.

AWS Fargate usage metrics

You can use CloudWatch usage metrics to provide visibility into your accounts usage of resources. Use these metrics to visualize your current service usage on CloudWatch graphs and dashboards.

AWS Fargate usage metrics correspond to AWS service quotas. You can configure alarms that alert you when your usage approaches a service quota. For more information about Fargate service quotas, see AWS Fargate service quotas.

AWS Fargate publishes the following metrics in the AWS/Usage namespace.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourceCount</td>
<td>The total number of the specified resource running on your account. The resource is defined by the dimensions associated with the metric.</td>
</tr>
</tbody>
</table>

The following dimensions are used to refine the usage metrics that are published by AWS Fargate.
### Dimension | Description
--- | ---
Service | The name of the AWS service containing the resource. For AWS Fargate usage metrics, the value for this dimension is Fargate.
Type | The type of entity that is being reported. Currently, the only valid value for AWS Fargate usage metrics is Resource.
Resource | The type of resource that is running. The type of resource that is running. Currently, the only valid value for AWS Fargate usage metrics is vCPU which returns information about the running instances.
Class | The class of resource being tracked. The class of resource being tracked. For AWS Fargate usage metrics with vCPU as the value of the Resource dimension, the valid values are Standard/OnDemand and Standard/Spot.

You can use the Service Quotas console to visualize your usage on a graph and configure alarms that alert you when your AWS Fargate usage approaches a service quota. For information about how to create a CloudWatch alarm to notify you when you're close to a quota value threshold, see Service Quotas and Amazon CloudWatch alarms in the Service Quotas User Guide.

### Viewing Amazon ECS metrics

After you have resources running in your cluster, you can view the metrics on the Amazon ECS and CloudWatch consoles. The Amazon ECS console provides a 24-hour maximum, minimum, and average view of your cluster and service metrics. The CloudWatch console provides a fine-grained and customizable display of your resources, as well as the number of running tasks in a service.

**Amazon ECS console**

Amazon ECS service CPU and memory utilization metrics are available on the Amazon ECS console. The view provided for service metrics shows the average, minimum, and maximum values for the
previous 24-hour period, with data points available in 5-minute intervals. For more information, see Service utilization.

2. Select the cluster that you want to view metrics for.
3. Determine the metrics to view.

<table>
<thead>
<tr>
<th>To view metrics from</th>
<th>Steps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clusters</td>
<td>On the cluster details page, choose the <strong>Metrics</strong> tab. There is also a link provided to the CloudWatch console to view your CloudWatch Container Insights metrics if you have those turned on.</td>
</tr>
<tr>
<td>Services</td>
<td>On the cluster details page, on the <strong>Services</strong> tab, select the service. The metrics are then available on the <strong>Health and metrics</strong> tab.</td>
</tr>
</tbody>
</table>

**CloudWatch console**

For the Fargate launch type, Amazon ECS service metrics can also be viewed on the CloudWatch console. The console provides the most detailed view of Amazon ECS metrics, and you can tailor the views to suit your needs. You can view the service utilization and service RUNNING task count.

For the EC2 launch type, Amazon ECS cluster and service metrics can also be viewed on the CloudWatch console. The console provides the most detailed view of Amazon ECS metrics, and you can tailor the views to suit your needs.

For information about how to view the metrics, see View available metrics the *Amazon CloudWatch User Guide*. 
Automate responses to Amazon ECS errors using EventBridge

Using Amazon EventBridge, you can automate your AWS services and respond automatically to system events such as application availability issues or resource changes. Events from AWS services are delivered to EventBridge in near real time. You can write simple rules to indicate which events are of interest to you and what automated actions to take when an event matches a rule. The actions that can be automatically configured to include the following:

- Adding events to log groups in CloudWatch Logs
- Invoking an AWS Lambda function
- Invoking Amazon EC2 Run Command
- Relaying the event to Amazon Kinesis Data Streams
- Activating an AWS Step Functions state machine
- Notifying an Amazon SNS topic or an Amazon Simple Queue Service (Amazon SQS) queue

For more information, see [Getting Started with Amazon EventBridge](https://docs.aws.amazon.com/eventbridge/latest/userguide/getting-started.html) in the *Amazon EventBridge User Guide*.

You can use Amazon ECS events for EventBridge to receive near real-time notifications regarding the current state of your Amazon ECS clusters. If your tasks are using the EC2 launch type, you can see the state of both the container instances and the current state of all tasks running on those container instances. If your tasks are using the Fargate launch type, you can see the state of the container instances.

Using EventBridge, you can build custom schedulers on top of Amazon ECS that are responsible for orchestrating tasks across clusters and monitoring the state of clusters in near real time. You can eliminate scheduling and monitoring code that continuously polls the Amazon ECS service for status changes and instead handle Amazon ECS state changes asynchronously using any EventBridge target. Targets might include AWS Lambda, Amazon Simple Queue Service, Amazon Simple Notification Service, or Amazon Kinesis Data Streams.

An Amazon ECS event stream ensures that every event is delivered at least one time. If duplicate events are sent, the event provides enough information to identify duplicates. For more information, see [Handling Amazon ECS events](https://docs.aws.amazon.com/ecs/latest/userguide/ecs-events.html).

Events are relatively ordered, so that you can easily tell when an event occurred in relation to other events.
Amazon ECS tracks the state of each of your tasks and services. If the state of a task or service changes, an event is generated and is sent to Amazon EventBridge. These events are classified as task state change events and service action events. These events and their possible causes are described in greater detail in the following sections.

Amazon ECS generated and sends the following types of events to EventBridge: container instance state change events, task state change events, service action, and service deployment state change events.

- Container instance state change
- Task state change
- Deployment state change
- Service action

Note

Amazon ECS may add other event types, sources, and details in the future. If you are deserializing event JSON data in code, make sure that your application is prepared to handle unknown properties to avoid issues if and when these additional properties are added.

In some cases, multiple events are generated for the same activity. For example, when a task is started on a container instance, a task state change event is generated for the new task. A container instance state change event is generated to account for the change in available resources, such as CPU, memory, and available ports, on the container instance. Likewise, if a container instance is terminated, events are generated for the container instance, the container agent connection status, and every task that was running on the container instance.
Container state change and task state change events contain two version fields: one in the main body of the event, and one in the detail object of the event. The following describes the differences between these two fields:

- The version field in the main body of the event is set to 0 on all events. For more information about EventBridge parameters, see [Events and Event Patterns](https://docs.aws.amazon.com/AmazonEventBridge/latest/userguide/EventsAndEventPatterns.html) in the *Amazon EventBridge User Guide*.

- The version field in the detail object of the event describes the version of the associated resource. Each time a resource changes state, this version is incremented. Because events can be sent multiple times, this field allows you to identify duplicate events. Duplicate events have the same version in the detail object. If you are replicating your Amazon ECS container instance and task state with EventBridge, you can compare the version of a resource reported by the Amazon ECS APIs with the version reported in EventBridge for the resource (inside the detail object) to verify that the version in your event stream is current.

Service action events only contain the version field in the main body.

For additional information about how to integrate Amazon ECS and EventBridge, see [Integrating Amazon EventBridge and Amazon ECS](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/integrating_eventbridge.html).

### Amazon ECS container instance state change events

The following scenarios cause container instance state change events:

You call the `StartTask`, `RunTask`, or `StopTask` API operations, either directly or with the AWS Management Console or SDKs.

Placing or stopping tasks on a container instance modifies the available resources on the container instance, such as CPU, memory, and available ports.

The Amazon ECS service scheduler starts or stops a task.

Placing or stopping tasks on a container instance modifies the available resources on the container instance, such as CPU, memory, and available ports.

The Amazon ECS container agent calls the `SubmitTaskStateChange` API operation with a STOPPED status for a task with a desired status of RUNNING.

The Amazon ECS container agent monitors the state of tasks on your container instances, and it reports any state changes. If a task that is supposed to be RUNNING is transitioned to STOPPED,
the agent releases the resources that were allocated to the stopped task, such as CPU, memory, and available ports.

You deregister the container instance with the `DeregisterContainerInstance` API operation, either directly or with the AWS Management Console or SDKs.

Deregistering a container instance changes the status of the container instance and the connection status of the Amazon ECS container agent.

A task was stopped when an EC2 instance was stopped.

When you stop a container instance, the tasks that are running on it are transitioned to the STOPPED status.

The Amazon ECS container agent registers a container instance for the first time.

The first time the Amazon ECS container agent registers a container instance (at launch or when first run manually), this creates a state change event for the instance.

The Amazon ECS container agent connects or disconnects from Amazon ECS.

When the Amazon ECS container agent connects or disconnects from the Amazon ECS backend, it changes the `agentConnected` status of the container instance.

**Note**

The Amazon ECS container agent disconnects and reconnects several times per hour as a part of its normal operation, so agent connection events should be expected. These events are not an indication that there is an issue with the container agent or your container instance.

You upgrade the Amazon ECS container agent on an instance.

The container instance detail contains an object for the container agent version. If you upgrade the agent, this version information changes and generates an event.

**Example Container instance state change event**

Container instance state change events are delivered in the following format. The detail section below resembles the `ContainerInstance` object that is returned from a `DescribeContainerInstances`
API operation in the *Amazon Elastic Container Service API Reference*. For more information about EventBridge parameters, see *Events and Event Patterns* in the *Amazon EventBridge User Guide*.

Amazon ECS task state change events

The following scenarios cause task state change events:

You call the StartTask, RunTask, or StopTask API operations, either directly or with the AWS Management Console, AWS CLI, or SDKs.

Starting or stopping tasks creates new task resources or modifies the state of existing task resources.

The Amazon ECS service scheduler starts or stops a task.

Starting or stopping tasks creates new task resources or modifies the state of existing task resources.

The Amazon ECS container agent calls the SubmitTaskStateChange API operation.

For the Fargate launch type, the Amazon ECS container agent monitors the state of your container instances. For the Amazon EC2 launch type, the Amazon ECS container agent monitors the state of your tasks on your container instances. The Amazon ECS container agent reports any state changes. State changes might include changes from PENDING to RUNNING or from RUNNING to STOPPED.

You force deregistration of the underlying container instance with the DeregisterContainerInstance API operation and the force flag, either directly or with the AWS Management Console or SDKs.

Deregistering a container instance changes the status of the container instance and the connection status of the Amazon ECS container agent. If tasks are running on the container instance, the force flag must be set to allow deregistration. This stops all tasks on the instance.

The underlying container instance is stopped or terminated.

When you stop or terminate a container instance, the tasks that are running on it are transitioned to the STOPPED status.

A container in the task changes state.

The Amazon ECS container agent monitors the state of containers within tasks. For example, if a container that is running within a task stops, this container state change generates an event.
A task using the Fargate Spot capacity provider receives a termination notice.

When a task is using the FARGATE_SPOT capacity provider and is stopped due to a Spot interruption, a task state change event is generated.

**Example Task state change event**

Task state change events are delivered in the following format. The `detail` section below resembles the `Task` object that is returned from a `DescribeTasks` API operation in the *Amazon Elastic Container Service API Reference*. If your containers are using an image hosted with Amazon ECR, the `imageDigest` field is returned.

```
{
  "version": "0",
  "id": "3317b2af-7005-947d-b652-f55e762e571a",
  "detail-type": "ECS Task State Change",
  "source": "aws.ecs",
  "account": "111122223333",
  "time": "2020-01-23T17:57:58Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:ecs:us-west-2:111122223333:task/FargateCluster/c13b4cb40f1f4fe4a2971f76ae5a47ad"
  ],
  "detail": {
```

---

Note

The values for the `createdAt`, `connectivityAt`, `pullStartedAt`, `startedAt`, `pullStoppedAt`, and `updatedAt` fields are UNIX timestamps in the response of a `DescribeTasks` action whereas in the task state change event they are ISO string timestamps.

For more information about CloudWatch Events parameters, see [Events and Event Patterns](https://docs.aws.amazon.com/AmazonEventBridge/latest/userguide/events-and-event-patterns.html) in the *Amazon EventBridge User Guide*.

For information about how to configure configure an Amazon EventBridge event rule that only captures task events where the task has stopped running because one of its essential containers has terminated, see [Sending Amazon Simple Notification Service alerts for task stopped events](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/task-events-topic.html).

Amazon ECS service action events

Amazon ECS sends service action events with the detail type ECS Service Action. Unlike the container instance and task state change events, the service action events do not include a version number in the details response field. The following is an event pattern that is used to create an EventBridge rule for Amazon ECS service action events. For more information, see Creating an EventBridge Rule in the Amazon EventBridge User Guide.
Amazon ECS sends events with INFO, WARN, and ERROR event types. The following are the service action events.

**Service action events with INFO event type**

**SERVICE_STEADY_STATE**

The service is healthy and at the desired number of tasks, thus reaching a steady state. The service scheduler reports the status periodically, so you might receive this message multiple times.

**TASKSET_STEADY_STATE**

The task set is healthy and at the desired number of tasks, thus reaching a steady state.

**CAPACITY_PROVIDER_STEADY_STATE**

A capacity provider associated with a service reaches a steady state.

**SERVICE_DESIRED_COUNT_UPDATED**

When the service scheduler updates the computed desired count for a service or task set. This event is not sent when the desired count is manually updated by a user.

**Service action events with WARN event type**

**SERVICE_TASK_START_IMPAIRED**

The service is unable to consistently start tasks successfully.

**SERVICE_DISCOVERY_INSTANCE_UNHEALTHY**

A service using service discovery contains an unhealthy task. The service scheduler detects that a task within a service registry is unhealthy.
Service action events with ERROR event type

SERVICE_DAEMON_PLACEMENT_CONSTRAINT_VIOLATED

A task in a service using the DAEMON service scheduler strategy no longer meets the placement constraint strategy for the service.

ECS_OPERATION_THROTTLED

The service scheduler has been throttled due to the Amazon ECS API throttle limits.

SERVICE_DISCOVERY_OPERATION_THROTTLED

The service scheduler has been throttled due to the AWS Cloud Map API throttle limits. This can occur on services configured to use service discovery.

SERVICE_TASK_PLACEMENT_FAILURE

The service scheduler is unable to place a task. The cause will be described in the reason field.

A common cause for this service event being generated is because of a lack of resources in the cluster to place the task. For example, not enough CPU or memory capacity on the available container instances or no container instances being available. Another common cause is when the Amazon ECS container agent is disconnected on the container instance, causing the scheduler to be unable to place the task.

SERVICE_TASK.Configuration_FAILURE

The service scheduler is unable to place a task due to a configuration error. The cause will be described in the reason field.

A common cause of this service event being generated is because tags were being applied to the service but the user or role had not opted in to the new Amazon Resource Name (ARN) format in the Region. For more information, see Amazon Resource Names (ARNs) and IDs. Another common cause is that Amazon ECS was unable to assume the task IAM role provided.

Example Service steady state event

Service steady state events are delivered in the following format. For more information about EventBridge parameters, see Events and Event Patterns in the Amazon EventBridge User Guide.

```json
{
    "version": "0",
```
Example Capacity provider steady state event

Capacity provider steady state events are delivered in the following format.

```json
{
    "version": "0",
    "id": "b9baa007-2f33-0eb1-5760-0d02a572d81f",
    "detail-type": "ECS Service Action",
    "source": "aws.ecs",
    "account": "111122223333",
    "time": "2019-11-19T19:37:00Z",
    "region": "us-west-2",
    "resources": [
    ],
    "detail": {
        "eventType": "INFO",
        "eventName": "CAPACITY_PROVIDER_STEADY_STATE",
        "capacityProviderArns": [
        ],
        "createdAt": "2019-11-19T19:37:00.807Z"
    }
}
```
Example Service task start impaired event

Service task start impaired events are delivered in the following format.

```
{
  "version": "0",
  "id": "57c9506e-9d21-294c-d2fe-e8738da7e67d",
  "detail-type": "ECS Service Action",
  "source": "aws.ecs",
  "account": "111122223333",
  "region": "us-west-2",
  "resources": [
  ],
  "detail": {
    "eventType": "WARN",
    "eventName": "SERVICE_TASK_START_IMPAIRED",
    "createdAt": "2019-11-19T19:55:38.725Z"
  }
}
```

Example Service task placement failure event

Service task placement failure events are delivered in the following format. For more information about EventBridge parameters, see Events and Event Patterns in the Amazon EventBridge User Guide.

In the following example, the task was attempting to use the FARGATE_SPOT capacity provider but the service scheduler was unable to acquire any Fargate Spot capacity.

```
{
  "version": "0",
  "id": "ddca6449-b258-46c0-8653-e0e3a6d0468b",
  "detail-type": "ECS Service Action",
  "source": "aws.ecs",
  "account": "111122223333",
  "region": "us-west-2",
  "resources": [
  ],
  "detail": {
    "eventType": "ERROR",
    "eventName": "SERVICE_TASK_PLACEMENT_FAILED",
    "createdAt": "2019-11-19T19:55:38.725Z"
  }
}
```
In the following example for the EC2 launch type, the task was attempted to launch on the Container Instance 2dd1b186f39845a584488d2ef155c131 but the service scheduler was unable to place the task because of insufficient CPU.
Amazon ECS service deployment state change events

Amazon ECS sends service deployment change state events with the detail type **ECS Deployment State Change**. The following is an event pattern that is used to create an EventBridge rule for Amazon ECS service deployment state change events. For more information, see [Creating an EventBridge Rule](#) in the *Amazon EventBridge User Guide*.

```
{
    "source": [
        "aws.ecs"
    ],
    "detail-type": [
        "ECS Deployment State Change"
    ]
}
```

Amazon ECS sends events with **INFO** and **ERROR** event types. The following are the service deployment state change events.

**SERVICE_DEPLOYMENT_IN_PROGRESS**

The service deployment is in progress. This event is sent for both initial deployments and rollback deployments.

**SERVICE_DEPLOYMENT_COMPLETED**

The service deployment has completed. This event is sent once a service reaches a steady state after a deployment.

**SERVICE_DEPLOYMENT_FAILED**

The service deployment has failed. This event is sent for services with deployment circuit breaker logic turned on.

**Example service deployment in progress event**

Service deployment in progress events are delivered when both an initial and a rollback deployment is started. The difference between the two is in the **reason** field. For more information about EventBridge parameters, see [Events and Event Patterns](#) in the *Amazon EventBridge User Guide*.

The following shows an example output for an initial deployment starting.
The following shows an example output for a rollback deployment starting. The `reason` field provides the ID of the deployment the service is rolling back to.

```
{
  "version": "0",
  "id": "ddca6449-b258-46c0-8653-e0e3a6EXAMPLE",
  "detail-type": "ECS Deployment State Change",
  "source": "aws.ecs",
  "account": "111122223333",
  "time": "2020-05-23T12:31:14Z",
  "region": "us-west-2",
  "resources": [
  ],
  "detail": {
    "eventType": "INFO",
    "eventName": "SERVICE_DEPLOYMENT_IN_PROGRESS",
    "deploymentId": "ecs-svc/123",
    "updatedAt": "2020-05-23T11:11:11Z",
    "reason": "ECS deployment circuit breaker: rolling back to deploymentId deploymentID."
  }
}
```
Example service deployment completed event

Service deployment completed state events are delivered in the following format. For more information, see Rolling update.

```json
{
    "version": "0",
    "id": "ddca6449-b258-46c0-8653-e0e3aEXAMPLE",
    "detail-type": "ECS Deployment State Change",
    "source": "aws.ecs",
    "account": "111122223333",
    "time": "2020-05-23T12:31:14Z",
    "region": "us-west-2",
    "resources": [
    ],
    "detail": {
        "eventType": "INFO",
        "eventName": "SERVICE_DEPLOYMENT_COMPLETED",
        "deploymentId": "ecs-svc/123",
        "updatedAt": "2020-05-23T11:11:11Z",
        "reason": "ECS deployment deploymentID completed."
    }
}
```

Example service deployment failed event

Service deployment failed state events are delivered in the following format. A service deployment failed state event will only be sent for services that have deployment circuit breaker logic turned on. For more information, see Rolling update.

```json
{
    "version": "0",
    "id": "ddca6449-b258-46c0-8653-e0e3aEXAMPLE",
    "detail-type": "ECS Deployment State Change",
    "source": "aws.ecs",
    "account": "111122223333",
    "time": "2020-05-23T12:31:14Z",
    "region": "us-west-2",
    "resources": [
    ],
    "detail": {
        "eventType": "INFO",
        "eventName": "SERVICE_DEPLOYMENT_FAILED",
        "deploymentId": "ecs-svc/123",
        "updatedAt": "2020-05-23T11:11:11Z",
        "reason": "ECS deployment deploymentID applied."
    }
}
```
Handling Amazon ECS events

Amazon ECS sends events on an at least once basis. This means you might receive multiple copies of a given event. Additionally, events may not be delivered to your event listeners in the order in which the events occurred.

To order of events properly, the detail section of each event contains a version property. Each time a resource changes state, this version is incremented. Duplicate events have the same version in the detail object. If you are replicating your Amazon ECS container instance and task state with EventBridge, you can compare the version of a resource reported by the Amazon ECS APIs with the version reported in EventBridge for the resource to verify that the version in your event stream is current. Events with a higher version property number should be treated as occurring later than events with lower version numbers.

Example: Handling events in an AWS Lambda function

The following example shows a Lambda function written in Python 3.9 that captures both task and container instance state change events and saves them to one of two Amazon DynamoDB tables:

- **ECSCtrlInstanceState** – Stores the latest state for a container instance. The table ID is the containerInstanceArn value of the container instance.
- **ECSTaskState** – Stores the latest state for a task. The table ID is the taskArn value of the task.

```python
import json
import boto3

def lambda_handler(event, context):
    id_name = ""
    new_record = {}
```
# For debugging so you can see raw event format.
print('Here is the event:)
print((json.dumps(event)))

if event['source'] != "aws.ecs":
    raise ValueError("Function only supports input from events with a source type of: aws.ecs")

# Switch on task/container events.
table_name = ""
if event['detail-type'] == "ECS Task State Change":
    table_name = "ECSTaskState"
    id_name = "taskArn"
    event_id = event['detail']["taskArn"]
elif event['detail-type'] == "ECS Container Instance State Change":
    table_name = "ECSCtrInstanceState"
    id_name = "containerInstanceArn"
    event_id = event['detail']["containerInstanceArn"]
else:
    raise ValueError("detail-type for event is not a supported type. Exiting without saving event.")

new_record['cw_version'] = event['version']
new_record.update(event['detail'])

# "status" is a reserved word in DDB, but it appears in containerPort # state change messages.
if "status" in event:
    new_record['current_status'] = event['status']
    new_record.pop("status")

# Look first to see if you have received a newer version of an event ID. # If the version is OLDER than what you have on file, do not process it. # Otherwise, update the associated record with this latest information.
print("Looking for recent event with same ID...")
dynamodb = boto3.resource("dynamodb", region_name="us-east-1")
table = dynamodb.Table(table_name)
saved_event = table.get_item(Key={
    id_name : event_id
})
if "Item" in saved_event:
The following Fargate example shows a Lambda function written in Python 3.9 that captures task state change events and saves them to the following Amazon DynamoDB table:

```python
import json
import boto3

def lambda_handler(event, context):
    id_name = ""
    new_record = {}

    # For debugging so you can see raw event format.
    print('Here is the event:')
    print(json.dumps(event))

    if event['source'] != "aws.ecs":
        raise ValueError("Function only supports input from events with a source type of: aws.ecs")

    # Switch on task/container events.
    table_name = ""
    if event['detail-type'] == "ECS Task State Change":
        table_name = "ECSTaskState"
        id_name = "taskArn"
        event_id = event['detail']['taskArn']
    else:
        print("Saving new event - ID " + event_id)

        table.put_item(
            Item=new_record
        )
```
raise ValueError("detail-type for event is not a supported type. Exiting without saving event.")

new_record["cw_version"] = event["version"]
new_record.update(event["detail"])

# "status" is a reserved word in DDB, but it appears in containerPort
# state change messages.
if "status" in event:
    new_record["current_status"] = event["status"]
    new_record.pop("status")

# Look first to see if you have received a newer version of an event ID.
# If the version is OLDER than what you have on file, do not process it.
# Otherwise, update the associated record with this latest information.
print("Looking for recent event with same ID...")
dynamodb = boto3.resource("dynamodb", region_name="us-east-1")
table = dynamodb.Table(table_name)
saved_event = table.get_item(
    Key={
        id_name : event_id
    }
)
if "Item" in saved_event:
    # Compare events and reconcile.
    print("EXISTING EVENT DETECTED: Id " + event_id + " - reconciling")
    if saved_event["Item"]["version"] < event["detail"]["version"]:
        print("Received event is a more recent version than the stored event - updating")
        table.put_item(
            Item=new_record
        )
    else:
        print("Received event is an older version than the stored event - ignoring")
else:
    print("Saving new event - ID " + event_id)

    table.put_item(
        Item=new_record
    )
Monitor Amazon ECS containers using Container Insights

CloudWatch Container Insights collects, aggregates, and summarizes metrics and logs from your containerized applications and microservices.

Container Insights uses a containerized version of the CloudWatch agent to discover all the running containers in a cluster and collect performance data at every layer of the performance stack. Operational data is collected as performance log events. These are entries that use a structured JSON schema for high-cardinality data to be ingested and stored at scale. From this data, CloudWatch creates higher-level aggregated metrics at the cluster, service, and task level as CloudWatch metrics. The metrics include utilization for resources such as CPU, memory, disk, and network. The metrics are available in CloudWatch automatic dashboards. For information about the available metrics, see Amazon ECS Container Insights metrics in the Amazon CloudWatch User Guide.

⚠️ Important

Metrics collected by CloudWatch Container Insights are charged as custom metrics. For more information about CloudWatch pricing, see CloudWatch Pricing. Amazon ECS also provides monitoring metrics that are provided at no additional cost. For more information, see Monitor Amazon ECS using CloudWatch.

Considerations

The following should be considered when using CloudWatch Container Insights.

- CloudWatch Container Insights metrics only reflect the resources with running tasks during the specified time range. For example, if you have a cluster with one service in it but that service has no tasks in a RUNNING state, there will be no metrics sent to CloudWatch. If you have two services and one of them has running tasks and the other doesn't, only the metrics for the service with running tasks will be sent.

- Network metrics are available for all tasks run on Fargate and tasks run on Amazon EC2 instances that use either the bridge or awsvpc network modes.
You can view Amazon ECS task and service lifecycle events within the CloudWatch Container Insights console. This helps you correlate your container metrics, logs, and events in a single view to give you a more complete operational visibility.

The events that you can view are the ones that Amazon ECS sends to Amazon EventBridge. For more information, see [Amazon ECS events](#).

You can choose to configure performance metrics for clusters, tasks, or services. Depending on the resource you choose, the following events are reported:

- Container instance state change events
- Service action events
- Task state change events

### Configuring CloudWatch Container Insights for Amazon ECS

You can configure Container Insights using the Amazon ECS console, the AWS CLI, API, and SDKs.

Use the following table to determine the action to take for adding Container Insights.

#### Tagging support for Amazon ECS resources

<table>
<thead>
<tr>
<th>Task</th>
<th>Console</th>
<th>AWS CLI</th>
<th>API action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change the default for all users</td>
<td>Modifying account settings</td>
<td>put-account-setting-default</td>
<td>PutAccountSettingDefault</td>
</tr>
<tr>
<td>Change the default for a specific user</td>
<td>Modifying account settings</td>
<td>put-account-setting</td>
<td>PutAccountSetting</td>
</tr>
<tr>
<td>Configure Container Insights for a specific cluster</td>
<td>Creating a cluster for the Fargate and External launch type using the console</td>
<td>create-cluster</td>
<td>CreateCluster</td>
</tr>
<tr>
<td></td>
<td>Creating a cluster for the Amazon EC2 launch type using the console</td>
<td>UpdateCluster</td>
<td>UpdateCluster</td>
</tr>
</tbody>
</table>
### Important

For clusters containing tasks or services using the EC2 launch type, your container instances must be running version 1.29.0 or later of the Amazon ECS agent. For more information, see [Linux container instance management](#).

### Required permissions for CloudWatch Container Insights to view Amazon ECS lifecycle events

You must configure the correct permissions, and then you can configure and view the events in the CloudWatch Container Insights console. For more information, see [Amazon ECS lifecycle events within Container Insights](#) in the *Amazon CloudWatch User Guide*. For more information on IAM policies for CloudWatch, see [AWS Identity and Access Management for CloudWatch](#).

#### Permissions required to configure Container Insights to view Amazon ECS lifecycle events

The following permissions are required in the task role to configure the lifecycle events:

- events:PutRule
- events:PutTargets
- logs:CreateLogGroup

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "events:PutRule",
            "events:PutTargets",
            "logs:CreateLogGroup"
         ]
      }
   ]
}
```
Permissions required to view Amazon ECS lifecycle events in Container Insights

The following permissions are required to view the lifecycle events. Add the following permissions as an inline policy to the task execution role. For more information, see Adding and Removing IAM Policies.

- events:DescribeRule
- events:ListTargetsByRule
- logs:DescribeLogGroups

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "events:DescribeRule",
                "events:ListTargetsByRule",
                "logs:DescribeLogGroups"
            ],
            "Resource": "**"
        }
    ]
}
```

Determine Amazon ECS task health using container health checks

When you create a task definition, you can configure a health check for your containers. Health checks are commands that run locally on a container and validate application health and availability.
The Amazon ECS container agent only monitors and reports on the health checks that are specified in the task definition. Amazon ECS doesn't monitor Docker health checks that are embedded in a container image but aren't specified in the container definition. Health check parameters that are specified in a container definition override any Docker health checks that exist in the container image.

When a health check is defined in a task definition, the container runs the health check process inside the container, and then evaluate the exit code to determine the application health.

The health check consists the following parameters:

- **Command** – The command that the container runs to determine if it's healthy. The string array can start with CMD to run the command arguments directly, or CMD-SHELL to run the command with the container's default shell.
- **Interval** – The period of time (in seconds) between each health check.
- **Timeout** – The period of time (in seconds) to wait for a health check to succeed before it's considered a failure.
- **Retries** – The number of times to retry a failed health check before the container is considered unhealthy.
- **Start period** – The optional grace period to provide containers time to bootstrap in before failed health checks count towards the maximum number of retries.

For information about how to specify a health check in a task definition, see [Health check](#).

The following describes the possible health status values for a container:

- **HEALTHY** – The container health check has passed successfully.
- **UNHEALTHY** – The container health check has failed.
- **UNKNOWN** – The container health check is being evaluated, there's no container health check defined, or Amazon ECS doesn't have the health status of the container.

The health check commands run on the container. Therefore you must include the commands in the container image.

The health check connects to the application through the container's loopback interface at `localhost` or `127.0.0.1`. An exit code of 0 indicates success, and non-zero exit code indicates failure.
Consider the following when using container health checks:

- When the Amazon ECS agent cannot connect to the Amazon ECS service, the service reports the container as UNHEALTHY.

- The health check statuses are the "last heard from" response from the Amazon ECS agent. There are no assumptions made about the status of the container health checks.

- Container health checks require version 1.17.0 or greater of the Amazon ECS container agent.

- Container health checks are supported for Fargate tasks if you're using Linux platform version 1.1.0 or greater or Windows platform version 1.1.0 or greater.

### How Amazon ECS determines task health

Containers that are essential and have health check command in the task definition are the only ones considered to determine the task health.

The following rules are evaluated in order:

1. If the status of one essential container is UNHEALTHY, then the task status is UNHEALTHY.
2. If the status of one essential container is UNKNOWN, then the task status is UNKNOWN.
3. If the status of all essential containers are HEALTHY, then the task status is HEALTHY.

Consider the following task health example with 2 essential containers.

<table>
<thead>
<tr>
<th>Container 1 health</th>
<th>Container 2 health</th>
<th>Task health</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNHEALTHY</td>
<td>UNKNOWN</td>
<td>UNHEALTHY</td>
</tr>
<tr>
<td>UNHEALTHY</td>
<td>HEALTHY</td>
<td>UNHEALTHY</td>
</tr>
<tr>
<td>HEALTHY</td>
<td>UNKNOWN</td>
<td>UNKNOWN</td>
</tr>
<tr>
<td>HEALTHY</td>
<td>HEALTHY</td>
<td>HEALTHY</td>
</tr>
</tbody>
</table>

Consider the following task health example with 3 containers.
### Container 1 health | Container 2 health | Container 3 health | Task health |
--- | --- | --- | --- |
UNHEALTHY | UNKNOWN | UNKNOWN | UNHEALTHY |
UNHEALTHY | UNKNOWN | HEALTHY | UNHEALTHY |
UNHEALTHY | HEALTHY, | HEALTHY | UNHEALTHY |
HEALTHY | UNKNOWN | HEALTHY | UNKNOWN |
HEALTHY | UNKNOWN | UNKNOWN | UNKNOWN |
HEALTHY | HEALTHY | HEALTHY | HEALTHY |

### View Amazon ECS container health

You can view the container health in console, and the DescribeTasks response. For more information, see [DescribeTasks](https://docs.aws.amazon.com/AmazonECS/latest/developer-guide/ecs-api-describetasks.html) in the Amazon Elastic Container Service API Reference.

If you use logging for your container, for example Amazon CloudWatch, you can configure the health check command to forward the container health output to your logs. Make sure to use `2>` to catch both the stdout and stderr information.

```
"command": [
    "CMD-SHELL",
    "curl -f http://localhost/ >> /proc/1/fd/1 2>&1 || exit 1"
],
```

### Monitor Amazon ECS container instance health

Amazon ECS provides container instance health monitoring. You can quickly determine whether Amazon ECS has detected any problems that might prevent your container instances from running containers. Amazon ECS performs automated checks on every running container instance with agent version 1.57.0 or later to identify issues. For more information on verifying the agent version on a container instance, see [Updating the Amazon ECS container agent](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/agent-update.html).
You must be using AWS CLI version 1.22.3 or later or AWS CLI version 2.3.6 or later. For information about how to update the AWS CLI, see Installing or updating the latest version of the AWS CLI in the AWS Command Line Interface User Guide Version 2.

Status checks are performed about twice per minute, returning a pass or a fail status. If all checks pass, the overall status of the instance is OK. If one or more checks fail, the overall status is IMPAIRED. Status checks are built into Amazon ECS container agent, so they cannot be turned off or deleted. You can view the results of these status checks to identify specific and detectable problems. For more information, see the section called “Health check”.

Run the DescribeContainerInstances API with the CONTAINER_INSTANCE_HEALTH option to retrieve the container instance health.

```bash
aws ecs describe-container-instances \
  --cluster cluster_name \
  --container-instances 47279cd2cadb41cbaef2dcEXAMPLE \
  --include CONTAINER_INSTANCE_HEALTH
```

The following is an example of the health status object in the output.

```
"healthStatus": {
  "overallStatus": "OK",
  "details": [{
    "type": "CONTAINER_RUNTIME",
    "status": "OK",
    "lastUpdated": "2021-11-10T03:30:26+00:00",
    "lastStatusChange": "2021-11-10T03:26:41+00:00"
  }]}
```

**Identify Amazon ECS optimization opportunities using application trace data**

Amazon ECS integrates with AWS Distro for OpenTelemetry to collect trace data from your application. Amazon ECS uses an AWS Distro for OpenTelemetry sidecar container to collect
and route trace data to AWS X-Ray. For more information, see Setting up AWS Distro for OpenTelemetry Collector in Amazon ECS. You can then use AWS X-Ray to identify errors and exceptions, analyze performance bottlenecks and response times.

For the AWS Distro for OpenTelemetry Collector to send trace data to AWS X-Ray, your application must be configured to create the trace data. For more information, see Instrumenting your application for AWS X-Ray in the AWS X-Ray Developer Guide.

**Required IAM permissions for AWS Distro for OpenTelemetry integration with AWS X-Ray**

The Amazon ECS integration with AWS Distro for OpenTelemetry requires that you create a task IAM role and specify the role in your task definition. We recommend that the AWS Distro for OpenTelemetry sidecar also be configured to route container logs to CloudWatch Logs which requires a task execution IAM role be created and specified in your task definition as well. The Amazon ECS console takes care of the task execution IAM role on your behalf, but the task IAM role must be created manually. For more information about creating a task execution IAM role, see Amazon ECS task execution IAM role.

⚠️ **Important**

If you're also collecting application metrics using the AWS Distro for OpenTelemetry integration, ensure your task IAM role also contains the permissions necessary for that integration. For more information, see Correlate Amazon ECS application performance using application metrics.

**To create the service role for Elastic Container Service (IAM console)**

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose Roles, and then choose Create role.
3. For Trusted entity type, choose AWS service.
4. For Service or use case, choose Elastic Container Service, and then choose the Elastic Container Service Task use case.
5. Choose Next.
6. In the **Add permissions** section, search for `AWSDistroOpenTelemetryPolicyForXray`, then select the policy.

7. (Optional) Set a **permissions boundary**. This is an advanced feature that is available for service roles, but not service-linked roles.

   a. Open the **Set permissions boundary** section, and then choose **Use a permissions boundary to control the maximum role permissions**.

      IAM includes a list of the AWS managed and customer-managed policies in your account.

   b. Select the policy to use for the permissions boundary.

8. Choose **Next**.

9. Enter a role name or a role name suffix to help you identify the purpose of the role.

   **Important**
   
   When you name a role, note the following:

   - Role names must be unique within your AWS account, and can't be made unique by case.

   For example, don't create roles named both `PRODROLE` and `prodrole`. When a role name is used in a policy or as part of an ARN, the role name is case sensitive, however when a role name appears to customers in the console, such as during the sign-in process, the role name is case insensitive.

   - You can't edit the name of the role after it's created because other entities might reference the role.

10. (Optional) For **Description**, enter a description for the role.

11. (Optional) To edit the use cases and permissions for the role, in the **Step 1: Select trusted entities** or **Step 2: Add permissions** sections, choose **Edit**.

12. (Optional) To help identify, organize, or search for the role, add tags as key-value pairs. For more information about using tags in IAM, see **Tagging IAM resources** in the **IAM User Guide**.

13. Review the role, and then choose **Create role**.
Specifying the AWS Distro for OpenTelemetry sidecar for AWS X-Ray integration in your task definition

The Amazon ECS console simplifies creating the AWS Distro for OpenTelemetry sidecar container by using the **Use trace collection** option. For more information, see [Creating a task definition using the console](#). If you're not using the Amazon ECS console, you can add the AWS Distro for OpenTelemetry sidecar container to your task definition. The following task definition snippet shows the container definition for adding the AWS Distro for OpenTelemetry sidecar for AWS X-Ray integration.

```json
{
    "family": "otel-using-xray",
    "taskRoleArn": "arn:aws:iam::111122223333:role/AmazonECS_OpenTelemetryXrayRole",
    "executionRoleArn": "arn:aws:iam::111122223333:role/ecsTaskExecutionRole",
    "containerDefinitions": [
        {
            "name": "aws-otel-emitter",
            "image": "application-image",
            "logConfiguration": {
                "logDriver": "awslogs",
                "options": {
                    "awslogs-create-group": "true",
                    "awslogs-group": "/ecs/aws-otel-emitter",
                    "awslogs-region": "us-east-1",
                    "awslogs-stream-prefix": "ecs"
                }
            },
            "dependsOn": [{
                "containerName": "aws-otel-collector",
                "condition": "START"
            }]
        },
        {
            "name": "aws-otel-collector",
            "image": "public.ecr.aws/aws-observability/aws-otel-collector:v0.30.0",
            "essential": true,
            "command": ["--config=/etc/ecs/otel-instance-metrics-config.yaml"],
            "logConfiguration": {
                "logDriver": "awslogs",
                "options": {
```

Correlate Amazon ECS application performance using application metrics

Amazon ECS on Fargate supports collecting metrics from your applications running on Fargate and exporting them to either Amazon CloudWatch or Amazon Managed Service for Prometheus.

You can use the collected metadata to correlate application performance data with underlying infrastructure data, reducing the mean time to resolve the problem.

Amazon ECS uses an AWS Distro for OpenTelemetry sidecar container to collect and route your application metrics to the destination. The Amazon ECS console experience simplifies the process of adding this integration when creating your task definitions.

Topics

- Exporting application metrics to Amazon CloudWatch
- Exporting application metrics to Amazon Managed Service for Prometheus

Exporting application metrics to Amazon CloudWatch

Amazon ECS on Fargate supports exporting your custom application metrics to Amazon CloudWatch as custom metrics. This is done by adding the AWS Distro for OpenTelemetry sidecar container to your task definition. The Amazon ECS console simplifies this process by adding the
metric collection option when creating a new task definition. For more information, see Creating a task definition using the console.

The application metrics are exported to CloudWatch Logs with log group name /aws/ecs/application/metrics and the metrics can be viewed in the ECS/AWSOTel/Application namespace. Your application must be instrumented with the OpenTelemetry SDK. For more information, see Introduction to AWS Distro for OpenTelemetry in the AWS Distro for OpenTelemetry documentation.

Considerations

The following should be considered when using the Amazon ECS on Fargate integration with AWS Distro for OpenTelemetry to send application metrics to Amazon CloudWatch.

- This integration only sends your custom application metrics to CloudWatch. If you want task-level metrics, you can turn on Container Insights in the Amazon ECS cluster configuration. For more information, see Monitor Amazon ECS containers using Container Insights.
- The AWS Distro for OpenTelemetry integration is supported for Amazon ECS workloads hosted on Fargate and Amazon ECS workloads hosted on Amazon EC2 instances. External instances aren't currently supported.
- CloudWatch supports a maximum of 30 dimensions per metric. By default, Amazon ECS defaults to including the TaskARN, ClusterARN, LaunchType, TaskDefinitionFamily, and TaskDefinitionRevision dimensions to the metrics. The remaining 25 dimensions can be defined by your application. If more than 30 dimensions are configured, CloudWatch can't display them. When this occurs, the application metrics will appear in the ECS/AWSOTel/Application CloudWatch metric namespace but without any dimensions. You can instrument your application to add additional dimensions. For more information, see Using CloudWatch metrics with AWS Distro for OpenTelemetry in the AWS Distro for OpenTelemetry documentation.

Required IAM permissions for AWS Distro for OpenTelemetry integration with Amazon CloudWatch

The Amazon ECS integration with AWS Distro for OpenTelemetry requires that you create a task IAM role and specify the role in your task definition. We recommend that the AWS Distro for OpenTelemetry sidecar also be configured to route container logs to CloudWatch Logs which requires a task execution IAM role be created and specified in your task definition as well. The
Amazon ECS console takes care of the task execution IAM role on your behalf, but the task IAM role must be created manually and added to your task definition. For more information about the task execution IAM role, see [Amazon ECS task execution IAM role](#).

**Important**

If you're also collecting application trace data using the AWS Distro for OpenTelemetry integration, ensure your task IAM role also contains the permissions necessary for that integration. For more information, see [Identify Amazon ECS optimization opportunities using application trace data](#). If your application requires any additional permissions, you should add them to this policy. Each task definition may only specify one task IAM role. For example, if you are using a custom configuration file stored in Systems Manager, you should add the `ssm:GetParameters` permission to this IAM policy.

---

**To create the service role for Elastic Container Service (IAM console)**

1. Sign in to the AWS Management Console and open the IAM console at [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/).
2. In the navigation pane of the IAM console, choose **Roles**, and then choose **Create role**.
3. For **Trusted entity type**, choose **AWS service**.
4. For **Service or use case**, choose **Elastic Container Service**, and then choose the **Elastic Container Service Task** use case.
5. Choose **Next**.
6. In the **Add permissions** section, search for `AWSDistroOpenTelemetryPolicyForXray`, then select the policy.
7. (Optional) Set a **permissions boundary**. This is an advanced feature that is available for service roles, but not service-linked roles.
   a. Open the **Set permissions boundary** section, and then choose **Use a permissions boundary to control the maximum role permissions**.

   IAM includes a list of the AWS managed and customer-managed policies in your account.
   b. Select the policy to use for the permissions boundary.
8. Choose **Next**.
9. Enter a role name or a role name suffix to help you identify the purpose of the role.

⚠️ **Important**

When you name a role, note the following:

- Role names must be unique within your AWS account, and can't be made unique by case.

  For example, don't create roles named both `PRODROLE` and `prodrole`. When a role name is used in a policy or as part of an ARN, the role name is case sensitive, however when a role name appears to customers in the console, such as during the sign-in process, the role name is case insensitive.

- You can't edit the name of the role after it's created because other entities might reference the role.

10. (Optional) For **Description**, enter a description for the role.

11. (Optional) To edit the use cases and permissions for the role, in the **Step 1: Select trusted entities** or **Step 2: Add permissions** sections, choose **Edit**.

12. (Optional) To help identify, organize, or search for the role, add tags as key-value pairs. For more information about using tags in IAM, see **Tagging IAM resources** in the **IAM User Guide**.

13. Review the role, and then choose **Create role**.

**Specifying the AWS Distro for OpenTelemetry sidecar in your task definition**

The Amazon ECS console simplifies the experience of creating the AWS Distro for OpenTelemetry sidecar container by using the **Use metric collection** option. For more information, see **Creating a task definition using the console**.

If you're not using the Amazon ECS console, you can add the AWS Distro for OpenTelemetry sidecar container to your task definition manually. The following task definition example shows the container definition for adding the AWS Distro for OpenTelemetry sidecar for Amazon CloudWatch integration.

```json
{
    "family": "otel-using-cloudwatch",
    "taskRoleArn": "arn:aws:iam::111122223333:role/AmazonECS_OpenTelemetryCloudWatchRole",
    "executionRoleArn": "arn:aws:iam::111122223333:role/ecsTaskExecutionRole",
    "streaming_logs": true,
    "containers": ["otel-using-cloudwatch"],
    "cpu": 1024,
    "memory": 512
}
```
"containerDefinitions": [{
  "name": "aws-otel-emitter",
  "image": "application-image",
  "logConfiguration": {
    "logDriver": "awslogs",
    "options": {
      "awslogs-create-group": "true",
      "awslogs-group": "/ecs/aws-otel-emitter",
      "awslogs-region": "us-east-1",
      "awslogs-stream-prefix": "ecs"
    }
  },
  "dependsOn": [{
    "containerName": "aws-otel-collector",
    "condition": "START"
  }]
},
{
  "name": "aws-otel-collector",
  "image": "public.ecr.aws/aws-observability/aws-otel-collector:v0.30.0",
  "essential": true,
  "command": [
    "--config=/etc/ecs/ecs-cloudwatch.yaml"
  ],
  "logConfiguration": {
    "logDriver": "awslogs",
    "options": {
      "awslogs-create-group": "True",
      "awslogs-group": "/ecs/aws-otel-sidecar-collector",
      "awslogs-region": "us-east-1",
      "awslogs-stream-prefix": "ecs"
    }
  }
}]
"networkMode": "awsvpc",
"requiresCompatibilities": ["FARGATE"
"cpu": "1024",
"memory": "3072"
}
Exporting application metrics to Amazon Managed Service for Prometheus

Amazon ECS supports exporting your task-level CPU, memory, network, and storage metrics and your custom application metrics to Amazon Managed Service for Prometheus. This is done by adding the AWS Distro for OpenTelemetry sidecar container to your task definition. The Amazon ECS console simplifies this process by adding the Use metric collection option when creating a new task definition. For more information, see Creating a task definition using the console.

The metrics are exported to Amazon Managed Service for Prometheus and can be viewed using the Amazon Managed Grafana dashboard. Your application must be instrumented with either Prometheus libraries or with the OpenTelemetry SDK. For more information about instrumenting your application with the OpenTelemetry SDK, see Introduction to AWS Distro for OpenTelemetry in the AWS Distro for OpenTelemetry documentation.

When using the Prometheus libraries, your application must expose a /metrics endpoint which is used to scrape the metrics data. For more information about instrumenting your application with Prometheus libraries, see Prometheus client libraries in the Prometheus documentation.

Considerations

The following should be considered when using the Amazon ECS on Fargate integration with AWS Distro for OpenTelemetry to send application metrics to Amazon Managed Service for Prometheus.

- The AWS Distro for OpenTelemetry integration is supported for Amazon ECS workloads hosted on Fargate and Amazon ECS workloads hosted on Amazon EC2 instances. External instances aren't supported currently.
- By default, AWS Distro for OpenTelemetry includes all available task-level dimensions for your application metrics when exporting to Amazon Managed Service for Prometheus. You can also instrument your application to add additional dimensions. For more information, see Getting Started with Prometheus Remote Write Exporter for Amazon Managed Service for Prometheus in the AWS Distro for OpenTelemetry documentation.

Required IAM permissions for AWS Distro for OpenTelemetry integration with Amazon Managed Service for Prometheus

The Amazon ECS integration with Amazon Managed Service for Prometheus using the AWS Distro for OpenTelemetry sidecar requires that you create a task IAM role and specify the role in your task
Definition. This task IAM role must be created manually using the steps below prior to registering your task definition.

We recommend that the AWS Distro for OpenTelemetry sidecar also be configured to route container logs to CloudWatch Logs which requires a task execution IAM role be created and specified in your task definition as well. The Amazon ECS console takes care of the task execution IAM role on your behalf, but the task IAM role must be created manually. For more information about creating a task execution IAM role, see Amazon ECS task execution IAM role.

⚠️ Important

If you're also collecting application trace data using the AWS Distro for OpenTelemetry integration, ensure your task IAM role also contains the permissions necessary for that integration. For more information, see Identify Amazon ECS optimization opportunities using application trace data.

To create the service role for Elastic Container Service (IAM console)

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane of the IAM console, choose Roles, and then choose Create role.
3. For Trusted entity type, choose AWS service.
4. For Service or use case, choose Elastic Container Service, and then choose the Elastic Container Service Task use case.
5. Choose Next.
6. In the Add permissions section, search for AmazonPrometheusRemoteWriteAccess, then select the policy.
7. (Optional) Set a permissions boundary. This is an advanced feature that is available for service roles, but not service-linked roles.
   a. Open the Set permissions boundary section, and then choose Use a permissions boundary to control the maximum role permissions.
      IAM includes a list of the AWS managed and customer-managed policies in your account.
   b. Select the policy to use for the permissions boundary.
8. Choose Next.
9. Enter a role name or a role name suffix to help you identify the purpose of the role.

⚠️ **Important**

When you name a role, note the following:

- Role names must be unique within your AWS account, and can't be made unique by case.

  For example, don't create roles named both **PRODROLE** and **prodrole**. When a role name is used in a policy or as part of an ARN, the role name is case sensitive, however when a role name appears to customers in the console, such as during the sign-in process, the role name is case insensitive.

- You can't edit the name of the role after it's created because other entities might reference the role.

10. (Optional) For **Description**, enter a description for the role.

11. (Optional) To edit the use cases and permissions for the role, in the **Step 1: Select trusted entities** or **Step 2: Add permissions** sections, choose **Edit**.

12. (Optional) To help identify, organize, or search for the role, add tags as key-value pairs. For more information about using tags in IAM, see [Tagging IAM resources](#) in the **IAM User Guide**.

13. Review the role, and then choose **Create role**.

### Specifying the AWS Distro for OpenTelemetry sidecar in your task definition

The Amazon ECS console simplifies the experience of creating the AWS Distro for OpenTelemetry sidecar container by using the **Use metric collection** option. For more information, see [Creating a task definition using the console](#).

If you're not using the Amazon ECS console, you can add the AWS Distro for OpenTelemetry sidecar container to your task definition manually. The following task definition example shows the container definition for adding the AWS Distro for OpenTelemetry sidecar for Amazon Managed Service for Prometheus integration.

```json
{
  "family": "otel-using-cloudwatch",
  "taskRoleArn": "arn:aws:iam::111122223333:role/AmazonECS_OpenTelemetryCloudWatchRole",
  "executionRoleArn": "arn:aws:iam::111122223333:role/ecsTaskExecutionRole",
```
"containerDefinitions": [{
  "name": "aws-otel-emitter",
  "image": "application-image",
  "logConfiguration": {
    "logDriver": "awslogs",
    "options": {
      "awslogs-create-group": "true",
      "awslogs-group": "/ecs/aws-otel-emitter",
      "awslogs-region": "aws-region",
      "awslogs-stream-prefix": "ecs"
    }
  },
  "dependsOn": [{
    "containerName": "aws-otel-collector",
    "condition": "START"
  }]
},
{
  "name": "aws-otel-collector",
  "image": "public.ecr.aws/aws-observability/aws-otel-collector:v0.30.0",
  "essential": true,
  "command": ["--config=/etc/ecs/ecs-amp.yaml"],
  "environment": [{
    "name": "AWS_PROMETHEUS_ENDPOINT",
    "value": "https://aps-workspaces.aws-region.amazonaws.com/workspaces/ws-a1b2c3d4-5678-90ab-cdef-EXAMPLE11111/api/v1/remote_write"
  }],
  "logConfiguration": {
    "logDriver": "awslogs",
    "options": {
      "awslogs-create-group": "True",
      "awslogs-group": "/ecs/aws-otel-sidecar-collector",
      "awslogs-region": "aws-region",
      "awslogs-stream-prefix": "ecs"
    }
  }
}]
"networkMode": "awsvpc",
"requiresCompatibilities": [
  "FARGATE"
]
Log Amazon ECS API calls using AWS CloudTrail

Amazon ECS is integrated with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Amazon ECS. CloudTrail captures all API calls for Amazon ECS as events, including calls from the Amazon ECS console and from code calls to the Amazon ECS API operations. To protect your VPC, requests that are denied by a VPC endpoint policy, but otherwise would have been allowed, are not recorded in CloudTrail.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Amazon ECS. If you don’t configure a trail, you can still view the most recent events in the CloudTrail console in Event history. Using the information collected by CloudTrail, you can determine the request that was made to Amazon ECS, the IP address from which the request was made, who made the request, when it was made, and additional details.

For more information, see the AWS CloudTrail User Guide.

Amazon ECS information in CloudTrail

CloudTrail is turned on in your AWS account when you create the account. When activity occurs in Amazon ECS, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for Amazon ECS, create a trail which CloudTrail uses to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see:

- Overview for Creating a Trail
- CloudTrail Supported Services and Integrations
- Configuring Amazon SNS Notifications for CloudTrail
• Receiving CloudTrail Log Files from Multiple Regions and Receiving CloudTrail Log Files from Multiple Accounts

All Amazon ECS actions are logged by CloudTrail and are documented in the Amazon Elastic Container Service API Reference. For example, calls to the CreateService, RunTask and DeleteCluster sections generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

• Whether the request was made with root user or user credentials.
• Whether the request was made with temporary security credentials for a role or federated user.
• Whether the request was made by another AWS service.

For more information, see the CloudTrail userIdentity Element.

Understanding Amazon ECS log file entries

A trail is a configuration that allows the delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An event represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

⚠️ Note

These examples have been formatted for improved readability. In a CloudTrail log file, all entries and events are concatenated into a single line. In addition, this example has been limited to a single Amazon ECS entry. In a real CloudTrail log file, you see entries and events from multiple AWS services.

The following example shows a CloudTrail log entry that demonstrates the CreateCluster action:

```json
{
   "eventVersion": "1.04",
   "userIdentity": {
```
"type": "AssumedRole",
"principalId": "AIDACKCEVSQ6C2EXAMPLE:account_name",
"arn": "arn:aws:sts::123456789012:user/Mary_Major",

"eventType": "AwsApiCall",
"recipientAccountId": "123456789012"
Identify unauthorized behavior using Runtime Monitoring

Amazon GuardDuty is a threat detection service that helps protect your accounts, containers, workloads, and the data within your AWS environment. Using machine learning (ML) models, and anomaly and threat detection capabilities, GuardDuty continuously monitors different log sources and runtime activity to identify and prioritize potential security risks and malicious activities in your environment.

Runtime Monitoring in GuardDuty protects workloads running on Fargate and EC2 container instances by continuously monitoring AWS log and networking activity to identify malicious or unauthorized behavior. Runtime Monitoring uses a lightweight, fully managed GuardDuty security agent that analyzes on-host behavior, such as file access, process execution, and network connections. This covers issues including escalation of privileges, use of exposed credentials, or communication with malicious IP addresses, domains, and the presence of malware on your Amazon EC2 instances and container workloads. For more information, see GuardDuty Runtime Monitoring in the GuardDuty User Guide.

Your security administrator enables Runtime Monitoring for a single or multiple accounts in AWS Organizations for GuardDuty. They also select whether GuardDuty automatically deploys the GuardDuty security agent when you use Fargate. All your clusters are automatically protected, and GuardDuty manages the security agent on your behalf.

You can also manually configure the GuardDuty security agent in the following cases:

- You use EC2 container instances
- You need granular control to enable Runtime Monitoring at the cluster level

To use Runtime Monitoring, you must configure the clusters that are protected, and install and manage the GuardDuty security agent on your EC2 container instances.

How Runtime Monitoring works with Amazon ECS

Runtime Monitoring uses a lightweight GuardDuty security agent that monitors Amazon ECS workload activity for how applications are requesting, gaining access and consuming underlying system resources.

For Fargate tasks, the GuardDuty security agent runs as a sidecar container for each task.
For EC2 container instances, the GuardDuty security agent runs as a process on the instance.

The GuardDuty security agent collects data from the following resources, and then sends the data to GuardDuty to process. You can view the findings in the GuardDuty console. You can also send them to other AWS services such as AWS Security Hub, or a third-party security vendor for aggregation and remediation. For information about how to view and manage findings, see [Managing Amazon GuardDuty findings](https://docs.aws.amazon.com/guardduty/latest/ug/finding-overview.html) in the *Amazon GuardDuty User Guide*.

- Responses from the following Amazon ECS API calls:
  - **DescribeClusters**
    
    The response parameters include the Runtime Monitoring tag (when the tag is set) when you use the `--include` `TAGS` option.
  - **DescribeTasks**
    
    For the Fargate launch type, the response parameters include the GuardDuty sidecar container.
  - **ListAccountSettings**
    
    The response parameters include the Runtime Monitoring account setting, which is set by your security administrator.
  - The container agent introspection data. For more information, see [Amazon ECS container introspection](https://docs.aws.amazon.com/ecs/latest/userguide/ecsוציאnzation.html).
  - The task metadata endpoint for the launch type:
    - [Amazon ECS task metadata endpoint version 4](https://docs.aws.amazon.com/ecs/latest/userguide/ecstaskmetadata.html)
    - [Amazon ECS task metadata endpoint version 4 for tasks on Fargate](https://docs.aws.amazon.com/ecs/latest/userguide/ecs姥姥sessment.html)

### Considerations

Consider the following when using Runtime Monitoring:

- Runtime Monitoring has a cost associated with it. For more information, see [Amazon GuardDuty Pricing](https://aws.amazon.com/guardduty/pricing/).
- Runtime Monitoring is not supported on Amazon ECS Anywhere.
- Runtime Monitoring is not supported for the Windows operating system.
- When you use Amazon ECS Exec on Fargate, you must specify the container name because the GuardDuty security agent runs as a sidecar container.
• You cannot use Amazon ECS Exec on the GuardDuty security agent sidecar container.
• The IAM user that controls Runtime Monitoring at the cluster level, must have the appropriate IAM permissions for tagging. For more information, see IAM tutorial: Define permissions to access AWS resources based on tags in the IAM User Guide.
• Fargate tasks must use a task execution role. This role grants the tasks permission to retrieve, update, and manage the GuardDuty security agent, which is stored in an Amazon ECR private repository, on your behalf.

Resource utilization

The tag that you add to the cluster counts toward the cluster tag quota.

The GuardDuty agent sidecar container does not count toward the containers per task definition quota.

As with most security software, there is a slight overhead for GuardDuty. For information about the Fargate memory limits, see CPU and memory limits in the GuardDuty User Guide. For information about the Amazon EC2 memory limits, see CPU and memory limit for GuardDuty agent.

GuardDuty agent management

If you use EC2 container instances, you must manually configure Runtime Monitoring. For more information, see Manual Runtime Monitoring management.

When you use GuardDuty agent management, GuardDuty performs the following operations:

• Creates VPC endpoints for GuardDuty for each VPC that hosts a cluster.
• Retrieves, and installs the latest GuardDuty security agent as a sidecar container on all new standalone Fargate tasks, and new service deployments.

   A new service deployment happens the first time you launch a service, or when you update an existing service with the force new deployment option.

Prerequisites

The following are prerequisites for using Runtime Monitoring:

• The Fargate platform version must be 1.4.0 or later for Linux.
For information about the supported Linux operating systems and architectures, see Which operating models and workloads does GuardDuty Runtime Monitoring support.

IAM roles and permissions for Amazon ECS:

- Fargate tasks must use a task execution role. This role grants the tasks permission to retrieve, update, and manage the GuardDuty security agent on your behalf. For more information see Amazon ECS task execution IAM role.
- You control Runtime Monitoring for a cluster with a pre-defined tag. If your access policies restrict access based on tags, you must grant explicit permissions to your IAM users to tag clusters. For more information, see IAM tutorial: Define permissions to access AWS resources based on tags in the IAM User Guide.

Connecting to the Amazon ECR repository:

The GuardDuty security agent is stored in an Amazon ECR repository. Each standalone and service task must have access to the repository. You can use one of the following options:

- For tasks in public subnets, you can either use a public IP address for the task, or create a VPC endpoint for Amazon ECR in the subnet where the task runs. For more information, see Amazon ECR interface VPC endpoints (AWS PrivateLink) in the Amazon Elastic Container Registry User Guide.
- For tasks in private subnets, you can use a Network Address Translation (NAT) gateway, or create a VPC endpoint for Amazon ECR in the subnet where the task runs.

For more information, see Using a private subnet and NAT gateway.

- You must have the AWSServiceRoleForAmazonGuardDuty role for GuardDuty. For more information, see Service-linked role permissions for GuardDuty in the Amazon GuardDuty User Guide.
- Any files that you want to protect with Runtime Monitoring must be accessible by the root user. If you manually changed the permissions of a file, you must set it to 755.

Enabling Runtime Monitoring

You enable Runtime Monitoring in GuardDuty. For information about how to enable the feature, see Enabling Runtime Monitoring in the Amazon GuardDuty User Guide.
Adding Runtime Monitoring to existing Fargate tasks

When you enable Runtime Monitoring, all new standalone tasks, and new service deployments in the cluster are protected automatically. In order to preserve the immutability constraint, existing tasks are not affected. To immediately protect a task, you need to perform one of the following actions:

- For standalone tasks, stop the tasks, and then start them.
- For tasks that are part of a service, update the service with the "force new deployment" option.

Removing Runtime Monitoring from a cluster

You might want to exclude certain clusters from protection, for example clusters that you use for testing. This causes GuardDuty to perform the following operations on resources in the cluster:

- No longer deploy the GuardDuty security agent to new standalone Fargate tasks, or new service deployments.

In order to preserve the immutability constraint, existing tasks and deployments with Runtime Monitoring enabled are not affected.

- Stop billing and no longer accepts run time events for tasks.

Perform the following operations to remove Runtime Monitoring from a cluster.

1. Use the Amazon ECS console or AWS CLI to set the `GuardDutyManaged` tag key on the cluster to `false`. For more information, see Updating a cluster or Working with tags using the CLI or API. Use the following values for the tag.

   **Note**
   
   The Key and Value are case sensitive and must exactly match the strings.

   Key = GuardDutyManaged, Value = false

2. Delete the GuardDuty VPC endpoint for the cluster. For more information about how to delete VPC endpoints, see Delete an interface endpoint in the AWS PrivateLink User Guide.
Removing Runtime Monitoring from an account

When you no longer want to use Runtime Monitoring, disable the feature in GuardDuty. For information about how to disable the feature, see Enabling Runtime Monitoring in the Amazon GuardDuty User Guide.

GuardDuty performs the following operations:

- Deletes the VPC endpoints for GuardDuty for each VPC that hosts a cluster.
- No longer deploys the GuardDuty security agent to new standalone Fargate tasks, or new service deployments.

  In order to preserve the immutability constraint, existing tasks and deployments are not affected until they are stopped, replicated, or scaled.
- Stops billing and no longer accepts run time events for tasks.

Manual Runtime Monitoring management

Use this when you use EC2 instances for your capacity, or when you need granular control of enabling Runtime Monitoring at the cluster-level on Fargate.

You provision the clusters for Runtime Monitoring by adding a pre-defined tag.

For EC2 container instances, you download, install, and manage the GuardDuty security agent.

For Fargate, GuardDuty manages the security agent on your behalf.

Prerequisites

The following are prerequisites for using Runtime Monitoring:

- The Fargate platform version must be 1.4.0 or later for Linux.
- IAM roles and permissions for Amazon ECS:
  - Fargate tasks must use a task execution role. This role grants the tasks permission to retrieve, update, and manage the GuardDuty security agent on your behalf. For more information see Amazon ECS task execution IAM role.
  - You control Runtime Monitoring for a cluster with a pre-defined tag. If your access policies restrict access based on tags, you must grant explicit permissions to your IAM users to tag
clusters. For more information, see IAM tutorial: Define permissions to access AWS resources based on tags in the IAM User Guide.

- Connecting to the Amazon ECR repository:

  The GuardDuty security agent is stored in an Amazon ECR repository. Each standalone and service task must have access to the repository. You can use one of the following options:

  - For tasks in public subnets, you can either use a public IP address for the task, or create a VPC endpoint for Amazon ECR in the subnet where the task runs. For more information, see Amazon ECR interface VPC endpoints (AWS PrivateLink) in the Amazon Elastic Container Registry User Guide.

  - For tasks in private subnets, you can use a Network Address Translation (NAT) gateway, or create a VPC endpoint for Amazon ECR in the subnet where the task runs.

    For more information, see Using a private subnet and NAT gateway.

  - You must have the AWSServiceRoleForAmazonGuardDuty role for GuardDuty. For more information, see Service-linked role permissions for GuardDuty in the Amazon GuardDuty User Guide.

  - Any files that you want to protect with Runtime Monitoring must be accessible by the root user. If you manually changed the permissions of a file, you must set it to 755.

The following are prerequisites for using Runtime Monitoring on EC2 container instances:

- You must use version 20230929 or later of the Amazon ECS-AMI.
- You must run Amazon ECS agent to version 1.77 or later on the container instances.
- You must use kernel version 5.10 or later.
- For information about the supported Linux operating systems and architectures, see Which operating models and workloads does GuardDuty Runtime Monitoring support.
- You can use Systems Manager to manage your container instances. For more information, see Setting up Systems Manager for EC2 instances in the AWS Systems Manager Session Manager User Guide.

Enabling Runtime Monitoring

You enable this feature in GuardDuty. For information about how to enable the feature, see Enabling Runtime Monitoring in the Amazon GuardDuty User Guide.
Configuring Runtime Monitoring for clusters

Configure Runtime Monitoring for the cluster, and then install the GuardDuty security agent on your EC2 container instances.

Adding Runtime Monitoring to a cluster

Perform the following operations to add Runtime Monitoring to a cluster.

1. Create a VPC endpoint for GuardDuty for each cluster VPC. For more information, see Creating Amazon VPC endpoint manually in the GuardDuty User Guide.

2. Configure the EC2 container instances.
   - Update the Amazon ECS agent to version 1.77 or later on the EC2 container instances in the cluster. For more information see Updating the Amazon ECS container agent.
   - Install the GuardDuty security agent on the EC2 container instances in the cluster. For more information, see Managing the security agent on an Amazon EC2 instance manually in the GuardDuty User Guide.

   All new and existing tasks, and deployments are immediately protected because the GuardDuty security agent runs as a process on the EC2 container instance.

3. Use the Amazon ECS console or AWS CLI to set the GuardDutyManaged tag key on the cluster to true. For more information, see Updating a cluster or Working with tags using the CLI or API. Use the following values for the tag.

   Key = GuardDutyManaged, Value = true

Adding Runtime Monitoring to existing Fargate tasks

When you enable Runtime Monitoring, all new standalone tasks, and new service deployments in the cluster are protected automatically. In order to preserve the immutability constraint, existing tasks are not affected. To immediately protect a task, you need to perform one of the following actions:
For standalone tasks, stop the tasks, and then start them.

For tasks that are part of a service, update the service with the "force new deployment" option.

Removing Runtime Monitoring from a cluster

You can remove Runtime Monitoring from a cluster. This causes GuardDuty to stop monitoring all resources in the cluster.

To remove Runtime Monitoring from a cluster.

1. Use the Amazon ECS console or AWS CLI to set the GuardDutyManaged tag key on the cluster to false. For more information, see Updating a cluster or Working with tags using the CLI or API.

   Note
   The Key and Value are case sensitive and must exactly match the strings.

   Key = GuardDutyManaged, Value = false

2. Uninstall the GuardDuty security agent on you EC2 container instances in the cluster.

   For more information, see Uninstalling the security agent manually in the GuardDuty User Guide.

3. Delete the GuardDuty VPC endpoint for each cluster VPC. For more information about how to delete VPC endpoints, see Delete an interface endpoint in the AWS PrivateLink User Guide.

Updating the GuardDuty security agent on your EC2 container instances

For information about how to update the GuardDuty security agent on your EC2 container instances, see Updating GuardDuty security agent in the Amazon GuardDuty User Guide.

Removing Runtime Monitoring from an account

When you no longer want to use Runtime Monitoring, disable the feature in GuardDuty. For information about how to disable the feature, see Enabling Runtime Monitoring in the Amazon GuardDuty User Guide.
Remove Runtime Monitoring from all clusters. For more information, see Removing Runtime Monitoring from a cluster.

Runtime Monitoring Troubleshooting FAQs

You might need to troubleshoot or verify that Runtime Monitoring is enabled and running on your tasks and containers.

Topics

- How can I tell if Runtime Monitoring is active on my account?
- How can I tell if Runtime Monitoring is active on a cluster?
- How can I tell if the GuardDuty security agent is running on a Fargate task?
- How can I tell if the GuardDuty security agent is running on an EC2 container instance?
- What happens when there is no task execution role for a task running on the cluster?
- How can I tell if I have the correct permissions to tag clusters for Runtime Monitoring?
- What happens when there is no connection Amazon ECR?
- How do I address out of memory errors on my Fargate tasks after enabling Runtime Monitoring?

How can I tell if Runtime Monitoring is active on my account?

In the Amazon ECS console, the information is in on the Account Settings page.

You can also run list-account-settings with the effective-settings option.

```
aws ecs list-account-settings --effective-settings
```

Output

The setting with name set to guardDutyActivate and value set to on indicates that the account is configured. You must check with your GuardDuty administrator to see if the management is automatic or manual.

```
{
    "setting": {
        "name": "guardDutyActivate",
        "value": "enabled",
        "principalArn": "arn:aws:iam::123456789012:root",
        "type": "aws-managed"
    }
}
```
How can I tell if Runtime Monitoring is active on a cluster?

In the Amazon ECS console, the information is on Tags tab of the Cluster detail page.

You can also run describe-clusters with the TAGS option.

The following example shows the output for the default cluster

```
aws ecs describe-clusters --cluster default --include TAGS
```

Output

The tag with Key set to GuardDutyManaged and Value set to true indicates that the cluster is configured for Runtime Monitoring.

```
{
   "clusters": [
    {
     "clusterArn": "arn:aws:ecs:us-east-1:1234567890:cluster/default",
     "clusterName": "default",
     "status": "ACTIVE",
     "registeredContainerInstancesCount": 0,
     "runningTasksCount": 1,
     "pendingTasksCount": 0,
     "activeServicesCount": 0,
     "statistics": [],
     "tags": [
      {
       "key": "GuardDutyManaged",
       "value": "true"
      }
     ],
     "settings": [],
     "capacityProviders": [],
     "defaultCapacityProviderStrategy": []
    }
   ],
   "failures": []
}
```
How can I tell if the GuardDuty security agent is running on a Fargate task?

The GuardDuty security agent runs as a sidecar container for Fargate tasks.

In the Amazon ECS console, the sidecar is displayed under **Containers** on the **Task details** page.

You can run `describe-tasks` and look for the container with a **name** set to `aws-gd-agent` and the **lastStatus** set to **RUNNING**.

The following example shows the output for the default cluster for task `aws:ecs:us-east-1:123456789012:task/0b69d5c0-d655-4695-98cd-5d2d5EXAMPLE`.

```
aws ecs describe-tasks --cluster default --tasks aws:ecs:us-east-1:123456789012:task/0b69d5c0-d655-4695-98cd-5d2d5EXAMPLE
```

**Output**

The container named `gd-agent` is in the **RUNNING** state.

```
"containers": [ 
    
    
    "containerArn": "arn:aws:ecs:us-east-1:123456789012:container/4df26bb4-f057-467b-a079-96167EXAMPLE", 
    "taskArn": "arn:aws:ecs:us-east-1:123456789012:task/0b69d5c0-d655-4695-98cd-5d2d5EXAMPLE", 
    "lastStatus": "RUNNING", 
    "healthStatus": "UNKNOWN", 
    "memory": "string", 
    "name": "aws-gd-agent"
] 
```

How can I tell if the GuardDuty security agent is running on an EC2 container instance?

Run the following command to view the status:

```
sudo systemctl status amazon-guardduty-agent
```

The log file is in the following location:
What happens when there is no task execution role for a task running on the cluster?

For Fargate tasks, the task starts without the GuardDuty security agent sidecar container. The GuardDuty dashboard will show that the task is missing protection in the coverage statistics dashboard.

How can I tell if I have the correct permissions to tag clusters for Runtime Monitoring?

In order to tag a cluster, you must have the `ecs:TagResource` action for both `CreateCluster` and `UpdateCluster`.

The following is a snippet of an example policy.

```json
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["ecs:TagResource"],
      "Resource": "+",
      "Condition": {
        "StringEquals": {
          "ecs:CreateAction": "CreateCluster",
          "ecs:CreateAction": "UpdateCluster",
        }
      }
    }
  ]
}
```

What happens when there is no connection Amazon ECR?

For Fargate tasks, the task starts without the GuardDuty security agent sidecar container. The GuardDuty dashboard will show that the task is missing protection in the coverage statistics dashboard.
How do I address out of memory errors on my Fargate tasks after enabling Runtime Monitoring?

The GuardDuty security agent is a lightweight process. However, the process still consumes resources according to the size of the workload. We recommend using container resource tracking tooling, such as Amazon CloudWatch Container Insights to stage GuardDuty deployments in your cluster. These tools help you to discover the consumption profile of the GuardDuty security agent for your applications. You can then adjust your Fargate task size, if required, to avoid potential out of memory conditions.

Monitor Amazon ECS containers with ECS Exec

With Amazon ECS Exec, you can directly interact with containers without needing to first interact with the host container operating system, open inbound ports, or manage SSH keys. You can use ECS Exec to run commands in or get a shell to a container running on an Amazon EC2 instance or on AWS Fargate. This makes it easier to collect diagnostic information and quickly troubleshoot errors. For example, in a development context, you can use ECS Exec to easily interact with various process in your containers and troubleshoot your applications. And in production scenarios, you can use it to gain break-glass access to your containers to debug issues.

You can run commands in a running Linux or Windows container using ECS Exec from the Amazon ECS API, AWS Command Line Interface (AWS CLI), AWS SDKs, or the AWS Copilot CLI. For details on using ECS Exec, as well as a video walkthrough, using the AWS Copilot CLI, see the Copilot GitHub documentation.

You can also use ECS Exec to maintain stricter access control policies and audit container access. By selectively turning on this feature, you can control who can run commands and on which tasks they can run those commands. With a log of each command and their output, you can use ECS Exec to audit which tasks were run and you can use CloudTrail to audit who accessed a container.

Considerations for using ECS Exec

For this topic, you should be familiar with the following aspects involved with using ECS Exec:

- ECS Exec is not currently supported using the AWS Management Console.
- ECS Exec is supported for tasks that run on the following infrastructure:
  - Linux containers on Amazon EC2 on any Amazon ECS-optimized AMI, including Bottlerocket
Linux and Windows containers on external instances (Amazon ECS Anywhere)

Linux and Windows containers on AWS Fargate

Windows containers on Amazon EC2 on the following Windows Amazon ECS-optimized AMIs (with the container agent version 1.56 or later):

- Amazon ECS-optimized Windows Server 2022 Full AMI
- Amazon ECS-optimized Windows Server 2022 Core AMI
- Amazon ECS-optimized Windows Server 2019 Full AMI
- Amazon ECS-optimized Windows Server 2019 Core AMI
- Amazon ECS-optimized Windows Server 20H2 Core AMI

ECS Exec and Amazon VPC

- If you are using interface Amazon VPC endpoints with Amazon ECS, you must create the interface Amazon VPC endpoints for the Systems Manager Session Manager (ssmmessages). For more information about Systems Manager VPC endpoints, see Use AWS PrivateLink to set up a VPC endpoint for Session Manager in the AWS Systems Manager User Guide.

- If you are using interface Amazon VPC endpoints with Amazon ECS, and you are using AWS KMS key for encryption, then you must create the interface Amazon VPC endpoint for AWS KMS key. For more information, see Connecting to AWS KMS key through a VPC endpoint in the AWS Key Management Service Developer Guide.

- When you have tasks that run on Amazon EC2 instances, use awsvpc networking mode. If you don't have internet access, such as not configured to use a NAT gateway), you must create the interface Amazon VPC endpoints for the Systems Manager Session Manager (ssmmessages). For more information about awsvpc network mode considerations, see Considerations. For more information about Systems Manager VPC endpoints, see Use AWS PrivateLink to set up a VPC endpoint for Session Manager in the AWS Systems Manager User Guide.

ECS Exec and SSM

- When a user runs commands on a container using ECS Exec, these commands are run as the root user. The SSM agent and its child processes run as root even when you specify a user ID for the container.

- The SSM agent requires that the container file system can be written to in order to create the required directories and files. Therefore, making the root file system read-only using the readonlyRootFilesystem task definition parameter, or any other method, isn't supported.

- While starting SSM sessions outside of the execute-command action is possible, this results in the sessions not being logged and being counted against the session limit. We recommend
limiting this access by denying the ssm:start-session action using an IAM policy. For more information, see Limiting access to the Start Session action.

- The following features run as a sidecar container. Therefore, you must specify the container name to run the command on.
  - Runtime Monitoring
  - Service Connect

- Users can run all of the commands that are available within the container context. The following actions might result in orphaned and zombie processes: terminating the main process of the container, terminating the command agent, and deleting dependencies. To cleanup zombie processes, we recommend adding the initProcessEnabled flag to your task definition.

- ECS Exec uses some CPU and memory. You'll want to accommodate for that when specifying the CPU and memory resource allocations in your task definition.

- You must be using AWS CLI version 1.22.3 or later or AWS CLI version 2.3.6 or later. For information about how to update the AWS CLI, see Installing or updating the latest version of the AWS CLI in the AWS Command Line Interface User Guide Version 2.

- You can have only one ECS Exec session per process ID (PID) namespace. If you are sharing a PID namespace in a task, you can only start ECS Exec sessions into one container.

- The ECS Exec session has an idle timeout time of 20 minutes. This value can't be changed.

- You can't turn on ECS Exec for existing tasks. It can only be turned on for new tasks.

- You can't use ECS Exec when you use run-task to launch a task on a cluster that uses managed scaling with asynchronous placement (launch a task with no instance).

- You can't run ECS Exec against Microsoft Nano Server containers. For more information about Nano Server containers, see Nano Server on the Docker web site.

## Prerequisites for using ECS Exec

Before you start using ECS Exec, make sure that you have completed these actions:

- Install and configure the AWS CLI. For more information, see AWS CLI.

- Install Session Manager plugin for the AWS CLI. For more information, see Install the Session Manager plugin for the AWS CLI.

- You must use a task role with the appropriate permissions for ECS Exec. For more information, see Task IAM role.
• ECS Exec has version requirements depending on whether your tasks are hosted on Amazon EC2 or AWS Fargate:
  • If you're using Amazon EC2, you must use an Amazon ECS optimized AMI that was released after January 20th, 2021, with an agent version of 1.50.2 or greater. For more information, see Amazon ECS optimized AMIs.
  • If you're using AWS Fargate, you must use platform version 1.4.0 or higher (Linux) or 1.0.0 (Windows). For more information, see AWS Fargate platform versions.

Architecture

ECS Exec makes use of AWS Systems Manager (SSM) Session Manager to establish a connection with the running container and uses AWS Identity and Access Management (IAM) policies to control access to running commands in a running container. This is made possible by bind-mounting the necessary SSM agent binaries into the container. The Amazon ECS or AWS Fargate agent is responsible for starting the SSM core agent inside the container alongside your application code. For more information, see Systems Manager Session Manager.

You can audit which user accessed the container using the ExecuteCommand event in AWS CloudTrail and log each command (and their output) to Amazon S3 or Amazon CloudWatch Logs. To encrypt data between the local client and container with your own encryption key, you must provide the AWS Key Management Service (AWS KMS) key.

Using ECS Exec

Optional task definition changes

If you set the task definition parameter initProcessEnabled to true, this starts the init process inside the container. This removes any zombie SSM agent child processes found. The following provides an example.

```json
{
    "taskRoleArn": "ecsTaskRole",
    "networkMode": "awsvpc",
    "requiresCompatibilities": [
        "EC2",
        "FARGATE"
    ],
    "executionRoleArn": "ecsTaskExecutionRole",
}```
Turning on ECS Exec for your tasks and services

You can turn on the ECS Exec feature for your services and standalone tasks by specifying the `--enable-execute-command` flag when using one of the following AWS CLI commands: `create-service`, `update-service`, `start-task`, or `run-task`.

For example, if you run the following command, the ECS Exec feature is turned on for a newly created service. For more information about creating services, see `create-service`.

```
aws ecs create-service \
  --cluster cluster-name \n  --task-definition task-definition-name \n  --enable-execute-command \n  --service-name service-name \n  --desired-count 1
```

After you turn on ECS Exec for a task, you can run the following command to confirm the task is ready to be used. If the `lastStatus` property of the `ExecuteCommandAgent` is listed as `RUNNING` and the `enableExecuteCommand` property is set to `true`, then your task is ready.

```
aws ecs describe-tasks \n  --cluster cluster-name \n  --tasks task-id
```

The following output snippet is an example of what you might see.

```json
"memory": ".5 gb",
"cpu": ".25 vcpu",
"containerDefinitions": [
  {
    "name": "amazon-linux",
    "image": "amazonlinux:latest",
    "essential": true,
    "command": ["sleep","3600"],
    "linuxParameters": {
      "initProcessEnabled": true
    }
  }
],
"family": "ecs-exec-task"
}
Running commands using ECS Exec

After you have confirmed the ExecuteCommandAgent is running, you can open an interactive shell on your container using the following command. If your task contains multiple containers, you must specify the container name using the `--container` flag. Amazon ECS only supports initiating interactive sessions, so you must use the `--interactive` flag.

The following command will run an interactive /bin/sh command against a container named `container-name` for a task with an ID of `task-id`.

The `task-id` is the Amazon Resource Name (ARN) of the task.

```
aws ecs execute-command --cluster cluster-name \
--task task-id \
--container container-name \
--interactive \
--command "/bin/sh"
```
Logging and Auditing using ECS Exec

Turning on logging and auditing in your tasks and services

⚠️ Important

For more information about CloudWatch pricing, see [CloudWatch Pricing](#). Amazon ECS also provides monitoring metrics that are provided at no additional cost. For more information, see [Monitor Amazon ECS using CloudWatch](#).

Amazon ECS provides a default configuration for logging commands run using ECS Exec by sending logs to CloudWatch Logs using the `awslogs` log driver that's configured in your task definition. If you want to provide a custom configuration, the AWS CLI supports a `--configuration` flag for both the `create-cluster` and `update-cluster` commands. It's also important to know that the container image requires `script` and `cat` to be installed in order to have command logs uploaded correctly to Amazon S3 or CloudWatch Logs. For more information about creating clusters, see [create-cluster](#).

⚠️ Note

This configuration only handles the logging of the `execute-command` session. It doesn't affect logging of your application.

The following example creates a cluster and then logs the output to your CloudWatch Logs LogGroup named `cloudwatch-log-group-name` and your Amazon S3 bucket named `s3-bucket-name`.

You must use an AWS KMS customer managed key to encrypt the log group when you set the `CloudWatchEncryptionEnabled` option to `true`. For information about how to encrypt the log group, see [Encrypt log data in CloudWatch Logs using AWS Key Management Service](#), in the [Amazon CloudWatch Logs User Guide](#).

```bash
aws ecs create-cluster \
  --cluster-name cluster-name \
  --configuration executeCommandConfiguration="{ \n    kmsKeyId=string, \n    ```
The logging property determines the behavior of the logging capability of ECS Exec:

- **NONE**: logging is turned off.
- **DEFAULT**: logs are sent to the configured awslogs driver. If the driver isn't configured, then no log is saved.
- **OVERRIDE**: logs are sent to the provided Amazon CloudWatch Logs LogGroup, Amazon S3 bucket, or both.

**IAM permissions required for Amazon CloudWatch Logs or Amazon S3 Logging**

To enable logging, the Amazon ECS task role that's referenced in your task definition needs to have additional permissions. These additional permissions can be added as a policy to the task role. They're different depending on if you direct your logs to Amazon CloudWatch Logs or Amazon S3.

**Amazon CloudWatch Logs**

The following example policy adds the required Amazon CloudWatch Logs permissions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "logs:DescribeLogGroups"
            ],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "logs:GetLogEvents"
            ],
            "Resource": "*"
        }
    ]
}
```
Amazon Elastic Container Service

The following example policy adds the required Amazon S3 permissions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["s3:GetBucketLocation"],
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": ["s3:GetEncryptionConfiguration"],
            "Resource": "arn:aws:s3:::s3-bucket-name"
        },
        {
            "Effect": "Allow",
            "Action": ["s3:PutObject"],
            "Resource": "arn:aws:s3:::s3-bucket-name/*"
        }
    ]
}
```

Amazon S3

The following example policy adds the required Amazon S3 permissions.
IAM permissions required for encryption using your own AWS KMS key (KMS key)

By default, the data transferred between your local client and the container uses TLS 1.2 encryption that AWS provides. To further encrypt data using your own KMS key, you must create a KMS key and add the kms:Decrypt permission to your task IAM role. This permission is used by your container to decrypt the data. For more information about creating a KMS key, see Creating keys.

You add the following inline policy to your task IAM role which requires the AWS KMS permissions. For more information, see IAM permissions required for ECS Exec.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt"
      ],
      "Resource": "kms-key-arn"
    }
  ]
}
```

For the data to be encrypted using your own KMS key, the user or group using the execute-command action must be granted the kms:GenerateDataKey permission.

The following example policy for your user or group contains the required permission to use your own KMS key. You must specify the Amazon Resource Name (ARN) of your KMS key.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:GenerateDataKey"
      ],
      "Resource": "kms-key-arn"
    }
  ]
}
```
Using IAM policies to limit access to ECS Exec

You limit user access to the execute-command API action by using one or more of the following IAM policy condition keys:

- `aws:ResourceTag/clusterTagKey`
- `ecs:ResourceTag/clusterTagKey`
- `aws:ResourceTag/taskTagKey`
- `ecs:ResourceTag/taskTagKey`
- `ecs:container-name`
- `ecs:cluster`
- `ecs:task`
- `ecs:enable-execute-command`

With the following example IAM policy, users can run commands in containers that are running within tasks with a tag that has an environment key and development value and in a cluster that's named `cluster-name`.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ecs:ExecuteCommand",
            "ecs:DescribeTasks"
         ],
         "Resource": [
            "arn:aws:ecs:region:aws-account-id:task/cluster-name/*",
            "arn:aws:ecs:region:aws-account-id:cluster/*"
         ],
         "Condition": {
            "StringEquals": {
               "ecs:ResourceTag/environment": "development"
            }
         }
      }
   ]
}
```
With the following IAM policy example, users can't use the `execute-command` API when the container name is `production-app`.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Deny",
            "Action": ["ecs:ExecuteCommand"],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "ecs:container-name": "production-app"
                }
            }
        }
    ]
}
```

With the following IAM policy, users can only launch tasks when ECS Exec is turned off.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["ecs:RunTask", "ecs:StartTask", "ecs:CreateService", "ecs:UpdateService"],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "ecs:enable-execute-command": "false"
                }
            }
        }
    ]
}
```
Because the execute-command API action contains only task and cluster resources in a request, only cluster and task tags are evaluated.

For more information about IAM policy condition keys, see Actions, resources, and condition keys for Amazon Elastic Container Service in the Service Authorization Reference.

Limiting access to the Start Session action

While starting SSM sessions on your container outside of ECS Exec is possible, this could potentially result in the sessions not being logged. Sessions started outside of ECS Exec also count against the session quota. We recommend limiting this access by denying the ssm:start-session action directly for your Amazon ECS tasks using an IAM policy. You can deny access to all Amazon ECS tasks or to specific tasks based on the tags used.

The following is an example IAM policy that denies access to the ssm:start-session action for tasks in all Regions with a specified cluster name. You can optionally include a wildcard with the cluster-name.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Deny",
      "Action": "ssm:StartSession",
      "Resource": [
        "arn:aws:ecs:region:aws-account-id:task/cluster-name/*",
        "arn:aws:ecs:region:aws-account-id:cluster/*"
      ]
    }
  ]
}
```

The following is an example IAM policy that denies access to the ssm:start-session action on resources in all Regions tagged with tag key Task-Tag-Key and tag value Exec-Task.
AWS Compute Optimizer recommendations for Amazon ECS

AWS Compute Optimizer generates recommendations for Amazon ECS task and container sizes. For more information, see What is AWS Compute Optimizer? in the AWS Compute Optimizer User Guide.

Task and container size recommendations for Amazon ECS services on AWS Fargate

AWS Compute Optimizer generates recommendations for Amazon ECS services on AWS Fargate. AWS Compute Optimizer recommends task CPU and task memory size and container CPU, container memory and container memory reservation sizes. These recommendations are displayed on the following pages of the Compute Optimizer console.

- Recommendations for Amazon ECS services on Fargate page
- Amazon ECS services on Fargate details page

For more information, see Viewing recommendations for Amazon ECS services on Fargate in the AWS Compute Optimizer User Guide.
Security in Amazon Elastic Container Service

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

Security is a shared responsibility between AWS and you. The shared responsibility model describes this as security of the cloud and security in the cloud:

- **Security of the cloud** – AWS is responsible for protecting the infrastructure that runs AWS services in the AWS Cloud. AWS also provides you with services that you can use securely. Third-party auditors regularly test and verify the effectiveness of our security as part of the AWS compliance programs. To learn about the compliance programs that apply to Amazon Elastic Container Service, see AWS Services in Scope by Compliance Program.

- **Security in the cloud** – Your responsibility is determined by the AWS service that you use. You are also responsible for other factors including the sensitivity of your data, your company’s requirements, and applicable laws and regulations.

This documentation helps you understand how to apply the shared responsibility model when using Amazon ECS. The following topics show you how to configure Amazon ECS to meet your security and compliance objectives. You also learn how to use other AWS services that help you to monitor and secure your Amazon ECS resources.

### Topics

- Identity and Access Management for Amazon Elastic Container Service
- Logging and Monitoring in Amazon Elastic Container Service
- Compliance validation for Amazon Elastic Container Service
- AWS Fargate Federal Information Processing Standard (FIPS-140)
- Infrastructure Security in Amazon Elastic Container Service
- Security Best Practices

### Identity and Access Management for Amazon Elastic Container Service
AWS Identity and Access Management (IAM) is an AWS service that helps an administrator securely control access to AWS resources. IAM administrators control who can be *authenticated* (signed in) and *authorized* (have permissions) to use Amazon ECS resources. IAM is an AWS service that you can use with no additional charge.

**Topics**

- **Audience**
- **Authenticating with identities**
- **Managing access using policies**
- **How Amazon Elastic Container Service works with IAM**
- **Identity-based policy examples for Amazon Elastic Container Service**
- **AWS managed policies for Amazon Elastic Container Service**
- **Using service-linked roles for Amazon ECS**

- **Amazon ECS task execution IAM role**
- **Task IAM role**
- **Amazon ECS infrastructure IAM role**
- **Additional configuration for Windows IAM roles for tasks**
- **Amazon ECS container instance IAM role**
- **ECS Anywhere IAM role**
- **Amazon ECS CodeDeploy IAM Role**
- **Amazon ECS EventBridge IAM Role**
- **IAM permissions required for service auto scaling**
- **Grant permission to tag resources on creation**
- **Troubleshooting Amazon Elastic Container Service identity and access**

**Audience**

How you use AWS Identity and Access Management (IAM) differs, depending on the work that you do in Amazon ECS.
**Service user** – If you use the Amazon ECS service to do your job, then your administrator provides you with the credentials and permissions that you need. As you use more Amazon ECS features to do your work, you might need additional permissions. Understanding how access is managed can help you request the right permissions from your administrator. If you cannot access a feature in Amazon ECS, see Troubleshooting Amazon Elastic Container Service identity and access.

**Service administrator** – If you're in charge of Amazon ECS resources at your company, you probably have full access to Amazon ECS. It's your job to determine which Amazon ECS features and resources your service users should access. You must then submit requests to your IAM administrator to change the permissions of your service users. Review the information on this page to understand the basic concepts of IAM. To learn more about how your company can use IAM with Amazon ECS, see How Amazon Elastic Container Service works with IAM.

**IAM administrator** – If you're an IAM administrator, you might want to learn details about how you can write policies to manage access to Amazon ECS. To view example Amazon ECS identity-based policies that you can use in IAM, see Identity-based policy examples for Amazon Elastic Container Service.

**Authenticating with identities**

Authentication is how you sign in to AWS using your identity credentials. You must be authenticated (signed in to AWS) as the AWS account root user, as an IAM user, or by assuming an IAM role.

You can sign in to AWS as a federated identity by using credentials provided through an identity source. AWS IAM Identity Center (IAM Identity Center) users, your company's single sign-on authentication, and your Google or Facebook credentials are examples of federated identities. When you sign in as a federated identity, your administrator previously set up identity federation using IAM roles. When you access AWS by using federation, you are indirectly assuming a role.

Depending on the type of user you are, you can sign in to the AWS Management Console or the AWS access portal. For more information about signing in to AWS, see How to sign in to your AWS account in the AWS Sign-In User Guide.

If you access AWS programmatically, AWS provides a software development kit (SDK) and a command line interface (CLI) to cryptographically sign your requests by using your credentials. If you don't use AWS tools, you must sign requests yourself. For more information about using the recommended method to sign requests yourself, see Signing AWS API requests in the IAM User Guide.
Regardless of the authentication method that you use, you might be required to provide additional security information. For example, AWS recommends that you use multi-factor authentication (MFA) to increase the security of your account. To learn more, see Multi-factor authentication in the AWS IAM Identity Center User Guide and Using multi-factor authentication (MFA) in AWS in the IAM User Guide.

AWS account root user

When you create an AWS account, you begin with one sign-in identity that has complete access to all AWS services and resources in the account. This identity is called the AWS account root user and is accessed by signing in with the email address and password that you used to create the account. We strongly recommend that you don't use the root user for your everyday tasks. Safeguard your root user credentials and use them to perform the tasks that only the root user can perform. For the complete list of tasks that require you to sign in as the root user, see Tasks that require root user credentials in the IAM User Guide.

Federated identity

As a best practice, require human users, including users that require administrator access, to use federation with an identity provider to access AWS services by using temporary credentials.

A federated identity is a user from your enterprise user directory, a web identity provider, the AWS Directory Service, the Identity Center directory, or any user that accesses AWS services by using credentials provided through an identity source. When federated identities access AWS accounts, they assume roles, and the roles provide temporary credentials.

For centralized access management, we recommend that you use AWS IAM Identity Center. You can create users and groups in IAM Identity Center, or you can connect and synchronize to a set of users and groups in your own identity source for use across all your AWS accounts and applications. For information about IAM Identity Center, see What is IAM Identity Center? in the AWS IAM Identity Center User Guide.

IAM users and groups

An IAM user is an identity within your AWS account that has specific permissions for a single person or application. Where possible, we recommend relying on temporary credentials instead of creating IAM users who have long-term credentials such as passwords and access keys. However, if you have specific use cases that require long-term credentials with IAM users, we recommend that you rotate access keys. For more information, see Rotate access keys regularly for use cases that require long-term credentials in the IAM User Guide.
An IAM group is an identity that specifies a collection of IAM users. You can’t sign in as a group. You can use groups to specify permissions for multiple users at a time. Groups make permissions easier to manage for large sets of users. For example, you could have a group named IAMAdmins and give that group permissions to administer IAM resources.

Users are different from roles. A user is uniquely associated with one person or application, but a role is intended to be assumable by anyone who needs it. Users have permanent long-term credentials, but roles provide temporary credentials. To learn more, see When to create an IAM user (instead of a role) in the IAM User Guide.

IAM roles

An IAM role is an identity within your AWS account that has specific permissions. It is similar to an IAM user, but is not associated with a specific person. You can temporarily assume an IAM role in the AWS Management Console by switching roles. You can assume a role by calling an AWS CLI or AWS API operation or by using a custom URL. For more information about methods for using roles, see Using IAM roles in the IAM User Guide.

IAM roles with temporary credentials are useful in the following situations:

- Federated user access – To assign permissions to a federated identity, you create a role and define permissions for the role. When a federated identity authenticates, the identity is associated with the role and is granted the permissions that are defined by the role. For information about roles for federation, see Creating a role for a third-party Identity Provider in the IAM User Guide. If you use IAM Identity Center, you configure a permission set. To control what your identities can access after they authenticate, IAM Identity Center correlates the permission set to a role in IAM. For information about permissions sets, see Permission sets in the AWS IAM Identity Center User Guide.

- Temporary IAM user permissions – An IAM user or role can assume an IAM role to temporarily take on different permissions for a specific task.

- Cross-account access – You can use an IAM role to allow someone (a trusted principal) in a different account to access resources in your account. Roles are the primary way to grant cross-account access. However, with some AWS services, you can attach a policy directly to a resource (instead of using a role as a proxy). To learn the difference between roles and resource-based policies for cross-account access, see How IAM roles differ from resource-based policies in the IAM User Guide.

- Cross-service access – Some AWS services use features in other AWS services. For example, when you make a call in a service, it's common for that service to run applications in Amazon EC2 or
store objects in Amazon S3. A service might do this using the calling principal's permissions, using a service role, or using a service-linked role.

- **Forward access sessions (FAS)** – When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](#).

- **Service role** – A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the [IAM User Guide](#).

- **Service-linked role** – A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

- **Applications running on Amazon EC2** – You can use an IAM role to manage temporary credentials for applications that are running on an EC2 instance and making AWS CLI or AWS API requests. This is preferable to storing access keys within the EC2 instance. To assign an AWS role to an EC2 instance and make it available to all of its applications, you create an instance profile that is attached to the instance. An instance profile contains the role and enables programs that are running on the EC2 instance to get temporary credentials. For more information, see [Using an IAM role to grant permissions to applications running on Amazon EC2 instances](#) in the [IAM User Guide](#).

To learn whether to use IAM roles or IAM users, see [When to create an IAM role (instead of a user)](#) in the [IAM User Guide](#).

### Managing access using policies

You control access in AWS by creating policies and attaching them to AWS identities or resources. A policy is an object in AWS that, when associated with an identity or resource, defines their permissions. AWS evaluates these policies when a principal (user, root user, or role session) makes a request. Permissions in the policies determine whether the request is allowed or denied. Most
policies are stored in AWS as JSON documents. For more information about the structure and contents of JSON policy documents, see Overview of JSON policies in the IAM User Guide.

Administrators can use AWS JSON policies to specify who has access to what. That is, which principal can perform actions on what resources, and under what conditions.

By default, users and roles have no permissions. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

IAM policies define permissions for an action regardless of the method that you use to perform the operation. For example, suppose that you have a policy that allows the `iam:GetRole` action. A user with that policy can get role information from the AWS Management Console, the AWS CLI, or the AWS API.

**Identity-based policies**

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

Identity-based policies can be further categorized as inline policies or managed policies. Inline policies are embedded directly into a single user, group, or role. Managed policies are standalone policies that you can attach to multiple users, groups, and roles in your AWS account. Managed policies include AWS managed policies and customer managed policies. To learn how to choose between a managed policy or an inline policy, see Choosing between managed policies and inline policies in the IAM User Guide.

**Resource-based policies**

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.
Resource-based policies are inline policies that are located in that service. You can't use AWS managed policies from IAM in a resource-based policy.

Access control lists (ACLs)

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.

Amazon S3, AWS WAF, and Amazon VPC are examples of services that support ACLs. To learn more about ACLs, see Access control list (ACL) overview in the Amazon Simple Storage Service Developer Guide.

Other policy types

AWS supports additional, less-common policy types. These policy types can set the maximum permissions granted to you by the more common policy types.

- **Permissions boundaries** – A permissions boundary is an advanced feature in which you set the maximum permissions that an identity-based policy can grant to an IAM entity (IAM user or role). You can set a permissions boundary for an entity. The resulting permissions are the intersection of an entity's identity-based policies and its permissions boundaries. Resource-based policies that specify the user or role in the Principal field are not limited by the permissions boundary. An explicit deny in any of these policies overrides the allow. For more information about permissions boundaries, see Permissions boundaries for IAM entities in the IAM User Guide.

- **Service control policies (SCPs)** – SCPs are JSON policies that specify the maximum permissions for an organization or organizational unit (OU) in AWS Organizations. AWS Organizations is a service for grouping and centrally managing multiple AWS accounts that your business owns. If you enable all features in an organization, then you can apply service control policies (SCPs) to any or all of your accounts. The SCP limits permissions for entities in member accounts, including each AWS account root user. For more information about Organizations and SCPs, see How SCPs work in the AWS Organizations User Guide.

- **Session policies** – Session policies are advanced policies that you pass as a parameter when you programmatically create a temporary session for a role or federated user. The resulting session's permissions are the intersection of the user or role's identity-based policies and the session policies. Permissions can also come from a resource-based policy. An explicit deny in any of these policies overrides the allow. For more information, see Session policies in the IAM User Guide.
Multiple policy types

When multiple types of policies apply to a request, the resulting permissions are more complicated to understand. To learn how AWS determines whether to allow a request when multiple policy types are involved, see Policy evaluation logic in the IAM User Guide.

How Amazon Elastic Container Service works with IAM

Before you use IAM to manage access to Amazon ECS, learn what IAM features are available to use with Amazon ECS.

IAM features you can use with Amazon Elastic Container Service

To get a high-level view of how Amazon ECS and other AWS services work with most IAM features, see AWS services that work with IAM in the IAM User Guide.
Identity-based policies for Amazon ECS

| Supports identity-based policies | Yes |

Identity-based policies are JSON permissions policy documents that you can attach to an identity, such as an IAM user, group of users, or role. These policies control what actions users and roles can perform, on which resources, and under what conditions. To learn how to create an identity-based policy, see Creating IAM policies in the IAM User Guide.

With IAM identity-based policies, you can specify allowed or denied actions and resources as well as the conditions under which actions are allowed or denied. You can't specify the principal in an identity-based policy because it applies to the user or role to which it is attached. To learn about all of the elements that you can use in a JSON policy, see IAM JSON policy elements reference in the IAM User Guide.

Identity-based policy examples for Amazon ECS

To view examples of Amazon ECS identity-based policies, see Identity-based policy examples for Amazon Elastic Container Service.

Resource-based policies within Amazon ECS

| Supports resource-based policies | No |

Resource-based policies are JSON policy documents that you attach to a resource. Examples of resource-based policies are IAM role trust policies and Amazon S3 bucket policies. In services that support resource-based policies, service administrators can use them to control access to a specific resource. For the resource where the policy is attached, the policy defines what actions a specified principal can perform on that resource and under what conditions. You must specify a principal in a resource-based policy. Principals can include accounts, users, roles, federated users, or AWS services.

To enable cross-account access, you can specify an entire account or IAM entities in another account as the principal in a resource-based policy. Adding a cross-account principal to a resource-based policy is only half of establishing the trust relationship. When the principal and the resource are in different AWS accounts, an IAM administrator in the trusted account must also grant...
the principal entity (user or role) permission to access the resource. They grant permission by attaching an identity-based policy to the entity. However, if a resource-based policy grants access to a principal in the same account, no additional identity-based policy is required. For more information, see [How IAM roles differ from resource-based policies](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_differences.html) in the *IAM User Guide*.

**Policy actions for Amazon ECS**

<table>
<thead>
<tr>
<th>Supports policy actions</th>
<th>Yes</th>
</tr>
</thead>
</table>

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The **Action** element of a JSON policy describes the actions that you can use to allow or deny access in a policy. Policy actions usually have the same name as the associated AWS API operation. There are some exceptions, such as **permission-only actions** that don't have a matching API operation. There are also some operations that require multiple actions in a policy. These additional actions are called **dependent actions**.

Include actions in a policy to grant permissions to perform the associated operation.

To see a list of Amazon ECS actions, see [Actions defined by Amazon Elastic Container Service](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/service-access-control.html) in the *Service Authorization Reference*.

Policy actions in Amazon ECS use the following prefix before the action:

```
ecs
```

To specify multiple actions in a single statement, separate them with commas.

```
"Action": [
    "ecs:action1",
    "ecs:action2"
]
```

You can specify multiple actions using wildcards (*). For example, to specify all actions that begin with the word Describe, include the following action:
To view examples of Amazon ECS identity-based policies, see [Identity-based policy examples for Amazon Elastic Container Service](#).

**Policy resources for Amazon ECS**

<table>
<thead>
<tr>
<th>Supports policy resources</th>
<th>Partial</th>
</tr>
</thead>
</table>

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Resource JSON policy element specifies the object or objects to which the action applies. Statements must include either a Resource or a NotResource element. As a best practice, specify a resource using its [Amazon Resource Name (ARN)](https://docs.aws.amazon.com/IAM/latest/UserGuide/id manhã第resource.html). You can do this for actions that support a specific resource type, known as **resource-level permissions**.

For actions that don't support resource-level permissions, such as listing operations, use a wildcard (*) to indicate that the statement applies to all resources.

```
"Resource": "*"
```

To see a list of Amazon ECS resource types and their ARNs, see [Resources defined by Amazon Elastic Container Service](https://docs.aws.amazon.com/ecs/latest/userguide/service授权资源参考.html) in the Service Authorization Reference. To learn with which actions you can specify the ARN of each resource, see [Actions defined by Amazon Elastic Container Service](https://docs.aws.amazon.com/ecs/latest/userguide/service授权资源参考.html).

Some Amazon ECS API actions support multiple resources. For example, multiple clusters can be referenced when calling the DescribeClusters API action. To specify multiple resources in a single statement, separate the ARNs with commas.

```
"Resource": [
    "EXAMPLE-RESOURCE-1",
    "EXAMPLE-RESOURCE-2"
]
```

For example, the Amazon ECS cluster resource has the following ARN:

```
arn:${Partition}:ecs:${Region}:${Account}:cluster/${clusterName}
```
To specify my-cluster-1 and my-cluster-2 cluster in your statement, use the following ARNs:

"Resource": [
    "arn:aws:ecs:us-east-1:123456789012:cluster/my-cluster-2"
]

To specify all clusters that belong to a specific account, use the wildcard (*):

"Resource": "arn:aws:ecs:us-east-1:123456789012:cluster/*"

For task definitions, you can specify the latest revision, or a specific revision.

To specify the latest task definition, use:

"Resource:arn:${Partition}:ecs:${Region}:${Account}:task-definition/${TaskDefinitionFamilyName}"

To specify a specific task definition revision, use ${TaskDefinitionRevisionNumber}:

"Resource:arn:${Partition}:ecs:${Region}:${Account}:task-definition/${TaskDefinitionFamilyName}:${TaskDefinitionRevisionNumber}"

To view examples of Amazon ECS identity-based policies, see Identity-based policy examples for Amazon Elastic Container Service.

**Policy condition keys for Amazon ECS**

<table>
<thead>
<tr>
<th>Supports service-specific policy condition keys</th>
<th>Yes</th>
</tr>
</thead>
</table>

Administrators can use AWS JSON policies to specify who has access to what. That is, which **principal** can perform **actions** on what **resources**, and under what **conditions**.

The Condition element (or Condition *block*) lets you specify conditions in which a statement is in effect. The Condition element is optional. You can create conditional expressions that use **condition operators**, such as equals or less than, to match the condition in the policy with values in the request.
If you specify multiple Condition elements in a statement, or multiple keys in a single Condition element, AWS evaluates them using a logical AND operation. If you specify multiple values for a single condition key, AWS evaluates the condition using a logical OR operation. All of the conditions must be met before the statement's permissions are granted.

You can also use placeholder variables when you specify conditions. For example, you can grant an IAM user permission to access a resource only if it is tagged with their IAM user name. For more information, see IAM policy elements: variables and tags in the IAM User Guide.

AWS supports global condition keys and service-specific condition keys. To see all AWS global condition keys, see AWS global condition context keys in the IAM User Guide.

Amazon ECS supports the following service-specific condition keys that you can use to provide fine-grained filtering for your IAM policies:

<table>
<thead>
<tr>
<th>Condition Key</th>
<th>Description</th>
<th>Evaluation Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws:RequestTag/${TagKey}</td>
<td>The context key is formatted &quot;aws:RequestTag/ tag-key&quot;:&quot;tag-value &quot; where tag-key and tag-value are a tag key and value pair. Checks that the tag key–value pair is present in an AWS request. For example, you could check to see that the request includes the tag key &quot;Dept&quot; and that it has the value &quot;Accounting&quot; .</td>
<td>String</td>
</tr>
<tr>
<td>aws:ResourceTag/${TagKey}</td>
<td>The context key is formatted &quot;aws:ResourceTag/ tag-key&quot;:&quot;tag-value &quot; where tag-key and tag-value are a tag key and value pair. Checks that the tag attached to the identity resource (user or role) matches the specified key name and value.</td>
<td>String</td>
</tr>
<tr>
<td>aws:TagKeys</td>
<td>This context key is formatted &quot;aws:TagKeys&quot;:&quot; tag-key&quot; where tag-key is a list of tag keys without values (for example, [&quot;Dept&quot;,&quot;Cost-Center&quot;] ). Checks the tag keys that are present in an AWS request.</td>
<td>String</td>
</tr>
<tr>
<td>Condition Key</td>
<td>Description</td>
<td>Evaluation Types</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
<td>------------------</td>
</tr>
<tr>
<td>ecs:ResourceTag/${TagKey}</td>
<td>The context key is formatted &quot;ecs:ResourceTag/ \textit{tag-key}:&quot; \textit{tag-value} &quot; where \textit{tag-key} and \textit{tag-value} are a tag key and value pair. Checks that the tag attached to the identity resource (user or role) matches the specified key name and value.</td>
<td>String</td>
</tr>
<tr>
<td>ecs:cluster</td>
<td>The context key is formatted &quot;ecs:cluster&quot;: &quot;cluster-arn&quot; where \textit{cluster-arn} is the ARN for the Amazon ECS cluster.</td>
<td>ARN, Null</td>
</tr>
<tr>
<td>ecs:container-instances</td>
<td>The context key is formatted &quot;ecs:container-instances&quot;: &quot;container-instance-arns&quot; where \textit{container-instance-arns} is one or more container instance ARNs.</td>
<td>ARN, Null</td>
</tr>
<tr>
<td>ecs:container-name</td>
<td>The context key is formatted &quot;ecs:container-name&quot;: &quot;container-name&quot; where \textit{container-instance} is the name of an Amazon ECS container which is defined in the task definition.</td>
<td>String</td>
</tr>
<tr>
<td>ecs:enable-execute-command</td>
<td>The context key is formatted &quot;ecs:enable-execute-command&quot;: &quot;value&quot; where \textit{value} is &quot;true&quot; or &quot;false&quot;.</td>
<td>String</td>
</tr>
<tr>
<td>ecs:enable-service-connect</td>
<td>The context key is formatted &quot;ecs:enable-service-connect&quot;: &quot;value&quot; where \textit{value} is &quot;true&quot; or &quot;false&quot;.</td>
<td>String</td>
</tr>
<tr>
<td>ecs:enable-ebs-volumes</td>
<td>The context key is formatted &quot;ecs:enable-ebs-volumes&quot;: &quot;value&quot; where \textit{value} is &quot;true&quot; or &quot;false&quot;.</td>
<td>String</td>
</tr>
<tr>
<td>Condition Key</td>
<td>Description</td>
<td>Evaluation Types</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>ecs:namespace</td>
<td>The context key is formatted &quot;ecs:namespace&quot;: &quot;namespace-arn &quot; where namespace-arn is the ARN for the AWS Cloud Map namespace.</td>
<td>ARN, Null</td>
</tr>
<tr>
<td>ecs:service</td>
<td>The context key is formatted &quot;ecs:service&quot;: &quot;service-arn &quot; where service-arn is the ARN for the Amazon ECS service.</td>
<td>ARN, Null</td>
</tr>
<tr>
<td>ecs:task-definition</td>
<td>The context key is formatted &quot;ecs:task-definition&quot;: &quot;task-definition-arn &quot; where task-definition-arn is the ARN for the Amazon ECS task definition.</td>
<td>ARN, Null</td>
</tr>
<tr>
<td>ecs:account-setting</td>
<td>The context key is formatted &quot;ecs:account-setting&quot;: &quot;account-setting &quot; where account-setting is the name of an Amazon ECS account setting.</td>
<td>String</td>
</tr>
</tbody>
</table>

To see a list of Amazon ECS condition keys, see [Condition keys for Amazon Elastic Container Service](#) in the [Service Authorization Reference](#). To learn with which actions and resources you can use a condition key, see [Actions defined by Amazon Elastic Container Service](#).

To view examples of Amazon ECS identity-based policies, see [Identity-based policy examples for Amazon Elastic Container Service](#).

**Access control lists (ACLs) in Amazon ECS**

<table>
<thead>
<tr>
<th>Supports ACLs</th>
<th>No</th>
</tr>
</thead>
</table>

Access control lists (ACLs) control which principals (account members, users, or roles) have permissions to access a resource. ACLs are similar to resource-based policies, although they do not use the JSON policy document format.
Important

Amazon ECS supports attributes-based access control for all Amazon ECS resources. To determine whether you can use attributes to scope an action, use the Actions defined by Amazon ECS table in Service Authorization Reference. First verify that there is a resource in the Resource column. Then, use the Condition keys column to see the keys for the action/resource combination.

<table>
<thead>
<tr>
<th>Supports ABAC (tags in policies)</th>
<th>Yes</th>
</tr>
</thead>
</table>

Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. In AWS, these attributes are called tags. You can attach tags to IAM entities (users or roles) and to many AWS resources. Tagging entities and resources is the first step of ABAC. Then you design ABAC policies to allow operations when the principal's tag matches the tag on the resource that they are trying to access.

ABAC is helpful in environments that are growing rapidly and helps with situations where policy management becomes cumbersome.

To control access based on tags, you provide tag information in the condition element of a policy using the aws:ResourceTag/key-name, aws:RequestTag/key-name, or aws:TagKeys condition keys.

If a service supports all three condition keys for every resource type, then the value is Yes for the service. If a service supports all three condition keys for only some resource types, then the value is Partial.

For more information about ABAC, see What is ABAC? in the IAM User Guide. To view a tutorial with steps for setting up ABAC, see Use attribute-based access control (ABAC) in the IAM User Guide.

For more information about tagging Amazon ECS resources, see Amazon ECS resource tagging.

To view an example identity-based policy for limiting access to a resource based on the tags on that resource, see Describing Amazon ECS services based on tags.
Using Temporary credentials with Amazon ECS

| Supports temporary credentials | Yes |

Some AWS services don't work when you sign in using temporary credentials. For additional information, including which AWS services work with temporary credentials, see [AWS services that work with IAM](https://docs.aws.amazon.com/iam/latest.GetUserGuide) in the IAM User Guide.

You are using temporary credentials if you sign in to the AWS Management Console using any method except a user name and password. For example, when you access AWS using your company's single sign-on (SSO) link, that process automatically creates temporary credentials. You also automatically create temporary credentials when you sign in to the console as a user and then switch roles. For more information about switching roles, see [Switching to a role (console)](https://docs.aws.amazon.com/iam/latest.GetUserGuide) in the IAM User Guide.

You can manually create temporary credentials using the AWS CLI or AWS API. You can then use those temporary credentials to access AWS. AWS recommends that you dynamically generate temporary credentials instead of using long-term access keys. For more information, see [Temporary security credentials in IAM](https://docs.aws.amazon.com/iam/latest.GetUserGuide).

Forward access sessions for Amazon ECS

| Supports forward access sessions (FAS) | Yes |

When you use an IAM user or role to perform actions in AWS, you are considered a principal. When you use some services, you might perform an action that then initiates another action in a different service. FAS uses the permissions of the principal calling an AWS service, combined with the requesting AWS service to make requests to downstream services. FAS requests are only made when a service receives a request that requires interactions with other AWS services or resources to complete. In this case, you must have permissions to perform both actions. For policy details when making FAS requests, see [Forward access sessions](https://docs.aws.amazon.com/iam/latest.GetUserGuide).

Service roles for Amazon ECS

| Supports service roles | Yes |
A service role is an IAM role that a service assumes to perform actions on your behalf. An IAM administrator can create, modify, and delete a service role from within IAM. For more information, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

⚠️ Warning

Changing the permissions for a service role might break Amazon ECS functionality. Edit service roles only when Amazon ECS provides guidance to do so.

Service-linked roles for Amazon ECS

| Supports service-linked roles | Yes |

A service-linked role is a type of service role that is linked to an AWS service. The service can assume the role to perform an action on your behalf. Service-linked roles appear in your AWS account and are owned by the service. An IAM administrator can view, but not edit the permissions for service-linked roles.

For details about creating or managing Amazon ECS service-linked roles, see Using service-linked roles for Amazon ECS.

Identity-based policy examples for Amazon Elastic Container Service

By default, users and roles don't have permission to create or modify Amazon ECS resources. They also can't perform tasks by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or AWS API. To grant users permission to perform actions on the resources that they need, an IAM administrator can create IAM policies. The administrator can then add the IAM policies to roles, and users can assume the roles.

To learn how to create an IAM identity-based policy by using these example JSON policy documents, see Creating IAM policies in the IAM User Guide.

For details about actions and resource types defined by Amazon ECS, including the format of the ARNs for each of the resource types, see Actions, resources, and condition keys for Amazon Elastic Container Service in the Service Authorization Reference.

Identity-based policy examples
Policy best practices

Identity-based policies determine whether someone can create, access, or delete Amazon ECS resources in your account. These actions can incur costs for your AWS account. When you create or edit identity-based policies, follow these guidelines and recommendations:

- **Get started with AWS managed policies and move toward least-privilege permissions** – To get started granting permissions to your users and workloads, use the *AWS managed policies* that grant permissions for many common use cases. They are available in your AWS account. We recommend that you reduce permissions further by defining AWS customer managed policies that are specific to your use cases. For more information, see [AWS managed policies](https://aws.amazon.com/documentation/iam/latest/bigguide/mapping-make-your-aws-iam-managed-policies-and-administrative-groups/) or [AWS managed policies for job functions](https://docs.aws.amazon.com/AmazonECS/latest/userguide/iam-roles-tutorial.html) in the *IAM User Guide*.

- **Apply least-privilege permissions** – When you set permissions with IAM policies, grant only the permissions required to perform a task. You do this by defining the actions that can be taken on specific resources under specific conditions, also known as *least-privilege permissions*. For more information about using IAM to apply permissions, see [Policies and permissions in IAM](https://docs.aws.amazon.com/AmazonECS/latest/userguide/security-groups.html) in the *IAM User Guide*.

- **Use conditions in IAM policies to further restrict access** – You can add a condition to your policies to limit access to actions and resources. For example, you can write a policy condition to specify that all requests must be sent using SSL. You can also use conditions to grant access to
service actions if they are used through a specific AWS service, such as AWS CloudFormation. For more information, see IAM JSON policy elements: Condition in the IAM User Guide.

- **Use IAM Access Analyzer to validate your IAM policies to ensure secure and functional permissions** – IAM Access Analyzer validates new and existing policies so that the policies adhere to the IAM policy language (JSON) and IAM best practices. IAM Access Analyzer provides more than 100 policy checks and actionable recommendations to help you author secure and functional policies. For more information, see IAM Access Analyzer policy validation in the IAM User Guide.

- **Require multi-factor authentication (MFA)** – If you have a scenario that requires IAM users or a root user in your AWS account, turn on MFA for additional security. To require MFA when API operations are called, add MFA conditions to your policies. For more information, see Configuring MFA-protected API access in the IAM User Guide.

For more information about best practices in IAM, see Security best practices in IAM in the IAM User Guide.

**Allow users to view their own permissions**

This example shows how you might create a policy that allows IAM users to view the inline and managed policies that are attached to their user identity. This policy includes permissions to complete this action on the console or programmatically using the AWS CLI or AWS API.

```json
{
   "Version": "2012-10-17",
   "Statement": [

   {
      "Sid": "ViewOwnUserInfo",
      "Effect": "Allow",
      "Action": [
         "iam:GetUserPolicy",
         "iam:ListGroupsForUser",
         "iam:ListAttachedUserPolicies",
         "iam:ListUserPolicies",
         "iam:GetUser"
      ],
      "Resource": ["arn:aws:iam::*:user/${aws:username}"],
   },
   {
      "Sid": "NavigateInConsole",
      "Effect": "Allow",
```
Cluster examples

The following IAM policy allows permission to create and list clusters. The CreateCluster and ListClusters actions do not accept any resources, so the resource definition is set to * for all resources.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ecs:CreateCluster",
            "ecs:ListClusters"
         ],
         "Resource": ["*"]
      }
   ]
}
```

The following IAM policy allows permission to describe and delete a specific cluster. The DescribeClusters and DeleteCluster actions accept cluster ARNs as resources.

```json
{
   "Version": "2012-10-17",
   "Statement": [  
      {
         "Effect": "Allow",
         "Action": [
            "ecs:DescribeCluster",
            "ecs:DeleteCluster"
         ],
         "Resource": ["<clusterARN>"]
      }
   ]
}
```
The following IAM policy can be attached to a user or group that would only allow that user or group to perform operations on a specific cluster.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ecs:DescribeClusters",
        "ecs:DeleteCluster"
      ],
      "Effect": "Allow",
      "Resource": "arn:aws:ecs:us-east-1:<aws_account_id>:cluster/<cluster_name>"
    }
  ]
}
```

Identity-based policy examples
```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecs:DeregisterContainerInstance",
        "ecs:ListContainerInstances"
      ],
      "Resource": ["arn:aws:ecs:<region>:<aws_account_id>:cluster/<cluster_name>"]
    }
  ]
}
```

The following IAM policy allows a user to describe a specified container instance in a specified cluster. To open this permission up to all container instances in a cluster, you can replace the container instance UUID with *.

## Container instance examples

Container instance registration is handled by the Amazon ECS agent, but there may be times where you want to allow a user to deregister an instance manually from a cluster. Perhaps the container instance was accidentally registered to the wrong cluster, or the instance was terminated with tasks still running on it.

The following IAM policy allows a user to list and deregister container instances in a specified cluster:
Task definition examples

Task definition IAM policies do not support resource-level permissions, but the following IAM policy allows a user to register, list, and describe task definitions:

If you use the console, you must add CloudFormation: CreateStack as an Action.

Run Task Example

The resources for RunTask are task definitions. To limit which clusters a user can run task definitions on, you can specify them in the Condition block. The advantage is that you don't have
to list both task definitions and clusters in your resources to allow the appropriate access. You can apply one, the other, or both.

The following IAM policy allows permission to run any revision of a specific task definition on a specific cluster:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": ["ecs:RunTask"],
            "Condition": {
                "Resource": ["arn:aws:ecs:<region>:<aws_account_id>:task-definition/<task_family>:*"]
            }
        }
    ]
}
```

**Start task example**

The resources for `StartTask` are task definitions. To limit which clusters and container instances a user can start task definitions on, you can specify them in the `Condition` block. The advantage is that you don't have to list both task definitions and clusters in your resources to allow the appropriate access. You can apply one, the other, or both.

The following IAM policy allows permission to start any revision of a specific task definition on a specific cluster and specific container instance.

**Note**

For this example, when you call the `StartTask` API with the AWS CLI or another AWS SDK, you must specify the task definition revision so that the `Resource` mapping matches.

```
{
    "Version": "2012-10-17",
    "Statement": [
```
List and describe task examples

The following IAM policy allows a user to list tasks for a specified cluster:

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["ecs:ListTasks"],
         "Condition": {
            "ArnEquals": {
               "ecs:cluster": "arn:aws:ecs:<region>:<aws_account_id>:cluster/<cluster_name>"
            }
         },
         "Resource": ["*"]
      }
   ]
}
```

The following IAM policy allows a user to describe a specified task in a specified cluster:

```
{
   "Version": "2012-10-17",
   "Statement": [ 
      {
         "Effect": "Allow",
         "Action": ["ecs:DescribeTasks"],
         "Condition": {
            "ArnEquals": {
               "ecs:task": "arn:aws:ecs:<region>:<aws_account_id>:task/<task_family>:*"
            }
         },
         "Resource": ["*"]
      }
   ]
}
```
Create service example

The following IAM policy allows a user to create Amazon ECS services in the AWS Management Console:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "application-autoscaling:Describe*",
                "application-autoscaling:PutScalingPolicy",
                "application-autoscaling:RegisterScalableTarget",
                "cloudwatch:DescribeAlarms",
                "cloudwatch:PutMetricAlarm",
                "ecs:List*",
                "ecs:Describe*",
                "ecs:CreateService",
                "elasticloadbalancing:Describe*",
                "iam:GetPolicy",
                "iam:GetPolicyVersion",
                "iam:GetRole",
                "iam:ListAttachedRolePolicies",
                "iam:ListRoles",
                "iam:ListGroups",
                "iam:ListUsers"
            ],
            "Resource": ["*"]
        }
    ]
}
```
Update service example

The following IAM policy allows a user to update Amazon ECS services in the AWS Management Console:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "application-autoscaling:Describe*",
                "application-autoscaling:PutScalingPolicy",
                "application-autoscaling:DeleteScalingPolicy",
                "application-autoscaling:RegisterScalableTarget",
                "cloudwatch:DescribeAlarms",
                "cloudwatch:PutMetricAlarm",
                "ecs:List*",
                "ecs:Describe*",
                "ecs:UpdateService",
                "iam:GetPolicy",
                "iam:GetPolicyVersion",
                "iam:GetRole",
                "iam:ListAttachedRolePolicies",
                "iam:ListRoles",
                "iam:ListGroups",
                "iam:ListUsers"
            ],
            "Resource": ["*"]
        }
    ]
}
```

Describing Amazon ECS services based on tags

You can use conditions in your identity-based policy to control access to Amazon ECS resources based on tags. This example shows how you might create a policy that allows describing your services. However, permission is granted only if the service tag Owner has the value of that user's user name. This policy also grants the permissions necessary to complete this action on the console.

Identity-based policy examples
You can attach this policy to the IAM users in your account. If a user named richard-roeh attempts to describe an Amazon ECS service, the service must be tagged Owner=richard-roeh or owner=richard-roeh. Otherwise he is denied access. The condition tag key Owner matches both Owner and owner because condition key names are not case-sensitive. For more information, see IAM JSON Policy Elements: Condition in the IAM User Guide.

Deny Service Connect Namespace Override Example

The following IAM policy denies a user from overriding the default Service Connect namespace in a service configuration. The default namespace is set in the cluster. However, you can override it in a service configuration. For consistency, consider setting all your new services to use the same namespace. Use the following context keys to require services to use a specific namespace. Replace the <region>, <aws_account_id>, <cluster_name> and <namespace_id> with your own in the following example.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "ecs:DescribeServices",
            "Resource": "*"
        },
        {
            "Sid": "ViewServiceIfOwner",
            "Effect": "Allow",
            "Action": "ecs:DescribeServices",
            "Resource": "arn:aws:ecs:*:*:service/*",
            "Condition": {
                "StringEquals": {"ecs:ResourceTag/Owner": "${aws:username}"}
            }
        }
    ]
}
```
AWS managed policies for Amazon Elastic Container Service

To add permissions to users, groups, and roles, it is easier to use AWS managed policies than to write policies yourself. It takes time and expertise to create IAM customer managed policies that provide your team with only the permissions they need. To get started quickly, you can use our AWS managed policies. These policies cover common use cases and are available in your AWS account. For more information about AWS managed policies, see AWS managed policies in the IAM User Guide.

AWS services maintain and update AWS managed policies. You can’t change the permissions in AWS managed policies. Services occasionally add additional permissions to an AWS managed policy to support new features. This type of update affects all identities (users, groups, and roles) where the policy is attached. Services are most likely to update an AWS managed policy when a new feature is launched or when new operations become available. Services do not remove permissions from an AWS managed policy, so policy updates won’t break your existing permissions.

Additionally, AWS supports managed policies for job functions that span multiple services. For example, the **ReadOnlyAccess** AWS managed policy provides read-only access to all AWS services and resources. When a service launches a new feature, AWS adds read-only permissions for new operations and resources. For a list and descriptions of job function policies, see AWS managed policies for job functions in the IAM User Guide.
Amazon ECS and Amazon ECR provide several managed policies and trust relationships that you can attach to users, groups, roles, Amazon EC2 instances, and Amazon ECS tasks that allow differing levels of control over resources and API operations. You can apply these policies directly, or you can use them as starting points for creating your own policies. For more information about the Amazon ECR managed policies, see Amazon ECR managed policies.

**AmazonECS_FullAccess**

You can attach the AmazonECS_FullAccess policy to your IAM identities.

This policy grants administrative access to Amazon ECS resources and grants an IAM identity (such as a user, group, or role) access to the AWS services that Amazon ECS is integrated with to use all of Amazon ECS features. Using this policy allows access to all of Amazon ECS features that are available in the AWS Management Console.

**Permissions details**

The AmazonECS_FullAccess managed IAM policy includes the following permissions. Following the best practice of granting least privilege, you can use the AmazonECS_FullAccess managed policy as a template for creating your own custom policy. That way, you can take away or add permissions to and from the managed policy based on your specific requirements.

- **ecs** – Allows principals full access to all Amazon ECS API operations.
- **application-autoscaling** – Allows principals to create, describe, and manage Application Auto Scaling resources. This is required when enabling service auto scaling for your Amazon ECS services.
- **appmesh** – Allows principals to list App Mesh service meshes and virtual nodes and describe App Mesh virtual nodes. This is required when integrating your Amazon ECS services with App Mesh.
- **autoscaling** – Allows principals to create, manage, and describe Amazon EC2 Auto Scaling resources. This is required when managing Amazon EC2 Auto Scaling groups when using the cluster auto scaling feature.
- **cloudformation** – Allows principals to create and manage AWS CloudFormation stacks. This is required when creating Amazon ECS clusters using the AWS Management Console and the subsequent managing of those clusters.
- **cloudwatch** – Allows principals to create, manage, and describe Amazon CloudWatch alarms.
- **codedeploy** – Allows principals to create and manage application deployments and view their configurations, revisions, and deployment targets.
• sns – Allows principals to view a list of Amazon SNS topics.
• lambda – Allows principals to view a list of AWS Lambda functions and their version specific configurations.
• ec2 – Allows principals to run Amazon EC2 instances and create and manage routes, route tables, internet gateways, launch groups, security groups, virtual private clouds, Spot Fleets, and subnets.
• elasticloadbalancing – Allows principals to create, describe, and delete Elastic Load Balancing load balancers. Principals will also be able to add tags to newly created target groups, listeners, and listener rules for load balancers.
• events – Allows principals to create, manage, and delete Amazon EventBridge rules and their targets.
• iam – Allows principals to list IAM roles and their attached policies. Principals can also list instance profiles available to your Amazon EC2 instances.
• logs – Allows principals to create and describe Amazon CloudWatch Logs log groups. Principals can also list log events for these log groups.
• route53 – Allows principals to create, manage, and delete Amazon Route 53 hosted zones. Principals can also view Amazon Route 53 health check configuration and information. For more information about hosted zones, see Working with hosted zones.
• servicediscovery – Allows principals to create, manage, and delete AWS Cloud Map services and create private DNS namespaces.

The following is an example AmazonECS_FullAccess policy.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {

AmazonECSInfrastructureRolePolicyForVolumes

The AmazonECSInfrastructureRolePolicyForVolumes managed IAM policy grants the permissions that are needed by Amazon ECS to make AWS API calls on your behalf. You can attach this policy to the IAM role that you provide with your volume configuration when launching Amazon ECS tasks and services. The role enables Amazon ECS to manage volumes attached to your tasks. For more information, see Amazon ECS infrastructure IAM role.

Permissions details

The AmazonECSInfrastructureRolePolicyForVolumes managed IAM policy includes the following permissions. Following the standard security advice of granting least privilege, you can use the AmazonECSInfrastructureRolePolicyForVolumes managed policy as a template for creating your own custom policy that includes only the permissions that you require.

- ec2:CreateVolume – Allows a principal to create an Amazon EBS volume if and only if they are tagged with the AmazonECSCreated and AmazonECSManaged tags. This permission is required...
to create Amazon EBS volumes that are attached to Amazon ECS tasks and minimize permissions provided to Amazon ECS by this policy.

- **ec2:CreateTags** – Allows a principal to add tags to an Amazon EBS volume as part of ec2:CreateVolume. This permission is required by Amazon ECS to add customer specified tags to Amazon EBS volumes created on your behalf.

- **ec2:AttachVolume** – Allows a principal to attach an Amazon EBS volume to an Amazon EC2 instance. This permission is required by Amazon ECS to attach Amazon EBS volumes to the Amazon EC2 instance hosting the associated Amazon ECS task.

- **ec2:DescribeVolume** – Allows a principal to retrieve information about Amazon EBS volumes. This permission is required to manage the lifecycle of Amazon EBS volumes.

- **ec2:DescribeAvailabilityZones** – Allows a principal to retrieve information about Availability Zones in your account. This is required to manage the lifecycle of EBS Volumes.

- **ec2:DetachVolume** – Allows a principal to detach an Amazon EBS volume from an Amazon EC2 instance. This permission is required by Amazon ECS to detach the Amazon EBS volume from the Amazon EC2 instance that's hosting the associated Amazon ECS task when the task terminates.

- **ec2:DeleteVolume** – Allows a principal to delete an Amazon EBS volume. This permission is required by Amazon ECS to delete Amazon EBS volumes that are no longer used by the Amazon ECS task.

- **ec2:DeleteTags** – Allows a principal to delete the AmazonECSManaged tag from an Amazon EBS volume. This permission is required by Amazon ECS to remove access to an Amazon EBS volume after it is no longer associated with an Amazon ECS workload. This is only applicable when an Amazon EBS volume is not deleted after task shutdown.

The following is an example AmazonECSInfrastructureRolePolicyForVolumes policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "CreateEBSManagedVolume",
            "Effect": "Allow",
            "Action": "ec2:CreateVolume",
            "Resource": "arn:aws:ec2:*:*:volume/**",
            "Condition": {
                "ArnLike": {
                    "aws:RequestTag/AmazonECSCreated": "arn:aws:ecs:*:*:task/**"
                }
            }
        }
    ]
}
```
"StringEquals": {
   "aws:RequestTag/AmazonECSManaged": "true"
}
},
{
   "Sid": "TagOnCreateVolume",
   "Effect": "Allow",
   "Action": "ec2:CreateTags",
   "Resource": "arn:aws:ec2:*:*:volume/**",
   "Condition": {
      "ArnLike": {
         "aws:RequestTag/AmazonECSCreated": "arn:aws:ecs:*:*:task/*"
      },
      "StringEquals": {
         "ec2:CreateAction": "CreateVolume",

   }
},

AmazonEC2ContainerServiceforEC2Role

Amazon ECS attaches this policy to a service role that allows Amazon ECS to perform actions on your behalf against Amazon EC2 instances or external instances.

This policy grants administrative permissions that allow Amazon ECS container instances to make calls to AWS on your behalf. For more information, see Amazon ECS container instance IAM role.

Considerations

You should consider the following recommendations and considerations when using the AmazonEC2ContainerServiceforEC2Role managed IAM policy.

- Following the standard security advice of granting least privilege, you can modify the AmazonEC2ContainerServiceforEC2Role managed policy to fit your specific needs. If any of the permissions granted in the managed policy aren't needed for your use case, create a custom policy and add only the permissions that you require. For example, the
UpdateContainerInstancesState permission is provided for Spot Instance draining. If that permission isn't needed for your use case, exclude it using a custom policy. For more information, see Permissions details.

- Containers that are running on your container instances have access to all of the permissions that are supplied to the container instance role through instance metadata. We recommend that you limit the permissions in your container instance role to the minimal list of permissions that are provided in the managed AmazonEC2ContainerServiceforEC2Role policy. If the containers in your tasks need extra permissions that aren't listed, we recommend providing those tasks with their own IAM roles. For more information, see Task IAM role.

You can prevent containers on the docker0 bridge from accessing the permissions supplied to the container instance role. You can do this while still allowing the permissions that are provided by Task IAM role by running the following iptables command on your container instances. Containers can't query instance metadata with this rule in effect. This command assumes the default Docker bridge configuration and it doesn't work with containers that use the host network mode. For more information, see Network mode.

```
sudo yum install -y iptables-services; sudo iptables --insert DOCKER USER 1 --in-interface docker+ --destination 169.254.169.254/32 --jump DROP
```

You must save this iptables rule on your container instance for it to survive a reboot. For the Amazon ECS-optimized AMI, use the following command. For other operating systems, consult the documentation for that OS.

- For the Amazon ECS-optimized Amazon Linux 2 AMI:

```
sudo iptables-save | sudo tee /etc/sysconfig/iptables && sudo systemctl enable --now iptables
```

- For the Amazon ECS-optimized Amazon Linux AMI:

```
sudo service iptables save
```

Permissions details

The AmazonEC2ContainerServiceforEC2Role managed IAM policy includes the following permissions. Following the standard security advice of granting least privilege, the AmazonEC2ContainerServiceforEC2Role managed policy can be used as a guide. If you don't
need any of the permissions that are granted in the managed policy for your use case, create a custom policy and add only the permissions that you need.

- **ec2:DescribeTags** – Allows a principal to describe the tags that are associated with an Amazon EC2 instance. This permission is used by the Amazon ECS container agent to support resource tag propagation. For more information, see [How resources are tagged](#).

- **ecs:CreateCluster** – Allows a principal to create an Amazon ECS cluster. This permission is used by the Amazon ECS container agent to create a default cluster, if one doesn't already exist.

- **ecs:DeregisterContainerInstance** – Allows a principal to deregister an Amazon ECS container instance from a cluster. The Amazon ECS container agent doesn't call this API operation, but this permission remains to help ensure backwards compatibility.

- **ecs:DiscoverPollEndpoint** – This action returns endpoints that the Amazon ECS container agent uses to poll for updates.

- **ecs:Poll** – Allows the Amazon ECS container agent to communicate with the Amazon ECS control plane to report task state changes.

- **ecs:RegisterContainerInstance** – Allows a principal to register a container instance with a cluster. This permission is used by the Amazon ECS container agent to register the Amazon EC2 instance with a cluster and to support resource tag propagation.

- **ecs:StartTelemetrySession** – Allows the Amazon ECS container agent to communicate with the Amazon ECS control plane to report health information and metrics for each container and task.

- **ecs:TagResource** – Allows the Amazon ECS container agent to tag cluster on creation and to tag container instances when they are registered to a cluster.

- **ecs:UpdateContainerInstancesState** – Allows a principal to modify the status of an Amazon ECS container instance. This permission is used by the Amazon ECS container agent for Spot Instance draining. For more information, see [Spot Instance draining](#).

- **ecs:Submit*** – This includes the SubmitAttachmentStateChanges, SubmitContainerStateChange, and SubmitTaskStateChange API actions. They're used by the Amazon ECS container agent to report state changes for each resource to the Amazon ECS control plane. The SubmitContainerStateChange permission is no longer used by the Amazon ECS container agent but remains to help ensure backwards compatibility.

- **ecr:GetAuthorizationToken** – Allows a principal to retrieve an authorization token. The authorization token represents your IAM authentication credentials and can be used to access
any Amazon ECR registry that the IAM principal has access to. The authorization token received is valid for 12 hours.

- **ecr:BatchCheckLayerAvailability** – When a container image is pushed to an Amazon ECR private repository, each image layer is checked to verify if it's already pushed. If it is, then the image layer is skipped.

- **ecr:GetDownloadUrlForLayer** – When a container image is pulled from an Amazon ECR private repository, this API is called once for each image layer that's not already cached.

- **ecr:BatchGetImage** – When a container image is pulled from an Amazon ECR private repository, this API is called once to retrieve the image manifest.

- **logs:CreateLogStream** – Allows a principal to create a CloudWatch Logs log stream for a specified log group.

- **logs:PutLogEvents** – Allows a principal to upload a batch of log events to a specified log stream.

The following is an example AmazonEC2ContainerServiceforEC2Role policy.

```json
{
   "Version": "2012-10-17",
   "Statement": [
   {
      "Effect": "Allow",
      "Action": [
         "ec2:DescribeTags",
         "ecs:CreateCluster",
         "ecs:DeregisterContainerInstance",
         "ecs:DiscoverPollEndpoint",
         "ecs:Poll",
         "ecs:RegisterContainerInstance",
         "ecs:StartTelemetrySession",
         "ecs:UpdateContainerInstancesState",
         "ecs:Submit*",
         "ecr:GetAuthorizationToken",
         "ecr:BatchCheckLayerAvailability",
         "ecr:GetDownloadUrlForLayer",
         "ecr:BatchGetImage",
         "logs:CreateLogStream",
         "logs:PutLogEvents"
      ],
      "Resource": "*"
   }
]}
```
This policy grants permissions that allow Amazon EventBridge (formerly CloudWatch Events) to run tasks on your behalf. This policy can be attached to the IAM role that's specified when you create scheduled tasks. For more information, see Amazon ECS EventBridge IAM Role.

Permissions details

This policy includes the following permissions.

- **ecs** – Allows a principal in a service to call the Amazon ECS RunTask API. Allows a principal in a service to add tags (TagResource) when they call the Amazon ECS RunTask API.
- **iam** – Allows passing any IAM service role to any Amazon ECS tasks.

The following is an example AmazonEC2ContainerServiceEventsRole policy.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": ["ecs:RunTask"],
      "Resource": ["*"]
    }
  ]
}
```
AmazonECSTaskExecutionRolePolicy

The AmazonECSTaskExecutionRolePolicy managed IAM policy grants the permissions that are needed by the Amazon ECS container agent and AWS Fargate container agents to make AWS API calls on your behalf. This policy can be added to your task execution IAM role. For more information, see Amazon ECS task execution IAM role.

Permissions details

The AmazonECSTaskExecutionRolePolicy managed IAM policy includes the following permissions. Following the standard security advice of granting least privilege, the AmazonECSTaskExecutionRolePolicy managed policy can be used as a guide. If any of the permissions that are granted in the managed policy aren't needed for your use case, create a custom policy and add only the permissions that you require.

- `ecr:GetAuthorizationToken` – Allows a principal to retrieve an authorization token. The authorization token represents your IAM authentication credentials and can be used to access any Amazon ECR registry that the IAM principal has access to. The authorization token received is valid for 12 hours.
• **ecr:BatchCheckLayerAvailability** – When a container image is pushed to an Amazon ECR private repository, each image layer is checked to verify if it's already pushed. If it's pushed, then the image layer is skipped.

• **ecr:GetDownloadUrlForLayer** – When a container image is pulled from an Amazon ECR private repository, this API is called once for each image layer that's not already cached.

• **ecr:BatchGetImage** – When a container image is pulled from an Amazon ECR private repository, this API is called once to retrieve the image manifest.

• **logs:CreateLogStream** – Allows a principal to create a CloudWatch Logs log stream for a specified log group.

• **logs:PutLogEvents** – Allows a principal to upload a batch of log events to a specified log stream.

The following is an example AmazonECSTaskExecutionRolePolicy policy.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ecr:GetAuthorizationToken",
            "ecr:BatchCheckLayerAvailability",
            "ecr:GetDownloadUrlForLayer",
            "ecr:BatchGetImage",
            "logs:CreateLogStream",
            "logs:PutLogEvents"
         ],
         "Resource": "*"
      }
   ]
}
```

**AmazonECSServiceRolePolicy**

The AmazonECSServiceRolePolicy managed IAM policy enables Amazon Elastic Container Service to manage your cluster. This policy can be added to your task execution IAM role. For more information, see [Amazon ECS task execution IAM role](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/iam-roles.html).
Permissions details

The AmazonECSServiceRolePolicy managed IAM policy includes the following permissions. Following the standard security advice of granting least privilege, the AmazonECSServiceRolePolicy managed policy can be used as a guide. If any of the permissions that are granted in the managed policy aren't needed for your use case, create a custom policy and add only the permissions that you require.

- **autoscaling** – Allows principals to create, manage, and describe Amazon EC2 Auto Scaling resources. This is required when managing Amazon EC2 Auto Scaling groups when using the cluster auto scaling feature.
- **autoscaling-plans** – Allows principals to create, delete, and describe autoscaling plans.
- **cloudwatch** – Allows principals to create, manage, and describe Amazon CloudWatch alarms.
- **ec2** – Allows principals run to Amazon EC2 instances and create and manage network interfaces and tags.
- **elasticloadbalancing** – Allows principals to create, describe, and delete Elastic Load Balancing load balancers. Principals will also be able to add and describe target groups.
- **logs** – Allows principals to create and describe Amazon CloudWatch Logs log groups. Principals can also list log events for these log groups.
- **route53** – Allows principals to create, manage, and delete Amazon Route 53 hosted zones. Principals can also view Amazon Route 53 health check configuration and information. For more information about hosted zones, see [Working with hosted zones](#).
- **servicediscovery** – Allows principals to create, manage, and delete AWS Cloud Map services and create private DNS namespaces.
- **events** – Allows principals to create, manage, and delete Amazon EventBridge rules and their targets.

The following is an example AmazonECSServiceRolePolicy policy.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "ECSTaskManagement",

AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity

Provides administrative access to AWS Private Certificate Authority, Secrets Manager and other AWS Services required to manage Amazon ECS Service Connect TLS features on your behalf.

Permissions details

The AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity managed IAM policy includes the following permissions. Following the standard security advice of granting least privilege, the AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity managed policy can be used as a guide. If any of the permissions that are granted in the managed policy aren't needed for your use case, create a custom policy and add only the permissions that you require.

- secretsmanager:CreateSecret – Allows principal to create the secret. It's required for Service Connect TLS, Amazon ECS keeps the customer’s private key in the customer’s Secrets Manager secret.
- secretsmanager:TagResource – Allows principal to attach tag on the created secret. It is required for Service Connect TLS, because Amazon ECS creates the secret on behalf of the
customer and attaches tag with resource. These tags provide an easier way for the customer to identify the managed secret and restrict actions on these secrets.

- **secretsmanager:DescribeSecret** – Allow principal to describe the secret and retrieve the current version stage. It is required for Amazon ECS to do Amazon ECS Service Connect TLS materials rotation.

- **secretsmanager:UpdateSecret** – Allow principal to update the secret. It is required for Amazon ECS to do Amazon ECS Service Connect TLS materials rotation and update the secret with new materials.

- **secretsmanager:GetSecretValue** – Allow principal to get the secret value. It is required for Amazon ECS to do Amazon ECS Service Connect TLS materials rotation.

- **secretsmanager:PutSecretValue** – Allow principal to put the secret value. It is required for Amazon ECS to do Amazon ECS Service Connect TLS materials rotation.

- **secretsmanager:UpdateSecretVersionStage** – Allow principal to update the secret version stage. It is required for Amazon ECS to do Amazon ECS Service Connect TLS materials rotation.

- **acm-pca:IssueCertificate** – Allow principal to call IssueCertificate for End entity certificate for Amazon ECS Service Connect TLS. It required for ECS to generate certificate for customer's upstream service.

- **acm-pca:GetCertificate** – Allow principal to call GetCertificate for End entity certificate for Amazon ECS Service Connect TLS.

- **acm-pca:GetCertificateAuthorityCertificate** – Allow principal to get certificate authorities certificate. It’s required for Amazon ECS Service Connect TLS so that customer’s downstream service can trust the upstream end entity certificate.

- **acm-pca:DescribeCertificateAuthority** – Allow principal to get details about the certificate authority. It is required for Amazon ECS Service Connect TLS to reuse information like signing algorithm to create the CSR (Certificate Signing Request).

The following is an example

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

AWSApplicationAutoscalingECSServicePolicy

You can't attach AWSApplicationAutoscalingECSServicePolicy to your IAM entities. This policy is attached to a service-linked role that allows Application Auto Scaling to perform actions on your behalf. For more information, see Service-linked roles for Application Auto Scaling.

AWSCodeDeployRoleForECS

You can't attach AWSCodeDeployRoleForECS to your IAM entities. This policy is attached to a service-linked role that allows CodeDeploy to perform actions on your behalf. For more information, see Create a service role for CodeDeploy in the AWS CodeDeploy User Guide.

AWSCodeDeployRoleForECSLimited

You can't attach AWSCodeDeployRoleForECSLimited to your IAM entities. This policy is attached to a service-linked role that allows CodeDeploy to perform actions on your behalf. For more information, see Create a service role for CodeDeploy in the AWS CodeDeploy User Guide.

Amazon ECS updates to AWS managed policies

View details about updates to AWS managed policies for Amazon ECS since this service started tracking these changes. For automatic alerts about changes to this page, subscribe to the RSS feed on the Amazon ECS Document history page.

### Phased out AWS managed IAM policies for Amazon Elastic Container Service

The following AWS managed IAM policies are phased out. These policies are now replaced by the updated policies. We recommend that you update your users or roles to use the updated policies.

**AmazonEC2ContainerServiceFullAccess**

⚠️ **Important**

The AmazonEC2ContainerServiceFullAccess managed IAM policy was phased out as of January 29, 2021, in response to a security finding with the iam:passRole permission. This permission grants access to all resources including credentials to roles in the account. Now that the policy is phased out, you can't attach the policy to any new users or roles. Any users or roles that already have the policy attached can continue using it. However, we recommend that you update your users or roles to use the
Amazon Elastic Container Service Developer Guide

AmazonECS_FullAccess

Important

The AmazonECS_FullAccess managed policy was phased out on January 29, 2021, in response to a security finding with the `iam:passRole` permission. This permission grants access to all resources including credentials to roles in the account. Now that the policy is phased out, you can't attach the policy to any new groups, users, or roles. Any groups, users, or roles that already have the policy attached can continue using it. However, we recommend that you update your groups, users, or roles to use the AmazonECS_FullAccess managed policy instead.

The permissions that are granted by the AmazonECS_FullAccess policy include the complete list of permissions that are necessary to use ECS as an administrator. If you currently use permissions that are granted by the AmazonECS_FullAccess policy that aren't in the AmazonECS_FullAccess policy, you can add them to an inline policy statement. For more information, see AWS managed policies for Amazon Elastic Container Service.

Migrating to the AmazonECS_FullAccess managed policy

AmazonEC2ContainerServiceRole

Important

The AmazonEC2ContainerServiceRole managed IAM policy is phased out. It's now replaced by the Amazon ECS service-linked role. For more information, see Using service-linked roles for Amazon ECS.

AmazonEC2ContainerServiceAutoscaleRole

Important

The AmazonEC2ContainerServiceAutoscaleRole managed IAM policy is phased out. It's now replaced by the Application Auto Scaling service-linked role for Amazon ECS. For more information, see Service-linked roles for Application Auto Scaling in the Application Auto Scaling User Guide.
Use the following steps to determine if you have any groups, users, or roles that are currently using the AmazonEC2ContainerServiceFullAccess managed IAM policy. Then, update them to detach the earlier policy and attach the AmazonECS_FullAccess policy.

**To update a group, user, or role to use the AmazonECS_FullAccess policy (AWS Management Console)**

2. In the navigation pane, choose **Policies** and search for and select the AmazonEC2ContainerServiceFullAccess policy.
3. Choose the **Policy usage** tab that displays any IAM role that's currently using this policy.
4. For each IAM role that's currently using the AmazonEC2ContainerServiceFullAccess policy, select the role and use the following steps to detach the phased out policy and attach the AmazonECS_FullAccess policy.
   a. On the **Permissions** tab, choose the X next to the AmazonEC2ContainerServiceFullAccess policy.
   b. Choose **Add permissions**.
   c. Choose **Attach existing policies directly**, search for and select the AmazonECS_FullAccess policy, and then choose **Next: Review**.
   d. Review the changes and then choose **Add permissions**.
   e. Repeat these steps for each group, user, or role that's using the AmazonEC2ContainerServiceFullAccess policy.

**To update a group, user, or role to use the AmazonECS_FullAccess policy (AWS CLI)**

1. Use the `generate-service-last-accessed-details` command to generate a report that includes details about when the phased out policy was last used.

   ```bash
   aws iam generate-service-last-accessed-details \
   --arn arn:aws:iam::aws:policy/AmazonEC2ContainerServiceFullAccess
   ```

   Example output:

   ```json
   {
     "JobId": "32bb1fb0-1ee0-b08e-3626-ae83EXAMPLE"
   }
   ```
2. Use the job ID from the previous output with the `get-service-last-accessed-details` command to retrieve the last accessed report of the service. This report displays the Amazon Resource Name (ARN) of the IAM entities that last used the phased out policy.

```bash
aws iam get-service-last-accessed-details \
--job-id 32bb1fb0-1ee0-b08e-3626-ae83EXAMPLE
```

3. Use one of the following commands to detach the AmazonEC2ContainerServiceFullAccess policy from a group, user, or role.

- `detach-group-policy`
- `detach-role-policy`
- `detach-user-policy`

4. Use one of the following commands to attach the AmazonECS_FullAccess policy to a group, user, or role.

- `attach-group-policy`
- `attach-role-policy`
- `attach-user-policy`

---

**Using service-linked roles for Amazon ECS**

Amazon Elastic Container Service uses AWS Identity and Access Management (IAM) [service-linked roles](https://docs.aws.amazon.com/iam/latest/dg/servcelinked-roles.html). A service-linked role is a unique type of IAM role that is linked directly to Amazon ECS. The service-linked role is predefined by Amazon ECS and includes all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up Amazon ECS easier because you don’t have to manually add the necessary permissions. Amazon ECS defines the permissions of its service-linked roles, and unless defined otherwise, only Amazon ECS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

For information about other services that support service-linked roles, see [AWS services that work with IAM](https://docs.aws.amazon.com/AmazonS3/latest/dev/using-with-s3-grants.html) and look for the services that have **Yes** in the **Service-linked roles** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.
Service-linked role permissions for Amazon ECS

Amazon ECS uses the service-linked role named **AWSServiceRoleForECS**.

The AWSServiceRoleForECS service-linked role trusts the following services to assume the role:

- `ecs.amazonaws.com`

The role permissions policy named AmazonECSServiceRolePolicy allows Amazon ECS to complete the following actions on the specified resources:

- **Action**: When using the awsvpc network mode for your Amazon ECS tasks, Amazon ECS manages the lifecycle of the elastic network interfaces associated with the task. This also includes tags that Amazon ECS adds to your elastic network interfaces.
- **Action**: When using a load balancer with your Amazon ECS service, Amazon ECS manages the registration and deregistration of resources with the load balancer.
- **Action**: When using Amazon ECS service discovery, Amazon ECS manages the required Route 53 and AWS Cloud Map resources for service discovery to work.
- **Action**: When using Amazon ECS service auto scaling, Amazon ECS manages the required Auto Scaling resources.
- **Action**: Amazon ECS creates and manages CloudWatch alarms and log streams that assist in the monitoring of your Amazon ECS resources.
- **Action**: When using Amazon ECS Exec, Amazon ECS manages the permissions needed to start Amazon ECS Exec sessions to your tasks.
- **Action**: When using Amazon ECS Service Connect, Amazon ECS manages the required AWS Cloud Map resources to use the feature.
- **Action**: When using Amazon ECS capacity providers, Amazon ECS manages the permissions required to modify the Auto Scaling group and its Amazon EC2 instances.

You must configure permissions to allow an IAM entity (such as a user, group, or role) to create, edit, or delete a service-linked role. For more information, see [Service-linked role permissions](#) in the [IAM User Guide](#).

Creating a service-linked role for Amazon ECS

In most cases you don't need to manually create a service-linked role. When you create a cluster or create or update a service in the AWS Management Console, the AWS CLI, or the AWS API, Amazon
ECS creates the service-linked role for you. If you do not see the `AWSServiceRoleForECS` role after you create a cluster, perform the following to fix the issue:

- Verify and configure the permissions to allow Amazon ECS to create, edit, or delete a service-linked role on your behalf. For more information, see Service-linked role permissions in the IAM User Guide.

- Retry the cluster creation operation, or manually create the service-linked role.

You can use the IAM console to create the `AWSServiceRoleForECS` service-linked role. In the AWS CLI or the AWS API, create a service-linked role with the `ecs.amazonaws.com` service name. For more information, see Creating a service-linked role in the IAM User Guide.

**Important**

This service-linked role can appear in your account if you completed an action in another service that uses the features supported by this role.

If you delete this service-linked role, and then need to create it again, you can use the same process to recreate the role in your account. When you create a cluster or create or update a service, Amazon ECS creates the service-linked role for you again.

If you delete this service-linked role, you can use the same IAM process to create the role again.

**Editing a service-linked role for Amazon ECS**

Amazon ECS doesn't allow you to edit the `AWSServiceRoleForECS` service-linked role. After you create a service-linked role, you cannot change the name of the role because various entities might reference the role. However, you can edit the description of the role using IAM. For more information, see Editing a service-linked role in the IAM User Guide.

**Deleting a service-linked role for Amazon ECS**

If you no longer need to use a feature or service that requires a service-linked role, we recommend that you delete that role. That way you don’t have an unused entity that is not actively monitored or maintained. However, you must clean up the resources for your service-linked role before you can manually delete it.
To check whether the service-linked role has an active session

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles and choose the AWSServiceRoleForECS name (not the check box).
3. On the Summary page, choose Access Advisor and review recent activity for the service-linked role.

To remove Amazon ECS resources used by the AWSServiceRoleForECS service-linked role

You must delete all Amazon ECS clusters in all AWS Regions before you can delete the AWSServiceRoleForECS role.

1. Scale all Amazon ECS services down to a desired count of 0 in all regions, and then delete the services. For more information, see Updating a service using the console and Deleting a service using the console.
2. Force deregister all container instances from all clusters in all regions. For more information, see Deregister an Amazon EC2 backed container instance.
3. Delete all Amazon ECS clusters in all regions. For more information, see Deleting a cluster using the console.

To manually delete the service-linked role using IAM
Use the IAM console, the AWS CLI, or the AWS API to delete the AWSServiceRoleForECS service-linked role. For more information, see [Deleting a service-linked role](#) in the [IAM User Guide](#).

**Supported regions for Amazon ECS service-linked roles**

Amazon ECS supports using service-linked roles in all of the regions where the service is available. For more information, see [AWS regions and endpoints](#).

**Permissions required for the Amazon ECS console**

Following the best practice of granting least privilege, you can use the AmazonECS_FullAccess managed policy as a template for creating your own custom policy. That way, you can take away or add permissions to and from the managed policy based on your specific requirements. For more information, see [Permissions details](#).

The Amazon ECS console is powered by AWS CloudFormation and requires additional IAM permissions in the following cases:

- Creating a cluster
- Creating a service
- Creating a capacity provider

You can create a policy for the additional permissions, and then attach them to the IAM role you use to access the console. For more information, see [Creating IAM policies](#) in the [IAM User Guide](#).

**IAM permissions required for creating a cluster**

When you create a cluster in the console, you need additional permissions that grant you permissions to manage AWS CloudFormation stacks.

The following additional permissions are required:

- `cloudformation` – Allows principals to create and manage AWS CloudFormation stacks. This is required when creating Amazon ECS clusters using the AWS Management Console and the subsequent managing of those clusters.

The following policy contains the required AWS CloudFormation permissions, and limits the actions to resources created in the Amazon ECS console.
If you have not created the Amazon ECS container instance role (ecsInstanceRole), and you are creating a cluster that uses Amazon EC2 instances, then the console will create the role on your behalf.

In addition, if you use Auto Scaling groups, then you need additional permissions so that the console can add tags to the auto scaling groups when using the cluster auto scaling feature.

The following additional permissions are required:

- **autoscaling** – Allows the console to tag Amazon EC2 Auto Scaling group. This is required when managing Amazon EC2 auto scaling groups when using the cluster auto scaling feature. The tag is the ECS-managed tag that the console automatically adds to the group to indicate it was created in the console.

- **iam** – Allows principals to list IAM roles and their attached policies. Principals can also list instance profiles available to your Amazon EC2 instances.

The following policy contains the required IAM permissions, and limits the actions to the ecsInstanceRole role.

The Auto Scaling permissions are not limited.

```json
{
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudformation:CreateStack",
                "cloudformation:DeleteStack",
                "cloudformation:DescribeStack*",
                "cloudformation:UpdateStack"
            ],
            "Resource": [
                "arn:*:cloudformation:*:*:stack/Infra-ECS-Cluster-**"
            ]
        }
    ]
}
```
IAM permissions required for creating a capacity provider

When you create a service in the console, you need additional permissions that grant you permissions to manage AWS CloudFormation stacks. The following additional permissions are required:

- `cloudformation` – Allows principals to create and manage AWS CloudFormation stacks. This is required when creating Amazon ECS capacity providers using the AWS Management Console and the subsequent managing of those capacity providers.

The following policy contains the required permissions, and limits the actions to resources created in the Amazon ECS console.

```json
{
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "cloudformation:CreateStack",
                "cloudformation:DeleteStack",
                "cloudformation:DescribeStacks",
                "cloudformation:UpdateStack"
            ],
            "Resource": "arn:aws:cloudformation::*:stack/*"
        }
    ]
}
```
IAM permissions required for creating a service

When you create a service in the console, you need additional permissions that grant you permissions to manage AWS CloudFormation stacks. The following additional permissions are required:

- `cloudformation` – Allows principals to create and manage AWS CloudFormation stacks. This is required when creating Amazon ECS services using the AWS Management Console and the subsequent managing of those services.

The following policy contains the required permissions, and limits the actions to resources created in the Amazon ECS console.

```
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "cloudformation:CreateStack",
        "cloudformation:DeleteStack",
        "cloudformation:DescribeStack*",
        "cloudformation:UpdateStack"
      ],
      "Resource": [
        "arn:*:cloudformation:*:*:stack/ECS-Console-V2-Service-*"
      ]
    }
  ]
}
```

Permissions for creating IAM roles

The following actions require additional permissions in order to complete the operation:
Registering an external instance - for more information, see ECS Anywhere IAM role

Registering a task definition - for more information, see Amazon ECS task execution IAM role

Creating an EventBridge rule to use for scheduling tasks - for more information, see Amazon ECS EventBridge IAM Role

You can add these permissions by creating a role in IAM before you use them in the Amazon ECS console. If you do not create the roles, the Amazon ECS console creates them on your behalf.

IAM permissions required for registering an external instance to a cluster

You need additional permissions when you register an external instance to a cluster and you want to create a new external instance (escExternalInstanceRole) role.

The following additional permissions are required:

- `iam` – Allows principals to create and list IAM roles and their attached policies.
- `ssm` – Allows principals to register the external instance with Systems Manager.

<i>Note</i>

In order to choose an existing escExternalInstanceRole, you must have the `iam:GetRole` and `iam:PassRole` permissions.

The following policy contains the required permissions, and limits the actions to the escExternalInstanceRole role.

```json
{
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "iam:AttachRolePolicy",
                "iam:CreateRole",
                "iam:CreateInstanceProfile",
                "iam:AddRoleToInstanceProfile",
                "iam:ListInstanceProfilesForRole",
                "iam:GetRole"
            ]
        }
    ]
}
```
IAM permissions required for registering a task definition

You need additional permissions when you register a task definition and you want to create a new task execution (ecsTaskExecutionRole) role.

The following additional permissions are required:

- `iam`– Allows principals to create and list IAM roles and their attached policies.

**Note**

In order to choose an existing `ecsTaskExecutionRole`, you must have the `iam:GetRole` permission.

The following policy contains the required permissions, and limits the actions to the `ecsTaskExecutionRole` role.

```json
{
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "iam:AttachRolePolicy",
            "iam:CreateRole",
            "iam:GetRole"
         ],
         "Resource": "arn:aws:iam::*:role/ecsTaskExecutionRole"
      }
   ]
}
```
IAM permissions required for creating an EventBridge rule for scheduled tasks

You need additional permissions when you schedule a task and you want to create a new CloudWatch Events role (ecsEventsRole) role.

The following additional permissions are required:

- **iam**: Allows principals to create and list IAM roles and their attached policies, and to allow Amazon ECS to pass the role to other services to assume the role.

  **Note**
  
  In order to choose an existing ecsEventsRole, you must have the `iam:GetRole` and `iam:PassRole` permissions.

The following policy contains the required permissions, and limits the actions to the ecsEventsRole role.

```json
{
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "iam:AttachRolePolicy",
        "iam:CreateRole",
        "iam:GetRole",
        "iam: PassRole"
      ],
      "Resource": "arn:aws:iam::*:role/ecsEventsRole"
    }
  ]
}
```

Amazon ECS task execution IAM role

The task execution role grants the Amazon ECS container and Fargate agents permission to make AWS API calls on your behalf. The task execution IAM role is required depending on the
requirements of your task. You can have multiple task execution roles for different purposes and services associated with your account. For the IAM permissions that your application needs to run, see **Task IAM role**.

The following are common use cases for a task execution IAM role:

- **Your task is hosted on AWS Fargate or on an external instance and:**
  - is pulling a container image from an Amazon ECR private repository.
  - is pulling a container image from an Amazon ECR private repository in a different account from the account that runs the task.
  - sends container logs to CloudWatch Logs using the `awslogs` log driver. For more information, see [Using the `awslogs` log driver](#).

- **Your tasks are hosted on either AWS Fargate or Amazon EC2 instances and...**
  - is using private registry authentication. For more information, see [Required IAM permissions for private registry authentication](#).
  - is using Runtime Monitoring.
  - the task definition is referencing sensitive data using Secrets Manager secrets or AWS Systems Manager Parameter Store parameters. For more information, see [Required IAM permissions for Amazon ECS secrets](#).

**Note**
The task execution role is supported by Amazon ECS container agent version 1.16.0 and later.

Amazon ECS provides the managed policy named `AmazonECSTaskExecutionRolePolicy` which contains the permissions the common use cases described above require. It might be necessary to add inline policies to your task execution role for special use cases which are outlined below.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecr:GetAuthorizationToken",
```
An Amazon ECS task execution role can be created for you in the Amazon ECS console; however, you should manually attach the managed IAM policy for tasks to allow Amazon ECS to add permissions for future features and enhancements as they are introduced. You can use IAM console search to search for `ecsTaskExecutionRole` and see if your account already has the task execution role. For more information, see IAM console search in the IAM user guide.

Creating the task execution (ecsTaskExecutionRole) role

If your account doesn't already have a task execution role, use the following steps to create the role.

AWS Management Console

To create a task execution IAM role (AWS Management Console)

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles, Create role.
3. In the Trusted entity type section, choose AWS service, Elastic Container Service.
4. For Use case, choose Elastic Container Service Task, and then choose Next.
5. In the Add permissions section, do the following:
   a. Search for AmazonECSTaskExecutionRolePolicy, then select the policy.
   b. Under Set permissions boundary - optional, choose Create role without a permissions boundary.
   c. Choose Next.
6. Under Name, review, and create, do the following:
   a. For Role name, type ecsTaskExecutionRole.
b. For **Add tags (optional)**, specify any custom tags to associate with the policy.

7. Choose **Create role**.

**AWS CLI**

Replace all *user input* with your own information.

1. Create a file named `ecs-tasks-trust-policy.json` that contains the trust policy to use for the IAM role. The file should contain the following:

```json
{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "",
        "Effect": "Allow",
        "Principal": {
          "Service": "ecs-tasks.amazonaws.com"
        },
        "Action": "sts:AssumeRole"
      }
    ]
}
```

2. Create an IAM role named `ecsTaskExecutionRole` using the trust policy created in the previous step.

   ```
   aws iam create-role \
   --role-name ecsTaskExecutionRole \
   --assume-role-policy-document file://ecs-tasks-trust-policy.json
   ```

3. Attach the AWS managed `AmazonECSTaskExecutionRolePolicy` policy to the `ecsTaskExecutionRole` role.

   ```
   aws iam attach-role-policy \
   --role-name ecsTaskExecutionRole \
   --policy-arn arn:aws:iam::aws:policy/service-role/AmazonECSTaskExecutionRolePolicy
   ```
Required IAM permissions for private registry authentication

The Amazon ECS task execution role is required to use this feature. This allows the container agent to pull the container image.

To provide access to the secrets that you create, add the following permissions as an inline policy to the task execution role. For more information, see Adding and Removing IAM Policies.

- `secretsmanager:GetSecretValue`
- `kms:Decrypt`—Required only if your key uses a custom KMS key and not the default key. The Amazon Resource Name (ARN) for your custom key must be added as a resource.

The following is an example inline policy that adds the permissions.

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt",
        "secretsmanager:GetSecretValue"
      ],
      "Resource": [
        "arn:aws:kms:<region>:<aws_account_id>:key/key_id"
      ]
    }
  ]
}

Required IAM permissions for Amazon ECS secrets

To use the Amazon ECS secrets feature, you must have the Amazon ECS task execution role and reference it in your task definition. This allows the container agent to pull the necessary AWS Systems Manager or Secrets Manager resources. For more information, see Passing sensitive data to a container.

Using Secrets Manager
To provide access to the Secrets Manager secrets that you create, manually add the following permission to the task execution role. For information about how to manage permissions, see Adding and Removing IAM identity permissions in the IAM User Guide.

- `secretsmanager:GetSecretValue`— Required if you are referencing a Secrets Manager secret. Adds the permission to retrieve the secret from Secrets Manager.

The following example policy adds the required permissions.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "secretsmanager:GetSecretValue"
            ],
            "Resource": [
                "arn:aws:secretsmanager:region:aws_account_id:secret:secret_name"
            ]
        }
    ]
}
```

### Using Systems Manager

**Important**

For tasks that use the EC2 launch type, you must use the ECS agent configuration variable `ECS_ENABLE_AWSLOGS_EXECUTIONROLE_OVERRIDE=true` to use this feature. You can add it to the `/etc/ecs/ecs.config` file during container instance creation or you can add it to an existing instance and then restart the ECS agent. For more information, see Amazon ECS container agent configuration.

To provide access to the Systems Manager Parameter Store parameters that you create, manually add the following permissions as a policy to the task execution role. For information about how to manage permissions, see Adding and Removing IAM identity permissions in the IAM User Guide.
• `ssm:GetParameters` — Required if you are referencing a Systems Manager Parameter Store parameter in a task definition. Adds the permission to retrieve Systems Manager parameters.

• `secretsmanager:GetSecretValue` — Required if you are referencing a Secrets Manager secret either directly or if your Systems Manager Parameter Store parameter is referencing a Secrets Manager secret in a task definition. Adds the permission to retrieve the secret from Secrets Manager.

• `kms:Decrypt` — Required only if your secret uses a customer managed key and not the default key. The ARN for your custom key should be added as a resource. Adds the permission to decrypt the customer managed key.

The following example policy adds the required permissions:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetParameters",
                "secretsmanager:GetSecretValue",
                "kms:Decrypt"
            ],
            "Resource": [
                "arn:aws:ssm:region:aws_account_id:parameter/parameter_name",
                "arn:aws:kms:region:aws_account_id:key/key_id"
            ]
        }
    ]
}
```

Optional IAM permissions for Fargate tasks pulling Amazon ECR images over interface endpoints

When launching tasks that use the Fargate launch type that pull images from Amazon ECR when Amazon ECR is configured to use an interface VPC endpoint, you can restrict the tasks access to a specific VPC or VPC endpoint. Do this by creating a task execution role for the tasks to use that use IAM condition keys.
Use the following IAM global condition keys to restrict access to a specific VPC or VPC endpoint. For more information, see AWS Global Condition Context Keys.

- **aws:SourceVpc**—Restricts access to a specific VPC.
- **aws:SourceVpce**—Restricts access to a specific VPC endpoint.

The following task execution role policy provides an example for adding condition keys:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecr:GetAuthorizationToken",
        "logs:CreateLogStream",
        "logs:PutLogEvents"
      ],
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "ecr:BatchCheckLayerAvailability",
        "ecr:GetDownloadUrlForLayer",
        "ecr:BatchGetImage"
      ],
      "Resource": "*",
      "Condition": {
        "StringEquals": {
          "aws:sourceVpce": "vpce-xxxxxx",
          "aws:sourceVpc": "vpc-xxxxxx"
        }
      }
    }
  ]
}
```

**Important**

The `ecr:GetAuthorizationToken` API action cannot have the `aws:sourceVpc` or `aws:sourceVpce` condition keys applied to it because the GetAuthorizationToken API call goes through the elastic network interface owned by AWS Fargate rather than the elastic network interface of the task.
Task IAM role

Your Amazon ECS tasks can have an IAM role associated with them. The permissions granted in the IAM role are assumed by the containers running in the task. For the IAM permissions that Amazon ECS needs to pull container images and run the task, see [Amazon ECS task execution IAM role](#).

If your containerized applications need to call AWS APIs, they must sign their AWS API requests with AWS credentials, and a task IAM role provides a strategy for managing credentials for your applications to use, similar to the way that an Amazon EC2 instance profile provides credentials to Amazon EC2 instances. Instead of creating and distributing your AWS credentials to the containers or using the Amazon EC2 instance's role, you can associate an IAM role with an Amazon ECS task definition or `RunTask` API operation. Your containers can then use the AWS SDK or AWS CLI to make API requests to authorized AWS services.

The following explain the benefits of using IAM roles with your tasks.

- **Credential Isolation**: A container can only retrieve credentials for the IAM role that is defined in the task definition to which it belongs; a container never has access to credentials that are intended for another container that belongs to another task.

- **Authorization**: Unauthorized containers cannot access IAM role credentials defined for other tasks.

- **Auditability**: Access and event logging is available through CloudTrail to ensure retrospective auditing. Task credentials have a context of `taskArn` that is attached to the session, so CloudTrail logs show which task is using which role.

**Note**

When you specify an IAM role for a task, the AWS CLI or other SDKs in the containers for that task use the AWS credentials provided by the task role exclusively and they no longer inherit any IAM permissions from the Amazon EC2 or external instance they are running on.
You can specify a task IAM role in your task definitions, or you can use a taskRoleArn override when running a task manually with the RunTask API operation. The Amazon ECS agent receives a payload message for starting the task with additional fields that contain the role credentials. The Amazon ECS agent sets a unique task credential ID as an identification token and updates its internal credential cache so that the identification token for the task points to the role credentials that are received in the payload. The Amazon ECS agent populates the AWS_CONTAINER_CREDENTIALS_RELATIVE_URI environment variable in the Env object (available with the docker inspect container_id command) for all containers that belong to this task with the following relative URI: /credential_provider_version/credentials?id=task_credential_id.

From inside the container, you can query the credential endpoint with the following command:

```bash
curl 169.254.170.2$AWS_CONTAINER_CREDENTIALS_RELATIVE_URI
```

Output:

```json
{
    "AccessKeyId": "ACCESS_KEY_ID",
    "Expiration": "EXPIRATION_DATE",
    "RoleArn": "TASK_ROLE_ARN",
    "SecretAccessKey": "SECRET_ACCESS_KEY",
    "Token": "SECURITY_TOKEN_STRING"
}
```

If your Amazon EC2 instance is using at least version 1.11.0 of the container agent and a supported version of the AWS CLI or SDKs, then the SDK client will see that the AWS_CONTAINER_CREDENTIALS_RELATIVE_URI variable is available, and it will use the provided credentials to make calls to the AWS APIs. For more information, see Using task IAM roles on your Amazon EC2 or external instances.

Each time the credential provider is used, the request is logged locally on the host container instance at /var/log/ecs/audit.log. YYYY-MM-DD-HH. For more information, see IAM Roles for Tasks Credential Audit Log.

**Considerations for tasks hosted on Amazon EC2 instances**

When using an IAM role with your tasks that are running on Amazon EC2 instances, the containers aren't prevented from accessing the credentials that are supplied to the Amazon EC2 instance profile (through the Amazon EC2 instance metadata server). We recommend that you limit
the permissions in your container instance role to the minimal list of permissions used in the AmazonEC2ContainerServiceforEC2Role managed IAM policy. For more information, see Amazon ECS container instance IAM role.

The following should also be considered when using a task IAM role for tasks hosted on Amazon EC2 instances.

- To prevent containers run by tasks that use the awsvpc network mode from accessing the credential information supplied to the Amazon EC2 instance profile, while still allowing the permissions that are provided by the task role, set the ECS_AWSVPC_BLOCK_IMDS agent configuration variable to true in the agent configuration file and restart the agent. For more information, see Amazon ECS container agent configuration.

- To prevent containers run by tasks that use the bridge network mode from accessing the credential information supplied to the Amazon EC2 instance profile, while still allowing the permissions that are provided by the task role, by running the following `iptables` command on your Amazon EC2 instances. This command doesn't affect containers in tasks that use the host or awsvpc network modes. For more information, see Network mode.

```
sudo yum install -y iptables-services; sudo iptables --insert DOCKER-USER 1 --in-interface docker+ --destination 169.254.169.254/32 --jump DROP
```

You must save this `iptables` rule on your Amazon EC2 instance for it to survive a reboot. When using the Amazon ECS-optimized AMI, you can use the following command. For other operating systems, consult the documentation for that operating system.

```
sudo iptables-save | sudo tee /etc/sysconfig/iptables && sudo systemctl enable --now iptables
```

**Using task IAM roles on your Amazon EC2 or external instances**

Your Amazon EC2 or external instances require at least version 1.11.0 of the container agent to use task IAM roles; however, we recommend using the latest container agent version. For information about checking your agent version and updating to the latest version, see Updating the Amazon ECS container agent. If you are using an Amazon ECS-optimized AMI, your instance needs at least 1.11.0-1 of the ecs-init package. If your instances are using the latest Amazon ECS-optimized AMI, then they contain the required versions of the container agent and ecs-init. For more information, see Amazon ECS-optimized AMI.
If you are not using the Amazon ECS-optimized AMI for your container instances, be sure to add the `--net=host` option to your `docker run` command that starts the agent and the following agent configuration variables for your desired configuration (for more information, see Amazon ECS container agent configuration):

- `ECS_ENABLE_TASK_IAM_ROLE=true`
  
  Uses IAM roles for tasks for containers with the bridge and default network modes.
- `ECS_ENABLE_TASK_IAM_ROLENETWORK_HOST=true`
  
  Uses IAM roles for tasks for containers with the host network mode. This variable is only supported on agent versions 1.12.0 and later.

For an example run command, see Manually updating the Amazon ECS container agent (for non-Amazon ECS-Optimized AMIs). You will also need to set the following networking commands on your container instance so that the containers in your tasks can retrieve their AWS credentials:

```
sudo sysctl -w net.ipv4.conf.all.route_localnet=1
sudo iptables -t nat -A PREROUTING -p tcp -d 169.254.170.2 --dport 80 -j DNAT --to-destination 127.0.0.1:51679
sudo iptables -t nat -A OUTPUT -d 169.254.170.2 -p tcp -m tcp --dport 80 -j REDIRECT --to-ports 51679
```

You must save these `iptables` rules on your container instance for them to survive a reboot. You can use the `iptables-save` and `iptables-restore` commands to save your `iptables` rules and restore them at boot. For more information, consult your specific operating system documentation.

**Creating an IAM role and policy for your tasks**

When creating an IAM policy for your tasks to use, the policy should include the permissions that you would like the containers in your tasks to assume. You can use an existing AWS managed policy, or you can create a custom policy from scratch that meets your specific needs. For more information, see Creating IAM policies in the IAM User Guide.

⚠️ **Important**

For Amazon ECS tasks (for all launch types), we recommend that you use the IAM policy and role for your tasks. These credentials allow your task to make AWS API requests without calling `sts:AssumeRole` to assume the same role that is already associated with
the task. If your task requires that a role assumes itself, you must create a trust policy that explicitly allows that role to assume itself. For more information, see Modifying a role trust policy in the IAM User Guide.

After the IAM policy is created, you can create an IAM role which includes that policy which you reference in your Amazon ECS task definition. You can create the role using the Elastic Container Service Task use case in the IAM console. Then, you can attach your specific IAM policy to the role that gives the containers in your task the permissions you desire. The procedures below describe how to do this.

If you have multiple task definitions or services that require IAM permissions, you should consider creating a role for each specific task definition or service with the minimum required permissions for the tasks to operate so that you can minimize the access that you provide for each task.

For information about the service endpoint for your Region, see Service endpoints in the Amazon Web Services General Reference Reference Guide.

The IAM task role must have a trust policy that specifies the ecs-tasks.amazonaws.com service. The sts:AssumeRole permission allows your tasks to assume an IAM role that's different from the one that the Amazon EC2 instance uses. This way, your task doesn't inherit the role associated with the Amazon EC2 instance. The following is an example trust policy. Replace the Region identifier and specify the AWS account number that you use when launching tasks.

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect":"Allow",
            "Principal": {
                "Service": [
                    "ecs-tasks.amazonaws.com"
                ],
            "Action": "sts:AssumeRole",
            "Condition": {
                "ArnLike": {
                },
                "StringEquals": {
                    "aws:SourceAccount": "111122223333"
                }
            }
        }
    ]
}
```
Important
When creating your task IAM role, it is recommended that you use the aws:SourceAccount or aws:SourceArn condition keys in either the trust relationship or the IAM policy associated with the role to scope the permissions further to prevent the confused deputy security issue. Using the aws:SourceArn condition key to specify a specific cluster is not currently supported, you should use the wildcard to specify all clusters. To learn more about the confused deputy problem and how to protect your AWS account, see The confused deputy problem in the IAM User Guide.

The following procedures describe how to create a policy to retrieve objects from Amazon S3 with an example policy. Replace all user input with your own values.

AWS Management Console

To use the JSON policy editor to create a policy

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane on the left, choose Policies.
   If this is your first time choosing Policies, the Welcome to Managed Policies page appears. Choose Get Started.
3. At the top of the page, choose Create policy.
4. In the Policy editor section, choose the JSON option.
5. Enter the following JSON policy document:

```json
{
    "Version":"2012-10-17",
    "Statement": [
        {
            "Effect":"Allow",
```
6. Choose **Next**.

**Note**

You can switch between the **Visual** and **JSON** editor options anytime. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](https://docs.aws.amazon.com/IAM/latest/UserGuide/IAM_policies.html) in the **IAM User Guide**.

7. On the **Review and create** page, enter a **Policy name** and a **Description** (optional) for the policy that you are creating. Review **Permissions defined in this policy** to see the permissions that are granted by your policy.

8. Choose **Create policy** to save your new policy.

**AWS CLI**

Replace all **user input** with your own values.

1. Create a file called `s3-policy.json` with the following content.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::my-task-secrets-bucket/*"
            ],
            "Condition": {
                "ArnLike": {
                    "aws:SourceArn": "arn:aws:ecs:region:123456789012:*"
                },
                "StringEquals": {
                    "aws:SourceAccount": "123456789012"
                }
            }
        }
    ]
}
```
2. Use the following command to create the IAM policy using the JSON policy document file.

```bash
aws iam create-policy \
   --policy-name taskRolePolicy \
   --policy-document file://s3-policy.json
```

The following procedures describe how to create a task IAM role by attaching an IAM policy that you create.

**AWS Management Console**

**To create an IAM role for your tasks (AWS Management Console)**

2. In the navigation pane, choose Roles, Create role.
3. For Select trusted entity section, choose AWS service.
4. For Use case, using the drop down menu, select Elastic Container Service and then the Elastic Container Service Task use case and then choose Next.
5. For Add permissions, search for and choose the policy you created, and then choose Next.
6. On Step 3: Name, review, and create, do the following:
a. For **Role name**, enter a name for your role. For this example, type `AmazonECSTaskS3BucketRole` to name the role.

b. (Optional) For **Description**, specify a description for this IAM role.

c. Review the trusted entity and permissions policy for the role.

d. For **Add tags (Optional)**, enter any metadata tags you want to associate with the IAM role, and then choose **Create role**.

**AWS CLI**

Replace all *user input* with your own values.

1. Create a file named `ecs-tasks-trust-policy.json` that contains the trust policy to use for the task IAM role. The file should contain the following. Replace the Region identifier and specify the AWS account number that you use when launching tasks.

```json
{
  "Version":"2012-10-17",
  "Statement": [
    {
      "Effect":"Allow",
      "Principal":{
        "Service": [
          "ecs-tasks.amazonaws.com"
        ],
      },
      "Action":"sts:AssumeRole",
      "Condition":{
        "ArnLike":{
        },
        "StringEquals":{
          "aws:SourceAccount":"111122223333"
        }
      }
    }
  ]
}
```

2. Create an IAM role named `ecsTaskRole` using the trust policy created in the previous step.
#!/bin/bash

aws iam create-role
--role-name ecsTaskRole
--assume-role-policy-document file://ecs-tasks-trust-policy.json

3. Retrieve the ARN of the IAM policy you created using the following command. Replace taskRolePolicy with the name of the policy you created.

```bash
aws iam list-policies --scope Local --query 'Policies[?PolicyName==`taskRolePolicy`].Arn'
```

4. Attach the IAM policy you created to the ecsTaskRole role. Replace the policy-arn with the ARN of the policy that you created.

```bash
aws iam attach-role-policy
--role-name ecsTaskRole
```

IAM permissions required for ECS Exec

The ECS Exec feature requires a task IAM role to grant containers the permissions needed for communication between the managed SSM agent (execute-command agent) and the SSM service. You should add the following permissions to a task IAM role and include the task IAM role in your task definition. For more information, see Adding and Removing IAM Policies in the IAM User Guide.

Use the following policy for your task IAM role to add the required SSM permissions.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssmmessages:CreateControlChannel",
        "ssmmessages:CreateDataChannel",
        "ssmmessages:OpenControlChannel",
        "ssmmessages:OpenDataChannel"
      ],
      "Resource": "*
    }
  ]
}
```
Specifying an IAM role for your tasks

After you have created a role and attached a policy to that role, you can run tasks that assume the role. You have several options to do this:

- Specify an IAM role for your tasks in the task definition. You can create a new task definition or a new revision of an existing task definition and specify the role you created previously. If you use the console to create your task definition, choose your IAM role in the Task Role field. For more information, see Creating a task definition using the console.

If you use the AWS CLI or SDKs, specify the Amazon Resource Name (ARN) of your task role using the taskRoleArn parameter. For more information, see TaskDefinition in the Amazon ECS API Reference and Task definition parameters.

Note

This option is required if you want to use IAM task roles in an Amazon ECS service.

- Specify an IAM task role override when running a task. You can specify an IAM task role override when running a task. If you use the AWS CLI or SDKs, specify your task role ARN using the taskRoleArn parameter in the overrides JSON object. For more information, about the overrides parameter, see RunTask and TaskOverride in the Amazon ECS API Reference. For more information about overriding using the console, see Run an application as an Amazon ECS task.

Note

In addition to the standard Amazon ECS permissions required to run tasks and services, users also require iam:PassRole permissions to use IAM roles for tasks.

Amazon ECS infrastructure IAM role

An Amazon ECS infrastructure IAM role allows Amazon ECS to manage infrastructure resources in your clusters on your behalf, and is used when:
• You want to attach Amazon EBS volumes to your Fargate or EC2 launch type Amazon ECS tasks. The infrastructure role allows Amazon ECS to manage Amazon EBS volumes for your tasks.

• You want to use Transport Layer Security (TLS) to encrypt traffic between your Amazon ECS Service Connect services.

When Amazon ECS assumes this role to take actions on your behalf, the events will be visible in AWS CloudTrail. If Amazon ECS uses the role to manage Amazon EBS volumes attached to your tasks, the CloudTrail log `roleSessionName` will be `ECSTaskVolumesForEBS`. If the role is used to encrypt traffic between your Amazon ECS Service Connect services, the CloudTrail log `roleSessionName` will be `ECSServiceConnectForTLS`. You can use this name to search events in the CloudTrail console by filtering for **User name**.

Amazon ECS provides the following managed policies named `AmazonECSInfrastructureRolePolicyForVolumes` and `AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity` which contain the permissions required for volume attachment and TLS respectively. For more information, see [AWS managed policies for Amazon Elastic Container Service](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/security-infrastructure-iam-roles.html).

### AmazonECSInfrastructureRolePolicyForVolumes

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "CreateEBSManagedVolume",
      "Effect": "Allow",
      "Action": "ec2:CreateVolume",
      "Resource": "arn:aws:ec2:*:*:volume/*",
      "Condition": {
        "ArnLike": {
          "aws:RequestTag/AmazonECSCreated": "arn:aws:ecs:*:*:task/*"
        },
        "StringEquals": {
          "aws:RequestTag/AmazonECSManaged": "true"
        }
      }
    },
    {
      "Sid": "TagOnCreateVolume",
      "Effect": "Allow",
      "Action": "ec2:CreateVolume",
      "Resource": "arn:aws:ec2:*:*:volume/*",
      "Condition": {
        "ArnLike": {
          "aws:RequestTag/AmazonECSCreated": "arn:aws:ecs:*:*:task/*"
        },
        "StringEquals": {
          "aws:RequestTag/AmazonECSManaged": "true"
        }
      }
    }
  ]
}
```
"Action": "ec2:CreateTags",
"Resource": "arn:aws:ec2:*:*:volume/**",
"Condition": {
  "ArnLike": {
    "aws:RequestTag/AmazonECSCreated": "arn:aws:ecs:*:*:task/**"
  },
  "StringEquals": {
    "ec2:CreateAction": "CreateVolume",
    "aws:RequestTag/AmazonECSManaged": "true"
  }
}
},
{
  "Sid": "DescribeVolumesForLifecycle",
  "Effect": "Allow",
  "Action": [
    "ec2:DescribeVolumes",
    "ec2:DescribeAvailabilityZones"
  ],
  "Resource": "**"
},
{
  "Sid": "ManageEBSVolumeLifecycle",
  "Effect": "Allow",
  "Action": [
    "ec2:AttachVolume",
    "ec2:DetachVolume"
  ],
  "Resource": "arn:aws:ec2:*:*:volume/**",
  "Condition": {
    "StringEquals": {
      "aws:ResourceTag/AmazonECSManaged": "true"
    }
  }
}
},
{
  "Sid": "ManageVolumeAttachmentsForEC2",
  "Effect": "Allow",
  "Action": [
    "ec2:AttachVolume",
    "ec2:DetachVolume"
  ],
  "Resource": "arn:aws:ec2:*:*:instance/**"
}
Amazon Elastic Container Service Developer Guide

```json
{
   "Sid": "DeleteEBSManagedVolume",
   "Effect": "Allow",
   "Action": "ec2:DeleteVolume",
   "Resource": "arn:aws:ec2::*:*:volume/*",
   "Condition": {
      "ArnLike": {
         "aws:ResourceTag/AmazonECSCreated": "arn:aws:ecs::*:*:task/*"
      },
      "StringEquals": {
         "aws:ResourceTag/AmazonECSManaged": "true"
      }
   }
}
```

AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity

```json
{
   "Version": "2012-10-17",
   "Statement": [ 
      {
         "Sid": "CreateSecret",
         "Effect": "Allow",
         "Action": "secretsmanager:CreateSecret",
         "Resource": "arn:aws:secretsmanager:*:*:secret:ecs-sc!*",
         "Condition": {
            "ArnLike": {
               "aws:RequestTag/AmazonECSCreated": [ 
                  "arn:aws:ecs::*:*:service/*/*",
                  "arn:aws:ecs::*:*:task-set/*/*"
               ],
               "StringEquals": {
                  "aws:RequestTag/AmazonECSManaged": "true",
                  "aws:ResourceAccount": "${aws:PrincipalAccount}"
               }
            }
         }
      },
      {
         "Sid": "TagOnCreateSecret",
         "Effect": "Allow",
         "Action": "cloudtrail:CreateTrail",
         "Resource": "arn:aws:cloudtrail:*:*:trail/ecs-sc!*",
         "Condition": {
            "ArnLike": {
               "aws:ResourceTag/AmazonECSCreated": "arn:aws:ecs::*:*:task/*"
            }
         }
      }
   ]
}
```

Infrastructure IAM role
"Action": "secretsmanager:TagResource",
"Resource": "arn:aws:secretsmanager:*:*:secret:ecs-sc!*",
"Condition": {
  "ArnLike": {
    "aws:RequestTag/AmazonECSCreated": [
      "arn:aws:ecs:*:*:service/\*/\*",
      "arn:aws:ecs:*:*:task-set/\*/\*
    ]
  },
  "StringEquals": {
    "aws:RequestTag/AmazonECSManaged": "true",
    "aws:ResourceAccount": "${aws:PrincipalAccount}"
  }
}
},
{
  "Sid": "RotateTLSCertificateSecret",
  "Effect": "Allow",
  "Action": [

    "acm-pca:DescribeCertificateAuthority"
  ],
Creating the ECS infrastructure role (ecsInfrastructureRole)

Replace all *user input* with your own information.

1. Create a file named `ecs-infrastructure-trust-policy.json` that contains the trust policy to use for the IAM role. The file should contain the following:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToECSForInfrastructureManagement",
      "Effect": "Allow",
      "Principal": {
        "Service": "ecs.amazonaws.com"
      }
    }
  ]
}
```

Infrastructure IAM role
2. Use the following AWS CLI command to create an IAM role named `ecsInfrastructureRole` by using the trust policy that you created in the previous step.

```bash
aws iam create-role \
  --role-name ecsInfrastructureRole \
  --assume-role-policy-document file://ecs-infrastructure-trust-policy.json
```

3. Depending on your use case, attach the AWS managed AmazonECSInfrastructureRolePolicyForVolumes or AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity policy to the `ecsInfrastructureRole` role.

```bash
aws iam attach-role-policy \
  --role-name ecsInfrastructureRole \
  --policy-arn arn:aws:iam::aws:policy/service-role/AmazonECSInfrastructureRolePolicyForVolumes

aws iam attach-role-policy \
  --role-name ecsInfrastructureRole \
  --policy-arn arn:aws:iam::aws:policy/service-role/AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity
```

You can also use the IAM console's Custom trust policy workflow ([https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/)) to create the role. For more information, see Creating a role using custom trust policies (console) in the IAM User Guide.

**Granting a user permission to pass the ECS infrastructure role to Amazon ECS**

To use an ECS infrastructure IAM role, you must grant your user permission to pass the role to Amazon ECS. Attach the following `iam:PassRole` permission to your user. Replace `ecsInfrastructureRole` with the name of the infrastructure role that you created.

```json
{
  "Version": "2012-10-17",
```
"Statement": [

  {
    "Action": "iam:PassRole",
    "Effect": "Allow",
    "Resource": ["arn:aws:iam::*:role/ecsInfrastructureRole"],
    "Condition": {
      "StringEquals": {"iam:PassedToService": "ecs.amazonaws.com"}
    }
  }
]
}

For more information about `iam:Passrole` and updating permissions for your user, see [Granting a user permissions to pass a role to an AWS service](https://docs.aws.amazon.com/IAM/latest/userguide/grant-permission-policy-for-service.html) and [Changing permissions for an IAM user](https://docs.aws.amazon.com/IAM/latest/userguide/permissions-management.html) in the AWS Identity and Access Management User Guide.

### Additional configuration for Windows IAM roles for tasks

⚠️ **Important**

For Windows containers on Fargate that use task roles, no further action is necessary. For Windows containers on EC2 that use task roles, follow these steps.

The IAM roles for tasks with Windows features requires additional configuration on EC2, but much of this configuration is similar to configuring IAM roles for tasks on Linux container instances. The following requirements must be met to configure IAM roles for tasks for Windows containers.

- **When you launch your container instances**, you must set the `-EnableTaskIAMRole` option in the container instances user data script. The `EnableTaskIAMRole` turns on the Task IAM roles feature for the tasks. For example:

  ```powershell
  Import-Module ECSTools
  Initialize-ECSAgent -Cluster 'windows' -EnableTaskIAMRole
  </powershell>
  
- **You must bootstrap your container with the networking commands that are provided in IAM roles for task container bootstrap script.**
You must create an IAM role and policy for your tasks. For more information, see [Creating an IAM role and policy for your tasks](#).

You must specify the IAM role you created for your tasks when you register the task definition, or as an override when you run the task. For more information, see [Specifying an IAM role for your tasks](#).

The IAM roles for the task credential provider use port 80 on the container instance. Therefore, if you configure IAM roles for tasks on your container instance, your containers can't use port 80 for the host port in any port mappings. To expose your containers on port 80, we recommend configuring a service for them that uses load balancing. You can use port 80 on the load balancer. By doing so, traffic can be routed to another host port on your container instances. For more information, see [Distribute Amazon ECS service traffic using load balancing](#).

If your Windows instance is restarted, you must delete the proxy interface and initialize the Amazon ECS container agent again to bring the credential proxy back up.

### IAM roles for task container bootstrap script

Before containers can access the credential proxy on the container instance to get credentials, the container must be bootstrapped with the required networking commands. The following code example script should be run on your containers when they start.

```

### Amazon ECS container instance IAM role

Amazon ECS container instances, including both Amazon EC2 and external instances, run the Amazon ECS container agent and require an IAM role for the service to know that the agent belongs to you. Before you launch container instances and register them to a cluster, you must create an IAM role for your container instances to use. The role is created in the account that you use to log into the console or run the AWS CLI commands.
Important

If you are registering external instances to your cluster, the IAM role you use requires Systems Manager permissions as well. For more information, see ECS Anywhere IAM role.

Amazon ECS provides the AmazonEC2ContainerServiceforEC2Role managed IAM policy which contains the permissions needed to use the full Amazon ECS feature set. This managed policy can be attached to an IAM role and associated with your container instances. Alternatively, you can use the managed policy as a guide when creating a custom policy to use. The container instance role provides permissions needed for the Amazon ECS container agent and Docker daemon to call AWS APIs on your behalf. For more information on the managed policy, see AmazonEC2ContainerServiceforEC2Role.

Amazon ECS supports launching container instances with increased ENI density using supported Amazon EC2 instance types. When you use this feature, we recommend that you create 2 container instance roles. Enable the awsvpcTrunking account setting for one role and use that role for tasks that require ENI trunking. For information about the awsvpcTrunking account setting, see Accessing Amazon ECS features through account settings.

Creating the container instance (ecsInstanceRole) role

Important

If you are registering external instances to your cluster, see ECS Anywhere IAM role.

You can manually create the role and attach the managed IAM policy for container instances to allow Amazon ECS to add permissions for future features and enhancements as they are introduced. Use the following procedure to attach the managed IAM policy if needed.

AWS Management Console

To create the ecsInstanceRole IAM role for your container instances

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles, and then choose Create role.
3. Choose the AWS service role type, and then under Use cases for other AWS services, choose Elastic Container Service.
4. Choose the **EC2 Role for Elastic Container Service** use case, and then choose **Next: Permissions**.

5. In the **Permissions policies** section, verify the **AmazonEC2ContainerServiceforEC2Role** policy is selected, and then choose **Next**.

   **Important**
   
   The **AmazonEC2ContainerServiceforEC2Role** managed policy should be attached to the container instance IAM role, otherwise you will receive an error using the AWS Management Console to create clusters.

6. For **Role name**, enter **ecsInstanceRole** and optionally you can enter a description.

7. For **Add tags (optional)**, enter any custom tags to associate with the policy, and then choose **Next: Review**.

8. Review your role information and then choose **Create role** to finish.

### AWS CLI

Replace all **user input** with your own values.

1. Create a file called **instance-role-trust-policy.json** with the following contents.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": { "Service": "ec2.amazonaws.com"},
         "Action": "sts:AssumeRole"
       }
     ]
   }
   ```

2. Use the following command to create the instance IAM role using the trust policy document.

   ```bash
   aws iam create-role \\
   --role-name ecsInstanceRole \\
   --assume-role-policy-document file://instance-role-trust-policy.json
   ```
3. Create an instance profile named ecsInstanceRole-profile using the `create-instance-profile` command.

```bash
aws iam create-instance-profile --instance-profile-name ecsInstanceRole-profile
```

**Example response**

```json
{
    "InstanceProfile": {
        "InstanceProfileId": "AIPAJTLBPJLEGREXAMPLE",
        "Roles": [],
        "CreateDate": "2022-04-12T23:53:34.093Z",
        "InstanceProfileName": "ecsInstanceRole-profile",
        "Path": "/",
        "Arn": "arn:aws:iam::123456789012:instance-profile/ecsInstanceRole-profile"
    }
}
```

4. Add the `ecsInstanceRole` role to the `ecsInstanceRole-profile` instance profile.

```bash
aws iam add-role-to-instance-profile \
    --instance-profile-name ecsInstanceRole-profile \
    --role-name ecsInstanceRole
```

5. Attach the `AmazonEC2ContainerServiceRoleForEC2Role` managed policy to the role using the following command.

```bash
aws iam attach-role-policy \
    --policy-arn arn:aws:iam::aws:policy/service-role/AmazonEC2ContainerServiceRoleforEC2Role \
    --role-name ecsInstanceRole
```

### Adding Amazon S3 read-only access to your container instance (ecsInstanceRole) role

Storing configuration information in a private bucket in Amazon S3 and granting read-only access to your container instance IAM role is a secure and convenient way to allow container instance configuration at launch time. You can store a copy of your `ecs.config` file in a private bucket, use
Amazon EC2 user data to install the AWS CLI and then copy your configuration information to /etc/ecs/ecs.config when the instance launches.

For more information about creating an ecs.config file, storing it in Amazon S3, and launching instances with this configuration, see Storing container instance configuration in Amazon S3.

You can use the following AWS CLI command to allow Amazon S3 read-only access for your container instance role. Replace ecsInstanceRole with the name of the role that you created.

```bash
aws iam attach-role-policy \
  --role-name ecsInstanceRole \
  --policy-arn arn:aws::iam::aws:policy/AmazonS3ReadOnlyAccess
```

You can also use the IAM console to add Amazon S3 read-only access (AmazonS3ReadOnlyAccess) to your role. For more information, see Modifying a role permissions policy (console) in the AWS Identity and Access Management User Guide.

**Required permissions for monitoring container instances**

Before your container instances can send log data to CloudWatch Logs, you must create an IAM policy to allow your container instances to use the CloudWatch Logs APIs, and then you must attach that policy to ecsInstanceRole.

AWS Management Console

**To use the JSON policy editor to create a policy**

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane on the left, choose Policies.
   
   If this is your first time choosing Policies, the Welcome to Managed Policies page appears. Choose Get Started.
3. At the top of the page, choose Create policy.
4. In the Policy editor section, choose the JSON option.
5. Enter the following JSON policy document:

   ```json
   {
     "Version": "2012-10-17",
   }
   ```
"Statement": [
   {
      "Effect": "Allow",
      "Action": ["logs:CreateLogGroup",
                  "logs:CreateLogStream",
                  "logs:PutLogEvents",
                  "logs:DescribeLogStreams"
               ],
      "Resource": ["arn:aws:logs:*:*:*"]
   }
]}

6. Choose Next.

Note

You can switch between the Visual and JSON editor options anytime. However, if you make changes or choose Next in the Visual editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see Policy restructuring in the IAM User Guide.

7. On the Review and create page, enter a Policy name and a Description (optional) for the policy that you are creating. Review Permissions defined in this policy to see the permissions that are granted by your policy.

8. Choose Create policy to save your new policy.

After you create the policy, attach the policy to the container instance role. For information about how to attach the policy to the role, see Modifying a role permissions policy (console) in the AWS Identity and Access Management User Guide.

AWS CLI

1. Create a file called instance-cw-logs.json with the following content.

    {
       "Version": "2012-10-17",
       "Statement": [
          {
             "Effect": "Allow",
             "Action": ["logs:CreateLogGroup",
                         "logs:CreateLogStream",
                         "logs:PutLogEvents",
                         "logs:DescribeLogStreams"
                      ],
             "Resource": ["arn:aws:logs:*:*:*"]
          }
     ]
    }
2. Use the following command to create the IAM policy using the JSON policy document file.

   ```bash
   aws iam create-policy
   --policy-name cwlogspolicy
   --policy-document file://instance-cw-logs.json
   ```

3. Retrieve the ARN of the IAM policy you created using the following command. Replace `cwlogspolicy` with the name of the policy you created.

   ```bash
   aws iam list-policies --scope Local --query 'Policies[?
   PolicyName==`cwlogsppolicy`].Arn'
   ```

4. Use the following command to attach the policy to the container instance IAM role using the policy ARN.

   ```bash
   aws iam attach-role-policy
   --role-name ecsInstanceRole
   ```

**ECS Anywhere IAM role**

When you register an on-premises server or virtual machine (VM) to your cluster, the server or VM requires an IAM role to communicate with AWS APIs. You only need to create this IAM role once for each AWS account. However, this IAM role must be associated with each server or VM that you register to a cluster. This role is the ECSAnywhereRole. You can create this role manually. Alternatively, Amazon ECS can create the role on your behalf when you register an external instance in the AWS Management Console. You can use IAM console search to search for ecsAnywhereRole and see if your account already has the role. For more information, see [IAM console search](#) in the [IAM user guide](#).
AWS provides two managed IAM policies that can be used when creating the ECS Anywhere IAM role, the AmazonSSMManagedInstanceCore and AmazonEC2ContainerServiceforEC2Role policies. The AmazonEC2ContainerServiceforEC2Role policy includes permissions that likely provide more access than you need. Therefore, depending on your specific use case, we recommend that you create a custom policy adding only the permissions from that policy that you require in it. For more information, see Amazon ECS container instance IAM role.

Creating the ECS Anywhere (ecsAnywhereRole) role

Replace all user input with your own information.

1. Create a local file named ssm-trust-policy.json with the following trust policy.

```json
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {
      "Service": [
        "ssm.amazonaws.com"
      ],
    "Action": "sts:AssumeRole"
  }
}
```

2. Create the role and attach the trust policy by using the following AWS CLI command.

   ```bash
   aws iam create-role --role-name ecsAnywhereRole --assume-role-policy-document file://ssm-trust-policy.json
   ```

3. Attach the AWS managed policies by using the following command.

   ```bash
   aws iam attach-role-policy --role-name ecsAnywhereRole --policy-arn arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
   aws iam attach-role-policy --role-name ecsAnywhereRole --policy-arn arn:aws:iam::aws:policy/service-role/AmazonEC2ContainerServiceforEC2Role
   ```

You can also use the IAM console's Custom trust policy workflow (https://console.aws.amazon.com/iam/) to create the role. For more information, see Creating a role using custom trust policies (console) in the IAM User Guide.
Conditional IAM permissions

The task execution IAM role grants the Amazon ECS container agent permission to make AWS API calls on your behalf. When a task execution IAM role is used, it must be specified in your task definition. For more information, see Amazon ECS task execution IAM role.

The task execution role is required if any of the following conditions apply:

- You're sending container logs to CloudWatch Logs using the awlogs log driver.
- Your task definition specifies a container image that's hosted in an Amazon ECR private repository. However, if the ECSAnywhereRole IAM role that's associated with your external instance also includes the permissions necessary to pull images from Amazon ECR then your task execution role doesn't need to include them.

Amazon ECS CodeDeploy IAM Role

Before you can use the CodeDeploy blue/green deployment type with Amazon ECS, the CodeDeploy service needs permissions to update your Amazon ECS service on your behalf. These permissions are provided by the CodeDeploy IAM role (ecsCodeDeployRole).

Note

Users also require permissions to use CodeDeploy; these permissions are described in Blue/green deployment required IAM permissions.

There are two managed policies provided. The AWSCodeDeployRoleForECS policy, shown below, gives CodeDeploy permission to update any resource using the associated action. The AWSCodeDeployRoleForECSLimited policy, shown below, gives CodeDeploy more limited permissions.

AWSCodeDeployRoleForECS

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "ecs:DescribeServices",
            ]
        }
    ]
}
```
"ecs:CreateTaskSet",
"ecs:UpdateServicePrimaryTaskSet",
"ecs:DeleteTaskSet",
"elasticloadbalancing:DescribeTargetGroups",
"elasticloadbalancing:DescribeListeners",
"elasticloadbalancing:ModifyListener",
"elasticloadbalancing:DescribeRules",
"elasticloadbalancing:ModifyRule",
"lambda:InvokeFunction",
"cloudwatch:DescribeAlarms",
"sns:Publish",
"s3:GetObject",
"s3:GetObjectVersion"
],
"Resource": "*",
"Effect": "Allow"
},
{
  "Action": ["iam:PassRole"],
  "Effect": "Allow",
  "Resource": "*",
  "Condition": {
    "StringLike": {
      "iam:PassedToService": ["ecs-tasks.amazonaws.com"]
    }
  }
}

AWSCodeDeployRoleForECSLimited

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ecs:DescribeServices",
        "ecs:CreateTaskSet",
        "ecs:UpdateServicePrimaryTaskSet",
        "ecs:DeleteTaskSet",
        "cloudwatch:DescribeAlarms"
      ],
    }
  ]
}
"Resource": "*",
"Effect": "Allow"
},
{
"Action": ["sns:Publish"],
"Resource": "arn:aws:sns::*:*:CodeDeployTopic_*",
"Effect": "Allow"
},
{
"Action": ["elasticloadbalancing:DescribeTargetGroups",
"elasticloadbalancing:DescribeListeners",
"elasticloadbalancing:ModifyListener",
"elasticloadbalancing:DescribeRules",
"elasticloadbalancing:ModifyRule"
],
"Resource": "*",
"Effect": "Allow"
},
{
"Action": ["lambda:InvokeFunction"],
"Resource": "arn:aws:lambda::*:*:function:CodeDeployHook_*",
"Effect": "Allow"
},
{
"Action": ["s3:GetObject",
"s3:GetObjectVersion"
],
"Resource": "*",
"Condition": {
"StringEquals": {"s3:ExistingObjectTag/UseWithCodeDeploy": "true"}
},
"Effect": "Allow"
},
{
"Action": ["iam:PassRole"],
"Effect": "Allow",
"Resource": ["arn:aws:iam::*:role/ecsTaskExecutionRole",
"arn:aws:iam::*:role/ECSTaskExecution*"
],
"Condition": {
"StringLike": {
Creating the CodeDeploy AWSCodeDeployRoleForECS role

You can use the following procedures to create a CodeDeploy role for Amazon ECS

AWS Management Console

To create an IAM role for CodeDeploy

1. Open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane, choose Roles, Create role.
3. For Select type of trusted entity section, choose AWS service.
4. For Choose the service that will use this role, choose CodeDeploy.
5. For Select your use case, choose CodeDeploy - ECS, Next.
6. In the Add permissions section, do the following
   a. Ensure that the AWSCodeDeployRoleForECS policy is selected.
   b. Under Set permissions boundary - optional, choose Create role without a permissions boundary.
   c. Choose Next.
7. Under Name, review, and create, do the following:
   a. For Role name, enter ecsCodeDeployRole, and enter an optional description.
   b. For Add tags (optional), enter any custom tags to associate with the policy.
8. Choose Create role.

AWS CLI

Replace all user input with your own information.
1. Create a file named `codedeploy-trust-policy.json` that contains the trust policy to use for the CodeDeploy IAM role.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "",
         "Effect": "Allow",
         "Principal": {
            "Service": ["codedeploy.amazonaws.com"]
         },
         "Action": "sts:AssumeRole"
      }
   ]
}
```

2. Create an IAM role named `ecsCodedeployRole` using the trust policy created in the previous step.

```bash
aws iam create-role \
   --role-name ecsCodedeployRole \
   --assume-role-policy-document file://codedeploy-trust-policy.json
```

3. Attach the `AWSCodeDeployRoleForECS` or `AWSCodeDeployRoleForECSLimited` managed policy to the `ecsTaskRole` role.

```bash
aws iam attach-role-policy \
   --role-name ecsCodedeployRole \
   --policy-arn arn:aws::iam::aws:policy/AWSCodeDeployRoleForECS

aws iam attach-role-policy \
   --role-name ecsCodedeployRole \
   --policy-arn arn:aws::iam::aws:policy/AWSCodeDeployRoleForECSLimited
```

**Adding permissions for blue/green deployments**

If the tasks in your Amazon ECS service using the blue/green deployment type require the use of the task execution role or a task role override, then you must add the `iam:PassRole` permission
for each task execution role or task role override to the CodeDeploy IAM role as a policy. For more information, see Amazon ECS task execution IAM role and Task IAM role.

Use the following procedure to create the policy

AWS Management Console

To use the JSON policy editor to create a policy

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane on the left, choose Policies.
   
   If this is your first time choosing Policies, the Welcome to Managed Policies page appears. Choose Get Started.
3. At the top of the page, choose Create policy.
4. In the Policy editor section, choose the JSON option.
5. Enter the following JSON policy document:

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": "iam:PassRole",
         "Resource": ["arn:aws:iam::<aws_account_id>:role/<ecsTaskExecutionRole_or_TaskRole_name>"]
       }
     ]
   }
   ```
6. Choose Next.

   ✨ Note
   You can switch between the Visual and JSON editor options anytime. However, if you make changes or choose Next in the Visual editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see Policy restructuring in the IAM User Guide.
7. On the **Review and create** page, enter a **Policy name** and a **Description** (optional) for the policy that you are creating. Review **Permissions defined in this policy** to see the permissions that are granted by your policy.

8. Choose **Create policy** to save your new policy.

After you create the policy, attach the policy to the CodeDeploy role. For information about how to attach the policy to the role, see [Modifying a role permissions policy (console)](https://docs.aws.amazon.com/IdentityAndAccessManagement/latest/UserGuide/iam MODIFY ROLE POLICY CONSOLE.html) in the *AWS Identity and Access Management User Guide*.

**AWS CLI**

Replace all *user input* with your own information.

1. Create a file called `blue-green-iam-passrole.json` with the following content.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": "iam:PassRole",
         "Resource": ["arn:aws:iam::<aws_account_id>:role/<ecsTaskExecutionRole_or_TaskRole_name>"
       }
     ]
   }
   
   2. Use the following command to create the IAM policy using the JSON policy document file.

   ```bash
   aws iam create-policy \
   --policy-name cdTaskExecutionPolicy \
   --policy-document file://blue-green-iam-passrole.json
   ```

   3. Retrieve the ARN of the IAM policy you created using the following command.

   ```bash
   aws iam list-policies --scope Local --query 'Policies[? PolicyName=='cdTaskExecutionPolicy'].Arn'
   ```

   4. Use the following command to attach the policy to the CodeDeploy IAM role.

   ```bash
   aws iam attach-role-policy \
   ```
Amazon ECS EventBridge IAM Role

Before you can use Amazon ECS scheduled tasks with EventBridge rules and targets, the EventBridge service needs permissions to run Amazon ECS tasks on your behalf. These permissions are provided by the EventBridge IAM role (ecsEventsRole).

The AmazonEC2ContainerServiceEventsRole policy is shown below.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": ["ecs:RunTask"],
         "Resource": ["*"]
      },
      {
         "Effect": "Allow",
         "Action": "iam:PassRole",
         "Resource": ["*"],
         "Condition": {
            "StringLike": {
               "iam:PassedToService": "ecs-tasks.amazonaws.com"
            }
         }
      },
      {
         "Effect": "Allow",
         "Action": "ecs:TagResource",
         "Resource": "*",
         "Condition": {
            "StringEquals": {
               "ecs:CreateAction": ["RunTask"]
            }
         }
      }
   ]
}
```
If your scheduled tasks require the use of the task execution role, a task role, or a task role override, then you must add `iam:PassRole` permissions for each task execution role, task role, or task role override to the EventBridge IAM role. For more information about the task execution role, see Amazon ECS task execution IAM role.

**Note**

Specify the full ARN of your task execution role or task role override.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "iam:PassRole",
            "Resource": ["arn:aws:iam::<aws_account_id>:role/<ecsTaskExecutionRole_or_TaskRole_name>"
        }
    ]
}
```

You can choose to let the AWS Management Console create the EventBridge role for you when you configure a scheduled task. For more information, see Run Amazon ECS tasks on schedules using Amazon EventBridge Scheduler.

**Creating the Amazon ECS EventBridge (ecsEventsRole) role**

Replace all user input with your own information.

1. Create a file named `eventbridge-trust-policy.json` that contains the trust policy to use for the IAM role. The file should contain the following:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": "events.amazonaws.com"
            }
        }
    ]
}
```
2. Use the following command to create an IAM role named `ecsEventsRole` by using the trust policy that you created in the previous step.

```bash
aws iam create-role
    --role-name ecsEventsRole
    --assume-role-policy-document file://eventbridge-policy.json
```

3. Attach the AWS managed `AmazonEC2ContainerServiceEventsRole` to the `ecsEventsRole` role using the following command.

```bash
aws iam attach-role-policy
    --role-name ecsEventsRole
    --policy-arn arn:aws:iam::aws:policy/service-role/AmazonEC2ContainerServiceEventsRole
```

You can also use the IAM console's **Custom trust policy** workflow (https://console.aws.amazon.com/iam/) to create the role. For more information, see [Creating a role using custom trust policies (console)](https://console.aws.amazon.com/iam/) in the IAM User Guide.

**Attaching a policy to the ecsEventsRole role**

You can use the following procedures to add permissions for the task execution role to the EventBridge IAM role.

**AWS Management Console**

**To use the JSON policy editor to create a policy**

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane on the left, choose Policies.

   If this is your first time choosing Policies, the Welcome to Managed Policies page appears. Choose Get Started.
3. At the top of the page, choose **Create policy**.

4. In the **Policy editor** section, choose the **JSON** option.

5. Enter the following JSON policy document:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": ["arn:aws:iam::<aws_account_id>:role/<ecsTaskExecutionRole_or_TaskRole_name>"]
    }
  ]
}
```

6. Choose **Next**.

⚠️ **Note**

You can switch between the **Visual** and **JSON** editor options anytime. However, if you make changes or choose **Next** in the **Visual** editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see [Policy restructuring](https://docs.aws.amazon.com/IAM/latest/userguide/policy-restructuring.html) in the **IAM User Guide**.

7. On the **Review and create** page, enter a **Policy name** and a **Description** (optional) for the policy that you are creating. Review **Permissions defined in this policy** to see the permissions that are granted by your policy.

8. Choose **Create policy** to save your new policy.

After you create the policy, attach the policy to the EventBridge role. For information about how to attach the policy to the role, see [Modifying a role permissions policy (console)](https://docs.aws.amazon.com/IAM/latest/userguide/iam-attach-policy.html) in the **AWS Identity and Access Management User Guide**.

**AWS CLI**

Replace all **user input** with your own information.

1. Create a file called `ev-iam-passrole.json` with the following content.
IAM permissions required for service auto scaling

Service Auto Scaling is made possible by a combination of the Amazon ECS, CloudWatch, and Application Auto Scaling APIs. Services are created and updated with Amazon ECS, alarms are created with CloudWatch, and scaling policies are created with Application Auto Scaling.
In addition to the standard IAM permissions for creating and updating services, the following permissions are required to interact with Service Auto Scaling settings as shown in the following example policy.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "application-autoscaling:*",
            "ecs:DescribeServices",
            "ecs:UpdateService",
            "cloudwatch:DescribeAlarms",
            "cloudwatch:PutMetricAlarm",
            "cloudwatch:DeleteAlarms",
            "cloudwatch:DescribeAlarmHistory",
            "cloudwatch:DescribeAlarmsForMetric",
            "cloudwatch:GetMetricStatistics",
            "cloudwatch:ListMetrics",
            "cloudwatch:DisableAlarmActions",
            "cloudwatch:EnableAlarmActions",
            "iam:CreateServiceLinkedRole",
            "sns:CreateTopic",
            "sns:Subscribe",
            "sns:Get*",
            "sns:List*"
         ],
         "Resource": ["*"]
      }
   ]
}
```

The [Create service example](#) and [Update service example](#) IAM policy examples show the required permissions to use Service Auto Scaling in the AWS Management Console.

The Application Auto Scaling service also needs permission to describe your Amazon ECS services and CloudWatch alarms, and permissions to modify your service's desired count on your behalf. The sns: permissions are for the notifications that CloudWatch sends to an Amazon SNS topic when a threshold has been exceeded. If you use automatic scaling for your Amazon ECS services, it creates a service-linked role named `AWSServiceRoleForApplicationAutoScaling_ECSService`. This service-linked role grants Application Auto Scaling permission to describe the alarms for
your policies, to monitor the current running task count of the service, and to modify the desired count of the service. The original managed Amazon ECS role for Application Auto Scaling was ecsAutoscaleRole, but it is no longer required. The service-linked role is the default role for Application Auto Scaling. For more information, see Service-linked roles for Application Auto Scaling in the Application Auto Scaling User Guide.

If you created your Amazon ECS container instance role before CloudWatch metrics are available for Amazon ECS, you might need to add the ecs:StartTelemetrySession permission. For more information, see Considerations.

**Grant permission to tag resources on creation**

The following tag-on create Amazon ECS API actions allow you to specify tags when you create the resource. If tags are specified in the resource-creating action, AWS performs additional authorization to verify that the correct permissions are assigned to create tags.

- CreateCapacityProvider
- CreateCluster
- CreateService
- CreateTaskSet
- RegisterContainerInstance
- RegisterTaskDefinition
- RunTask
- StartTask

You can use resource tags to implement attribute-based control (ABAC). For more information, see the section called “Control access to Amazon ECS resources using resource tags” and Amazon ECS resource tagging.

To allow tagging on creation, create or modify a policy to include both the permissions to use the action that creates the resource, such as ecs:CreateCluster or ecs:RunTask and the ecs:TagResource action.

The following example demonstrates a policy that allows users to create clusters ans add tags during the cluster creation. Users are not permitted to tag any existing resources (they cannot call the ecs:TagResource action directly).
The `ecs:TagResource` action is only evaluated if tags are applied during the resource-creating action. Therefore, a user that has permissions to create a resource (assuming there are no tagging conditions) does not require permissions to use the `ecs:TagResource` action if no tags are specified in the request. However, if the user attempts to create a resource with tags, the request fails if the user does not have permissions to use the `ecs:TagResource` action.
Control access to specific tags

You can use additional conditions in the `Condition` element of your IAM policies to control the tag keys and values that can be applied to resources.

The following condition keys can be used with the examples in the preceding section:

- `aws:RequestTag`: To indicate that a particular tag key or tag key and value must be present in a request. Other tags can also be specified in the request.
  - Use with the `StringEquals` condition operator to enforce a specific tag key and value combination, for example, to enforce the tag `cost-center=cc123`:
    
    ```json
    "StringEquals": { "aws:RequestTag/cost-center": "cc123" }
    ```
  - Use with the `StringLike` condition operator to enforce a specific tag key in the request; for example, to enforce the tag key `purpose`:
    
    ```json
    "StringLike": { "aws:RequestTag/purpose": "*" }
    ```

- `aws:TagKeys`: To enforce the tag keys that are used in the request.
  - Use with the `ForAllValues` modifier to enforce specific tag keys if they are provided in the request (if tags are specified in the request, only specific tag keys are allowed; no other tags are allowed). For example, the tag keys `environment` or `cost-center` are allowed:
    
    ```json
    "ForAllValues:StringEquals": { "aws:TagKeys": ["environment","cost-center"] }
    ```
  - Use with the `ForAnyValue` modifier to enforce the presence of at least one of the specified tag keys in the request. For example, at least one of the tag keys `environment` or `webserver` must be present in the request:
    
    ```json
    "ForAnyValue:StringEquals": { "aws:TagKeys": ["environment","webserver"] }
    ```

These condition keys can be applied to resource-creating actions that support tagging, as well as the `ecs:TagResource` action. To learn whether an Amazon ECS API action supports tagging, see Actions, resources, and condition keys for Amazon ECS.

To force users to specify tags when they create a resource, you must use the `aws:RequestTag` condition key or the `aws:TagKeys` condition key with the `ForAnyValue` modifier on the resource-
creating action. The `ecs:TagResource` action is not evaluated if a user does not specify tags for the resource-creating action.

For conditions, the condition key is not case-sensitive and the condition value is case-sensitive. Therefore, to enforce the case-sensitivity of a tag key, use the `aws:TagKeys` condition key, where the tag key is specified as a value in the condition.

For more information about multi-value conditions, see [Creating a Condition That Tests Multiple Key Values](https://docs.aws.amazon.com/IAM/latest/UserGuide/idромecondcond.html) in the *IAM User Guide*.

**Control access to Amazon ECS resources using resource tags**

When you create an IAM policy that grants users permission to use Amazon ECS resources, you can include tag information in the `Condition` element of the policy to control access based on tags. This is known as attribute-based access control (ABAC). ABAC provides better control over which resources a user can modify, use, or delete. For more information, see [What is ABAC for AWS?](https://docs.aws.amazon.com/IAM/latest/UserGuide/id蓉mecondcond.html).

For example, you can create a policy that allows users to delete a cluster, but denies the action if the cluster has the tag `environment=production`. To do this, you use the `aws:ResourceTag` condition key to allow or deny access to the resource based on the tags that are attached to the resource.

```json
"StringEquals": { "aws:ResourceTag/environment": "production" }
```

To learn whether an Amazon ECS API action supports controlling access using the `aws:ResourceTag` condition key, see [Actions, resources, and condition keys for Amazon ECS](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/ecs_api_operations.html). Note that the `Describe` actions do not support resource-level permissions, so you must specify them in a separate statement without conditions.

For example IAM policies, see [Example policies](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/iam_policies.html).

If you allow or deny users access to resources based on tags, you must consider explicitly denying users the ability to add those tags to or remove them from the same resources. Otherwise, it's possible for a user to circumvent your restrictions and gain access to a resource by modifying its tags.

**Example policies**

You can use IAM policies to grant users permissions to view and work with specific resources in the Amazon ECS console. You can use the example policies in the previous section; however, they are designed for requests that are made with the AWS CLI or an AWS SDK.
Example: Allow users to delete a cluster based on tags

The following policy allows users to delete clusters when the tag has a key/value pair of "Purpose/Testing".

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Action": [
            "ecs:DeleteCluster"
         ],
         "Effect": "Allow",
         "Condition": {
            "StringEquals": {
               "aws:ResourceTag/Purpose": "Testing"
            }
         }
      }
   ]
}
```

Troubleshooting Amazon Elastic Container Service identity and access

Use the following information to help you diagnose and fix common issues that you might encounter when working with Amazon ECS and IAM.

Topics

- [I am not authorized to perform an action in Amazon ECS](#)
- [I am not authorized to perform iam:PassRole](#)
- [I want to allow people outside of my AWS account to access my Amazon ECS resources](#)

I am not authorized to perform an action in Amazon ECS

If you receive an error that you're not authorized to perform an action, your policies must be updated to allow you to perform the action.
The following example error occurs when the mateojackson IAM user tries to use the console to view details about a fictional my-example-widget resource but doesn't have the fictional ecs:GetWidget permissions.

```
User: arn:aws:iam::123456789012:user/mateojackson is not authorized to perform: ecs:GetWidget on resource: my-example-widget
```

In this case, the policy for the mateojackson user must be updated to allow access to the my-example-widget resource by using the ecs:GetWidget action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

**I am not authorized to perform iam:PassRole**

If you receive an error that you're not authorized to perform the iam:PassRole action, your policies must be updated to allow you to pass a role to Amazon ECS.

Some AWS services allow you to pass an existing role to that service instead of creating a new service role or service-linked role. To do this, you must have permissions to pass the role to the service.

The following example error occurs when an IAM user named marymajor tries to use the console to perform an action in Amazon ECS. However, the action requires the service to have permissions that are granted by a service role. Mary does not have permissions to pass the role to the service.

```
User: arn:aws:iam::123456789012:user/marymajor is not authorized to perform: iam:PassRole
```

In this case, Mary's policies must be updated to allow her to perform the iam:PassRole action.

If you need help, contact your AWS administrator. Your administrator is the person who provided you with your sign-in credentials.

**I want to allow people outside of my AWS account to access my Amazon ECS resources**

You can create a role that users in other accounts or people outside of your organization can use to access your resources. You can specify who is trusted to assume the role. For services that support
resource-based policies or access control lists (ACLs), you can use those policies to grant people access to your resources.

To learn more, consult the following:

- To learn whether Amazon ECS supports these features, see [How Amazon Elastic Container Service works with IAM](#).
- To learn how to provide access to your resources across AWS accounts that you own, see [Providing access to an IAM user in another AWS account that you own](#) in the IAM User Guide.
- To learn how to provide access to your resources to third-party AWS accounts, see [Providing access to AWS accounts owned by third parties](#) in the IAM User Guide.
- To learn how to provide access through identity federation, see [Providing access to externally authenticated users (identity federation)](#) in the IAM User Guide.
- To learn the difference between using roles and resource-based policies for cross-account access, see [How IAM roles differ from resource-based policies](#) in the IAM User Guide.

Logging and Monitoring in Amazon Elastic Container Service

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon Elastic Container Service and your AWS solutions. You should collect monitoring data from all of the parts of your AWS solution so that you can more easily debug a multi-point failure if one occurs. AWS provides several tools for monitoring your Amazon ECS resources and responding to potential incidents:

Amazon CloudWatch Alarms

Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see [Monitor Amazon ECS using CloudWatch](#).

For services with tasks that use the Fargate launch type, you can use CloudWatch alarms to scale in and scale out the tasks in your service based on CloudWatch metrics, such as CPU and memory utilization. For more information, see [Automatically scale your Amazon ECS service](#).
For clusters with tasks or services using the EC2 launch type, you can use CloudWatch alarms to scale in and scale out the container instances based on CloudWatch metrics, such as cluster memory reservation.

**Amazon CloudWatch Logs**

Monitor, store, and access the log files from the containers in your Amazon ECS tasks by specifying the awslogs log driver in your task definitions. For more information, see [Using the awslogs driver](#).

You can also monitor, store, and access the operating system and Amazon ECS container agent log files from your Amazon ECS container instances. This method for accessing logs can be used for containers using the EC2 launch type.

**Amazon CloudWatch Events**

Match events and route them to one or more target functions or streams to make changes, capture state information, and take corrective action. For more information, see [Automate responses to Amazon ECS errors using EventBridge](#) in this guide and [What Is Amazon CloudWatch Events?](#) in the *Amazon CloudWatch Events User Guide*.

**AWS CloudTrail Logs**

CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon ECS. Using the information collected by CloudTrail, you can determine the request that was made to Amazon ECS, the IP address from which the request was made, who made the request, when it was made, and additional details. For more information, see [Log Amazon ECS API calls using AWS CloudTrail](#).

**AWS Trusted Advisor**

Trusted Advisor draws upon best practices learned from serving hundreds of thousands of AWS customers. Trusted Advisor inspects your AWS environment and then makes recommendations when opportunities exist to save money, improve system availability and performance, or help close security gaps. All AWS customers have access to five Trusted Advisor checks. Customers with a Business or Enterprise support plan can view all Trusted Advisor checks.

For more information, see [AWS Trusted Advisor](#) in the *AWS Support User Guide*.

**AWS Compute Optimizer**

AWS Compute Optimizer is a service that analyzes the configuration and utilization metrics of your AWS resources. It reports whether your resources are optimal, and generates optimization recommendations to reduce the cost and improve the performance of your workloads.
For more information, see AWS Compute Optimizer recommendations for Amazon ECS.

Another important part of monitoring Amazon ECS involves manually monitoring those items that the CloudWatch alarms don't cover. The CloudWatch, Trusted Advisor, and other AWS console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on your container instances and the containers in your tasks.

Compliance validation for Amazon Elastic Container Service

To learn whether an AWS service is within the scope of specific compliance programs, see AWS services in Scope by Compliance Program and choose the compliance program that you are interested in. For general information, see AWS Compliance Programs.

You can download third-party audit reports using AWS Artifact. For more information, see Downloading Reports in AWS Artifact.

Your compliance responsibility when using AWS services is determined by the sensitivity of your data, your company's compliance objectives, and applicable laws and regulations. AWS provides the following resources to help with compliance:

- **Security and Compliance Quick Start Guides** – These deployment guides discuss architectural considerations and provide steps for deploying baseline environments on AWS that are security and compliance focused.
- **Architecting for HIPAA Security and Compliance on Amazon Web Services** – This whitepaper describes how companies can use AWS to create HIPAA-eligible applications.

Note

Not all AWS services are HIPAA eligible. For more information, see the HIPAA Eligible Services Reference.

- **AWS Compliance Resources** – This collection of workbooks and guides might apply to your industry and location.
- **AWS Customer Compliance Guides** – Understand the shared responsibility model through the lens of compliance. The guides summarize the best practices for securing AWS services and map the guidance to security controls across multiple frameworks (including National Institute of Standards and Technology (NIST), Payment Card Industry Security Standards Council (PCI), and International Organization for Standardization (ISO)).
• **Evaluating Resources with Rules** in the *AWS Config Developer Guide* – The AWS Config service assesses how well your resource configurations comply with internal practices, industry guidelines, and regulations.

• **AWS Security Hub** – This AWS service provides a comprehensive view of your security state within AWS. Security Hub uses security controls to evaluate your AWS resources and to check your compliance against security industry standards and best practices. For a list of supported services and controls, see Security Hub controls reference.

• **AWS Audit Manager** – This AWS service helps you continuously audit your AWS usage to simplify how you manage risk and compliance with regulations and industry standards.

### AWS Fargate Federal Information Processing Standard (FIPS-140)

Federal Information Processing Standard (FIPS). FIPS-140 is a U.S. and Canadian government standard that specifies the security requirements for cryptographic modules that protect sensitive information. FIPS-140 defines a set of validated cryptography functions that can be used to encrypt data in transit and data at rest.

When you turn on FIPS-140 compliance, you can run workloads on Fargate in a manner that is compliant with FIPS-140. For more information about FIPS-140 compliance, see Federal Information Processing Standard (FIPS) 140-2.

### Considerations

Consider the following when using FIPS-140 compliance on Fargate:

• FIPS-140 compliance is only available in the AWS GovCloud (US) Regions.

• FIPS-140 compliance is turned off by default. You must turn it on.

• Your tasks must use the following configuration for FIPS-140 compliance:
  • The operatingSystemFamily must be LINUX.
  • The cpuArchitecture must be X86_64.
  • The Fargate platform version must be 1.4.0 or later.
Use FIPS on Fargate

Use the following procedure to use FIPS-140 compliance on Fargate.

1. Turn on FIPS-140 compliance. For more information, see the section called “AWS Fargate Federal Information Processing Standard (FIPS-140) compliance”.

2. You can optionally use ECS Exec to run the following command to verify the FIPS-140 compliance status for a cluster.

   Replace *my-cluster* with the name of your cluster.

   A return value of "1" indicates that you are using FIPS.

   ```bash
   aws ecs execute-command --cluster *cluster-name* \
   --interactive \
   --command "cat /proc/sys/crypto/fips_enabled"
   ```

Use CloudTrail for auditing

CloudTrail is turned on in your AWS account when you create the account. When API and console activity occurs in Amazon ECS, that activity is recorded in a CloudTrail event along with other AWS service events in Event history. You can view, search, and download recent events in your AWS account. For more information, see Viewing Events with CloudTrail Event History.

For an ongoing record of events in your AWS account, including events for Amazon ECS, create a trail which CloudTrail uses to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all regions. The trail logs events from all Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the section called “Log Amazon ECS API calls using AWS CloudTrail”.

The following example shows a CloudTrail log entry that demonstrates the PutAccountSettingDefault API action:

```json
{
   "eventVersion": "1.08",
   "userIdentity": {
```

Infrastructure Security in Amazon Elastic Container Service

As a managed service, Amazon Elastic Container Service is protected by AWS global network security. For information about AWS security services and how AWS protects infrastructure, see...
AWS Cloud Security. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in Security Pillar AWS Well-Architected Framework.

You use AWS published API calls to access Amazon ECS through the network. Clients must support the following:

- Transport Layer Security (TLS). We require TLS 1.2 and recommend TLS 1.3.
- Cipher suites with perfect forward secrecy (PFS) such as DHE (Ephemeral Diffie-Hellman) or ECDHE (Elliptic Curve Ephemeral Diffie-Hellman). Most modern systems such as Java 7 and later support these modes.

Additionally, requests must be signed by using an access key ID and a secret access key that is associated with an IAM principal. Or you can use the AWS Security Token Service (AWS STS) to generate temporary security credentials to sign requests.

You can call these API operations from any network location. Amazon ECS supports resource-based access policies, which can include restrictions based on the source IP address, so make sure that the policies account for the IP address for the network location. You can also use Amazon ECS policies to control access from specific Amazon Virtual Private Cloud endpoints or specific VPCs. Effectively, this isolates network access to a given Amazon ECS resource from only the specific VPC within the AWS network. For more information, see Amazon ECS interface VPC endpoints (AWS PrivateLink).

Amazon ECS interface VPC endpoints (AWS PrivateLink)

You can improve the security posture of your VPC by configuring Amazon ECS to use an interface VPC endpoint. Interface endpoints are powered by AWS PrivateLink, a technology that allows you to privately access Amazon ECS APIs by using private IP addresses. AWS PrivateLink restricts all network traffic between your VPC and Amazon ECS to the Amazon network. You don't need an internet gateway, a NAT device, or a virtual private gateway.

For more information about AWS PrivateLink and VPC endpoints, see VPC Endpoints in the Amazon VPC User Guide.

Considerations for Amazon ECS VPC endpoints

Considerations for Amazon ECS VPC endpoints for the Fargate launch type

Before you set up interface VPC endpoints for Amazon ECS, be aware of the following considerations:
• Tasks using the Fargate launch type don't require the interface VPC endpoints for Amazon ECS, but you might need interface VPC endpoints for Amazon ECR, Secrets Manager, or Amazon CloudWatch Logs described in the following points.

• To allow your tasks to pull private images from Amazon ECR, you must create the interface VPC endpoints for Amazon ECR. For more information, see Interface VPC Endpoints (AWS PrivateLink) in the Amazon Elastic Container Registry User Guide.

If your VPC doesn't have an internet gateway, you must create the gateway endpoint for Amazon S3. For more information, see Create the Amazon S3 gateway endpoint in the Amazon Elastic Container Registry User Guide. The interface endpoints for Amazon S3 can't be used with Amazon ECR.

⚠️ Important

If you configure Amazon ECR to use an interface VPC endpoint, you can create a task execution role that includes condition keys to restrict access to a specific VPC or VPC endpoint. For more information, see Optional IAM permissions for Fargate tasks pulling Amazon ECR images over interface endpoints.

• To allow your tasks to pull sensitive data from Secrets Manager, you must create the interface VPC endpoints for Secrets Manager. For more information, see Using Secrets Manager with VPC Endpoints in the AWS Secrets Manager User Guide.

• If your VPC doesn't have an internet gateway and your tasks use the awslogs log driver to send log information to CloudWatch Logs, you must create an interface VPC endpoint for CloudWatch Logs. For more information, see Using CloudWatch Logs with Interface VPC Endpoints in the Amazon CloudWatch Logs User Guide.

• VPC endpoints currently don't support cross-Region requests. Ensure that you create your endpoint in the same Region where you plan to issue your API calls to Amazon ECS. For example, assume that you want to run tasks in US East (N. Virginia). Then, you must create the Amazon ECS VPC endpoint in US East (N. Virginia). An Amazon ECS VPC endpoint created in any other region can't run tasks in US East (N. Virginia).

• VPC endpoints only support Amazon-provided DNS through Amazon Route 53. If you want to use your own DNS, you can use conditional DNS forwarding. For more information, see DHCP Options Sets in the Amazon VPC User Guide.

• The security group attached to the VPC endpoint must allow incoming connections on TCP port 443 from the private subnet of the VPC.
- Service Connect management of the Envoy proxy uses the com.amazonaws.region.ecs-agent VPC endpoint. When you don't use the VPC endpoints, Service Connect management of the Envoy proxy uses the ecs-sc endpoint in that Region. For a list of the Amazon ECS endpoints in each Region, see [Amazon ECS endpoints and quotas](#).

**Considerations for Amazon ECS VPC endpoints for the EC2 launch type**

Before you set up interface VPC endpoints for Amazon ECS, be aware of the following considerations:

- Tasks using the EC2 launch type require that the container instances that they're launched on to run version 1.25.1 or later of the Amazon ECS container agent. For more information, see [Linux container instance management](#).
- To allow your tasks to pull sensitive data from Secrets Manager, you must create the interface VPC endpoints for Secrets Manager. For more information, see [Using Secrets Manager with VPC Endpoints](#) in the [AWS Secrets Manager User Guide](#).
- If your VPC doesn't have an internet gateway and your tasks use the awslogs log driver to send log information to CloudWatch Logs, you must create an interface VPC endpoint for CloudWatch Logs. For more information, see [Using CloudWatch Logs with Interface VPC Endpoints](#) in the [Amazon CloudWatch Logs User Guide](#).
- VPC endpoints currently don't support cross-Region requests. Ensure that you create your endpoint in the same Region where you plan to issue your API calls to Amazon ECS. For example, assume that you want to run tasks in US East (N. Virginia). Then, you must create the Amazon ECS VPC endpoint in US East (N. Virginia). An Amazon ECS VPC endpoint created in any other region can't run tasks in US East (N. Virginia).
- VPC endpoints only support Amazon-provided DNS through Amazon Route 53. If you want to use your own DNS, you can use conditional DNS forwarding. For more information, see [DHCP Options Sets](#) in the [Amazon VPC User Guide](#).
- The security group attached to the VPC endpoint must allow incoming connections on TCP port 443 from the private subnet of the VPC.

**Creating the VPC Endpoints for Amazon ECS**

To create the VPC endpoint for the Amazon ECS service, use the [Creating an Interface Endpoint](#) procedure in the [Amazon VPC User Guide](#) to create the following endpoints. If you have existing container instances within your VPC, you should create the endpoints in the order that they're
listed. If you plan on creating your container instances after your VPC endpoint is created, the order doesn't matter.

- com.amazonaws.region.ecs-agent
- com.amazonaws.region.ecs-telemetry
- com.amazonaws.region.ecs

**Note**

`region` represents the Region identifier for an AWS Region supported by Amazon ECS, such as us-east-2 for the US East (Ohio) Region.

The `ecs-agent` endpoint uses the `ecs:poll` API, and the `ecs-telemetry` endpoint uses the `ecs:poll` and `ecs:StartTelemetrySession` API.

If you have existing tasks that are using the EC2 launch type, after you have created the VPC endpoints, each container instance needs to pick up the new configuration. For this to happen, you must either reboot each container instance or restart the Amazon ECS container agent on each container instance. To restart the container agent, do the following.

**To restart the Amazon ECS container agent**

1. Log in to your container instance via SSH.
2. Stop the container agent.
   
   ```bash
   sudo docker stop ecs-agent
   ```
3. Start the container agent.
   
   ```bash
   sudo docker start ecs-agent
   ```

After you have created the VPC endpoints and restarted the Amazon ECS container agent on each container instance, all newly launched tasks pick up the new configuration.
Creating a VPC endpoint policy for Amazon ECS

You can attach an endpoint policy to your VPC endpoint that controls access to Amazon ECS. The policy specifies the following information:

- The principal that can perform actions.
- The actions that can be performed.
- The resources on which actions can be performed.

For more information, see Controlling access to services with VPC endpoints in the Amazon VPC User Guide.

Example: VPC endpoint policy for Amazon ECS actions

The following is an example of an endpoint policy for Amazon ECS. When attached to an endpoint, this policy grants access to permission to create and list clusters. The CreateCluster and ListClusters actions do not accept any resources, so the resource definition is set to * for all resources.

```json
{
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ecs:CreateCluster",
                "ecs:ListClusters"
            ],
            "Resource": [
                "*
            ]
        }
    ]
}
```

Security Best Practices

This guide provides security and compliance recommendations for protecting your information, systems, and other assets that are reliant on Amazon ECS. It also introduces some risk assessments and mitigation strategies that you can use to have a better grip on the security controls that are
built for Amazon ECS clusters and the workloads that they support. Each topic in this guide starts with a brief overview, followed by a list of recommendations and best practices that you can use to secure your Amazon ECS clusters.

**Topics**

- [AWS Identity and Access Management](#)
- [Using IAM roles with Amazon ECS tasks](#)
- [Network security](#)
- [Secrets management](#)
- [Using temporary security credentials with API operations](#)
- [Compliance and security](#)
- [Logging and monitoring](#)
- [AWS Fargate security](#)
- [EC2 container instance security considerations](#)
- [Task and container security](#)
- [Runtime security](#)
- [AMI best practices](#)
- [AWS Partners](#)

**AWS Identity and Access Management**

You can use AWS Identity and Access Management (IAM) to manage and control access to your AWS services and resources through rule-based policies for authentication and authorization purposes. More specifically, through this service, you control access to your AWS resources by using policies that are applied to users, groups, or roles. Among these three, users are accounts that can have access to your resources. And, an IAM role is a set of permissions that can be assumed by an authenticated identity, which isn't associated with a particular identity outside of IAM. For more information, see [Overview of access management: Permissions and policies](#).

**Managing access to Amazon ECS**

You can control access to Amazon ECS by creating and applying IAM policies. These policies are composed of a set of actions that apply to a specific set of resources. The action of a policy defines
the list of operations (such as Amazon ECS APIs) that are allowed or denied, whereas the resource controls what are the Amazon ECS objects that the action applies to. Conditions can be added to a policy to narrow its scope. For example, a policy can be written to only allow an action to be performed against tasks with a particular set of tags. For more information, see How Amazon ECS works with IAM in the Amazon Elastic Container Service Developer Guide.

**Recommendations**

We recommend that you do the following when setting up your IAM roles and policies.

**Follow the policy of least privileged access**

Create policies that are scoped to allow users to perform their prescribed jobs. For example, if a developer needs to periodically stop a task, create a policy that only permits that particular action. The following example only allows a user to stop a task that belongs to a particular task_family on a cluster with a specific Amazon Resource Name (ARN). Referring to an ARN in a condition is also an example of using resource-level permissions. You can use resource-level permissions to specify the resource that you want an action to apply to.

---

**Note**

When referencing an ARN in a policy, use the new longer ARN format. For more information, see Amazon Resource Names (ARNs) and IDs in the Amazon Elastic Container Service Developer Guide.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecs:StopTask"
      ],
      "Condition": {
        "ArnEquals": {
          "ecs:cluster": "arn:aws:ecs:region:account_id:cluster/cluster_name"
        }
      },
      "Resource": [
```
Let the cluster resource serve as the administrative boundary

Policies that are too narrowly scoped can cause a proliferation of roles and increase administrative overhead. Rather than creating roles that are scoped to particular tasks or services only, create roles that are scoped to clusters and use the cluster as your primary administrative boundary.

Isolate end-users from the Amazon ECS API by creating automated pipelines

You can limit the actions that users can use by creating pipelines that automatically package and deploy applications onto Amazon ECS clusters. This effectively delegates the job of creating, updating, and deleting tasks to the pipeline. For more information, see Tutorial: Amazon ECS standard deployment with CodePipeline in the AWS CodePipeline User Guide.

Use policy conditions for an added layer of security

When you need an added layer of security, add a condition to your policy. This can be useful if you're performing a privileged operation or when you need to restrict the set of actions that can be performed against particular resources. The following example policy requires multi-factor authorization when deleting a cluster.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ecs:DeleteCluster"
      ],
      "Condition": {
        "Bool": {
          "aws:MultiFactorAuthPresent": "true"
        }
      },
      "Resource": ["*"]
    }
  ]
}
```
Tags applied to services are propagated to all the tasks that are part of that service. Because of this, you can create roles that are scoped to Amazon ECS resources with specific tags. In the following policy, an IAM principals starts and stops all tasks with a tag-key of `Department` and a tag-value of `Accounting`.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ecs:StartTask",
            "ecs:StopTask",
            "ecs:RunTask"
         ],
         "Resource": "arn:aws:ecs:*",
         "Condition": {
            "StringEquals": {
               "ecs:ResourceTag/Department": "Accounting"
            }
         }
      }
   ]
}
```

**Periodically audit access to the Amazon ECS APIs**

A user might change roles. After they change roles, the permissions that were previously granted to them might no longer apply. Make sure that you audit who has access to the Amazon ECS APIs and whether that access is still warranted. Consider integrating IAM with a user lifecycle management solution that automatically revokes access when a user leaves the organization. For more information, see [Amazon ECS security audit guidelines](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/security-guidelines.html) in the *Amazon Web Services General Reference*.

**Using IAM roles with Amazon ECS tasks**

We recommend that you assign a task an IAM role. Its role can be distinguished from the role of the Amazon EC2 instance that it's running on. Assigning each task a role aligns with the principle of least privileged access and allows for greater granular control over actions and resources.
When assigning IAM roles for a task, you must use the following trust policy so that each of your tasks can assume an IAM role that's different from the one that your EC2 instance uses. This way, your task doesn't inherit the role of your EC2 instance.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": "ecs-tasks.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

When you add a task role to a task definition, the Amazon ECS container agent automatically creates a token with a unique credential ID (for example, 12345678-90ab-cdef-1234-567890abcdef) for the task. This token and the role credentials are then added to the agent's internal cache. The agent populates the environment variable AWS_CONTAINER_CREDENTIALS_RELATIVE_URI in the container with the URI of the credential ID (for example, /v2/credentials/12345678-90ab-cdef-1234-567890abcdef).
You can manually retrieve the temporary role credentials from inside a container by appending the environment variable to the IP address of the Amazon ECS container agent and running the `curl` command on the resulting string.

```
curl 169.254.170.2$AWS_CONTAINER_CREDENTIALS_RELATIVE_URI
```

The expected output is as follows:

```
{
    "RoleArn": "arn:aws:iam::123456789012:role/SSMTaskRole-SSMFargateTaskIAMRole-DASWWSF2WG6",
    "AccessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "SecretAccessKey": "wJalrXUtFEMI/K7MvDENG/bPxFiCYEXAMPLEKEY",
    "Token": "IqQjB3JpZ2luX2VjEEM/Example==",
    "Expiration": "2021-01-16T00:51:53Z"
}
```
Newer versions of the AWS SDKs automatically fetch these credentials from the AWS_CONTAINER_CREDENTIALS_RELATIVE_URI environment variable when making AWS API calls.

The output includes an access key-pair consisting of a secret access key ID and a secret key which your application uses to access AWS resources. It also includes a token that AWS uses to verify that the credentials are valid. By default, credentials assigned to tasks using task roles are valid for six hours. After that, they are automatically rotated by the Amazon ECS container agent.

**Task execution role**

The task execution role is used to grant the Amazon ECS container agent permission to call specific AWS API actions on your behalf. For example, when you use AWS Fargate, Fargate needs an IAM role that allows it to pull images from Amazon ECR and write logs to CloudWatch Logs. An IAM role is also required when a task references a secret that's stored in AWS Secrets Manager, such as an image pull secret.

**Note**

If you're pulling images as an authenticated user, you're less likely to be impacted by the changes that occurred to [Docker Hub's pull rate limits](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/private-registry-authentication.html). For more information see, [Private registry authentication for container instances](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/private-registry-authentication.html).

By using Amazon ECR and Amazon ECR Public, you can avoid the limits imposed by Docker. If you pull images from Amazon ECR, this also helps shorten network pull times and reduces data transfer changes when traffic leaves your VPC.

**Important**

When you use Fargate, you must authenticate to a private image registry using repositoryCredentials. It's not possible to set the Amazon ECS container agent environment variables ECS_ENGINE_AUTH_TYPE or ECS_ENGINE_AUTH_DATA or modify the ecs.config file for tasks hosted on Fargate. For more information, see [Private registry authentication for tasks](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/private-registry-authentication.html).
Amazon EC2 container instance role

The Amazon ECS container agent is a container that runs on each Amazon EC2 instance in an Amazon ECS cluster. It's initialized outside of Amazon ECS using the \texttt{init} command that's available on the operating system. Consequently, it can't be granted permissions through a task role. Instead, the permissions have to be assigned to the Amazon EC2 instances that the agents run on. The actions list in the example AmazonEC2ContainerServiceforEC2Role policy need to be granted to the \texttt{ecsInstanceRole}. If you don't do this, your instances cannot join the cluster.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "ec2:DescribeTags",
            "ecs:CreateCluster",
            "ecs:DeregisterContainerInstance",
            "ecs:DiscoverPollEndpoint",
            "ecs:Poll",
            "ecs:RegisterContainerInstance",
            "ecs:StartTelemetrySession",
            "ecs:UpdateContainerInstancesState",
            "ecs:Submit*",
            "ecr:GetAuthorizationToken",
            "ecr:BatchCheckLayerAvailability",
            "ecr:GetDownloadUrlForLayer",
            "ecr:BatchGetImage",
            "logs:CreateLogStream",
            "logs:PutLogEvents"
         ],
         "Resource": "*"
      }
   ]
}
```

In this policy, the \texttt{ecr} and \texttt{logs} API actions allow the containers that are running on your instances to pull images from Amazon ECR and write logs to Amazon CloudWatch. The \texttt{ecs} actions allow the agent to register and de-register instances and to communicate with the Amazon ECS control plane. Of these, the \texttt{ecs:CreateCluster} action is optional.
Service-linked roles

You can use the service-linked role for Amazon ECS to grant the Amazon ECS service permission to call other service APIs on your behalf. Amazon ECS needs the permissions to create and delete network interfaces, register, and de-register targets with a target group. It also needs the necessary permissions to create and delete scaling policies. These permissions are granted through the service-linked role. This role is created on your behalf the first time that you use the service.

⚠️ Note

If you inadvertently delete the service-linked role, you can recreate it. For instructions, see Create the service-linked role.

Recommendations

We recommend that you do the following when setting up your task IAM roles and policies.

Block access to Amazon EC2 metadata

When you run your tasks on Amazon EC2 instances, we strongly recommend that you block access to Amazon EC2 metadata to prevent your containers from inheriting the role assigned to those instances. If your applications have to call an AWS API action, use IAM roles for tasks instead.

To prevent tasks running in bridge mode from accessing Amazon EC2 metadata, run the following command or update the instance's user data. For more instruction on updating the user data of an instance, see this AWS Support Article. For more information about the task definition bridge mode, see task definition network mode.

```
sudo yum install -y iptables-services; sudo iptables --insert FORWARD 1 --in-interface docker+ --destination 192.0.2.0/32 --jump DROP
```

For this change to persist after a reboot, run the following command that's specific for your Amazon Machine Image (AMI):

- Amazon Linux 2

```
sudo iptables-save | sudo tee /etc/sysconfig/iptables & & sudo systemctl enable --now iptables
```
For tasks that use awsvpc network mode, set the environment variable ECS_AWSVPC_BLOCK_IMDS to true in the /etc/ecs/ecs.config file.

You should set the ECS_ENABLE_TASK_IAM_ROLE_NETWORK_HOST variable to false in the ecs-agent config file to prevent the containers that are running within the host network from accessing the Amazon EC2 metadata.

Use awsvpc network mode

Use the network awsvpc network mode to restrict the flow of traffic between different tasks or between your tasks and other services that run within your Amazon VPC. This adds an additional layer of security. The awsvpc network mode provides task-level network isolation for tasks that run on Amazon EC2. It is the default mode on AWS Fargate. It’s the only network mode that you can use to assign a security group to tasks.

Use IAM Access Advisor to refine roles

We recommend that you remove any actions that were never used or haven’t been used for some time. This prevents unwanted access from happening. To do this, review the results produced by IAM Access Advisor, and then remove actions that were never used or haven’t been used recently. You can do this by following the following steps.

Run the following command to generate a report showing the last access information for the referenced policy:

```bash
aws iam generate-service-last-accessed-details --arn arn:aws:iam::123456789012:policy/ExamplePolicy1
```

use the JobId that was in the output to run the following command. After you do this, you can view the results of the report.

```bash
aws iam get-service-last-accessed-details --job-id 98a765b4-3cde-2101-2345-example678f9
```

For more information, see IAM Access Advisor.
Monitor AWS CloudTrail for suspicious activity

You can monitor AWS CloudTrail for any suspicious activity. Most AWS API calls are logged to AWS CloudTrail as events. They are analyzed by AWS CloudTrail Insights, and you're alerted of any suspicious behavior that's associated with write API calls. This might include a spike in call volume. These alerts include such information as the time the unusual activity occurred and the top identity ARN that contributed to the APIs.

You can identify actions that are performed by tasks with an IAM role in AWS CloudTrail by looking at the event's `userIdentity` property. In the following example, the `arn` includes of the name of the assumed role, `s3-write-go-bucket-role`, followed by the name of the task, `7e9894e088ad416eb5cab92afExample`.

```
"userIdentity": {
    "type": "AssumedRole",
    "principalId": "AROA36C6WWEJ2YEXAMPLE:7e9894e088ad416eb5cab92afExample",
    "arn": "arn:aws:sts::123456789012:assumed-role/s3-write-go-bucket-role/7e9894e088ad416eb5cab92afExample",
    ...
}
```

Note

When tasks that assume a role are run on Amazon EC2 container instances, a request is logged by Amazon ECS container agent to the audit log of the agent that's located at an address in the `/var/log/ecs/audit.log. YYYY-MM-DD-HH` format. For more information, see [Task IAM Roles Log](#) and [Logging Insights Events for Trails](#).

Network security

Network security is a broad topic that encompasses several subtopics. These include encryption-in-transit, network segmentation and isolation, firewalls, traffic routing, and observability.

Encryption in transit

Encrypting network traffic prevents unauthorized users from intercepting and reading data when that data is transmitted across a network. With Amazon ECS, network encryption can be implemented in any of the following ways.
With a service mesh (TLS):

With AWS App Mesh, you can configure TLS connections between the Envoy proxies that are deployed with mesh endpoints. Two examples are virtual nodes and virtual gateways. The TLS certificates can come from AWS Certificate Manager (ACM). Or, it can come from your own private certificate authority.

- **Enabling Transport Layer Security (TLS)**
- **Enable traffic encryption between services in AWS App Mesh using ACM certificates or customer provided certs**
- **TLS ACM walkthrough**
- **TLS file walkthrough**
- **Envoy**

Using Nitro instances:

By default, traffic is automatically encrypted between the following Nitro instance types: C5n, G4, I3en, M5dn, M5n, P3dn, R5dn, and R5n. Traffic isn't encrypted when it's routed through a transit gateway, load balancer, or similar intermediary.

- **Encryption in transit**
- **What's new announcement from 2019**
- **This talk from re:Inforce 2019**

Using Server Name Indication (SNI) with an Application Load Balancer:

The Application Load Balancer (ALB) and Network Load Balancer (NLB) support Server Name Indication (SNI). By using SNI, you can put multiple secure applications behind a single listener. For this, each has its own TLS certificate. We recommend that you provision certificates for the load balancer using AWS Certificate Manager (ACM) and then add them to the listener's certificate list. The AWS load balancer uses a smart certificate selection algorithm with SNI. If the hostname that's provided by a client matches a single certificate in the certificate list, the load balancer chooses that certificate. If a hostname that's provided by a client matches multiple certificates in the list, the load balancer selects a certificate that the client can support. Examples include self-signed certificate or a certificate generated through the ACM.

- **SNI with Application Load Balancer**
- **SNI with Network Load Balancer**

End-to-end encryption with TLS certificates:
This involves deploying a TLS certificate with the task. This can either be a self-signed certificate or a certificate from a trusted certificate authority. You can obtain the certificate by referencing a secret for the certificate. Otherwise, you can choose to run an container that issues a Certificate Signing Request (CSR) to ACM and then mounts the resulting secret to a shared volume.

- Maintaining transport layer security all the way to your containers using the Network Load Balancer with Amazon ECS part 1
- Maintaining Transport Layer Security (TLS) all the way to your container part 2: Using AWS Private Certificate Authority

Task networking

The following recommendations are in consideration of how Amazon ECS works. Amazon ECS doesn't use an overlay network. Instead, tasks are configured to operate in different network modes. For example, tasks that are configured to use bridge mode acquire a non-routable IP address from a Docker network that runs on each host. Tasks that are configured to use the awsvpc network mode acquire an IP address from the subnet of the host. Tasks that are configured with host networking use the host's network interface. awsvpc is the preferred network mode. This is because it's the only mode that you can use to assign security groups to tasks. It's also the only mode that's available for AWS Fargate tasks on Amazon ECS.

Security groups for tasks

We recommend that you configure your tasks to use the awsvpc network mode. After you configure your task to use this mode, the Amazon ECS agent automatically provisions and attaches an Elastic Network Interface (ENI) to the task. When the ENI is provisioned, the task is enrolled in an AWS security group. The security group acts as a virtual firewall that you can use to control inbound and outbound traffic.

AWS PrivateLink

AWS PrivateLink is a networking technology that allows you to create private endpoints for different AWS services, including Amazon ECS. The endpoints are required in sandboxed environments where there is no Internet Gateway (IGW) attached to the Amazon VPC and no alternative routes to the Internet. Using AWS PrivateLink ensures that calls to the Amazon ECS service stay within the Amazon VPC and do not traverse the internet. For instructions on how to create AWS PrivateLink endpoints for Amazon ECS and other related services, see Amazon ECS interface Amazon VPC endpoints.
Important
AWS Fargate tasks don't require a AWS PrivateLink endpoint for Amazon ECS.

Amazon ECR and Amazon ECS both support endpoint policies. These policies allow you to refine access to a service's APIs. For example, you could create an endpoint policy for Amazon ECR that only allows images to be pushed to registries in particular AWS accounts. A policy like this could be used to prevent data from being exfiltrated through container images while still allowing users to push to authorized Amazon ECR registries. For more information, see Use VPC endpoint policies.

The following policy allows all AWS principals in your account to perform all actions against only your Amazon ECR repositories:

```
{
   "Statement": [
      {
         "Sid": "LimitECRAccess",
         "Principal": "*",
         "Action": "*",
         "Effect": "Allow",
         "Resource": "arn:aws:ecr:region:account_id:repository/*"
      },
   ]
}
```

You can enhance this further by setting a condition that uses the new PrincipalOrgID property. This prevents pushing and pulling of images by an IAM principal that isn't part of your AWS Organizations. For more information, see aws:PrincipalOrgID.

We recommend applying the same policy to both the com.amazonaws.region.ecr.dkr and the com.amazonaws.region.ecr.api endpoints.

Amazon ECS container agent settings

The Amazon ECS container agent configuration file includes several environment variables that relate to network security. ECS_AWSVPC_BLOCK_IMDS and ECS_ENABLE_TASK_IAM_ROLE_NETWORK_HOST are used to block a task's access to Amazon EC2 metadata. HTTP_PROXY is used to configure the agent to route through a HTTP proxy to connect...
to the internet. For instructions on configuring the agent and the Docker runtime to route through a proxy, see [HTTP Proxy Configuration](#).

⚠️ **Important**

These settings aren't available when you use AWS Fargate.

**Recommendations**

We recommend that you do the following when setting up your Amazon VPC, load balancers, and network.

**Use network encryption where applicable**

You should use network encryption where applicable. Certain compliance programs, such as PCI DSS, require that you encrypt data in transit if the data contains cardholder data. If your workload has similar requirements, configure network encryption.

Modern browsers warn users when connecting to insecure sites. If your service is fronted by a public facing load balancer, use TLS/SSL to encrypt the traffic from the client's browser to the load balancer and re-encrypt to the backend if warranted.

**Use awsvpc network mode and security groups when you need to control traffic between tasks or between tasks and other network resources**

You should use `awsvpc` network mode and security groups when you need to control traffic between tasks and between tasks and other network resources. If your service behind an ALB, use security groups to only allow inbound traffic from other network resources using the same security group as your ALB. If your application is behind an NLB, configure the task's security group to only allow inbound traffic from the Amazon VPC CIDR range and the static IP addresses assigned to the NLB.

Security groups should also be used to control traffic between tasks and other resources within the Amazon VPC such as Amazon RDS databases.

**Create clusters in separate Amazon VPCs when network traffic needs to be strictly isolated**

You should create clusters in separate Amazon VPCs when network traffic needs to be strictly isolated. Avoid running workloads that have strict security requirements on clusters with workloads that don't have to adhere to those requirements. When strict network isolation is mandatory,
create clusters in separate Amazon VPCs and selectively expose services to other Amazon VPCs using Amazon VPC endpoints. For more information, see Amazon VPC endpoints.

**Configure AWS PrivateLink endpoints when warranted**

You should configure AWS PrivateLink endpoints endpoints when warranted. If your security policy prevents you from attaching an Internet Gateway (IGW) to your Amazon VPCs, configure AWS PrivateLink endpoints for Amazon ECS and other services such as Amazon ECR, AWS Secrets Manager, and Amazon CloudWatch.

**Use Amazon VPC Flow Logs to analyze the traffic to and from long-running tasks**

You should use Amazon VPC Flow Logs to analyze the traffic to and from long-running tasks. Tasks that use awsvpc network mode get their own ENI. Doing this, you can monitor traffic that goes to and from individual tasks using Amazon VPC Flow Logs. A recent update to Amazon VPC Flow Logs (v3), enriches the logs with traffic metadata including the vpc ID, subnet ID, and the instance ID. This metadata can be used to help narrow an investigation. For more information, see Amazon VPC Flow Logs.

**Note**

Because of the temporary nature of containers, flow logs might not always be an effective way to analyze traffic patterns between different containers or containers and other network resources.

**Secrets management**

Secrets, such as API keys and database credentials, are frequently used by applications to gain access other systems. They often consist of a username and password, a certificate, or API key. Access to these secrets should be restricted to specific IAM principals that are using IAM and injected into containers at runtime.

Secrets can be seamlessly injected into containers from AWS Secrets Manager and Amazon EC2 Systems Manager Parameter Store. These secrets can be referenced in your task as any of the following.

1. They're referenced as environment variables that use the secrets container definition parameter.
2. They're referenced as secretOptions if your logging platform requires authentication. For more information, see logging configuration options.

3. They're referenced as secrets pulled by images that use the repositoryCredentials container definition parameter if the registry where the container is being pulled from requires authentication. Use this method when pulling images from Amazon ECR Public Gallery. For more information, see Private registry authentication for tasks.

Recommendations

We recommend that you do the following when setting up secrets management.

Use AWS Secrets Manager or Amazon EC2 Systems Manager Parameter Store for storing secret materials

You should securely store API keys, database credentials, and other secret materials in AWS Secrets Manager or as an encrypted parameter in Amazon EC2 Systems Manager Parameter Store. These services are similar because they're both managed key-value stores that use AWS KMS to encrypt sensitive data. AWS Secrets Manager, however, also includes the ability to automatically rotate secrets, generate random secrets, and share secrets across AWS accounts. If you deem these important features, use AWS Secrets Manager otherwise use encrypted parameters.

Note

Tasks that reference a secret from AWS Secrets Manager or Amazon EC2 Systems Manager Parameter Store require a Task Execution Role with a policy that grants the Amazon ECS access to the desired secret and, if applicable, the AWS KMS key used to encrypt and decrypt that secret.

Important

Secrets that are referenced in tasks aren't rotated automatically. If your secret changes, you must force a new deployment or launch a new task to retrieve the latest secret value. For more information, see the following topics:

- AWS Secrets Manager: Injecting data as environment variables
- Amazon EC2 Systems Manager Parameter Store: Injecting data as environment variables
Retrieving data from an encrypted Amazon S3 bucket

Because the value of environment variables can inadvertently leak in logs and are revealed when running `docker inspect`, you should store secrets in an encrypted Amazon S3 bucket and use task roles to restrict access to those secrets. When you do this, your application must be written to read the secret from the Amazon S3 bucket. For instructions, see [Setting default server-side encryption behavior for Amazon S3 buckets](#).

Mount the secret to a volume using a sidecar container

Because there's an elevated risk of data leakage with environment variables, you should run a sidecar container that reads your secrets from AWS Secrets Manager and write them to a shared volume. This container can run and exit before the application container by using [Amazon ECS container ordering](#). When you do this, the application container subsequently mounts the volume where the secret was written. Like the Amazon S3 bucket method, your application must be written to read the secret from the shared volume. Because the volume is scoped to the task, the volume is automatically deleted after the task stops. For an example of a sidecar container, see the [aws-secret-sidecar-injector](#) project.

️ Note

On Amazon EC2, the volume that the secret is written to can be encrypted with a AWS KMS customer managed key. On AWS Fargate, volume storage is automatically encrypted using a service managed key.

Additional resources

- [Passing secrets to containers in an Amazon ECS task](#)
- [Chamber](#) is a wrapper for storing secrets in Amazon EC2 Systems Manager Parameter Store

Using temporary security credentials with API operations

If you're making direct HTTPS API requests to AWS, you can sign those requests with the temporary security credentials that you get from the AWS Security Token Service. For more information, see [Signing AWS API requests](#) in the *AWS General Reference*.
Compliance and security

Your compliance responsibility when using Amazon ECS is determined by the sensitivity of your data, and the compliance objectives of your company, and applicable laws and regulations.

AWS provides the following resources to help with compliance:

- **Security and compliance quick start guides**: These deployment guides discuss architectural considerations and provide steps for deploying security and compliance-focused baseline environments on AWS.

- **Architecting for HIPAA Security and Compliance Whitepaper**: This whitepaper describes how companies can use AWS to create HIPAA-compliant applications.

- **AWS Services in Scope by Compliance Program**: This list contains the AWS services in scope of specific compliance programs. For more information, see [AWS Compliance Programs](aws.compliance).

Payment Card Industry Data Security Standards (PCI DSS)

It's important that you understand the complete flow of cardholder data (CHD) within the environment when adhering to PCI DSS. The CHD flow determines the applicability of the PCI DSS, defines the boundaries and components of a cardholder data environment (CDE), and therefore the scope of a PCI DSS assessment. Accurate determination of the PCI DSS scope is key to defining the security posture and ultimately a successful assessment. Customers must have a procedure for scope determination that assures its completeness and detects changes or deviations from the scope.

The temporary nature of containerized applications provides additional complexities when auditing configurations. As a result, customers need to maintain an awareness of all container configuration parameters to ensure compliance requirements are addressed throughout all phases of a container lifecycle.

For additional information on achieving PCI DSS compliance on Amazon ECS, refer to the following whitepapers.

- **Architecting on Amazon ECS for PCI DSS compliance**

- **Architecting for PCI DSS Scoping and Segmentation on AWS**
HIPAA (U.S. Health Insurance Portability and Accountability Act)

Using Amazon ECS with workloads that process protected health information (PHI) requires no additional configuration. Amazon ECS acts as an orchestration service that coordinates the launch of containers on Amazon EC2. It doesn't operate with or upon data within the workload being orchestrated. Consistent with HIPAA regulations and the AWS Business Associate Addendum, PHI should be encrypted in transit and at-rest when accessed by containers launched with Amazon ECS.

Various mechanisms for encrypting at-rest are available with each AWS storage option, such as Amazon S3, Amazon EBS, and AWS KMS. You may deploy an overlay network (such as VNS3 or Weave Net) to ensure complete encryption of PHI transferred between containers or to provide a redundant layer of encryption. Complete logging should also be enabled and all container logs should be directed to Amazon CloudWatch. To design your AWS environment using the best practices for infrastructure security, see Infrastructure Protection in Security Pillar AWS Well-Architected Framework.

AWS Security Hub

Use AWS Security Hub to monitor your usage of Amazon ECS as it relates to security best practices. Security Hub uses controls to evaluate resource configurations and security standards to help you comply with various compliance frameworks. For more information about using Security Hub to evaluate Amazon ECS resources, see Amazon ECS controls in the AWS Security Hub User Guide.

Amazon GuardDuty Runtime Monitoring

Amazon GuardDuty is a threat detection service that helps protect your accounts, containers, workloads, and the data within your AWS environment. Using machine learning (ML) models, and anomaly and threat detection capabilities, GuardDuty continuously monitors different log sources and runtime activity to identify and prioritize potential security risks and malicious activities in your environment.

Use Runtime Monitoring in GuardDuty to identify malicious or unauthorized behavior. Runtime Monitoring protects workloads running on Fargate and EC2 by continuously monitoring AWS log and networking activity to identify malicious or unauthorized behavior. Runtime Monitoring uses a lightweight, fully managed GuardDuty security agent that analyzes on-host behavior, such as file access, process execution, and network connections. This covers issues including escalation of privileges, use of exposed credentials, or communication with malicious IP addresses, domains, and the presence of malware on your Amazon EC2 instances and container workloads. For more information, see GuardDuty Runtime Monitoring in the GuardDuty User Guide.
Recommendations

You should engage the compliance program owners within your business early and use the [AWS shared responsibility model](https://aws.amazon.com/sharedResponsibility) to identify compliance control ownership for success with the relevant compliance programs.

Logging and monitoring

Logging and monitoring are an important aspect of maintaining the reliability, availability, and performance of Amazon ECS and your AWS solutions. AWS provides several tools for monitoring your Amazon ECS resources and responding to potential incidents:

- Amazon CloudWatch Alarms
- Amazon CloudWatch Logs
- Amazon CloudWatch Events
- AWS CloudTrail Logs

You can configure the containers in your tasks to send log information to Amazon CloudWatch Logs. If you're using the AWS Fargate launch type for your tasks, you can view the logs from your containers. If you're using the Amazon EC2 launch type, you can view different logs from your containers in one convenient location. This also prevents your container logs from taking up disk space on your container instances.

For more information about Amazon CloudWatch Logs, see [Monitor Logs from Amazon EC2 Instances](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/monitor-logs-from-ec2.html) in the [Amazon CloudWatch User Guide](https://docs.aws.amazon.com/AmazonCloudWatch/latest/userguide/monitor-logs-from-ec2.html). For instruction on sending container logs from your tasks to Amazon CloudWatch Logs, see [Using the awslogs log driver](https).

Container logging with Fluent Bit

AWS provides a Fluent Bit image with plugins for both Amazon CloudWatch Logs and Amazon Data Firehose. This image provides the capability to route logs to Amazon CloudWatch and Amazon Data Firehose destinations (which include Amazon S3, Amazon OpenSearch Service, and Amazon Redshift). We recommend using Fluent Bit as your log router because it has a lower resource utilization rate than Fluentd. For more information, see [Amazon CloudWatch Logs for Fluent Bit](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/custom-log-driver.html) and [Amazon Data Firehose for Fluent Bit](https://docs.aws.amazon.com/AmazonDMS/latest/UserGuide/monitoring-data-firehose-fluent-bit.html).

The AWS for Fluent Bit image is available on:
The following shows the syntax to use for the Docker CLI.

```bash
docker pull public.ecr.aws/aws-observability/aws-for-fluent-bit:tag
```

For example, you can pull the latest AWS for Fluent Bit image using this Docker CLI command:

```bash
docker pull public.ecr.aws/aws-observability/aws-for-fluent-bit:latest
```

Also refer to the following blog posts for more information on Fluent Bit and related features:

- Fluent Bit for Amazon EKS on AWS Fargate
- Centralized Container Logging with Fluent Bit
- Building a scalable log solution aggregator with AWS Fargate, Fluentd, and Amazon Data Firehose

**Custom log routing - FireLens for Amazon ECS**

With FireLens for Amazon ECS, you can use task definition parameters to route logs to an AWS service or AWS Partner Network (APN) destination for log storage and analytics. FireLens works with Fluentd and Fluent Bit. We provide the AWS for Fluent Bit image. Or, you can alternatively use your own Fluentd or Fluent Bit image.

You should consider the following conditions and considerations when using FireLens for Amazon ECS:

- FireLens for Amazon ECS is supported for tasks that are hosted both on AWS Fargate and Amazon EC2.
- FireLens for Amazon ECS is supported in AWS CloudFormation templates. For more information, see `AWS::ECS::TaskDefinition FirelensConfiguration` in the *AWS CloudFormation User Guide*.
- For tasks that use the bridge network mode, containers with the FireLens configuration must start before any of the application containers that rely on it start. To control the order that your containers start in, use dependency conditions in your task definition. For more information, see `Container dependency`. 
AWS Fargate security

We recommend that you take into account the following best practices when you use AWS Fargate. For additional guidance, see Security overview of AWS Fargate.

Use AWS KMS to encrypt ephemeral storage

You should have your ephemeral storage encrypted by AWS KMS. For Amazon ECS tasks that are hosted on AWS Fargate using platform version 1.4.0 or later, each task receives 20 GiB of ephemeral storage. You can increase the total amount of ephemeral storage, up to a maximum of 200 GiB, by specifying the `ephemeralStorage` parameter in your task definition. For such tasks that were launched on May 28, 2020 or later, the ephemeral storage is encrypted with an AES-256 encryption algorithm using an encryption key managed by AWS Fargate.

For more information, see Using data volumes in tasks.

Example: Launching an Amazon ECS task on AWS Fargate platform version 1.4.0 with ephemeral storage encryption

The following command will launch an Amazon ECS task on AWS Fargate platform version 1.4. Because this task is launched as part of the Amazon ECS cluster, it uses the 20 GiB of ephemeral storage that's automatically encrypted.

```
aws ecs run-task --cluster clustername \\
    --task-definition taskdefinition:version \\
    --count 1 \\
    --launch-type "FARGATE" \\
    --platform-version 1.4.0 \\
    --network-configuration "awsvpcConfiguration={subnets=[subnetid],securityGroups=[securitygroupid]}" \\
    --region region
```

SYS_PTRACE capability for kernel syscall tracing

The default configuration of Linux capabilities that are added or removed from your container are provided by Docker. For more information about the available capabilities, see Runtime privilege and Linux capabilities in the Docker run documentation.

Tasks that are launched on AWS Fargate only support adding the SYS_PTRACE kernel capability.
Refer to the tutorial video below that shows how to use this feature through the Sysdig Falco project.

#ContainersFromTheCouch - Troubleshooting your AWS Fargate Task using SYS_PTRACE capability

The code discussed in the previous video can be found on GitHub here.

**Use Amazon GuardDuty Runtime Monitoring**

Amazon GuardDuty is a threat detection service that helps protect your accounts, containers, workloads, and the data within your AWS environment. Using machine learning (ML) models, and anomaly and threat detection capabilities, GuardDuty continuously monitors different log sources and runtime activity to identify and prioritize potential security risks and malicious activities in your environment.

Runtime Monitoring in GuardDuty protects workloads running on Fargate by continuously monitoring AWS log and networking activity to identify malicious or unauthorized behavior. Runtime Monitoring uses a lightweight, fully managed GuardDuty security agent that analyzes on-host behavior, such as file access, process execution, and network connections. This covers issues including escalation of privileges, use of exposed credentials, or communication with malicious IP addresses, domains, and the presence of malware on your Amazon EC2 instances and container workloads. For more information, see GuardDuty Runtime Monitoring in the GuardDuty User Guide.

**AWS Fargate security considerations**

Each task has a dedicated infrastructure capacity because Fargate runs each workload on an isolated virtual environment. Workloads that run on Fargate do not share network interfaces, ephemeral storage, CPU, or memory with other tasks. You can run multiple containers within a task including application containers and sidecar containers, or simply sidecars. A sidecar is a container that runs alongside an application container in an Amazon ECS task. While the application container runs core application code, processes running in sidecars can augment the application. Sidecars help you segregate application functions into dedicated containers, making it easier for you to update parts of your application.

Containers that are part of the same task share resources for the Fargate launch type because these containers will always run on the same host and share compute resources. These containers also share the ephemeral storage provided by Fargate. Linux containers in a task share network namespaces, including the IP address and network ports. Inside a task, containers that belong to the task can inter-communicate over localhost.
The runtime environment in Fargate prevents you from using certain controller features that are supported on EC2 instances. Consider the following when you architect workloads that run on Fargate:

- **No privileged containers or access** - Features such as privileged containers or access are currently unavailable on Fargate. This will affect use cases such as running Docker in Docker.

- **Limited access to Linux capabilities** - The environment in which containers run on Fargate is locked down. Additional Linux capabilities, such as CAP_SYS_ADMIN and CAP_NET_ADMIN, are restricted to prevent a privilege escalation. Fargate supports adding the `CAP_SYS_PTRACE` Linux capability to tasks to allow observability and security tools deployed within the task to monitor the containerized application.

- **No access to the underlying host** - Neither customers nor AWS operators can connect to a host running customer workloads. You can use ECS exec to run commands in or get a shell to a container running on Fargate. You can use ECS exec to help collect diagnostic information for debugging. Fargate also prevents containers from accessing the underlying host’s resources, such as the file system, devices, networking, and container runtime.

- **Networking** - You can use security groups and network ACLs to control inbound and outbound traffic. Fargate tasks receive an IP address from the configured subnet in your VPC.

### EC2 container instance security considerations

You should consider a single container instance and its access within your threat model. For example, a single affected task might be able to leverage the IAM permissions of a non-infected task on the same instance.

We recommend that you use the following to help prevent this:

- **Do not use administrator privileges when running your tasks.**
- **Assign a task role with least-privileged access to your tasks.**

  The container agent automatically creates a token with a unique credential ID which are used to access Amazon ECS resources.

- **To prevent containers run by tasks that use the awsvpc network mode from accessing the credential information supplied to the Amazon EC2 instance profile, while still allowing the permissions that are provided by the task role set the ECS_AWSVPC_BLOCK_IMDS agent configuration variable to true in the agent configuration file and restart the agent.**
• Use Amazon GuardDuty Runtime Monitoring to detect threats for clusters and containers within your AWS environment. Runtime Monitoring uses a GuardDuty security agent that adds runtime visibility into individual Amazon ECS workloads, for example, file access, process execution, and network connections. For more information, see GuardDuty Runtime Monitoring in the GuardDuty User Guide.

Task and container security

You should consider the container image as your first line of defense against an attack. An insecure, poorly constructed image can allow an attacker to escape the bounds of the container and gain access to the host. You should do the following to mitigate the risk of this happening.

Recommendations

We recommend that you do the following when setting up your tasks and containers.

Create minimal or use distroless images

Start by removing all extraneous binaries from the container image. If you're using an unfamiliar image from Amazon ECR Public Gallery, inspect the image to refer to the contents of each of the container's layers. You can use an application such as Dive to do this.

Alternatively, you can use distroless images that only include your application and its runtime dependencies. They don't contain package managers or shells. Distroless images improve the "signal to noise of scanners and reduces the burden of establishing provenance to just what you need." For more information, see the GitHub documentation on distroless.

Docker has a mechanism for creating images from a reserved, minimal image known as scratch. For more information, see Creating a simple parent image using scratch in the Docker documentation. With languages like Go, you can create a static linked binary and reference it in your Dockerfile. The following example shows how you can accomplish this.

```
# STEP 1 build executable binary
FROM golang:alpine AS builder
# Install git.
# Git is required for fetching the dependencies.
RUN apk update && apk add --no-cache git
```
WORKDIR $GOPATH/src/mypackage/myapp/
COPY . .
# Fetch dependencies.
# Using go get.
RUN go get -d -v
# Build the binary.
RUN go build -o /go/bin/hello
############################
# STEP 2 build a small image
############################
FROM scratch
# Copy our static executable.
COPY --from=builder /go/bin/hello /go/bin/hello
# Run the hello binary.
ENTRYPOINT ["/go/bin/hello"]
This creates a container image that consists of your application and nothing else, making it extremely secure.

The previous example is also an example of a multi-stage build. These types of builds are attractive from a security standpoint because you can use them to minimize the size of the final image pushed to your container registry. Container images devoid of build tools and other extraneous binaries improves your security posture by reducing the attack surface of the image. For more information about multi-stage builds, see creating multi-stage builds.

**Scan your images for vulnerabilities**

Similar to their virtual machine counterparts, container images can contain binaries and application libraries with vulnerabilities or develop vulnerabilities over time. The best way to safeguard against exploits is by regularly scanning your images with an image scanner.

Images that are stored in Amazon ECR can be scanned on push or on-demand (once every 24 hours). Amazon ECR basic scanning uses Clair, an open-source image scanning solution. Amazon ECR enhanced scanning uses Amazon Inspector. After an image is scanned, the results are logged to the Amazon ECR event stream in Amazon EventBridge. You can also see the results of a scan from within the Amazon ECR console or by calling the DescribeImageScanFindings API. Images with a HIGH or CRITICAL vulnerability should be deleted or rebuilt. If an image that has been deployed develops a vulnerability, it should be replaced as soon as possible.

Docker Desktop Edge version 2.3.6.0 or later can scan local images. The scans are powered by Snyk, an application security service. When vulnerabilities are discovered, Snyk identifies the layers and dependencies with the vulnerability in the Dockerfile. It also recommends safe alternatives like
using a slimmer base image with fewer vulnerabilities or upgrading a particular package to a newer version. By using Docker scan, developers can resolve potential security issues before pushing their images to the registry.

- **Automating image compliance using Amazon ECR and AWS Security Hub** explains how to surface vulnerability information from Amazon ECR in AWS Security Hub and automate remediation by blocking access to vulnerable images.

**Remove special permissions from your images**

The access rights flags `setuid` and `setgid` allow running an executable with the permissions of the owner or group of the executable. Remove all binaries with these access rights from your image as these binaries can be used to escalate privileges. Consider removing all shells and utilities like `nc` and `curl` that can be used for malicious purposes. You can find the files with `setuid` and `setgid` access rights by using the following command.

```bash
find / -perm /6000 -type f -exec ls -ld {} \;
```

To remove these special permissions from these files, add the following directive to your container image.

```bash
RUN find / -xdev -perm /6000 -type f -exec chmod a-s {} \; || true
```

**Create a set of curated images**

Rather than allowing developers to create their own images, create a set of vetted images for the different application stacks in your organization. By doing so, developers can forego learning how to compose Dockerfiles and concentrate on writing code. As changes are merged into your codebase, a CI/CD pipeline can automatically compile the asset and then store it in an artifact repository. And, last, copy the artifact into the appropriate image before pushing it to a Docker registry such as Amazon ECR. At the very least you should create a set of base images that developers can create their own Dockerfiles from. You should avoid pulling images from Docker Hub. You don't always know what is in the image and about a fifth of the top 1000 images have vulnerabilities. A list of those images and their vulnerabilities can be found at [https://vulnerablecontainers.org/](https://vulnerablecontainers.org/).
Scan application packages and libraries for vulnerabilities

Use of open source libraries is now common. As with operating systems and OS packages, these libraries can have vulnerabilities. As part of the development lifecycle these libraries should be scanned and updated when critical vulnerabilities are found.

Docker Desktop performs local scans using Snyk. It can also be used to find vulnerabilities and potential licensing issues in open source libraries. It can be integrated directly into developer workflows giving you the ability to mitigate risks posed by open source libraries. For more information, see the following topics:

- Open Source Application Security Tools includes a list of tools for detecting vulnerabilities in applications.

Perform static code analysis

You should perform static code analysis before building a container image. It's performed against your source code and is used to identify coding errors and code that could be exploited by a malicious actor, such as fault injections. SonarQube is a popular option for static application security testing (SAST), with support for a variety of different programming languages.

Run containers as a non-root user

You should run containers as a non-root user. By default, containers run as the root user unless the USER directive is included in your Dockerfile. The default Linux capabilities that are assigned by Docker restrict the actions that can be run as root, but only marginally. For example, a container running as root is still not allowed to access devices.

As part of your CI/CD pipeline you should lint Dockerfiles to look for the USER directive and fail the build if it's missing. For more information, see the following topics:

- Dockerfile-lint is an open-source tool from RedHat that can be used to check if the file conforms to best practices.
- Hadolint is another tool for building Docker images that conform to best practices.

Use a read-only root file system

You should use a read-only root file system. A container's root file system is writable by default. When you configure a container with a R0 (read-only) root file system it forces you to explicitly
define where data can be persisted. This reduces your attack surface because the container's file system can't be written to unless permissions are specifically granted.

**Note**

Having a read-only root file system can cause issues with certain OS packages that expect to be able to write to the filesystem. If you're planning to use read-only root file systems, thoroughly test beforehand.

---

**Configure tasks with CPU and Memory limits (Amazon EC2)**

You should configure tasks with CPU and memory limits to minimize the following risk. A task's resource limits set an upper bound for the amount of CPU and memory that can be reserved by all the containers within a task. If no limits are set, tasks have access to the host's CPU and memory. This can cause issues where tasks deployed on a shared host can starve other tasks of system resources.

**Note**

Amazon ECS on AWS Fargate tasks require you to specify CPU and memory limits because it uses these values for billing purposes. One task hogging all of the system resources isn't an issue for Amazon ECS Fargate because each task is run on its own dedicated instance. If you don't specify a memory limit, Amazon ECS allocates a minimum of 4MB to each container. Similarly, if no CPU limit is set for the task, the Amazon ECS container agent assigns it a minimum of 2 CPUs.

---

**Use immutable tags with Amazon ECR**

With Amazon ECR, you can and should use configure images with immutable tags. This prevents pushing an altered or updated version of an image to your image repository with an identical tag. This protects against an attacker pushing a compromised version of an image over your image with the same tag. By using immutable tags, you effectively force yourself to push a new image with a different tag for each change.

**Avoid running containers as privileged (Amazon EC2)**

You should avoid running containers as privileged. For background, containers run as privileged are run with extended privileges on the host. This means the container inherits all of the Linux
Capabilities assigned to root on the host. It's use should be severely restricted or forbidden. We advise setting the Amazon ECS container agent environment variable ECS_DISABLE_PRIVILEGED to true to prevent containers from running as privileged on particular hosts if privileged isn't needed. Alternatively you can use AWS Lambda to scan your task definitions for the use of the privileged parameter.

**Note**

Running a container as privileged isn't supported on Amazon ECS on AWS Fargate.

Remove unnecessary Linux capabilities from the container

The following is a list of the default Linux capabilities assigned to Docker containers. For more information about each capability, see [Overview of Linux Capabilities](#).

```plaintext
CAP_CHOWN, CAP_DAC_OVERRIDE, CAP_FOWNER, CAP_FSETID, CAP_KILL,
CAP_SETCAP, CAP_SETGID, CAP_SETUID, CAP_SETFCAP,
CAP_NET_RAW, CAP_SYS_CHROOT, CAP_MKNOD, CAP_AUDIT_WRITE,
CAP_NET_BIND_SERVICE
```

If a container doesn't require all of the Docker kernel capabilities listed above, consider dropping them from the container. For more information about each Docker kernel capability, see [KernalCapabilities](#). You can find out which capabilities are in use by doing the following:

- Install the OS package `libcap-ng` and run the `pscap` utility to list the capabilities that each process is using.
- You can also use `capsh` to decipher which capabilities a process is using.
- Refer to [Linux Capabilities 101](#) for more information.

Use a customer managed key (CMK) to encrypt images pushed to Amazon ECR

You should use a customer managed key (CMK) to encrypt images that are pushed to Amazon ECR. Images that are pushed to Amazon ECR are automatically encrypted at rest with a AWS Key Management Service (AWS KMS) managed key. If you would rather use your own key, Amazon ECR now supports AWS KMS encryption with customer managed keys (CMK). Before enabling server
side encryption with a CMK, review the Considerations listed in the documentation on encryption at rest.

**Runtime security**

Runtime security provides active protection for your containers while they're running. The idea is to detect and prevent malicious activity from occurring on your containers. Runtime security configuration differs between Windows and Linux containers.

To secure a Microsoft Windows container, see [Secure Windows containers](#).

To secure a Linux container, you can add or drop Linux kernel capabilities using the `linuxParameters` and apply SELinux labels, or an AppArmor profile using the `dockerSecurityOptions`, both per container within a task definition. SELinux or AppArmor have to be configured on the container instance before they can be used. SELinux and AppArmor are not available in AWS Fargate. For more information, see [dockerSecurityOptions](#) in the Amazon Elastic Container Service API Reference, and [Security configuration](#) in the Docker run reference.

AppArmor is a Linux security module that restricts a container's capabilities including accessing parts of the file system. It can be run in either enforcement or complain mode. Because building AppArmor profiles can be challenging, we recommend that you use a tool like `bane`. For more information about AppArmor, see the official [AppArmor](#) page.

⚠️ **Important**

AppArmor is only available for Ubuntu and Debian distributions of Linux.

**Recommendations**

We recommend that you take the following actions when setting up your runtime security.

**Use Amazon GuardDuty Runtime Monitoring**

Amazon GuardDuty is a threat detection service that helps protect your accounts, containers, workloads, and the data within your AWS environment. Using machine learning (ML) models, and anomaly and threat detection capabilities, GuardDuty continuously monitors different log sources and runtime activity to identify and prioritize potential security risks and malicious activities in your environment.
Runtime Monitoring in GuardDuty protects workloads running on Fargate by continuously monitoring AWS log and networking activity to identify malicious or unauthorized behavior. Runtime Monitoring uses a lightweight, fully managed GuardDuty security agent that analyzes on-host behavior, such as file access, process execution, and network connections. This covers issues including escalation of privileges, use of exposed credentials, or communication with malicious IP addresses, domains, and the presence of malware on your Amazon EC2 instances and container workloads. For more information, see GuardDuty Runtime Monitoring in the GuardDuty User Guide.

Use a third-party solution for runtime defense

Use a third-party solution for runtime defense. If you're familiar with how Linux security works, create and manage AppArmor profiles. Both are open-source projects. Otherwise, consider using a different third-party service instead. Most use machine learning to block or alert on suspicious activity. For a list of available third-party solutions, see AWS Marketplace for Containers.

AMI best practices

Amazon ECS provides the Amazon ECS-optimized AMIs that are preconfigured with the requirements and recommendations to run your container workloads. We recommend that you use the Amazon ECS-optimized Amazon Linux 2023 AMI for your Amazon EC2 instances unless your application requires Amazon EC2 GPU-based instances, a specific operating system or a Docker version that is not yet available in that AMI. For information about the the Amazon Linux 2 and Amazon Linux 2023 instances, see Comparing Amazon Linux 2 and Amazon Linux 2023 in the Amazon Linux 2023 User Guide.

Although you can create your own Amazon EC2 instance AMI that meets the basic specifications needed to run your containerized workloads on Amazon ECS, the Amazon ECS-optimized AMIs are preconfigured and tested on Amazon ECS by AWS engineers. It is the simplest way for you to get started and to get your containers running on AWS quickly.

AWS Partners

You can use any of the following AWS Partner products to add additional security and features to your Amazon ECS workloads. For more information, see Amazon ECS Partners.

Aqua Security

You can use Aqua Security to secure your cloud-native applications from development to production. The Aqua Cloud Native Security Platform integrates with your cloud-native resources.
and orchestration tools to provide transparent and automated security. It can prevent suspicious activity and attacks in real time, and help to enforce policy and simplify regulatory compliance.

**Palo Alto Networks**

Palo Alto Networks provides security and protection for your hosts, containers, and serverless infrastructure in the cloud and throughout the development and software lifecycle.

Twistlock is supplied by Palo Alto Networks and can be integrated with Amazon ECS FireLens. With it, you have access to high fidelity security logs and incidents that are seamlessly aggregated into several AWS services. These include Amazon CloudWatch, Amazon Athena, and Amazon Kinesis. Twistlock secures workloads that are deployed on AWS container services.

**Sysdig**

You can use Sysdig to run secure and compliant cloud-native workloads in production scenarios. The Sysdig Secure DevOps Platform has embedded security and compliance features to protect your cloud-native workloads, and also offers enterprise-grade scalability, performance, and customization.
Retrieve Amazon ECS metadata

Amazon ECS provides various metadata for your configuration.

You can use the metadata to get task information including:

- Task-level attributes that provide information about where the task is running.
- Container-level attributes that provide the Docker ID, name, and image details. This provides visibility into the container.
- Network settings such as IP addresses, subnets, and network mode. This helps with network configuration and troubleshooting.
- Task status and health

You can view metadata by any of the following methods:

- Container metadata file

  Beginning with version 1.15.0 of the Amazon ECS container agent, various container metadata is available within your containers or the host container instance. By enabling this feature, you can query the information about a task, container, and container instance from within the container or the host container instance. The metadata file is created on the host instance and mounted in the container as a Docker volume and therefore is not available when a task is hosted on AWS Fargate.

- Task metadata endpoint

  The Amazon ECS container agent injects an environment variable into each container, referred to as the task metadata endpoint which provides various task metadata and Docker stats to the container.

- Container introspection

  The Amazon ECS container agent provides an API operation for gathering details about the container instance on which the agent is running and the associated tasks running on that instance.
Amazon ECS container metadata file

Beginning with version 1.15.0 of the Amazon ECS container agent, various container metadata is available within your containers or the host container instance. By enabling this feature, you can query the information about a task, container, and container instance from within the container or the host container instance. The metadata file is created on the host instance and mounted in the container as a Docker volume and therefore is not available when a task is hosted on AWS Fargate.

The container metadata file is cleaned up on the host instance when the container is cleaned up. You can adjust when this happens with the ECS_ENGINE_TASK_CLEANUP_WAIT_DURATION container agent variable. For more information, see Automated task and image cleanup.

Topics

- Container metadata file locations
- Turning on Amazon ECS container metadata
- Amazon ECS container metadata file format

Container metadata file locations

By default, the container metadata file is written to the following host and container paths.

- **For Linux instances:**
  - Host path: `/var/lib/ecs/data/metadata/cluster_name/task_id/container_name/ecs-container-metadata.json`
  - Container path: `/opt/ecs/metadata/random_ID/ecs-container-metadata.json`

  **Note**

  The Linux host path assumes that the default data directory mount path (`/var/lib/ecs/data`) is used when the agent is started. If you are not using an Amazon ECS-optimized AMI (or the `ecs-init` package to start and maintain the container agent), be sure to set the `ECS_HOST_DATA_DIR` agent configuration variable to the host path where the container agent's state file is located. For more information, see Amazon ECS container agent configuration.

- **For Windows instances:**
- Host path: C:\ProgramData\Amazon\ECS\data\metadata\task_id\container_name\ecs-container-metadata.json
- Container path: C:\ProgramData\Amazon\ECS\metadata\random_ID\ecs-container-metadata.json

However, for easy access, the container metadata file location is set to the ECS_CONTAINER_METADATA_FILE environment variable inside the container. You can read the file contents from inside the container with the following command:

- For Linux instances:

  ```
  cat $ECS_CONTAINER_METADATA_FILE
  ```

- For Windows instances (PowerShell):

  ```
  Get-Content -path $env:ECS_CONTAINER_METADATA_FILE
  ```

---

**Turning on Amazon ECS container metadata**

You can turn on container metadata at the container instance level by setting the ECS_ENABLE_CONTAINER_METADATA container agent variable to `true`. You can set this variable in the `/etc/ecs/ecs.config` configuration file and restart the agent. You can also set it as a Docker environment variable at runtime when the agent container is started. For more information, see [Amazon ECS container agent configuration](#).

If the ECS_ENABLE_CONTAINER_METADATA is set to `true` when the agent starts, metadata files are created for any containers created from that point forward. The Amazon ECS container agent cannot create metadata files for containers that were created before the ECS_ENABLE_CONTAINER_METADATA container agent variable was set to `true`. To ensure that all containers receive metadata files, you should set this agent variable at container instance launch. The following is an example user data script that will set this variable as well as register your container instance with your cluster.

```bash
#!/bin/bash
cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=your_cluster_name
ECS_ENABLE_CONTAINER_METADATA=true
EOF
```
Amazon ECS container metadata file format

The following information is stored in the container metadata JSON file.

Cluster

   The name of the cluster that the container's task is running on.

ContainerInstanceARN

   The full Amazon Resource Name (ARN) of the host container instance.

TaskARN

   The full Amazon Resource Name (ARN) of the task that the container belongs to.

TaskDefinitionFamily

   The name of the task definition family the container is using.

TaskDefinitionRevision

   The task definition revision the container is using.

ContainerID

   The Docker container ID (and not the Amazon ECS container ID) for the container.

ContainerName

   The container name from the Amazon ECS task definition for the container.

DockerContainerName

   The container name that the Docker daemon uses for the container (for example, the name that shows up in `docker ps` command output).

ImageID

   The SHA digest for the Docker image used to start the container.

ImageName

   The image name and tag for the Docker image used to start the container.

PortMappings

   Any port mappings associated with the container.
ContainerPort

The port on the container that is exposed.

HostPort

The port on the host container instance that is exposed.

BindIp

The bind IP address that is assigned to the container by Docker. This IP address is only applied with the bridge network mode, and it is only accessible from the container instance.

Protocol

The network protocol used for the port mapping.

Networks

The network mode and IP address for the container.

NetworkMode

The network mode for the task to which the container belongs.

IPv4Addresses

The IP addresses associated with the container.

⚠️ Important

If your task is using the awsvpc network mode, the IP address of the container will not be returned. In this case, you can retrieve the IP address by reading the /etc/hosts file with the following command:

```
tail -1 /etc/hosts | awk '{print $1}'
```

MetadataFileStatus

The status of the metadata file. When the status is READY, the metadata file is current and complete. If the file is not ready yet (for example, the moment the task is started), a truncated version of the file format is available. To avoid a likely race condition where the container has started, but the metadata has not yet been written, you can parse the metadata file and
wait for this parameter to be set to READY before depending on the metadata. This is usually available in less than 1 second from when the container starts.

**AvailabilityZone**

The Availability Zone the host container instance resides in.

**HostPrivateIPv4Address**

The private IP address for the task the container belongs to.

**HostPublicIPv4Address**

The public IP address for the task the container belongs to.

**Example Amazon ECS container metadata file (READY)**

The following example shows a container metadata file in the READY status.

```json
{
   "Cluster": "default",
   "ContainerInstanceARN": "arn:aws:ecs:us-west-2:012345678910:container-instance/default/1f73d099-b914-411c-a9ff-81633b7741dd",
   "TaskARN": "arn:aws:ecs:us-west-2:012345678910:task/default/2b88376d-aba3-4950-9ddf-bcb0f388a40c",
   "TaskDefinitionFamily": "console-sample-app-static",
   "TaskDefinitionRevision": "1",
   "ContainerID": "aec2557997f4eed9b280c2efd7afcccedfda4ac399f7480caeq870cfc7e163fd",
   "ContainerName": "simple-app",
   "CreatedAt": "2023-10-08T20:09:11.44527186Z",
   "StartedAt": "2023-10-08T20:09:11.44527186Z",
   "DockerContainerName": "/ecs-console-sample-app-static-1-simple-app-e4e8e495e8baa5de1a00",
   "ImageID": "sha256:2ae34abc2ed0a22e280d17e13f9c01aaf725688b09b7a1525d1a2750e2c0d1de",
   "ImageName": "httpd:2.4",
   "PortMappings": [
      {
         "ContainerPort": 80,
         "HostPort": 80,
         "BindIp": "0.0.0.0",
         "Protocol": "tcp"
      }
   ],
   "Networks": [
```
Example Incomplete Amazon ECS container metadata file (not yet READY)

The following example shows a container metadata file that has not yet reached the READY status. The information in the file is limited to a few parameters that are known from the task definition. The container metadata file should be ready within 1 second after the container starts.

```json
{
  "Cluster": "default",
  "ContainerInstanceARN": "arn:aws:ecs:us-west-2:012345678910:container-instance/default/1f73d099-b914-411c-a9ff-81633b7741dd",
  "ContainerName": "metadata"
}
```

Task metadata available for Amazon ECS tasks on EC2

The Amazon ECS container agent provides a method to retrieve various task metadata and Docker stats. This is referred to as the task metadata endpoint. The following versions are available:

- Task metadata endpoint version 4 – Provides a variety of metadata and Docker stats to containers. Can also provide network rate data. Available for Amazon ECS tasks launched on Amazon EC2 Linux instances running at least version 1.39.0 of the Amazon ECS container agent. For Amazon EC2 Windows instances that use awsvpc network mode, the Amazon ECS container agent must be at least version 1.54.0. For more information, see Amazon ECS task metadata endpoint version 4.

- Task metadata endpoint version 3 – Provides a variety of metadata and Docker stats to containers. Available for Amazon ECS tasks launched on Amazon EC2 Linux instances running at least version 1.21.0 of the Amazon ECS container agent. For Amazon EC2 Windows instances
that use awsvpc network mode, the Amazon ECS container agent must be at least version 1.54.0. For more information, see Amazon ECS task metadata endpoint version 3.

- Task metadata endpoint version 2 – Available for Amazon ECS tasks launched on Amazon EC2 Linux instances running at least version 1.17.0 of the Amazon ECS container agent. For Amazon EC2 Windows instances that use awsvpc network mode, the Amazon ECS container agent must be at least version 1.54.0. For more information, see Amazon ECS task metadata endpoint version 2.

If your Amazon ECS task is hosted on Amazon EC2, you can also access task host metadata using the Instance Metadata Service (IMDS) endpoint. The following command, when run from within the instance hosting the task, lists the ID of the host instance.

```bash
```

The information you can obtain from the endpoint is divided into categories such as `instance-id`. For more information on the different categories of host instance metadata you can obtain using the endpoint, see Instance metadata categories.

**Amazon ECS task metadata endpoint version 4**

The Amazon ECS container agent injects an environment variable into each container, referred to as the task metadata endpoint which provides various task metadata and Docker stats to the container.

The task metadata and network rate stats are sent to CloudWatch Container Insights and can be viewed in the AWS Management Console. For more information, see Monitor Amazon ECS containers using Container Insights.

**Note**

Amazon ECS provides earlier versions of the task metadata endpoint. To avoid the need to create new task metadata endpoint versions in the future, additional metadata may be added to the version 4 output. We will not remove any existing metadata or change the metadata field names.

The environment variable is injected by default into the containers of Amazon ECS tasks launched on Amazon EC2 Linux instances that are running at least version 1.39.0 of the Amazon ECS.
container agent. For Amazon EC2 Windows instances that use awsvpc network mode, the Amazon ECS container agent must be at least version 1.54.0. For more information, see Linux container instance management.

Note
You can add support for this feature on Amazon EC2 instances using older versions of the Amazon ECS container agent by updating the agent to the latest version. For more information, see Updating the Amazon ECS container agent.

Task metadata endpoint version 4 paths

The following task metadata endpoint paths are available to containers.

${ECS_CONTAINER_METADATA_URI_V4}

This path returns metadata for the container.

${ECS_CONTAINER_METADATA_URI_V4}/task

This path returns metadata for the task, including a list of the container IDs and names for all of the containers associated with the task. For more information about the response for this endpoint, see Amazon ECS task metadata V4 JSON response.

${ECS_CONTAINER_METADATA_URI_V4}/taskWithTags

This path returns the metadata for the task included in the /task endpoint in addition to the task and container instance tags that can be retrieved using the ListTagsForResource API. Any errors received when retrieving the tag metadata will be included in the Errors field in the response.

Note
The Errors field is only in the response for tasks hosted on Amazon EC2 Linux instances running at least version 1.50.0 of the container agent. For Amazon EC2 Windows instances that use awsvpc network mode, the Amazon ECS container agent must be at least version 1.54.0. This endpoint requires the ecs.ListTagsForResource permission.
${ECS_CONTAINER_METADATA_URI_V4}/stats

This path returns Docker stats for the specific container. For more information about each of the returned stats, see ContainerStats in the Docker API documentation.

For Amazon ECS tasks that use the awsvpc or bridge network modes hosted on Amazon EC2 Linux instances running at least version 1.43.0 of the container agent, there will be additional network rate stats included in the response. For all other tasks, the response will only include the cumulative network stats.

${ECS_CONTAINER_METADATA_URI_V4}/task/stats

This path returns Docker stats for all of the containers associated with the task. This can be used by sidecar containers to extract network metrics. For more information about each of the returned stats, see ContainerStats in the Docker API documentation.

For Amazon ECS tasks that use the awsvpc or bridge network modes hosted on Amazon EC2 Linux instances running at least version 1.43.0 of the container agent, there will be additional network rate stats included in the response. For all other tasks, the response will only include the cumulative network stats.

Amazon ECS task metadata V4 JSON response

The following information is returned from the task metadata endpoint (${ECS_CONTAINER_METADATA_URI_V4}/task) JSON response. This includes metadata associated with the task in addition to the metadata for each container within the task.

Cluster

The Amazon Resource Name (ARN) or short name of the Amazon ECS cluster to which the task belongs.

ServiceName

The name of the service to which the task belongs. ServiceName will appear for Amazon EC2 and Amazon ECS Anywhere container instances if the task is associated with a service.

Note

The ServiceName metadata is only included when using Amazon ECS container agent version 1.63.1 or later.
VPCID

The VPC ID of the Amazon EC2 container instance. This field only appears for Amazon EC2 instances.

```
Note

The VPCID metadata is only included when using Amazon ECS container agent version 1.63.1 or later.
```

TaskARN

The full Amazon Resource Name (ARN) of the task to which the container belongs.

Family

The family of the Amazon ECS task definition for the task.

Revision

The revision of the Amazon ECS task definition for the task.

DesiredStatus

The desired status for the task from Amazon ECS.

KnownStatus

The known status for the task from Amazon ECS.

Limits

The resource limits specified at the task level, such as CPU (expressed in vCPUs) and memory. This parameter is omitted if no resource limits are defined.

PullStartedAt

The timestamp for when the first container image pull began.

PullStoppedAt

The timestamp for when the last container image pull finished.

AvailabilityZone

The Availability Zone the task is in.
Note

The Availability Zone metadata is only available for Fargate tasks using platform version 1.4 or later (Linux) or 1.0.0 (Windows).

LaunchType

The launch type the task is using. When using cluster capacity providers, this indicates whether the task is using Fargate or EC2 infrastructure.

Note

This LaunchType metadata is only included when using Amazon ECS Linux container agent version 1.45.0 or later (Linux) or 1.0.0 or later (Windows).

Containers

A list of container metadata for each container associated with the task.

DockerId

The Docker ID for the container.

When you use Fargate, the id is a 32-digit hex followed by a 10 digit number.

Name

The name of the container as specified in the task definition.

DockerName

The name of the container supplied to Docker. The Amazon ECS container agent generates a unique name for the container to avoid name collisions when multiple copies of the same task definition are run on a single instance.

Image

The image for the container.

ImageID

The SHA-256 digest for the image.
Ports

Any ports exposed for the container. This parameter is omitted if there are no exposed ports.

Labels

Any labels applied to the container. This parameter is omitted if there are no labels applied.

DesiredStatus

The desired status for the container from Amazon ECS.

KnownStatus

The known status for the container from Amazon ECS.

ExitCode

The exit code for the container. This parameter is omitted if the container has not exited.

Limits

The resource limits specified at the container level, such as CPU (expressed in CPU units) and memory. This parameter is omitted if no resource limits are defined.

CreatedAt

The time stamp for when the container was created. This parameter is omitted if the container has not been created yet.

StartedAt

The time stamp for when the container started. This parameter is omitted if the container has not started yet.

FinishedAt

The time stamp for when the container stopped. This parameter is omitted if the container has not stopped yet.

Type

The type of the container. Containers that are specified in your task definition are of type NORMAL. You can ignore other container types, which are used for internal task resource provisioning by the Amazon ECS container agent.

LogDriver

The log driver the container is using.
### Note
This LogDriver metadata is only included when using Amazon ECS Linux container agent version 1.45.0 or later.

LogOptions

The log driver options defined for the container.

### Note
This LogOptions metadata is only included when using Amazon ECS Linux container agent version 1.45.0 or later.

ContainerARN

The full Amazon Resource Name (ARN) of the container.

### Note
This ContainerARN metadata is only included when using Amazon ECS Linux container agent version 1.45.0 or later.

Networks

The network information for the container, such as the network mode and IP address. This parameter is omitted if no network information is defined.

ExecutionStoppedAt

The time stamp for when the tasks DesiredStatus moved to STOPPED. This occurs when an essential container moves to STOPPED.

### Amazon ECS task metadata v4 examples

The following examples show example outputs from each of the task metadata endpoints.
Example container metadata response

When querying the ${ECS_CONTAINER_METADATA_URI_V4} endpoint you are returned only metadata about the container itself. The following is an example output.

```
{
    "DockerId": "ea32192c8553fbff06c9340478a2ff089b2bb5646fb718b4ee206641c9086d66",

},
Example task with tags with an error metadata response

When querying the ${ECS_CONTAINER_METADATA_URI_V4}/taskWithTags endpoint you are returned metadata about the task, including the task and container instance tags. If there is an error retrieving the tagging data, the error is returned in the response. The following is an example output for when the IAM role associated with the container instance doesn't have the ecs:ListTagsForResource permission allowed.

```json

Example container stats response

When querying the `${ECS_CONTAINER_METADATA_URI_V4}/stats` endpoint you are returned network metrics for the container. For Amazon ECS tasks that use the `awsvpc` or bridge network modes hosted on Amazon EC2 instances running at least version 1.43.0 of the container agent, there will be additional network rate stats included in the response. For all other tasks, the response will only include the cumulative network stats.

The following is an example output from an Amazon ECS task on Amazon EC2 that uses the bridge network mode.

```json
{
    "read": "2020-10-02T00:51:13.410254284Z",

Amazon ECS task metadata endpoint version 3

Important
The task metadata version 3 endpoint is no longer being actively maintained. We recommend that you update the task metadata version 4 endpoint to get the latest metadata endpoint information. For more information, see the section called “Task metadata endpoint version 4”.

If you are using Amazon ECS tasks hosted on AWS Fargate, see Task metadata endpoint version 3 in the Amazon Elastic Container Service User Guide for AWS Fargate.

Beginning with version 1.21.0 of the Amazon ECS container agent, the agent injects an environment variable called ECS_CONTAINER_METADATA_URI into each container in a task. When you query the task metadata version 3 endpoint, various task metadata and Docker stats are available to tasks. For tasks that use the bridge network mode, network metrics are available when querying the /stats endpoints.

The task metadata endpoint version 3 feature is enabled by default for tasks that use the Fargate launch type on platform version v1.3.0 or later and tasks that use the EC2 launch type and are launched on Amazon EC2 Linux infrastructure running at least version 1.21.0 of the Amazon ECS container agent or on Amazon EC2 Windows infrastructure running at least version 1.54.0 of the Amazon ECS container agent and use awsvpc network mode. For more information, see Linux container instance management.

You can add support for this feature on older container instances by updating the agent to the latest version. For more information, see Updating the Amazon ECS container agent.

Important
For tasks using the Fargate launch type and platform versions prior to v1.3.0, the task metadata version 2 endpoint is supported. For more information, see Amazon ECS task metadata endpoint version 2.

Task Metadata endpoint version 3 paths

The following task metadata endpoints are available to containers:
${ECS_CONTAINER_METADATA_URI}

This path returns metadata JSON for the container.

${ECS_CONTAINER_METADATA_URI}/task

This path returns metadata JSON for the task, including a list of the container IDs and names for all of the containers associated with the task. For more information about the response for this endpoint, see Amazon ECS task metadata v3 JSON response.

${ECS_CONTAINER_METADATA_URI}/taskWithTags

This path returns the metadata for the task included in the /task endpoint in addition to the task and container instance tags that can be retrieved using the ListTagsForResource API.

${ECS_CONTAINER_METADATA_URI}/stats

This path returns Docker stats JSON for the specific Docker container. For more information about each of the returned stats, see ContainerStats in the Docker API documentation.

${ECS_CONTAINER_METADATA_URI}/task/stats

This path returns Docker stats JSON for all of the containers associated with the task. For more information about each of the returned stats, see ContainerStats in the Docker API documentation.

Amazon ECS task metadata v3 JSON response

The following information is returned from the task metadata endpoint (${ECS_CONTAINER_METADATA_URI}/task) JSON response.

Cluster

The Amazon Resource Name (ARN) or short name of the Amazon ECS cluster to which the task belongs.

TaskARN

The full Amazon Resource Name (ARN) of the task to which the container belongs.

Family

The family of the Amazon ECS task definition for the task.
Revision

The revision of the Amazon ECS task definition for the task.

DesiredStatus

The desired status for the task from Amazon ECS.

KnownStatus

The known status for the task from Amazon ECS.

Limits

The resource limits specified at the task level, such as CPU (expressed in vCPUs) and memory. This parameter is omitted if no resource limits are defined.

PullStartedAt

The timestamp for when the first container image pull began.

PullStoppedAt

The timestamp for when the last container image pull finished.

AvailabilityZone

The Availability Zone the task is in.

Note

The Availability Zone metadata is only available for Fargate tasks using platform version 1.4 or later (Linux) or 1.0.0 or later (Windows).

Containers

A list of container metadata for each container associated with the task.

DockerId

The Docker ID for the container.

Name

The name of the container as specified in the task definition.
DockerName

The name of the container supplied to Docker. The Amazon ECS container agent generates a unique name for the container to avoid name collisions when multiple copies of the same task definition are run on a single instance.

Image

The image for the container.

ImageID

The SHA-256 digest for the image.

Ports

Any ports exposed for the container. This parameter is omitted if there are no exposed ports.

Labels

Any labels applied to the container. This parameter is omitted if there are no labels applied.

DesiredStatus

The desired status for the container from Amazon ECS.

KnownStatus

The known status for the container from Amazon ECS.

ExitCode

The exit code for the container. This parameter is omitted if the container has not exited.

Limits

The resource limits specified at the container level, such as CPU (expressed in CPU units) and memory. This parameter is omitted if no resource limits are defined.

CreatedAt

The time stamp for when the container was created. This parameter is omitted if the container has not been created yet.

StartedAt

The time stamp for when the container started. This parameter is omitted if the container has not started yet.
FinishedAt

The time stamp for when the container stopped. This parameter is omitted if the container has not stopped yet.

Type

The type of the container. Containers that are specified in your task definition are of type NORMAL. You can ignore other container types, which are used for internal task resource provisioning by the Amazon ECS container agent.

Networks

The network information for the container, such as the network mode and IP address. This parameter is omitted if no network information is defined.

ClockDrift

The information about the difference between the reference time and the system time. This applies to the Linux operating system. This capability uses Amazon Time Sync Service to measure clock accuracy and provide the clock error bound for containers. For more information, see Set the time for your Linux instance in the Amazon EC2 User Guide for Linux instances.

ReferenceTime

The basis of clock accuracy. Amazon ECS uses the Coordinated Universal Time (UTC) global standard through NTP, for example 2021-09-07T16:57:44Z.

ClockErrorBound

The measure of clock error, defined as the offset to UTC. This error is the difference in milliseconds between the reference time and the system time.

ClockSynchronizationStatus

Indicates whether the most recent synchronization attempt between the system time and the reference time was successful.

The valid values are SYNCHRONIZED and NOT_SYNCHRONIZED.

ExecutionStoppedAt

The time stamp for when the tasks DesiredStatus moved to STOPPED. This occurs when an essential container moves to STOPPED.
Amazon ECS task metadata v3 examples

The following examples show sample outputs from the task metadata endpoints.

Example Container Metadata Response

When querying the \${ECS_CONTAINER_METADATA_URI} endpoint you are returned only metadata about the container itself. The following is an example output.

```
{
    "DockerId": "43481a6ce4842e8fe72fc28500c6b52edcc0917f105b83379f88c1ff3946",
    "Name": "nginx-curl",
    "DockerName": "ecs-nginx-5-nginx-curl-ccccb9f49db0dfe0d901",
    "Image": "nrdlngr/nginx-curl",
    "ImageID": "sha256:2e00ae64383cf865ba0a2ba37f61b50a120d2d9378559dcd458dc0d47bc165",
    "Labels": {
        "com.amazonaws.ecs.cluster": "default",
        "com.amazonaws.ecs.container-name": "nginx-curl",
        "com.amazonaws.ecs.task-definition-family": "nginx",
        "com.amazonaws.ecs.task-definition-version": "5"
    },
    "DesiredStatus": "RUNNING",

Task metadata endpoint version 3

1143
Amazon ECS task metadata endpoint version 2

⚠️ Important

The task metadata version 2 endpoint is no longer being actively maintained. We recommend that you update the task metadata version 4 endpoint to get the latest metadata endpoint information. For more information, see the section called “Task metadata endpoint version 4”.

Beginning with version 1.17.0 of the Amazon ECS container agent, various task metadata and Docker stats are available to tasks that use the awsvpc network mode at an HTTP endpoint that is provided by the Amazon ECS container agent.

All containers belonging to tasks that are launched with the awsvpc network mode receive a local IPv4 address within a predefined link-local address range. When a container queries the metadata endpoint, the Amazon ECS container agent can determine which task the container belongs to based on its unique IP address, and metadata and stats for that task are returned.

Enabling task metadata

The task metadata version 2 feature is enabled by default for the following:

- Tasks using the Fargate launch type that use platform version v1.1.0 or later. For more information, see Fargate Linux platform versions.

- Tasks using the EC2 launch type that also use the awsvpc network mode and are launched on Amazon EC2 Linux infrastructure running at least version 1.17.0 of the Amazon ECS container agent or on Amazon EC2 Windows infrastructure running at least version 1.54.0 of the Amazon ECS container agent. For more information, see Linux container instance management.

You can add support for this feature on older container instances by updating the agent to the latest version. For more information, see Updating the Amazon ECS container agent.

Task metadata endpoint paths

The following API endpoints are available to containers:
169.254.170.2/v2/metadata

This endpoint returns metadata JSON for the task, including a list of the container IDs and names for all of the containers associated with the task. For more information about the response for this endpoint, see Task metadata JSON response.

169.254.170.2/v2/metadata/<container-id>

This endpoint returns metadata JSON for the specified Docker container ID.

169.254.170.2/v2/metadata/taskWithTags

This path returns the metadata for the task included in the /task endpoint in addition to the task and container instance tags that can be retrieved using the ListTagsForResource API.

169.254.170.2/v2/stats

This endpoint returns Docker stats JSON for all of the containers associated with the task. For more information about each of the returned stats, see ContainerStats in the Docker API documentation.

169.254.170.2/v2/stats/<container-id>

This endpoint returns Docker stats JSON for the specified Docker container ID. For more information about each of the returned stats, see ContainerStats in the Docker API documentation.

Task metadata JSON response

The following information is returned from the task metadata endpoint (169.254.170.2/v2/metadata) JSON response.

Cluster

The Amazon Resource Name (ARN) or short name of the Amazon ECS cluster to which the task belongs.

TaskARN

The full Amazon Resource Name (ARN) of the task to which the container belongs.

Family

The family of the Amazon ECS task definition for the task.
Revision

The revision of the Amazon ECS task definition for the task.

DesiredStatus

The desired status for the task from Amazon ECS.

KnownStatus

The known status for the task from Amazon ECS.

Limits

The resource limits specified at the task level, such as CPU (expressed in vCPUs) and memory. This parameter is omitted if no resource limits are defined.

PullStartedAt

The timestamp for when the first container image pull began.

PullStoppedAt

The timestamp for when the last container image pull finished.

AvailabilityZone

The Availability Zone the task is in.

Note

The Availability Zone metadata is only available for Fargate tasks using platform version 1.4 or later (Linux) or 1.0.0 or later (Windows).

Containers

A list of container metadata for each container associated with the task.

DockerId

The Docker ID for the container.

Name

The name of the container as specified in the task definition.
DockerName

The name of the container supplied to Docker. The Amazon ECS container agent generates a unique name for the container to avoid name collisions when multiple copies of the same task definition are run on a single instance.

Image

The image for the container.

ImageID

The SHA-256 digest for the image.

Ports

Any ports exposed for the container. This parameter is omitted if there are no exposed ports.

Labels

Any labels applied to the container. This parameter is omitted if there are no labels applied.

DesiredStatus

The desired status for the container from Amazon ECS.

KnownStatus

The known status for the container from Amazon ECS.

ExitCode

The exit code for the container. This parameter is omitted if the container has not exited.

Limits

The resource limits specified at the container level, such as CPU (expressed in CPU units) and memory. This parameter is omitted if no resource limits are defined.

CreatedAt

The time stamp for when the container was created. This parameter is omitted if the container has not been created yet.

StartedAt

The time stamp for when the container started. This parameter is omitted if the container has not started yet.
FinishedAt

The time stamp for when the container stopped. This parameter is omitted if the container has not stopped yet.

Type

The type of the container. Containers that are specified in your task definition are of type NORMAL. You can ignore other container types, which are used for internal task resource provisioning by the Amazon ECS container agent.

Networks

The network information for the container, such as the network mode and IP address. This parameter is omitted if no network information is defined.

ClockDrift

The information about the difference between the reference time and the system time. This applies to the Linux operating system. This capability uses Amazon Time Sync Service to measure clock accuracy and provide the clock error bound for containers. For more information, see Set the time for your Linux instance in the Amazon EC2 User Guide for Linux instances.

ReferenceTime

The basis of clock accuracy. Amazon ECS uses the Coordinated Universal Time (UTC) global standard through NTP, for example 2021-09-07T16:57:44Z.

ClockErrorBound

The measure of clock error, defined as the offset to UTC. This error is the difference in milliseconds between the reference time and the system time.

ClockSynchronizationStatus

Indicates whether the most recent synchronization attempt between the system time and the reference time was successful.

The valid values are SYNCHRONIZED and NOT_SYNCHRONIZED.

ExecutionStoppedAt

The time stamp for when the tasks DesiredStatus moved to STOPPED. This occurs when an essential container moves to STOPPED.
Example task metadata response

The following JSON response is for a single-container task.

```json
{
    "Cluster": "default",
    "Family": "nginx",
    "Revision": "5",
    "DesiredStatus": "RUNNING",
    "KnownStatus": "RUNNING",

Amazon ECS task metadata available for tasks on Fargate

Amazon ECS on Fargate provides a method to retrieve various metadata, network metrics, and Docker stats about your containers and the tasks they are a part of. This is referred to as the task metadata endpoint. The following task metadata endpoint versions are available for Amazon ECS on Fargate tasks:

- Task metadata endpoint version 4 – Available for tasks that use platform version 1.4.0 or later.
- Task metadata endpoint version 3 – Available for tasks that use platform version 1.1.0 or later.

All containers belonging to tasks that are launched with the awsvpc network mode receive a local IPv4 address within a predefined link-local address range. When a container queries the metadata endpoint, the container agent can determine which task the container belongs to based on its unique IP address, and metadata and stats for that task are returned.

Topics
- Amazon ECS task metadata endpoint version 4 for tasks on Fargate
- Amazon ECS task metadata endpoint version 3 for tasks on Fargate

Amazon ECS task metadata endpoint version 4 for tasks on Fargate

⚠️ Important

If you are using Amazon ECS tasks hosted on Amazon EC2 instances, see Amazon ECS task metadata endpoint.

Beginning with Fargate platform version 1.4.0, an environment variable named ECS_CONTAINER_METADATA_URI_V4 is injected into each container in a task. When you query the task metadata endpoint version 4, various task metadata and Docker stats are available to tasks.

The task metadata endpoint version 4 functions like the version 3 endpoint but provides additional network metadata for your containers and tasks. Additional network metrics are available when querying the /stats endpoints as well.

The task metadata endpoint is on by default for all Amazon ECS tasks run on AWS Fargate that use platform version 1.4.0 or later.
Note
To avoid the need to create new task metadata endpoint versions in the future, additional metadata may be added to the version 4 output. We will not remove any existing metadata or change the metadata field names.

Fargate task metadata endpoint version 4 paths

The following task metadata endpoints are available to containers:

${ECS_CONTAINER_METADATA_URI_V4}

This path returns metadata for the container.

${ECS_CONTAINER_METADATA_URI_V4}/task

This path returns metadata for the task, including a list of the container IDs and names for all of the containers associated with the task. For more information about the response for this endpoint, see Amazon ECS task metadata v4 JSON response for tasks on Fargate.

${ECS_CONTAINER_METADATA_URI_V4}/stats

This path returns Docker stats for the Docker container. For more information about each of the returned stats, see ContainerStats in the Docker API documentation.

Note
Amazon ECS tasks on AWS Fargate require that the container run for ~1 second prior to returning the container stats.

${ECS_CONTAINER_METADATA_URI_V4}/task/stats

This path returns Docker stats for all of the containers associated with the task. For more information about each of the returned stats, see ContainerStats in the Docker API documentation.
Amazon ECS tasks on AWS Fargate require that the container run for ~1 second prior to returning the container stats.

Amazon ECS task metadata v4 JSON response for tasks on Fargate

The following metadata is returned in the task metadata endpoint (${ECS_CONTAINER_METADATA_URI_V4}/task) JSON response.

Cluster

The Amazon Resource Name (ARN) or short name of the Amazon ECS cluster to which the task belongs.

VPCID

The VPC ID of the Amazon EC2 container instance. This field only appears for Amazon EC2 instances.

Note

The VPCID metadata is only included when using Amazon ECS container agent version 1.63.1 or later.

TaskARN

The full Amazon Resource Name (ARN) of the task to which the container belongs.

Family

The family of the Amazon ECS task definition for the task.

Revision

The revision of the Amazon ECS task definition for the task.

DesiredStatus

The desired status for the task from Amazon ECS.
KnownStatus

The known status for the task from Amazon ECS.

Limits

The resource limits specified at the task levels such as CPU (expressed in vCPUs) and memory. This parameter is omitted if no resource limits are defined.

PullStartedAt

The timestamp for when the first container image pull began.

PullStoppedAt

The timestamp for when the last container image pull finished.

AvailabilityZone

The Availability Zone the task is in.

Note

The Availability Zone metadata is only available for Fargate tasks using platform version 1.4 or later (Linux) or 1.0.0 (Windows).

LaunchType

The launch type the task is using. When using cluster capacity providers, this indicates whether the task is using Fargate or EC2 infrastructure.

Note

This LaunchType metadata is only included when using Amazon ECS Linux container agent version 1.45.0 or later (Linux) or 1.0.0 or later (Windows).

EphemeralStorageMetrics

The reserved size and current usage of the ephemeral storage of this task.
Note

Fargate reserves space on disk. It is only used by Fargate. You aren't billed for it. It isn't shown in these metrics. However, you can see this additional storage in other tools such as `df`.

Utilized

The current ephemeral storage usage (in MiB) of this task.

Reserved

The reserved ephemeral storage (in MiB) of this task. The size of the ephemeral storage can't be changed in a running task. You can specify the `ephemeralStorage` object in your task definition to change the amount of ephemeral storage. The `ephemeralStorage` is specified in GiB, not MiB. The `ephemeralStorage` and the `EphemeralStorageMetrics` are only available on Fargate Linux platform version 1.4.0 or later.

Containers

A list of container metadata for each container associated with the task.

DockerId

The Docker ID for the container.

When you use Fargate, the id is a 32-digit hex followed by a 10 digit number.

Name

The name of the container as specified in the task definition.

DockerName

The name of the container supplied to Docker. The Amazon ECS container agent generates a unique name for the container to avoid name collisions when multiple copies of the same task definition are run on a single instance.

Image

The image for the container.

ImageID

The SHA-256 digest for the image.
Ports

Any ports exposed for the container. This parameter is omitted if there are no exposed ports.

Labels

Any labels applied to the container. This parameter is omitted if there are no labels applied.

DesiredStatus

The desired status for the container from Amazon ECS.

KnownStatus

The known status for the container from Amazon ECS.

ExitCode

The exit code for the container. This parameter is omitted if the container has not exited.

Limits

The resource limits specified at the container level such as CPU (expressed in CPU units) and memory. This parameter is omitted if no resource limits are defined.

CreatedAt

The time stamp for when the container was created. This parameter is omitted if the container has not been created yet.

StartedAt

The time stamp for when the container started. This parameter is omitted if the container has not started yet.

FinishedAt

The time stamp for when the container stopped. This parameter is omitted if the container has not stopped yet.

Type

The type of the container. Containers that are specified in your task definition are of type NORMAL. You can ignore other container types, which are used for internal task resource provisioning by the Amazon ECS container agent.

LogDriver

The log driver the container is using.
Note
This LogDriver metadata is only included when using Amazon ECS Linux container agent version 1.45.0 or later.

LogOptions
The log driver options defined for the container.

Note
This LogOptions metadata is only included when using Amazon ECS Linux container agent version 1.45.0 or later.

ContainerARN
The full Amazon Resource Name (ARN) of the container.

Note
This ContainerARN metadata is only included when using Amazon ECS Linux container agent version 1.45.0 or later.

Networks
The network information for the container, such as the network mode and IP address. This parameter is omitted if no network information is defined.

Snapshotter
The snapshotter that was used by containerd to download this container image. Valid values are overlayfs, which is the default, and soci, used when lazy loading with a SOCI index. This parameter is only available for tasks that run on Linux platform version 1.4.0.

ClockDrift
The information about the difference between the reference time and the system time. This capability uses Amazon Time Sync Service to measure clock accuracy and provide the clock
error bound for containers. For more information, see Set the time for your Linux instance in the Amazon EC2 User Guide for Linux instances.

ReferenceTime

The basis of clock accuracy. Amazon ECS uses the Coordinated Universal Time (UTC) global standard through NTP, for example 2021-09-07T16:57:44Z.

ClockErrorBound

The measure of clock error, defined as the offset to UTC. This error is the difference in milliseconds between the reference time and the system time.

ClockSynchronizationStatus

Indicates whether the most recent synchronization attempt between the system time and the reference time was successful.

The valid values are SYNCHRONIZED and NOT_SYNCHRONIZED.

ExecutionStoppedAt

The time stamp for when the tasks DesiredStatus moved to STOPPED. This occurs when an essential container moves to STOPPED.

Amazon ECS task metadata v4 examples for tasks on Fargate

The following examples show sample outputs from the task metadata endpoints for Amazon ECS tasks run on AWS Fargate.

From the container, you can use curl followed by the task meta data endpoint to query the endpoint for example curl ${ECS_CONTAINER_METADATA_URI_V4}/task.

Example container metadata response

When querying the ${ECS_CONTAINER_METADATA_URI_V4} endpoint you are returned only metadata about the container itself. The following is an example output.

```json
{

The task metadata version 3 endpoint is no longer being actively maintained. We recommend that you update the task metadata version 4 endpoint to get the latest metadata endpoint information. For more information, see the section called “Task metadata endpoint version 4 for tasks on Fargate”.

Beginning with Fargate platform version 1.1.0, an environment variable named ECS_CONTAINER_METADATA_URI is injected into each container in a task. When you query the task metadata version 3 endpoint, various task metadata and Docker stats are available to tasks.

The task metadata endpoint feature is enabled by default for Amazon ECS tasks hosted on Fargate that use platform version 1.1.0 or later. For more information, see Fargate Linux platform versions.

Task metadata endpoint paths for tasks on Fargate

The following API endpoints are available to containers:

```
{ "eth1": {
    "rx_bytes": 2398415937,
    "rx_packets": 1898631,
    "rx_errors": 0,
    "rx_dropped": 0,
    "tx_bytes": 1259037719,
    "tx_packets": 428002,
    "tx_errors": 0,
    "tx_dropped": 0
  },
  "network_rate_stats": {
    "rx_bytes_per_sec": 43.298687872232854,
    "tx_bytes_per_sec": 215.39347269466413
  }
}
```
${ECS_CONTAINER_METADATA_URI}

This path returns metadata JSON for the container.

${ECS_CONTAINER_METADATA_URI}/task

This path returns metadata JSON for the task, including a list of the container IDs and names for all of the containers associated with the task. For more information about the response for this endpoint, see Amazon ECS task metadata v3 JSON response for tasks on Fargate.

${ECS_CONTAINER_METADATA_URI}/stats

This path returns Docker stats JSON for the specific Docker container. For more information about each of the returned stats, see ContainerStats in the Docker API documentation.

${ECS_CONTAINER_METADATA_URI}/task/stats

This path returns Docker stats JSON for all of the containers associated with the task. For more information about each of the returned stats, see ContainerStats in the Docker API documentation.

Amazon ECS task metadata v3 JSON response for tasks on Fargate

The following information is returned from the task metadata endpoint (${ECS_CONTAINER_METADATA_URI}/task) JSON response.

Cluster

The Amazon Resource Name (ARN) or short name of the Amazon ECS cluster to which the task belongs.

TaskARN

The full Amazon Resource Name (ARN) of the task to which the container belongs.

Family

The family of the Amazon ECS task definition for the task.

Revision

The revision of the Amazon ECS task definition for the task.

DesiredStatus

The desired status for the task from Amazon ECS.
KnownStatus

The known status for the task from Amazon ECS.

Limits

The resource limits specified at the task level, such as CPU (expressed in vCPUs) and memory. This parameter is omitted if no resource limits are defined.

PullStartedAt

The timestamp for when the first container image pull began.

PullStoppedAt

The timestamp for when the last container image pull finished.

AvailabilityZone

The Availability Zone the task is in.

Note

The Availability Zone metadata is only available for Fargate tasks using platform version 1.4 or later (Linux) or 1.0.0 or later (Windows).

Containers

A list of container metadata for each container associated with the task.

DockerId

The Docker ID for the container.

Name

The name of the container as specified in the task definition.

DockerName

The name of the container supplied to Docker. The Amazon ECS container agent generates a unique name for the container to avoid name collisions when multiple copies of the same task definition are run on a single instance.

Image

The image for the container.
ImageID

The SHA-256 digest for the image.

Ports

Any ports exposed for the container. This parameter is omitted if there are no exposed ports.

Labels

Any labels applied to the container. This parameter is omitted if there are no labels applied.

DesiredStatus

The desired status for the container from Amazon ECS.

KnownStatus

The known status for the container from Amazon ECS.

ExitCode

The exit code for the container. This parameter is omitted if the container has not exited.

Limits

The resource limits specified at the container level, such as CPU (expressed in CPU units) and memory. This parameter is omitted if no resource limits are defined.

CreatedAt

The time stamp for when the container was created. This parameter is omitted if the container has not been created yet.

StartedAt

The time stamp for when the container started. This parameter is omitted if the container has not started yet.

FinishedAt

The time stamp for when the container stopped. This parameter is omitted if the container has not stopped yet.

Type

The type of the container. Containers that are specified in your task definition are of type NORMAL. You can ignore other container types, which are used for internal task resource provisioning by the Amazon ECS container agent.
Networks

The network information for the container, such as the network mode and IP address. This parameter is omitted if no network information is defined.

ClockDrift

The information about the difference between the reference time and the system time. This applies to the Linux operating system. This capability uses Amazon Time Sync Service to measure clock accuracy and provide the clock error bound for containers. For more information, see [Set the time for your Linux instance](https://docs.aws.amazon.com/AmazonEC2/latest/UserGuide/) in the *Amazon EC2 User Guide for Linux instances*.

ReferenceTime

The basis of clock accuracy. Amazon ECS uses the Coordinated Universal Time (UTC) global standard through NTP, for example 2021-09-07T16:57:44Z.

ClockErrorBound

The measure of clock error, defined as the offset to UTC. This error is the difference in milliseconds between the reference time and the system time.

ClockSynchronizationStatus

Indicates whether the most recent synchronization attempt between the system time and the reference time was successful.

The valid values are SYNCHRONIZED and NOT_SYNCHRONIZED.

ExecutionStoppedAt

The time stamp for when the tasks DesiredStatus moved to STOPPED. This occurs when an essential container moves to STOPPED.

### Amazon ECS task metadata v3 examples for tasks on Fargate

The following JSON response is for a single-container task.

```json
{
    "Cluster": "default",
    "Family": "nginx",

Amazon ECS container introspection

The Amazon ECS container agent provides an API operation for gathering details about the container instance on which the agent is running and the associated tasks running on that instance. You can use the curl command from within the container instance to query the Amazon ECS container agent (port 51678) and return container instance metadata or task information.

⚠️ Important

Your container instance must have an IAM role that allows access to Amazon ECS in order to retrieve the metadata. For more information, see Amazon ECS container instance IAM role.
To view container instance metadata, log in to your container instance via SSH and run the following command. Metadata includes the container instance ID, the Amazon ECS cluster in which the container instance is registered, and the Amazon ECS container agent version information.

```
curl -s http://localhost:51678/v1/metadata | python -mjson.tool
```

Output:

```
{
   "Cluster": "cluster_name",
   "Version": "Amazon ECS Agent - v1.30.0 (02ff320c)"
}
```

To view information about all of the tasks that are running on a container instance, log in to your container instance via SSH and run the following command:

```
curl http://localhost:51678/v1/tasks
```

Output:

```
{
   "Tasks": [
      {
         "Arn": "arn:aws:ecs:us-west-2:012345678910:task/default/example5-58ff-46c9-ae05-543f8example",
         "DesiredStatus": "RUNNING",
         "KnownStatus": "RUNNING",
         "Family": "hello_world",
         "Version": "8",
         "Containers": [
            {
               "DockerId": "9581a69a761a557fbbf8e0d0f6745e4af5b9d6f8b86b6b2e54df156f1a5932ff1",
               "DockerName": "ecs-hello_world-8-mysql-fcae8ac8f9f1d89d8301",
               "Name": "mysql",
               "CreatedAt": "2023-10-08T20:09:11.44527186Z",
               "StartedAt": "2023-10-08T20:09:11.44527186Z",
               "ImageID": "sha256:2ae34abc2ed0a22e280d17e13f9c01aaf725688b09b7a1525d1a2750e2c0d1de"
            }
         ]
      }
   ]
}```
You can view information for a particular task that is running on a container instance. To specify a specific task or container, append one of the following to the request:

- The task ARN (`?taskarn=task_arn`)
- The Docker ID for a container (`?dockerid=docker_id`)

To get task information with a container's Docker ID, log in to your container instance via SSH and run the following command.

```bash
Note
Amazon ECS container agents before version 1.14.2 require full Docker container IDs for the introspection API, not the short version that is shown with `docker ps`. You can get the full Docker ID for a container by running the `docker ps --no-trunc` command on the container instance.

```bash
curl http://localhost:51678/v1/tasks?dockerid=79c796ed2a7f
```

Output:

```json
{
   "Arn": "arn:aws:ecs:us-west-2:012345678910:task/default/e01d58a8-151b-40e8-bc01-22647b9ecfec",
   "Containers": [
      
```
"DockerId": "79c796ed2a7f864f485c76f83f3165488097279d296a7c05bd5201a1c69b2920",
   "DockerName": "ecs-nginx-efs-2-nginx-9ac0808dd0afa495f001",
   "Name": "nginx",
   "CreatedAt": "2023-10-08T20:09:11.44527186Z",
   "StartedAt": "2023-10-08T20:09:11.44527186Z",
   "ImageID": "sha256:2ae34abc2ed0a22e280d17e13f9c01aaf725688b09b7a1525d1a2750e2c0d1de"
   }
],
"DesiredStatus": "RUNNING",
"Family": "nginx-efs",
"KnownStatus": "RUNNING",
"Version": "2"
AWS services integrated with Amazon ECS

Amazon ECS works with other AWS services to provide additional solutions for your business challenges. This topic identifies services that either use Amazon ECS to add functionality, or services that Amazon ECS uses to perform tasks.

Contents

• Using Amazon ECR with Amazon ECS
• AWS Deep Learning Containers on Amazon ECS
• Using AWS User Notifications with Amazon ECS

Using Amazon ECR with Amazon ECS

Amazon ECR is a managed AWS Docker registry service. Customers can use the familiar Docker CLI to push, pull, and manage images. Amazon ECR provides a secure, scalable, and reliable registry. Amazon ECR supports private Docker repositories with resource-based permissions using AWS IAM so that specific users or Amazon EC2 instances can access repositories and images. Developers can use the Docker CLI to author and manage images.

For more information on how to create repositories, push and pull images from Amazon ECR, and set access controls on your repositories, see the Amazon Elastic Container Registry User Guide.

Using Amazon ECR Images with Amazon ECS

You can use your ECR images with Amazon ECS, but you need to satisfy the following prerequisites.

• Your container instances must be using at least version 1.7.0 of the Amazon ECS container agent. The latest version of the Amazon ECS–optimized AMI supports ECR images in task definitions. For more information, including the latest Amazon ECS–optimized AMI IDs, see Amazon ECS Container Agent Versions in the Amazon Elastic Container Service Developer Guide.

• The Amazon ECS container instance role (ecsInstanceRole) that you use with your container instances must possess the following IAM policy permissions for Amazon ECR:

```json
{
    "Version": "2012-10-17",
    "Statement": [
```
If you use the AmazonEC2ContainerServiceforEC2Role managed policy for your container instances, then your role has the proper permissions. To check that your role supports Amazon ECR, see Amazon ECS Container Instance IAM Role in the Amazon Elastic Container Service Developer Guide.

- In your ECS task definitions, make sure that you are using the full registry/repository:tag naming for your ECR images. For example, `aws_account_id.dkr.ecr.region.amazonaws.com/my-web-app:latest`.

## AWS Deep Learning Containers on Amazon ECS

AWS Deep Learning Containers provide a set of Docker images for training and serving models in TensorFlow and Apache MXNet (Incubating) on Amazon ECS. Deep Learning Containers enable optimized environments with TensorFlow, NVIDIA CUDA (for GPU instances), and Intel MKL (for CPU instances) libraries. Container images for Deep Learning Containers are available in Amazon ECR to reference in Amazon ECS task definitions. You can use Deep Learning Containers along with Amazon Elastic Inference to lower your inference costs.

To get started using Deep Learning Containers without Elastic Inference on Amazon ECS, see Deep Learning Containers on Amazon ECS in the AWS Deep Learning AMI Developer Guide.

## Deep Learning Containers with Elastic Inference on Amazon ECS

> **Note**
>
> Starting April 15, 2023, AWS will not onboard new customers to Amazon Elastic Inference (EI), and will help current customers migrate their workloads to options that offer better...
price and performance. After April 15, 2023, new customers will not be able to launch instances with Amazon EI accelerators in Amazon SageMaker, Amazon ECS, or Amazon EC2. However, customers who have used Amazon EI at least once during the past 30-day period are considered current customers and will be able to continue using the service.

AWS Deep Learning Containers provide a set of Docker images for serving models in TensorFlow and Apache MXNet (Incubating) that take advantage of Amazon Elastic Inference accelerators. Amazon ECS provides task definition parameters to attach Elastic Inference accelerators to your containers. When you specify an Elastic Inference accelerator type in your task definition, Amazon ECS manages the lifecycle of, and configuration for, the accelerator. The Amazon ECS service-linked role is required when using this feature. For more information about Elastic Inference accelerators, see Amazon Elastic Inference Basics.

⚠️ Important

Your Amazon ECS container instances require at least version 1.30.0 of the container agent. For information about checking your agent version and updating to the latest version, see Updating the Amazon ECS container agent.

To get started using Deep Learning Containers with Elastic Inference on Amazon ECS, see Deep Learning Containers with Elastic Inference on Amazon ECS in the Amazon Elastic Inference Developer Guide.

Using AWS User Notifications with Amazon ECS

You can use AWS User Notifications to set up delivery channels to get notified about Amazon ECS events. You receive a notification when an event matches a rule that you specify. You can receive notifications for events through multiple channels, including email, AWS Chatbot chat notifications, or AWS Console Mobile Application push notifications. You can also see notifications in the Console Notifications Center. User Notifications supports aggregation, which can reduce the number of notifications you receive during specific events.

Example

The following event pattern matches a task state change on the cluster named default.
{
    "source": ["aws.ecs"],
    "detail-type": ["ECS Task State Change"]
    "detail": {
        "clusterArn": [
            "default"
        ]
    }
}
Tutorials for Amazon ECS

The following tutorials show you how to perform common tasks when using Amazon ECS.

Topics

- Using Windows containers on AWS Fargate
- Creating a cluster with a Fargate Linux task using the AWS CLI
- Creating a cluster with a Fargate Windows task using the AWS CLI
- Creating a cluster with an EC2 task using the AWS CLI
- Using cluster auto scaling with the AWS Management Console and the Amazon ECS console
- Specifying Sensitive Data Using Secrets Manager Secrets
- Creating a service using Service Discovery
- Creating a service using a blue/green deployment
- Listening for Amazon ECS CloudWatch Events
- Sending Amazon Simple Notification Service alerts for task stopped events
- Concatenate multiline or stack-trace log messages
- Using Amazon EFS file systems with Amazon ECS using the console
- Using FSx for Windows File Server file systems with Amazon ECS
- Deploying Fluent Bit on Amazon ECS for Windows containers
- Using gMSAs for Windows Containers on Amazon EC2
- Using Windows Containers with Domainless gMSA using the AWS CLI
- Using gMSA for Linux Containers on Amazon EC2
- Using gMSA for Linux containers on Fargate
- Using EC2 Image Builder to build customized Amazon ECS-optimized AMIs

Using Windows containers on AWS Fargate

Get started with Amazon ECS on AWS Fargate by using the Fargate launch type for your tasks in the Regions where Amazon ECS supports AWS Fargate.

Complete the following steps to get started with Amazon ECS on AWS Fargate.
Prerequisites

Before you begin, complete the steps in Set up to use Amazon ECS and that your AWS user has the permissions specified in the AdministratorAccess IAM policy example.

The console attempts to automatically create the task execution IAM role, which is required for Fargate tasks. To ensure that the console is able to create this IAM role, one of the following must be true:

- Your user has administrator access. For more information, see Set up to use Amazon ECS.
- Your user has the IAM permissions to create a service role. For more information, see Creating a Role to Delegate Permissions to an AWS Service.
- A user with administrator access has manually created the task execution role so that it is available on the account to be used. For more information, see Amazon ECS task execution IAM role.

⚠️ Important

The security group you select when creating a service with your task definition must have port 80 open for inbound traffic. Add the following inbound rule to your security group. For information about how to create a security group, see Add rules to your security group in the Amazon EC2 User Guide for Linux Instances.

- Type: HTTP
- Protocol: TCP
- Port range: 80
- Source: Anywhere (0.0.0.0/0)

Step 1: Create a cluster

You can create a new cluster called windows that uses the default VPC.

To create a cluster with the AWS Management Console

2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose Clusters.
4. On the Clusters page, choose Create cluster.
5. Under Cluster configuration, for Cluster name, enter windows.
6. (Optional) To turn on Container Insights, expand Monitoring, and then turn on Use Container Insights.
7. (Optional) To help identify your cluster, expand Tags, and then configure your tags.
   [Add a tag] Choose Add tag and do the following:
   • For Key, enter the key name.
   • For Value, enter the key value.
   [Remove a tag] Choose Remove to the right of the tag’s Key and Value.
8. Choose Create.

**Step 2: Register a Windows task definition**

Before you can run Windows containers in your Amazon ECS cluster, you must register a task definition. The following task definition example displays a simple webpage on port 8080 of a container instance with the mcr.microsoft.com/windows/servercore/iis container image.

To register the sample task definition with the AWS Management Console

1. In the navigation pane, choose Task definitions.
2. Choose Create new task definition, Create new task definition with JSON.
3. Copy and paste the following example task definition into the box and then choose Save.

```json
{
    "containerDefinitions": [
        {
            "command": ["New-Item -Path C:\inetpub\wwwroot\index.html -Type file -Value '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon ECS.</p>'; C:\ServiceMonitor.exe w3svc"],
            "entryPoint": ["cmd", "cscript", "ServiceMonitor.vbs"]
        }
    ]
}
```
4. Verify your information and choose Create.

**Step 3: Create a service with your task definition**

After you have registered your task definition, you can place tasks in your cluster with it. The following procedure creates a service with your task definition and places one task in your cluster.

To create a service from your task definition with the console

1. In the navigation pane, choose Clusters, and then select the cluster you created in Step 1: Create a cluster.
2. From the Services tab, choose Create.
3. Under Deployment configuration, specify how your application is deployed.
a. For **Task definition**, choose the task definition you created in [Step 2: Register a Windows task definition](#).

b. For **Service name**, enter a name for your service.

c. For **Desired tasks**, enter 1.

4. Under **Networking**, you can create a security group or choose an existing group. Ensure that the security group you use has the inbound rule listed under [Prerequisites](#).

5. Choose **Create**.

---

**Step 4: View your service**

After your service has launched a task into your cluster, you can view the service and open the IIS test page in a browser to verify that the container is running.

---

**Note**

It can take up to 15 minutes for your container instance to download and extract the Windows container base layers.

---

**To view your service**

2. In the navigation pane, choose **Clusters**.

3. Choose the cluster where you ran the service.

4. In the **Services** tab, under **Service name**, choose the service you created in [Step 3: Create a service with your task definition](#).

5. Choose the **Tasks** tab, and then choose the task in your service.

6. On the task page, in the **Configuration** section, under **Public IP**, choose **Open address**.

---

**Step 5: Clean Up**

When you are finished using an Amazon ECS cluster, you should clean up the resources associated with it to avoid incurring charges for resources that you are not using.
Some Amazon ECS resources, such as tasks, services, clusters, and container instances, are cleaned up using the Amazon ECS console. Other resources, such as Amazon EC2 instances, Elastic Load Balancing load balancers, and Auto Scaling groups, must be cleaned up manually in the Amazon EC2 console or by deleting the AWS CloudFormation stack that created them.

1. In the navigation pane, choose **Clusters**.
2. On the Clusters page, select the cluster you created for this tutorial.
3. Choose the **Services** tab.
4. Select the service, and then choose **Delete**.
5. At the confirmation prompt, enter `delete` and then choose **Delete**.
   
   Wait until the service is deleted.
6. Choose **Delete Cluster**. At the confirmation prompt, enter `delete cluster-name`, and then choose **Delete**. Deleting the cluster cleans up the associated resources that were created with the cluster, including Auto Scaling groups, VPCs, or load balancers.

### Creating a cluster with a Fargate Linux task using the AWS CLI

The following steps help you set up a cluster, register a task definition, run a Linux task, and perform other common scenarios in Amazon ECS with the AWS CLI. Ensure that you are using the latest version of the AWS CLI. For more information on how to upgrade to the latest version, see [Installing the AWS Command Line Interface](#).}

**Topics**

- **Prerequisites**
- **Step 1: Create a Cluster**
- **Step 2: Register a Linux Task Definition**
- **Step 3: List Task Definitions**
- **Step 4: Create a Service**
- **Step 5: List Services**
- **Step 6: Describe the Running Service**
- **Step 7: Test**
- **Step 8: Clean Up**

---

Creating a cluster with a Fargate Linux task using the AWS CLI

The following steps help you set up a cluster, register a task definition, run a Linux task, and perform other common scenarios in Amazon ECS with the AWS CLI. Ensure that you are using the latest version of the AWS CLI. For more information on how to upgrade to the latest version, see [Installing the AWS Command Line Interface](#).
Prerequisites

This tutorial assumes that the following prerequisites have been completed.

- The latest version of the AWS CLI is installed and configured. For more information about installing or upgrading your AWS CLI, see Installing the AWS Command Line Interface.
- The steps in Set up to use Amazon ECS have been completed.
- Your AWS user has the required permissions specified in the AmazonECS_FullAccess IAM policy example.
- You have a VPC and security group created to use. This tutorial uses a container image hosted on Amazon ECR Public so your task must have internet access. To give your task a route to the internet, use one of the following options.
  - Use a private subnet with a NAT gateway that has an elastic IP address.
  - Use a public subnet and assign a public IP address to the task.

For more information, see the section called “Create a virtual private cloud”.

For information about security groups and rules, see, Default security groups for your VPCs and Example rules in the Amazon Virtual Private Cloud User Guide.

- If you follow this tutorial using a private subnet, you can use Amazon ECS Exec to directly interact with your container and test the deployment. You will need to create a task IAM role to use ECS Exec. For more information on the task IAM role and other prerequisites, see Using Amazon ECS Exec for debugging.
- (Optional) AWS CloudShell is a tool that gives customers a command line without needing to create their own EC2 instance. For more information, see What is AWS CloudShell? in the AWS CloudShell User Guide.

Step 1: Create a Cluster

By default, your account receives a default cluster.

⚠️ Note

The benefit of using the default cluster that is provided for you is that you don't have to specify the --cluster cluster_name option in the subsequent commands. If you do
create your own, non-default, cluster, you must specify `--cluster` *cluster_name* for each command that you intend to use with that cluster.

Create your own cluster with a unique name with the following command:

```
aws ecs create-cluster --cluster-name fargate-cluster
```

Output:

```
{
  "cluster": {
    "status": "ACTIVE",
    "defaultCapacityProviderStrategy": [],
    "statistics": [],
    "capacityProviders": [],
    "tags": [],
    "clusterName": "fargate-cluster",
    "settings": [
      {
        "name": "containerInsights",
        "value": "disabled"
      }
    ],
    "registeredContainerInstancesCount": 0,
    "pendingTasksCount": 0,
    "runningTasksCount": 0,
    "activeServicesCount": 0,
    "clusterArn": "arn:aws:ecs::region:aws_account_id:cluster/fargate-cluster"
  }
}
```

**Step 2: Register a Linux Task Definition**

Before you can run a task on your ECS cluster, you must register a task definition. Task definitions are lists of containers grouped together. The following example is a simple task definition that creates a PHP web app using the httpd container image hosted on Docker Hub. For more information about the available task definition parameters, see [Amazon ECS task definitions](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/task-definition-parameters.html). For this tutorial, the `taskRoleArn` is only needed if you are deploying the task in a private subnet and wish to test the deployment. Replace the `taskRoleArn` with the IAM task role you created to use ECS Exec as mentioned in [Prerequisites](#).

---

**Step 2: Register a Linux Task Definition**

Before you can run a task on your ECS cluster, you must register a task definition. Task definitions are lists of containers grouped together. The following example is a simple task definition that creates a PHP web app using the httpd container image hosted on Docker Hub. For more information about the available task definition parameters, see [Amazon ECS task definitions](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/task-definition-parameters.html). For this tutorial, the `taskRoleArn` is only needed if you are deploying the task in a private subnet and wish to test the deployment. Replace the `taskRoleArn` with the IAM task role you created to use ECS Exec as mentioned in [Prerequisites](#).
```json
{
    "family": "sample-fargate",
    "networkMode": "awsvpc",
    "taskRoleArn": "arn:aws:iam::aws_account_id:role/execCommandRole",
    "containerDefinitions": [
        {
            "name": "fargate-app",
            "image": "public.ecr.aws/docker/library/httpd:latest",
            "portMappings": [
                {
                    "containerPort": 80,
                    "hostPort": 80,
                    "protocol": "tcp"
                }
            ],
            "essential": true,
            "entryPoint": [
                "sh",
                "-c"
            ],
            "command": [
                "/bin/sh -c \"echo '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon ECS.</p> </div></body></html>' > /usr/local/apache2/htdocs/index.html && httpd-foreground\"
            ]
        }
    ],
    "requiresCompatibilities": [
        "FARGATE"
    ],
    "cpu": "256",
    "memory": "512"
}
```

Save the task definition JSON as a file and pass it with the `--cli-input-json` option:

```
file://path_to_file.json
```

To use a JSON file for container definitions:
aws ecs register-task-definition --cli-input-json file://$HOME/tasks/fargate-task.json

The register-task-definition command returns a description of the task definition after it completes its registration.

**Step 3: List Task Definitions**

You can list the task definitions for your account at any time with the list-task-definitions command. The output of this command shows the family and revision values that you can use together when calling run-task or start-task.

aws ecs list-task-definitions

Output:

```
{
  "taskDefinitionArns": [
    "arn:aws:ecs:region:aws_account_id:task-definition/sample-fargate:1"
  ]
}
```

**Step 4: Create a Service**

After you have registered a task for your account, you can create a service for the registered task in your cluster. For this example, you create a service with one instance of the sample-fargate:1 task definition running in your cluster. The task requires a route to the internet, so there are two ways you can achieve this. One way is to use a private subnet configured with a NAT gateway with an elastic IP address in a public subnet. Another way is to use a public subnet and assign a public IP address to your task. We provide both examples below.

Example using a private subnet. The enable-execute-command option is needed to use Amazon ECS Exec.

```
aws ecs create-service --cluster fargate-cluster --service-name fargate-service --task-definition sample-fargate:1 --desired-count 1 --launch-type "FARGATE" --network-configuration "awsvpcConfiguration={subnets=[subnet-abcd1234],securityGroups=[sg-abcd1234]}" --enable-execute-command
```

Example using a public subnet.
aws ecs create-service --cluster fargate-cluster --service-name fargate-service --task-definition sample-fargate:1 --desired-count 1 --launch-type "FARGATE" --network-configuration "awsvpcConfiguration={subnets=[subnet-abcd1234],securityGroups=[sg-abcd1234],assignPublicIp=ENABLED}"  

The `create-service` command returns a description of the task definition after it completes its registration.

**Step 5: List Services**

List the services for your cluster. You should see the service that you created in the previous section. You can take the service name or the full ARN that is returned from this command and use it to describe the service later.

```bash
aws ecs list-services --cluster fargate-cluster
```

Output:

```
{
    "serviceArns": [
        "arn:aws:ecs:region:aws_account_id:service/fargate-cluster/fargate-service"
    ]
}
```

**Step 6: Describe the Running Service**

Describe the service using the service name retrieved earlier to get more information about the task.

```bash
aws ecs describe-services --cluster fargate-cluster --services fargate-service
```

If successful, this will return a description of the service failures and services. For example, in the `services` section, you will find information on deployments, such as the status of the tasks as running or pending. You may also find information on the task definition, the network configuration and time-stamped events. In the `failures` section, you will find information on failures, if any, associated with the call. For troubleshooting, see [Service Event Messages](#). For more information about the service description, see [Describe Services](#).

```
{
}
```
"services": [  
  {  
    "networkConfiguration": {  
      "awsvpcConfiguration": {  
        "subnets": [  
          "subnet-abcd1234"
        ],  
        "securityGroups": [  
          "sg-abcd1234"

"roleArn": "arn:aws:iam::aws_account_id:role/aws-service-role/ecs.amazonaws.com/AWSServiceRoleForECS",
"taskDefinition": "arn:aws:ecs:region:aws_account_id:task-definition/sample-fargate:1"
Step 7: Test

Testing task deployed using public subnet

Describe the task in the service so that you can get the Elastic Network Interface (ENI) for the task.

First, get the task ARN.

```bash
aws ecs list-tasks --cluster fargate-cluster --service fargate-service
```

The output contains the task ARN.

```json
{
  "taskArns": [
    "arn:aws:ecs:us-east-1:123456789012:task/fargate-service/EXAMPLE"
  ]
}
```

Describe the task and locate the ENI ID. Use the task ARN for the `tasks` parameter.

```bash
aws ecs describe-tasks --cluster fargate-cluster --tasks arn:aws:ecs:us-east-1:123456789012:task/service/EXAMPLE
```

The attachment information is listed in the output.

```json
{
  "tasks": [
    {
      "attachments": [
        {
          "id": "d9e7735a-16aa-4128-bc7a-b2d5115029e9",
          "type": "ElasticNetworkInterface",
          "status": "ATTACHED",
          "details": [
```

```json
```
Describe the ENI to get the public IP address.

```
aws ec2 describe-network-interfaces --network-interface-id eni-0fa40520aeEXAMPLE
```

The public IP address is in the output.

```
{
    "NetworkInterfaces": [
      {
        "Association": {
          "IpOwnerId": "amazon",
          "PublicDnsName": "ec2-34-229-42-222.compute-1.amazonaws.com",
          "PublicIp": "198.51.100.2"
        },
        "PrivateIp": "10.0.0.2"
      }
    ]
}
```

Enter the public IP address in your web browser and you should see a webpage that displays the Amazon ECS sample application.

**Testing task deployed using private subnet**

Describe the task and locate managedAgents to verify that the ExecuteCommandAgent is running. Note the privateIPv4Address for later use.

```
aws ecs describe-tasks --cluster fargate-cluster --tasks arn:aws:ecs:us-east-1:123456789012:task/fargate-service/EXAMPLE
```

The managed agent information is listed in the output.
After verifying that the `ExecuteCommandAgent` is running, you can run the following command to run an interactive shell on the container in the task.

```bash
aws ecs execute-command --cluster fargate-cluster \
--task arn:aws:ecs:us-east-1:123456789012:task/fargate-service/EXAMPLE \
```
After the interactive shell is running, run the following commands to install cURL.

```
apt update
```

```
apt install curl
```

After installing cURL, run the following command using the private IP address you obtained earlier.

```
curl 10.0.143.156
```

You should see the HTML equivalent of the Amazon ECS sample application webpage.

```
<html>
  <head>
    <title>Amazon ECS Sample App</title>
    <style>body {margin-top: 40px; background-color: #333;}</style>
  </head>
  <body>
    <div style=color:white;text-align:center>
      <h1>Amazon ECS Sample App</h1>
      <h2>Congratulations!</h2>
      <p>Your application is now running on a container in Amazon ECS.</p>
    </div>
  </body>
</html>
```

**Step 8: Clean Up**

When you are finished with this tutorial, you should clean up the associated resources to avoid incurring charges for unused resources.

Delete the service.

```
aws ecs delete-service --cluster fargate-cluster --service fargate-service --force
```

Delete the cluster.
Creating a cluster with a Fargate Windows task using the AWS CLI

The following steps help you set up a cluster, register a task definition, run a Windows task, and perform other common scenarios in Amazon ECS with the AWS CLI. Ensure that you are using the latest version of the AWS CLI. For more information on how to upgrade to the latest version, see Installing the AWS Command Line Interface.

Topics

• Prerequisites
• Step 1: Create a Cluster
• Step 2: Register a Windows Task Definition
• Step 3: List task definitions
• Step 4: Create a service
• Step 5: List services
• Step 6: Describe the Running Service
• Step 7: Clean Up

Prerequisites

This tutorial assumes that the following prerequisites have been completed.

• The latest version of the AWS CLI is installed and configured. For more information about installing or upgrading your AWS CLI, see Installing the AWS Command Line Interface.
• The steps in Set up to use Amazon ECS have been completed.
• Your AWS user has the required permissions specified in the AmazonECS_FullAccess IAM policy example.
• You have a VPC and security group created to use. This tutorial uses a container image hosted on Docker Hub so your task must have internet access. To give your task a route to the internet, use one of the following options.
  • Use a private subnet with a NAT gateway that has an elastic IP address.
• Use a public subnet and assign a public IP address to the task.

For more information, see the section called “Create a virtual private cloud”.

For information about security groups and rules, see, Default security groups for your VPCs and Example rules in the Amazon Virtual Private Cloud User Guide.

• (Optional) AWS CloudShell is a tool that gives customers a command line without needing to create their own EC2 instance. For more information, see What is AWS CloudShell? in the AWS CloudShell User Guide.

Step 1: Create a Cluster

By default, your account receives a default cluster.

Note

The benefit of using the default cluster that is provided for you is that you don't have to specify the --cluster cluster_name option in the subsequent commands. If you do create your own, non-default, cluster, you must specify --cluster cluster_name for each command that you intend to use with that cluster.

Create your own cluster with a unique name with the following command:

```
aws ecs create-cluster --cluster-name fargate-cluster
```

Output:

```
{
    "cluster": {
        "status": "ACTIVE",
        "statistics": [],
        "clusterName": "fargate-cluster",
        "registeredContainerInstancesCount": 0,
        "pendingTasksCount": 0,
        "runningTasksCount": 0,
        "activeServicesCount": 0,
        "clusterArn": "arn:aws:ecs:region:aws_account_id:cluster/fargate-cluster"
    }
}
```
Step 2: Register a Windows Task Definition

Before you can run a Windows task on your Amazon ECS cluster, you must register a task definition. Task definitions are lists of containers grouped together. The following example is a simple task definition that creates a web app. For more information about the available task definition parameters, see Amazon ECS task definitions.

```json
{
    "containerDefinitions": [
        {
            "command": ["New-Item -Path C:\inetpub\wwwroot\index.html -Type file -Value '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon ECS.</p>'; C:\ServiceMonitor.exe w3svc"],
            "entryPoint": ["powershell", "-Command"],
            "essential": true,
            "cpu": 2048,
            "memory": 4096,
            "image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-ltsc2019",
            "name": "sample_windows_app",
            "portMappings": [
                {
                    "hostPort": 80,
                    "containerPort": 80,
                    "protocol": "tcp"
                }
            ],
            "memory": "4096",
            "cpu": "2048",
            "networkMode": "awsvpc",
            "family": "windows-simple-iis-2019-core",
            "executionRoleArn": "arn:aws:iam::012345678910:role/ecsTaskExecutionRole",
            "runtimePlatform": {"operatingSystemFamily": "WINDOWS_SERVER_2019_CORE"},
        }
    ],
    "memory": "4096",
    "cpu": "2048",
    "networkMode": "awsvpc",
    "family": "windows-simple-iis-2019-core",
    "executionRoleArn": "arn:aws:iam::012345678910:role/ecsTaskExecutionRole",
    "runtimePlatform": {"operatingSystemFamily": "WINDOWS_SERVER_2019_CORE"},
}
```
The above example JSON can be passed to the AWS CLI in two ways: You can save the task definition JSON as a file and pass it with the --cli-input-json file://path_to_file.json option.

To use a JSON file for container definitions:

```bash
aws ecs register-task-definition --cli-input-json file://$HOME/tasks/fargate-task.json
```

The `register-task-definition` command returns a description of the task definition after it completes its registration.

**Step 3: List task definitions**

You can list the task definitions for your account at any time with the `list-task-definitions` command. The output of this command shows the family and revision values that you can use together when calling `run-task` or `start-task`.

```bash
aws ecs list-task-definitions
```

Output:

```json
{
  "taskDefinitionArns": [
  ]
}
```

**Step 4: Create a service**

After you have registered a task for your account, you can create a service for the registered task in your cluster. For this example, you create a service with one instance of the sample-fargate:1 task definition running in your cluster. The task requires a route to the internet, so there are two ways you can achieve this. One way is to use a private subnet configured with a NAT gateway with an elastic IP address in a public subnet. Another way is to use a public subnet and assign a public IP address to your task. We provide both examples below.

Example using a private subnet.
aws ecs create-service --cluster fargate-cluster --service-name fargate-service --task-definition sample-fargate-windows:1 --desired-count 1 --launch-type "FARGATE" --network-configuration "awsvpcConfiguration={subnets=[subnet-abcd1234],securityGroups=[sg-abcd1234]}"

Example using a public subnet.

aws ecs create-service --cluster fargate-cluster --service-name fargate-service --task-definition sample-fargate-windows:1 --desired-count 1 --launch-type "FARGATE" --network-configuration "awsvpcConfiguration={subnets=[subnet-abcd1234],securityGroups=[sg-abcd1234],assignPublicIp=ENABLED}"

The create-service command returns a description of the task definition after it completes its registration.

Step 5: List services

List the services for your cluster. You should see the service that you created in the previous section. You can take the service name or the full ARN that is returned from this command and use it to describe the service later.

aws ecs list-services --cluster fargate-cluster

Output:

```
{
  "serviceArns": [
    "arn:aws:ecs:region:aws_account_id:service/fargate-service"
  ]
}
```

Step 6: Describe the Running Service

Describe the service using the service name retrieved earlier to get more information about the task.

aws ecs describe-services --cluster fargate-cluster --services fargate-service

If successful, this will return a description of the service failures and services. For example, in services section, you will find information on deployments, such as the status of the tasks
as running or pending. You may also find information on the task definition, the network configuration and time-stamped events. In the failures section, you will find information on failures, if any, associated with the call. For troubleshooting, see [Service Event Messages](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/service_eventmessages.html). For more information about the service description, see [Describe Services](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/service_eventmessages.html).

```json
{
  "services": [
    {
      "status": "ACTIVE",
      "pendingCount": 2,
      "launchType": "FARGATE",
      "loadBalancers": [],
      "roleArn": "arn:aws:iam:aws_account_id:role/aws-service-role/ecs.amazonaws.com/AWSServiceRoleForECS",
      "placementConstraints": [],
      "createdAt": 1510811361.128,
      "desiredCount": 2,
      "networkConfiguration": {
        "awsvpcConfiguration": {
          "subnets": ["subnet-abcd1234"],
          "securityGroups": ["sg-abcd1234"],
          "assignPublicIp": "DISABLED"
        }
      },
      "platformVersion": "LATEST",
      "serviceName": "fargate-service",
      "serviceArn": "arn:aws:ecs:region:aws_account_id:service/fargate-service",
      "deploymentConfiguration": {
        "maximumPercent": 200,
        "minimumHealthyPercent": 100
      },
      "deployments": [
        {
          "status": "PRIMARY",
          "networkConfiguration": {
            "awsvpcConfiguration": {
```
Step 6: Describe the Running Service
Step 7: Clean Up

When you are finished with this tutorial, you should clean up the associated resources to avoid incurring charges for unused resources.

Delete the service.

```bash
aws ecs delete-service --cluster fargate-cluster --service fargate-service --force
```

Delete the cluster.

```bash
aws ecs delete-cluster --cluster fargate-cluster
```

Creating a cluster with an EC2 task using the AWS CLI

The following steps help you set up a cluster, register a task definition, run a task, and perform other common scenarios in Amazon ECS with the AWS CLI. Ensure that you are using the latest version of the AWS CLI. For more information on how to upgrade to the latest version, see [Installing the AWS Command Line Interface](https://docs.aws.amazon.com/cli/latest/userguide/installing.html).

Topics

- Prerequisites
- Step 1: Create a Cluster
- Step 2: Launch an Instance with the Amazon ECS AMI
- Step 3: List Container Instances
- Step 4: Describe your Container Instance
- Step 5: Register a Task Definition
- Step 6: List Task Definitions
- Step 7: Run a Task
- Step 8: List Tasks
- Step 9: Describe the Running Task
Prerequisites

This tutorial assumes that the following prerequisites have been completed:

- The latest version of the AWS CLI is installed and configured. For more information about installing or upgrading your AWS CLI, see Installing the AWS Command Line Interface.
- The steps in Set up to use Amazon ECS have been completed.
- Your AWS user has the required permissions specified in the AmazonECS_FullAccess IAM policy example.
- You have a VPC and security group created to use. For more information, see the section called “Create a virtual private cloud”.
- (Optional) AWS CloudShell is a tool that gives customers a command line without needing to create their own EC2 instance. For more information, see What is AWS CloudShell? in the AWS CloudShell User Guide.

Step 1: Create a Cluster

By default, your account receives a default cluster when you launch your first container instance.

⚠️ Note

The benefit of using the default cluster that is provided for you is that you don't have to specify the --cluster cluster_name option in the subsequent commands. If you do create your own, non-default, cluster, you must specify --cluster cluster_name for each command that you intend to use with that cluster.

Create your own cluster with a unique name with the following command:

```
aws ecs create-cluster --cluster-name MyCluster
```

Output:

```
{
  "cluster": {
    "clusterName": "MyCluster",
    "status": "ACTIVE",
    "clusterArn": "arn:aws:ecs:region:aws_account_id:cluster/MyCluster"
  }
}
```
Step 2: Launch an Instance with the Amazon ECS AMI

You must have an Amazon ECS container instance in your cluster before you can run tasks on it. If you do not have any container instances in your cluster, see Launching an Amazon ECS Linux container instance for more information.

Step 3: List Container Instances

Within a few minutes of launching your container instance, the Amazon ECS agent registers the instance with your default cluster. You can list the container instances in a cluster by running the following command:

```
aws ecs list-container-instances --cluster default
```

Output:

```
{
    "containerInstanceArns": [
        "arn:aws:ecs:us-east-1:aws_account_id:container-instance/container_instance_ID"
    ]
}
```

Step 4: Describe your Container Instance

After you have the ARN or ID of a container instance, you can use the describe-container-instances command to get valuable information on the instance, such as remaining and registered CPU and memory resources.

```
aws ecs describe-container-instances --cluster default --container-instances container_instance_ID
```

Output:

```
{
    "failures": [],
    "containerInstances": [
        
    ]
}
```
"status": "ACTIVE",
"registeredResources": [
  {
    "integerValue": 1024,
    "longValue": 0,
    "type": "INTEGER",
    "name": "CPU",
    "doubleValue": 0.0
  },
  {
    "integerValue": 995,
    "longValue": 0,
    "type": "INTEGER",
    "name": "MEMORY",
    "doubleValue": 0.0
  },
  {
    "name": "PORTS",
    "longValue": 0,
    "doubleValue": 0.0,
    "stringSetValue": [
      "22",
      "2376",
      "2375",
      "51678"
    ],
    "type": "STRINGSET",
    "integerValue": 0
  },
  {
    "name": "PORTS_UDP",
    "longValue": 0,
    "doubleValue": 0.0,
    "stringSetValue": [],
    "type": "STRINGSET",
    "integerValue": 0
  }
],
"ec2InstanceId": "instance_id",
"agentConnected": true,
"pendingTasksCount": 0,
"remainingResources": [}
Step 4: Describe your Container Instance

```
{
  "integerValue": 1024,
  "longValue": 0,
  "type": "INTEGER",
  "name": "CPU",
  "doubleValue": 0.0
},
{
  "integerValue": 995,
  "longValue": 0,
  "type": "INTEGER",
  "name": "MEMORY",
  "doubleValue": 0.0
},
{
  "name": "PORTS",
  "longValue": 0,
  "doubleValue": 0.0,
  "stringSetValue": [
    "22",
    "2376",
    "2375",
    "51678"
  ],
  "type": "STRINGSET",
  "integerValue": 0
},
{
  "name": "PORTS_UDP",
  "longValue": 0,
  "doubleValue": 0.0,
  "stringSetValue": [],
  "type": "STRINGSET",
  "integerValue": 0
}
],
"runningTasksCount": 0,
"attributes": [
  {
    "name": "com.amazonaws.ecs.capability.privileged-container"
  },
  {
    "name": "com.amazonaws.ecs.capability.docker-remote-api.1.17"
  }
]```
You can also find the Amazon EC2 instance ID that you can use to monitor the instance in the Amazon EC2 console or with the `aws ec2 describe-instances --instance-id instance_id` command.

**Step 5: Register a Task Definition**

Before you can run a task on your ECS cluster, you must register a task definition. Task definitions are lists of containers grouped together. The following example is a simple task definition that uses a `busybox` image from Docker Hub and simply sleeps for 360 seconds. For more information about the available task definition parameters, see Amazon ECS task definitions.

```json
{
    "containerDefinitions": [
        {
            "name": "sleep",
            "image": "busybox",
            "cpu": 10,
            "command": [
                "sleep",
                "360"
            ]
        }
    ],
    "versionInfo": {
        "agentVersion": "1.5.0",
        "agentHash": "b197edd",
        "dockerVersion": "DockerVersion: 1.7.1"
    }
}
```
The above example JSON can be passed to the AWS CLI in two ways: You can save the task definition JSON as a file and pass it with the `--cli-input-json` file://path_to_file.json option. Or, you can escape the quotation marks in the JSON and pass the JSON container definitions on the command line as in the below example. If you choose to pass the container definitions on the command line, your command additionally requires a `--family` parameter that is used to keep multiple versions of your task definition associated with each other.

To use a JSON file for container definitions:

```bash
aws ecs register-task-definition --cli-input-json file://$HOME/tasks/sleep360.json
```

To use a JSON string for container definitions:

```bash
aws ecs register-task-definition --family sleep360 --container-definitions "[{"name":"sleep","image":"busybox","cpu":10,"command":["sleep","360"],"memory":10,"essential":true}]"
```

The `register-task-definition` returns a description of the task definition after it completes its registration.

```json
{
    "taskDefinition": {
        "volumes": [],
        "taskDefinitionArn": "arn:aws:ec2:us-east-1:aws_account_id:task-definition/sleep360:1",
        "containerDefinitions": [
            {
                "environment": [],
                "name": "sleep",
                "mountPoints": [],
                "image": "busybox",
                "cpu": 10,
                "portMappings": []
            }
        ]
    }
}
```
Step 6: List Task Definitions

You can list the task definitions for your account at any time with the `list-task-definitions` command. The output of this command shows the family and revision values that you can use together when calling `run-task` or `start-task`.

```bash
aws ecs list-task-definitions
```

Output:

```
{
   "taskDefinitionArns": [
      "arn:aws:ec2:us-east-1:aws_account_id:task-definition/sleep300:1",
      "arn:aws:ec2:us-east-1:aws_account_id:task-definition/sleep300:2",
      "arn:aws:ec2:us-east-1:aws_account_id:task-definition/wordpress:6"
   ]
}
```

Step 7: Run a Task

After you have registered a task for your account and have launched a container instance that is registered to your cluster, you can run the registered task in your cluster. For this example, you place a single instance of the `sleep360:1` task definition in your default cluster.
aws ecs run-task --cluster default --task-definition sleep360:1 --count 1

Output:

```
{
    "tasks": [
        {
            "taskArn": "arn:aws:ecs:us-east-1:aws_account_id:task/task_ID",
            "overrides": {
                "containerOverrides": [
                    {
                        "name": "sleep"
                    }
                ]
            },
            "lastStatus": "PENDING",
            "containerInstanceArn": "arn:aws:ecs:us-east-1:aws_account_id:container-instance/container_instance_ID",
            "clusterArn": "arn:aws:ecs:us-east-1:aws_account_id:cluster/default",
            "desiredStatus": "RUNNING",
            "taskDefinitionArn": "arn:aws:ecs:us-east-1:aws_account_id:task-definition/sleep360:1",
            "containers": [
                {
                    "containerArn": "arn:aws:ecs:us-east-1:aws_account_id:container/container_ID",
                    "taskArn": "arn:aws:ecs:us-east-1:aws_account_id:task/task_ID",
                    "lastStatus": "PENDING",
                    "name": "sleep"
                }
            ]
        }
    ]
}
```

**Step 8: List Tasks**

List the tasks for your cluster. You should see the task that you ran in the previous section. You can take the task ID or the full ARN that is returned from this command and use it to describe the task later.
Step 9: Describe the Running Task

Describe the task using the task ID retrieved earlier to get more information about the task.

```
aws ecs describe-tasks --cluster default --task task_ID
```

Output:

```
{
    "failures": [],
    "tasks": [
        {
            "taskArn": "arn:aws:ecs:us-east-1:aws_account_id:task/task_ID",
            "overrides": {
                "containerOverrides": [
                    {
                        "name": "sleep"
                    }
                ]
            },
            "lastStatus": "RUNNING",
            "containerInstanceArn": "arn:aws:ecs:us-east-1:aws_account_id:container-instance/container_instance_ID",
            "clusterArn": "arn:aws:ecs:us-east-1:aws_account_id:cluster/default",
            "desiredStatus": "RUNNING",
            "taskDefinitionArn": "arn:aws:ecs:us-east-1:aws_account_id:task-definition/sleep360:1",
            "containers": [
                {
                    "containerArn": "arn:aws:ecs:us-east-1:aws_account_id:container/container_ID"
                }
            ]
        }
    ]
}
```
Using cluster auto scaling with the AWS Management Console and the Amazon ECS console

This tutorial walks you through creating the resources for cluster auto scaling using the AWS Management Console. Where resources require a name, we will use the prefix ConsoleTutorial to ensure they all have unique names and to make them easy to locate.

Topics

• Prerequisites
• Step 1: Create an Amazon ECS cluster
• Step 2: Register a task definition
• Step 3: Run a task
• Step 4: Verify
• Step 5: Clean up

Prerequisites

This tutorial assumes that the following prerequisites have been completed:

• The steps in Set up to use Amazon ECS have been completed.
• Your AWS user has the required permissions specified in the AmazonECS_FullAccess IAM policy example.
• The Amazon ECS container instance IAM role is created. For more information, see Amazon ECS container instance IAM role.
• The Amazon ECS service-linked IAM role is created. For more information, see Using service-linked roles for Amazon ECS.
• The Auto Scaling service-linked IAM role is created. For more information, see [Service-Linked Roles for Amazon EC2 Auto Scaling](https://docs.aws.amazon.com/autoscaling/ec2/userguide/service-linked-roles.html) in the *Amazon EC2 Auto Scaling User Guide*.

• You have a VPC and security group created to use. For more information, see [the section called “Create a virtual private cloud”](https://docs.aws.amazon.com/elasticbeanstalk/latest/dg/using-elasticloadbalancing-vpc.html).

### Step 1: Create an Amazon ECS cluster

Use the following steps to create an Amazon ECS cluster.

Amazon ECS creates an Amazon EC2 Auto Scaling launch template and Auto Scaling group on your behalf as part of the AWS CloudFormation stack.

2. In the navigation pane, choose **Clusters**, and then choose **Create cluster**.
3. Under **Cluster configuration**, for **Cluster name**, enter `ConsoleTutorial-cluster`.
4. Under **Infrastructure**, clear AWS Fargate (serverless), and then select **Amazon EC2 instances**. Next, configure the Auto Scaling group which acts as the capacity provider.
   - Under **Auto Scaling group (ASG)**, select **Create new ASG**, and then provide the following details about the group:
     - For **Operating system/Architecture**, choose Amazon Linux 2.
     - For **EC2 instance type**, choose `t3.nano`.
     - For **Capacity**, enter the minimum number and the maximum number of instances to launch in the Auto Scaling group.
5. (Optional) To manage the cluster tags, expand **Tags**, and then perform one of the following operations:
   - [Add a tag] Choose **Add tag** and do the following:
     - For **Key**, enter the key name.
     - For **Value**, enter the key value.
   - [Remove a tag] Choose **Remove** to the right of the tag's Key and Value.
6. Choose **Create**.
Step 2: Register a task definition

Before you can run a task on your cluster, you must register a task definition. Task definitions are lists of containers grouped together. The following example is a simple task definition that uses an amazonlinux image from Docker Hub and simply sleeps. For more information about the available task definition parameters, see Amazon ECS task definitions.

2. In the navigation pane, choose Task definitions.
3. Choose Create new task definition, Create new task definition with JSON.
4. In the JSON editor box, paste the following contents.

```
{
    "family": "ConsoleTutorial-taskdef",
    "containerDefinitions": [
        {
            "name": "sleep",
            "image": "amazonlinux:2",
            "memory": 20,
            "essential": true,
            "command": [
                "sh",
                "-c",
                "sleep infinity"
            ]
        }
    ],
    "requiresCompatibilities": [
        "EC2"
    ]
}
```

5. Choose Create.

Step 3: Run a task

After you have registered a task definition for your account, you can run a task in the cluster. For this tutorial, you run five instances of the ConsoleTutorial-taskdef task definition in your ConsoleTutorial-cluster cluster.
2. On the Clusters page, choose ConsoleTutorial-cluster.
3. Under Tasks, choose Run new task.
4. In the Environment section, under Compute options, choose Capacity provider strategy.
5. Under Deployment configuration, for Application type, choose Task.
6. Choose ConsoleTutorial-taskdef from the Family dropdown list.
7. Under Desired tasks, enter 5.
8. Choose Create.

Step 4: Verify

At this point in the tutorial, you should have a cluster with five tasks running and an Auto Scaling group with a capacity provider. The capacity provider has Amazon ECS managed scaling enabled.

We can verify that everything is working properly by viewing the CloudWatch metrics, the Auto Scaling group settings, and finally the Amazon ECS cluster task count.

To view the CloudWatch metrics for your cluster

2. On the navigation bar at the top of the screen, select the Region.
3. On the navigation pane, under Metrics, choose All metrics.
4. On the All metrics page, under the Browse tab, choose AWS/ECS/ManagedScaling.
5. Choose CapacityProviderName, ClusterName.
6. Select the check box that corresponds to the ConsoleTutorial-cluster ClusterName.
7. Under the Graphed metrics tab, change Period to 30 seconds and Statistic to Maximum.

    The value displayed in the graph shows the target capacity value for the capacity provider. It should begin at 100, which was the target capacity percent we set. You should see it scale up to 200, which will trigger an alarm for the target tracking scaling policy. The alarm will then trigger the Auto Scaling group to scale out.

Use the following steps to view your Auto Scaling group details to confirm that the scale-out action occurred.
To verify the Auto Scaling group scaled out

1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
2. On the navigation bar at the top of the screen, select the Region.
3. On the navigation pane, under Auto Scaling, choose Auto Scaling Groups.
4. Choose the ConsoleTutorial-cluster Auto Scaling group created in this tutorial. View the value under Desired capacity and view the instances under the Instance management tab to confirm your group scaled out to two instances.

Use the following steps to view your Amazon ECS cluster to confirm that the Amazon EC2 instances were registered with the cluster and your tasks transitioned to a RUNNING status.

To verify the instances in the Auto Scaling group

2. In the navigation pane, choose Clusters.
3. On the Clusters page, choose the ConsoleTutorial-cluster cluster.
4. On the Tasks tab, confirm you see five tasks in the RUNNING status.

Step 5: Clean up

When you have finished this tutorial, clean up the resources associated with it to avoid incurring charges for resources that you aren't using. Deleting capacity providers and task definitions are not supported, but there is no cost associated with these resources.

To clean up the tutorial resources

2. In the navigation pane, choose Clusters.
4. On the ConsoleTutorial-cluster page, choose the Tasks tab, and then choose Stop, Stop all.
5. In the navigation pane, choose Clusters.
7. In the upper-right of the page, choose Delete cluster.
8. In the confirmation box, enter delete ConsoleTutorial-cluster and choose Delete.
9. Delete the Auto Scaling groups using the following steps.
   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. On the navigation bar at the top of the screen, select the Region.
   c. On the navigation pane, under Auto Scaling, choose Auto Scaling Groups.
   d. Select the ConsoleTutorial-cluster Auto Scaling group, then choose Actions.
   e. From the Actions menu, choose Delete. Enter delete in the confirmation box and then choose Delete.

Specifying Sensitive Data Using Secrets Manager Secrets

Amazon ECS enables you to inject sensitive data into your containers by storing your sensitive data in AWS Secrets Manager secrets and then referencing them in your container definition. For more information, see Passing sensitive data to a container.

The following tutorial shows how to create an Secrets Manager secret, reference the secret in an Amazon ECS task definition, and then verify it worked by querying the environment variable inside a container showing the contents of the secret.

Prerequisites

This tutorial assumes that the following prerequisites have been completed:

- The steps in Set up to use Amazon ECS have been completed.
- Your AWS user has the required IAM permissions to create the Secrets Manager and Amazon ECS resources described.

Step 1: Create an Secrets Manager Secret

You can use the Secrets Manager console to create a secret for your sensitive data. In this tutorial we will be creating a basic secret for storing a username and password to reference later in a container. For more information, see Creating a Basic Secret in the AWS Secrets Manager User Guide.

The key/value pairs to be stored in this secret is the environment variable value in your container at the end of the tutorial.
Save the **Secret ARN** to reference in your task execution IAM policy and task definition in later steps.

## Step 2: Update Your Task Execution IAM Role

In order for Amazon ECS to retrieve the sensitive data from your Secrets Manager secret, you must have the Amazon ECS task execution role and reference it in your task definition. This allows the container agent to pull the necessary Secrets Manager resources. If you have not already created your task execution IAM role, see [Amazon ECS task execution IAM role](#).

The following steps assume you already have the task execution IAM role created and properly configured.

### To update your task execution IAM role

Use the IAM console to update your task execution role with the required permissions.

2. In the navigation pane, choose Roles.
3. Search the list of roles for `ecsTaskExecutionRole` and select it.
4. Choose Permissions, Add inline policy.
5. Choose the JSON tab and specify the following JSON text, ensuring that you specify the full ARN of the Secrets Manager secret you created in step 1.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "secretsmanager:GetSecretValue"
         ],
         "Resource": [
            "arn:aws:secretsmanager:region:aws_account_id:secret:username_value"
         ]
      }
   ]
}
```

6. Choose Review policy. For Name specify `ECSSecretsTutorial`, then choose Create policy.
Step 3: Create an Amazon ECS Task Definition

You can use the Amazon ECS console to create a task definition that references a Secrets Manager secret.

To create a task definition that specifies a secret

Use the IAM console to update your task execution role with the required permissions.

2. In the navigation pane, choose Task definitions.
3. Choose Create new task definition, Create new task definition with JSON.
4. In the JSON editor box, enter the following task definition JSON text, ensuring that you specify the full ARN of the Secrets Manager secret you created in step 1 and the task execution IAM role you updated in step 2. Choose Save.

```
{
  "executionRoleArn": "arn:aws:iam::aws_account_id:role/ecsTaskExecutionRole",
  "containerDefinitions": [
    {
      "entryPoint": [
        "sh",
        "-c"
      ],
      "portMappings": [
        {
          "hostPort": 80,
          "protocol": "tcp",
          "containerPort": 80
        }
      ],
      "command": [
        "/bin/sh -c "echo '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon ECS.</p> </div></body></html>' > /usr/local/apache2/htdocs/index.html && httpd-foreground"
    ],
    "cpu": 10,
    "secrets": [
      {
        "name": "my-secret",
        "arn": "arn:aws:secretsmanager::aws_account_id:secret/my-secret"
      }
    ]
  }
}
```
6. Choose **Create**.

**Step 4: Create an Amazon ECS Cluster**

You can use the Amazon ECS console to create a cluster containing a container instance to run the task on. If you have an existing cluster with at least one container instance registered to it with the available resources to run one instance of the task definition created for this tutorial you can skip to the next step.

For this tutorial we will be creating a cluster with one **t2.micro** container instance using the Amazon ECS-optimized Amazon Linux 2 AMI.

For information about how to create a cluster for the EC2 launch type, see **the section called “Creating a cluster for the Amazon EC2 launch type using the console”**.

**Step 5: Run an Amazon ECS Task**

You can use the Amazon ECS console to run a task using the task definition you created. For this tutorial we will be running a task using the EC2 launch type, using the cluster we created in the previous step.

For information about how to run a task, see **the section called “Run an application as an Amazon ECS task”**.
**Step 6: Verify**

You can verify all of the steps were completed successfully and the environment variable was created properly in your container using the following steps.

**To verify that the environment variable was created**

1. Find the public IP or DNS address for your container instance.
   b. In the navigation pane, choose **Clusters**, and then choose the cluster you created.
   c. Choose **Infrastructure**, and then choose the container instance.
   d. Record the **Public IP** or **Public DNS** for your instance.

2. If you are using a macOS or Linux computer, connect to your instance with the following command, substituting the path to your private key and the public address for your instance:

   ```bash
   $ ssh -i /path/to/my-key-pair.pem ec2-user@ec2-198-51-100-1.compute-1.amazonaws.com
   ```

   For more information about using a Windows computer, see [Connecting to Your Linux Instance from Windows Using PuTTY](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/using-putty.html) in the *Amazon EC2 User Guide for Linux Instances*.

   **Important**

   For more information about any issues while connecting to your instance, see [Troubleshooting Connecting to Your Instance](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/troubleshooting-connecting-to-instance.html) in the *Amazon EC2 User Guide for Linux Instances*.

3. List the containers running on the instance. Note the container ID for `ecs-secrets-tutorial` container.

   ```bash
docker ps
   ```

4. Connect to the `ecs-secrets-tutorial` container using the container ID from the output of the previous step.

   ```bash
docker exec -it container_ID /bin/bash
   ```

5. Use the `echo` command to print the value of the environment variable.
echo $username_value

If the tutorial was successful, you should see the following output:

password_value

Note
Alternatively, you can list all environment variables in your container using the `env` (or `printenv`) command.

Step 7: Clean Up

When you are finished with this tutorial, you should clean up the associated resources to avoid incurring charges for unused resources.

To clean up the resources

2. In the navigation pane, choose Clusters.
3. On the Clusters page, choose the cluster.
4. Choose Delete Cluster.
5. In the confirmation box, enter delete cluster name, and then choose Delete.
7. In the navigation pane, choose Roles.
8. Search the list of roles for ecsTaskExecutionRole and select it.
9. Choose Permissions, then choose the X next to ECSSecretsTutorial. Choose Remove.
11. Select the username_value secret you created and choose Actions, Delete secret.
Creating a service using Service Discovery

Service discovery is now integrated into the Create Service wizard in the Amazon ECS console. For more information, see Creating a service using the console.

The following tutorial shows how to create an ECS service containing a Fargate task that uses service discovery with the AWS CLI.

For a list of AWS Regions that support service discovery, see Service discovery.

For information about the Regions that support Fargate, see the section called “AWS Fargate Regions”.

Prerequisites

Before you start this tutorial, make sure that the following prerequisites are met:

- The latest version of the AWS CLI is installed and configured. For more information, see Installing the AWS Command Line Interface.
- The steps described in Set up to use Amazon ECS are complete.
- Your AWS user has the required permissions specified in the AmazonECS_FullAccess IAM policy example.
- You have created at least one VPC and one security group. For more information, see the section called “Create a virtual private cloud”.

Step 1: Create the Service Discovery resources in AWS Cloud Map

Follow these steps to create your service discovery namespace and service discovery service:

1. Create a private Cloud Map service discovery namespace. This example creates a namespace that's called tutorial. Replace vpc-abcd1234 with the ID of one of your existing VPCs.

   ```bash
   aws servicediscovery create-private-dns-namespace \
     --name tutorial \
     --vpc vpc-abcd1234
   ```

   The output of this command is as follows.
2. Using the OperationId from the output of the previous step, verify that the private namespace was created successfully. Make note of the namespace ID because you use it in subsequent commands.

```bash
aws servicediscovery get-operation \
    --operation-id h2qe3s6dxftvvt7riu6lfy2f6c3jlhf4-je6chs2e
```

The output is as follows.

```
{
"Operation": {
    "Id": "h2qe3s6dxftvvt7riu6lfy2f6c3jlhf4-je6chs2e",
    "Type": "CREATE_NAMESPACE",
    "Status": "SUCCESS",
    "CreateDate": 1519777852.502,
    "UpdateDate": 1519777856.086,
    "Targets": {
        "NAMESPACE": "ns-uejictsjen2i4eeg"
    }
}
```

3. Using the NAMESPACE ID from the output of the previous step, create a service discovery service. This example creates a service named myapplication. Make note of the service ID and ARN because you use them in subsequent commands.

```bash
aws servicediscovery create-service \
    --name myapplication \
    --dns-config "NamespaceId="ns-uejictsjen2i4eeg",DnsRecords=[["Type="A",TTL="300"]]" \
    --health-check-custom-config FailureThreshold=1
```

The output is as follows.

```
{
    "Service": {
```
Step 2: Create the Amazon ECS resources

Follow these steps to create your Amazon ECS cluster, task definition, and service:

1. Create an Amazon ECS cluster. This example creates a cluster that's named tutorial.

   ```bash
   aws ecs create-cluster
   --cluster-name tutorial
   ```

2. Register a task definition that's compatible with Fargate and uses the awsvpc network mode. Follow these steps:

   a. Create a file that's named fargate-task.json with the contents of the following task definition.

   ```json
   {
       "family": "tutorial-task-def",
       "networkMode": "awsvpc",
       "containerDefinitions": [
           {
               "name": "sample-app",
               "image": "$AWS_REGION/190387766757/dotnet",
               "cpu": 1024,
               "memory": 1024
           }
       ]
   }
   ```
"image": "httpd:2.4",
"portMappings": [
    {
        "containerPort": 80,
        "hostPort": 80,
        "protocol": "tcp"
    }
],
"essential": true,
"entryPoint": [
    "sh",
    "-c"
],
"command": [
    "/bin/sh -c "\"echo '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon ECS.</p> </div></body></html>' > /usr/local/apache2/htdocs/index.html && httpd-foreground"
]}
]
,"requiresCompatibilities": [
"FARGATE"
],
"cpu": "256",
"memory": "512"
}

b. Register the task definition using fargate-task.json.

```
aws ecs register-task-definition \
    --cli-input-json file://fargate-task.json
```

3. Create an ECS service by following these steps:

   a. Create a file that's named ecs-service-discovery.json with the contents of the ECS service that you're creating. This example uses the task definition that was created in the previous step. An awsvpcConfiguration is required because the example task definition uses the awsvpc network mode.
When you create the ECS service, specify the Fargate launch type, and the LATEST platform version that supports service discovery. When the service discovery service is created in AWS Cloud Map, registryArn is the ARN returned. The securityGroups and subnets must belong to the VPC that's used to create the Cloud Map namespace. You can obtain the security group and subnet IDs from the Amazon VPC Console.

```
{
    "cluster": "tutorial",
    "serviceName": "ecs-service-discovery",
    "taskDefinition": "tutorial-task-def",
    "serviceRegistries": [
        {
            "registryArn": "arn:aws:servicediscovery:region:aws_account_id:service/srv-utcrh6wavdkggqtk"
        }
    ],
    "launchType": "FARGATE",
    "platformVersion": "LATEST",
    "networkConfiguration": {
        "awsvpcConfiguration": {
            "assignPublicIp": "ENABLED",
            "securityGroups": [ "sg-abcd1234" ],
            "subnets": [ "subnet-abcd1234" ]
        }
    },
    "desiredCount": 1
}
```

b. Create your ECS service using `ecs-service-discovery.json`.

```
aws ecs create-service \
    --cli-input-json file://ecs-service-discovery.json
```

**Step 3: Verify Service Discovery in AWS Cloud Map**

You can verify that everything is created properly by querying your service discovery information. After service discovery is configured, you can either use AWS Cloud Map API operations, or call dig from an instance within your VPC. Follow these steps:
1. Using the service discovery service ID, list the service discovery instances. Make note of the instance ID (marked in bold) for resource cleanup.

```
aws servicediscovery list-instances \
   --service-id srv-utcrh6wavdkgqtk
```

The output is as follows.

```
{
   "Instances": [
      {
         "Id": "16becc26-8558-4af1-9fbd-f81be062a266",
         "Attributes": {
            "AWS_INSTANCE_IPV4": "172.31.87.2",
            "AWS_INSTANCE_PORT": "80",
            "AVAILABILITY_ZONE": "us-east-1a",
            "REGION": "us-east-1",
            "ECS_SERVICE_NAME": "ecs-service-discovery",
            "ECS_CLUSTER_NAME": "tutorial",
            "ECS_TASK_DEFINITION_FAMILY": "tutorial-task-def"
         }
      }
   ]
}
```

2. Use the service discovery namespace, service, and additional parameters such as ECS cluster name to query details about the service discovery instances.

```
aws servicediscovery discover-instances \
   --namespace-name tutorial \
   --service-name myapplication \
   --query-parameters ECS_CLUSTER_NAME=tutorial
```

3. The DNS records that are created in the Route 53 hosted zone for the service discovery service can be queried with the following AWS CLI commands:

   a. Using the namespace ID, get information about the namespace, which includes the Route 53 hosted zone ID.

   ```
   aws servicediscovery \
      get-namespace --id ns-uejictsjen2i4eeg
   ```
The output is as follows.

```json
{
   "Namespace": {
      "Id": "ns-uejictsjen2i4eeg",
      "Name": "tutorial",
      "Type": "DNS_PRIVATE",
      "Properties": {
         "DnsProperties": {
            "HostedZoneId": "Z35JQ4ZFDRYPLV"
         }
      },
      "CreateDate": 1519777852.502,
      "CreatorRequestId": "9049a1d5-25e4-4115-8625-96dbda9a6093"
   }
}
```

b. Using the Route 53 hosted zone ID from the previous step (see the text in bold), get the resource record set for the hosted zone.

```
aws route53 list-resource-record-sets \
   --hosted-zone-id Z35JQ4ZFDRYPLV
```

4. You can also query the DNS from an instance within your VPC using `dig`.

```
dig +short myapplication.tutorial
```

**Step 4: Clean up**

When you're finished with this tutorial, clean up the associated resources to avoid incurring charges for unused resources. Follow these steps:

1. Deregister the service discovery service instances using the service ID and instance ID that you noted previously.

```
aws servicediscovery deregister-instance \
   --service-id srv-utcrh6wavdkgggqtk \
```
The output is as follows.

```
{
  "OperationId": "xhu73bserltyffhm3faqi7kumsmx274n-jh0zimzv"
}
```

2. Using the OperationId from the output of the previous step, verify that the service discovery service instances were deregistered successfully.

```
aws servicediscovery get-operation \
  --operation-id xhu73bserltyffhm3faqi7kumsmx274n-jh0zimzv
```

```
{
  "Operation": {
    "Id": "xhu73bserltyffhm3faqi7kumsmx274n-jh0zimzv",
    "Type": "DEREGISTER_INSTANCE",
    "Status": "SUCCESS",
    "CreateDate": 1525984073.707,
    "UpdateDate": 1525984076.426,
    "Targets": {
      "INSTANCE": "16becc26-8558-4af1-9fbd-f81be062a266",
      "ROUTE_53_CHANGE_ID": "C5NSRG1J4I1FH",
      "SERVICE": "srv-utcrh6wavdkggqtk"
    }
  }
}
```

3. Delete the service discovery service using the service ID.

```
aws servicediscovery delete-service \
  --id srv-utcrh6wavdkggqtk
```

4. Delete the service discovery namespace using the namespace ID.

```
aws servicediscovery delete-namespace \
  --id ns-uejictsjen2i4eeg
```

The output is as follows.

---

Step 4: Clean up
5. Using the `OperationId` from the output of the previous step, verify that the service discovery namespace was deleted successfully.

```bash
aws servicediscovery get-operation \
   --operation-id c3ncqglftesw4ibgj5baz6ktaoh6cg4t-jh0ztysj
```

The output is as follows.

```json
{
   "Operation": {
      "Id": "c3ncqglftesw4ibgj5baz6ktaoh6cg4t-jh0ztysj",
      "Type": "DELETE_NAMESPACE",
      "Status": "SUCCESS",
      "CreateDate": 1525984602.211,
      "UpdateDate": 1525984602.558,
      "Targets": {
         "NAMESPACE": "ns-rymlehshst7hhukh",
         "ROUTE_53_CHANGE_ID": "CJP2A2M86XW3O"
      }
   }
}
```

6. Update the desired count for the Amazon ECS service to 0. You must do this to delete the service in the next step.

```bash
aws ecs update-service \
   --cluster tutorial \
   --service ecs-service-discovery \
   --desired-count 0
```

7. Delete the Amazon ECS service.

```bash
aws ecs delete-service \
   --cluster tutorial \
   --service ecs-service-discovery
```

8. Delete the Amazon ECS cluster.
Creating a service using a blue/green deployment

The following tutorial shows how to create an Amazon ECS service containing a Fargate task that uses the blue/green deployment type with the AWS CLI.

**Note**
Support for performing a blue/green deployment has been added for AWS CloudFormation. For more information, see Perform Amazon ECS blue/green deployments through CodeDeploy using AWS CloudFormation in the AWS CloudFormation User Guide.

**Prerequisites**

This tutorial assumes that you have completed the following prerequisites:

- The latest version of the AWS CLI is installed and configured. For more information about installing or upgrading the AWS CLI, see Installing the AWS Command Line Interface.
- The steps in Set up to use Amazon ECS have been completed.
- Your AWS user has the required permissions specified in the AmazonECS_FullAccess IAM policy example.
- You have a VPC and security group created to use. For more information, see the section called “Create a virtual private cloud”.
- The Amazon ECS CodeDeploy IAM role is created. For more information, see Amazon ECS CodeDeploy IAM Role.

**Step 1: Create an Application Load Balancer**

Amazon ECS services using the blue/green deployment type require the use of either an Application Load Balancer or a Network Load Balancer. This tutorial uses an Application Load Balancer.
To create an Application Load Balancer

1. Use the `create-load-balancer` command to create an Application Load Balancer. Specify two subnets that aren't from the same Availability Zone as well as a security group.

   ```
   aws elbv2 create-load-balancer \
     --name bluegreen-alb \
     --subnets subnet-abcd1234 subnet-abcd5678 \
     --security-groups sg-abcd1234 \
     --region us-east-1
   ```

   The output includes the Amazon Resource Name (ARN) of the load balancer, with the following format:

   ```
   arn:aws:elasticloadbalancing:region:aws_account_id:loadbalancer/app/bluegreen-alb/e5ba62739c16e642
   ```

2. Use the `create-target-group` command to create a target group. This target group will route traffic to the original task set in your service.

   ```
   aws elbv2 create-target-group \
     --name bluegreentarget1 \
     --protocol HTTP \
     --port 80 \
     --target-type ip \
     --vpc-id vpc-abcd1234 \
     --region us-east-1
   ```

   The output includes the ARN of the target group, with the following format:

   ```
   arn:aws:elasticloadbalancing:region:aws_account_id:targetgroup/bluegreentarget1/209a844cd01825a4
   ```

3. Use the `create-listener` command to create a load balancer listener with a default rule that forwards requests to the target group.

   ```
   aws elbv2 create-listener \
     --load-balancer-arn arn:aws:elasticloadbalancing:region:aws_account_id:loadbalancer/app/bluegreen-alb/e5ba62739c16e642 \
     --protocol HTTP \
   ```
Step 2: Create an Amazon ECS cluster

Use the `create-cluster` command to create a cluster named `tutorial-bluegreen-cluster` to use.

```
aws ecs create-cluster \
  --cluster-name tutorial-bluegreen-cluster \
  --region us-east-1
```

The output includes the ARN of the cluster, with the following format:

```
```

Step 3: Register a task definition

Use the `register-task-definition` command to register a task definition that is compatible with Fargate. It requires the use of the `awsvpc` network mode. The following is the example task definition used for this tutorial.

First, create a file named `fargate-task.json` with the following contents. Ensure that you use the ARN for your task execution role. For more information, see Amazon ECS task execution IAM role.

```json
{
  "family": "tutorial-task-def",
  "networkMode": "awsvpc",
  "containerDefinitions": [
    
  ]
}
```
"name": "sample-app",
"image": "httpd:2.4",
"portMappings": [
  {
    "containerPort": 80,
    "hostPort": 80,
    "protocol": "tcp"
  }
],
"essential": true,
"entryPoint": [
  "sh",
  "-c"
],
"command": [
  "/bin/sh -c \"echo 'html<head><title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #00FFFF;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon ECS.</p> </div></body></html>' > /usr/local/apache2/htdocs/index.html && httpd-foreground"
]
"requiresCompatibilities": [
  "FARGATE"
],
"cpu": "256",
"memory": "512",
"executionRoleArn": "arn:aws:iam::aws_account_id:role/ecsTaskExecutionRole"
}

Then register the task definition using the fargate-task.json file that you created.

```bash
aws ecs register-task-definition \
  --cli-input-json file://fargate-task.json \ 
  --region us-east-1
```

**Step 4: Create an Amazon ECS service**

Use the `create-service` command to create a service.

First, create a file named `service-bluegreen.json` with the following contents.
Then create your service using the service-bluegreen.json file that you created.

```
aws ecs create-service \
  --cli-input-json file://service-bluegreen.json \
  --region us-east-1
```

The output includes the ARN of the service, with the following format:

```
arn:aws:ecs:region:aws_account_id:service/service-bluegreen
```

Obtain the DNS name of the load balancer using the following command.

Step 4: Create an Amazon ECS service
Enter the DNS name in your web browser and you should see a webpage that displays the sample app with a blue background.

**Step 5: Create the AWS CodeDeploy resources**

Use the following steps to create your CodeDeploy application, the Application Load Balancer target group for the CodeDeploy deployment group, and the CodeDeploy deployment group.

**To create CodeDeploy resources**

1. Use the `create-application` command to create a CodeDeploy application. Specify the ECS compute platform.

   ```bash
   aws deploy create-application 
   --application-name tutorial-bluegreen-app 
   --compute-platform ECS 
   --region us-east-1
   ```

   The output includes the application ID, with the following format:

   ```json
   {
     "applicationId": "b8e9c1ef-3048-424e-9174-885d7dc9dc11"
   }
   ```

2. Use the `create-target-group` command to create a second Application Load Balancer target group, which will be used when creating your CodeDeploy deployment group.

   ```bash
   aws elbv2 create-target-group 
   --name bluegreentarget2 
   --protocol HTTP 
   --port 80 
   --target-type ip 
   --vpc-id "vpc-0b6dd82c67d8012a1" 
   --region us-east-1
   ```

   The output includes the ARN for the target group, with the following format:
3. Use the `create-deployment-group` command to create a CodeDeploy deployment group.

First, create a file named `tutorial-deployment-group.json` with the following contents. This example uses the resource that you created. For the `serviceRoleArn`, specify the ARN of your Amazon ECS CodeDeploy IAM role. For more information, see Amazon ECS CodeDeploy IAM Role.

```
{
    "applicationName": "tutorial-bluegreen-app",
    "autoRollbackConfiguration": {
        "enabled": true,
        "events": [ "DEPLOYMENT_FAILURE" ]
    },
    "blueGreenDeploymentConfiguration": {
        "deploymentReadyOption": {
            "actionOnTimeout": "CONTINUE_DEPLOYMENT",
            "waitTimeInMinutes": 0
        },
        "terminateBlueInstancesOnDeploymentSuccess": {
            "action": "TERMINATE",
            "terminationWaitTimeInMinutes": 5
        }
    },
    "deploymentGroupName": "tutorial-bluegreen-dg",
    "deploymentStyle": {
        "deploymentOption": "WITH_TRAFFIC_CONTROL",
        "deploymentType": "BLUE_GREEN"
    },
    "loadBalancerInfo": {
        "targetGroupPairInfoList": [
            {
                "targetGroups": [
                    {
                        "name": "bluegreentarget1"
                    },
                    {
                        "name": "bluegreentarget2"
                    }
                ]
            }
        ]
    }
}
```
Then create the CodeDeploy deployment group.

```
aws deploy create-deployment-group \\
  --cli-input-json file://tutorial-deployment-group.json \\
  --region us-east-1
```

The output includes the deployment group ID, with the following format:

```
{
  "deploymentGroupId": "6fd9bdc6-dc51-4af5-ba5a-0a4a72431c88"
}
```

**Step 6: Create and monitor a CodeDeploy deployment**

Before creating a CodeDeploy deployment, update the task definition command in `fargate-task.json` as follows to change the sample app background color to green.

```
{
  ...
  "containerDefinitions": [
   {
   ...
Register the updated task definition using the following command.

```
aws ecs register-task-definition \\
  --cli-input-json file://fargate-task.json \\
  --region us-east-1
```

Now, use the following steps to create and upload an application specification file (AppSpec file) and an CodeDeploy deployment.

**To create and monitor a CodeDeploy deployment**

1. Create and upload an AppSpec file using the following steps.
   a. Create a file named `appspec.yaml` with the contents of the CodeDeploy deployment group. This example uses the updated task definition.

```
version: 0.0
Resources:
  - TargetService:
      Type: AWS::ECS::Service
      Properties:
        LoadBalancerInfo:
          ContainerName: "sample-app"
          ContainerPort: 80
          PlatformVersion: "LATEST"
```

   b. Use the `s3 mb` command to create an Amazon S3 bucket for the AppSpec file.
c. Use the `s3 cp` command to upload the AppSpec file to the Amazon S3 bucket.

```
aws s3 cp ./appspec.yaml s3://tutorial-bluegreen-bucket/appspec.yaml
```

2. Create the CodeDeploy deployment using the following steps.

a. Create a file named `create-deployment.json` with the contents of the CodeDeploy deployment. This example uses the resources that you created earlier in the tutorial.

```json
{
    "applicationName": "tutorial-bluegreen-app",
    "deploymentGroupName": "tutorial-bluegreen-dg",
    "revision": {
        "revisionType": "S3",
        "s3Location": {
            "bucket": "tutorial-bluegreen-bucket",
            "key": "appspec.yaml",
            "bundleType": "YAML"
        }
    }
}
```

b. Use the `create-deployment` command to create the deployment.

```
aws deploy create-deployment \
    --cli-input-json file://create-deployment.json \
    --region us-east-1
```

The output includes the deployment ID, with the following format:

```json
{
    "deploymentId": "d-RPCR1U3TW"
}
```

3. Use the `get-deployment-target` command to get the details of the deployment, specifying the deploymentId from the previous output.

```
aws deploy get-deployment-target \
    --deployment-id "d-IMJU3A8TW"
```
Initially, the deployment status is InProgress. Traffic is directed to the original task set, which has a taskSetLabel of BLUE, a status of PRIMARY, and a trafficWeight of 100.0. The replacement task set has a taskSetLabel of GREEN, a status of ACTIVE, and a trafficWeight of 0.0. The web browser you entered the DNS name in still displays the sample app with a blue background.

```json
{
  "deploymentTarget": {
    "deploymentTargetType": "ECSTarget",
    "ecsTarget": {
      "deploymentId": "d-RPCR1U3TW",
      "targetId": "tutorial-bluegreen-cluster:service-bluegreen",
      "targetArn": "arn:aws:ecs:region:aws_account_id:service/service-bluegreen",
      "lastUpdatedAt": "2023-08-10T12:07:24.797000-05:00",
      "lifecycleEvents": [
        {
          "lifecycleEventName": "BeforeInstall",
          "startTime": "2023-08-10T12:06:22.493000-05:00",
          "endTime": "2023-08-10T12:06:22.790000-05:00",
          "status": "Succeeded"
        },
        {
          "lifecycleEventName": "Install",
          "startTime": "2023-08-10T12:06:22.936000-05:00",
          "status": "InProgress"
        },
        {
          "lifecycleEventName": "AfterInstall",
          "status": "Pending"
        },
        {
          "lifecycleEventName": "BeforeAllowTraffic",
          "status": "Pending"
        },
        {
          "lifecycleEventName": "AllowTraffic",
          "status": "Pending"
        }
      ]
    }
  }
}
```
Continue to retrieve the deployment details using the command until the deployment status is Succeeded, as shown in the following output. Traffic is now redirected to the replacement task set, which now has a status of PRIMARY and a trafficWeight of 100.0. Refresh the web browser you entered the load balancer DNS name in, and you should now see the sample app with a green background.
Step 6: Create and monitor a CodeDeploy deployment

```
"deploymentTarget": {
  "deploymentTargetType": "ECSTarget",
  "ecsTarget": {
    "deploymentId": "d-RPCR1U3TW",
    "targetId": "tutorial-bluegreen-cluster:service-bluegreen",
    "targetArn": "arn:aws:ecs:region:aws_account_id:service/service-bluegreen",
    "lastUpdatedAt": "2023-08-10T12:07:24.797000-05:00",
    "lifecycleEvents": [
      {
        "lifecycleEventName": "BeforeInstall",
        "startTime": "2023-08-10T12:06:22.493000-05:00",
        "endTime": "2023-08-10T12:06:22.790000-05:00",
        "status": "Succeeded"
      },
      {
        "lifecycleEventName": "Install",
        "startTime": "2023-08-10T12:06:22.936000-05:00",
        "endTime": "2023-08-10T12:08.25939000-05:00",
        "status": "Succeeded"
      },
      {
        "lifecycleEventName": "AfterInstall",
        "startTime": "2023-08-10T12:08.26.089000-05:00",
        "endTime": "2023-08-10T12:08.26.403000-05:00",
        "status": "Succeeded"
      },
      {
        "lifecycleEventName": "BeforeAllowTraffic",
        "startTime": "2023-08-10T12:08.26.926000-05:00",
        "endTime": "2023-08-10T12:08.27.256000-05:00",
        "status": "Succeeded"
      },
      {
        "lifecycleEventName": "AllowTraffic",
        "startTime": "2023-08-10T12:08.27.416000-05:00",
        "endTime": "2023-08-10T12:08.28.195000-05:00",
        "status": "Succeeded"
      },
      {
        "lifecycleEventName": "AfterAllowTraffic",
        "startTime": "2023-08-10T12:08.28.715000-05:00",
        "endTime": "2023-08-10T12:08.28.994000-05:00",
        "status": "Succeeded"
      }
    ]
  }
}
```
Step 7: Clean up

When you have finished this tutorial, clean up the resources associated with it to avoid incurring charges for resources that you aren’t using.

Cleaning up the tutorial resources

1. Use the `delete-deployment-group` command to delete the CodeDeploy deployment group.

    ```bash
    aws deploy delete-deployment-group
    ```
2. Use the `delete-application` command to delete the CodeDeploy application.

   aws deploy delete-application \\
   --application-name tutorial-bluegreen-app \\
   --region us-east-1

3. Use the `delete-service` command to delete the Amazon ECS service. Using the `--force` flag allows you to delete a service even if it has not been scaled down to zero tasks.

   aws ecs delete-service \\
   --service arn:aws:ecs:region:aws_account_id:service/service-bluegreen \\
   --force \\
   --region us-east-1

4. Use the `delete-cluster` command to delete the Amazon ECS cluster.

   aws ecs delete-cluster \\
   --cluster tutorial-bluegreen-cluster \\
   --region us-east-1

5. Use the `s3 rm` command to delete the AppSpec file from the Amazon S3 bucket.

   aws s3 rm s3://tutorial-bluegreen-bucket/appspec.yaml

6. Use the `s3 rb` command to delete the Amazon S3 bucket.

   aws s3 rb s3://tutorial-bluegreen-bucket

7. Use the `delete-load-balancer` command to delete the Application Load Balancer.

   aws elbv2 delete-load-balancer \\
   --load-balancer-arn \\
   arn:aws:elasticloadbalancing:region:aws_account_id:loadbalancer/app/bluegreen-alb/e5ba62739c16e642 \\
   --region us-east-1

8. Use the `delete-target-group` command to delete the two Application Load Balancer target groups.
**Listening for Amazon ECS CloudWatch Events**

In this tutorial, you set up a simple AWS Lambda function that listens for Amazon ECS task events and writes them out to a CloudWatch Logs log stream.

**Prerequisite: Set up a test cluster**

If you do not have a running cluster to capture events from, follow the steps in the section called “Creating a cluster for the Fargate and External launch type using the console” to create one. At the end of this tutorial, you run a task on this cluster to test that you have configured your Lambda function correctly.

**Step 1: Create the Lambda function**

In this procedure, you create a simple Lambda function to serve as a target for Amazon ECS event stream messages.

1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. Choose Create function.
3. On the Author from scratch screen, do the following:
   a. For Name, enter a value.
   b. For Runtime, choose your version of Python, for example, Python 3.9.
   c. For Role, choose Create a new role with basic Lambda permissions.
4. Choose Create function.
5. In the **Function code** section, edit the sample code to match the following example:

```python
import json

def lambda_handler(event, context):
    if event['source'] != "aws.ecs":
        raise ValueError("Function only supports input from events with a source type of: aws.ecs")

    print('Here is the event:')
    print(json.dumps(event))
```

This is a simple Python 3.9 function that prints the event sent by Amazon ECS. If everything is configured correctly, at the end of this tutorial, you see that the event details appear in the CloudWatch Logs log stream associated with this Lambda function.

6. Choose **Save**.

### Step 2: Register an event rule

Next, you create a CloudWatch Events event rule that captures task events coming from your Amazon ECS clusters. This rule captures all events coming from all clusters within the account where it is defined. The task messages themselves contain information about the event source, including the cluster on which it resides, that you can use to filter and sort events programmatically.

**Note**

When you use the AWS Management Console to create an event rule, the console automatically adds the IAM permissions necessary to grant CloudWatch Events permission to call your Lambda function. If you are creating an event rule using the AWS CLI, you need to grant this permission explicitly. For more information, see [Events and Event Patterns](https://docs.aws.amazon.com/AmazonCloudWatch/latest/events/events-and-event-patterns.html) in the *Amazon CloudWatch Events User Guide*.

### To route events to your Lambda function

2. On the navigation pane, choose **Events, Rules, Create rule**.
3. For **Event Source**, choose **ECS** as the event source. By default, the rule applies to all Amazon ECS events for all of your Amazon ECS groups. Alternatively, you can select specific events or a specific Amazon ECS group.

4. For **Targets**, choose **Add target**, for **Target type**, choose **Lambda function**, and then select your Lambda function.

5. Choose **Configure details**.

6. For **Rule definition**, type a name and description for your rule and choose **Create rule**.

**Step 3: Create a task definition**

Create a task definition.

2. In the navigation pane, choose **Task Definitions**.
3. Choose **Create new Task Definition**, **Create new revision with JSON**.
4. Copy and paste the following example task definition into the box and then choose **Save**.

```json
{
    "containerDefinitions": [
        {
            "entryPoint": [
                "sh",
                "-c"
            ],
            "portMappings": [
                {
                    "hostPort": 80,
                    "protocol": "tcp",
                    "containerPort": 80
                }
            ],
            "command": [
                "/bin/sh -c \"echo '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>Congratulations!</h2> <p>Your application is now running on a container in Amazon ECS.</p> </div></body></html>' &>/usr/local/apache2/htdocs/index.html && httpd-foreground""
        }
    ],
    "networkConfiguration": {
        "awsvpcConfiguration": {
            "subnets": [
                "subnet-001",
                "subnet-002"
            ],
            "securityGroups": [
                "sg-001",
                "sg-002"
            ],
            "assignPublicIp": "ENABLED"
        }
    }
}
```
5. Choose Create.

**Step 4: Test your rule**

Finally, you create a CloudWatch Events event rule that captures task events coming from your Amazon ECS clusters. This rule captures all events coming from all clusters within the account where it is defined. The task messages themselves contain information about the event source, including the cluster on which it resides, that you can use to filter and sort events programmatically.

**To test your rule**

2. Choose Task definitions.
3. Choose console-sample-app-static, and then choose Deploy, Run new task.
4. For Cluster, choose default, and then choose Deploy.
6. On the navigation pane, choose Logs and select the log group for your Lambda function (for example, /aws/lambda/my-function).
7. Select a log stream to view the event data.

**Sending Amazon Simple Notification Service alerts for task stopped events**

In this tutorial, you configure an Amazon EventBridge event rule that only captures task events where the task has stopped running because one of its essential containers has terminated. The event sends only task events with a specific stoppedReason property to the designated Amazon SNS topic.
Prerequisite: Set up a test cluster

If you do not have a running cluster to capture events from, follow the steps in [Getting started with the console using Linux containers on AWS Fargate](#) to create one. At the end of this tutorial, you run a task on this cluster to test that you have configured your Amazon SNS topic and EventBridge rule correctly.

Prerequisite: Configure permissions for Amazon SNS

To allow EventBridge to publish to an Amazon SNS topic, use the `aws sns get-topic-attributes` and `aws sns set-topic-attributes` commands.

For information about how to add the permission, see [Amazon SNS permissions](#) in the *Amazon Simple Notification Service Developer Guide*.

Add the following permissions:

```json
{
    "Sid": "PublishEventsToMyTopic",
    "Effect": "Allow",
    "Principal": {
        "Service": "events.amazonaws.com"
    },
    "Action": "sns: Publish",
}
```

Step 1: Create and subscribe to an Amazon SNS topic

For this tutorial, you configure an Amazon SNS topic to serve as an event target for your new event rule.

For information about how to create and subscribe to an Amazon SNS topic, see [Getting started with Amazon SNS](#) in the *Amazon Simple Notification Service Developer Guide* and use the following table to determine what options to select.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Standard</td>
</tr>
</tbody>
</table>
Step 2: Register an event rule

Next, you register an event rule that captures only task-stopped events for tasks with stopped containers.

For information about how to create and subscribe to an Amazon SNS topic, see Create a rule in Amazon EventBridge in the Amazon EventBridge User Guide and use the following table to determine what options to select.

<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>TaskStoppedAlert</td>
</tr>
<tr>
<td>Protocol</td>
<td>Email</td>
</tr>
<tr>
<td>Endpoint</td>
<td>An email address to which you currently have access</td>
</tr>
</tbody>
</table>

```json
{
    "source":[
        "aws.ecs"
    ],
    "detail-type":[
        "ECS Task State Change"
    ],
    "detail":{
        "lastStatus":[
            "STOPPED"
        ],
        "stoppedReason":[
```
<table>
<thead>
<tr>
<th>Option</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target type</td>
<td>AWS service</td>
</tr>
<tr>
<td>Target</td>
<td>SNS topic</td>
</tr>
<tr>
<td>Topic</td>
<td>TaskStoppedAlert (The topic you created in Step 1)</td>
</tr>
</tbody>
</table>

**Step 3: Test your rule**

Verify that the rule is working by running a task that exits shortly after it starts. If your event rule is configured correctly, you receive an email message within a few minutes with the event text. If you have an existing task definition that can satisfy the rule requirements, run a task using it. If you do not, the following steps will walk you through registering a Fargate task definition and running it that will.

2. In the navigation pane, choose **Task definitions**.
3. Choose **Create new task definition, Create new task definition with JSON**.
4. In the JSON editor box, edit your JSON file, copy the following into the editor.

```json
{
    "containerDefinitions": [
        {
            "command": [
                "sh",
                "-c",
                "sleep 5"
            ],
            "essential": true,
            "image": "amazonlinux:2",
            "Essential container in task exited"
        }
    ]
}
```
"name":"test-sleep"
],
"cpu":"256",
"executionRoleArn":"arn:aws:iam::012345678910:role/ecsTaskExecutionRole",
"family":"fargate-task-definition",
"memory":"512",
"networkMode":"awsvpc",
"requiresCompatibilities":[
  "FARGATE"
]
}

5. Choose **Create**.

**To run a task from the console**

2. On the **Clusters** page, choose the cluster you created in the prerequisites.
3. From the **Tasks** tab, choose **Run new task**.
4. For **Application type**, choose **Task**.
5. For **Task definition**, choose **fargate-task-definition**.
6. For **Desired tasks**, enter the number of tasks to launch.
7. Choose **Create**.

**Concatenate multiline or stack-trace log messages**

Beginning with AWS for Fluent Bit version 2.22.0, a multiline filter is included. The multiline filter helps concatenate log messages that originally belong to one context but were split across multiple records or log lines. For more information about the multiline filter, see the [Fluent Bit documentation](https://docs.fluentd.org/en/orbital/fluent-bit-guide).

Common examples of split log messages are:

- Stack traces.
- Applications that print logs on multiple lines.
Log messages that were split because they were longer than the specified runtime max buffer size. You can concatenate log messages split by the container runtime by following the example on GitHub: FireLens Example: Concatenate Partial/Split Container Logs.

Required IAM permissions

You have the necessary IAM permissions for the container agent to pull the container images from Amazon ECR and for the container to route logs to CloudWatch Logs.

For these permissions, you must have the following roles:

- A task IAM role.
- An Amazon ECS task execution IAM role.

To use the JSON policy editor to create a policy

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.
2. In the navigation pane on the left, choose Policies.
   
   If this is your first time choosing Policies, the Welcome to Managed Policies page appears. Choose Get Started.
3. At the top of the page, choose Create policy.
4. In the Policy editor section, choose the JSON option.
5. Enter the following JSON policy document:

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "logs:CreateLogStream",
            "logs:CreateLogGroup",
            "logs:PutLogEvents"
         ],
         "Resource": "*
      }
   ]
}
```
6. Choose Next.

Note

You can switch between the Visual and JSON editor options anytime. However, if you make changes or choose Next in the Visual editor, IAM might restructure your policy to optimize it for the visual editor. For more information, see Policy restructuring in the IAM User Guide.

7. On the Review and create page, enter a Policy name and a Description (optional) for the policy that you are creating. Review Permissions defined in this policy to see the permissions that are granted by your policy.

8. Choose Create policy to save your new policy.

Determine when to use the multiline log setting

The following are example log snippets that you see in the CloudWatch Logs console with the default log setting. You can look at the line that starts with log to determine if you need the multiline filter. When the context is the same, you can use the multiline log setting, in this example, the context is "

```
2022-09-20T15:47:56:595-05-00   {"container_id":
  "82ba37cada1d44d389b03e78caf74faa-EXAMPLE", "container_name": "example-app", "source": "stdout", "log": "at com.myproject.model.MyProject.badMethod(MyProject.java:22)",
  {
    "container_id": "82ba37cada1d44d389b03e78caf74faa-EXAMPLE",
    "container_name": "example-app",
    "source": "stdout",
    "log": "at com.myproject.model.MyProject.badMethod(MyProject.java:22)",
    "ecs_cluster": "default",
    "ecs_task_arn": "arn:aws:region:123456789012:task/default/b23c940d29ed4714971c872cEXAMPLE",
    "ecs_task_definition": "firelense-example-multiline:3"
  }
```
After you use the multiline log setting, the output will look similar to the example below.

```
2022-09-20T15:47:56:595-05-00   {"container_id":
"82ba37cada1d44d389b03e78caf74faa-EXAMPLE", "container_name": "example-app", "stdout",
"log": " at com.myproject.model.MyProject.oneMoreMethod(MyProject.java:18)",
{
"container_id": "82ba37cada1d44d389b03e78caf74faa-EXAMPLE",
"container_name": "example-app",
"source": "stdout",
"log": " at com.myproject.module.MyProject.badMethod(MyProject.java:22)"
"ecs_cluster": "default",
"ecs_task_arn": "arn:aws:region:123456789012:task/default/b23c940d29ed4714971cbe72cEXAMPLE",
"ecs_task_definition": "firelense-example-multiline:2"
}

Parse and concatenate options

To parse logs and concatenate lines that were split because of newlines, you can use either of these two options.
```
• Use your own parser file that contains the rules to parse and concatenate lines that belong to the same message.

• Use a Fluent Bit built-in parser. For a list of languages supported by the Fluent Bit built-in parsers, see Fluent Bit documentation.

The following tutorial walks you through the steps for each use case. The steps show you how to concatenate multilines and send the logs to Amazon CloudWatch. You can specify a different destination for your logs.

Example: Use a parser that you create

In this example, you will complete the following steps:

1. Build and upload the image for a Fluent Bit container.
2. Build and upload the image for a demo multiline application that runs, fails, and generates a multiline stack trace.
3. Create the task definition and run the task.
4. View the logs to verify that messages that span multiple lines appear concatenated.

Build and upload the image for a Fluent Bit container

This image will include the parser file where you specify the regular expression and a configuration file that references the parser file.

1. Create a folder with the name FluentBitDockerImage.
2. Within the folder, create a parser file that contains the rules to parse the log and concatenate lines that belong in the same message.
   a. Paste the following contents in the parser file:

```plaintext
[MULTILINE_PARSER]
name       multiline-regex-test
type       regex
flush_timeout 1000
#
# Regex rules for multiline parsing
# ---------------------------------
#
# configuration hints:
```

Parse and concatenate options
As you customize your regex pattern, we recommend you use a regular expression editor to test the expression.

b. Save the file as parsers_multiline.conf.

3. Within the FluentBitDockerImage folder, create a custom configuration file that references the parser file that you created in the previous step.

For more information about the custom configuration file, see Specifying a custom configuration file in the Amazon Elastic Container Service Developer Guide

a. Paste the following contents in the file:

```
[SERVICE]
flush                 1
log_level             info
parsers_file          /parsers_multiline.conf

[FILTER]
name                  multiline
match                 *
multiline.key_content log
multiline.parser      multiline-regex-test
```

**Note**

You must use the absolute path of the parser.

b. Save the file as extra.conf.

4. Within the FluentBitDockerImage folder, create the Dockerfile with the Fluent Bit image and the parser and configuration files that you created.

a. Paste the following contents in the file:
FROM public.ecr.aws/aws-observability/aws-for-fluent-bit:latest

ADD parsers_multiline.conf /parsers_multiline.conf
ADD extra.conf /extra.conf

b. Save the file as Dockerfile.

5. Using the Dockerfile, build a custom Fluent Bit image with the parser and custom configuration files included.

   a. Build the image: docker build -t fluent-bit-multiline-image .

      Where: fluent-bit-multiline-image is the name for the image in this example.

   b. Verify that the image was created correctly: docker images --filter reference=fluent-bit-multiline-image

      If successful, the output shows the image and the latest tag.

6. Upload the custom Fluent Bit image to Amazon Elastic Container Registry.

   a. Create an Amazon ECR repository to store the image: aws ecr create-repository --repository-name fluent-bit-multiline-repo --region us-east-1

      Where: fluent-bit-multiline-repo is the name for the repository and us-east-1 is the region in this example.

      The output gives you the details of the new repository.

   b. Tag your image with the repositoryUri value from the previous output: docker tag fluent-bit-multiline-image repositoryUri

      Example: docker tag fluent-bit-multiline-image xxxxxxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com/fluent-bit-multiline-repo
c. Run the docker image to verify it ran correctly: `docker images --filter reference=repositoryUri`

   In the output, the repository name changes from fluent-bit-multiline-repo to the repositoryUri.

d. Authenticate to Amazon ECR by running the `aws ecr get-login-password` command and specifying the registry ID you want to authenticate to: `aws ecr get-login-password | docker login --username AWS --password-stdin registry ID.dkr.ecr.region.amazonaws.com`

   Example: `ecr get-login-password | docker login --username AWS --password-stdin xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com`

   A successful login message appears.

e. Push the image to Amazon ECR: `docker push registry ID.dkr.ecr.region.amazonaws.com/repository name`

   Example: `docker push xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com/fluent-bit-multiline-repo`

**Build and upload the image for a demo multiline application**

This image will include a Python script file that runs the application and a sample log file.

When you run the task, the application simulates runs, then fails and creates a stack trace.

1. Create a folder named `multiline-app`: `mkdir multiline-app`

2. Create a Python script file.

   a. Within the `multiline-app` folder, create a file and name it `main.py`.

   b. Paste the following contents in the file:

```python
import os
import time
file1 = open('/test.log', 'r')
Lines = file1.readlines()
count = 0
```

Parse and concatenate options 1264
for i in range(10):
    print("app running normally...")
    time.sleep(1)

    # Strips the newline character
for line in Lines:
    count += 1
    print(line.rstrip())
print(count)
print("app terminated.")

c. Save the main.py file.

3. Create a sample log file.

   a. Within the multiline-app folder, create a file and name it test.log.
   b. Paste the following contents in the file:

   single line...
Dec 14 06:41:08 Exception in thread "main" java.lang.RuntimeException: Something has gone wrong, aborting!
   at com.myproject.module.MyProject.badMethod(MyProject.java:22)
   at com.myproject.module.MyProject.oneMoreMethod(MyProject.java:18)
   at com.myproject.module.MyProject.anotherMethod(MyProject.java:14)
   at com.myproject.module.MyProject.someMethod(MyProject.java:10)
   at com.myproject.module.MyProject.main(MyProject.java:6)
   another line...

c. Save the test.log file.

4. Within the multiline-app folder, create the Dockerfile.

   a. Paste the following contents in the file:

   FROM public.ecr.aws/amazonlinux/amazonlinux:latest
ADD test.log /test.log

RUN yum upgrade -y && yum install -y python3

WORKDIR /usr/local/bin

COPY main.py .
b. Save the Dockerfile file.

5. Using the Dockerfile, build an image.

   a. Build the image: docker build -t multiline-app-image .

      Where: multiline-app-image is the name for the image in this example.

   b. Verify that the image was created correctly: docker images --filter reference=multiline-app-image

      If successful, the output shows the image and the latest tag.

6. Upload the image to Amazon Elastic Container Registry.

   a. Create an Amazon ECR repository to store the image: aws ecr create-repository --repository-name multiline-app-repo --region us-east-1

      Where: multiline-app-repo is the name for the repository and us-east-1 is the region in this example.

      The output gives you the details of the new repository. Note the repositoryUri value as you will need it in the next steps.

   b. Tag your image with the repositoryUri value from the previous output: docker tag multiline-app-image repositoryUri

      Example: docker tag multiline-app-image xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com/multiline-app-repo

   c. Run the docker image to verify it ran correctly: docker images --filter reference=repositoryUri

      In the output, the repository name changes from multiline-app-repo to the repositoryUri value.

   d. Push the image to Amazon ECR: docker push aws_account_id.dkr.ecr.region.amazonaws.com/repository name

      Example: docker push xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com/multiline-app-repo
Create the task definition and run the task

1. Create a task definition file with the file name `multiline-task-definition.json`.
2. Paste the following contents in the `multiline-task-definition.json` file:

```json
{
  "family": "firelens-example-multiline",
  "taskRoleArn": "task role ARN",
  "executionRoleArn": "execution role ARN",
  "containerDefinitions": [
    {
      "essential": true,
      "image": "aws_account_id.dkr.ecr.us-east-1.amazonaws.com/fluent-bit-multiline-image:latest",
      "name": "log_router",
      "firelensConfiguration": {
        "type": "fluentbit",
        "options": {
          "config-file-type": "file",
          "config-file-value": "/extra.conf"
        }
      },
      "memoryReservation": 50
    },
    {
      "essential": true,
      "image": "aws_account_id.dkr.ecr.us-east-1.amazonaws.com/multiline-app-image:latest",
      "name": "app",
      "logConfiguration": {
        "logDriver": "awsfirelens",
        "options": {
          "Name": "cloudwatch_logs",
          "region": "us-east-1",
          "log_group_name": "multiline-test/application",
          "auto_create_group": "true",
          "log_stream_prefix": "multiline-"
        }
      },
      "memoryReservation": 100
    }
  ],
  "requiresCompatibilities": ["FARGATE"],
```
Replace the following in the `multiline-task-definition.json` task definition:

a. **task role ARN**

   To find the task role ARN, go to the IAM console. Choose **Roles** and find the `ecs-task-role-for-firelens` task role that you created. Choose the role and copy the ARN that appears in the **Summary** section.

b. **execution role ARN**

   To find the execution role ARN, go to the IAM console. Choose **Roles** and find the `ecsTaskExecutionRole` role. Choose the role and copy the ARN that appears in the **Summary** section.

c. **aws_account_id**

   To find your `aws_account_id`, log into the AWS Management Console. Choose your username on the top right and copy your Account ID.

d. **us-east-1**

   Replace the region if necessary.

3. Register the task definition file: `aws ecs register-task-definition --cli-input-json file://multiline-task-definition.json --region region`

5. In the navigation pane, choose **Task Definitions** and then choose the `firelens-example-multiline` family because we registered the task definition to this family in the first line of the task definition above.

6. Choose the latest version.

7. Choose the **Deploy, Run task**.

8. On the **Run Task** page, for **Cluster**, choose the cluster, and then under **Networking**, for **Subnets**, choose the available subnets for your task.

9. Choose **Create**.
Verify that multiline log messages in Amazon CloudWatch appear concatenated

2. From the navigation pane, expand Logs and choose Log groups.
3. Choose the multiline-test/applicatio log group.
4. Choose the log. View messages. Lines that matched the rules in the parser file are concatenated and appear as a single message.

The following log snippet shows lines concatenated in a single Java stack trace event:

```json
{
  "container_id": "xxxxxx",
  "container_name": "app",
  "source": "stdout",
  "log": "Dec 14 06:41:08 Exception in thread "main"
  "ecs_cluster": "default",
  "ecs_task_arn": "arn:aws:ecs:us-east-1:xxxxxxxxxxxx:task/default/xxxxxx",
  "ecs_task_definition": "firelens-example-multiline:2"
}
```

The following log snippet shows how the same message appears with just a single line if you run an Amazon ECS container that is not configured to concatenate multiline log messages.

```json
{
  "log": "Dec 14 06:41:08 Exception in thread "main"
java.lang.RuntimeException: Something has gone wrong, aborting!",
  "container_id": "xxxxxx-xxxxxx",
  "container_name": "app",
  "source": "stdout",
  "ecs_cluster": "default",
  "ecs_task_arn": "arn:aws:ecs:us-east-1:xxxxxxxxxxxx:task/default/xxxxxx",
  "ecs_task_definition": "firelens-example-multiline:3"
}
```
Example: Use a Fluent Bit built-in parser

In this example, you will complete the following steps:

1. Build and upload the image for a Fluent Bit container.
2. Build and upload the image for a demo multiline application that runs, fails, and generates a multiline stack trace.
3. Create the task definition and run the task.
4. View the logs to verify that messages that span multiple lines appear concatenated.

Build and upload the image for a Fluent Bit container

This image will include a configuration file that references the Fluent Bit parser.

1. Create a folder with the name FluentBitDockerImage.
2. Within the FluentBitDockerImage folder, create a custom configuration file that references the Fluent Bit built-in parser file.

   For more information about the custom configuration file, see Specifying a custom configuration file in the Amazon Elastic Container Service Developer Guide

   a. Paste the following contents in the file:

      ```
      [FILTER]
      name                  multiline
      match                 *
      multiline.key_content log
      multiline.parser      go
      ```

   b. Save the file as extra.conf.

3. Within the FluentBitDockerImage folder, create the Dockerfile with the Fluent Bit image and the parser and configuration files that you created.

   a. Paste the following contents in the file:

      ```
      FROM public.ecr.aws/aws-observability/aws-for-fluent-bit:latest
      ADD extra.conf /extra.conf
      ```

   b. Save the file as Dockerfile.
4. Using the Dockerfile, build a custom Fluent Bit image with the custom configuration file included.

   a. Build the image: `docker build -t fluent-bit-multiline-image .`

      Where: `fluent-bit-multiline-image` is the name for the image in this example.
   
   b. Verify that the image was created correctly: `docker images --filter reference=fluent-bit-multiline-image`

      If successful, the output shows the image and the latest tag.

5. Upload the custom Fluent Bit image to Amazon Elastic Container Registry.

   a. Create an Amazon ECR repository to store the image: `aws ecr create-repository --repository-name fluent-bit-multiline-repo --region us-east-1`

      Where: `fluent-bit-multiline-repo` is the name for the repository and `us-east-1` is the region in this example.

      The output gives you the details of the new repository.
   
   b. Tag your image with the `repositoryUri` value from the previous output: `docker tag fluent-bit-multiline-image repositoryUri`

      Example: `docker tag fluent-bit-multiline-image xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com/fluent-bit-multiline-repo`
   
   c. Run the docker image to verify it ran correctly: `docker images --filter reference=repositoryUri`

      In the output, the repository name changes from `fluent-bit-multiline-repo` to the `repositoryUri`.
   
   d. Authenticate to Amazon ECR by running the `aws ecr get-login-password` command and specifying the registry ID you want to authenticate to: `aws ecr get-login-`
password | docker login --username AWS --password-stdin registry ID.dkr.ecr.region.amazonaws.com

e.g.  ecr get-login-password | docker login --username AWS --password-stdin xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com

A successful login message appears.

e. Push the image to Amazon ECR: docker push registry ID.dkr.ecr.region.amazonaws.com/repository name

Example: docker push xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com/fluent-bit-multiline-repo

Build and upload the image for a demo multiline application

This image will include a Python script file that runs the application and a sample log file.

1. Create a folder named multiline-app: mkdir multiline-app

2. Create a Python script file.

   a. Within the multiline-app folder, create a file and name it main.py.

   b. Paste the following contents in the file:

```python
import os
import time

file1 = open('/test.log', 'r')
Lines = file1.readlines()

count = 0

for i in range(10):
    print("app running normally...")
    time.sleep(1)

# Strips the newline character
for line in Lines:
    count += 1
    print(line.rstrip())
print(count)
print("app terminated.")
```
c. Save the `main.py` file.

3. Create a sample log file.

   a. Within the multiline-app folder, create a file and name it `test.log`.
   
   b. Paste the following contents in the file:

   ```
   panic: my panic
   
goroutine 4 [running]:
panic(0x45cb40, 0x47ad70)
   /usr/local/go/src/runtime/panic.go:542 +0x46c fp=0xc42003f7b8 sp=0xc42003f710
   pc=0x422f7c
   main.main.func1(0xc420024120)
   foo.go:6 +0x39 fp=0xc42003f7d8 sp=0xc42003f7b8 pc=0x451339
   runtime.goexit() 
   /usr/local/go/src/runtime/asm_amd64.s:2337 +0x1 fp=0xc42003f7e0
   sp=0xc42003f7d8 pc=0x44b4d1
   created by main.main

   foo.go:9 +0x6f fp=0xc20053f80 sp=0xc20053f50 pc=0x4512ef
routine.main() 
   /usr/local/go/src/runtime/proc.go:185 +0x20d fp=0xc20053fe0 sp=0xc20053f80
   pc=0x424bad
runtime.goexit() 
   /usr/local/go/src/runtime/asm_amd64.s:2337 +0x1 fp=0xc20053fe8
   sp=0xc20053f00 pc=0x44b4d1
   ```
c. Save the test.log file.

4. Within the multiline-app folder, create the Dockerfile.

a. Paste the following contents in the file:

```
FROM public.ecr.aws/amazonlinux/amazonlinux:latest
ADD test.log /test.log

RUN yum upgrade -y && yum install -y python3
```
WORKDIR /usr/local/bin
COPY main.py .
CMD ["python3", "main.py"]

b. Save the Dockerfile file.

5. Using the Dockerfile, build an image.
   a. Build the image: docker build -t multiline-app-image .
      Where: multiline-app-image is the name for the image in this example.
   b. Verify that the image was created correctly: docker images --filter reference=multiline-app-image
      If successful, the output shows the image and the latest tag.

6. Upload the image to Amazon Elastic Container Registry.
   a. Create an Amazon ECR repository to store the image: aws ecr create-repository --repository-name multiline-app-repo --region us-east-1
      Where: multiline-app-repo is the name for the repository and us-east-1 is the region in this example.
      The output gives you the details of the new repository. Note the repositoryUri value as you will need it in the next steps.
   b. Tag your image with the repositoryUri value from the previous output: docker tag multiline-app-image repositoryUri
      Example: docker tag multiline-app-image xxxxxxxxxxxx.dkr.ecr.us-east-1.amazonaws.com/multiline-app-repo
   c. Run the docker image to verify it ran correctly: docker images --filter reference=repositoryUri
      In the output, the repository name changes from multiline-app-repo to the repositoryUri value.
   d. Push the image to Amazon ECR: docker push aws_account_id.dkr.ecr.region.amazonaws.com/repository_name
Example: docker push $xxxxx$.dkr.ecr.us-east-1.amazonaws.com/multiline-app-repo

Create the task definition and run the task

1. Create a task definition file with the file name multiline-task-definition.json.
2. Paste the following contents in the multiline-task-definition.json file:

```json
{
    "family": "firelens-example-multiline",
    "taskRoleArn": "task role ARN",
    "executionRoleArn": "execution role ARN",
    "containerDefinitions": [
        {
            "essential": true,
            "image": "aws_account_id.dkr.ecr.us-east-1.amazonaws.com/fluent-bit-multiline-image:latest",
            "name": "log_router",
            "firelensConfiguration": {
                "type": "fluentbit",
                "options": {
                    "config-file-type": "file",
                    "config-file-value": "/extra.conf"
                }
            },
            "memoryReservation": 50
        },
        {
            "essential": true,
            "image": "aws_account_id.dkr.ecr.us-east-1.amazonaws.com/multiline-app-image:latest",
            "name": "app",
            "logConfiguration": {
                "logDriver": "awsfirelens",
                "options": {
                    "Name": "cloudwatch_logs",
                    "region": "us-east-1",
                    "log_group_name": "multiline-test/application",
                    "auto_create_group": "true",
                    "log_stream_prefix": "multiline-"
                }
            }
        }
    ]
}
```

Parse and concatenate options
Replace the following in the multiline-task-definition.json task definition:

a. **task role ARN**

   To find the task role ARN, go to the IAM console. Choose **Roles** and find the ecs-task-role-for-firelens task role that you created. Choose the role and copy the **ARN** that appears in the **Summary** section.

b. **execution role ARN**

   To find the execution role ARN, go to the IAM console. Choose **Roles** and find the ecsTaskExecutionRole role. Choose the role and copy the **ARN** that appears in the **Summary** section.

c. **aws_account_id**

   To find your **aws_account_id**, log into the AWS Management Console. Choose your user name on the top right and copy your Account ID.

d. **us-east-1**

   Replace the region if necessary.

3. Register the task definition file: `aws ecs register-task-definition --cli-input-json file://multiline-task-definition.json --region us-east-1`

5. In the navigation pane, choose **Task Definitions** and then choose the firelens-example-multiline family because we registered the task definition to this family in the first line of the task definition above.

6. Choose the latest version.

7. Choose the **Deploy, Run task**.
8. On the Run Task page, For Cluster, choose the cluster, and then under Networking, for Subnets, choose the available subnets for your task.

9. Choose Create.

**Verify that multiline log messages in Amazon CloudWatch appear concatenated**

2. From the navigation pane, expand Logs and choose Log groups.
3. Choose the multiline-test/applicatio log group.
4. Choose the log and view the messages. Lines that matched the rules in the parser file are concatenated and appear as a single message.

The following log snippet shows a Go stack trace that is concatenated into a single event:

```json
{
    "log": "panic: my panic
    
    goroutine 4 [running]:
    panic(0x45cb40, 0x47ad70) /usr/local/go/src/runtime/panic.go:542 +0x46c fp=0xc42003f7b8 sp=0xc42003f710 pc=0x422f7c
    main.main.func1(0xc420024120) /usr/local/go/src/runtime/asm_amd64.s:2337 +0x1 fp=0xc42003f7e0 sp=0xc42003f7d8 pc=0x44b4d1
    created by main.main
    foo.go:6
    +0x39 fp=0xc42003f7d8 sp=0xc42003f7b8 pc=0x451339
    runtime.goexit() /usr/local/go/src/runtime/asm_amd64.s:2337 +0x1 fp=0xc42003f7e0 sp=0xc42003f7d8 pc=0x44b4d1
    
    goroutine 1 [chan receive]:
    runtime.gopark(0x4739b8, 0xc420024178, 0x46fcd7, 0xc, 0xc420028e17, 0x3) /usr/local/go/src/runtime/proc.go:280 +0x12c fp=0xc420053e30 sp=0xc420053e0 pc=0xc420053e70 pc=0x42512d
    runtime.chanrecv1(0xc420024120, 0x0, 0xc420053f01, 0x4512d8) /usr/local/go/src/runtime/chan.go:388 +0x2b fp=0xc420053f50 sp=0xc420053f20 pc=0x40439b
    main.main() foo.go:9 +0x6f fp=0xc420053f80 sp=0xc420053f50 pc=0x4512ef
    runtime.main() /usr/local/go/src/runtime/proc.go:185 +0x20d fp=0xc420053fe0 sp=0xc420053f80 pc=0x424bad
    runtime.goexit() /usr/local/go/src/runtime/asm_amd64.s:2337 +0x1 fp=0xc420053fe8 sp=0xc420053f80 pc=0x44b4d1
    
    goroutine 2 [force gc (idle)]:
    runtime.gopark(0x4739b8, 0x4ad720, 0x4f7001e, 0xf, 0x14, 0x1) /usr/local/go/src/runtime/proc.go:280 +0x12c fp=0xc42003e78 sp=0xc42003e768 pc=0x42503c
    runtime.goparkunlock(0x4ad720, 0x4f7001e, 0xf, 0xc420000114, 0x1) /usr/local/go/src/runtime/asm_amd64.s:2337 +0x1 fp=0xc42003e768 sp=0xc42003e768 pc=0x42512d
    runtime.forcegchelper() /usr/local/go/src/runtime/proc.go:238 +0x5e fp=0xc42003e7a8 sp=0xc42003e7a8 pc=0x424e5c
    runtime.goexit() /usr/local/go/src/runtime/asm_amd64.s:2337 +0x1 fp=0xc42003e7e0 sp=0xc42003e7e0
```
The following log snippet shows how the same event appears if you run an ECS container that is not configured to concatenate multiline log messages. The log field contains a single line.

{  
  "log": "panic: my panic",  
  "container_id": "xxxxxx-xxxxxx",  
  "container_name": "app",  
  "source": "stdout",  
  "ecs_cluster": "default",  
  "ecs_task_arn": "arn:aws:ecs:us-east-1:xxxxxxxxxxxx:task/default/xxxxxx",  
  "ecs_task_definition": "firelens-example-multiline:3"
}

Note

If your logs go to log files instead of the standard output, we recommend specifying the multiline.parser and multiline.key_content configuration parameters in the Tail input plugin instead of the Filter.
Using Amazon EFS file systems with Amazon ECS using the console

Amazon Elastic File System (Amazon EFS) provides simple, scalable file storage for use with your Amazon ECS tasks. With Amazon EFS, storage capacity is elastic, growing and shrinking automatically as you add and remove files. Your applications can have the storage they need, when they need it.

You can use Amazon EFS file systems with Amazon ECS to access file system data across your fleet of Amazon ECS tasks. That way, your tasks have access to the same persistent storage, no matter the infrastructure or container instance on which they land. When you reference your Amazon EFS file system and container mount point in your Amazon ECS task definition, Amazon ECS takes care of mounting the file system in your container. The following sections help you get started using Amazon EFS with Amazon ECS.

This feature is supported by tasks that use both the EC2 and Fargate launch types, however this tutorial will use an Amazon ECS task that uses the EC2 launch type. This tutorial is also meant to be followed step by step, however if you already have some of these resources created on your account then you may be able to skip some steps.

### Note

Amazon EFS may not be available in all Regions. For more information about which Regions support Amazon EFS, see [Amazon Elastic File System Endpoints and Quotas](https://docs.aws.amazon.com/efs/latest/ug/endpoints.html) in the AWS General Reference.

### Step 1: Create an Amazon ECS cluster

Use the following steps to create an Amazon ECS cluster.

**To create a new cluster (Amazon ECS console)**

Before you begin, assign the appropriate IAM permission. For more information, see the section called “Cluster examples”.

2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, choose **Create cluster**.
5. Under **Cluster configuration**, for **Cluster name**, enter EFS-tutorial for the cluster name.
6. (Optional) To change the VPC and subnets where your tasks and services launch, under **Networking**, perform any of the following operations:
   - To remove a subnet, under **Subnets**, choose X for each subnet that you want to remove.
   - To change to a VPC other than the default VPC, under **VPC**, choose an existing **VPC**, and then under **Subnets**, select each subnet.
7. To add Amazon EC2 instances to your cluster, expand **Infrastructure**, and then select **Amazon EC2 instances**. Next, configure the Auto Scaling group which acts as the capacity provider:
   - To create a Auto Scaling group, from **Auto Scaling group (ASG)**, select **Create new group**, and then provide the following details about the group:
     - For **Operating system/Architecture**, choose Amazon Linux 2.
     - For **EC2 instance type**, choose **t2.micro**.
     - For **SSH key pair**, choose the pair that proves your identity when you connect to the instance.
     - For **Capacity**, enter 1.
8. Choose **Create**.

**Step 2: Create a security group for Amazon EC2 instances and the Amazon EFS file system**

In this step, you create a security group for your Amazon EC2 instances that allows inbound network traffic on port 80 and your Amazon EFS file system that allows inbound access from your container instances.

Create a security group for your Amazon EC2 instances with the following options:

- **Security group name** - a unique name for your security group.
- **VPC** - the VPC that you identified earlier for your cluster.
- **Inbound rule**
  - **Type** - HTTP
• Source - 0.0.0.0/0.

Create a security group for your Amazon EFS file system with the following options:

• **Security group name** - a unique name for your security group. For example, EFS-access-for-sg-\textit{dc025fa2}.

• **VPC** - the VPC that you identified earlier for your cluster.

• **Inbound rule**
  • **Type** - NFS
  • **Source** - **Custom** with the ID of the security group you created for your instances.

For information about how to create a security group, see Create a security group in the Amazon EC2 User Guide for Linux Instances.

### Step 3: Create an Amazon EFS file system

In this step, you create an Amazon EFS file system.

**To create an Amazon EFS file system for Amazon ECS tasks.**

2. Choose Create file system.
3. Enter a name for your file system and then choose the VPC that your container instances are hosted in. By default, each subnet in the specified VPC receives a mount target that uses the default security group for that VPC. Then, choose Customize.

   **Note**

   This tutorial assumes that your Amazon EFS file system, Amazon ECS cluster, container instances, and tasks are in the same VPC. For more information about mounting a file system from a different VPC, see Walkthrough: Mount a file system from a different VPC in the Amazon EFS User Guide.

4. On the File system settings page, configure optional settings and then under Performance settings, choose the Bursting throughput mode for your file system. After you have configured settings, select Next.
a. (Optional) Add tags for your file system. For example, you could specify a unique name for the file system by entering that name in the **Value** column next to the **Name** key.

b. (Optional) Enable lifecycle management to save money on infrequently accessed storage. For more information, see [EFS Lifecycle Management](#) in the *Amazon Elastic File System User Guide*.

c. (Optional) Enable encryption. Select the check box to enable encryption of your Amazon EFS file system at rest.

5. On the **Network access** page, under **Mount targets**, replace the existing security group configuration for every availability zone with the security group you created for the file system in Step 2: Create a security group for Amazon EC2 instances and the Amazon EFS file system and then choose **Next**.

6. You do not need to configure **File system policy** for this tutorial, so you can skip the section by choosing **Next**.

7. Review your file system options and choose **Create** to complete the process.

8. From the **File systems** screen, record the **File system ID**. In the next step, you will reference this value in your Amazon ECS task definition.

### Step 4: Add content to the Amazon EFS file system

In this step, you mount the Amazon EFS file system to an Amazon EC2 instance and add content to it. This is for testing purposes in this tutorial, to illustrate the persistent nature of the data. When using this feature you would normally have your application or another method of writing data to your Amazon EFS file system.

**To create an Amazon EC2 instance and mount the Amazon EFS file system**

1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
2. Choose **Launch Instance**.
3. Under **Application and OS Images (Amazon Machine Image)**, select the **Amazon Linux 2 AMI (HVM)**.
4. Under **Instance type**, keep the default instance type, **t2.micro**.
5. Under **Key pair (login)**, select a key pair for SSH access to the instance.
6. Under **Network settings**, select the VPC that you specified for your Amazon EFS file system and Amazon ECS cluster. Select a subnet and the instance security group created in Step 2:
Create a security group for Amazon EC2 instances and the Amazon EFS file system. Configure the instance's security group. Ensure that **Auto-assign public IP** is enabled.

7. Under **Configure storage**, choose the **Edit** button for file systems and then choose **EFS**. Select the file system you created in [Step 3: Create an Amazon EFS file system](#). You can optionally change the mount point or leave the default value.

8. Clear the **Automatically create and attach security groups**. Leave the other check box selected. Choose **Add shared file system**.

9. Under **Advanced Details**, ensure that the user data script is populated automatically with the Amazon EFS file system mounting steps.

10. Under **Summary**, ensure the **Number of instances** is 1. Choose **Launch instance**.

11. On the **Launch an instance** page, choose **View all instances** to see the status of your instances. Initially, the **Instance state** status is **PENDING**. After the state changes to **RUNNING** and the instance passes all status checks, the instance is ready for use.

Now, you connect to the Amazon EC2 instance and add content to the Amazon EFS file system.

**To connect to the Amazon EC2 instance and add content to the Amazon EFS file system**

1. SSH to the Amazon EC2 instance you created. For more information, see [Connect to Your Linux Instance](#) in the Amazon EC2 User Guide for Linux Instances.

2. From the terminal window, run the **df -T** command to verify that the Amazon EFS file system is mounted. In the following output, we have highlighted the Amazon EFS file system mount.

```
$ df -T
    Filesystem  Type       1K-blocks  Used  Available  Use% Mounted
 devtmpfs  devtmpfs  485468     0  485468     0%  /dev
 tmpfs     tmpfs     503480     0  503480     0%  /dev/shm
 tmpfs     tmpfs     503480   424  503056    1%  /run
 tmpfs     tmpfs     503480     0  503480     0%  /sys/fs/cgroup
 /dev/xvda1 xfs     8376300 1310952 7065348  16%  /
 127.0.0.1:/ nfs4  9007199254739968  0  9007199254739968  0%  /mnt/efs/fs1
```
3. Navigate to the directory that the Amazon EFS file system is mounted at. In the example above, that is /mnt/efs/fs1.

4. Create a file named index.html with the following content:

```html
<html>
<body>
<h1>It Works!</h1>
<p>You are using an Amazon EFS file system for persistent container storage.</p>
</body>
</html>
```

**Step 5: Create a task definition**

The following task definition creates a data volume named efs-html. The nginx container mounts the host data volume at the NGINX root, /usr/share/nginx/html.

**To create a new task definition using the Amazon ECS console**

2. In the navigation pane, choose Task definitions.
3. Choose Create new task definition, Create new task definition with JSON.
4. In the JSON editor box, copy and paste the following JSON text, replacing the fileSystemId with the ID of your Amazon EFS file system.

```json
{
    "containerDefinitions": [
        {
            "memory": 128,
            "portMappings": [
                {
                    "hostPort": 80,
                    "containerPort": 80,
                    "protocol": "tcp"
                }
            ]
        }
    ]
}
```
Note
You can add the following permissions to your Amazon ECS task execution IAM role to allow the Amazon ECS agent to locate and mount an Amazon EFS file system to a task at startup.

- elasticfilesystem:ClientMount
- elasticfilesystem:ClientWrite
- elasticfilesystem:DescribeMountTargets
- elasticfilesystem:DescribeFileSystems

5. Choose Create.
Step 6: Run a task and view the results

Now that your Amazon EFS file system is created and there is web content for the NGINX container to serve, you can run a task using the task definition that you created. The NGINX web server serves your simple HTML page. If you update the content in your Amazon EFS file system, those changes are propagated to any containers that have also mounted that file system.

The task runs in the subnet that you defined for the cluster.

To run a task and view the results using the console

2. On the Clusters page, select the cluster to run the standalone task in.

Determine the resource from where you launch the service.

<table>
<thead>
<tr>
<th>To start a service from</th>
<th>Steps</th>
</tr>
</thead>
</table>
| Clusters                | a. On the Clusters page, select the cluster to create the service in.  
b. From the Tasks tab, choose Run new task. |
| Launch type             | a. On the Task page, choose the task definition.  
b. If there is more than one revision, select the revision.  
c. Choose Create, Run task. |

3. (Optional) Choose how your scheduled task is distributed across your cluster infrastructure. Expand Compute configuration, and then do the following:
<table>
<thead>
<tr>
<th>Distribution method</th>
<th>Steps</th>
</tr>
</thead>
</table>
| Launch type         | a. In the **Compute options** section, select **Launch type**.  
|                     | b. For **Launch type**, choose **EC2**. |

4. For **Application type**, choose **Task**.
5. For **Task definition**, choose the `efs-tutorial` task definition that you created earlier.
6. For **Desired tasks**, enter 1.
7. Choose **Create**.
8. On the **Cluster** page, choose **Infrastructure**.
9. Under **Container Instances**, choose the container instance to connect to.
10. On the **Container Instance** page, under **Networking**, record the **Public IP** for your instance.
11. Open a browser and enter the public IP address. You should see the following message:

   ![](It works!)
   You are using an Amazon EFS file system for persistent container storage.

**Note**
If you do not see the message, make sure that the security group for your container instance allows inbound network traffic on port 80 and the security group for your file system allows inbound access from the container instance.

**Using FSx for Windows File Server file systems with Amazon ECS**

FSx for Windows File Server provides fully managed Microsoft Windows file servers, that are backed by a fully native Windows file system. When using FSx for Windows File Server together with Amazon ECS, you can provision your Windows tasks with persistent, distributed, shared, and

You can use FSx for Windows File Server to deploy Windows workloads that require access to shared external storage, highly available regional storage, or high-throughput storage. You can mount one or more FSx for Windows File Server file system volumes to a container running on an EC2 Windows instance. You can share FSx for Windows File Server file system volumes among multiple containers within a single ECS task.

⚠️ Note

FSx for Windows File Server might not be available in all Regions. For more information about which Regions support FSx for Windows File Server, see Amazon FSx Endpoints and Quotas in the AWS General Reference.

In this tutorial, you launch an ECS Optimized Windows instance that hosts an FSx for Windows File Server file system and containers that can access the file system. To do this, you first create an AWS Directory Service AWS Managed Microsoft Active Directory. Then, you create an Amazon FSx for Windows File Server file system and an ECS cluster with an Amazon EC2 instance and an ECS task definition. You configure the task definition for your containers to use the FSx for Windows File Server file system. Finally, you test the file system.

It takes 20 to 45 minutes each time you launch or delete either the Active Directory or the FSx for Windows File Server file system. Be prepared to reserve at least 90 minutes to complete the tutorial or complete the tutorial over a few sessions.

Prerequisites for the tutorial

- An administrative user. See Set up to use Amazon ECS.
- (Optional) A PEM key pair for connecting to your EC2 Windows instance through RDP access. For information about how to create key pairs, see Amazon EC2 key pairs and Windows instances in the User Guide for Windows Instances.
- A VPC with at least one public and one private subnet, and one security group. You can use your default VPC. You don't need a NAT gateway or device. AWS Directory Service doesn't support Network Address Translation (NAT) with Active Directory. For this to work, the Active Directory, FSx for Windows File Server file system, ECS Cluster, and EC2 instance must be located within...
your VPC. For more information regarding VPCs and Active Directories, see Amazon VPC console wizard configurations and AWS Managed Microsoft AD Prerequisites.

- The IAM ecsInstanceRole and ecsTaskExecutionRole permissions are associated with your account. These service-linked roles allow services to make API calls and access containers, secrets, directories, and file servers on your behalf.

**Step 1: Create IAM access roles**

Create a cluster with the AWS Management Console.

1. See Amazon ECS container instance IAM role to check whether you have an ecsInstanceRole and to see how you can create one if you don't have one.

2. We recommend that role policies are customized for minimum permissions in an actual production environment. For the purpose of working through this tutorial, verify that the following AWS managed policy is attached to your ecsInstanceRole. Attach the policy if it is not already attached.

   - AmazonEC2ContainerServiceforEC2Role
   - AmazonSSMManagedInstanceCore
   - AmazonSSMDirectoryServiceAccess

   To attach AWS managed policies.

   a. Open the IAM console.
   b. In the navigation pane, choose Roles.
   c. Choose an AWS managed role.
   d. Choose Permissions, Attach policies.
   e. To narrow the available policies to attach, use Filter.
   f. Select the appropriate policy and choose Attach policy.

3. See Amazon ECS task execution IAM role to check whether you have an ecsTaskExecutionRole and to see how you can create one if you don't have one.

   We recommend that role policies are customized for minimum permissions in an actual production environment. For the purpose of working through this tutorial, verify that the following AWS managed policies are attached to your ecsTaskExecutionRole. Attach the
policies if they are not already attached. Use the procedure given in the preceding section to attach the AWS managed policies.

- SecretsManagerReadWrite
- AmazonFSxReadOnlyAccess
- AmazonSSMReadOnlyAccess
- AmazonECSTaskExecutionRolePolicy

**Step 2: Create Windows Active Directory (AD)**

1. Follow the steps described in [Create Your AWS Managed AD Directory](https://docs.aws.amazon.com/_directory_service/latest/ad_directory_service_management/Create-Your-Windows-AD-Domain.html) in the AWS Directory Service Administration Guide. Use the VPC you have designated for this tutorial. On Step 3 of Create Your AWS Managed AD Directory, save the user name and password for use in a following step. Also, note the fully qualified domain name for future steps. You can go on to complete the following step while the Active Directory is being created.

2. Create an AWS Secrets Manager secret to use in the following steps. For more information, see [Getting Started with AWS Secrets Manager](https://docs.aws.amazon.com/secretsmanager/latest/userguide/getting-started.html) in the AWS Secrets Manager User Guide.
   a. Open the Secrets Manager console.
   b. Click **Store a new secret**.
   c. Select **Other type of secrets**.
   d. For **Secret key/value**, in the first row, create a key **username** with value **admin**. Click on + **Add row**.
   e. In the new row, create a key **password**. For value, type in the password you entered in Step 3 of Create Your AWS Managed AD Directory.
   f. Click on the **Next** button.
   g. Provide a secret name and description. Click **Next**.
   h. Click **Next**. Click **Store**.
   i. From the list of **Secrets** page, click on the secret you have just created.
   j. Save the ARN of the new secret for use in the following steps.
   k. You can proceed to the next step while your Active Directory is being created.
Step 3: Verify and update your security group

In this step, you verify and update the rules for the security group that you're using. For this, you can use the default security group that was created for your VPC.

Verify and update security group.

You need to create or edit your security group to send data from and to the ports, which are described in Amazon VPC Security Groups in the FSx for Windows File Server User Guide. You can do this by creating the security group inbound rule shown in the first row of the following table of inbound rules. This rule allows inbound traffic from network interfaces (and their associated instances) that are assigned to the security group. All of the cloud resources you create are within the same VPC and attached to the same security group. Therefore, this rule allows traffic to be sent to and from the FSx for Windows File Server file system, Active Directory, and ECS instance as required. The other inbound rules allow traffic to serve the website and RDP access for connecting to your ECS instance.

The following table shows which security group inbound rules are required for this tutorial.

<table>
<thead>
<tr>
<th>Type</th>
<th>Protocol</th>
<th>Port range</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>All traffic</td>
<td>All</td>
<td>All</td>
<td>sg-securitygroup</td>
</tr>
<tr>
<td>HTTPS</td>
<td>TCP</td>
<td>443</td>
<td>0.0.0.0/0</td>
</tr>
<tr>
<td>RDP</td>
<td>TCP</td>
<td>3389</td>
<td>your laptop IP address</td>
</tr>
</tbody>
</table>

The following table shows which security group outbound rules are required for this tutorial.

<table>
<thead>
<tr>
<th>Type</th>
<th>Protocol</th>
<th>Port range</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>All traffic</td>
<td>All</td>
<td>All</td>
<td>0.0.0.0/0</td>
</tr>
</tbody>
</table>
1. Open the EC2 console and select Security Groups from the left-hand menu.

2. From the list of security groups now displayed, select check the check-box to the left of the security group that you are using for this tutorial.

   Your security group details are displayed.

3. Edit the inbound and outbound rules by selecting the Inbound rules or Outbound rules tabs and choosing the Edit inbound rules or Edit outbound rules buttons. Edit the rules to match those displayed in the preceding tables. After you create your EC2 instance later on in this tutorial, edit the inbound rule RDP source with the public IP address of your EC2 instance as described in Connect to your Windows instance from the Amazon EC2 User Guide for Windows Instances.

**Step 4: Create an FSx for Windows File Server file system**

After your security group is verified and updated and your Active Directory is created and is in the active status, create the FSx for Windows File Server file system in the same VPC as your Active Directory. Use the following steps to create an FSx for Windows File Server file system for your Windows tasks.

**Create your first file system.**

1. Open the Amazon FSx console.

2. On the dashboard, choose Create file system to start the file system creation wizard.

3. On the Select file system type page, choose FSx for Windows File Server, and then choose Next. The Create file system page appears.

4. In the File system details section, provide a name for your file system. Naming your file systems makes it easier to find and manage your them. You can use up to 256 Unicode characters. Allowed characters are letters, numbers, spaces, and the special characters plus sign (+), minus sign (-), equal sign (=), period (.), underscore (_), colon (:), and forward slash (/).

5. For Deployment type choose Single-AZ to deploy a file system that is deployed in a single Availability Zone. Single-AZ 2 is the latest generation of single Availability Zone file systems, and it supports SSD and HDD storage.

6. For Storage type, choose HDD.

7. For Storage capacity, enter the minimum storage capacity.

8. Keep Throughput capacity at its default setting.
9. In the **Network & security** section, choose the same Amazon VPC that you chose for your AWS Directory Service directory.

10. For **VPC Security Groups**, choose the security group that you verified in *Step 3: Verify and update your security group*.

11. For **Windows authentication**, choose **AWS Managed Microsoft Active Directory**, and then choose your AWS Directory Service directory from the list.

12. For **Encryption**, keep the default **Encryption key** setting of **aws/fsx (default)**.

13. Keep the default settings for **Maintenance preferences**.

14. Click on the **Next** button.

15. Review the file system configuration shown on the **Create file system** page. For your reference, note which file system settings you can modify after file system is created. Choose **Create file system**.

16. Note the file system ID. You will need to use it in a later step.

You can go on to the next steps to create a cluster and EC2 instance while the FSx for Windows File Server file system is being created.

---

**Step 5: Create an Amazon ECS cluster**

**Create a cluster using the Amazon ECS console**

2. From the navigation bar, select the Region to use.
3. In the navigation pane, choose **Clusters**.
4. On the **Clusters** page, choose **Create cluster**.
5. Under **Cluster configuration**, for **Cluster name**, enter **windows-fsx-cluster**.
6. Expand **Infrastructure**, clear AWS Fargate (serverless) and then select **Amazon EC2 instances**.
   - To create a Auto Scaling group, from **Auto Scaling group (ASG)**, select **Create new group**, and then provide the following details about the group:
     - For **Operating system/Architecture**, choose **Windows Server 2019 Core**.
     - For **EC2 instance type**, choose t2.medium or t2.micro.
7. Choose **Create**.
Step 6: Create an Amazon ECS optimized Amazon EC2 instance

Create an Amazon ECS Windows container instance.

To create an Amazon ECS instance

1. Use the `aws ssm get-parameters` command to retrieve the AMI name for the Region that hosts your VPC. For more information, see Retrieving Amazon ECS-Optimized AMI metadata.
2. Use the Amazon EC2 console to launch the instance.
   a. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.
   b. From the navigation bar, select the Region to use.
   c. From the EC2 Dashboard, choose Launch instance.
   d. For Name, enter a unique name.
   e. For Application and OS Images (Amazon Machine Image), in the search field, enter the AMI name that you retrieved.
   f. For Instance type, choose t2.medium or t2.micro.
   g. For Key pair (login), choose a key pair. If you don't specify a key pair, you
   h. Under Network settings, for VPC and Subnet, choose your VPC and a public subnet.
   i. Under Network settings, for Security group, choose an existing security group, or create a new one. Ensure that the security group you choose has the inbound and outbound rules defined in Prerequisites for the tutorial
   j. Under Network settings, for Auto-assign Public IP, select Enable.
   k. Expand Advanced details, and then for Domain join directory, select the ID of the Active Directory that you created. This option domain joins your AD when the EC2 instance is launched.
   l. Under Advanced details, for IAM instance profile, choose ecsInstanceRole.
   m. Configure your Amazon ECS container instance with the following user data. Under Advanced Details, paste the following script into the User data field, replacing `cluster_name` with the name of your cluster.

```powershell
Initialize-ECSAgent -Cluster windows-fsx-cluster -EnableTaskIAMRole
</powershell>
```

n. When you are ready, select the acknowledgment field, and then choose Launch Instances.
A confirmation page lets you know that your instance is launching. Choose **View Instances** to close the confirmation page and return to the console.

4. In the navigation pane, choose **Clusters**, and then choose **windows-fsx-cluster**.

5. Choose the **Infrastructure** tab and verify that your instance has been registered in the **windows-fsx-cluster** cluster.

### Step 7: Register a Windows task definition

Before you can run Windows containers in your Amazon ECS cluster, you must register a task definition. The following task definition example displays a simple web page. The task launches two containers that have access to the FSx file system. The first container writes an HTML file to the file system. The second container downloads the HTML file from the file system and serves the webpage.

2. In the navigation pane, choose **Task definitions**.

3. Choose **Create new task definition**, **Create new task definition with JSON**.

4. In the JSON editor box, replace the values for your task execution role and the details about your FSx file system and then choose **Save**.

```json
{
    "containerDefinitions": [
        {
            "entryPoint": [
                "powershell",
                "-Command"
            ],
            "portMappings": [],
            "command": ["New-Item -Path C:\fsx-windows-dir\index.html -ItemType file -Value '<html> <head> <title>Amazon ECS Sample App</title> <style>body {margin-top: 40px; background-color: #333;} </style> </head><body> <div style=color:white;text-align:center> <h1>Amazon ECS Sample App</h1> <h2>It Works!</h2> <p>You are using Amazon FSx for Windows File Server file system for persistent container storage.</p>" -Force"],
            "cpu": 512,
            "memory": 256,
        }
    ]
}
```
"image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-ltsc2019",
   "essential": false,
   "name": "container1",
   "mountPoints": [
       {
           "sourceVolume": "fsx-windows-dir",
           "containerPath": "C:\\fsx-windows-dir",
           "readOnly": false
       }
   ],
   "entryPoint": [
       "powershell",
       "-Command"
   ],
   "portMappings": [
       {
           "hostPort": 443,
           "protocol": "tcp",
           "containerPort": 80
       }
   ],
   "command": ["Remove-Item -Recurse C:\inetpub\wwwroot\* -Force; Start-Sleep -Seconds 120; Move-Item -Path C:\fsx-windows-dir\index.html -Destination C:\inetpub\wwwroot\index.html -Force; C:\ServiceMonitor.exe w3svc"],
   "mountPoints": [
       {
           "sourceVolume": "fsx-windows-dir",
           "containerPath": "C:\fsx-windows-dir",
           "readOnly": false
       }
   ],
   "cpu": 512,
   "memory": 256,
   "image": "mcr.microsoft.com/windows/servercore/iis:windowsservercore-ltsc2019",
   "essential": true,
   "name": "container2"
  },
  "family": "fsx-windows"
"executionRoleArn": "arn:aws:iam::111122223333:role/ecsTaskExecutionRole",
"volumes": [
  {
    "name": "fsx-windows-dir",
    "fsxWindowsFileServerVolumeConfiguration": {
      "fileSystemId": "fs-0eeb5730b2EXAMPLE",
      "authorizationConfig": {
        "domain": "example.com",
        "credentialsParameter": "arn:arn-1234"
      },
      "rootDirectory": "share"
    }
  }
]

---

**Step 8: Run a task and view the results**

Before running the task, verify that the status of your FSx for Windows File Server file system is **Available**. After it is available, you can run a task using the task definition that you created. The task starts out by creating containers that shuffle an HTML file between them using the file system. After the shuffle, a web server serves the simple HTML page.

**Note**

You might not be able to connect to the website from within a VPN.

---

**Run a task and view the results with the Amazon ECS console.**

2. In the navigation pane, choose **Clusters**, and then choose **windows-fsx-cluster**.
3. Choose the **Tasks** tab, and then choose **Run new task**.
4. For **Launch Type**, choose **EC2**.
5. Under Deployment configuration, for **Task Definition**, choose the **fsx-windows**, and then choose **Create**.
6. When your task status is **RUNNING**, choose the task ID.
7. Under **Containers**, when the container's status is **STOPPED**, select container2 to view the container's details.

8. Under **Container details for container2**, select **Network bindings** and then click on the external IP address that is associated with the container. Your browser will open and display the following message.

```
Amazon ECS Sample App
It Works!
You are using Amazon FSx for Windows File Server file system for persistent container storage.
```

**Note**

It may take a few minutes for the message to be displayed. If you don't see this message after a few minutes, check that you aren't running in a VPN and make sure that the security group for your container instance allows inbound network HTTP traffic on port 443.

---

**Step 9: Clean up**

**Note**

It takes 20 to 45 minutes to delete the FSx for Windows File Server file system or the AD. You must wait until the FSx for Windows File Server file system delete operations are complete before starting the AD delete operations.

**Delete FSx for Windows File Server file system.**

1. Open the [Amazon FSx console](#).
2. Choose the radio button to the left of the FSx for Windows File Server file system that you just created.
3. Choose **Actions**.
4. Select **Delete file system**.
Delete AD.

1. Open the AWS Directory Service console.
2. Choose the radio button to the left of the AD you just created.
3. Choose Actions.
4. Select Delete directory.

Delete the cluster.

2. In the navigation pane, choose Clusters, and then choose fsx-windows-cluster.
3. Choose Delete cluster.
4. Enter the phrase and then choose Delete.

Terminate EC2 instance.

1. Open the Amazon EC2 console.
2. From the left-hand menu, select Instances.
3. Check the box to the left of the EC2 instance you created.
4. Click the Instance state, Terminate instance.

Delete secret.

1. Open the Secrets Manager console.
2. Select the secret you created for this walk through.
3. Click Actions.
4. Select Delete secret.

Deploying Fluent Bit on Amazon ECS for Windows containers

Fluent Bit is a fast and flexible log processor and router supported by various operating systems. It can be used to route logs to various AWS destinations such as Amazon CloudWatch Logs, Firehose Amazon S3, and Amazon OpenSearch Service. Fluent Bit supports common partner solutions such
as Datadog, Splunk, and custom HTTP servers. For more information about Fluent Bit, see the Fluent Bit website.

The AWS for Fluent Bit image is available on Amazon ECR on both the Amazon ECR Public Gallery and in an Amazon ECR repository in most Regions for high availability. For more information, see aws-for-fluent-bit on the GitHub website.

This tutorial walks you through how to deploy Fluent Bit containers on their Windows instances running in Amazon ECS to stream logs generated by the Windows tasks to Amazon CloudWatch for centralized logging.

This tutorial uses the following approach:

- Fluent Bit runs as a service with the Daemon scheduling strategy. This strategy ensures that a single instance of Fluent Bit always runs on the container instances in the cluster.
- Listens on port 24224 using the forward input plug-in.
- Expose port 24224 to the host so that the docker runtime can send logs to Fluent Bit using this exposed port.
- Has a configuration which allows Fluent Bit to send the logs records to specified destinations.
- Launch all other Amazon ECS task containers using the fluentd logging driver. For more information, see Fluentd logging driver on the Docker documentation website.
- Docker connects to the TCP socket 24224 on localhost inside the host namespace.
- The Amazon ECS agent adds labels to the containers which includes the cluster name, task definition family name, task definition revision number, task ARN, and the container name. The same information is added to the log record using the labels option of the fluentd docker logging driver. For more information, see labels, labels-regex, env, and env-regex on the Docker documentation website.
- Because the async option of the fluentd logging driver is set to true, when the Fluent Bit container is restarted, docker buffers the logs until the Fluent Bit container is restarted. You can increase the buffer limit by setting the fluentd-buffer-limit option. For more information, see fluentd-buffer-limit on the Docker documentation website.

The work flow is as follows:

- The Fluent Bit container starts and listens on port 24224 which is exposed to the host.
- Fluent Bit uses the task IAM role credentials specified in its task definition.
Other tasks launched on the same instance use the fluentd docker logging driver to connect to the Fluent Bit container on port 24224.

When the application containers generate logs, docker runtime tags those records, adds additional metadata specified in labels, and then forwards them on port 24224 in the host namespace.

Fluent Bit receives the log record on port 24224 because it is exposed to the host namespace.

Fluent Bit performs its internal processing and routes the logs as specified.

This tutorial uses the default CloudWatch Fluent Bit configuration which does the following:

- Creates a new log group for each cluster and task definition family.
- Creates a new log stream for each task container in above generated log group whenever a new task is launched. Each stream will be marked with the task id to which the container belongs.
- Adds additional metadata including the cluster name, task ARN, task container name, task definition family, and the task definition revision number in each log entry.

For example, if you have task_1 with container_1 and container_2 and task_2 with container_3, then the following are the CloudWatch log streams:

- /aws/ecs/windows.ecs_task_1
task-out.\textit{TASK\_ID}.container_1
  task-out.\textit{TASK\_ID}.container_2
- /aws/ecs/windows.ecs_task_2
task-out.\textit{TASK\_ID}.container_3

Steps

- **Prerequisites**
- **Step 1: Create the IAM access roles**
- **Step 2: Create an Amazon ECS Windows container instance**
- **Step 3: Configure Fluent Bit**
- **Step 4: Register a Windows Fluent Bit task definition which routes the logs to CloudWatch**
- **Step 5: Run the ecs-windows-fluent-bit task definition as an Amazon ECS service using the daemon scheduling strategy**
• **Step 6:** Register a Windows task definition which generates the logs

• **Step 7:** Run the windows-app-task task definition

• **Step 8:** Verify the logs on CloudWatch

• **Step 9:** Clean up

**Prerequisites**

This tutorial assumes that the following prerequisites have been completed:

• The latest version of the AWS CLI is installed and configured. For more information, see [Installing the AWS Command Line Interface](#).

• The `aws-for-fluent-bit` container image is available for the following Windows operating systems:
  - Windows Server 2019 Core
  - Windows Server 2019 Full
  - Windows Server 2022 Core
  - Windows Server 2022 Full

• The steps in [Set up to use Amazon ECS](#) have been completed.

• You have a cluster. In this tutorial, the cluster name is **FluentBit-cluster**.

• You have a VPC with a public subnet where the EC2 instance will be launched. You can use your default VPC. You can also use a private subnet that allows Amazon CloudWatch endpoints to reach the subnet. For more information about Amazon CloudWatch endpoints, see [Amazon CloudWatch endpoints and quotas](#) in the *AWS General Reference*. For information about how to use the Amazon VPC wizard to create a VPC, see the section called “Create a virtual private cloud”.

**Step 1: Create the IAM access roles**

Create the Amazon ECS IAM roles.

1. Create the Amazon ECS container instance role named "ecsInstanceRole". For more information, see [Amazon ECS container instance IAM role](#).

2. Create an IAM role for the Fluent Bit task named `fluentTaskRole`. For more information, see the section called “Task IAM role”.
The IAM permissions granted in this IAM role are assumed by the task containers. In order to allow Fluent Bit to send logs to CloudWatch, you need to attach the following permissions to the task IAM role.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Resource": "*",
      }
   ],
   "Resource": "*"
}
```

3. Attach the policy to the role.
   a. Save the above content in a file named `fluent-bit-policy.json`.
   b. Run the following command to attach the inline policy to `fluentTaskRole` IAM role.

   ```bash
   aws iam put-role-policy --role-name fluentTaskRole --policy-name fluentTaskPolicy --policy-document file://fluent-bit-policy.json
   ```

**Step 2: Create an Amazon ECS Windows container instance**

Create an Amazon ECS Windows container instance.

**To create an Amazon ECS instance**

1. Use the `aws ssm get-parameters` command to retrieve the AMI ID for the Region that hosts your VPC. For more information, see [Retrieving Amazon ECS-Optimized AMI metadata](#).
2. Use the Amazon EC2 console to launch the instance.

   a. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).
b. From the navigation bar, select the Region to use.

c. From the **EC2 Dashboard**, choose **Launch instance**.

d. For **Name**, enter a unique name.

e. For **Application and OS Images (Amazon Machine Image)**, choose the AMI that you retrieved in the first step.

f. For **Instance type**, choose `t3.xlarge`.

g. For **Key pair (login)**, choose a key pair.

h. Under **Network settings**, for **Security group**, choose an existing security group, or create a new one.

i. Under **Network settings**, for **Auto-assign Public IP**, select **Enable**.

j. Under **Advanced details**, for **IAM instance profile**, choose **ecsInstanceRole**.

k. Configure your Amazon ECS container instance with the following user data. Under **Advanced Details**, paste the following script into the **User data** field, replacing `cluster_name` with the name of your cluster.

   ```powershell
   Import-Module ECSTools
   Initialize-ECSAgent -Cluster cluster-name -EnableTaskENI -EnableTaskIAMRole -LoggingDrivers ['"awslogs","fluentd"']
   ```

l. When you are ready, select the acknowledgment field, and then choose **Launch Instances**.

m. A confirmation page lets you know that your instance is launching. Choose **View Instances** to close the confirmation page and return to the console.

### Step 3: Configure Fluent Bit

You can use the following default configuration provided by AWS to get quickly started:

- **Amazon CloudWatch** which is based on the Fluent Bit plug-in for **Amazon CloudWatch** on the **Fluent Bit Official Manual**.

Alternatively, you can use other default configurations provided by AWS. For more information, see **Overriding the entrypoint for the Windows image** on the [aws-for-fluent-bit](https://github.com/aws/aws-for-fluent-bit) Github website.
The default Amazon CloudWatch Fluent Bit configuration is shown below.

Replace the following variables:

- `region` with the Region where you want to send the Amazon CloudWatch logs.

```plaintext
[SERVICE]
Flush               5
Log_Level           info
Daemon              off

[INPUT]
Name                forward
Listen              0.0.0.0
Port                24224
Buffer_Chunk_Size   1M
Buffer_Max_Size     6M
Tag_Prefix          ecs.

# Amazon ECS agent adds the following log keys as labels to the docker container.
# We would use fluentd logging driver to add these to log record while sending it to
# Fluent Bit.
[FILTER]
Name                modify
Match               ecs.*
Rename              com.amazonaws.ecs.cluster ecs_cluster
Rename              com.amazonaws.ecs.container-name ecs_container_name
Rename              com.amazonaws.ecs.task-arn ecs_task_arn
Rename              com.amazonaws.ecs.task-definition-family ecs_task_definition_family
Rename              com.amazonaws.ecs.task-definition-version ecs_task_definition_version

[FILTER]
Name                rewrite_tag
Match               ecs.*
Rule                $ecs_task_arn ^([a-z-0-9]+)/([a-zA-Z0-9-_.]+)/([a-z0-9]+)$
out.$3.$ecs_container_name false
Emitter_Name        re_emitted

[OUTPUT]
Name                cloudwatch_logs
Match               out.*
```
Every log which gets into Fluent Bit has a tag which you specify, or is automatically generated when you do not supply one. The tags can be used to route different logs to different destinations. For additional information, see Tag in the Fluent Bit Official Manual.

The Fluent Bit configuration described above has the following properties:

- The forward input plug-in listens for incoming traffic on TCP port 24224.
- Each log entry received on that port has a tag which the forward input plug-in modifies to prefix the record with *ecs*. *string*.
- The Fluent Bit internal pipeline routes the log entry to modify the filter using the Match regex. This filter replaces the keys in the log record JSON to the format which Fluent Bit can consume.
- The modified log entry is then consumed by the rewrite_tag filter. This filter changes the tag of the log record to the format *out*.Task ID.Container Name.
- The new tag will be routed to output cloudwatch_logs plug-in which creates the log groups and streams as described earlier by using the log_group_template and log_stream_prefix options of the CloudWatch output plug-in. For additional information, see Configuration parameters in the Fluent Bit Official Manual.

Step 4: Register a Windows Fluent Bit task definition which routes the logs to CloudWatch

Register a Windows Fluent Bit task definition which routes the logs to CloudWatch.

**Note**

This task definition exposes Fluent Bit container port 24224 to the host port 24224. Verify that this port is not open in your EC2 instance security group to prevent access from outside.
To register a task definition

1. Create a file named `fluent-bit.json` with the following contents.

Replace the following variables:

- `task-iam-role` with the Amazon Resource Name (ARN) of your task IAM role
- `region` with the Region where your task runs

```json
{
  "family": "ecs-windows-fluent-bit",
  "taskRoleArn": "task-iam-role",
  "containerDefinitions": [
    {
      "name": "fluent-bit",
      "image": "public.ecr.aws/aws-observability/aws-for-fluent-bit:windowsservercore-latest",
      "cpu": 512,
      "portMappings": [
        {
          "hostPort": 24224,
          "containerPort": 24224,
          "protocol": "tcp"
        }
      ],
      "entryPoint": ["Powershell", "-Command"],
      "command": ["C:\entrypoint.ps1 -ConfigFile C:\ecs_windows_forward_daemon\cloudwatch.conf"],
      "environment": [
        {
          "name": "AWS_REGION",
          "value": "region"
        }
      ],
      "memory": 512,
      "essential": true,
      "logConfiguration": {}
    }
  ]
}
```
Amazon Elastic Container Service

Developer Guide

"logDriver": "awslogs",
"options": {
  "awslogs-group": "/ecs/fluent-bit-logs",
  "awslogs-region": "region",
  "awslogs-stream-prefix": "flb",
  "awslogs-create-group": "true"
}
}
]
"memory": "512",
"cpu": "512"
}

2. Run the following command to register the task definition.

```bash
aws ecs register-task-definition --cli-input-json file://fluent-bit.json --region region
```

You can list the task definitions for your account by running the list-task-definitions command. The output of displays the family and revision values that you can use together with run-task or start-task.

**Step 5: Run the ecs-windows-fluent-bit task definition as an Amazon ECS service using the daemon scheduling strategy**

After you register a task definition for your account, you can run a task in the cluster. For this tutorial, you run one instance of the ecs-windows-fluent-bit:1 task definition in your FluentBit-cluster cluster. Run the task in a service which uses the daemon scheduling strategy, which ensures that a single instance of Fluent Bit always runs on each of your container instances.

**To run a task**

1. Run the following command to start the ecs-windows-fluent-bit:1 task definition (registered in the previous step) as a service.
Replace the following variables:

- **region** with the Region where your service runs

```bash
aws ecs create-service
   --cluster FluentBit-cluster
   --service-name FluentBitForwardDaemonService
   --task-definition ecs-windows-fluent-bit:1
   --launch-type EC2
   --scheduling-strategy DAEMON
   --region region
```

2. Run the following command to list your tasks.

Replace the following variables:

- **region** with the Region where your service tasks run

```bash
aws ecs list-tasks --cluster FluentBit-cluster --region region
```

### Step 6: Register a Windows task definition which generates the logs

Register a task definition which generates the logs. This task definition deploys Windows container image which will write a incremental number to stdout every second.

The task definition uses the fluentd logging driver which connects to port 24224 which the Fluent Bit plug-in listens to. The Amazon ECS agent labels each Amazon ECS container with tags including the cluster name, task ARN, task definition family name, task definition revision number and the task container name. These key-value labels are passed to Fluent Bit.
Note

This task uses the default network mode. However, you can also use the awsvpc network mode with the task.

To register a task definition

1. Create a file named windows-app-task.json with the following contents.

```json
{
    "family": "windows-app-task",
    "containerDefinitions": [
        {
            "name": "sample-container",
            "image": "mcr.microsoft.com/windows/servercore:ltsc2019",
            "cpu": 512,
            "memory": 512,
            "essential": true,
            "entryPoint": [
                "Powershell",
                "-Command"
            ],
            "command": [
                "$count=1;while(1) { Write-Host $count; sleep 1; $count=$count+1;}
            ],
            "logConfiguration": {
                "logDriver": "fluentd",
                "options": {
                    "fluentd-address": "localhost:24224",
                    "tag": "{\{ index .ContainerLabels \"com.amazonaws.ecs.task-definition-family\"}}",
                    "fluentd-async": "true",
                    "labels": "com.amazonaws.ecs.cluster,com.amazonaws.ecs.container-name,com.amazonaws.ecs.task-arn,com.amazonaws.ecs.task-definition-family,com.amazonaws.ecs.task-definition-version"
                }
            }
        }
    ],
    "memory": "512",
    "cpu": "512"
}
```
2. Run the following command to register the task definition.

   Replace the following variables:

   - `region` with the Region where your task runs

   ```
   aws ecs register-task-definition --cli-input-json file://windows-app-task.json --region region
   ```

   You can list the task definitions for your account by running the `list-task-definitions` command. The output of displays the family and revision values that you can use together with `run-task` or `start-task`.

**Step 7: Run the `windows-app-task` task definition**

After you register the `windows-app-task` task definition, run it in your `FluentBit-cluster` cluster.

**To run a task**

1. Run the `windows-app-task:1` task definition you registered in the previous step.

   Replace the following variables:

   - `region` with the Region where your task runs

   ```
   aws ecs run-task --cluster FluentBit-cluster --task-definition windows-app-task:1 --count 2 --region region
   ```

2. Run the following command to list your tasks.

   ```
   aws ecs list-tasks --cluster FluentBit-cluster
   ```
Step 8: Verify the logs on CloudWatch

In order to verify your Fluent Bit setup, check for the following log groups in the CloudWatch console:

- /ecs/fluent-bit-logs - This is the log group which corresponds to the Fluent Bit daemon container which is running on the container instance.

- /aws/ecs/FluentBit-cluster.windows-app-task - This is the log group which corresponds to all the tasks launched for windows-app-task task definition family inside FluentBit-cluster cluster.

  task-out.FIRST_TASK_ID.sample-container - This log stream contains all the logs generated by the first instance of the task in the sample-container task container.

  task-out.SECOND_TASK_ID.sample-container - This log stream contains all the logs generated by the second instance of the task in the sample-container task container.

The task-out.TASK_ID.sample-container log stream has fields similar to the following:

```
{
  "source": "stdout",
  "ecs_task_arn": "arn:aws:ecs:region:0123456789012:task/FluentBit-cluster/13EXAMPLE",
  "container_name": "/ecs-windows-app-task-1-sample-container-cEXAMPLE",
  "ecs_cluster": "FluentBit-cluster",
  "ecs_container_name": "sample-container",
  "ecs_task_definition_version": "1",
  "container_id": "61f5e6EXAMPLE",
  "log": "10",
  "ecs_task_definition_family": "windows-app-task"
}
```

To verify the Fluent Bit setup

2. In the navigation pane, choose Log groups. Make sure that you're in the Region where you deployed Fluent Bit to your containers.

   In the list of log groups in the AWS Region, you should see the following:
• /ecs/fluent-bit-logs
• /aws/ecs/FluentBit-cluster.windows-app-task

If you see these log groups, the Fluent Bit setup is verified.

**Step 9: Clean up**

When you have finished this tutorial, clean up the resources associated with it to avoid incurring charges for resources that you aren't using.

**To clean up the tutorial resources**

1. Stop the `windows-simple-task` task and the `ecs-fluent-bit` task. For more information, see the section called “Stop an Amazon ECS task”.

2. Run the following command to delete the `/ecs/fluent-bit-logs` log group. For more information, about deleting log groups see `delete-log-group` in the *AWS Command Line Interface Reference.*
   ```bash
   aws logs delete-log-group --log-group-name /ecs/fluent-bit-logs
   aws logs delete-log-group --log-group-name /aws/ecs/FluentBit-cluster.windows-app-task
   ```

3. Run the following command to terminate the instance.
   ```bash
   aws ec2 terminate-instances --instance-ids instance-id
   ```

4. Run the following commands to delete the IAM roles.
   ```bash
   aws iam delete-role --role-name ecsInstanceRole
   aws iam delete-role --role-name fluentTaskRole
   ```

5. Run the following command to delete the Amazon ECS cluster.
   ```bash
   aws ecs delete-cluster --cluster FluentBit-cluster
   ```
Using gMSAs for Windows Containers on Amazon EC2

Amazon ECS supports Active Directory authentication for Windows containers through a special kind of service account called a group Managed Service Account (gMSA).

Windows based network applications such as .NET applications often use Active Directory to facilitate authentication and authorization management between users and services. Developers commonly design their applications to integrate with Active Directory and run on domain-joined servers for this purpose. Because Windows containers cannot be domain-joined, you must configure a Windows container to run with gMSA.

A Windows container running with gMSA relies on its host Amazon EC2 instance to retrieve the gMSA credentials from the Active Directory domain controller and provide them to the container instance. For more information, see Create gMSAs for Windows containers.

Note

This feature is not supported on Windows containers on Fargate.

Topics

• Considerations
• Prerequisites
• Setting up gMSA for Windows Containers on Amazon ECS

Considerations

The following should be considered when using gMSAs for Windows containers:

• When using the Amazon ECS-optimized Windows Server 2016 Full AMI for your container instances, the container hostname must be the same as the gMSA account name defined in the credential spec file. To specify a hostname for a container, use the hostname container definition parameter. For more information, see Network settings.

• You chose between domainless gMSA and joining each instance to a single domain. By using domainless gMSA, the container instance isn't joined to the domain, other applications on the instance can't use the credentials to access the domain, and tasks that join different domains can run on the same instance.

Then, choose the data storage for the CredSpec and optionally, for the Active Directory user credentials for domainless gMSA.

Amazon ECS uses an Active Directory credential specification file (CredSpec). This file contains the gMSA metadata that's used to propagate the gMSA account context to the container. You generate the CredSpec file and then store it in one of the CredSpec storage options in the following table, specific to the Operating System of the container instances. To use the domainless method, an optional section in the CredSpec file can specify credentials in one of the domainless user credentials storage options in the following table, specific to the Operating System of the container instances.

### gMSA data storage options by Operating System

<table>
<thead>
<tr>
<th>Storage location</th>
<th>Linux</th>
<th>Windows</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Simple Storage Service</td>
<td>CredSpec</td>
<td>CredSpec</td>
</tr>
<tr>
<td>AWS Secrets Manager</td>
<td>domainless user credentials</td>
<td>domainless user credentials</td>
</tr>
<tr>
<td>Amazon EC2 Systems Manager Parameter Store</td>
<td>CredSpec</td>
<td>CredSpec, domainless user credentials</td>
</tr>
<tr>
<td>Local file</td>
<td>N/A</td>
<td>CredSpec</td>
</tr>
</tbody>
</table>

### Prerequisites

Before you use the gMSA for Windows containers feature with Amazon ECS, make sure to complete the following:

- You set up an Active Directory domain with the resources that you want your containers to access. Amazon ECS supports the following setups:
  - An AWS Directory Service Active Directory. AWS Directory Service is an AWS managed Active Directory that's hosted on Amazon EC2. For more information, see [Getting Started with AWS Managed Microsoft AD](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/ads-managed-microsoft-ad.html) in the [AWS Directory Service Administration Guide](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/ads-managed-microsoft-ad.html).
  - An on-premises Active Directory. You must ensure that the Amazon ECS Linux container instance can join the domain. For more information, see [AWS Direct Connect](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/ads-on-premises.html).
• You have an existing gMSA account in the Active Directory. For more information, see Create gMSAs for Windows containers.

• You chose to use **domainless gMSA** or the Amazon ECS Windows container instance hosting the Amazon ECS task must be **domain joined** to the Active Directory and be a member of the Active Directory security group that has access to the gMSA account.

By using domainless gMSA, the container instance isn't joined to the domain, other applications on the instance can't use the credentials to access the domain, and tasks that join different domains can run on the same instance.

• You added the required IAM permissions. The permissions that are required depend on the methods that you choose for the initial credentials and for storing the credential specification:
  
  • If you use **domainless gMSA** for initial credentials, IAM permissions for AWS Secrets Manager are required on the Amazon EC2 instance role.
  
  • If you store the credential specification in SSM Parameter Store, IAM permissions for Amazon EC2 Systems Manager Parameter Store are required on the task execution role.
  
  • If you store the credential specification in Amazon S3, IAM permissions for Amazon Simple Storage Service are required on the task execution role.

### Setting up gMSA for Windows Containers on Amazon ECS

To set up gMSA for Windows Containers on Amazon ECS, you can follow the complete tutorial that includes configuring the prerequisites [Using Windows Containers with Domainless gMSA using the AWS CLI](#).

The following sections cover the CredSpec configuration in detail.

**Topics**

- [Example CredSpec](#)
- [Domainless gMSA setup](#)
- [Referencing a Credential Spec File in a Task Definition](#)

**Example CredSpec**

Amazon ECS uses a credential spec file that contains the gMSA metadata used to propagate the gMSA account context to the Windows container. You can generate the credential spec file and
reference it in the credentialSpec field in your task definition. The credential spec file does not contain any secrets.

The following is an example credential spec file:

```json
{
   "CmsPlugins": [
      "ActiveDirectory"
   ],
   "DomainJoinConfig": {
      "Sid": "S-1-5-21-2554468230-2647958158-2204241789",
      "MachineAccountName": "WebApp01",
      "Guid": "8665abd4-e947-4dd0-9a51-f8254943c90b",
      "DnsTreeName": "contoso.com",
      "DnsName": "contoso.com",
      "NetBiosName": "contoso"
   },
   "ActiveDirectoryConfig": {
      "GroupManagedServiceAccounts": [
         {
            "Name": "WebApp01",
            "Scope": "contoso.com"
         }
      ]
   }
}
```

**Domainless gMSA setup**

We recommend domainless gMSA instead of joining the container instances to a single domain. By using domainless gMSA, the container instance isn't joined to the domain, other applications on the instance can't use the credentials to access the domain, and tasks that join different domains can run on the same instance.

1. Before uploading the CredSpec to one of the storage options, add information to the CredSpec with the ARN of the secret in Secrets Manager or SSM Parameter Store. For more information, see [Additional credential spec configuration for non-domain-joined container host use case](https://learn.microsoft.com/en-us) on the Microsoft Learn website.

**Domainless gMSA credential format**
The following is the JSON format for the domainless gMSA credentials for your Active Directory. Store the credentials in Secrets Manager or SSM Parameter Store.

```
{
    "username": "WebApp01",
    "password": "Test123!",
    "domainName": "contoso.com"
}
```

2. Add the following information to the CredSpec file inside the `ActiveDirectoryConfig`. Replace the ARN with the secret in Secrets Manager or SSM Parameter Store.

   Note that the `PluginGUID` value must match the GUID in the following example snippet and is required.

```
"HostAccountConfig": {
    "PortableCcgVersion": "1",
    "PluginGUID": "{859E1386-BDB4-49E8-85C7-3070B13920E1}"
}
```

You can also use a secret in SSM Parameter Store by using the ARN in this format: \"arn:aws:ssm:aws-region:111122223333:parameter/gmsa-plugin-input\".

3. After you modify the CredSpec file, it should look like the following example:

```
{
    "CmsPlugins": ["ActiveDirectory"],
    "DomainJoinConfig": {
        "Sid": "S-1-5-21-4066351383-705263209-1606769140",
        "MachineAccountName": "WebApp01",
        "Guid": "ac822f13-583e-49f7-aa7b-284f9a8c97b6",
        "DnsTreeName": "contoso",
        "DnsName": "contoso",
        "NetBiosName": "contoso"
    },
    "ActiveDirectoryConfig": {
```
Referencing a Credential Spec File in a Task Definition

Amazon ECS supports the following ways to reference the file path in the credentialSpecs field of the task definition. For each of these options, you can provide credentialspec: or domainlesscredentialspec:, depending on whether you are joining the container instances to a single domain, or using domainless gMSA, respectively.

**Amazon S3 Bucket**

Add the credential spec to an Amazon S3 bucket and then reference the Amazon Resource Name (ARN) of the Amazon S3 bucket in the credentialSpecs field of the task definition.

```json
{
   "family": "",
   "executionRoleArn": "",
   "containerDefinitions": [
      {
         "name": "",
         ...
         "credentialSpecs": [
            "credentialspecdomainless:arn:aws:s3:::${BucketName}/${ObjectName}"
         ],
         ...
```
You must also add the following permissions as an inline policy to the Amazon ECS task execution IAM role to give your tasks access to the Amazon S3 bucket.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor",
      "Effect": "Allow",
      "Action": [
        "s3:Get*",
        "s3:List*
      ],
      "Resource": [
        "arn:aws:s3:::{bucket_name}",
        "arn:aws:s3:::{bucket_name}/{object}
      ]
    }
  ]
}
```

**SSM Parameter Store parameter**

Add the credential spec to an SSM Parameter Store parameter and then reference the Amazon Resource Name (ARN) of the SSM Parameter Store parameter in the `credentialSpecs` field of the task definition.

```
{
  "family": "",
  "executionRoleArn": "",
  "containerDefinitions": [
    {
      "name": "",
      ...
      "credentialSpecs": [
        "credentialspecdomainless:arn:aws:ssm:region:111122223333:parameter/parameter_name"
      ]
    }
  ]
}
```
You must also add the following permissions as an inline policy to the Amazon ECS task execution IAM role to give your tasks access to the SSM Parameter Store parameter.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetParameters"
            ],
            "Resource": [
                "arn:aws:ssm:region:111122223333:parameter/parameter_name"
            ]
        }
    ]
}
```

**Local File**

With the credential spec details in a local file, reference the file path in the credentialSpecs field of the task definition. The file path referenced must be relative to the C:\ProgramData\Docker\CredentialSpecs directory and use the backslash (\) as the file path separator.

```
{
    "family": "",
    "executionRoleArn": "",
    "containerDefinitions": [
        {
            "name": "",
            ...
            "credentialSpecs": [
                "credentialspec:file://CredentialSpecDir\CredentialSpecFile.json"
            ],
            ...
```

---

**Setup**

1322
Using Windows Containers with Domainless gMSA using the AWS CLI

The following tutorial shows how to create an Amazon ECS task that runs a Windows container that has credentials to access Active Directory with the AWS CLI. By using domainless gMSA, the container instance isn’t joined to the domain, other applications on the instance can’t use the credentials to access the domain, and tasks that join different domains can run on the same instance.

Topics

- Prerequisites
- Step 1: Create and configure the gMSA account on Active Directory Domain Services (AD DS)
- Step 2: Upload Credentials to Secrets Manager
- Step 3: Modify your CredSpec JSON to include domainless gMSA information
- Step 4: Upload CredSpec to Amazon S3
- Step 5: (Optional) Create an Amazon ECS cluster
- Step 6: Create an IAM role for container instances
- Step 7: Create a custom task execution role
- Step 8: Create a task role for Amazon ECS Exec
- Step 9: Register a task definition that uses domainless gMSA
- Step 10: Register a Windows container instance to the cluster
- Step 11: Verify the container instance
- Step 12: Run a Windows task
- Step 13: Verify the container has gMSA credentials
- Step 14: Clean up
- Debugging Amazon ECS domainless gMSA for Windows containers
Prerequisites

This tutorial assumes that the following prerequisites have been completed:

- The steps in Set up to use Amazon ECS have been completed.
- Your AWS user has the required permissions specified in the AmazonECS_FullAccess IAM policy example.
- The latest version of the AWS CLI is installed and configured. For more information about installing or upgrading your AWS CLI, see Installing the AWS Command Line Interface.
- You set up an Active Directory domain with the resources that you want your containers to access. Amazon ECS supports the following setups:
  - An AWS Directory Service Active Directory. AWS Directory Service is an AWS managed Active Directory that's hosted on Amazon EC2. For more information, see Getting Started with AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.
  - An on-premises Active Directory. You must ensure that the Amazon ECS Linux container instance can join the domain. For more information, see AWS Direct Connect.
- You have a VPC and subnets that can resolve the Active Directory domain name.
- You chose between domainless gMSA and joining each instance to a single domain. By using domainless gMSA, the container instance isn't joined to the domain, other applications on the instance can't use the credentials to access the domain, and tasks that join different domains can run on the same instance.

Then, choose the data storage for the CredSpec and optionally, for the Active Directory user credentials for domainless gMSA.

Amazon ECS uses an Active Directory credential specification file (CredSpec). This file contains the gMSA metadata that's used to propagate the gMSA account context to the container. You generate the CredSpec file and then store it in one of the CredSpec storage options in the following table, specific to the Operating System of the container instances. To use the domainless method, an optional section in the CredSpec file can specify credentials in one of the domainless user credentials storage options in the following table, specific to the Operating System of the container instances.
gMSA data storage options by Operating System

<table>
<thead>

• (Optional) AWS CloudShell is a tool that gives customers a command line without needing to create their own EC2 instance. For more information, see What is AWS CloudShell? in the AWS CloudShell User Guide.

Step 1: Create and configure the gMSA account on Active Directory Domain Services (AD DS)

Create and configure a gMSA account on the Active Directory domain.

1. **Generate a Key Distribution Service root key**

   > Note
   
   If you are using AWS Directory Service, then you can skip this step.

   The KDS root key and gMSA permissions are configured with your AWS managed Microsoft AD.

   If you have not already created a gMSA Service Account in your domain, you’ll need to first generate a Key Distribution Service (KDS) root key. The KDS is responsible for creating, rotating, and releasing the gMSA password to authorized hosts. When the ccg.exe needs to retrieve gMSA credentials, it contact KDS to retrieve the current password.

   To check if the KDS root key has already been created, run the following PowerShell cmdlet with domain admin privileges on a domain controller using the ActiveDirectory
PowerShell module. For more information about the module, see ActiveDirectory Module on the Microsoft Learn website.

If the command returns a key ID, you can skip the rest of this step. Otherwise, create the KDS root key by running the following command:

```
PS C:\> Add-KdsRootKey -EffectiveImmediately
```

Although the argument EffectiveImmediately to the command implies the key is effective immediately, you need to wait 10 hours before the KDS root key is replicated and available for use on all domain controllers.

2. **Create the gMSA account**

To create the gMSA account and allow the ccg.exe to retrieve the gMSA password, run the following PowerShell commands from a Windows Server or client with access to the domain. Replace ExampleAccount with the name that you want for your gMSA account.

- a. `PS C:\> Install-WindowsFeature RSAT-AD-PowerShell`
- b. `PS C:\> New-ADGroup -Name "ExampleAccount Authorized Hosts" -SamAccountName "ExampleAccountHosts" -GroupScope DomainLocal`
- c. `PS C:\> New-ADServiceAccount -Name "ExampleAccount" -DnsHostName "contoso" -ServicePrincipalNames "host/ExampleAccount", "host/contoso" -PrincipalsAllowedToRetrieveManagedPassword "ExampleAccountHosts"`
- d. Create a user with a permanent password that doesn't expire. These credentials are stored in AWS Secrets Manager and used by each task to join the domain.
  ```
  PS C:\> New-ADUser -Name "ExampleAccount" -AccountPassword (ConvertTo-SecureString -AsPlainText "Test123" -Force) -Enabled 1 -PasswordNeverExpires 1
  ```
- e. `PS C:\> Add-ADGroupMember -Identity "ExampleAccountHosts" -Members "ExampleAccount"`
f. Install the PowerShell module for creating CredSpec objects in Active Directory and output the CredSpec JSON.

```powershell
PS C:\> Install-PackageProvider -Name NuGet -Force
```

```powershell
PS C:\> Install-Module CredentialSpec
```

```powershell
PS C:\> New-CredentialSpec -AccountName ExampleAccount
```

g. Copy the JSON output from the previous command into a file called gmsa-cred-spec.json. This is the CredSpec file. It is used in Step 3, Step 3: Modify your CredSpec JSON to include domainless gMSA information.

### Step 2: Upload Credentials to Secrets Manager

Copy the Active Directory credentials into a secure credential storage system, so that each task retrieves it. This is the domainless gMSA method. By using domainless gMSA, the container instance isn't joined to the domain, other applications on the instance can't use the credentials to access the domain, and tasks that join different domains can run on the same instance.

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.

- Run the following AWS CLI command and replace the username, password, and domain name to match your environment. Keep the ARN of the secret to use in the next step, Step 3: Modify your CredSpec JSON to include domainless gMSA information

The following command uses backslash continuation characters that are used by sh and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

```bash
$ aws secretsmanager create-secret
   --name gmsa-plugin-input
   --description "Amazon ECS - gMSA Portable Identity."
   --secret-string "{"username":"ExampleAccount","password":"Test123","domainName":"contoso.com"}"
```

Step 3: Modify your CredSpec JSON to include domainless gMSA information

Before uploading the CredSpec to one of the storage options, add information to the CredSpec with the ARN of the secret in Secrets Manager from the previous step. For more information, see [Additional credential spec configuration for non-domain-joined container host use case](https://docs.microsoft.com/en-us/azure/container-instance/register-advanced) on the Microsoft Learn website.

1. Add the following information to the CredSpec file inside the `ActiveDirectoryConfig`. Replace the ARN with the secret in Secrets Manager from the previous step.

   Note that the `PluginGUID` value must match the GUID in the following example snippet and is required.

   ```json
   "HostAccountConfig": { 
   "PortableCcgVersion": "1",
   "PluginGUID": "{859E1386-BDB4-49E8-85C7-3070B13920E1}",
   }
   
   You can also use a secret in SSM Parameter Store by using the ARN in this format: \"arn:aws:ssm:aws-region:111122223333:parameter/gmsa-plugin-input\".

2. After you modify the CredSpec file, it should look like the following example:

   ```json
   { 
   "CmsPlugins": [ 
   "ActiveDirectory"
   ],
   "DomainJoinConfig": { 
   "Sid": "S-1-5-21-4066351383-705263209-1606769140",
   "MachineAccountName": "ExampleAccount",
   "Guid": "ac822f13-583e-49f7-aa7b-284f9a8c97b6",
   "DnsTreeName": "contoso",
   "DnsName": "contoso",
   "NetBiosName": "contoso"
   },
   "ActiveDirectoryConfig": { 
   "GroupManagedServiceAccounts": [ 
   
   ]
   }
   ```
"Name": "ExampleAccount",
  "Scope": "contoso"
},
{
  "Name": "ExampleAccount",
  "Scope": "contoso"
}
],

"HostAccountConfig": {
  "PortableCcgVersion": "1",
  "PluginGUID": "{859E1386-BDB4-49E8-85C7-3070B13920E1}"
}
}

Step 4: Upload CredSpec to Amazon S3

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.

1. Copy the CredSpec file to the computer or environment that you are running AWS CLI commands in.

2. Run the following AWS CLI command to upload the CredSpec to Amazon S3. Replace MyBucket with the name of your Amazon S3 bucket. You can store the file as an object in any bucket and location, but you must allow access to that bucket and location in the policy that you attach to the task execution role.

   The following command uses backslash continuation characters that are used by sh and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

   $ aws s3 cp gmsa-cred-spec.json s3://MyBucket/ecs-domainless-gmsa-credspec
Step 5: (Optional) Create an Amazon ECS cluster

By default, your account has an Amazon ECS cluster named default. This cluster is used by default in the AWS CLI, SDKs, and AWS CloudFormation. You can use additional clusters to group and organize tasks and infrastructure, and assign defaults for some configuration.

You can create a cluster from the AWS Management Console, AWS CLI, SDKs, or AWS CloudFormation. The settings and configuration in the cluster don't affect gMSA.

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.

$ aws ecs create-cluster --cluster-name windows-domainless-gmsa-cluster

**Important**

If you choose to create your own cluster, you must specify --cluster clusterName for each command that you intend to use with that cluster.

Step 6: Create an IAM role for container instances

A *container instance* is a host computer to run containers in ECS tasks, for example Amazon EC2 instances. Each container instance registers to an Amazon ECS cluster. Before you launch Amazon EC2 instances and register them to a cluster, you must create an IAM role for your container instances to use.

To create the container instance role, see Amazon ECS container instance IAM role. The default ecsInstanceRole has sufficient permissions to complete this tutorial.

Step 7: Create a custom task execution role

Amazon ECS can use a different IAM role for the permissions needed to start each task, instead of the container instance role. This role is the *task execution role*. We recommend creating a task execution role with only the permissions required for ECS to run the task, also known as *least-privilege permissions*. For more information about the principle of least privilege, see SEC03-BP02 Grant least privilege access in the AWS Well-Architected Framework.
1. To create a task execution role, see Creating the task execution (ecsTaskExecutionRole) role. The default permissions allow the container instance to pull container images from Amazon Elastic Container Registry and stdout and stderr from your applications to be logged to Amazon CloudWatch Logs.

Because the role needs custom permissions for this tutorial, you can give the role a different name than ecsTaskExecutionRole. This tutorial uses ecsTaskExecutionRole in further steps.

2. Add the following permissions by creating a custom policy, either an inline policy that only exists in for this role, or a policy that you can reuse. Replace the ARN for the Resource in the first statement with the Amazon S3 bucket and location, and the second Resource with the ARN of the secret in Secrets Manager.

If you encrypt the secret in Secrets Manager with a custom key, you must also allow kms:Decrypt for the key.

If you use SSM Parameter Store instead of Secrets Manager, you must allow ssm:GetParameter for the parameter, instead of secretsmanager:GetSecretValue.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject"
      ],
      "Resource": "arn:aws:s3:::MyBucket/ecs-domainless-gmsa-credspec/gmsa-credspec.json"
    },
    {
      "Effect": "Allow",
      "Action": [
        "secretsmanager:GetSecretValue"
      ],
    }
  ]
}
```
Step 8: Create a task role for Amazon ECS Exec

This tutorial uses Amazon ECS Exec to verify functionality by running a command inside a running task. To use ECS Exec, the service or task must turn on ECS Exec and the task role (but not the task execution role) must have ssmmessages permissions. For the required IAM policy, see IAM permissions required for ECS Exec.

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.

To create a task role using the AWS CLI, follow these steps.

1. Create a file called `ecs-tasks-trust-policy.json` with the following contents:

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Principal": {
           "Service": "ecs-tasks.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
       }
     ]
   }
   ```

2. Create an IAM role. You can replace the name `ecs-exec-demo-task-role` but keep the name for following steps.

   The following command uses backslash continuation characters that are used by sh and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

   ```bash
   $ aws iam create-role --role-name ecs-exec-demo-task-role
   --assume-role-policy-document file://ecs-tasks-trust-policy.json
   ```

   You can delete the file `ecs-tasks-trust-policy.json`.

3. Create a file called `ecs-exec-demo-task-role-policy.json` with the following contents:

   ```json
   {
   ```
4. Create an IAM policy and attach it to the role from the previous step.

The following command uses backslash continuation characters that are used by sh and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

```
$ aws iam put-role-policy \
   --role-name ecs-exec-demo-task-role \
   --policy-name ecs-exec-demo-task-role-policy \
   --policy-document file://ecs-exec-demo-task-role-policy.json
```

You can delete the file ecs-exec-demo-task-role-policy.json.

**Step 9: Register a task definition that uses domainless gMSA**

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.

1. Create a file called windows-gmsa-domainless-task-def.json with the following contents:

```
{
   "family": "windows-gmsa-domainless-task",
   "containerDefinitions": [
   
   
   
   ```
2. Register the task definition by running the following command:

The following command uses backslash continuation characters that are used by sh and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

```
$ aws ecs register-task-definition \
--cli-input-json file://windows-gmsa-domainless-task-def.json
```
Step 10: Register a Windows container instance to the cluster

Launch an Amazon EC2 Windows instance and run the ECS container agent to register it as a container instance in the cluster. ECS runs tasks on the container instances that are registered to the cluster that the tasks are started in.

1. To launch an Amazon EC2 Windows instance that is configured for Amazon ECS in the AWS Management Console, see Launching an Amazon ECS Windows container instance. Stop at the step for user data.

2. For gMSA, the user data must set the environment variable ECS_GMSA_SUPPORTED before starting the ECS container agent.

   For ECS Exec, the agent must start with the argument -EnableTaskIAMRole.

   To secure the instance IAM role by preventing tasks from reaching the EC2 IMDS web service to retrieve the role credentials, add the argument -AwsvpcBlockIMDS. This only applies to tasks that use the awsvpc network mode.

   ```powershell
   [Environment]::SetEnvironmentVariable("ECS_GMSA_SUPPORTED", $TRUE, "Machine")
   Import-Module ECSTools
   Initialize-ECSAgent -Cluster windows-domainless-gmsa-cluster -EnableTaskIAMRole -AwsvpcBlockIMDS
   </powershell>

3. Review a summary of your instance configuration in the Summary panel, and when you're ready, choose Launch instance.

Step 11: Verify the container instance

You can verify that there is a container instance in the cluster using the AWS Management Console. However, gMSA needs additional features that are indicated as attributes. These attributes aren't visible in the AWS Management Console, so this tutorial uses the AWS CLI.

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.
1. List the container instances in the cluster. Container instances have an ID that is different from the ID of the EC2 instance.

$ aws ecs list-container-instances

Output:

{
    "containerInstanceArns": [
        "arn:aws:ecs:aws-region:111122223333:container-instance/default/MyContainerInstanceID"
    ]
}

For example, 526bd5d0ced448a788768334e79010fd is a valid container instance ID.

2. Use the container instance ID from the previous step to get the details for the container instance. Replace MyContainerInstanceID with the ID.

The following command uses backslash continuation characters that are used by sh and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

$ aws ecs describe-container-instances \
   ----container-instances MyContainerInstanceID

Note that the output is very long.

3. Verify that the attributes list has an object with the key called name and a value ecs.capability.gmsa-domainless. The following is an example of the object.

Output:

{
    "name": "ecs.capability.gmsa-domainless"
}
Step 12: Run a Windows task

Run an Amazon ECS task. If there is only 1 container instance in the cluster, you can use `run-task`. If there are many different container instances, it might be easier to use `start-task` and specify the container instance ID to run the task on, than to add placement constraints to the task definition to control what type of container instance to run this task on.

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.

1. The following command uses backslash continuation characters that are used by sh and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

   ```
   aws ecs run-task --task-definition windows-gmsa-domainless-task --enable-execute-command --cluster windows-domainless-gmsa-cluster
   ```

   Note the task ID that is returned by the command.

2. Run the following command to verify that the task has started. This command waits and doesn't return the shell prompt until the task starts. Replace `MyTaskID` with the task ID from the previous step.

   ```
   $ aws ecs wait tasks-running --task MyTaskID
   ```

Step 13: Verify the container has gMSA credentials

Verify that the container in the task has a Kerberos token. gMSA

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.

1. The following command uses backslash continuation characters that are used by sh and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

   ```
   $ aws ecs execute-command \
   ```
The output will be a PowerShell prompt.

2. Run the following command in the PowerShell terminal inside the container.

```
PS C:\> klist get ExampleAccount$
```

In the output, note the Principal is the one that you created previously.

**Step 14: Clean up**

When you are finished with this tutorial, you should clean up the associated resources to avoid incurring charges for unused resources.

This step uses the AWS CLI. You can run these commands in AWS CloudShell in the default shell, which is bash.

1. Stop the task. Replace MyTaskID with the task ID from step 12, [Step 12: Run a Windows task](#).

```
$ aws ecs stop-task --task MyTaskID
```

2. Terminate the Amazon EC2 instance. Afterwards, the container instance in the cluster will be deleted automatically after one hour. For more information, see [Capacity management](#).

```
$ aws ec2 terminate-instances --instance-ids MyInstanceID
```

3. Delete the CredSpec file in Amazon S3. Replace MyBucket with the name of your Amazon S3 bucket.

```
$ aws s3api delete-object --bucket MyBucket --key ecs-domainless-gmsa-credspec/gmsa-cred-spec.json
```
4. Delete the secret from Secrets Manager. If you used SSM Parameter Store instead, delete the parameter.

The following command uses backslash continuation characters that are used by `sh` and compatible shells. This command isn't compatible with PowerShell. You must modify the command to use it with PowerShell.

```
$ aws secretsmanager delete-secret --secret-id gmsa-plugin-input \\
   --force-delete-without-recovery
```

5. Deregister and delete the task definition. By deregistering the task definition, you mark it as inactive so it can't be used to start new tasks. Then, you can delete the task definition.

   a. Deregister the task definition by specifying the version. ECS automatically makes versions of task definitions, that are numbered starting from 1. You refer to the versions in the same format as the labels on container images, such as `:1`.

```
$ aws ecs deregister-task-definition --task-definition windows-gmsa-domainless-task:1
```

   b. Delete the task definition.

```
$ aws ecs delete-task-definitions --task-definition windows-gmsa-domainless-task:1
```

6. (Optional) Delete the ECS cluster, if you created a cluster.

```
$ aws ecs delete-cluster --cluster windows-domainless-gmsa-cluster
```

**Debugging Amazon ECS domainless gMSA for Windows containers**

**Amazon ECS task status**

ECS tries to start a task exactly once. Any task that has an issue is stopped, and set to the status STOPPED. There are two common types of issues with tasks. First, tasks that couldn't be started. Second, tasks where the application has stopped inside one of the containers. In the AWS Management Console, look at the **Stopped reason** field of the task for the reason why the task
was stopped. In the AWS CLI, describe the task and look at the stoppedReason. For steps in the AWS Management Console and AWS CLI, see Checking stopped tasks for errors.

Windows Events

Windows Events for gMSA in containers are logged in the Microsoft-Windows-Containers-CCG log file and can be found in the Event Viewer in the section Applications and Services in Logs\Microsoft\Windows\Containers-CCG\Admin. For more debugging tips, see Troubleshoot gMSAs for Windows containers on the Microsoft Learn website.

ECS agent gMSA plugin

Logging for gMSA plugin for the ECS agent on the Windows container instance is in the following directory, C:/ProgramData/Amazon/gmsa-plugin/. Look in this log to see if the domainless user credentials were downloaded from the storage location, such as Secrets Manager, and that the credential format was read correctly.

Using gMSA for Linux Containers on Amazon EC2

Amazon ECS supports Active Directory authentication for Linux containers on EC2 through a special kind of service account called a group Managed Service Account (gMSA).

Linux based network applications, such as .NET Core applications, can use Active Directory to facilitate authentication and authorization management between users and services. You can use this feature by designing applications that integrate with Active Directory and run on domain-joined servers. But, because Linux containers can't be domain-joined, you need to configure a Linux container to run with gMSA.

A Linux container that runs with gMSA relies on the credentials-fetcher daemon that runs on the container's host Amazon EC2 instance. That is, the daemon retrieves the gMSA credentials from the Active Directory domain controller and then transfers these credentials to the container instance. For more information about service accounts, see Create gMSAs for Windows containers on the Microsoft Learn website.

Topics

- Considerations
- Prerequisites
- Setting up gMSA-capable Linux Containers on Amazon ECS
Considerations

Consider the following before you use gMSA for Linux containers:

- If your containers run on EC2, you can use gMSA for Windows containers and Linux containers. For information about how to use gMSA for Linux container on Fargate, see Using gMSA for Linux containers on Fargate.
- You might need a Windows computer that's joined to the domain to complete the prerequisites. For example, you might need a Windows computer that's joined to the domain to create the gMSA in Active Directory with PowerShell. The RSAT Active Director PowerShell tools are only available for Windows. For more information, see Installing the Active Directory administration tools.
- You chose between domainless gMSA and joining each instance to a single domain. By using domainless gMSA, the container instance isn't joined to the domain, other applications on the instance can't use the credentials to access the domain, and tasks that join different domains can run on the same instance.

Then, choose the data storage for the CredSpec and optionally, for the Active Directory user credentials for domainless gMSA.

Amazon ECS uses an Active Directory credential specification file (CredSpec). This file contains the gMSA metadata that's used to propagate the gMSA account context to the container. You generate the CredSpec file and then store it in one of the CredSpec storage options in the following table, specific to the Operating System of the container instances. To use the domainless method, an optional section in the CredSpec file can specify credentials in one of the domainless user credentials storage options in the following table, specific to the Operating System of the container instances.

**gMSA data storage options by Operating System**

<table>
<thead>
<tr>
<th>Storage location</th>
<th>Linux</th>
<th>Windows</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Simple Storage Service</td>
<td>CredSpec</td>
<td>CredSpec</td>
</tr>
<tr>
<td>AWS Secrets Manager</td>
<td>domainless user credentials</td>
<td>domainless user credentials</td>
</tr>
</tbody>
</table>
### Prerequisites

Before you use the gMSA for Linux containers feature with Amazon ECS, make sure to complete the following:

- You set up an Active Directory domain with the resources that you want your containers to access. Amazon ECS supports the following setups:
  - An AWS Directory Service Active Directory. AWS Directory Service is an AWS managed Active Directory that’s hosted on Amazon EC2. For more information, see [Getting Started with AWS Managed Microsoft AD](https://docs.aws.amazon.com/active-directory/latest/admguides/get-started-aws-managed.html) in the *AWS Directory Service Administration Guide*.
  - An on-premises Active Directory. You must ensure that the Amazon ECS Linux container instance can join the domain. For more information, see [AWS Direct Connect](https://docs.aws.amazon.com/vpc/latest/dg/aws-direct-connect.html).

- You have an existing gMSA account in the Active Directory. For more information, see [Using gMSA for Linux Containers on Amazon EC2](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/gmsa-ec2-regions.html).

- You installed and are running the `credentials-fetcher` daemon on an Amazon ECS Linux container instance. You also added an initial set of credentials to the `credentials-fetcher` daemon to authenticate with the Active Directory.

**Note**

The `credentials-fetcher` daemon is only available for Amazon Linux 2023 and Fedora 37 and later. The daemon isn't available for Amazon Linux 2. For more information, see [aws/credentials-fetcher](https://github.com/aws/credentials-fetcher) on GitHub.

- You set up the credentials for the `credentials-fetcher` daemon to authenticate with the Active Directory. The credentials must be a member of the Active Directory security group that has access to the gMSA account. There are multiple options in [Decide if you want to join the instances to the domain, or use domainless gMSA.](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/gmsa-ec2-regions.html)
• You added the required IAM permissions. The permissions that are required depend on the methods that you choose for the initial credentials and for storing the credential specification:
  • If you use domainless gMSA for initial credentials, IAM permissions for AWS Secrets Manager are required on the task execution role.
  • If you store the credential specification in SSM Parameter Store, IAM permissions for Amazon EC2 Systems Manager Parameter Store are required on the task execution role.
  • If you store the credential specification in Amazon S3, IAM permissions for Amazon Simple Storage Service are required on the task execution role.

Setting up gMSA-capable Linux Containers on Amazon ECS

Prepare the infrastructure

The following steps are considerations and setup that are performed once. After you complete these steps, you can automate creating container instances to reuse this configuration.

Decide how the initial credentials are provided and configure the EC2 user data in a reusable EC2 launch template to install the credentials-fetcher daemon.

1. Decide if you want to join the instances to the domain, or use domainless gMSA.
   • Join EC2 instances to the Active Directory domain
     • Join the instances by user data
       Add the steps to join the Active Directory domain to your EC2 user data in an EC2 launch template. Multiple Amazon EC2 Auto Scaling groups can use the same launch template.
       You can use these steps Joining an Active Directory or FreeIPA domain in the Fedora Docs.
     • Make an Active Directory user for domainless gMSA
       The credentials-fetcher daemon has a feature that's called domainless gMSA. This feature requires a domain, but the EC2 instance doesn't need to be joined to the domain. By using domainless gMSA, the container instance isn't joined to the domain, other applications on the instance can't use the credentials to access the domain, and tasks that join different domains can run on the same instance. Instead, you provide the name of a
secret in AWS Secrets Manager in the CredSpec file. The secret must contain a username, password, and the domain to log in to.

This feature is supported and can be used with Linux and Windows containers.

This feature is similar to the gMSA support for non-domain-joined container hosts feature. For more information about the Windows feature, see gMSA architecture and improvements on the Microsoft Learn website.

a. Make a user in your Active Directory domain. The user in Active Directory must have permission to access the gMSA service accounts that you use in the tasks.

b. Create a secret in AWS Secrets Manager, after you made the user in Active Directory. For more information, see Create an AWS Secrets Manager secret.

c. Enter the user's username, password, and the domain into JSON key-value pairs called username, password and domainName, respectively.

```
{"username":"username","password":"passw0rd", "domainName":"example.com"}
```

d. Add configuration to the CredSpec file for the service account. The additional HostAccountConfig contains the Amazon Resource Name (ARN) of the secret in Secrets Manager.

On Windows, the PluginGUID must match the GUID in the following example snippet. On Linux, the PluginGUID is ignored. Replace MySecret with example with the Amazon Resource Name (ARN) of your secret.

```
"ActiveDirectoryConfig": { 
   "HostAccountConfig": { 
      "PortableCcgVersion": "1", 
      "PluginGUID": "{859E1386-BDB4-49E8-85C7-3070B13920E1}",
      "PluginInput": { 
      }
   }
}
```

e. The domainless gMSA feature needs additional permissions in the task execution role. Follow the step (Optional) domainless gMSA secret.
2. **Configure instances and install credentials-fetcher daemon**

You can install the credentials-fetcher daemon with a user data script in your EC2 Launch Template. The following examples demonstrate two types of user data, cloud-config YAML or bash script. These examples are for Amazon Linux 2023 (AL2023). Replace `MyCluster` with the name of the Amazon ECS cluster that you want these instances to join.

- **cloud-config YAML**

```
package_reboot_if_required: true
packages:
  # prerequisites
  - dotnet
  - realmd
  - oddjob
  - oddjob-mkhomedir
  - sssd
  - adcli
  - krb5-workstation
  - samba-common-tools
# https://github.com/aws/credentials-fetcher gMSA credentials management for containers
  - credentials-fetcher
write_files:
  # configure the ECS Agent to join your cluster.
  # replace MyCluster with the name of your cluster.
  - path: /etc/ecs/ecs.config
    owner: root:root
    permissions: '0644'
    content: |
      ECS_CLUSTER=MyCluster
      ECS_GMSA_SUPPORTED=true
runcmd:
  # start the credentials-fetcher daemon and if it succeeded, make it start after every reboot
  - "systemctl start credentials-fetcher"
  - "systemctl is-active credentials-fetcher && systemctl enable credentials-fetcher"
```
• **bash script**

If you're more comfortable with bash scripts and have multiple variables to write to /etc/ecs/ecs.config, use the following heredoc format. This format writes everything between the lines beginning with `cat` and `EOF` to the configuration file.

```bash
#!/usr/bin/env bash
set -euxo pipefail

# prerequisites
timeout 30 dnf install -y dotnet realm oddjob oddjob-mkhomedir sssd adcli krb5-workstation samba-common-tools
# install https://github.com/aws/credentials-fetcher gMSA credentials management for containers
timeout 30 dnf install -y credentials-fetcher

# start credentials-fetcher
systemctl start credentials-fetcher
systemctl is-active credentials-fetch & & systemctl enable credentials-fetcher

cat <<'EOF' >> /etc/ecs/ecs.config
ECS_CLUSTER=MyCluster
ECS_GMSA_SUPPORTED=true
EOF
```

There are optional configuration variables for the credentials-fetcher daemon that you can set in /etc/ecs/ecs.config. We recommend that you set the variables in the user data in the YAML block or heredoc similar to the previous examples. Doing so prevents issues with partial configuration that can happen with editing a file multiple times. For more information about the ECS agent configuration, see [Amazon ECS Container Agent](https://github.com/aws/ecs-agent) on GitHub.

• Optionally, you can use the variable CREDENTIALS_FETCHER_HOST if you change the credentials-fetcher daemon configuration to move the socket to another location.

### Setting up permissions and secrets

Do the following steps once for each application and each task definition. We recommend that you use the best practice of granting the least privilege and narrow the permissions used in the policy. This way, each task can only read the secrets that it needs.
1. **(Optional) domainless gMSA secret**

If you use the domainless method where the instance isn't joined to the domain, follow this step.

You must add the following permissions as an inline policy to the task execution IAM role. Doing so gives the credentials-fetcher daemon access to the Secrets Manager secret. Replace the `MySecret` example with the Amazon Resource Name (ARN) of your secret in the `Resource` list.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Action": [
            "secretsmanager:GetSecretValue"
         ],
         "Resource": [
         ]
      }
   ]
}
```

**Note**

If you use your own KMS key to encrypt your secret, you must add the necessary permissions to this role and add this role to the AWS KMS key policy.

2. **Decide if you're using SSM Parameter Store or S3 to store the CredSpec**

Amazon ECS supports the following ways to reference the file path in the `credentialSpecs` field of the task definition.

If you join the instances to a single domain, use the prefix `credentialspec:` at the start of the ARN in the string. If you use domainless gMSA, then use `credentialspecdomainless:`.

For more information about the CredSpec, see [Credential specification file](#).
Amazon S3 Bucket

Add the credential spec to an Amazon S3 bucket. Then, reference the Amazon Resource Name (ARN) of the Amazon S3 bucket in the credentialSpecs field of the task definition.

```
{
    "family": "",
    "executionRoleArn": "",
    "containerDefinitions": [
        {
            "name": "",
            ...
            "credentialSpecs": [
                "credentialSpecDomainless:arn:aws:s3:::
                    ${BucketName}/
                    ${ObjectName}
            ]
        }
    ],
    ...
}
```

To give your tasks access to the S3 bucket, add the following permissions as an inline policy to the Amazon ECS task execution IAM role.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor",
            "Effect": "Allow",
            "Action": [
                "s3:Get*",
                "s3:List*"
            ],
            "Resource": [
                "arn:aws:s3:::${bucket_name}",
                "arn:aws:s3:::${bucket_name}/${object}
            ]
        }
    ]
}
```
• **SSM Parameter Store parameter**

Add the credential spec to an SSM Parameter Store parameter. Then, reference the Amazon Resource Name (ARN) of the SSM Parameter Store parameter in the `credentialSpecs` field of the task definition.

```json
{
    "family": "",
    "executionRoleArn": "",
    "containerDefinitions": [
        {
            "name": "",
            ...
            "credentialSpecs": [
                "credentialspecdomainless:arn:aws:ssm:aws-region:111122223333:parameter/parameter_name"
            ],
            ...
        }
    ],
    ...
}
```

To give your tasks access to the SSM Parameter Store parameter, add the following permissions as an inline policy to the Amazon ECS task execution IAM role.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "ssm:GetParameters"
            ],
            "Resource": [
                "arn:aws:ssm:aws-region:111122223333:parameter/parameter_name"
            ]
        }
    ]
}
```
Credential specification file

Amazon ECS uses an Active Directory credential specification file (CredSpec). This file contains the gMSA metadata that's used to propagate the gMSA account context to the Linux container. You generate the CredSpec and reference it in the credentialSpecs field in your task definition. The CredSpec file doesn't contain any secrets.

The following is an example CredSpec file.

```json
{
    "CmsPlugins": [
        "ActiveDirectory"
    ],
    "DomainJoinConfig": {
        "Sid": "S-1-5-21-2554468230-2647958158-2204241789",
        "MachineAccountName": "WebApp01",
        "Guid": "8665abd4-e947-4dd0-9a51-f8254943c90b",
        "DnsTreeName": "example.com",
        "DnsName": "example.com",
        "NetBiosName": "example"
    },
    "ActiveDirectoryConfig": {
        "GroupManagedServiceAccounts": [
            {
                "Name": "WebApp01",
                "Scope": "example.com"
            }
        ],
        "HostAccountConfig": {
            "PortableCcgVersion": "1",
            "PluginGUID": "{859E1386-BDB4-49E8-85C7-3070B13920E1}"
        }
    }
}
```

Creating a CredSpec
You create a CredSpec by using the CredSpec PowerShell module on a Windows computer that's joined to the domain. Follow the steps in Create a credential spec on the Microsoft Learn website.

**Using gMSA for Linux containers on Fargate**

Amazon ECS supports Active Directory authentication for Linux containers on Fargate through a special kind of service account called a *group Managed Service Account* (gMSA).

Linux based network applications, such as .NET Core applications, can use Active Directory to facilitate authentication and authorization management between users and services. You can use this feature by designing applications that integrate with Active Directory and run on domain-joined servers. But, because Linux containers can't be domain-joined, you need to configure a Linux container to run with gMSA.

**Considerations**

Consider the following before you use gMSA for Linux containers on Fargate:

- You must be running Platform Version 1.4 or later.
- You might need a Windows computer that's joined to the domain to complete the prerequisites. For example, you might need a Windows computer that's joined to the domain to create the gMSA in Active Directory with PowerShell. The RSAT Active Directory PowerShell tools are only available for Windows. For more information, see [Installing the Active Directory administration tools](#).
- You must use **domainless gMSA**.

Amazon ECS uses an Active Directory credential specification file (CredSpec). This file contains the gMSA metadata that's used to propagate the gMSA account context to the container. You generate the CredSpec file, and then store it in an Amazon S3 bucket.

- A task can only support one Active Directory.

**Prerequisites**

Before you use the gMSA for Linux containers feature with Amazon ECS, make sure to complete the following:

- You set up an Active Directory domain with the resources that you want your containers to access. Amazon ECS supports the following setups:
An AWS Directory Service Active Directory. AWS Directory Service is an AWS managed Active Directory that's hosted on Amazon EC2. For more information, see Getting Started with AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

An on-premises Active Directory. You must ensure that the Amazon ECS Linux container instance can join the domain. For more information, see AWS Direct Connect.

You have an existing gMSA account in the Active Directory and a user that has permission to access the gMSA service account. For more information, see Make an Active Directory user for domainless gMSA.

You have an Amazon S3 bucket. For more information, see Creating a bucket in the Amazon S3 User Guide.

Setting up gMSA-capable Linux Containers on Amazon ECS

Prepare the infrastructure

The following steps are considerations and setup that are performed once.

- **Make an Active Directory user for domainless gMSA**

  When you use domainless gMSA, the container isn't joined to the domain. Other applications that run on the container can't use the credentials to access the domain. Tasks that use a different domain can run on the same container. You provide the name of a secret in AWS Secrets Manager in the CredSpec file. The secret must contain a username, password, and the domain to log in to.

  This feature is similar to the gMSA support for non-domain-joined container hosts feature. For more information about the Windows feature, see gMSA architecture and improvements on the Microsoft Learn website.

  a. Configure a user in your Active Directory domain. The user in the Active Directory must have permission to access the gMSA service account that you use in the tasks.

  b. You have a VPC and subnets that can resolve the Active Directory domain name. Configure the VPC with DHCP options with the domain name that points to the Active Directory service name. For information about how to configure DHCP options for a VPC, see Work with DHCP option sets in the Amazon Virtual Private Cloud User Guide.

  c. Create a secret in AWS Secrets Manager.

  d. Create the credential specification file.
Setting up permissions and secrets

Do the following steps one time for each application and each task definition. We recommend that you use the best practice of granting the least privilege and narrow the permissions used in the policy. This way, each task can only read the secrets that it needs.

1. Make a user in your Active Directory domain. The user in Active Directory must have permission to access the gMSA service accounts that you use in the tasks.

2. After you make the Active Directory user, create a secret in AWS Secrets Manager. For more information, see Create an AWS Secrets Manager secret.

3. Enter the user's username, password, and the domain into JSON key-value pairs called `username`, `password` and `domainName`, respectively.

   ```json
   {
     "username": "<username>",
     "password": "<password>",
     "domainName": "example.com"
   }
   ```

4. You must add the following permissions as an inline policy to the task execution IAM role. Doing so gives the credentials-fetcher daemon access to the Secrets Manager secret. Replace the `MySecret` example with the Amazon Resource Name (ARN) of your secret in the Resource list.

   ```json
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": [
           "secretsmanager:GetSecretValue"
         ],
         "Resource": [
         ]
       }
     ]
   }
   ```

**Note**

If you use your own KMS key to encrypt your secret, you must add the necessary permissions to this role and add this role to the AWS KMS key policy.
5. Add the credential spec to an Amazon S3 bucket. Then, reference the Amazon Resource Name (ARN) of the Amazon S3 bucket in the `credentialSpecs` field of the task definition.

```json
{
    "family": "",
    "executionRoleArn": "",
    "containerDefinitions": [ 
        {
            "name": "",
            ...
            "credentialSpecs": [
                "credentialSpecDomainless:arn:aws:s3:::${BucketName}/${ObjectName}"
            ],
            ...
        },
        ...
    ],
    ...
}
```

To give your tasks access to the S3 bucket, add the following permissions as an inline policy to the Amazon ECS task execution IAM role.

```json
{
    "Version": "2012-10-17",
    "Statement": [ 
        {
            "Sid": "VisualEditor",
            "Effect": "Allow",
            "Action": [ 
                "s3:GetObject",
                "s3:ListObject"
            ],
            "Resource": [ 
                "arn:aws:s3:::${bucket_name}",
                "arn:aws:s3:::${bucket_name}/${object}"
            ]
        }
    ]
}
```
Credential specification file

Amazon ECS uses an Active Directory credential specification file (CredSpec). This file contains the gMSA metadata that's used to propagate the gMSA account context to the Linux container. You generate the CredSpec and reference it in the credentialSpecs field in your task definition. The CredSpec file doesn't contain any secrets.

The following is an example CredSpec file.

```json
{
    "CmsPlugins": [
        "ActiveDirectory"
    ],
    "DomainJoinConfig": {
        "Sid": "S-1-5-21-2554468230-2647958158-2204241789",
        "MachineAccountName": "WebApp01",
        "Guid": "8665abd4-e947-4dd0-9a51-f8254943c90b",
        "DnsTreeName": "example.com",
        "DnsName": "example.com",
        "NetBiosName": "example"
    },
    "ActiveDirectoryConfig": {
        "GroupManagedServiceAccounts": [{
            "Name": "WebApp01",
            "Scope": "example.com"
        }],
        "HostAccountConfig": {
            "PortableCcgVersion": "1",
            "PluginGUID": "{859E1386-BDB4-49E8-85C7-3070B13920E1}",
            "PluginInput": {
            }
        }
    }
}
```

Creating a CredSpec and uploading it to an Amazon S3
You create a CredSpec by using the CredSpec PowerShell module on a Windows computer that's joined to the domain. Follow the steps in Create a credential spec on the Microsoft Learn website.

After you create the credential specification file, upload it to an Amazon S3 bucket. Copy the CredSpec file to the computer or environment that you are running AWS CLI commands in.

Run the following AWS CLI command to upload the CredSpec to Amazon S3. Replace MyBucket with the name of your Amazon S3 bucket. You can store the file as an object in any bucket and location, but you must allow access to that bucket and location in the policy that you attach to the task execution role.

For PowerShell, use the following command:

```powershell
$ Write-S3Object -BucketName "MyBucket" -Key "ecs-domainless-gmsa-credspec" -File "gmsa-cred-spec.json"
```

The following AWS CLI command uses backslash continuation characters that are used by sh and compatible shells.

```bash
$ aws s3 cp gmsa-cred-spec.json s3://MyBucket/ecs-domainless-gmsa-credspec
```

**Using EC2 Image Builder to build customized Amazon ECS-optimized AMIs**

AWS recommends the you use the Amazon ECS-optimized AMIs because they are preconfigured with the requirements and recommendations to run your container workloads. There might be times when you need to customize your AMI to add additional software. You can use EC2 Image Builder for the creation, management, and deployment of your server images. You retain ownership of the customized images created in your account. You can use EC2 Image Builder pipelines to automate updates and system patching for your images, or use a stand-alone command to create an image with your defined configuration resources.

You create a recipe for your image. The recipe includes a parent image, and any additional components. You also create a pipeline which distributes your customized AMI.

You create a recipe for your image. An Image Builder image recipe is a document that defines the base image and the components that are applied to the base image to produce the desired
configuration for the output AMI image. You also create a pipeline which distributes your customized AMI. For more information, see How EC2 Image Builder works in the EC2 Image Builder User Guide.

We recommend that you use one of the following Amazon ECS-optimized AMIs as your "Parent image" in EC2 Image Builder:

- **Linux**
  - Amazon ECS-optimized AL2023 x86
  - Amazon ECS-optimized Amazon Linux 2023 (arm64) AMI
  - Amazon ECS-optimized Amazon Linux 2 kernel 5 AMI
  - Amazon ECS-optimized Amazon Linux 2 x86 AMI
- **Windows**
  - Amazon ECS-optimized Windows 2022 Full x86
  - Amazon ECS-optimized Windows 2022 Core x86
  - Amazon ECS-optimized Windows 2019 Full x86
  - Amazon ECS-optimized Windows 2019 Core x86
  - Amazon ECS-optimized Windows 2016 Full x86

We also recommend that you select "Use latest available OS version". The pipeline will use semantic versioning for the parent image, which helps detect the dependency updates in automatically scheduled jobs. For more information, see Semantic versioning in the EC2 Image Builder User Guide.

AWS regularly updates Amazon ECS-optimized AMI images with security patches and the new container agent version. When you use an AMI ID as your parent image in your image recipe, you need to regularly check for updates to the parent image. If there are updates, you must create a new version of your recipe with the updated AMI. This ensures that your custom images incorporate the latest version of the parent image. For information about how to create a workflow to automatically update your EC2 instances in your Amazon ECS cluster with the newly created AMIs, see How to create an AMI hardening pipeline and automate updates to your ECS instance fleet.

You can also specify the Amazon Resource Name (ARN) of a parent image that's published through a managed EC2 Image Builder pipeline. Amazon routinely publishes Amazon ECS-optimized AMI images through managed pipelines. These images are publicly accessible. You must have the
correct permissions to access the image. When you use an image ARN instead of an AMI in your Image Builder recipe, your pipeline automatically uses the most recent version of the parent image each time it runs. This approach eliminates the need to manually create new recipe versions for each update.

**Using the image ARN with infrastructure as code (IaC)**

You can configure the recipe using the EC2 Image Builder console, or infrastructure as code (for example, AWS CloudFormation), or the AWS SDK. When you specify a parent image in your recipe, you can specify an EC2 AMI ID, Image Builder image ARN, AWS Marketplace product ID, or container image. AWS publishes both AMI IDs and Image Builder image ARNs of Amazon ECS-Optimized AMIs publicly. The following is the ARN format for the image:

```
arn:${Partition}:imagebuilder:${Region}:${Account}:image/${ImageName}/${ImageVersion}
```

The ImageVersion has the following format. Replace *major*, *minor* and *patch* with the latest values.

```
<major>.<minor>.<patch>
```

You can replace *major*, *minor* and *patch* to specific values or you can use Versionless ARN of an image, so your pipeline remains up-to-date with the latest version of the parent image. A versionless ARN uses wildcard format ‘x.x.x’ to represent the image version. This approach allows the Image Builder service to automatically resolve to the most recent version of the image. Using versionless ARN ensures that your reference always point to the latest image available, streamlining the process of maintaining up to date images in your deployment. When you create a recipe with the console, EC2 Image Builder automatically identifies the ARN for your parent image. When you use IaC to create the recipe, you must identify the ARN and select the desired image version or use versionless arn to indicate latest available image. We recommend that you create an automated script to filter and only display images that align with your criteria. The following Python script shows how to retrieve a list of Amazon ECS-optimized AMIs.

The script accepts two optional arguments: `owner` and `platform`, with default values of “Amazon”, and “Windows” respectively. The valid values for the owner argument are: Self, Shared, Amazon, and ThirdParty. The valid values for the platform argument are Windows and Linux. For example, if you run the script with the `owner` argument set to Amazon and the `platform` set to Linux, the script generates a list of images published by Amazon including Amazon ECS-Optimized images.
import boto3
import argparse

def list_images(owner, platform):
    # Create a Boto3 session
    session = boto3.Session()

    # Create an EC2 Image Builder client
    client = session.client('imagebuilder')

    # Define the initial request parameters
    request_params = {
        'owner': owner,
        'filters': [
            {
                'name': 'platform',
                'values': [platform]
            }
        ]
    }

    # Initialize the results list
    all_images = []

    # Get the initial response with the first page of results
    response = client.list_images(**request_params)

    # Extract images from the response
    all_images.extend(response['imageVersionList'])

    # While 'nextToken' is present, continue paginating
    while 'nextToken' in response and response['nextToken']:
        # Update the token for the next request
        request_params['nextToken'] = response['nextToken']

        # Get the next page of results
        response = client.list_images(**request_params)

        # Extract images from the response
        all_images.extend(response['imageVersionList'])

    return all_images
def main():
    # Initialize the parser
    parser = argparse.ArgumentParser(description="List AWS images based on owner and platform")

    # Add the parameters/arguments
    parser.add_argument("--owner", default="Amazon", help="The owner of the images. Default is 'Amazon'.")
    parser.add_argument("--platform", default="Windows", help="The platform type of the images. Default is 'Windows'.")

    # Parse the arguments
    args = parser.parse_args()

    # Retrieve all images based on the provided owner and platform
    images = list_images(args.owner, args.platform)

    # Print the details of the images
    for image in images:
        print(f"Name: {image['name']}, Version: {image['version']}, ARN: {image['arn']}")

if __name__ == '__main__':
    main()

Using the image ARN with AWS CloudFormation

An Image Builder image recipe is a blueprint that specifies the parent image and components required to achieve the intended configuration of the output image. You use the AWS::ImageBuilder::ImageRecipe resource. Set the ParentImage value to the image ARN. Use the versionless ARN of your desired image to ensure your pipeline always uses the most recent version of the image. For example, arn:aws:imagebuilder:us-east-1:aws:image/amazon-linux-2023-ecs-optimized-x86/x.x.x. The following AWS::ImageBuilder::ImageRecipe resource definition uses an Amazon managed image ARN:

ECSRecipe:
  Type: AWS::ImageBuilder::ImageRecipe
  Properties:
    Name: MyRecipe
    Version: '1.0.0'
    Components:
      - ComponentArn: [The component arns of the image recipe]
ParentImage: "arn:aws:imagebuilder:us-east-1:aws:image/amazon-linux-2023-ecs-optimized-x86/x.x.x"

For more information about the AWS::ImageBuilder::ImageRecipe resource see in the AWS CloudFormation User Guide.

You can automate the creation of new images in your pipeline by setting the Schedule property of the AWS::ImageBuilder::ImagePipeline resource. The schedule includes a start condition and cron expression. For more information, see AWS::ImageBuilder::ImagePipeline in the AWS CloudFormation User Guide.

The following of AWS::ImageBuilder::ImagePipeline example has the pipeline run a build at 10:00AM Coordinated Universal Time (UTC) every day. Set the following Schedule values:

- Set PipelineExecutionStartCondition to EXPRESSION_MATCH_AND_DEPENDENCY_UPDATES_AVAILABLE. The build initiates only if dependent resources like the parent image or components, which use the wildcard ‘x’ in their semantic versions, are updated. This ensures the build incorporates the latest updates of those resources.
- Set ScheduleExpression to the cron expression (0 10 * * ? *).

ECSPipeline:
Type: AWS::ImageBuilder::ImagePipeline
Properties:
  Name: my-pipeline
  ImageRecipeArn: <arn of the recipe you created in previous step>
  InfrastructureConfigurationArn: <ARN of the infrastructure configuration associated with this image pipeline>
Schedule:
  PipelineExecutionStartCondition: EXPRESSION_MATCH_AND_DEPENDENCY_UPDATES_AVAILABLE
  ScheduleExpression: 'cron(0 10 * * ? *)'

Using the image ARN with Terraform

The approach for specifying your pipeline's parent image and schedule in Terraform aligns with that in AWS CloudFormation. You use the aws_imagebuilder_image_recipe resource. Set the parent_image value to the image ARN. Use the versionless ARN of your desired image to
ensure your pipeline always uses the most recent version of the image. For more information, see `aws_imagebuilder_image_recipe` in the Terraform documentation.

In the schedule configuration block of the `aws_imagebuilder_image_pipeline` resource, set the `schedule_expression` argument value to a cron expression of your choice to specify how often the pipeline runs, and set the `pipeline_execution_start_condition` to `EXPRESSION_MATCH_AND_DEPENDENCY_UPDATES_AVAILABLE`. For more information, see `aws_imagebuilder_image_pipeline` in the Terraform documentation.
Amazon ECS troubleshooting

You might need to troubleshoot issues with your load balancers, tasks, services, or container instances. This chapter helps you find diagnostic information from the Amazon ECS container agent, the Docker daemon on the container instance, and the service event log in the Amazon ECS console.

Topics

• Troubleshooting issues with ECS Exec
• Troubleshooting Amazon ECS Anywhere issues
• Checking stopped tasks for errors
• Stopped tasks error codes
• CannotPullContainer task errors
• Service event messages
• Invalid CPU or memory value specified
• CannotCreateContainerError: API error (500): devmapper
• Troubleshooting service load balancers
• Troubleshooting Amazon EBS volume attachment
• Troubleshooting service auto scaling
• Using Docker debug output
• Amazon ECS log file locations
• Amazon ECS logs collector
• Agent introspection diagnostics
• Docker diagnostics
• AWS Fargate throttling quotas
• API failure reasons
• Best practices for handling Amazon ECS throttling issues

Troubleshooting issues with ECS Exec

The following are troubleshooting notes to help diagnose why you may be getting an error when using ECS Exec.
Verify using the Amazon ECS Exec Checker

The ECS Exec Checker script provides a way to verify and validate that your Amazon ECS cluster and task have met the prerequisites for using the ECS Exec feature. The ECS Exec Checker script verifies both your AWS CLI environment and cluster and tasks are ready for ECS Exec, by calling various APIs on your behalf. The tool requires the latest version of the AWS CLI and that the jq is available. For more information, see ECS Exec Checker on GitHub.

Error when calling execute-command

If a The `execute-command` command failed error occurs, the following are possible causes.

• The task does not have the required permissions. Verify that the task definition used to launch your task has a task IAM role defined and that the role has the required permissions. For more information, see IAM permissions required for ECS Exec.
• The SSM agent isn't installed or isn't running.
• There is an interface Amazon VPC endpoint for Amazon ECS, but there isn't one for Systems Manager Session Manager.

Troubleshooting Amazon ECS Anywhere issues

Amazon ECS Anywhere provides support for registering an external instance such as an on-premises server or virtual machine (VM) to your Amazon ECS cluster. The following are common issues that you might encounter and general troubleshooting recommendations for them.

Topics

• External instance registration issues
• External instance network issues
• Issues running tasks on your external instance

External instance registration issues

When registering an external instance with your Amazon ECS cluster, the following requirements must be met:

• An AWS Systems Manager activation, which consists of an activation ID and activation code, must be retrieved. You use it to register the external instance as a Systems Manager managed
instance. When a Systems Manager activation is requested, specify a registration limit and expiration date. The registration limit specifies the maximum number of instances that can be registered using the activation. The default value for registration limit is 1 instance. The expiration date specifies when the activation expires. The default value is 24 hours. If the Systems Manager activation that you're using to register your external instance isn't valid, request a new one. For more information, see Registering an external instance to a cluster.

- An IAM policy is used to provide your external instance the permissions that it needs to communicate with AWS API operations. If this managed policy isn't created properly and doesn't contain the required permissions, external instance registration fails. For more information, see ECS Anywhere IAM role.

- Amazon ECS provides an installation script that installs Docker, the Amazon ECS container agent, and the Systems Manager Agent on your external instance. If the installation script fails, it's likely that the script can't be run again on the same instance without an error occurring. If this happens, follow the cleanup process to clear AWS resources from the instance so you can run the installation script again. For more information, see Deregistering an external instance.

Note

Be aware that, if the installation script successfully requested and used the Systems Manager activation, running the installation script a second time uses the Systems Manager activation again. This might in turn cause you to reach the registration limit for that activation. If this limit is reached, you must create a new activation.

- When running the installation script on an external instance for GPU workloads, if the NVIDIA driver is not detected or configured properly, an error will occur. The installation script uses the nvidia-smi command to confirm the existence of the NVIDIA driver.

External instance network issues

To communicate any changes, your external instance requires a network connection to AWS. If your external instance loses its network connection to AWS, tasks that are running on your instances continue to run anyway unless stopped manually. After the connection to AWS is restored, the AWS credentials that are used by the Amazon ECS container agent and Systems Manager Agent on the external instance renew automatically. For more information about the AWS domains that are used for communication between your external instance and AWS, see Networking with ECS Anywhere.
Issues running tasks on your external instance

If your tasks or containers fail to run on your external instance, the most common causes are either network or permission related. If your containers are pulling their images from Amazon ECR or are configured to send container logs to CloudWatch Logs, your task definition must specify a valid task execution IAM role. Without a valid task execution IAM role, your containers will fail to start. For more information about network related issues, see External instance network issues.

⚠️ Important

Amazon ECS provides the Amazon ECS logs collection tool. You can use it to collect logs from your external instances for troubleshooting purposes. For more information, see Amazon ECS logs collector.

Checking stopped tasks for errors

If you have trouble starting a task, your task might be stopping because of application or configuration errors. For example, you run the task and the task displays a PENDING status and then disappears. You can view stopped task errors like this in the Amazon ECS console by viewing the stopped task and inspecting it for error messages.

If your task definition uses the awslogs log driver, the application logs that are written to Amazon CloudWatch Logs are displayed on the Logs tab in the Amazon ECS console for as long as the stopped task appears.

If your task was created by an Amazon ECS service, the actions that Amazon ECS takes to maintain the service are published in the service events. You can view the events in the AWS Management Console, AWS CLI, AWS SDKs, the Amazon ECS API, or tools that use the SDKs and API. These events include Amazon ECS stopping and replaces a task because the containers in the task have stopped running, or have failed too many health checks from Elastic Load Balancing. For more information, see Service event messages.

If your task ran on a container instance on Amazon EC2 or external computers, you can also look at the logs of the container runtime and the Amazon ECS Agent. These logs are on the host Amazon EC2 instance or external computer. For more information, see Amazon ECS log file locations.
Important

Stopped tasks only appear in the Amazon ECS console, AWS CLI, and AWS SDKs for at least 1 hour after the task stops. After that, the details of the stopped task expire and aren’t available in Amazon ECS.

Amazon ECS also sends task state change events to Amazon EventBridge. You can't view events in EventBridge. Instead, you create rules to send the events to other persistent storage such as Amazon CloudWatch Logs. You can use the storage to view your stopped task details after it has expired from view in the Amazon ECS console. For more information, see Amazon ECS task state change events.

For a sample EventBridge configuration to archive Amazon ECS events to Amazon CloudWatch Logs, see ECS Stopped Tasks in CloudWatch Logs on the GitHub website.

Follow these steps to check stopped tasks for errors.

Console

AWS Management Console

The following steps can be used to check stopped tasks for errors using the new AWS Management Console.

2. In the navigation pane, choose Clusters.
3. On the Clusters page, choose the cluster.
4. On the Cluster : name page, choose the Tasks tab.
5. Configure the filter to display stopped tasks. For Filter desired status, choose Stopped or Any desired status.

The Stopped option displays your stopped tasks and Any desired status displays all of your tasks.

6. Choose the stopped task to inspect.
7. In the row for your stopped task, in the Last Status column, choose Stopped.

A pop-up window displays the stopped reason.
AWS CLI

1. List the stopped tasks in a cluster. The output contains the Amazon Resource Name (ARN) of the task, which you need to describe the task.

   ```bash
   aws ecs list-tasks \
   --cluster cluster_name \
   --desired-status STOPPED \
   --region us-west-2
   ```

2. Describe the stopped task to retrieve the stoppedReason in the response.

   ```bash
   aws ecs describe-tasks \
   --cluster cluster_name \
   --tasks arn:aws:ecs:us-west-2:account_id:task/cluster_name/task_ID \
   --region us-west-2
   ```

Additional resources

The following pages provide additional information about error codes:

- [Why is my Amazon ECS task stopped](#)
- [Stopped tasks error codes](#)

**Stopped tasks error codes**

The following are the possible error messages you may receive when your Fargate task is stopped unexpectedly. The error messages are returned by the container agent and the prefix is dependent on the platform version the task is using.

To check your stopped tasks for an error message using the AWS Management Console, see [Checking stopped tasks for errors](#).

ContainerRuntimeTimeoutError, DockerTimeoutError (Linux platform version 1.3.0 or earlier)

This error occurs when a container can't transition to either a RUNNING or STOPPED state within the timeout period. The reason and timeout value is provided in the error message.
Example: ContainerRuntimeTimeoutError: Could not transition to running; timed out after waiting 1m: <reason>

CannotStartContainerError

This error occurs when a container can't be started.

Example: CannotStartContainerError: failed to get container status: <reason>

CannotStopContainerError

This error occurs when a container can’t be stopped.

Example: CannotStopContainerError: failed sending SIGTERM to container: <reason>

CannotInspectContainerError

This error occurs when the container agent can't describe the container through the container runtime.

When using platform version 1.3 or prior, the Amazon ECS agent returns the reason from Docker.

When using platform version 1.4 or later 1.4.0 or later (Linux) or 1.0.0 or later (Windows), the Fargate agent returns the reason from containerd.

Example: CannotInspectContainerError: <reason>

ResourceInitializationError

This error occurs when the container agent for your Fargate task fails to create or bootstrap the resources required to start the container or the task it belongs to.

A common cause for this error is using a VPC that doesn't have DNS resolution enabled.

This error only occurs if you use platform version 1.4.0 or later (Linux) or 1.0.0 or later (Windows).

Example: ResourceInitializationError: failed to initialize logging driver: <reason>
CannotPullContainerError

This error occurs when the agent is unable to pull the container image specified in the task definition. For more information, see CannotPullContainer task errors.

Example: CannotPullContainerError: <reason>

CannotCreateVolumeError

This error occurs when the agent can't create the volume mount specified in the task definition.

This error only occurs if you use platform version 1.4.0 or later (Linux) or 1.0.0 or later (Windows).

Example: CannotCreateVolumeError: <reason>

ContainerRuntimeError

This error occurs when the agent receives an unexpected error from containerd for a runtime-specific operation. This error is usually caused by an internal failure in the agent or the containerd runtime.

This error only occurs if you use platform version 1.4.0 or later (Linux) or 1.0.0 or later (Windows).

Example: ContainerRuntimeError: failed to create container IO set: <reason>

OutOfMemoryError

This error occurs when a container exits due to processes in the container consuming more memory than was allocated in the task definition.

Example: OutOfMemoryError: container killed due to memory usage

InternalError

This error occurs when the agent encounters an unexpected, non-runtime related internal error.

This error only occurs if using platform version 1.4 or later.

Example: InternalError: <reason>

TaskFailedToStart

This error occurs when an ENI attachment is requested. Amazon EC2 asynchronously handles the provisioning of the ENI. The provisioning process takes time. Amazon ECS has a timeout
in case there are long wait times or unreported failures. There are times when the ENI is provisioned, but the report comes to Amazon ECS after the failure timeout. In this case, Amazon ECS sees the reported task failure with an in-use ENI.

Example: InternalError: `<reason>`

**SpotInterruption**

This error occurs when there is no Fargate Spot capacity or when Fargate takes back Spot capacity.

Example: SpotInterruption: Your Spot Task was interrupted

Example: InternalError: `<reason>`

**TaskFailedToStart**

This error occurs when the subnet that hosts the instances does not have enough IP addresses. The number of available IP addresses is available on the subnet details page, or by using `describe-subnets`. For more information, see [View your subnet](#) in the Amazon VPC User Guide.

Example: Unexpected EC2 error while attempting to Create Network Interface with public IP assignment enabled in subnet 'subnet-id': InsufficientFreeAddressesInSubnet

**TaskFailedToStart**

This error occurs when you chose a task definition with a launch type that does not match the cluster capacity type. For more information, see [Amazon ECS launch types](#).

Example: The selected task definition is not compatible with the selected compute strategy

### CannotPullContainer task errors

The following errors indicate that, when creating a task, the container image specified can't be retrieved.

**Note**

The 1.4 Fargate platform version truncates long error messages.
Connection timed out

When a Fargate task is launched, its elastic network interface requires a route to the internet to pull container images. If you receive an error similar to the following when launching a task, it's because a route to the internet doesn't exist:

```
```

To resolve this issue, you can:

- For tasks in public subnets, specify **ENABLED** for **Auto-assign public IP** when launching the task. For more information, see [Run an application as an Amazon ECS task](#).
- For tasks in private subnets, specify **DISABLED** for **Auto-assign public IP** when launching the task, and configure a NAT gateway in your VPC to route requests to the internet. For more information, see [NAT Gateways](#) in the [Amazon VPC User Guide](#).

Context canceled

The common cause for this error is because the VPC your task is using doesn't have a route to pull the container image from Amazon ECR.

Image not found

When you specify an Amazon ECR image in your container definition, you must use the full URI of your Amazon ECR repository along with the image name in that repository. If the repository or image can't be found, you receive the following error:

```
CannotPullContainerError: API error (404): repository 111122223333.dkr.ecr.us-east-1.amazonaws.com/<repo>/<image> not found
```

To resolve this issue, verify the repository URI and the image name. Also make sure that you have set up the proper access using the task execution IAM role. For more information about the task execution role, see [Amazon ECS task execution IAM role](#).

Amazon ECR endpoint connection issue

If you are trying to pull an Amazon ECR image and you don't have the correct permissions for the Amazon ECR endpoint, you see an error similar to the following:

```
CannotPullContainerError: API error
```
To resolve this issue, Amazon ECS must communicate with the Amazon ECR endpoint. For information about how to resolve this issue, see How can I resolve the Amazon ECR error "CannotPullContainerError: API error" in Amazon ECS on the AWS Support website.

**Insufficient disk space**

If the root volume of your container instance has insufficient disk space when pulling the container image, you see an error similar to the following:

```
CannotPullContainerError: write /var/lib/docker/tmp/GetImageBlob111111111: no space left on device
```

To resolve this issue, free up disk space.

If you are using the Amazon ECS-optimized AMI, you can use the following command to retrieve the 20 largest files on your file system:

```
du -Sh / | sort -rh | head -20
```

**Example output:**

```
5.7G    /var/lib/docker/
containers/50501b5f4cbf90b406e0ca60bf4e6d4ec8f773a6c1d2b451ed8e0195418ad0d2
1.2G    /var/log/ecs
594M    /var/lib/docker/devicemapper/mnt/c8e3010e36ce4c089bf286a623699f5233097ca126ebd5a700af023a5127633d/rootfs/data/logs ...
```

In some cases, similar to the preceding example, the root volume might be filled out by a running container. If the container is using the default json-file log driver without a max-size limit, it may be that the log file is responsible for most of that space used. You can use the `docker ps` command to verify which container is using the space by mapping the directory name from the output above to the container ID. For example:

```
CONTAINER ID   IMAGE                            COMMAND             CREATED             STATUS              PORTS                           NAMES
50501b5f4cbf   amazon/amazon-ecs-agent:latest   "/agent"            4 days ago          Up 4 days           172.17.0.102:20000/0.0.0.0/0.0.0.0:2375/0.0.0.0:22/0.0.0.0:4755     ecs-agent
```

By default, when using the json-file log driver, Docker captures the standard output (and standard error) of all of your containers and writes them in files using the JSON format. You can
set the max-size as a log driver option, which prevents the log file from taking up too much space. For more information, see Configure logging drivers in the Docker documentation.

The following is a container definition snippet showing how to use this option:

```json
{
    "log-driver": "json-file",
    "log-opts": {
        "max-size": "256m"
    }
}
```

An alternative, if your container logs are taking up too much disk space, is to use the awslogs log driver. The awslogs log driver sends the logs to CloudWatch, which frees up the disk space that would otherwise be used for your container logs on the container instance. For more information, see Using the awslogs log driver.

Docker Hub rate limiting

If you receive one of the following errors, you're likely hitting the Docker Hub rate limits:

ERROR: toomanyrequests: Too Many Requests.

You have reached your pull rate limit. You may increase the limit by authenticating and upgrading: https://www.docker.com/increase-rate-limits.

For more information about the Docker Hub rate limits, see Understanding Docker Hub rate limiting.

If you have increased the Docker Hub rate limit and you need to authenticate your Docker pulls for your container instances, see Private registry authentication for container instances in the Amazon Elastic Container Service Developer Guide.

Fail to copy image

If you receive an error similar to the following when launching a task, it's because there is no access to the image:

```
CannotPullContainerError: ref pull has been retried 1 time(s): failed to copy: httpReaderSeeker: failed open: unexpected status code
```

To resolve this issue, you can:
For Fargate tasks, see How do I resolve the "cannotpullcontainererror" error for my Amazon ECS tasks on Fargate.

For other tasks, see How do I resolve the "cannotpullcontainererror" error for my Amazon ECS tasks.

Pull access denied

If you receive an error similar to the following when launching a task, it's because there is no access to the image:

```
CannotPullContainerError: pull access denied
```

To resolve this issue, you might need to authenticate your Docker client with Amazon ECR. For more information, see Private registry authentication in the Amazon ECR User Guide.

Invalid memory address or nil pointer dereference

If you receive an error similar to the following when launching a task, it's because there is no access to the image:

```
CannotPullContainerError: containerd: pull command failed: panic: runtime error: invalid memory address or nil pointer dereference
```

To resolve this issue:

- Check that you have the security group rules to reach Amazon S3.
- When you use gateway endpoints, you must add a route in the route table to access the endpoint.

Error pulling image configuration

If you receive an error similar to the following when launching a task, it's because of a rate limit reached or network error:

```
CannotPullContainerError: error pulling image conf/error pulling image configuration
```

To resolve this issue, see How can I resolve the "CannotPullContainerError" error in my Amazon ECS EC2 Launch Type Task.

For additional information about STOPPED errors, see Stopped tasks error codes in the Amazon Elastic Container Service User Guide for AWS Fargate.
Service event messages

When troubleshooting a problem with a service, the first place you should check for diagnostic information is the service event log. You can view service events using the DescribeServices API, the AWS CLI, or by using the AWS Management Console.

When viewing service event messages using the Amazon ECS API, only the events from the service scheduler are returned. These include the most recent task placement and instance health events. However, the Amazon ECS console displays service events from the following sources.

- Task placement and instance health events from the Amazon ECS service scheduler. These events have a prefix of `service (service-name)`. To ensure that this event view is helpful, we only show the 100 most recent events and duplicate event messages are omitted until either the cause is resolved or six hours passes. If the cause is not resolved within six hours, you receive another service event message for that cause.

- Service Auto Scaling events. These events have a prefix of `Message`. The 10 most recent scaling events are shown. These events only occur when a service is configured with an Application Auto Scaling scaling policy.

Use the following steps to view your current service event messages.

Console

2. In the navigation pane, choose Clusters.
3. On the Clusters page, choose the cluster.
4. Choose the service to inspect.
5. Choose Deployments and events, under Events, view the messages.

AWS CLI

Use the `describe-services` command to view the service event messages for a specified service.

The following AWS CLI example describes the `service-name` service in the `default` cluster, which will provide the latest service event messages.

```
aws ecs describe-services \
```
Service event messages

The following are examples of service event messages you may see in the Amazon ECS console.

**service (service-name) has reached a steady state.**

The service scheduler sends a service (service-name) has reached a steady state. service event when the service is healthy and at the desired number of tasks, thus reaching a steady state.

The service scheduler reports the status periodically, so you might receive this message multiple times.

**service (service-name) was unable to place a task because no container instance met all of its requirements.**

The service scheduler sends this event message when it couldn't find the available resources to add another task. The possible causes for this are:

No container instances were found in your cluster

If no container instances are registered in the cluster you attempt to run a task in, you receive this error. You should add container instances to your cluster. For more information, see [Launching an Amazon ECS Linux container instance](#).

Not enough ports

If your task uses fixed host port mapping (for example, your task uses port 80 on the host for a web server), you must have at least one container instance per task, because only one container can use a single host port at a time. You should add container instances to your cluster or reduce your number of desired tasks.

Too many ports registered

The closest matching container instance for task placement can't exceed the maximum allowed reserved port limit of 100 host ports per container instance. Using dynamic host port mapping may remediate the issue.
Port already in-use

The task definition of this task uses the same port in its port mapping as a task already running on the container instance that was chosen. The service event message would have the chosen container instance ID as part of the message below.

The closest matching container-instance is already using a port required by your task.

Not enough memory

If your task definition specifies 1000 MiB of memory, and the container instances in your cluster each have 1024 MiB of memory, you can only run one copy of this task per container instance. You can experiment with less memory in your task definition so that you could launch more than one task per container instance, or launch more container instances into your cluster.

Note

If you're trying to maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type, see Container instance memory management.

Not enough CPU

A container instance has 1,024 CPU units for every CPU core. If your task definition specifies 1,000 CPU units, and the container instances in your cluster each have 1,024 CPU units, you can only run one copy of this task per container instance. You can experiment with fewer CPU units in your task definition so that you could launch more than one task per container instance, or launch more container instances into your cluster.

Not enough available ENI attachment points

Tasks that use the awsvpc network mode each receive their own elastic network interface (ENI), which is attached to the container instance that hosts it. Amazon EC2 instances have a limit to the number of ENIs that can be attached to them and there are no container instances in the cluster that have ENI capacity available.

The ENI limit for individual container instances depends on the following conditions:
• If you **have not** opted in to the `awsvpcTrunking` account setting, the ENI limit for each container instance depends on the instance type. For more information, see [IP Addresses Per Network Interface Per Instance Type](#) in the *Amazon EC2 User Guide for Linux Instances*.

• If you **have** opted in to the `awsvpcTrunking` account setting but you **have not** launched new container instances using a supported instance type after opting in, the ENI limit for each container instance is still at the default value. For more information, see [IP Addresses Per Network Interface Per Instance Type](#) in the *Amazon EC2 User Guide for Linux Instances*.

• If you **have** opted in to the `awsvpcTrunking` account setting and you **have** launched new container instances using a supported instance type after opting in, additional ENIs are available. For more information, see [Supported Amazon EC2 instance types](#).

For more information about opting in to the `awsvpcTrunking` account setting, see [Elastic network interface trunking](#).

You can add container instances to your cluster to provide more available network adapters.

Container instance missing required attribute

Some task definition parameters require a specific Docker remote API version to be installed on the container instance. Others, such as the logging driver options, require the container instances to register those log drivers with the `ECS_AVAILABLE_LOGGING_DRIVERS` agent configuration variable. If your task definition contains a parameter that requires a specific container instance attribute, and you don't have any available container instances that can satisfy this requirement, the task can't be placed.

A common cause of this error is if your service is using tasks that use the `awsvpc` network mode and the EC2 launch type. The cluster you specified doesn't have a container instance registered to it in the same subnet that was specified in the `awsvpcConfiguration` when the service was created.

For more information on which attributes are required for specific task definition parameters and agent configuration variables, see [Task definition parameters](#) and [Amazon ECS container agent configuration](#).
service *(service-name)* was unable to place a task because no container instance met all of its requirements. The closest matching container-instance *container-instance-id* has insufficient CPU units available.

The closest matching container instance for task placement doesn't contain enough CPU units to meet the requirements in the task definition. Review the CPU requirements in both the task size and container definition parameters of the task definition.

service *(service-name)* was unable to place a task because no container instance met all of its requirements. The closest matching container-instance *container-instance-id* encountered error "AGENT".

The Amazon ECS container agent on the closest matching container instance for task placement is disconnected. If you can connect to the container instance with SSH, you can examine the agent logs; for more information, see Amazon ECS Container Agent log. You should also verify that the agent is running on the instance. If you are using the Amazon ECS-optimized AMI, you can try stopping and restarting the agent with the following command.

- For the Amazon ECS-optimized Amazon Linux 2 AMI and Amazon ECS-optimized Amazon Linux 2023 AMI
  
  ```
  sudo systemctl restart ecs
  ```

- For the Amazon ECS-optimized Amazon Linux AMI
  
  ```
  sudo stop ecs & & sudo start ecs
  ```

service *(service-name)* *(instance instance-id)* is unhealthy in *(elb elb-name)* due to *(reason)*. Instance has failed at least the UnhealthyThreshold number of health checks consecutively.

This service is registered with a load balancer and the load balancer health checks are failing. For more information, see Troubleshooting service load balancers.

service *(service-name)* is unable to consistently start tasks successfully.

This service contains tasks that have failed to start after consecutive attempts. At this point, the service scheduler begins to incrementally increase the time between retries. You should troubleshoot why your tasks are failing to launch. For more information, see Amazon ECS service throttle logic.
After the service is updated, for example with an updated task definition, the service scheduler resumes normal behavior.

**service** *(service-name)* operations are being throttled. Will try again later.

This service is unable to launch more tasks due to API throttling limits. Once the service scheduler is able to launch more tasks, it will resume.

To request an API rate limit quota increase, open the [AWS Support Center](https://aws.amazon.com/support/) page, sign in if necessary, and choose **Create case**. Choose **Service limit increase**. Complete and submit the form.

**service** *(service-name)* was unable to stop or start tasks during a deployment because of the service deployment configuration. Update the minimumHealthyPercent or maximumPercent value and try again.

This service is unable to stop or start tasks during a service deployment due to the deployment configuration. The deployment configuration consists of the minimumHealthyPercent and maximumPercent values, which are defined when the service is created. Those values can also be updated on an existing service.

The minimumHealthyPercent represents the lower limit on the number of tasks that should be running for a service during a deployment or when a container instance is draining. It's a percent of the desired number of tasks for the service. This value is rounded up. For example, if the minimum healthy percent is 50 and the desired task count is four, then the scheduler can stop two existing tasks before starting two new tasks. Likewise, if the minimum healthy percent is 75% and the desired task count is two, then the scheduler can't stop any tasks due to the resulting value also being two.

The maximumPercent represents the upper limit on the number of tasks that should be running for a service during a deployment or when a container instance is draining. It's a percent of the desired number of tasks for a service. This value is rounded down. For example, if the maximum percent is 200 and the desired task count is four, then the scheduler can start four new tasks before stopping four existing tasks. Likewise, if the maximum percent is 125 and the desired task count is three, the scheduler can't start any tasks due to the resulting value also being three.

When setting a minimum healthy percent or a maximum percent, you should ensure that the scheduler can stop or start at least one task when a deployment is triggered.
service (*service-name*) was unable to place a task. Reason: You’ve reached the limit on the number of tasks you can run concurrently

You can request a quota increase for the resource that caused the error. For more information, see *Service quotas*. To request a quota increase, see *Requesting a quota increase* in the *Service Quotas User Guide*.

service (*service-name*) was unable to place a task. Reason: Internal error.

The following are the possible reasons for this error:

- The service is unable to start a task due to a subnet being in an unsupported Availability Zone.
  
  For information about the supported Fargate Regions and Availability Zones, see *the section called “AWS Fargate Regions”*.  
  
  For information about how to view the subnet Availability Zone, see *View your subnet* in the *Amazon VPC User Guide*.

- You are trying to run a task definition that uses the ARM architecture on Fargate Spot.

service (*service-name*) was unable to place a task. Reason: The requested CPU configuration is above your limit.

You can request a quota increase for the resource that caused the error. For more information, see *Service quotas*. To request a quota increase, see *Requesting a quota increase* in the *Service Quotas User Guide*.

service (*service-name*) was unable to place a task. Reason: The requested MEMORY configuration is above your limit.

You can request a quota increase for the resource that caused the error. For more information, see *Service quotas*. To request a quota increase, see *Requesting a quota increase* in the *Service Quotas User Guide*.

service (*service-name*) was unable to place a task. Reason: You’ve reached the limit on the number of vCPUs you can run concurrently

AWS Fargate is transitioning from task count-based quotas to vCPU-based quotas.
You can request a quota increase for the Fargate vCPU-based quota. For more information, see *Service quotas*. To request a Fargate quota increase, see *Requesting a quota increase* in the *Service Quotas User Guide*.

**service** *(service-name)* was unable to reach steady state because **task set** *(taskSet-ID)* was unable to scale in. Reason: The number of protected tasks are more than the desired count of tasks.

The service has more protected tasks than the desired count of tasks. You can do one of the following:

- Wait until the protection on the current tasks expire, enabling them to be terminated.
- Determine which tasks can be stopped and use the `UpdateTaskProtection` API with the `protectionEnabled` option set to false to unset protection for these tasks.
- Increase the desired task count of the service to more than the number of protected tasks.

**service** *(service-name)* was unable to reach steady state. Reason: No Container Instances were found in your capacity provider.

The service scheduler sends this event message when it couldn't find the available resources to add another task. The possible causes for this are:

No container instances were found in your cluster

- If no container instances are registered in the cluster you attempt to run a task in, you receive this error. You should add container instances to your cluster. For more information, see *Launching an Amazon ECS Linux container instance*.

Not enough ports

- If your task uses fixed host port mapping (for example, your task uses port 80 on the host for a web server), you must have at least one container instance per task. Only one container can use a single host port at a time. You should add container instances to your cluster or reduce your number of desired tasks.

Too many ports registered

- The closest matching container instance for task placement can't exceed the maximum allowed reserved port limit of 100 host ports per container instance. Using dynamic host port mapping may remediate the issue.
Port already in-use

The task definition of this task uses the same port in its port mapping as a task already running on the container instance that was chosen. The service event message would have the chosen container instance ID as part of the message below.

The closest matching container-instance is already using a port required by your task.

Not enough memory

If your task definition specifies 1000 MiB of memory, and the container instances in your cluster each have 1024 MiB of memory, you can only run one copy of this task per container instance. You can experiment with less memory in your task definition so that you could launch more than one task per container instance, or launch more container instances into your cluster.

Note

If you are trying to maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type, see Container instance memory management.

Not enough available ENI attachment points

Tasks that use the awsvpc network mode each receive their own elastic network interface (ENI), which is attached to the container instance that hosts it. Amazon EC2 instances have a limit to the number of ENIs that can be attached to them, and there are no container instances in the cluster that have ENI capacity available.

The ENI limit for individual container instances depends on the following conditions:

- If you have not opted in to the awsvpcTrunking account setting, the ENI limit for each container instance depends on the instance type. For more information, see IP Addresses Per Network Interface Per Instance Type in the Amazon EC2 User Guide for Linux Instances.
- If you have opted in to the awsvpcTrunking account setting but you have not launched new container instances using a supported instance type after opting in, the ENI limit for each container instance is still at the default value. For more information, see IP Addresses Per Network Interface Per Instance Type in the Amazon EC2 User Guide for Linux Instances.
• If you have opted in to the awsvpcTrunking account setting and you have launched new container instances using a supported instance type after opting in, additional ENIs are available. For more information, see Supported Amazon EC2 instance types.

For more information about opting in to the awsvpcTrunking account setting, see Elastic network interface trunking.

You can add container instances to your cluster to provide more available network adapters.

Container instance missing required attribute

Some task definition parameters require a specific Docker remote API version to be installed on the container instance. Others, such as the logging driver options, require the container instances to register those log drivers with the ECSAVAILABLE_LOGGING_DRIVERS agent configuration variable. If your task definition contains a parameter that requires a specific container instance attribute, and you don't have any available container instances that can satisfy this requirement, the task cannot be placed.

A common cause of this error is if your service is using tasks that use the awsvpc network mode and the EC2 launch type and the cluster you specified doesn't have a container instance registered to it in the same subnet that was specified in the awsvpcConfiguration when the service was created.

For more information on which attributes are required for specific task definition parameters and agent configuration variables, see Task definition parameters and Amazon ECS container agent configuration.

service (service-name) was unable to place a task. Reason: Capacity is unavailable at this time. Please try again later or in a different availability zone.

There is currently no available capacity to run your service on.

You can do one the following:

• Wait until the Fargate capacity or EC2 container instances become available.
• Relaunch the service and specify additional subnets.

service (service-name) deployment failed: tasks failed to start.

The tasks in your service failed to start.
For information about how to debug stopped tasks, see [Stopped tasks error codes](#).

**service (service-name)** Timed out waiting for Amazon ECS Agent to start. Please check logs at /var/log/ecs/ecs-agent.log.

The Amazon ECS container agent on the closest matching container instance for task placement is disconnected. If you can connect to the container instance with SSH, you can examine the agent logs. For more information, see [Amazon ECS Container Agent log](#). You should also verify that the agent is running on the instance. If you are using the Amazon ECS-optimized AMI, you can try stopping and restarting the agent with the following command.

- For the Amazon ECS-optimized Amazon Linux 2 AMI

  ```
  sudo systemctl restart ecs
  ```

- For the Amazon ECS-optimized Amazon Linux AMI

  ```
  sudo stop ecs && sudo start ecs
  ```

**service (service-name)** task set (taskSet-ID) is not healthy in target-group (targetGroup-ARN) due to TARGET GROUP IS NOT FOUND.

The task set for the service is failing health checks because the target group isn't found. You should delete and recreate the service. Don't delete any Elastic Load Balancing target group unless the corresponding Amazon ECS service is already deleted.

**service (service-name)** task set (taskSet-ID) is not healthy in target-group (targetGroup-ARN) due to TARGET IS NOT FOUND.

The task set for the service is failing health checks because the target isn't found.

**Invalid CPU or memory value specified**

When registering a task definition using the Amazon ECS API or AWS CLI, if you specify an invalid cpu or memory value, the following error is returned.

```
When using Terraform, the following error might be returned.

```
Error: ClientException: No Fargate configuration exists for given values.
```

To resolve this issue, you must specify a supported value for the task CPU and memory in your task definition. The `cpu` value can be expressed in CPU units or vCPUs in a task definition. It's converted to an integer indicating the CPU units when the task definition is registered. The `memory` value can be expressed in MiB or GB in a task definition. It's converted to an integer indicating the MiB when the task definition is registered.

For task definitions that only specify EC2 for the `requiresCompatibilities` parameter, the supported CPU values are between 256 CPU units (0.25 vCPUs) and 16384 CPU units (16 vCPUs). The memory value must be an integer, and the limit is dependent upon the amount of available memory on the underlying Amazon EC2 instance you use.

For task definitions that specify FARGATE for the `requiresCompatibilities` parameter (even if EC2 is also specified), you must use one of the values in the following table. These values determine your range of supported values for the CPU and memory parameter.

For tasks hosted on Fargate, the following table shows the valid CPU and memory combinations. The memory values in the JSON file are specified in MiB. You can convert the GB value to MiB by multiplying the value by 1024. For example 1 GB = 1024 MiB.

<table>
<thead>
<tr>
<th>CPU value</th>
<th>Memory value</th>
<th>Operating systems supported for AWS Fargate</th>
</tr>
</thead>
<tbody>
<tr>
<td>256 (.25 vCPU)</td>
<td>512 MiB, 1 GB, 2 GB</td>
<td>Linux</td>
</tr>
<tr>
<td>512 (.5 vCPU)</td>
<td>1 GB, 2 GB, 3 GB, 4 GB</td>
<td>Linux</td>
</tr>
<tr>
<td>1024 (1 vCPU)</td>
<td>2 GB, 3 GB, 4 GB, 5 GB, 6 GB, 7 GB, 8 GB</td>
<td>Linux, Windows</td>
</tr>
<tr>
<td>2048 (2 vCPU)</td>
<td>Between 4 GB and 16 GB in 1 GB increments</td>
<td>Linux, Windows</td>
</tr>
<tr>
<td>CPU value</td>
<td>Memory value</td>
<td>Operating systems supported for AWS Fargate</td>
</tr>
<tr>
<td>----------------</td>
<td>--------------------------------------------------</td>
<td>--------------------------------------------</td>
</tr>
<tr>
<td>4096 (4 vCPU)</td>
<td>Between 8 GB and 30 GB in 1 GB increments</td>
<td>Linux, Windows</td>
</tr>
<tr>
<td>8192 (8 vCPU)</td>
<td>Between 16 GB and 60 GB in 4 GB increments</td>
<td>Linux</td>
</tr>
<tr>
<td>16384 (16vCPU)</td>
<td>Between 32 GB and 120 GB in 8 GB increments</td>
<td>Linux</td>
</tr>
</tbody>
</table>

**Note**

This option requires Linux platform 1.4.0 or later.

For tasks hosted on Amazon EC2, supported task CPU values are between 0.25 vCPUs and 192 vCPUs.

**Note**

Task-level CPU and memory parameters are ignored for Windows containers.

---

**CannotCreateContainerError: API error (500): devmapper**

The following Docker error indicates that the thin pool storage on your container instance is full, and that the Docker daemon cannot create new containers:
By default, Amazon ECS-optimized Amazon Linux AMIs from version 2015.09.d and later launch with an 8-GiB volume for the operating system that's attached at /dev/xvda and mounted as the root of the file system. There's an additional 22-GiB volume that's attached at /dev/xvdcz that Docker uses for image and metadata storage. If this storage space is filled up, the Docker daemon cannot create new containers.

The easiest way to add storage to your container instances is to terminate the existing instances and launch new ones with larger data storage volumes. However, if you can't do this, you can add storage to the volume group that Docker uses and extend its logical volume by following the procedures in Amazon ECS-optimized AMI.

If your container instance storage is filling up too quickly, there are a few actions that you can take to reduce this effect:

- To view the thin pool information, run the following command on your container instance:

  `docker info`

- (Amazon ECS container agent 1.8.0 and later) You can reduce the amount of time that stopped or exited containers remain on your container instances. The `ECS_ENGINE_TASK_CLEANUP_WAIT_DURATION` agent configuration variable sets the time duration to wait from when a task is stopped until the Docker container is removed (by default, this value is 3 hours). This removes the Docker container data. If this value is set too low, you might not be able to inspect your stopped containers or view the logs before they are removed. For more information, see Amazon ECS container agent configuration.

- You can remove non-running containers and unused images from your container instances. You can use the following example commands to manually remove stopped containers and unused images. Deleted containers can't be inspected later, and deleted images must be pulled again before starting new containers from them.

  To remove non-running containers, run the following command on your container instance:

  `docker rm $(docker ps -aq)`
To remove unused images, run the following command on your container instance:

```
docker rmi $(docker images -q)
```

- You can remove unused data blocks within containers. You can use the following command to run `fstrim` on any running container and discard any data blocks that are unused by the container file system.

```
sudo sh -c "docker ps -q | xargs docker inspect --format='{{ .State.Pid }}' | xargs -IZ fstrim /proc/Z/root/"
```

## Troubleshooting service load balancers

Amazon ECS services can register tasks with an Elastic Load Balancing load balancer. Load balancer configuration errors are common causes for stopped tasks. If your stopped tasks were started by services that use a load balancer, consider the following possible causes.

### Amazon ECS service-linked role doesn't exist

The Amazon ECS service-linked role allows Amazon ECS services to register container instances with Elastic Load Balancing load balancers. The service-linked role must be created in your account. For more information, see [Using service-linked roles for Amazon ECS](#).

### Container instance security group

If your container is mapped to port 80 on your container instance, your container instance security group must allow inbound traffic on port 80 for the load balancer health checks to pass.

### Elastic Load Balancing load balancer not configured for all Availability Zones

Your load balancer should be configured to use all of the Availability Zones in a Region, or at least all of the Availability Zones where your container instances reside. If a service uses a load balancer and starts a task on a container instance that resides in an Availability Zone that the load balancer isn't configured to use, the task never passes the health check. This results in the task being killed.
Elastic Load Balancing load balancer health check misconfigured

The load balancer health check parameters can be overly restrictive or point to resources that don't exist. If a container instance is determined to be unhealthy, it's removed from the load balancer. Be sure to verify that the following parameters are configured correctly for your service load balancer.

Ping Port

The **Ping Port** value for a load balancer health check is the port on the container instances that the load balancer checks to determine if it is healthy. If this port is misconfigured, the load balancer likely deregisters your container instance from itself. This port should be configured to use the **hostPort** value for the container in your service's task definition that you're using with the health check.

Ping Path

This value is often set to `index.html`, but if your service doesn't respond to that request, then the health check fails. If your container doesn't have an `index.html` file, you can set this to `/` to target the base URL for the container instance.

Response Timeout

This is the amount of time that your container has to return a response to the health check ping. If this value is lower than the amount of time required for a response, the health check fails.

Health Check Interval

This is the amount of time between health check pings. The shorter your health check intervals are, the faster your container instance can reach the **Unhealthy Threshold**.

Unhealthy Threshold

This is the number of times your health check can fail before your container instance is considered unhealthy. If you have an unhealthy threshold of 2, and a health check interval of 30 seconds, then your task has 60 seconds to respond to the health check ping before it's assumed unhealthy. You can raise the unhealthy threshold or the health check interval to give your tasks more time to respond.
Unable to update the service **servicename**: Load balancer container name or port changed in task definition

If your service uses a load balancer, you can use the AWS CLI or SDK to modify the load balancer configuration. For information about how to modify the configuration, see `UpdateService` in the *Amazon Elastic Container Service API Reference*. If you update the task definition for the service, the container name and container port that are specified in the load balancer configuration must remain in the task definition.

You've reached the limit on the number of tasks that you can run concurrently.

For a new account, your quotas might be lower than the service quotas. The service quota for your account can be viewed in the Service Quotas console. To request a quota increase, see [Requesting a quota increase](service-quotas-user-guide.html) in the *Service Quotas User Guide*.

### Troubleshooting Amazon EBS volume attachment

Amazon EBS volumes can be configured for attachment to a standalone Amazon ECS task when you run the task. They can also be configured for attachment to tasks launched via an Amazon ECS service when you create or update the service. At most one volume can be attached per task. If your task or service doesn't launch as planned, you can check for volume attachment failure reasons using the AWS Management Console. You can then use the list of failure scenarios for next steps. For more information about Amazon EBS volumes for Amazon ECS tasks, see [Amazon EBS volumes](amazon-ebs-volumes.html).

### Checking for volume attachment failure reasons

To view a volume's attachment status and failure reason

2. On the **Clusters** page, choose the cluster that your task is running in. The cluster's details page appears.
3. On the cluster's details page, choose the **Tasks** tab.
4. For **Filter desired status**, choose **Stopped**, and then choose the stopped task that you want to troubleshoot.
5. On the task's details page, choose the **Volumes** tab. You will be able to see the attachment status of the Amazon EBS volume under **Attachment status**.
6. Choose the attachment status to see the failure reason appear in a popover.
To further understand why the volume attachment failed, you can set up Amazon EventBridge to send events to a target, such as Amazon CloudWatch groups. You can send Amazon EBS volume events and Amazon ECS task state change events and use these events for diagnosing issues. For more information, see How can I create a CloudWatch log group to use as a target for an EventBridge rule? on AWS re:Post. For more information about Amazon ECS task state change events, see Task state change events. For more information about Amazon EBS volume events, see EventBridge for Amazon EBS in the Amazon EC2 User Guide.

Amazon EBS volume attachment failure scenarios

Use the following scenarios to help you diagnose and fix issues that you might encounter when you configure Amazon EBS volumes for attachment to Amazon ECS tasks.

ECS infrastructure AWS Identity and Access Management (IAM) role

The following IAM role scenarios can result in Amazon EBS volume-attachment issues:

- You don't provide an IAM role Amazon Resource Name (ARN). To attach an Amazon EBS volume to an Amazon ECS task, you must provide an ARN for an IAM role with the permissions necessary for Amazon ECS to manage the Amazon EBS volume on your behalf.

- You provide an IAM role without the necessary trust policy attached. Amazon ECS can't access the Amazon ECS infrastructure IAM role that you provide if the role doesn't have the necessary trust policy. You see the following error message: ECS was unable to assume the configured ECS Infrastructure Role 'arn:aws:iam::111122223333:role/ecsInfrastructureRole'. Please verify that the role being passed has the proper trust relationship with Amazon ECS. The task can get stuck in the DEPROVISIONING state. For more information about the necessary trust policy, see Amazon ECS infrastructure IAM role.

  Note

You may also see this error message due to a delay in role propagation. If retrying to use the role after waiting for a few minutes doesn't fix the issue, you might have misconfigured the trust policy for the role.

- Your IAM user doesn't have permission to pass the Amazon ECS infrastructure role to Amazon ECS. The task can get stuck in the DEPROVISIONING state. To avoid this problem, you can attach the PassRole permission to your user. For more information, see Amazon ECS infrastructure IAM role.
• Your IAM role doesn't have the necessary permissions for Amazon EBS volume attachment. The task can get stuck in the DEPROVISIONING state. For more information about the specific permissions necessary for attaching Amazon EBS volumes to tasks, see Amazon ECS infrastructure IAM role.

AWS Key Management Service (AWS KMS) key

The following AWS KMS key scenarios can lead to Amazon EBS volume-attachment issues:

• You specify a KMS key ARN, ID, or alias that isn't valid. In this scenario, the task might appear to launch successfully, but the task eventually fails because AWS authenticates the KMS key asynchronously. For more information, see Amazon EBS encryption in the Amazon EC2 User Guide.

• You provide a customer managed key that lacks the permissions that allow the Amazon ECS infrastructure IAM role to use the key for encryption. To avoid key-policy permission issues, see the example AWS KMS key policy in Data encryption for Amazon EBS volumes.

In these scenarios, you may encounter the following status reason message in the Volumes view of the stopped task in the AWS Management Console: IdempotentParameterMismatch"; "The client token you have provided is associated with a resource that is already deleted. Please use a different client token."

configuredAtLaunch task definition parameter

You can't attach an Amazon EBS volume to a task if you don't specify configuredAtLaunch in your task definition, or if you set configuredAtLaunch to false. To avoid this issue, set configuredAtLaunch to true in your task definition.

Volume name

The following volume-name scenarios can result in Amazon EBS volume attachment issues:

• You don't provide a volume name during volume configuration.

• The volume name that you provide during configuration doesn't match the volume name that you specify in the task definition.

File system format

The following file system format scenarios can result in Amazon EBS volume attachment issues:

• The file system format that you specify during configuration isn't compatible with the task's operating system.

• You configure an Amazon EBS volume to be created from a snapshot, and the snapshot's file system format isn't compatible with the task's operating system. For volumes created from
a snapshot, you must specify the same filesystem type that the volume was using when the
snapshot was created. If there is a filesystem type mismatch, the task fails to start with the
following status reason in the **Volumes** view of the stopped task in the AWS Management
Console: ECS timed out while configuring the EBS volume attachment to your Task. To
understand the issue better, you can view the Amazon ECS container agent logs. For more
information, see [Amazon ECS log file locations](#) and [Amazon ECS log collector](#).

**Tags**

The following tagging scenarios can cause the Amazon ECS task to fail to launch:

- You attempt to propagate tags from a service to a volume that's configured for attachment
to a standalone task. To avoid this problem, set `propagateTags` to `TASK_DEFINITION` if
you're configuring a volume for attachment to a standalone task.

- You attempt to provide a tag resource type that isn't valid. The only supported tag resource
type for Amazon EBS volumes attached to tasks is `volume`.

- You attempt to provide a value for `propagateTags` that isn't valid. The valid values for
`propagateTags` are `TASK_DEFINITION`, `SERVICE`, and `NONE`.

- You provide a tag that isn't valid. For more information, see [Tagging your Amazon ECS
resources](#).

- You provide too many tags. Amazon ECS adds the `AmazonECSManaged` and
`AmazonECSCreated` tags automatically to the volume. This means an additional 48 user-
defined and propagated tags can be added to a volume for a total of 50 tags maximum per
volume.

- You provide a reserved tag already used by Amazon ECS like `AmazonECSManaged` or
`AmazonECSCreated`.

**Volume limits**

If you're trying to configure an Amazon EBS volume for attachment to an EC2 launch type
Amazon ECS task, and if the Nitro-based container instances associated with the cluster are at
the volume limit, you can't run the task. A single Amazon EBS volume can be attached per task.
The volume limit of your container instance determines the number of tasks with Amazon EBS
volumes configured for attachment that can be launched on an instance. For more information
about volume limits, see [Instance volume limits](#) in the *Amazon EC2 User Guide*.

**Container instance type**

You can't attach an Amazon EBS volume to an EC2 launch type task that's launched on a
container instance based on the Xen System. You encounter the following error message:
(service-name) was unable to place a task because no container instance met all of its requirements. The closest matching (container-instance instance-id) is missing an attribute required by your task.

Amazon EBS volume type

You can't attach an Amazon EBS volume to a task if you configure a magnetic (standard) Amazon EBS volume for attachment to a Fargate task.

Amazon EBS throughput and IOPS

You won't be able to attach an Amazon EBS volume to a task if you configure throughput or IOPS for a volume type that doesn't support these parameters. You can configure IOPS only for Provisioned IOPS SSD (io1 and io2) and General Purpose SSD (gp2 and gp3) volumes. You can configure throughput only for Throughput Optimized HDD (st1), Cold HDD (sc1), and General Purpose SSD (gp3) volumes.

Mount points

To use data volumes with your Amazon ECS tasks, you must configure mount points in your task definition. To avoid failures, make sure that you specify a mount point in your task definition and refer to the source volume specified in the task definition during volume configuration.

AWS Regions and Availability Zones

You can't attach Amazon EBS volumes to tasks if you try to configure an Amazon EBS volume at deployment in an AWS Region or Availability Zone that doesn't support Amazon EBS volume attachment. For AWS Region and Availability Zone information, see AWS Regions and Availability Zones for Amazon EBS volumes.

AMI for Amazon ECS tasks on Amazon EC2

If the host container instances for your Amazon ECS tasks in your cluster don't have an Amazon ECS-optimized AMI, or if they have an Amazon ECS-optimized AMI that doesn't support Amazon EBS volume attachment, volume attachment fails. Amazon EBS volume attachment is supported on Amazon ECS-optimized AMIs 20231219 and later.

Container agent

You won't be able to attach an Amazon EBS volume to an EC2 launch type Amazon ECS task if the container agent running on the container instance is not 1.79.0 or later. You encounter the following error message:service (service-name) was unable to place a task because no container instance met all of its requirements. The closest matching (container-instance instance-id) is missing an attribute required by your task.
Fargate platform version

You won't be able to attach an Amazon EBS volume to a Fargate launch type Amazon ECS task if the Linux Fargate platform version is not 1.4.0 or later.

Service and task failures

You might encounter service or task failures unrelated to volume attachment that can affect volume attachment. For more information about troubleshooting problems with services, see Service event messages. For more information about troubleshooting problems with tasks, see Stopped task error codes. For API failure reasons, see API failure reasons.

Troubleshooting service auto scaling

Application Auto Scaling turns off scale-in processes while Amazon ECS deployments are in progress, and they resume once the deployment has completed. However, scale-out processes continue to occur, unless suspended, during a deployment. For more information, see Suspending and resuming scaling for Application Auto Scaling.

Using Docker debug output

If you're having trouble with Docker containers or images, you can turn on debug mode on your Docker daemon. Enabling debugging provides more verbose output from the daemon, and you can use this information to find out more about why your containers or images are having issues.

Enabling Docker debug mode can be especially useful in retrieving error messages that are sent from container registries, such as Amazon ECR, and, in many circumstances, enabling debug mode is the only way to see these error messages.

⚠️ Important

This procedure is written for the Amazon ECS-optimized Amazon Linux AMI. For other operating systems, see Enable debugging and Control and configure Docker with systemd in the Docker documentation.

To enable Docker daemon debug mode on the Amazon ECS-optimized Amazon Linux AMI

1. Connect to your container instance.
2. Open the Docker options file with a text editor, such as `vi`. For the Amazon ECS-optimized Amazon Linux AMI, the Docker options file is at `/etc/sysconfig/docker`.

3. Find the Docker options statement and add the `-D` option to the string, inside the quotes.

   **Note**
   If the Docker options statement begins with a `#`, remove that character to uncomment the statement and enable the options.

For the Amazon ECS-optimized Amazon Linux AMI, the Docker options statement is called `OPTIONS`. For example:

```
# Additional startup options for the Docker daemon, for example:
# OPTIONS="--ip-forward=true --iptables=true"
# By default we limit the number of open files per container
OPTIONS="-D --default-ulimit nofile=1024:4096"
```

4. Save the file and exit your text editor.

5. Restart the Docker daemon.

   ```
   sudo service docker restart
   ```

   The output is as follows:

   ```
   Stopping docker: [ OK ]
   Starting docker: . [ OK ]
   ```

6. Restart the Amazon ECS agent.

   ```
   sudo service ecs restart
   ```

   Your Docker logs should now show more verbose output.

   ```
   ```
Amazon ECS log file locations

Amazon ECS stores logs in the /var/log/ecs folder of your container instances. There are logs available from the Amazon ECS container agent and from the ecs-init service that controls the state of the agent (start/stop) on the container instance. You can view these log files by connecting to a container instance using SSH.

Note

If you are not sure how to collect all of the logs on your container instances, you can use the Amazon ECS logs collector. For more information, see Amazon ECS logs collector.

Amazon ECS Container Agent log

The Amazon ECS container agent stores logs on your container instances.

For container agent version 1.36.0 and later, by default the logs are located at /var/log/ecs/ecs-agent.log on Linux instances and at C:\ProgramData\Amazon\ECS\log\ecs-agent.log on Windows instances.

For container agent version 1.35.0 and earlier, by default the logs are located at /var/log/ecs/ecs-agent.log.timestamp on Linux instances and at C:\ProgramData\Amazon\ECS\log\ecs-agent.log.timestamp on Windows instances.

By default, the agent logs are rotated hourly with a maximum of 24 logs being stored.

The following are the container agent configuration variables that can be used to change the default agent logging behavior. For more information, see Amazon ECS container agent configuration.

ECS_LOGFILE

Example values: /ecs-agent.log

Default value on Linux: Null
Default value on Windows: Null

The location where agent logs should be written. If you are running the agent via ecs-init, which is the default method when using the Amazon ECS-optimized AMI, the in-container path is /log, and ecs-init mounts that out to /var/log/ecs/ on the host.

**ECS_LOGLEVEL**

Example values: crit, error, warn, info, debug

Default value on Linux: info

Default value on Windows: info

The level of detail to log.

**ECS_LOGLEVEL_ON_INSTANCE**

Example values: none, crit, error, warn, info, debug

Default value on Linux: none, if ECS_LOG_DRIVER is explicitly set to a non-empty value; otherwise the same value as ECS_LOGLEVEL

Default value on Windows: none, if ECS_LOG_DRIVER is explicitly set to a non-empty value; otherwise the same value as ECS_LOGLEVEL

Can be used to override ECS_LOGLEVEL and set a level of detail that should be logged in the on-instance log file, separate from the level that is logged in the logging driver. If a logging driver is explicitly set, on-instance logs are turned off by default. They can be turned back on with this variable.

**ECS_LOG_DRIVER**

Example values: awslogs, fluentd, gelf, json-file, journald, logentries syslog, splunk

Default value on Linux: json-file

Default value on Windows: Not applicable

Determines the logging driver the agent container uses.

**ECS_LOG_ROLLOVER_TYPE**

Example values: size, hourly
Default value on Linux: hourly

Default value on Windows: hourly

Determines whether the container agent log file is rotated hourly or based on size. By default, the agent log file is rotated each hour.

ECS_LOG_OUTPUT_FORMAT

Example values: logfmt, json

Default value on Linux: logfmt

Default value on Windows: logfmt

Determines the log output format. When the json format is used, each line in the log is a structured JSON map.

ECS_LOG_MAX_FILE_SIZE_MB

Example values: 10

Default value on Linux: 10

Default value on Windows: 10

When the ECS_LOG_ROLLOVER_TYPE variable is set to size, this variable determines the maximum size (in MB) of the log file before it's rotated. If the rollover type is set to hourly, then this variable is ignored.

ECS_LOG_MAX_ROLL_COUNT

Example values: 24

Default value on Linux: 24

Default value on Windows: 24

Determines the number of rotated log files to keep. Older log files are deleted after this limit is reached.

For container agent version 1.36.0 and later, the following is an example log file when the logfmt format is used.

```
level=info time=2019-12-12T23:43:29Z msg="Loading configuration" module=agent.go
```
The following is an example log file when the JSON format is used.

```
```

For container agent versions 1.35.0 and earlier, the following is the format of the log file.

```
2016-08-15T15:54:41Z [INFO] Starting Agent: Amazon ECS Agent - v1.12.0 (895f3c1)
2016-08-15T15:54:41Z [INFO] Loading configuration
2016-08-15T15:54:41Z [WARN] Invalid value for task cleanup duration, will be overridden to 3h0m0s, parsed value 0, minimum threshold 1m0s
2016-08-15T15:54:41Z [INFO] Checkpointing is enabled. Attempting to load state
2016-08-15T15:54:41Z [INFO] Loading state! module="statemanager"
2016-08-15T15:54:41Z [INFO] Detected Docker versions [1.17 1.18 1.19 1.20 1.21 1.22]
2016-08-15T15:54:41Z [INFO] Registered! module="api client"
```

**Amazon ECS ecs-init Log**

The `ecs-init` process stores logs at `/var/log/ecs/ecs-init.log`.

You can use the following command to view the log files.

```
cat /var/log/ecs/ecs-init.log
```
IAM Roles for Tasks Credential Audit Log

When the credential provider for the IAM role is used to provide credentials to tasks, these requests are saved in an audit log. The audit log inherits the same log rotation settings as the container agent log. The ECS_LOG_ROLLOVER_TYPE, ECS_LOG_MAX_FILE_SIZE_MB, and ECS_LOG_MAX_ROLL_COUNT container agent configuration variables can be set to affect the behavior of the audit log. For more information, see Amazon ECS Container Agent log.

For container agent version 1.36.0 and later, the audit log is located at /var/log/ecs/audit.log. When the log is rotated, a timestamp in YYYY-MM-DD-HH format is added to the end of the log file name.

For container agent version 1.35.0 and earlier, the audit log is located at /var/log/ecs/audit.log. YYYY-MM-DD-HH.

The log entry format is as follows:

- Timestamp
- HTTP response code
- IP address and port number of request origin
- Relative URI of the credential provider
- The user agent that made the request
- The ARN of the task to which the requesting container belongs
- The GetCredentials API name and version number
- The name of the Amazon ECS cluster to which the container instance is registered
- The container instance ARN

An example log entry is shown below.

You can use the following command to view the log files.
cat /var/log/ecs/audit.log.2016-07-13-16

Output:

2016-07-13T16:11:53Z 200 172.17.0.5:52444 "/v1/credentials" "python-requests/2.7.0 CPython/2.7.6 Linux/4.4.14-24.50.amzn1.x86_64" TASK_ARN GetCredentials 1 CLUSTER_NAME CONTAINER_INSTANCE_ARN

Amazon ECS logs collector

If you are unsure how to collect all of the various logs on your container instances, you can use the Amazon ECS logs collector. It is available on GitHub for both Linux and Windows. The script collects general operating system logs as well as Docker and Amazon ECS container agent logs, which can be helpful for troubleshooting AWS Support cases. It then compresses and archives the collected information into a single file that can easily be shared for diagnostic purposes. It also supports enabling debug mode for the Docker daemon and the Amazon ECS container agent on Amazon Linux variants, such as the Amazon ECS-optimized AMI. Currently, the Amazon ECS logs collector supports the following operating systems:

- Amazon Linux
- Red Hat Enterprise Linux 7
- Debian 8
- Ubuntu 14.04
- Ubuntu 16.04
- Ubuntu 18.04
- Windows Server 2016

Note

The source code for the Amazon ECS logs collector is available on GitHub for both Linux and Windows. We encourage you to submit pull requests for changes that you would like to have included. However, Amazon Web Services doesn't currently support running modified copies of this software.
To download and run the Amazon ECS logs collector for Linux

1. Connect to your container instance.
2. Download the Amazon ECS logs collector script.
   
   ```
   ```
3. Run the script to collect the logs and create the archive.

   ![Note]
   
   To enable the debug mode for the Docker daemon and the Amazon ECS container agent, add the `--mode=enable-debug` option to the following command. This might restart the Docker daemon, which kills all containers that are running on the instance. Consider draining the container instance and moving any important tasks to other container instances before enabling debug mode. For more information, see [Container instance draining](#).

   ```
[ec2-user ~]$ sudo bash ./ecs-logs-collector.sh
   ```

After you have run the script, you can examine the collected logs in the `collect` folder that the script created. The `collect.tgz` file is a compressed archive of all of the logs, which you can share with AWS Support for diagnostic help.

To download and run the Amazon ECS logs collector for Windows

1. Connect to your container instance. For more information, see [Connecting to Your Windows Instance](#) in the [Amazon EC2 User Guide for Windows Instances](#).
2. Download the Amazon ECS logs collector script using PowerShell.
   
   ```
   ```
3. Run the script to collect the logs and create the archive.
Note

To enable the debug mode for the Docker daemon and the Amazon ECS container agent, add the `-RunMode debug` option to the following command. This restarts the Docker daemon, which kills all containers that are running on the instance. Consider draining the container instance and moving any important tasks to other container instances before enabling debug mode. For more information, see Container instance draining.

```bash
\ecs-logs-collector.ps1
```

After you have run the script, you can examine the collected logs in the `collect` folder that the script created. The `collect.tgz` file is a compressed archive of all of the logs, which you can share with AWS Support for diagnostic help.

**Agent introspection diagnostics**

The Amazon ECS agent introspection API can provide helpful diagnostic information. For example, you can use the agent introspection API to get the Docker ID for a container in your task. You can use the agent introspection API by connecting to a container instance using SSH.

Important

Your container instance must have an IAM role that allows access to Amazon ECS in order to reach the introspection API. For more information, see Amazon ECS container instance IAM role.

The following example shows two tasks, one that is currently running and one that was stopped.

Note

The following command is piped through the `python -mjson.tool` for greater readability.
curl http://localhost:51678/v1/tasks | python -mjson.tool

Output:

```
% Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
Dload  Upload   Total   Spent    Left  Speed
100  1095  100  1095    0     0   117k      0 --:--:-- --:--:-- --:--:--  133k
{
    "Tasks": [ 
    
        "Arn": "arn:aws:ecs:us-west-2:aws_account_id:task/090eff9b-1ce3-4db6-848a-a8d14064fd24",
        "Containers": [

            "DockerName": "ecs-console-sample-app-static-6-simple-app-86caf9bcabe3e9c61600",
            "Name": "simple-app"
        ],
        "DockerId": "f7f1f8a7a245c5da83aa92729bd28c6bcb004d1f6a35409e4207e1d34030e966",
        "DockerName": "ecs-console-sample-app-static-6-busybox-ce83ce978a87a890ab01",
        "Name": "busybox"
    ],
    "Family": "console-sample-app-static",
    "KnownStatus": "STOPPED",
    "Version": "6"
    },
    
    "Containers": [ 
    
        "DockerId": "dc7240fe892ab233dbbceee5044d95e1456c120dba9a6b56ec513da45c38e3aeb",
        "DockerName": "ecs-console-sample-app-static-6-simple-app-f0e5859699a7aeccfb101",
        "Name": "simple-app"
    ],
}
```

Agent introspection diagnostics
In the preceding example, the stopped task (090eff9b-1ce3-4db6-848a-a8d14064fd24) has two containers. You can use `docker inspect container-ID` to view detailed information on each container. For more information, see Amazon ECS container introspection.

**Docker diagnostics**

Docker provides several diagnostic tools that help you troubleshoot problems with your containers and tasks. For more information about all of the available Docker command line utilities, see the Docker Command Line topic in the Docker documentation. You can access the Docker command line utilities by connecting to a container instance using SSH.

The exit codes that Docker containers report can also provide some diagnostic information (for example, exit code 137 means that the container received a SIGKILL signal). For more information, see Exit Status in the Docker documentation.

**List Docker containers**

You can use the `docker ps` command on your container instance to list the running containers. In the following example, only the Amazon ECS container agent is running. For more information, see docker ps in the Docker documentation.

```
docker ps
```

Output:
You can use the `docker ps -a` command to see all containers (even stopped or killed containers). This is helpful for listing containers that are unexpectedly stopping. In the following example, container `f7f1f8a7a245` exited 9 seconds ago, so it doesn't show up in a `docker ps` output without the `-a` flag.

```bash
docker ps -a
```

Output:

<table>
<thead>
<tr>
<th>CONTAINER ID</th>
<th>IMAGE</th>
<th>COMMAND</th>
<th>CREATED</th>
<th>STATUS</th>
<th>NAMES</th>
</tr>
</thead>
<tbody>
<tr>
<td>cee0d6986de0</td>

<td>/agent</td>
<td>22 hours ago</td>
<td>Up 22 hours</td>
<td>ecs-agent</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

View Docker Logs

You can view the STDOUT and STDERR streams for a container with the `docker logs` command. In this example, the logs are displayed for the `dc7240fe892a` container and piped through the `head` command for brevity. For more information, go to `docker logs` in the Docker documentation.
Note

Docker logs are only available on the container instance if you are using the default json log driver. If you have configured your tasks to use the awslogs log driver, then your container logs are available in CloudWatch Logs. For more information, see Using the awslogs log driver.

docker logs dc7240fe892a | head

Output:

AH00558: httpd: Could not reliably determine the server's fully qualified domain name, using 172.17.0.11. Set the 'ServerName' directive globally to suppress this message
AH00558: httpd: Could not reliably determine the server's fully qualified domain name, using 172.17.0.11. Set the 'ServerName' directive globally to suppress this message

Inspect Docker Containers

If you have the Docker ID of a container, you can inspect it with the docker inspect command. Inspecting containers provides the most detailed view of the environment in which a container was launched. For more information, see docker inspect in the Docker documentation.

docker inspect dc7240fe892a
AWS Fargate throttling quotas

AWS Fargate limits Amazon ECS tasks and Amazon EKS pods launch rates to quotas (formerly referred to as limits) using a token bucket algorithm for each AWS account on a per-Region basis. With this algorithm, your account has a bucket that holds a specific number of tokens. The number of tokens in the bucket represents your rate quota at any given second. Each customer account has a tasks and pods token bucket that depletes based on the number of tasks and pods launched by the customer account. This token bucket has a bucket maximum that allows you to periodically make a higher number of requests, and a refill rate that allows you to sustain a steady rate of requests for as long as needed.
For example, the tasks and pods token bucket size for a Fargate customer account is 100 tokens, and the refill rate is 20 tokens per second. Therefore, you can immediately launch up to 100 Amazon ECS tasks and Amazon EKS pods per customer account, with a sustained launch rate of 20 Amazon ECS tasks and Amazon EKS pods per second.

<table>
<thead>
<tr>
<th>Actions</th>
<th>Bucket maximum capacity (or Burst rate)</th>
<th>Bucket refill rate (or Sustained rate)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fargate Resource rate quota for On Demand Amazon ECS tasks and Amazon EKS pods(^1)</td>
<td>100</td>
<td>20</td>
</tr>
<tr>
<td>Fargate Resource rate quota for Spot Amazon ECS tasks</td>
<td>100</td>
<td>20</td>
</tr>
</tbody>
</table>

\(^1\) Accounts launching only Amazon EKS pods have a burst rate of 20 with a sustained pod launch rate of 20 pod launches per second when using the platform versions called out in the Amazon EKS platform versions.

**Throttling the RunTask API**

In addition, Fargate limits the request rate when launching tasks using the Amazon ECS RunTask API using a separate quota. Fargate limits Amazon ECS RunTask API requests for each AWS account on a per-Region basis. Each request that you make removes one token from the bucket. We do this to help the performance of the service, and to ensure fair usage for all Fargate customers. API calls are subject to the request quotas whether they originate from the Amazon Elastic Container Service console, a command line tool, or a third-party application. The rate quota for calls to the Amazon ECS RunTask API is 20 calls per second (burst and sustained). Each call to this API can, however, launch up to 10 tasks. This means you can launch 100 tasks in one second by making 10 calls to this API, requesting 10 tasks to be launched in each call. Similarly, you could also make 20 calls to this API, requesting 5 tasks to be launched in each call. For more information on API throttling for Amazon ECS RunTask API, see [API request throttling](#) in the Amazon ECS API Reference.

In practice, task and pod launch rates are also dependent on other considerations such as container images to be downloaded and unpacked, health checks and other integrations enabled, such as
registering tasks or pods into a load balancer. Customers see variations in task and pod launch rates compared with the quotas represented earlier based on the features that customers enable.

**Adjusting rate quotas**

You can request an increase for Fargate rate throttling quotas for your AWS account. To request a quota adjustment, contact the [AWS Support Center](https://aws.amazon.com/support/).  

**API failure reasons**

When an API action that you have triggered through the Amazon ECS API, console, or the AWS CLI exits with a failures error message, the following might assist in troubleshooting the cause. The failure returns a reason and the Amazon Resource Name (ARN) of the resource associated with the failure.

Many resources are Region-specific, so when using the console ensure that you set the correct Region for your resources. When using the AWS CLI, make sure that your AWS CLI commands are being sent to the correct Region with the --region `region` parameter.

For more information about the structure of the Failure data type, see [Failure](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/security-how-to-monitor-api.html) in the Amazon Elastic Container Service API Reference.

The following are examples of failure messages that you might receive when running API commands.

<table>
<thead>
<tr>
<th>API action</th>
<th>Failure reason or Stopped reason</th>
<th>Cause</th>
</tr>
</thead>
<tbody>
<tr>
<td>DescribeClusters</td>
<td>MISSING</td>
<td>The specified cluster wasn't found. Verify the spelling of the cluster name.</td>

</tr>
</tbody>
</table>

**Note**

Besides the failure scenarios described here, API operations can also fail due to exceptions, resulting in error responses. For a list of such exceptions, see [Common Errors](#).

### Best practices for handling Amazon ECS throttling issues

Throttling errors fall into two major categories: *synchronous* throttling and *asynchronous* throttling.
Synchronous throttling

When synchronous throttling occurs, you immediately receive an error response from Amazon ECS. This category of throttling typically occurs when you call Amazon ECS APIs while running tasks or creating services. For more information about the throttling involved and the relevant throttle limits, see Request throttling for the Amazon ECS API.

When your application initiates API requests, for example, by using the AWS CLI or an AWS SDK, you can remediate API throttling. You can do this by either architecting your application to handle the errors or by implementing an exponential backoff and jitter strategy with retry logic for the API calls. For more information, see Timeouts, retries, and backoff with jitter.

If you use an AWS SDK, the automatic retry logic is already built-in and configurable.

Asynchronous throttling

Asynchronous throttling occurs because of asynchronous workflows where Amazon ECS or AWS CloudFormation might be calling APIs on your behalf to provision resources. It's important to know which AWS APIs that Amazon ECS invokes on your behalf. For example, the CreateNetworkInterface API is invoked for tasks that use the awsvpc network mode, and the DescribeTargetHealth API is invoked when performing health checks for tasks registered to a load balancer.

When your workloads reach a considerable scale, these API operations might be throttled. That is, they might be throttled enough to breach the limits enforced by Amazon ECS or the AWS service that is being called. For example, if you deploy hundreds of services, each having hundreds of tasks concurrently that use the awsvpc network mode, Amazon ECS invokes Amazon EC2 API operations such as CreateNetworkInterface and Elastic Load Balancing API operations such as RegisterTarget or DescribeTargetHealth to register the elastic network interface and load balancer, respectively. These API calls can exceed the API limits, resulting in throttling errors. The following is an example of an Elastic Load Balancing throttling error that's included in the service event message.

```json
{
    "userIdentity": {
        "arn": "arn:aws:sts::111122223333:assumed-role/AWSServiceRoleForECS/ecs-service-scheduler",
        "eventTime": "2022-03-21T08:11:24Z",
        "eventSource": "elasticloadbalancing.amazonaws.com"
    }
}
```
When these API calls share limits with other API traffic in your account, they might be difficult to monitor even though they're emitted as service events.

**Monitoring throttling**

It's important to identify which API requests are throttled and who issues these requests. You can use AWS CloudTrail which monitors throttling, and integrates with CloudWatch, Amazon Athena, and Amazon EventBridge. You can configure CloudTrail to send specific events to CloudWatch Logs. CloudWatch Logs log insights parses and analyzes the events. This identifies details in throttling events such as the user or IAM role that made the call and the number of API calls that were made. For more information, see [Monitoring CloudTrail log files with CloudWatch Logs](https://aws.amazon.com/premiumsupport/knowledge-center/cloudtrail-cloudwatch-logs/).

For more information about CloudWatch Logs insights and instructions on how to query log files, see [Analyzing log data with CloudWatch Logs Insights](https://aws.amazon.com/premiumsupport/knowledge-center/cloudwatch-log-insights/).

With Amazon Athena, you can create queries and analyze data using standard SQL. For example, you can create an Athena table to parse CloudTrail events. For more information, see [Using the CloudTrail console to create an Athena table for CloudTrail logs](https://aws.amazon.com/premiumsupport/knowledge-center/cloudtrail-console-athena-kit/).

After creating an Athena table, you can use simple SQL queries such as the following one to investigate ThrottlingException errors.

```sql
SELECT eventname, errorcode, eventsourcE, awsregion, userAgent, COUNT(*) count
FROM cloudtrail-table-name
WHERE errorcode = 'ThrottlingException'
AND eventtime between '2022-01-14T03:00:08Z' and '2022-01-23T07:15:08Z'
group by errorcode, awsregion, eventsourcE, username, eventname
order by count desc;
```

Amazon ECS also emits event notifications to Amazon EventBridge. There are resource state change events and service action events. They include API throttling events such as...
ECS_OPERATION_THROTTLED and SERVICE_DISCOVERY_OPERATION_THROTTLED. For more information, see Amazon ECS service action events.

These events can be consumed by a service such as AWS Lambda to perform actions in response. For more information, see Handling Amazon ECS events.

If you run standalone tasks, some API operations such as RunTask are asynchronous, and retry operations aren't automatically performed. In such cases, you can use services such as AWS Step Functions with EventBridge integration to retry throttled or failed operations. For more information, see Manage a container task (Amazon ECS, Amazon SNS).

Using CloudWatch to monitor throttling

CloudWatch offers API usage monitoring on the Usage namespace under By AWS Resource. These metrics are logged with type API and metric name CallCount. You can create alarms to start whenever these metrics reach a certain threshold. For more information, see Visualizing your service quotas and setting alarms.

CloudWatch also offers anomaly detection. This feature uses machine learning to analyze and establish baselines based on the particular behavior of the metric that you enabled it on. If there's unusual API activity, you can use this feature together with CloudWatch alarms. For more information, see Using CloudWatch anomaly detection.

By proactively monitoring throttling errors, you can contact AWS Support to increase the relevant throttling limits and also receive guidance for your unique application needs.
Parameter references and resource templates

The following sections describe the task definition and service definition parameters.

Topics

- Task definition parameters
- Task definition template
- Service definition parameters

Task definition parameters

Task definitions are split into separate parts: the task family, the AWS Identity and Access Management (IAM) task role, the network mode, container definitions, volumes, task placement constraints, and launch types. The family and container definitions are required in a task definition. In contrast, task role, network mode, volumes, task placement constraints, and launch type are optional.

You can use these parameters in a JSON file to configure your task definition. For more information, see the section called “Example logging option task definitions”.

The following are more detailed descriptions for each task definition parameter.

Family

family

Type: String

Required: Yes

When you register a task definition, you give it a family, which is similar to a name for multiple versions of the task definition, specified with a revision number. The first task definition that's registered into a particular family is given a revision of 1, and any task definitions registered after that are given a sequential revision number.
Launch types

When you register a task definition, you can specify a launch type that Amazon ECS should validate the task definition against. If the task definition doesn't validate against the compatibilities specified, a client exception is returned. For more information, see Amazon ECS launch types.

The following parameter is allowed in a task definition.

**requiresCompatibilities**

Type: String array

Required: No

Valid Values: EC2 | FARGATE | EXTERNAL

The launch type to validate the task definition against. This initiates a check to ensure that all of the parameters that are used in the task definition meet the requirements of the launch type.

Task role

taskRoleArn

Type: String

Required: No

When you register a task definition, you can provide a task role for an IAM role that allows the containers in the task permission to call the AWS APIs that are specified in its associated policies on your behalf. For more information, see Task IAM role.

When you launch the Amazon ECS-optimized Windows Server AMI, IAM roles for tasks on Windows require that the -EnableTaskIAMRole option is set. Your containers must also run some configuration code to use the feature. For more information, see Additional configuration for Windows IAM roles for tasks.

Task execution role

executionRoleArn

Type: String
Required: Conditional

The Amazon Resource Name (ARN) of the task execution role that grants the Amazon ECS container agent permission to make AWS API calls on your behalf.

Note

The task execution IAM role is required depending on the requirements of your task. For more information, see Amazon ECS task execution IAM role.

Network mode

networkMode

Type: String

Required: No

The Docker networking mode to use for the containers in the task. For Amazon ECS tasks that are hosted on Amazon EC2 Linux instances, the valid values are none, bridge, awsvpc, and host. If no network mode is specified, the default network mode is bridge. For Amazon ECS tasks hosted on Amazon EC2 Windows instances, the valid values are default, and awsvpc. If no network mode is specified, the default network mode is used. For Amazon ECS tasks hosted on Fargate, the awsvpc network mode is required.

If the network mode is set to none, the task’s containers don't have external connectivity and port mappings can't be specified in the container definition.

If the network mode is bridge, the task uses Docker's built-in virtual network on Linux, which runs inside each Amazon EC2 instance that hosts the task. The built-in virtual network on Linux uses the bridge Docker network driver.

If the network mode is host, the task uses the host's network which bypasses Docker's built-in virtual network by mapping container ports directly to the ENI of the Amazon EC2 instance that hosts the task. Dynamic port mappings can’t be used in this network mode. A container in a task definition that uses this mode must specify a specific hostPort number. A port number on a host can’t be used by multiple tasks. As a result, you can’t run multiple tasks of the same task definition on a single Amazon EC2 instance.
**Important**

When running tasks that use the host network mode, do not run containers using the root user (UID 0) for better security. As a security best practice, always use a non-root user.

For the Amazon EC2 launch types, if the network mode is awsvpc, the task is allocated an elastic network interface, and you must specify a NetworkConfiguration when you create a service or run a task with the task definition. For more information, see [Task networking for tasks on Amazon EC2 instances](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/task-networking.html).

If the network mode is default, the task uses Docker's built-in virtual network on Windows, which runs inside each Amazon EC2 instance that hosts the task. The built-in virtual network on Windows uses the nat Docker network driver.

For the Fargate launch types, when the network mode is awsvpc, the task is allocated an elastic network interface, and you must specify a NetworkConfiguration when you create a service or run a task with the task definition. For more information, see [Fargate Task Networking](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/fargate-task-networking.html). The awsvpc network mode offers the highest networking performance for containers because they use the Amazon EC2 network stack. Exposed container ports are mapped directly to the attached elastic network interface port. Because of this, you can't use dynamic host port mappings.

The host and awsvpc network modes offer the highest networking performance for containers because they use the Amazon EC2 network stack. With the host and awsvpc network modes, exposed container ports are mapped directly to the corresponding host port (for the host network mode) or the attached elastic network interface port (for the awsvpc network mode). Because of this, you can't use dynamic host port mappings.

If using the Fargate launch type, the awsvpc network mode is required. If using the EC2 launch type, the allowable network mode depends on the underlying EC2 instance's operating system. If Linux, any network mode can be used. If Windows, the default, and awsvpc modes can be used.
Runtime platform

operatingSystemFamily

Type: String

Required: Conditional

Default: LINUX

This parameter is required for Amazon ECS tasks that are hosted on Fargate.

When you register a task definition, you specify the operating system family.

The valid values for Amazon ECS tasks that are hosted on Fargate are LINUX, WINDOWS_SERVER_2019_FULL, WINDOWS_SERVER_2019_CORE, WINDOWS_SERVER_2022_FULL, and WINDOWS_SERVER_2022_CORE.

The valid values for Amazon ECS tasks hosted on EC2 are LINUX, WINDOWS_SERVER_2022_CORE, WINDOWS_SERVER_2022_FULL, WINDOWS_SERVER_2019_FULL, and WINDOWS_SERVER_2019_CORE, WINDOWS_SERVER_2016_FULL, WINDOWS_SERVER_2004_CORE, and WINDOWS_SERVER_20H2_CORE.

All task definitions that are used in a service must have the same value for this parameter.

When a task definition is part of a service, this value must match the service platformFamily value.

cpuArchitecture

Type: String

Required: Conditional

Default: X86_64

This parameter is required for Amazon ECS tasks hosted on Fargate. If the parameter is left as null, the default value is automatically assigned upon the initiation of a task hosted on Fargate.

When you register a task definition, you specify the CPU architecture. The valid values are X86_64 and ARM64.
All task definitions that are used in a service must have the same value for this parameter.

When you have Linux tasks for either the Fargate launch type, or the EC2 launch type, you can set the value to ARM64. For more information, see the section called “Working with 64-bit ARM workloads on Amazon ECS”.

**Task size**

When you register a task definition, you can specify the total CPU and memory used for the task. This is separate from the `cpu` and `memory` values at the container definition level. For tasks that are hosted on Amazon EC2 instances, these fields are optional. For tasks that are hosted on Fargate (both Linux and Windows), these fields are required and there are specific values for both `cpu` and `memory` that are supported.

**Note**

Task-level CPU and memory parameters are ignored for Windows containers. We recommend specifying container-level resources for Windows containers.

The following parameter is allowed in a task definition:

`cpu`

Type: String

Required: Conditional

**Note**

This parameter is not supported for Windows containers.

The hard limit of CPU units to present for the task. It can be expressed using CPU units (for example, 1024) or using vCPUs (for example, 1 vCPU or 1 vcpu) in a task definition. When the task definition is registered, a vCPU value is converted to an integer indicating the CPU units.

For tasks that run on EC2 or external instances, this field is optional. If your cluster doesn't have any registered container instances with the requested CPU units available, the task fails.
Supported values for tasks that run on EC2 or external instances are between 0.125 vCPUs and 10 vCPUs.

For tasks that run on Fargate (both Linux and Windows containers), this field is required and you must use one of the following values, which determines your range of supported values for the memory parameter. The table below shows the valid combinations of task-level CPU and memory.

<table>
<thead>
<tr>
<th>CPU value</th>
<th>Memory value</th>
<th>Operating systems supported for AWS Fargate</th>
</tr>
</thead>
<tbody>
<tr>
<td>256 (.25 vCPU)</td>
<td>512 MiB, 1 GB, 2 GB</td>
<td>Linux</td>
</tr>
<tr>
<td>512 (.5 vCPU)</td>
<td>1 GB, 2 GB, 3 GB, 4 GB</td>
<td>Linux</td>
</tr>
<tr>
<td>1024 (1 vCPU)</td>
<td>2 GB, 3 GB, 4 GB, 5 GB, 6 GB, 7 GB, 8 GB</td>
<td>Linux, Windows</td>
</tr>
<tr>
<td>2048 (2 vCPU)</td>
<td>Between 4 GB and 16 GB in 1 GB increments</td>
<td>Linux, Windows</td>
</tr>
<tr>
<td>4096 (4 vCPU)</td>
<td>Between 8 GB and 30 GB in 1 GB increments</td>
<td>Linux, Windows</td>
</tr>
<tr>
<td>8192 (8 vCPU)</td>
<td>Between 16 GB and 60 GB in 4 GB increments</td>
<td>Linux</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>This option requires Linux platform 1.4.0 or later.</td>
<td></td>
</tr>
<tr>

<td>Between 32 GB and 120 GB in 8 GB increments</td>
<td>Linux</td>
</tr>
<tr>
<td>CPU value</td>
<td>Memory value</td>
<td>Operating systems supported for AWS Fargate</td>
</tr>
<tr>
<td>-----------</td>
<td>--------------</td>
<td>---------------------------------------------</td>
</tr>
</tbody>
</table>

### Note
This option requires Linux platform 1.4.0 or later.

### memory

**Type:** String

**Required:** Conditional

#### Note
This parameter is not supported for Windows containers.

The hard limit of memory (in MiB) to present to the task. It can be expressed using MiB (for example 1024) or using GB (for example 1GB or 1 GB) in a task definition. When the task definition is registered, a GB value is converted to an integer indicating the MiB.

For tasks that are hosted on Amazon EC2 instances, this field is optional and any value can be used. If a task-level memory value is specified, then the container-level memory value is optional. If your cluster doesn't have any registered container instances with the requested memory available, the task fails. You can maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type. For more information, see Container instance memory management.

For tasks hosted on Fargate (both Linux and Windows containers), this field is required and you must use one of the following values, which determines your range of supported values for the cpu parameter:
<table>
<thead>
<tr>
<th>Memory value (in MiB, with approximate equivalent value in GB)</th>
<th>CPU value</th>
<th>Operating systems supported for Fargate</th>
</tr>
</thead>
<tbody>
<tr>
<td>512 (0.5 GB), 1024 (1 GB), 2048 (2 GB)</td>
<td>256 (.25 vCPU)</td>
<td>Linux</td>
</tr>
<tr>
<td>1024 (1 GB), 2048 (2 GB), 3072 (3 GB), 4096 (4 GB)</td>
<td>512 (.5 vCPU)</td>
<td>Linux</td>
</tr>
<tr>
<td>2048 (2 GB), 3072 (3 GB), 4096 (4GB), 5120 (5 GB), 6144 (6 GB), 7168 (7 GB), 8192 (8 GB)</td>
<td>1024 (1 vCPU)</td>
<td>Linux, Windows</td>
</tr>
<tr>
<td>Between 4096 (4 GB) and 16384 (16 GB) in increments of 1024 (1 GB)</td>
<td>2048 (2 vCPU)</td>
<td>Linux, Windows</td>
</tr>
<tr>
<td>Between 8192 (8 GB) and 30720 (30 GB) in increments of 1024 (1 GB)</td>
<td>4096 (4 vCPU)</td>
<td>Linux, Windows</td>
</tr>
<tr>
<td>Between 16 GB and 60 GB in 4 GB increments</td>
<td>8192 (8 vCPU)</td>
<td>Linux</td>
</tr>
<tr>
<td>Note</td>
<td></td>
<td></td>
</tr>
<tr>
<td>This option requires Linux platform 1.4.0 or later.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Between 32 GB and 120 GB in 8 GB increments</td>
<td>16384 (16vCPU)</td>
<td>Linux</td>
</tr>
</tbody>
</table>
Container definitions

When you register a task definition, you must specify a list of container definitions that are passed to the Docker daemon on a container instance. The following parameters are allowed in a container definition.

Topics
- Standard container definition parameters
- Advanced container definition parameters
- Other container definition parameters

Standard container definition parameters

The following task definition parameters are either required or used in most container definitions.

Topics
- Name
- Image
- Memory
- Port mappings
- Private Repository Credentials
Name

ame

Type: String

Required: No

The name of a container. Up to 255 letters (uppercase and lowercase), numbers, hyphens, and underscores are allowed. If you're linking multiple containers in a task definition, the name of one container can be entered in the links of another container. This is to connect the containers.

Image

image

Type: String

Required: No

The image used to start a container. This string is passed directly to the Docker daemon. By default, images in the Docker Hub registry are available. You can also specify other repositories with either repository-url/image:tag or repository-url/image@digest. Up to 255 letters (uppercase and lowercase), numbers, hyphens, underscores, colons, periods, forward slashes, and number signs are allowed. This parameter maps to Image in the Create a container section of the Docker Remote API and the IMAGE parameter of docker run.

- When a new task starts, the Amazon ECS container agent pulls the latest version of the specified image and tag for the container to use. However, subsequent updates to a repository image aren't propagated to already running tasks.

- Images in private registries are supported. For more information, see Private registry authentication for tasks.

- Images in Amazon ECR repositories can be specified by using either the full registry/repository:tag or registry/repository@digest naming convention (for example, aws_account_id.dkr.ecr.region.amazonaws.com/my-web-app:latest or aws_account_id.dkr.ecr.region.amazonaws.com/my-web-app@sha256:94afdf1f2e64d90bc90dbca0035a5b567EXAMPLE).

- Images in official repositories on Docker Hub use a single name (for example, ubuntu or mongo).
Images in other repositories on Docker Hub are qualified with an organization name (for example, amazon/amazon-ecs-agent).

Images in other online repositories are qualified further by a domain name (for example, quay.io/assemblyline/ubuntu).

### Memory

**memory**

*Type: Integer*

**Required: No**

The amount (in MiB) of memory to present to the container. If your container attempts to exceed the memory specified here, the container is killed. The total amount of memory reserved for all containers within a task must be lower than the task **memory** value, if one is specified. This parameter maps to *memory* in the [Create a container](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/instance-types.html) section of the [Docker Remote API](https://docs.docker.com/engine/api/v1.37/) and the --memory option to [docker run](https://docs.docker.com/engine/reference/run/).

If you're using the Fargate launch type, this parameter is optional.

If you're using the EC2 launch type, you must specify either a task-level memory value or a container-level memory value. If you specify both a container-level memory and **memoryReservation** value, the memory value must be greater than the **memoryReservation** value. If you specify **memoryReservation**, then that value is subtracted from the available memory resources for the container instance that the container is placed on. Otherwise, the value of **memory** is used.

The Docker 20.10.0 or later daemon reserves a minimum of 6 MiB of memory for a container. So, don't specify less than 6 MiB of memory for your containers.

The Docker 19.03.13-ce or earlier daemon reserves a minimum of 4 MiB of memory for a container. So, don't specify less than 4 MiB of memory for your containers.

> **Note**

If you're trying to maximize your resource utilization by providing your tasks as much memory as possible for a particular instance type, see [Container instance memory management](https://docs.aws.amazon.com/AmazonECS/latest/developerguide/instance-types.html).
memoryReservation

Type: Integer

Required: No

The soft limit (in MiB) of memory to reserve for the container. When system memory is under contention, Docker attempts to keep the container memory to this soft limit. However, your container can use more memory when needed. The container can use up to the hard limit that's specified with the memory parameter (if applicable) or all of the available memory on the container instance, whichever comes first. This parameter maps to MemoryReservation in the Create a container section of the Docker Remote API and the --memory-reservation option to docker run.

If a task-level memory value isn't specified, you must specify a non-zero integer for one or both of memory or memoryReservation in a container definition. If you specify both, memory must be greater than memoryReservation. If you specify memoryReservation, then that value is subtracted from the available memory resources for the container instance that the container is placed on. Otherwise, the value of memory is used.

For example, suppose that your container normally uses 128 MiB of memory, but occasionally bursts to 256 MiB of memory for short periods of time. You can set a memoryReservation of 128 MiB, and a memory hard limit of 300 MiB. This configuration allows the container to only reserve 128 MiB of memory from the remaining resources on the container instance. At the same time, this configuration also allows the container to use more memory resources when needed.

Note

- This parameter isn't supported for Windows containers.

The Docker 20.10.0 or later daemon reserves a minimum of 6 MiB of memory for a container. So, don't specify less than 6 MiB of memory for your containers.

The Docker 19.03.13-ce or earlier daemon reserves a minimum of 4 MiB of memory for a container. So, don't specify less than 4 MiB of memory for your containers.
Port mappings

portMappings

Type: Object array

Required: No

Port mappings allow containers to access ports on the host container instance to send or receive traffic.

For task definitions that use the awsvpc network mode, only specify the containerPort. The hostPort can be kept blank or the same value as the containerPort.

Port mappings on Windows use the NetNAT gateway address rather than localhost. There's no loopback for port mappings on Windows, so you can't access a container's mapped port from the host itself.

Most fields of this parameter (including containerPort, hostPort, protocol) map to PortBindings in the Create a container section of the Docker Remote API and the --publish option to docker run. If the network mode of a task definition is set to host, host ports must either be undefined or match the container port in the port mapping.

Note

After a task reaches the RUNNING status, manual and automatic host and container port assignments are visible in the following locations:

- Console: The Network Bindings section of a container description for a selected task.
- AWS CLI: The networkBindings section of the describe-tasks command output.
- API: The DescribeTasks response.
- Metadata: The task metadata endpoint.
appProtocol

Type: String

Required: No

The application protocol that's used for the port mapping. This parameter only applies to Service Connect. We recommend that you set this parameter to be consistent with the protocol that your application uses. If you set this parameter, Amazon ECS adds protocol-specific connection handling to the service connect proxy. If you set this parameter, Amazon ECS adds protocol-specific telemetry in the Amazon ECS console and CloudWatch.

If you don't set a value for this parameter, then TCP is used. However, Amazon ECS doesn't add protocol-specific telemetry for TCP.

For more information, see the section called “Service Connect”.

Valid protocol values: "HTTP" | "HTTP2" | "GRPC"

ccontainerPort

Type: Integer

Required: Yes, when portMappings are used

The port number on the container that's bound to the user-specified or automatically assigned host port.

If using containers in a task with the Fargate launch type, exposed ports must be specified using containerPort.

For Windows containers on Fargate, you can't use port 3150 for the containerPort. This is because it's reserved.

Suppose that you're using containers in a task with the EC2 launch type and you specify a container port and not a host port. Then, your container automatically receives a host port in the ephemeral port range. For more information, see hostPort. Port mappings that are automatically assigned in this way don't count toward the 100 reserved ports quota of a container instance.

ccontainerPortRange

Type: String
Required: No

The port number range on the container that's bound to the dynamically mapped host port range.

You can only set this parameter by using the register-task-definition API. The option is available in the portMappings parameter. For more information, see register-task-definition in the AWS Command Line Interface Reference.

The following rules apply when you specify a containerPortRange:

- You must use either the bridge network mode or the awsvpc network mode.
- This parameter is available for both the EC2 and AWS Fargate launch types.
- This parameter is available for both the Linux and Windows operating systems.
- The container instance must have at least version 1.67.0 of the container agent and at least version 1.67.0-1 of the ecs-init package.
- You can specify a maximum of 100 port ranges for each container.
- You don't specify a hostPortRange. The value of the hostPortRange is set as follows:
  - For containers in a task with the awsvpc network mode, the hostPort is set to the same value as the containerPort. This is a static mapping strategy.
  - For containers in a task with the bridge network mode, the Amazon ECS agent finds open host ports from the default ephemeral range and passes it to docker to bind them to the container ports.
- The containerPortRange valid values are between 1 and 65535.
- A port can only be included in one port mapping for each container.
- You can't specify overlapping port ranges.
- The first port in the range must be less than last port in the range.
- Docker recommends that you turn off the docker-proxy in the Docker daemon config file when you have a large number of ports.

For more information, see Issue #11185 on GitHub.

For information about how to turn off the docker-proxy in the Docker daemon config file, see Docker daemon in the Amazon ECS Developer Guide.

You can call DescribeTasks to view the hostPortRange, which are the host ports that are bound to the container ports.
The port ranges aren't included in the Amazon ECS task events, which are sent to EventBridge. For more information, see the section called “Automate responses to Amazon ECS errors using EventBridge”.

**hostPortRange**

Type: String

Required: No

The port number range on the host that's used with the network binding. This is assigned by Docker and delivered by the Amazon ECS agent.

**hostPort**

Type: Integer

Required: No

The port number on the container instance to reserve for your container.

If using containers in a task with the Fargate launch type, the *hostPort* can either be kept blank or be the same value as *containerPort*.

Suppose that you're using containers in a task with the EC2 launch type. You can specify a non-reserved host port for your container port mapping. This is referred to as *static* host port mapping. Or, you can omit the *hostPort* (or set it to 0) while specifying a *containerPort*. Your container automatically receives a port in the ephemeral port range for your container instance operating system and Docker version. This is referred to as *dynamic* host port mapping.

The default ephemeral port range Docker version 1.6.0 and later is listed on the instance under `/proc/sys/net/ipv4/ip_local_port_range`. If this kernel parameter is unavailable, the default ephemeral port range from 49153–65535 is used. Don't attempt to specify a host port in the ephemeral port range. This is because these are reserved for automatic assignment. In general, ports under 32768 are outside of the ephemeral port range.

The default reserved ports are 22 for SSH, the Docker ports 2375 and 2376, and the Amazon ECS container agent ports 51678–51680. Any host port that was previously user-specified for a running task is also reserved while the task is running. After a task stops, the
host port is released. The current reserved ports are displayed in the remainingResources of **describe-container-instances** output. A container instance might have up to 100 reserved ports at a time, including the default reserved ports. Automatically assigned ports don't count toward the 100 reserved ports quota.

name

Type: String

Required: No, required for Service Connect to be configured in a service

The name that's used for the port mapping. This parameter only applies to Service Connect. This parameter is the name that you use in the Service Connect configuration of a service.

For more information, see [Service Connect](#).

In the following example, both of the required fields for Service Connect are used.

```json
"portMappings": [
  {
    "name": string,
    "containerPort": integer
  }
]
```

protocol

Type: String

Required: No

The protocol that's used for the port mapping. Valid values are tcp and udp. The default is tcp.

⚠️ **Important**

Only tcp is supported for Service Connect. Remember that tcp is implied if this field isn't set.
Important

UDP support is only available on container instances that were launched with version 1.2.0 of the Amazon ECS container agent (such as the amzn-ami-2015.03.0-amazon-ecs-optimized AMI) or later, or with container agents that have been updated to version 1.3.0 or later. To update your container agent to the latest version, see Updating the Amazon ECS container agent.

If you're specifying a host port, use the following syntax.

```
"portMappings": [
    {
      "containerPort": integer,
      "hostPort": integer
    }
  ...
]
```

If you want an automatically assigned host port, use the following syntax.

```
"portMappings": [
    {
      "containerPort": integer
    }
  ...
]
```

Private Repository Credentials

repositoryCredentials

Type: RepositoryCredentials object

Required: No

The repository credentials for private registry authentication.

For more information, see Private registry authentication for tasks.
credentialsParameter

Type: String

Required: Yes, when repositoryCredentials are used

The Amazon Resource Name (ARN) of the secret containing the private repository credentials.

For more information, see Private registry authentication for tasks.

Note

When you use the Amazon ECS API, AWS CLI, or AWS SDKs, if the secret exists in the same Region as the task that you're launching then you can use either the full ARN or the name of the secret. When you use the AWS Management Console, you must specify the full ARN of the secret.

The following is a snippet of a task definition that shows the required parameters:

```json
"containerDefinitions": [ 
  
  
  "image": "private-repo/private-image",
  
  "repositoryCredentials": {
    
    "credentialsParameter": "arn:aws:secretsmanager:region:aws_account_id:secret:secret_name"
  
  
  
  } 

] 
```

Advanced container definition parameters

The following advanced container definition parameters provide extended capabilities to the docker run command that's used to launch containers on your Amazon ECS container instances.

Topics

- Health check
Health check

healthCheck

The container health check command and the associated configuration parameters for the container. For more information, see Determine Amazon ECS task health using container health checks.

command

A string array that represents the command that the container runs to determine if it's healthy. The string array can start with CMD to run the command arguments directly, or CMD-SHELL to run the command with the container's default shell. If neither is specified, CMD is used.

When registering a task definition in the AWS Management Console, use a comma separated list of commands. These commands are converted to a string after the task definition is created. An example input for a health check is the following.

```
CMD-SHELL, curl -f http://localhost/ || exit 1
```

When registering a task definition using the AWS Management Console JSON panel, the AWS CLI, or the APIs, enclose the list of commands in brackets. An example input for a health check is the following.

```
[ "CMD-SHELL", "curl -f http://localhost/ || exit 1" ]
```

An exit code of 0, with no stderr output, indicates success, and a non-zero exit code indicates failure. For more information, see HealthCheck in the Create a container section of the Docker Remote API.
interval

The period of time (in seconds) between each health check. You can specify between 5 and 300 seconds. The default value is 30 seconds.

timeout

The period of time (in seconds) to wait for a health check to succeed before it's considered a failure. You can specify between 2 and 60 seconds. The default value is 5 seconds.

retries

The number of times to retry a failed health check before the container is considered unhealthy. You can specify between 1 and 10 retries. The default value is three retries.

startPeriod

The optional grace period to provide containers time to bootstrap in before failed health checks count towards the maximum number of retries. You can specify between 0 and 300 seconds. By default, startPeriod is disabled.

Environment

cpu

Type: Integer

Required: No

The number of cpu units the Amazon ECS container agent reserves for the container. On Linux, this parameter maps to CpuShares in the Create a container section of the Docker Remote API and the --cpu-shares option to docker run.

This field is optional for tasks that use the Fargate launch type. The total amount of CPU reserved for all the containers that are within a task must be lower than the task-level cpu value.

Note

You can determine the number of CPU units that are available to each Amazon EC2 instance type. To do this, multiply the number of vCPUs listed for that instance type on the Amazon EC2 Instances detail page by 1,024.
Linux containers share unallocated CPU units with other containers on the container instance with the same ratio as their allocated amount. For example, assume that you run a single-container task on a single-core instance type with 512 CPU units specified for that container. Moreover, that task is the only task running on the container instance. In this example, the container can use the full 1,024 CPU unit share at any given time. However, assume then that you launched another copy of the same task on that container instance. Each task is guaranteed a minimum of 512 CPU units when needed. Similarly, if the other container isn’t using the remaining CPU, each container can float to higher CPU usage. However, if both tasks were 100% active all of the time, they are limited to 512 CPU units.

On Linux container instances, the Docker daemon on the container instance uses the CPU value to calculate the relative CPU share ratios for running containers. For more information, see CPU share constraint in the Docker documentation. The minimum valid CPU share value that the Linux kernel allows is 2. However, the CPU parameter isn’t required, and you can use CPU values below two in your container definitions. For CPU values below two (including null), the behavior varies based on your Amazon ECS container agent version:

- **Agent versions <= 1.1.0**: Null and zero CPU values are passed to Docker as 0. Docker then converts this value to 1,024 CPU shares. CPU values of one are passed to Docker as one, which the Linux kernel converts to two CPU shares.

- **Agent versions >= 1.2.0**: Null, zero, and CPU values of one are passed to Docker as two CPU shares.

On Windows container instances, the CPU quota is enforced as an absolute quota. Windows containers only have access to the specified amount of CPU that’s defined in the task definition. A null or zero CPU value is passed to Docker as 0. Windows then interprets this value as 1% of one CPU.

For more examples, see How Amazon ECS manages CPU and memory resources.

gpu

**Type**: ResourceRequirement object

**Required**: No

The number of physical GPUs that the Amazon ECS container agent reserves for the container. The number of GPUs reserved for all containers in a task must not exceed the number of available GPUs on the container instance the task is launched on. For more information, see Working with GPUs on Amazon ECS.
Amazon Elastic Container Service  

**Note**

This parameter isn't supported for Windows containers or containers that are hosted on Fargate.

---

Elastic Inference accelerator

Type: [ResourceRequirement](#) object

Required: No

For the `InferenceAccelerator` type, the value matches the `deviceName` for an `InferenceAccelerator` specified in a task definition. For more information, see the section called “Elastic Inference accelerator name”.

---

**Note**

Starting April 15, 2023, AWS will not onboard new customers to Amazon Elastic Inference (EI), and will help current customers migrate their workloads to options that offer better price and performance. After April 15, 2023, new customers will not be able to launch instances with Amazon EI accelerators in Amazon SageMaker, Amazon ECS, or Amazon EC2. However, customers who have used Amazon EI at least once during the past 30-day period are considered current customers and will be able to continue using the service.

---

**Note**

This parameter isn't supported for Windows containers or containers that are hosted on Fargate.

---

essential

Type: Boolean

Required: No

---

Container definitions
Suppose that the essential parameter of a container is marked as true, and that container fails or stops for any reason. Then, all other containers that are part of the task are stopped. If the essential parameter of a container is marked as false, then its failure doesn't affect the rest of the containers in a task. If this parameter is omitted, a container is assumed to be essential.

All tasks must have at least one essential container. Suppose that you have an application that's composed of multiple containers. Then, group containers that are used for a common purpose into components, and separate the different components into multiple task definitions. For more information, see Architecting your application.

```
"essential": true|false
```

**entryPoint**

⚠️ **Important**

Early versions of the Amazon ECS container agent don't properly handle entryPoint parameters. If you have problems using entryPoint, update your container agent or enter your commands and arguments as command array items instead.

Type: String array

Required: No

The entry point that's passed to the container. This parameter maps to Entrypoint in the Create a container section of the Docker Remote API and the --entrypoint option to docker run. For more information about the Docker ENTRYPOINT parameter, see https://docs.docker.com/engine/reference/builder/#entrypoint.

```
"entryPoint": ["string", ...]
```

**command**

Type: String array

Required: No
The command that's passed to the container. This parameter maps to `Cmd` in the Create a container section of the Docker Remote API and the COMMAND parameter to `docker run`. For more information about the Docker CMD parameter, see https://docs.docker.com/engine/reference/builder/#cmd. If there are multiple arguments, make sure that each argument is a separated string in the array.

```
"command": ["string", ...]
```

workingDirectory

Type: String

Required: No

The working directory to run commands inside the container in. This parameter maps to `WorkingDir` in the Create a container section of the Docker Remote API and the `--workdir` option to `docker run`.

```
"workingDirectory": "string"
```

environmentFiles

Type: Object array

Required: No

A list of files containing the environment variables to pass to a container. This parameter maps to the `--env-file` option to `docker run`.

This isn't available for Windows containers.

You can specify up to 10 environment files. The file must have a `.env` file extension. Each line in an environment file contains an environment variable in VARIABLE=VALUE format. Lines that start with `#` are treated as comments and are ignored. For more information about the appropriate environment variable file syntax, see Declare default environment variables in file.

If there are individual environment variables specified in the container definition, they take precedence over the variables contained within an environment file. If multiple environment files are specified that contain the same variable, they're processed from the top down. We recommend that you use unique variable names. For more information, see Use task definition parameters to pass environment variables to a container.
value

  Type: String
  Required: Yes

  The Amazon Resource Name (ARN) of the Amazon S3 object containing the environment variable file.

type

  Type: String
  Required: Yes

  The file type to use. The only supported value is s3.

environment

  Type: Object array
  Required: No

  The environment variables to pass to a container. This parameter maps to Env in the Create a container section of the Docker Remote API and the --env option to docker run.

⚠️ Important

  We do not recommend using plaintext environment variables for sensitive information, such as credential data.

name

  Type: String
  Required: Yes, when environment is used

  The name of the environment variable.

value

  Type: String
  Required: Yes, when environment is used
The value of the environment variable.

```json
"environment" : [
    { "name" : "string", "value" : "string" },
    { "name" : "string", "value" : "string" }
]
```

**secrets**

**Type:** Object array

**Required:** No

An object that represents the secret to expose to your container. For more information, see [Passing sensitive data to a container](#).

**name**

**Type:** String

**Required:** Yes

The value to set as the environment variable on the container.

**valueFrom**

**Type:** String

**Required:** Yes

The secret to expose to the container. The supported values are either the full Amazon Resource Name (ARN) of the AWS Secrets Manager secret or the full ARN of the parameter in the AWS Systems Manager Parameter Store.

**Note**

If the Systems Manager Parameter Store parameter exists in the same AWS Region as the task that you're launching, you can use either the full ARN or name of the secret. If the parameter exists in a different Region, then the full ARN must be specified.

```json
"secrets": [
```
Network settings

disableNetworking

Type: Boolean
Required: No

When this parameter is true, networking is off within the container. This parameter maps to
NetworkDisabled in the Create a container section of the Docker Remote API.

Note

This parameter isn't supported for Windows containers or tasks using the awsvpc
network mode.

The default is false.

"disableNetworking": true|false

links

Type: String array
Required: No

The link parameter allows containers to communicate with each other without the need for
port mappings. This parameter is only supported if the network mode of a task definition is set
to bridge. The name:internalName construct is analogous to name:alias in Docker links.
Up to 255 letters (uppercase and lowercase), numbers, hyphens, and underscores are allowed.
For more information about linking Docker containers, see https://docs.docker.com/engine/
userguide/networking/default_network/dockerlinks/. This parameter maps to Links in the
Create a container section of the Docker Remote API and the --link option to docker run.
Note

This parameter isn't supported for Windows containers or tasks using the awsvpc network mode.

Important

Containers that are collocated on the same container instance might communicate with each other without requiring links or host port mappings. The network isolation on a container instance is controlled by security groups and VPC settings.

"links": ["name:internalName", ...]

hostname

Type: String
Required: No

The hostname to use for your container. This parameter maps to Hostname in the Create a container section of the Docker Remote API and the --hostname option to docker run.

Note

If you're using the awsvpc network mode, the hostname parameter isn't supported.

"hostname": "string"

dnsServers

Type: String array
Required: No

A list of DNS servers that are presented to the container. This parameter maps to Dns in the Create a container section of the Docker Remote API and the --dns option to docker run.
Note

This parameter isn't supported for Windows containers or tasks using the awsvpc network mode.

"dnsServers": ["string", ...]

dnsSearchDomains

Type: String array

Required: No

Pattern: ^[a-zA-Z0-9-\.]\{0,253\}[a-zA-Z0-9]$

A list of DNS search domains that are presented to the container. This parameter maps to DnsSearch in the Create a container section of the Docker Remote API and the --dns-search option to docker run.

Note

This parameter isn't supported for Windows containers or tasks that use the awsvpc network mode.

"dnsSearchDomains": ["string", ...]

eextraHosts

Type: Object array

Required: No

A list of hostnames and IP address mappings to append to the /etc/hosts file on the container.

This parameter maps to ExtraHosts in the Create a container section of the Docker Remote API and the --add-host option to docker run.
Note
This parameter isn't supported for Windows containers or tasks that use the awsvpc network mode.

"extraHosts": [
    {
        "hostname": "string",
        "ipAddress": "string"
    }
    ...
]

hostname
Type: String
Required: Yes, when extraHosts are used
The hostname to use in the /etc/hosts entry.

ipAddress
Type: String
Required: Yes, when extraHosts are used
The IP address to use in the /etc/hosts entry.

Storage and logging

readonlyRootFilesystem
Type: Boolean
Required: No
When this parameter is true, the container is given read-only access to its root file system. This parameter maps to ReadonlyRootfs in the Create a container section of the Docker Remote API and the --read-only option to docker run.
This parameter is not supported for Windows containers.

The default is false.

"readonlyRootFilesystem": true|false

**mountPoints**

Type: Object array

Required: No

The mount points for the data volumes in your container. This parameter maps to Volumes in the [Create a container](https://docs.docker.com/engine/api/v1.41/#create-a-container) section of the [Docker Remote API](https://docs.docker.com/engine/api/v1.41/) and the `--volume` option to [docker run](https://docs.docker.com/engine/reference/run/).

Windows containers can mount whole directories on the same drive as `$env:ProgramData`. Windows containers cannot mount directories on a different drive, and mount points cannot be used across drives.

**sourceVolume**

Type: String

Required: Yes, when `mountPoints` are used

The name of the volume to mount.

**containerPath**

Type: String

Required: Yes, when `mountPoints` are used

The path in the container where the volume will be mounted.

**readOnly**

Type: Boolean
Required: No

If this value is true, the container has read-only access to the volume. If this value is false, then the container can write to the volume. The default value is false.

**volumesFrom**

Type: Object array

Required: No

Data volumes to mount from another container. This parameter maps to VolumesFrom in the Create a container section of the Docker Remote API and the --volumes-from option to docker run.

**sourceContainer**

Type: String

Required: Yes, when volumesFrom is used

The name of the container to mount volumes from.

**readOnly**

Type: Boolean

Required: No

If this value is true, the container has read-only access to the volume. If this value is false, then the container can write to the volume. The default value is false.

```json
"volumesFrom": [
  {
    "sourceContainer": "string",
    "readOnly": true|false
  }
]
```

**logConfiguration**

Type: LogConfiguration Object

Required: No
The log configuration specification for the container.

For example task definitions that use a log configuration, see [Example task definitions](#).

This parameter maps to `LogConfig` in the [Create a container](#) section of the [Docker Remote API](#) and the `--log-driver` option to `docker run`. By default, containers use the same logging driver that the Docker daemon uses. However, the container might use a different logging driver than the Docker daemon by specifying a log driver with this parameter in the container definition. To use a different logging driver for a container, the log system must be configured properly on the container instance (or on a different log server for remote logging options). For more information about the options for different supported log drivers, see [Configure logging drivers](#) in the Docker documentation.

Consider the following when specifying a log configuration for your containers:

- Amazon ECS supports a subset of the logging drivers that are available to the Docker daemon. Additional log drivers might be available in future releases of the Amazon ECS container agent.

- This parameter requires version 1.18 or later of the Docker Remote API on your container instance.

- For tasks that use the EC2 launch type, the Amazon ECS container agent that runs on a container instance must register the logging drivers that are available on that instance with the `ECS_AVAILABLE_LOGGING_DRIVERS` environment variable before containers that are placed on that instance can use these log configuration options. For more information, see [Amazon ECS container agent configuration](#).

- For tasks that use the Fargate launch type, because you don't have access to the underlying infrastructure your tasks are hosted on, any additional software needed must be installed outside of the task. For example, the Fluentd output aggregators or a remote host running Logstash to send Gelf logs to.

```json
"logConfiguration": {  
    "logDriver": "awslogs","fluentd","gelf","json-file","journald","logentries","splunk","syslog","awsfirelens",  
    "options": {"string": "string"  
    ...},  
    "secretOptions": [{  
        "name": "string",  
        "valueFrom": "string"  
    }]  
}
```
logDriver

Type: String

Valid values: "awslogs","fluentd","gelf","json-file","journald","logentries","splunk","syslog","awsfirelens"

Required: Yes, when logConfiguration is used

The log driver to use for the container. By default, the valid values that are listed earlier are log drivers that the Amazon ECS container agent can communicate with.

For tasks that use the Fargate launch type, the supported log drivers are awslogs, splunk, and awsfirelens.

For tasks that use the EC2 launch type, the supported log drivers are awslogs, fluentd, gelf, json-file, journald, logentries, syslog, splunk, and awsfirelens.

For more information about how to use the awslogs log driver in task definitions to send your container logs to CloudWatch Logs, see Using the awslogs log driver.

For more information about using the awsfirelens log driver, see Custom Log Routing.

Note

If you have a custom driver that isn't listed, you can fork the Amazon ECS container agent project that's available on GitHub and customize it to work with that driver. We encourage you to submit pull requests for changes that you want to have included. However, we don't currently support running modified copies of this software.

This parameter requires version 1.18 of the Docker Remote API or greater on your container instance.

options

Type: String to string map

Required: No
The key/value map of configuration options to send to the log driver.

When you use FireLens to route logs to an AWS service or AWS Partner Network destination for log storage and analytics, you can set the log-driver-buffer-limit option to limit the number of events that are buffered in memory, before being sent to the log router container. It can help to resolve potential log loss issue because high throughput might result in memory running out for the buffer inside of Docker. For more information, see the section called “Fluentd buffer limit”.

This parameter requires version 1.19 of the Docker Remote API or greater on your container instance.

secretOptions

Type: Object array

Required: No

An object that represents the secret to pass to the log configuration. Secrets that are used in log configuration can include an authentication token, certificate, or encryption key. For more information, see Passing sensitive data to a container.

name

Type: String

Required: Yes

The value to set as the environment variable on the container.

valueFrom

Type: String

Required: Yes

The secret to expose to the log configuration of the container.

```
"logConfiguration": {
  "logDriver": "splunk",
  "options": {
    "splunk-url": "https://cloud.splunk.com:8080",
    "splunk-token": "...",
    "tag": "...",
```
firelensConfiguration

Type: FirelensConfiguration Object

Required: No

The FireLens configuration for the container. This is used to specify and configure a log router for container logs. For more information, see Using custom log routing.

```json
{
    "firelensConfiguration": {
        "type": "fluentd",
        "options": {
            "KeyName": ""
        }
    }
}
```

options

Type: String to string map

Required: No

The key/value map of options to use when configuring the log router. This field is optional and can be used to specify a custom configuration file or to add additional metadata, such as the task, task definition, cluster, and container instance details to the log event. If specified, the syntax to use is "options":{"enable-ecs-log-metadata":"true|false","config-file-type":"s3|file","config-file-value":"arn:aws:s3:::mybucket/fluent.conf|filepath"}. For more information, see Specifying a FireLens configuration in a task definition.

type

Type: String
Required: Yes

The log router to use. The valid values are fluentd or fluentbit.

Security

For more information about container security, see Task and container security in the Amazon ECS Best Practices Guide.

credentialSpecs

Type: String array

Required: No

A list of ARNs in SSM or Amazon S3 to a credential spec (CredSpec) file that configures the container for Active Directory authentication. We recommend that you use this parameter instead of the dockerSecurityOptions. The maximum number of ARNs is 1.

There are two formats for each ARN.

credentialspecdomainless:MyARN

You use credentialspecdomainless:MyARN to provide a CredSpec with an additional section for a secret in Secrets Manager. You provide the login credentials to the domain in the secret.

Each task that runs on any container instance can join different domains.

You can use this format without joining the container instance to a domain.

credentialspec:MyARN

You use credentialspec:MyARN to provide a CredSpec for a single domain.

You must join the container instance to the domain before you start any tasks that use this task definition.

In both formats, replace MyARN with the ARN in SSM or Amazon S3.

The credspec must provide a ARN in Secrets Manager for a secret containing the username, password, and the domain to connect to. For better security, the instance isn't joined to the domain for domainless authentication. Other applications on the instance can't use the
domainless credentials. You can use this parameter to run tasks on the same instance, even if the tasks need to join different domains. For more information, see Using gMSAs for Windows Containers and Using gMSAs for Linux Containers.

privileged

Type: Boolean

Required: No

When this parameter is true, the container is given elevated privileges on the host container instance (similar to the root user). We recommend against running containers with privileged. In most cases, you can specify the exact privileges that you need by using the specific parameters instead of using privileged.

This parameter maps to Privileged in the Create a container section of the Docker Remote API and the --privileged option to docker run.

Note

This parameter is not supported for Windows containers or tasks using the Fargate launch type.

The default is false.

"privileged": true|false

user

Type: String

Required: No

The user to use inside the container. This parameter maps to User in the Create a container section of the Docker Remote API and the --user option to docker run.

Important

When running tasks that use the host network mode, don’t run containers using the root user (UID 0). As a security best practice, always use a non-root user.
You can specify the user using the following formats. If specifying a UID or GID, you must specify it as a positive integer.

- user
- user:group
- uid
- uid:gid
- user:gid
- uid:group

**Note**

This parameter is not supported for Windows containers.

"user": "string"

dockerSecurityOptions

Type: String array

Valid values: "no-new-privileges" | "apparmor:PROFILE" | "label: value" | "credentialspec: CredentialSpecFilePath"

Required: No

A list of strings to provide custom configuration for multiple security systems. For more information about valid values, see [Docker Run Security Configuration](#). This field isn't valid for containers in tasks using the Fargate launch type.

For Linux tasks on EC2, this parameter can be used to reference custom labels for SELinux and AppArmor multi-level security systems.

For any tasks on EC2, this parameter can be used to reference a credential spec file that configures a container for Active Directory authentication. For more information, see [Using gMSAs for Windows Containers on Amazon EC2](#) and [Using gMSA for Linux Containers on Amazon EC2](#).

This parameter maps to SecurityOpt in the [Create a container](#) section of the [Docker Remote API](#) and the --security-opt option to [docker](#).
"dockerSecurityOptions": ["string", ...]

**Note**
The Amazon ECS container agent that run on a container instance must register with the ECS_SELINUX_CAPABLE=true or ECS_APPARMOR_CAPABLE=true environment variables before containers that are placed on that instance can use these security options. For more information, see [Amazon ECS container agent configuration](#).

### Resource limits

**ulimits**

*Type: Object array*

*Required: No*

A list of ulimit values to define for a container. This value overwrites the default resource quota setting for the operating system. This parameter maps to Ulimits in the Create a container section of the [Docker Remote API](#) and the --ulimit option to [docker run](#).

Amazon ECS tasks hosted on Fargate use the default resource limit values set by the operating system with the exception of the nofile resource limit parameter. The nofile resource limit sets a restriction on the number of open files that a container can use. On Fargate, the default nofile soft limit is 1024 and hard limit is 65535. You can set the values of both limits up to 1048576. For more information, see [Task resource limits](#).

This parameter requires version 1.18 of the Docker Remote API or greater on your container instance.

**Note**
This parameter is not supported for Windows containers.

"ulimits": [
{
  "name": "core" | "cpu" | "data" | "fsize" | "locks" | "memlock" | "msgqueue" | "nice" | "nofile" | "nproc" | "rss" | "rttime" | "rtprio" | "sigpending" | "stack",
}]

---

Container definitions 1467
name

Type: String

Valid values: "core" | "cpu" | "data" | "fsize" | "locks" | "memlock" | "msgqueue" | "nice" | "nofile" | "nproc" | "rss" | "rtprio" | "rttime" | "sigpending" | "stack"

Required: Yes, when ulimits are used

The type of the ulimit.

hardLimit

Type: Integer

Required: Yes, when ulimits are used

The hard limit for the ulimit type.

softLimit

Type: Integer

Required: Yes, when ulimits are used

The soft limit for the ulimit type.

Docker labels

dockerLabels

Type: String to string map

Required: No

A key/value map of labels to add to the container. This parameter maps to Labels in the Create a container section of the Docker Remote API and the --label option to docker run.
This parameter requires version 1.18 of the Docker Remote API or greater on your container instance.

```
"dockerLabels": {"string": "string"
...
```

### Other container definition parameters

The following container definition parameters can be used when registering task definitions in the Amazon ECS console by using the **Configure via JSON** option. For more information, see [Creating a task definition using the console](#).

**Topics**

- [Linux parameters](#)
- [Container dependency](#)
- [Container timeouts](#)
- [System controls](#)
- [Interactive](#)
- [Pseudo terminal](#)

#### Linux parameters

**linuxParameters**

Type: [LinuxParameters](#) object

Required: No

Linux-specific options that are applied to the container, such as [KernelCapabilities](#).

**Note**

This parameter isn't supported for Windows containers.

```
"linuxParameters": {
  "capabilities": {
```
capabilities

Type: **KernelCapabilities** object

Required: No

The Linux capabilities for the container that are added to or dropped from the default configuration provided by Docker. For more information about the default capabilities and the other available capabilities, see [Runtime privilege and Linux capabilities](#) in the *Docker run reference*. For more information about these Linux capabilities, see the [capabilities(7)](#) Linux manual page.

**add**

Type: String array

Valid values: "ALL" | "AUDIT_CONTROL" | "AUDIT_READ" | "AUDIT_WRITE" | "BLOCK_SUSPEND" | "CHOWN" | "DAC_OVERRIDE" | "DAC_READ_SEARCH" | "FOWNER" | "FSETID" | "IPC_LOCK" | "IPC_OWNER" | "KILL" | "LEASE" | "LINUX_IMMUTABLE" | "MAC_ADMIN" | "MAC_OVERRIDE" | "MKNOD" | "NET_ADMIN" | "NET_BIND_SERVICE" | "NET_BROADCAST" | "NET_RAW" | "SETFCAP" | "SETGID" | "SETPCAP" | "SETUID" | "SYS_ADMIN" | "SYS_BOOT" | "SYS_CHROOT" | "SYS_MODULE" | "SYS_NICE" | "SYS_PACCT" | "SYS_PTRACE" | "SYS_RAWIO" | "SYS_RESOURCE" | "SYS_TIME" | "SYS_TTY_CONFIG" | "SYSLOG" | "WAKE_ALARM"

Required: No

The Linux capabilities for the container to add to the default configuration provided by Docker. This parameter maps to CapAdd in the [Create a container](#) section of the *Docker Remote API* and the \-\-cap\-add option to `docker run`.

**Note**

Tasks that are launched on Fargate only support adding the SYS_PTRACE kernel capability.
add

Type: String array

Valid values: "SYS_PTRACE"

Required: No

The Linux capabilities for the container to add to the default configuration that's provided by Docker. This parameter maps to CapAdd in the [Create a container](https://docs.aws.amazon.com/elastickeystore/latest/api/API_CreateContainer.html) section of the [Docker Remote API](https://docs.docker.com/engine/api/v1.41/), and the `--cap-add` option to `docker run`.

drop

Type: String array

Valid values: "ALL" | "AUDIT_CONTROL" | "AUDIT_WRITE" | "BLOCK_SUSPEND" | "CHOWN" | "DAC_OVERRIDE" | "DAC_READ_SEARCH" | "FOWNER" | "FSETID" | "IPC_LOCK" | "IPC_OWNER" | "KILL" | "LEASE" | "LINUX_IMMUTABLE" | "MAC_ADMIN" | "MAC_OVERRIDE" | "MKNOD" | "NET_ADMIN" | "NET_BIND_SERVICE" | "NET_BROADCAST" | "NET_RAW" | "SETFCAP" | "SETGID" | "SETPCAP" | "SETUID" | "SYS_ADMIN" | "SYS_BOOT" | "SYS_CHROOT" | "SYS_MODULE" | "SYS_NICE" | "SYS_PACCT" | "SYS_PTRACE" | "SYS_RAWIO" | "SYS_RESOURCE" | "SYS_TIME" | "SYS_TTY_CONFIG" | "SYSLOG" | "WAKE_ALARM"

Required: No

The Linux capabilities for the container to remove from the default configuration that's provided by Docker. This parameter maps to CapDrop in the [Create a container](https://docs.aws.amazon.com/elastickeystore/latest/api/API_CreateContainer.html) section of the [Docker Remote API](https://docs.docker.com/engine/api/v1.41/), and the `--cap-drop` option to `docker run`.

devices

Any host devices to expose to the container. This parameter maps to Devices in the [Create a container](https://docs.aws.amazon.com/elastickeystore/latest/api/API_CreateContainer.html) section of the [Docker Remote API](https://docs.docker.com/engine/api/v1.41/), and the `--device` option to `docker run`.

**Note**

The `devices` parameter isn't supported when you use the Fargate launch type, or Windows containers.
Type: Array of `Device` objects

Required: No

hostPath

The path for the device on the host container instance.

Type: String

Required: Yes

containerPath

The path inside the container to expose the host device at.

Type: String

Required: No

permissions

The explicit permissions to provide to the container for the device. By default, the container has permissions for `read`, `write`, and `mknod` on the device.

Type: Array of strings

Valid Values: `read` | `write` | `mknod`

initProcessEnabled

Run an init process inside the container that forwards signals and reaps processes. This parameter maps to the `--init` option to `docker run`.

This parameter requires version 1.25 of the Docker Remote API or greater on your container instance.

maxSwap

The total amount of swap memory (in MiB) a container can use. This parameter is translated to the `--memory-swap` option to `docker run` where the value is the sum of the container memory plus the `maxSwap` value.

If a `maxSwap` value of 0 is specified, the container doesn't use swap. Accepted values are 0 or any positive integer. If the `maxSwap` parameter is omitted, the container uses the swap configuration for the container instance that it's running on. A `maxSwap` value must be set for the `swappiness` parameter to be used.
**sharedMemorySize**

The value for the size (in MiB) of the `/dev/shm` volume. This parameter maps to the `--shm-size` option to `docker run`.

**Note**
If you're using tasks that use the Fargate launch type, the `sharedMemorySize` parameter isn't supported.

**Type:** Integer

**swappiness**

You can use this parameter to tune a container's memory swappiness behavior. A swappiness value of 0 prevents swapping from happening unless required. A swappiness value of 100 causes pages to be swapped frequently. Accepted values are whole numbers between 0 and 100. If you don't specify a value, the default value of 60 is used. Moreover, if you don't specify a value for `maxSwap`, then this parameter is ignored. This parameter maps to the `--memory-swappiness` option to `docker run`.

**Note**
If you're using tasks that use the Fargate launch type, the swappiness parameter isn't supported.

If you're using tasks on Amazon Linux 2023 the swappiness parameter isn't supported.

**tmpfs**

The container path, mount options, and maximum size (in MiB) of the tmpfs mount. This parameter maps to the `--tmpfs` option to `docker run`.
Note

If you're using tasks that use the Fargate launch type, the tmpfs parameter isn't supported.

Type: Array of `Tmpfs` objects

Required: No

containerPath

The absolute file path where the tmpfs volume is to be mounted.

Type: String

Required: Yes

mountOptions

The list of tmpfs volume mount options.

Type: Array of strings

Required: No

Valid Values: "defaults" | "ro" | "rw" | "suid" | "nosuid" | "dev" | "nodev" | "exec" | "noexec" | "sync" | "async" | "dirsycn" | "remount" | "mand" | "nomand" | "atime" | "noatime" | "diratime" | "nodiratime" | "bind" | "rbind" | "unbindable" | "runbindable" | "private" | "rprivate" | "shared" | "rshared" | "slave" | "rslave" | "relatime" | "norelatime" | "strictatime" | "nostRICTatime" | "mode" | "uid" | "gid" | "nr_inodes" | "nr_blocks" | "mpol"

size

The maximum size (in MiB) of the tmpfs volume.

Type: Integer

Required: Yes
Container dependency

dependsOn

Type: Array of ContainerDependency objects

Required: No

The dependencies defined for container startup and shutdown. A container can contain multiple dependencies. When a dependency is defined for container startup, for container shutdown it is reversed. For an example, see Container dependency.

Note

If a container doesn't meet a dependency constraint or times out before meeting the constraint, Amazon ECS doesn't progress dependent containers to their next state.

For Amazon ECS tasks that are hosted on Amazon EC2 instances, the instances require at least version 1.26.0 of the container agent to enable container dependencies. However, we recommend using the latest container agent version. For information about checking your agent version and updating to the latest version, see Updating the Amazon ECS container agent. If you're using an Amazon ECS-optimized Amazon Linux AMI, your instance needs at least version 1.26.0-1 of the ecs-init package. If your container instances are launched from version 20190301 or later, they contain the required versions of the container agent and ecs-init. For more information, see Amazon ECS-optimized AMI.

For Amazon ECS tasks that are hosted on Fargate, this parameter requires that the task or service uses platform version 1.3.0 or later (Linux) or 1.0.0 (Windows).

"dependsOn": [
  {
    "containerName": "string",
    "condition": "string"
  }
]

containerName

Type: String
Required: Yes

The container name that must meet the specified condition.

type: String

Required: Yes

The dependency condition of the container. The following are the available conditions and their behavior:

- **START** – This condition emulates the behavior of links and volumes today. The condition validates that a dependent container is started before permitting other containers to start.

- **COMPLETE** – This condition validates that a dependent container runs to completion (exits) before permitting other containers to start. This can be useful for non-essential containers that run a script and then exit. This condition can't be set on an essential container.

- **SUCCESS** – This condition is the same as COMPLETE, but it also requires that the container exits with a zero status. This condition can't be set on an essential container.

- **HEALTHY** – This condition validates that the dependent container passes its container health check before permitting other containers to start. This requires that the dependent container has health checks configured in the task definition. This condition is confirmed only at task startup.

**Container timeouts**

**startTime**

Type: Integer

Required: No

Example values: 120

Time duration (in seconds) to wait before giving up on resolving dependencies for a container.

For example, you specify two containers in a task definition with containerA having a dependency on containerB reaching a COMPLETE, SUCCESS, or HEALTHY status. If a startTime value is specified for containerB and it doesn't reach the desired status within that time, then containerA doesn't start.
If a container doesn’t meet a dependency constraint or times out before meeting the constraint, Amazon ECS doesn’t progress dependent containers to their next state.

For Amazon ECS tasks that are hosted on Fargate, this parameter requires that the task or service uses platform version 1.3.0 or later (Linux). The maximum value is 120 seconds.

**stopTimeout**

Type: Integer

Required: No

Example values: 120

Time duration (in seconds) to wait before the container is forcefully killed if it doesn’t exit normally on its own.

For Amazon ECS tasks that are hosted on Fargate, this parameter requires that the task or service uses platform version 1.3.0 or later (Linux). If the parameter isn’t specified, then the default value of 30 seconds is used. The maximum value is 120 seconds.

For tasks that use the EC2 launch type, if the stopTimeout parameter isn’t specified, the value set for the Amazon ECS container agent configuration variable ECS_CONTAINER_STOP_TIMEOUT is used. If neither the stopTimeout parameter or the ECS_CONTAINER_STOP_TIMEOUT agent configuration variable is set, the default values of 30 seconds for Linux containers and 30 seconds on Windows containers are used. Container instances require at least version 1.26.0 of the container agent to enable a container stop timeout value. However, we recommend using the latest container agent version. For information about how to check your agent version and update to the latest version, see Updating the Amazon ECS container agent. If you’re using an Amazon ECS-optimized Amazon Linux AMI, your instance needs at least version 1.26.0-1 of the ecs-init package. If your container instances are launched from version 20190301 or later, they contain the required versions of the container agent and ecs-init. For more information, see Amazon ECS-optimized AMI.
**System controls**

`systemControls`

Type: `SystemControl` object

Required: No

A list of namespace kernel parameters to set in the container. This parameter maps to `Sysctl` in the Create a container section of the Docker Remote API and the `--sysctl` option to `docker run`. For example, you can configure `net.ipv4.tcp_keepalive_time` setting to maintain longer lived connections.

We don't recommend that you specify network-related `systemControls` parameters for multiple containers in a single task that also uses either the `awsvpc` or host network mode. Doing this has the following disadvantages:

- For tasks that use the `awsvpc` network mode including Fargate, if you set `systemControls` for any container, it applies to all containers in the task. If you set different `systemControls` for multiple containers in a single task, the container that's started last determines which `systemControls` take effect.

- For tasks that use the host network mode, the network namespace `systemControls` aren't supported.

If you're setting an IPC resource namespace to use for the containers in the task, the following conditions apply to your system controls. For more information, see IPC mode.

- For tasks that use the host IPC mode, IPC namespace `systemControls` aren't supported.

- For tasks that use the task IPC mode, IPC namespace `systemControls` values apply to all containers within a task.

**Note**

This parameter is not supported for Windows containers.
Note

This parameter is only supported for tasks that are hosted on AWS Fargate if the tasks are using platform version 1.4.0 or later (Linux). This isn't supported for Windows containers on Fargate.

"systemControls": [
    {
        "namespace": "string",
        "value": "string"
    }
]

namespace

Type: String

Required: No

The namespace kernel parameter to set a value for.

Valid IPC namespace values: "kernel.msgmax" | "kernel.msgmnb" | "kernel.msgmni" | "kernel.sem" | "kernel.shmall" | "kernel.shmmax" | "kernel.shmmni" | "kernel.shm_rmid_forced", and Sysctls that start with "fs.mqueue."

Valid network namespace values: Sysctls that start with "net."

All of these values are supported by Fargate.

value

Type: String

Required: No

The value for the namespace kernel parameter that's specified in namespace.
Interactive

interactive

Type: Boolean

Required: No

When this parameter is true, you can deploy containerized applications that require stdin or a tty to be allocated. This parameter maps to OpenStdin in the Create a container section of the Docker Remote API and the --interactive option to docker run.

The default is false.

Pseudo terminal

pseudoTerminal

Type: Boolean

Required: No

When this parameter is true, a TTY is allocated. This parameter maps to Tty in the Create a container section of the Docker Remote API and the --tty option to docker run.

The default is false.

Elastic Inference accelerator name

Note

Starting April 15, 2023, AWS will not onboard new customers to Amazon Elastic Inference (EI), and will help current customers migrate their workloads to options that offer better price and performance. After April 15, 2023, new customers will not be able to launch instances with Amazon EI accelerators in Amazon SageMaker, Amazon ECS, or Amazon EC2. However, customers who have used Amazon EI at least once during the past 30-day period are considered current customers and will be able to continue using the service.
The Elastic Inference accelerator resource requirement for your task definition. For more information, see What Is Amazon Elastic Inference? in the Amazon Elastic Inference Developer Guide.

The following parameters are allowed in a task definition:

deviceName

Type: String

Required: Yes

The Elastic Inference accelerator device name. The deviceName must also be referenced in a container definition see Elastic Inference accelerator.

deviceType

Type: String

Required: Yes

The Elastic Inference accelerator to use.

Task placement constraints

When you register a task definition, you can provide task placement constraints that customize how Amazon ECS places tasks.

If you're using the Fargate launch type, task placement constraints aren't supported. By default Fargate tasks are spread across Availability Zones.

For tasks that use the EC2 launch type, you can use constraints to place tasks based on Availability Zone, instance type, or custom attributes. For more information, see Define which container instances Amazon ECS uses for tasks.

The following parameters are allowed in a container definition:

expression

Type: String

Required: No
A cluster query language expression to apply to the constraint. For more information, see Create expressions to define container instances for Amazon ECS tasks.

**type**

Type: String

Required: Yes

The type of constraint. Use `memberOf` to restrict the selection to a group of valid candidates.

**Proxy configuration**

**proxyConfiguration**

Type: `ProxyConfiguration` object

Required: No

The configuration details for the App Mesh proxy.

For tasks that use the EC2 launch type, the container instances require at least version 1.26.0 of the container agent and at least version 1.26.0-1 of the `ecs-init` package to enable a proxy configuration. If your container instances are launched from the Amazon ECS-optimized AMI version 20190301 or later, then they contain the required versions of the container agent and `ecs-init`. For more information, see Amazon ECS-optimized AMI.

For tasks that use the Fargate launch type, this feature requires that the task or service uses platform version 1.3.0 or later.

**Note**

This parameter is not supported for Windows containers.

```json
"proxyConfiguration": {
   "type": "APPMESH",
   "containerName": "string",
   "properties": [
      {
         "name": "string",
```
type

Type: String

Value values: APPMESH

Required: No

The proxy type. The only supported value is APPMESH.

countersName

Type: String

Required: Yes

The name of the container that serves as the App Mesh proxy.

properties

Type: Array of KeyValuePair objects

Required: No

The set of network configuration parameters to provide the Container Network Interface (CNI) plugin, specified as key-value pairs.

- IgnoredUID – (Required) The user ID (UID) of the proxy container as defined by the user parameter in a container definition. This is used to ensure the proxy ignores its own traffic. If IgnoredGID is specified, this field can be empty.
- IgnoredGID – (Required) The group ID (GID) of the proxy container as defined by the user parameter in a container definition. This is used to ensure the proxy ignores its own traffic. If IgnoredUID is specified, this field can be empty.
- AppPorts – (Required) The list of ports that the application uses. Network traffic to these ports is forwarded to the ProxyIngressPort and ProxyEgressPort.
- ProxyIngressPort – (Required) Specifies the port that incoming traffic to the AppPorts is directed to.
• **ProxyEgressPort** – (Required) Specifies the port that outgoing traffic from the AppPorts is directed to.

• **EgressIgnoredPorts** – (Required) The outbound traffic going to these specified ports is ignored and not redirected to the ProxyEgressPort. It can be an empty list.

• **EgressIgnoredIPs** – (Required) The outbound traffic going to these specified IP addresses is ignored and not redirected to the ProxyEgressPort. It can be an empty list.

```
name
    Type: String
    Required: No
    The name of the key-value pair.

d value
    Type: String
    Required: No
    The value of the key-value pair.
```

---

## Volumes

When you register a task definition, you can optionally specify a list of volumes to be passed to the Docker daemon on a container instance, which then becomes available for access by other containers on the same container instance.

The following are the types of data volumes that can be used:

- **Amazon EBS volumes** — Provides cost-effective, durable, high-performance block storage for data intensive containerized workloads. You can attach 1 Amazon EBS volume per Amazon ECS task when running a standalone task, or when creating or updating a service. Amazon EBS volumes are supported for Linux tasks hosted on Fargate or Amazon EC2 instances. For more information, see [Amazon EBS volumes](#).

- **Amazon EFS volumes** — Provides simple, scalable, and persistent file storage for use with your Amazon ECS tasks. With Amazon EFS, storage capacity is elastic. It grows and shrinks automatically as you add and remove files. Your applications can have the storage that they need and when they need it. Amazon EFS volumes are supported for tasks that are hosted on Fargate or Amazon EC2 instances. For more information, see [Amazon EFS volumes](#).
• **FSx for Windows File Server volumes** — Provides fully managed Microsoft Windows file servers. These file servers are backed by a Windows file system. When using FSx for Windows File Server together with Amazon ECS, you can provision your Windows tasks with persistent, distributed, shared, and static file storage. For more information, see [FSx for Windows File Server volumes](#).

Windows containers on Fargate do not support this option.

• **Docker volumes** – A Docker-managed volume that is created under `/var/lib/docker/volumes` on the host Amazon EC2 instance. Docker volume drivers (also referred to as plugins) are used to integrate the volumes with external storage systems, such as Amazon EBS. The built-in *local* volume driver or a third-party volume driver can be used. Docker volumes are supported only when running tasks on Amazon EC2 instances. Windows containers support only the use of the *local* driver. To use Docker volumes, specify a `dockerVolumeConfiguration` in your task definition. For more information, see [Using volumes](#).

• **Bind mounts** – A file or directory on the host machine that is mounted into a container. Bind mount host volumes are supported when running tasks on either AWS Fargate or Amazon EC2 instances. To use bind mount host volumes, specify a `host` and optional `sourcePath` value in your task definition. For more information, see [Using bind mounts](#).

For more information, see [Using data volumes in tasks](#).

The following parameters are allowed in a container definition.

**name**

- **Type:** String
- **Required:** No

The name of the volume. Up to 255 letters (uppercase and lowercase), numbers, hyphens (-), and underscores (_) are allowed. This name is referenced in the `sourceVolume` parameter of the container definition `mountPoints` object.

**host**

- **Required:** No

The host parameter is used to tie the lifecycle of the bind mount to the host Amazon EC2 instance, rather than the task, and where it is stored. If the host parameter is empty, then the Docker daemon assigns a host path for your data volume, but the data is not guaranteed to persist after the containers associated with it stop running.
Windows containers can mount whole directories on the same drive as $env:ProgramData.

**Note**

The `sourcePath` parameter is supported only when using tasks that are hosted on Amazon EC2 instances.

**sourcePath**

Type: String

Required: No

When the `host` parameter is used, specify a `sourcePath` to declare the path on the host Amazon EC2 instance that is presented to the container. If this parameter is empty, then the Docker daemon assigns a host path for you. If the `host` parameter contains a `sourcePath` file location, then the data volume persists at the specified location on the host Amazon EC2 instance until you delete it manually. If the `sourcePath` value does not exist on the host Amazon EC2 instance, the Docker daemon creates it. If the location does exist, the contents of the source path folder are exported.

**configuredAtLaunch**

Type: Boolean

Required: No

Specifies whether a volume is configurable at launch. When set to `true`, you can configure the volume when running a standalone task, or when creating or updating a service. When set to `true`, you won't be able to provide another volume configuration in the task definition. This parameter must be set to `true` to configure an Amazon EBS volume for attachment to a task. Setting `configuredAtLaunch` to `true` and deferring volume configuration to the launch phase allows you to create task definitions that aren't constrained to a volume type or to specific volume settings. Doing this makes your task definition reusable across different execution environments. For more information, see [Amazon EBS volumes](#).

**dockerVolumeConfiguration**

Type: `DockerVolumeConfiguration` Object
Required: No

This parameter is specified when using Docker volumes. Docker volumes are supported only when running tasks on EC2 instances. Windows containers support only the use of the `local` driver. To use bind mounts, specify a host instead.

**scope**

Type: String

Valid Values: `task` | `shared`

Required: No

The scope for the Docker volume, which determines its lifecycle. Docker volumes that are scoped to a `task` are automatically provisioned when the task starts and destroyed when the task stops. Docker volumes that are scoped as `shared` persist after the task stops.

**autoprovision**

Type: Boolean

Default value: `false`

Required: No

If this value is `true`, the Docker volume is created if it doesn't already exist. This field is used only if the `scope` is `shared`. If the `scope` is `task`, then this parameter must either be omitted or set to `false`.

**driver**

Type: String

Required: No

The Docker volume driver to use. The driver value must match the driver name provided by Docker because this name is used for task placement. If the driver was installed by using the Docker plugin CLI, use `docker plugin ls` to retrieve the driver name from your container instance. If the driver was installed by using another method, use Docker plugin discovery to retrieve the driver name. For more information, see [Docker plugin discovery](#). This parameter maps to `Driver` in the Create a volume section of the [Docker Remote API](#) and the `--driver` option to `docker volume create`. Volumes
driverOpts

Type: String

Required: No

A map of Docker driver-specific options to pass through. This parameter maps to DriverOpts in the Create a volume section of the Docker Remote API and the --opt option to docker volume create.

labels

Type: String

Required: No

Custom metadata to add to your Docker volume. This parameter maps to Labels in the Create a volume section of the Docker Remote API and the --label option to docker volume create.

efsVolumeConfiguration

Type: EFSVolumeConfiguration Object

Required: No

This parameter is specified when using Amazon EFS volumes.

fileSystemId

Type: String

Required: Yes

The Amazon EFS file system ID to use.

rootDirectory

Type: String

Required: No

The directory within the Amazon EFS file system to mount as the root directory inside the host. If this parameter is omitted, the root of the Amazon EFS volume will be used. Specifying / has the same effect as omitting this parameter.
Important

If an EFS access point is specified in the authorizationConfig, the root directory parameter must either be omitted or set to /, which will enforce the path set on the EFS access point.

transitEncryption

Type: String

Valid values: ENABLED | DISABLED

Required: No

Specifies whether to enable encryption for Amazon EFS data in transit between the Amazon ECS host and the Amazon EFS server. If Amazon EFS IAM authorization is used, transit encryption must be enabled. If this parameter is omitted, the default value of DISABLED is used. For more information, see Encrypting Data in Transit in the Amazon Elastic File System User Guide.

transitEncryptionPort

Type: Integer

Required: No

The port to use when sending encrypted data between the Amazon ECS host and the Amazon EFS server. If you don't specify a transit encryption port, the task will use the port selection strategy that the Amazon EFS mount helper uses. For more information, see EFS Mount Helper in the Amazon Elastic File System User Guide.

authorizationConfig

Type: EFSAuthorizationConfiguration Object

Required: No

The authorization configuration details for the Amazon EFS file system.

accessPointId

Type: String
The access point ID to use. If an access point is specified, the root directory value in the `efsVolumeConfiguration` must either be omitted or set to `/`, which will enforce the path set on the EFS access point. If an access point is used, transit encryption must be enabled in the `efsVolumeConfiguration`. For more information, see [Working with Amazon EFS Access Points](https://docs.aws.amazon.com/efs/latest/APIReference/API_RegistryEntry.html) in the [Amazon Elastic File System User Guide](https://docs.aws.amazon.com/efs/latest/APIReference/).

**iam**

Type: String

Valid values: ENABLED | DISABLED

Required: No

Specifies whether to use the Amazon ECS task IAM role that's defined in a task definition when mounting the Amazon EFS file system. If enabled, transit encryption must be enabled in the `efsVolumeConfiguration`. If this parameter is omitted, the default value of DISABLED is used. For more information, see [IAM Roles for Tasks](https://docs.aws.amazon.com/).
authorizationConfig
credentialsParameter

Type: String

Required: Yes

The authorization credential options.

options:

• Amazon Resource Name (ARN) of an AWS Secrets Manager secret.
• ARN of an AWS Systems Manager parameter.

domain

Type: String

Required: Yes

A fully qualified domain name hosted by an AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) directory or a self-hosted EC2 Active Directory.

Tags

When you register a task definition, you can optionally specify metadata tags that are applied to the task definition. Tags help you categorize and organize your task definition. Each tag consists of a key and an optional value. You define both of them. For more information, see Amazon ECS resource tagging.

⚠️ Important

Don't add personally identifiable information or other confidential or sensitive information in tags. Tags are accessible to many AWS services, including billing. Tags aren't intended to be used for private or sensitive data.

The following parameters are allowed in a tag object.

key

Type: String
Required: No

One part of a key-value pair that make up a tag. A key is a general label that acts like a category for more specific tag values.

value

Type: String

Required: No

The optional part of a key-value pair that make up a tag. A value acts as a descriptor within a tag category (key).

Other task definition parameters

The following task definition parameters can be used when registering task definitions in the Amazon ECS console by using the Configure via JSON option. For more information, see Creating a task definition using the console.

Topics

- Ephemeral storage
- IPC mode
- PID mode

Ephemeral storage

ephemeralStorage

Type: EphemeralStorage object

Required: No

The amount of ephemeral storage (in GB) to allocate for the task. This parameter is used to expand the total amount of ephemeral storage available, beyond the default amount, for tasks that are hosted on AWS Fargate. For more information, see the section called “Bind mounts”.
Note

This parameter is only supported for tasks that are hosted on AWS Fargate using platform version 1.4.0 or later (Linux) or 1.0.0 or later (Windows).

IPC mode

ipcMode

Type: String

Required: No

The IPC resource namespace to use for the containers in the task. The valid values are host, task, or none. If host is specified, then all the containers that are within the tasks that specified the host IPC mode on the same container instance share the same IPC resources with the host Amazon EC2 instance. If task is specified, all the containers that are within the specified task share the same IPC resources. If none is specified, then IPC resources within the containers of a task are private and not shared with other containers in a task or on the container instance. If no value is specified, then the IPC resource namespace sharing depends on the Docker daemon setting on the container instance. For more information, see IPC settings in the Docker run reference.

If the host IPC mode is used, there's a heightened risk of undesired IPC namespace exposure. For more information, see Docker security.

If you're setting namespaced kernel parameters that use systemControls for the containers in the task, the following applies to your IPC resource namespace. For more information, see System controls.

• For tasks that use the host IPC mode, IPC namespace that's related systemControls aren't supported.

• For tasks that use the task IPC mode, systemControls that relate to the IPC namespace apply to all containers within a task.
**Note**

This parameter is not supported for Windows containers or tasks using the Fargate launch type.

**PID mode**

`pidMode`

Type: String

Valid Values: `host` | `task`

Required: No

The process namespace to use for the containers in the task. The valid values are `host` or `task`. On Fargate for Linux containers, the only valid value is `task`. For example, monitoring sidecars might need `pidMode` to access information about other containers running in the same task.

If `host` is specified, all containers within the tasks that specified the `host` PID mode on the same container instance share the same process namespace with the host Amazon EC2 instance.

If `task` is specified, all containers within the specified task share the same process namespace.

If no value is specified, the default is a private namespace for each container. For more information, see [PID settings](#) in the *Docker run reference*.

If the `host` PID mode is used, there's a heightened risk of undesired process namespace exposure. For more information, see [Docker security](#).

**Note**

This parameter is not supported for Windows containers.
Note

This parameter is only supported for tasks that are hosted on AWS Fargate if the tasks are using platform version 1.4.0 or later (Linux). This isn't supported for Windows containers on Fargate.

Task definition template

An empty task definition template is shown as follows. You can use this template to create your task definition, which can then be pasted into the console JSON input area or saved to a file and used with the AWS CLI --cli-input-json option. For more information, see Task definition parameters.

}]}
You can generate this task definition template using the following AWS CLI command.

```
aws ecs register-task-definition --generate-cli-skeleton
```

## Service definition parameters

A service definition defines how to run your Amazon ECS service. The following parameters can be specified in a service definition.

### Launch type

**launchType**

Type: String

Valid values: EC2 | FARGATE | EXTERNAL

Required: No
The launch type on which to run your service. If a launch type is not specified, the default capacityProviderStrategy is used by default. For more information, see Amazon ECS launch types.

If a launchType is specified, the capacityProviderStrategy parameter must be omitted.

**Capacity provider strategy**

capacityProviderStrategy

Type: Array of objects

Required: No

The capacity provider strategy to use for the service.

A capacity provider strategy consists of one or more capacity providers along with the base and weight to assign to them. A capacity provider must be associated with the cluster to be used in a capacity provider strategy. The PutClusterCapacityProviders API is used to associate a capacity provider with a cluster. Only capacity providers with an ACTIVE or UPDATING status can be used.

If a capacityProviderStrategy is specified, the launchType parameter must be omitted. If no capacityProviderStrategy or launchType is specified, the defaultCapacityProviderStrategy for the cluster is used.

If you want to specify a capacity provider that uses an Auto Scaling group, the capacity provider must already be created. New capacity providers can be created with the CreateCapacityProvider API operation.

To use an AWS Fargate capacity provider, specify either the FARGATE or FARGATE_SPOT capacity providers. The AWS Fargate capacity providers are available to all accounts and only need to be associated with a cluster to be used.

The PutClusterCapacityProviders API operation is used to update the list of available capacity providers for a cluster after the cluster is created.

capacityProvider

Type: String
Required: Yes

The short name or full Amazon Resource Name (ARN) of the capacity provider.

weight

Type: Integer

Valid range: Integers between 0 and 1,000.

Required: No

The weight value designates the relative percentage of the total number of tasks launched that use the specified capacity provider.

For example, assume that you have a strategy that contains two capacity providers and both have a weight of one. When the base is satisfied, the tasks split evenly across the two capacity providers. Using that same logic, assume that you specify a weight of 1 for capacityProviderA and a weight of 4 for capacityProviderB. Then, for every one task that is run using capacityProviderA, four tasks use capacityProviderB.

base

Type: Integer

Valid range: Integers between 0 and 100,000.

Required: No

The base value designates how many tasks, at a minimum, to run on the specified capacity provider. Only one capacity provider in a capacity provider strategy can have a base defined.

Task definition

taskDefinition

Type: String

Required: No

The family and revision (family:revision) or full Amazon Resource Name (ARN) of the task definition to run in your service. If a revision isn't specified, the latest ACTIVE revision of the specified family is used.
A task definition must be specified when using the rolling update (ECS) deployment controller.

**Platform operating system**

`platformFamily`

Type: string

Required: Conditional

Default: Linux

This parameter is required for Amazon ECS services hosted on Fargate.

This parameter is ignored for Amazon ECS services hosted on Amazon EC2.

The operating system on the containers that runs the service. The valid values are LINUX, WINDOWS_SERVER_2019_FULL, WINDOWS_SERVER_2019_CORE, WINDOWS_SERVER_2022_FULL, and WINDOWS_SERVER_2022_CORE.

The `platformFamily` value for every task that you specify for the service must match the service `platformFamily` value. For example, if you set the `platformFamily` to WINDOWS_SERVER_2019_FULL, the `platformFamily` value for all the tasks must be WINDOWS_SERVER_2019_FULL.

**Platform version**

`platformVersion`

Type: String

Required: No

The platform version on which your tasks in the service are running. A platform version is only specified for tasks using the Fargate launch type. If one is not specified, the latest version (LATEST) is used by default.

AWS Fargate platform versions are used to refer to a specific runtime environment for the Fargate task infrastructure. When specifying the LATEST platform version when running a task or creating a service, you get the most current platform version available for your tasks. When
you scale up your service, those tasks receive the platform version that was specified on the service's current deployment. For more information, see Fargate Linux platform versions.

Note
Platform versions are not specified for tasks using the EC2 launch type.

Cluster

cluster
type: String
required: No

The short name or full Amazon Resource Name (ARN) of the cluster on which to run your service. If you do not specify a cluster, the default cluster is assumed.

Service name

serviceName
type: String
required: Yes

The name of your service. Up to 255 letters (uppercase and lowercase), numbers, hyphens, and underscores are allowed. Service names must be unique within a cluster, but you can have similarly named services in multiple clusters within a Region or across multiple Regions.

Scheduling strategy

schedulingStrategy
type: String
valid values: REPLICA | DAEMON
required: No
The scheduling strategy to use. If no scheduling strategy is specified, the REPLICA strategy is used. For more information, see Service scheduler concepts.

There are two service scheduler strategies available:

- REPLICA—The replica scheduling strategy places and maintains the desired number of tasks across your cluster. By default, the service scheduler spreads tasks across Availability Zones. You can use task placement strategies and constraints to customize task placement decisions. For more information, see Replica.

- DAEMON—The daemon scheduling strategy deploys exactly one task on each active container instance that meets all of the task placement constraints that you specify in your cluster. When using this strategy, there is no need to specify a desired number of tasks, a task placement strategy, or use Service Auto Scaling policies. For more information, see Daemon.

Note
Fargate tasks do not support the DAEMON scheduling strategy.

**Desired count**

desiredCount

Type: Integer

Required: No

The number of instantiations of the specified task definition to place and keep running in your service.

This parameter is required if the REPLICA scheduling strategy is used. If the service uses the DAEMON scheduling strategy, this parameter is optional.

**Deployment configuration**

deploymentConfiguration

Type: Object

Required: No
Optional deployment parameters that control how many tasks run during the deployment and the ordering of stopping and starting tasks.

**maximumPercent**

Type: Integer

Required: No

If a service is using the rolling update (ECS) deployment type, the `maximumPercent` parameter represents an upper limit on the number of your service's tasks that are allowed in the RUNNING, STOPPING, or PENDING state during a deployment. It is expressed as a percentage of the `desiredCount` that is rounded down to the nearest integer. You can use this parameter to define the deployment batch size. For example, if your service is using the REPLICA service scheduler and has a `desiredCount` of four tasks and a `maximumPercent` value of 200%, the scheduler might start four new tasks before stopping the four older tasks. This is provided that the cluster resources required to do this are available. The default `maximumPercent` value for a service using the REPLICA service scheduler is 200%.

If your service is using the DAEMON service scheduler type, the `maximumPercent` should remain at 100%. This is the default value.

The maximum number of tasks during a deployment is the `desiredCount` multiplied by the `maximumPercent/100`, rounded down to the nearest integer value.

If a service is using either the blue/green (CODE_DEPLOY) or EXTERNAL deployment types and tasks that use the EC2 launch type, the `maximum percent` value is set to the default value and is used to define the upper limit on the number of the tasks in the service that remain in the RUNNING state while the container instances are in the DRAINING state. If the tasks in the service use the Fargate launch type, the maximum percent value isn't used, although it's returned when describing your service.

**minimumHealthyPercent**

Type: Integer

Required: No

If a service is using the rolling update (ECS) deployment type, the `minimumHealthyPercent` represents a lower limit on the number of your service's tasks that must remain in the RUNNING state during a deployment. This is expressed as a
percentage of the desiredCount that is rounded up to the nearest integer. You can use this parameter to deploy without using additional cluster capacity. For example, if your service has a desiredCount of four tasks and a minimumHealthyPercent of 50%, the service scheduler might stop two existing tasks to free up cluster capacity before starting two new tasks.

For services that do not use a load balancer, consider the following:

- A service is considered healthy if all essential containers within the tasks in the service pass their health checks.
- If a task has no essential containers with a health check defined, the service scheduler waits for 40 seconds after a task reaches a RUNNING state before the task is counted towards the minimum healthy percent total.
- If a task has one or more essential containers with a health check defined, the service scheduler waits for the task to reach a healthy status before counting it towards the minimum healthy percent total. A task is considered healthy when all essential containers within the task have passed their health checks. The amount of time the service scheduler can wait for is determined by the container health check settings. For more information, see Health check.

For services that do use a load balancer, consider the following:

- If a task has no essential containers with a health check defined, the service scheduler waits for the load balancer target group health check to return a healthy status before counting the task towards the minimum healthy percent total.
- If a task has an essential container with a health check defined, the service scheduler waits for both the task to reach a healthy status and the load balancer target group health check to return a healthy status before counting the task towards the minimum healthy percent total.

The default value for a replica service for minimumHealthyPercent is 100%. The default minimumHealthyPercent value for a service using the DAEMON service schedule is 0% for the AWS CLI, the AWS SDKs, and the APIs and 50% for the AWS Management Console.

The minimum number of healthy tasks during a deployment is the desiredCount multiplied by the minimumHealthyPercent/100, rounded up to the nearest integer value.

If a service is using either the blue/green (CODE_DEPLOY) or EXTERNAL deployment types and is running tasks that use the EC2 launch type, the minimum healthy percent value is
set to the default value and is used to define the lower limit on the number of the tasks in the service that remain in the RUNNING state while the container instances are in the DRAINING state. If a service is using either the blue/green (CODE_DEPLOY) or EXTERNAL deployment types and is running tasks that use the Fargate launch type, the minimum healthy percent value is not used, although it is returned when describing your service.

**Deployment controller**

**deploymentController**

Type: Object

Required: No

The deployment controller to use for the service. If no deployment controller is specified, the ECS controller is used. For more information, see [Amazon ECS Deployment types](#).

**type**

Type: String

Valid values: ECS | CODE_DEPLOY | EXTERNAL

Required: yes

The deployment controller type to use. There are three deployment controller types available:

**ECS**

The rolling update (ECS) deployment type involves replacing the current running version of the container with the latest version. The number of containers Amazon ECS adds or removes from the service during a rolling update is controlled by adjusting the minimum and maximum number of healthy tasks allowed during a service deployment, as specified in the `deploymentConfiguration`.

**CODE_DEPLOY**

The blue/green (CODE_DEPLOY) deployment type uses the blue/green deployment model powered by CodeDeploy, which allows you to verify a new deployment of a service before sending production traffic to it.
EXTERNAL

Use the external deployment type when you want to use any third-party deployment controller for full control over the deployment process for an Amazon ECS service.

Task placement

placementConstraints

Type: Array of objects

Required: No

An array of placement constraint objects to use for tasks in your service. You can specify a maximum of 10 constraints per task. This limit includes constraints in the task definition and those specified at run time. If you use the Fargate launch type, task placement constraints aren't supported.

type

Type: String

Required: No

The type of constraint. Use distinctInstance to ensure that each task in a particular group is running on a different container instance. Use memberOf to restrict the selection to a group of valid candidates. The value distinctInstance is not supported in task definitions.

expression

Type: String

Required: No

A cluster query language expression to apply to the constraint. You can't specify an expression if the constraint type is distinctInstance. For more information, see Create expressions to define container instances for Amazon ECS tasks.

placementStrategy

Type: Array of objects

Required: No
The placement strategy objects to use for tasks in your service. You can specify a maximum of four strategy rules per service.

**type**

Type: String

Valid values: random | spread | binpack

Required: No

The type of placement strategy. The random placement strategy randomly places tasks on available candidates. The spread placement strategy spreads placement across available candidates evenly based on the field parameter. The binpack strategy places tasks on available candidates that have the least available amount of the resource that's specified with the field parameter. For example, if you binpack on memory, a task is placed on the instance with the least amount of remaining memory but still enough to run the task.

**field**

Type: String

Required: No

The field to apply the placement strategy against. For the spread placement strategy, valid values are instanceId (or host, which has the same effect), or any platform or custom attribute that's applied to a container instance, such as attribute:ecs.availability-zone. For the binpack placement strategy, valid values are cpu and memory. For the random placement strategy, this field is not used.

**Tags**

tags

Type: Array of objects

Required: No

The metadata that you apply to the service to help you categorize and organize them. Each tag consists of a key and an optional value, both of which you define. When a service is deleted, the tags are deleted as well. A maximum of 50 tags can be applied to the service. For more information, see Amazon ECS resource tagging.
key

Type: String
Required: No

One part of a key-value pair that make up a tag. A key is a general label that acts like a category for more specific tag values.

value

Type: String
Length Constraints: Minimum length of 0. Maximum length of 256.
Required: No

The optional part of a key-value pair that make up a tag. A value acts as a descriptor within a tag category (key).

enableECSManagedTags

Type: Boolean
Valid values: true | false
Required: No

Specifies whether to use Amazon ECS managed tags for the tasks in the service. If no value is specified, the default value is false. For more information, see Tagging your resources for billing.

propagateTags

Type: String
Valid values: TASK_DEFINITION | SERVICE
Required: No

Specifies whether to copy the tags from the task definition or the service to the tasks in the service. If no value is specified, the tags are not copied. Tags can only be copied to the tasks within the service during service creation. To add tags to a task after service creation or task creation, use the TagResource API action.
Network configuration

networkConfiguration

  Type: Object
  Required: No

The network configuration for the service. This parameter is required for task definitions that use the awsvpc network mode to receive their own Elastic Network Interface, and it isn't supported for other network modes. If using the Fargate launch type, the awsvpc network mode is required. For more information about networking for the Amazon EC2 launch type, see Task networking for tasks on Amazon EC2 instances. For more information about networking for the Fargate launch type, see Fargate Task Networking.

awsvpcConfiguration

  Type: Object
  Required: No

An object representing the subnets and security groups for a task or service.

subnets

  Type: Array of strings
  Required: Yes

The subnets that are associated with the task or service. There is a limit of 16 subnets that can be specified according to awsvpcConfiguration.

securityGroups

  Type: Array of strings
  Required: No

The security groups associated with the task or service. If you don't specify a security group, the default security group for the VPC is used. There's a limit of five security groups that can be specified based on awsvpcConfiguration.

assignPublicIP

  Type: String
Valid values: ENABLED | DISABLED

Required: No

Whether the task's elastic network interface receives a public IP address. If no value is specified, the default value of DISABLED is used.

**healthCheckGracePeriodSeconds**

Type: Integer

Required: No

The period of time, in seconds, that the Amazon ECS service scheduler should ignore unhealthy Elastic Load Balancing target health checks, container health checks, and Route 53 health checks after a task enters a RUNNING state. This is only valid if your service is configured to use a load balancer. If your service has a load balancer defined and you do not specify a health check grace period value, the default value of 0 is used.

If your service's tasks take a while to start and respond to health checks, you can specify a health check grace period of up to 2,147,483,647 seconds during which the ECS service scheduler ignores the health check status. This grace period can prevent the ECS service scheduler from marking tasks as unhealthy and stopping them before they have time to come up.

If you do not use an Elastic Load Balancing, we recommend that you use the `startPeriod` in the task definition health check parameters. For more information, see [Health check](#).

**loadBalancers**

Type: Array of objects

Required: No

A load balancer object representing the load balancers to use with your service. For services that use an Application Load Balancer or Network Load Balancer, there's a limit of five target groups that you can attach to a service.

After you create a service, the load balancer configuration can't be changed from the AWS Management Console. You can use the AWS Copilot, AWS CloudFormation, AWS CLI or SDK to modify the load balancer configuration for the ECS rolling deployment controller only, not AWS CodeDeploy blue/green or external. When you add, update, or remove a load balancer configuration, Amazon ECS starts a new deployment with the updated Elastic Load Network configuration.
Balancing configuration. This causes tasks to register to and deregister from load balancers. We recommend that you verify this on a test environment before you update the Elastic Load Balancing configuration. For information about how to modify the configuration, see UpdateService in the Amazon Elastic Container Service API Reference.

For Application Load Balancers and Network Load Balancers, this object must contain the load balancer target group ARN, the container name (as it appears in a container definition), and the container port to access from the load balancer. When a task from this service is placed on a container instance, the container instance and port combination is registered as a target in the target group specified.

targetGroupArn

Type: String
Required: No

The full Amazon Resource Name (ARN) of the Elastic Load Balancing target group that's associated with a service.

A target group ARN is only specified when using an Application Load Balancer or Network Load Balancer.

loadBalancerName

Type: String
Required: No

The name of the load balancer to associate with the service.

If you're using an Application Load Balancer or a Network Load Balancer, omit the load balancer name parameter.

containerName

Type: String
Required: No

The name of the container (as it appears in a container definition) to associate with the load balancer.

containerPort

Type: Integer
port

Required: No

The port on the container to associate with the load balancer. This port must correspond to a containerPort in the task definition used by tasks in the service. For tasks that use the EC2 launch type, the container instance must allow inbound traffic on the hostPort of the port mapping.

role

Type: String

Required: No

The short name or full ARN of the IAM role that allows Amazon ECS to make calls to your load balancer on your behalf. This parameter is only permitted if you are using a load balancer with a single target group for your service, and your task definition does not use the awsvpc network mode. If you specify the role parameter, you must also specify a load balancer object with the loadBalancers parameter.

If your specified role has a path other than /, then you must either specify the full role ARN (this is recommended) or prefix the role name with the path. For example, if a role with the name bar has a path of /foo/ then you would specify /foo/bar as the role name. For more information, see Friendly Names and Paths in the IAM User Guide.

Important

If your account has already created the Amazon ECS service-linked role, that role is used by default for your service unless you specify a role here. The service-linked role is required if your task definition uses the awsvpc network mode, in which case you should not specify a role here. For more information, see Using service-linked roles for Amazon ECS.

serviceConnectConfiguration

Type: Object

Required: No

The configuration for this service to discover and connect to services, and be discovered by, and connected from, other services within a namespace.
For more information, see Service Connect.

enabled

Type: Boolean

Required: Yes

Specifies whether to use Service Connect with this service.

namespace

Type: String

Required: No

The short name or full Amazon Resource Name (ARN) of the AWS Cloud Map namespace for use with Service Connect. The namespace must be in the same AWS Region as the Amazon ECS service and cluster. The type of namespace doesn't affect Service Connect. For more information about AWS Cloud Map, see Working with Services in the AWS Cloud Map Developer Guide.

services

Type: Array of objects

Required: No

An array of Service Connect service objects. These are names and aliases (also known as endpoints) that are used by other Amazon ECS services to connect to this service.

This field isn't required for a "client" Amazon ECS service that's a member of a namespace only to connect to other services within the namespace. An example is frontend application that accepts incoming requests from either a load balancer that's attached to the service or by other means.

An object selects a port from the task definition, assigns a name for the AWS Cloud Map service, and an array of aliases (also known as endpoints) and ports for client applications to refer to this service.

portName

Type: String

Required: Yes
The `portName` must match the name of one of the `portMappings` from all of the containers in the task definition of this Amazon ECS service.

**discoveryName**

*Type: String*

*Required: No*

The `discoveryName` is the name of the new AWS Cloud Map service that Amazon ECS creates for this Amazon ECS service. This must be unique within the AWS Cloud Map namespace.

If this field isn't specified, `portName` is used.

**clientAliases**

*Type: Array of objects*

*Required: No*

The list of client aliases for this service connect service. You use these to assign names that can be used by client applications. The maximum number of client aliases that you can have in this list is 1.

Each alias ("endpoint") is a DNS name and port number that other Amazon ECS services ("clients") can use to connect to this service.

Each name and port combination must be unique within the namespace.

These names are configured within each task of the client service, not in AWS Cloud Map. DNS requests to resolve these names don't leave the task, and don't count toward the quota of DNS requests per second per elastic network interface.

**port**

*Type: Integer*

*Required: Yes*

The listening port number for the service connect proxy. This port is available inside of all of the tasks within the same namespace.

To avoid changing your applications in client Amazon ECS services, set this to the same port that the client application uses by default.
dnsName

Type: String
Required: No

The dnsName is the name that you use in the applications of client tasks to connect to this service. The name must be a valid DNS label.

The default value is the discoveryName.namespace if this field is not specified. If the discoveryName isn't specified, the portName from the task definition is used.

To avoid changing your applications in client Amazon ECS services, set this to the same name that the client application uses by default. For example, a few common names are database, db, or the lowercase name of a database, such as mysql or redis.

ingressPortOverride

Type: Integer
Required: No

(Optional) The port number for the Service Connect proxy to listen on.

Use the value of this field to bypass the proxy for traffic on the port number that's specified in the named portMapping in the task definition of this application, and then use it in your Amazon VPC security groups to allow traffic into the proxy for this Amazon ECS service.

In awsvpc mode, the default value is the container port number that's specified in the named portMapping in the task definition of this application. In bridge mode, the default value is the dynamic ephemeral port of the Service Connect proxy.

logConfiguration

Type: LogConfiguration Object
Required: No

This defines where the Service Connect proxy logs are published. Use the logs for debugging during unexpected events. This configuration sets the logConfiguration parameter in the Service Connect proxy container in each task in this Amazon ECS service. The proxy container isn't specified in the task definition.
We recommend that you use the same log configuration as the application containers of the task definition for this Amazon ECS service. For FireLens, this is the log configuration of the application container. It's not the FireLens log router container that uses the fluent-bit or fluentd container image.

serviceRegistries

Type: Array of objects

Required: No

The details of the service discovery configuration for your service. For more information, see Service discovery.

registryArn

Type: String

Required: No

The Amazon Resource Name (ARN) of the service registry. The currently supported service registry is AWS Cloud Map. For more information, see Working with Services in the AWS Cloud Map Developer Guide.

port

Type: Integer

Required: No

The port value that's used if your service discovery service specified an SRV record. This field is required if both the awsvpc network mode and SRV records are used.

containerName

Type: String

Required: No

The container name value to be used for your service discovery service. This value is specified in the task definition. If the task definition that your service task specifies uses the bridge or host network mode, you must specify a containerName and containerPort combination from the task definition. If the task definition that your service task specifies uses the awsvpc network mode and a type SRV DNS record is used, you must specify either a containerName and containerPort combination or a port value, but not both.
containerPort

Type: Integer

Required: No

The port value to be used for your service discovery service. This value is specified in the task definition. If the task definition your service task specifies uses the bridge or host network mode, you must specify a containerName and containerPort combination from the task definition. If the task definition your service task specifies uses the awsvpc network mode and a type SRV DNS record is used, you must specify either a containerName and containerPort combination or a port value, but not both.

Client token

clientToken

Type: String

Required: No

The unique, case-sensitive identifier that you provide to ensure the idempotency of the request. It can be up to 32 ASCII characters long.

Volume configurations

volumeConfigurations

Type: Object

Required: No

The configuration that will be used to create volumes for tasks that are managed by the service. One volume is created for each task in the service. Only volumes that are marked as configuredAtLaunch in the task definition can be configured by using this object. This object is required for attaching Amazon EBS data volumes to tasks that are managed by a service. For more information, see Amazon EBS volumes.

name

Type: String
Required: Yes

The name of a volume that's configured when creating or updating a service. Up to 255 letters (uppercase and lowercase), numbers, underscores (_), and hyphens (-) are allowed. This value must match the volume name that's specified in the task definition.

**managedEBSVolume**

Type: Object

Required: No

The volume configuration for Amazon EBS volumes that are attached to tasks that are managed by a service when a service is created or updated.

**encrypted**

Type: Boolean

Required: No

Valid values: true|false

Specifies whether the Amazon EBS volume that's attached to tasks managed by a service will be encrypted. If you've turned on Amazon EBS encryption by default for your account, this setting will be overridden, and the volume will be encrypted. For more information about EBS encryption by default, see [Encryption by default](#) in the *Amazon EC2 User Guide*.

**kmsKeyId**

Type: String

Required: No

The identifier of the AWS Key Management Service (AWS KMS) key to use for Amazon EBS encryption. If this parameter is not specified, your AWS KMS key for Amazon EBS is used. If `kmsKeyId` is specified, the encrypted state must be true.

You can specify the KMS key by using any of the following:

- **Key ID** – For example, 1234abcd-12ab-34cd-56ef-1234567890ab.
- **Key alias** – For example, alias/ExampleAlias.
- **Key ARN** – For example, arn:aws:kms:us-east-1:012345678910:key/1234abcd-12ab-34cd-56ef-1234567890ab.
• **Alias ARN** – For example, `arn:aws:kms:us-east-1:012345678910:alias/ExampleAlias`.

**Important**

AWS authenticates the KMS key asynchronously. Therefore, if you specify an ID, alias, or ARN that isn't valid, the action can appear to succeed, but it eventually fails. For more information, see [Troubleshooting Amazon EBS volume attachment issues](#).

**volumeType**

Type: String

Required: No

Valid values: `gp2|gp3|io1|io2|sc1|st1|standard`

The EBS volume type. For more information about volume types, see [Amazon EBS volume types](#) in the *Amazon EC2 User Guide*. The default volume type is `gp3`.

**Note**

The **standard** volume type is not supported for Amazon EBS volumes configured for attachment to Fargate tasks.

**sizeInGiB**

Type: Integer

Required: No

Valid range: Integers between 1 and 16,384

The size of the EBS volume in gibibytes (GiB). If you do not provide a snapshot ID to configure a volume for attachment, you must provide a size value. If you configure a volume for attachment by using a snapshot, you must specify a size that is equal to or larger than the snapshot size. If you do not specify a size, the default value is the snapshot size.

For `gp2` and `gp3` volume types, the valid range is 1-16,384.
For io1 and io2 volume types, the valid range is 4-16,384.

For st1 and sc1 volume types, the valid range is 125-16,384.

For the standard volume type, the valid range is 1-1,024.

**snapshotId**

Type: String

Required: No

The ID of the snapshot of an existing EBS volume that's used to create a new volume that's attached to the ECS task.

**iops**

Type: Integer

Required: No

The number of I/O operations per second (IOPS). For gp3, io1, and io2 volumes, this represents the number of IOPS that are provisioned for the volume. For gp2 volumes, this value represents the baseline performance of the volume and the rate at which the volume accumulates I/O credits for bursting. This parameter is required for io1 and io2 volumes. This parameter is not supported for gp2, st1, sc1, or standard volumes.

For gp3 volumes, the valid range of values is 3,000 to 16,000.

For io1 volumes, the valid range of values is 100 to 64,000.

For io2 volumes, the valid range of values is 100 to 64,000.

**throughput**

Type: Integer

Required: No

The throughput to provision for volumes that are attached to tasks that are managed by a service.

⚠️ **Important**

This parameter is supported only for gp3 volumes.
roleArn

Type: String

Required: Yes

The Amazon Resource ARN (ARN) of the infrastructure AWS Identity and Access Management (IAM) role that provides Amazon ECS permissions to manage Amazon EBS resources for your tasks. For more information, see Amazon ECS infrastructure IAM role.

tagSpecifications

Type: Object

Required: No

The specification for tags to be applied to service managed Amazon EBS volumes.

resourceType

Type: String

Required: Yes

Valid values: volume

The type of resource to tag on creation.

tags

Type: Array of objects

Required: No

The metadata that you apply to volumes to help you categorize and organize them. Each tag consists of a key and an optional value, both of which you define. AmazonECSCreated and AmazonECSManaged are reserved tags that are added by Amazon ECS on your behalf, so you can specify a maximum of 48 tags of your own. When a volume is deleted, the tags are deleted as well. For more information, see Amazon ECS resource tagging.

tags

Type: Array of objects

Required: No

The metadata that you apply to volumes to help you categorize and organize them. Each tag consists of a key and an optional value, both of which you define. AmazonECSCreated and AmazonECSManaged are reserved tags that are added by Amazon ECS on your behalf, so you can specify a maximum of 48 tags of your own. When a volume is deleted, the tags are deleted as well. For more information, see Amazon ECS resource tagging.

key

Type: String

Required: No

One part of a key-value pair that makes up a tag. A key is a general label that acts like a category for more specific tag values.

value

Type: String

Length Constraints: Minimum length of 0. Maximum length of 256.

Required: No

The optional part of a key-value pair that makes up a tag. A value acts as a descriptor within a tag category (key).

propagateTags

Type: String

Valid values: TASK_DEFINITION | SERVICE | NONE

Required: No

Specifies whether to copy the tags from the task definition or the service to a volume. If NONE is specified or no value is specified, the tags aren't copied.

fileSystemType

Type: String

Required: No

Valid values: xfs|ext3|ext4

The type of file system on a volume. The volume's file system type determines how data is stored and retrieved in the volume. For volumes created from a snapshot, you must specify the same filesystem type that the volume was using when the snapshot was created. If there is a filesystem type mismatch, the task will fail to start. The default for volumes that are attached to Linux tasks is XFS.

**Service definition template**

The following shows the JSON representation of an Amazon ECS service definition.
Amazon EC2 launch type

You can create this service definition template using the following AWS CLI command.

```
aws ecs create-service --generate-cli-skeleton
```
Amazon ECS service quotas

The following tables provide the default service quotas, also referred to as limits, for Amazon ECS for an AWS account. For more information about the service quotas for other AWS services that you can use with Amazon ECS, such as Elastic Load Balancing and Auto Scaling, see AWS service quotas in the Amazon Web Services General Reference. For information about API throttling in the Amazon ECS API, see Request throttling for the Amazon ECS API.

Amazon ECS service quotas

The following are Amazon ECS service quotas.

New AWS accounts might have initial lower quotas that can increase over time. Amazon ECS constantly monitors the account usage within each Region, and then automatically increases the quotas based on your usage. You can also request a quota increase for values that are shown as adjustable, see Requesting a quota increase in the Service Quotas User Guide.

</tr>
</tbody>
</table>

**Note**

The default values are the initial quotas set by AWS, which are separate from the actual applied quota value and maximum possible service quota. For more information, see [Terminology in Service Quotas](#) in the [Service Quotas User Guide](#).

**Note**

Services configured to use Amazon ECS service discovery have a limit of 1,000 tasks per service. This is due to the AWS Cloud Map service quota for the number of instances per service. For more information, see [AWS Cloud Map service quotas](#) in the [Amazon Web Services General Reference](#).
Note
In practice, task launch rates are also dependent on other considerations such as container images to be downloaded and unpacked, health checks and other integrations enabled, such as registering tasks with a load balancer. You might see variations in task launch rates compared with the quotas that are represented here. These variations are causes by the features that you have enabled for your Amazon ECS services. For more information, see speeding up Amazon ECS deployments in the Amazon ECS Best Practices Guide.

Note
Services configured to use Amazon ECS Service Connect have a limit of 1,000 tasks per service. This is due to the AWS Cloud Map service quota for the number of instances per service. For more information, see AWS Cloud Map service quotas in the Amazon Web Services General Reference.

AWS Fargate service quotas

The following are Amazon ECS on AWS Fargate service quotas and are listed under the AWS Fargate service in the Service Quotas console.

New AWS accounts might have initial lower quotas that can increase over time. Fargate constantly monitors the account usage within each Region, and then automatically increases the quotas based on your usage. You can also request a quota increase for values that are shown as adjustable, see Requesting a quota increase in the Service Quotas User Guide.

</table>

**Note**

The default values are the initial quotas set by AWS, which are separate from the actual applied quota value and maximum possible service quota. For more information, see Terminology in Service Quotas in the Service Quotas User Guide.

**Note**

Fargate additionally enforces Amazon ECS tasks and Amazon EKS pods launch rate limits. For more information, see Fargate throttling limits.

### Managing your Amazon ECS and AWS Fargate service quotas in the AWS Management Console

Amazon ECS has integrated with Service Quotas, an AWS service that enables you to view and manage your quotas from a central location. For more information, see What Is Service Quotas? in the Service Quotas User Guide.

Service Quotas makes it easy to look up the value of your Amazon ECS service quotas.

**AWS Management Console**

1. **To view Amazon ECS and Fargate service quotas using the AWS Management Console**
   2. In the navigation pane, choose AWS services.
3. From the **AWS services** list, search for and select **Amazon Elastic Container Service (Amazon ECS)** or **AWS Fargate**.

   In the **Service quotas** list, you can see the service quota name, applied value (if it is available), AWS default quota, and whether the quota value is adjustable.

4. To view additional information about a service quota, such as the description, choose the quota name.

5. (Optional) To request a quota increase, select the quota that you want to increase, select **Request quota increase**, enter or select the required information, and select **Request**.

To work more with service quotas using the AWS Management Console see the **Service Quotas User Guide**. To request a quota increase, see **Requesting a quota increase** in the **Service Quotas User Guide**.

**AWS CLI**

**To view Amazon ECS and Fargate service quotas using the AWS CLI**

Run the following command to view the default Amazon ECS quotas.

```bash
aws service-quotas list-aws-default-service-quotas |
    --query 'Quotas[*].
    {Adjustable:Adjustable,Name:QuotaName,Value:Value,Code:QuotaCode}' |
    --service-code ecs |
    --output table
```

Run the following command to view the default Fargate quotas.

```bash
aws service-quotas list-aws-default-service-quotas |
    --query 'Quotas[*].
    {Adjustable:Adjustable,Name:QuotaName,Value:Value,Code:QuotaCode}' |
    --service-code fargate |
    --output table
```

Run the following command to view your applied Fargate quotas.

```bash
aws service-quotas list-service-quotas |
    --service-code fargate
```
Note

Amazon ECS doesn't support applied quotas.

For more information about working with service quotas using the AWS CLI, see the Service Quotas AWS CLI Command Reference. To request a quota increase, see the request-service-quota-increase command in the AWS CLI Command Reference.

Best practices for Amazon ECS service quotas and API throttling limits

Amazon ECS is integrated with several AWS services, including Elastic Load Balancing, AWS Cloud Map, and Amazon EC2. With this tight integration, Amazon ECS includes several features such as service load balancing, Service Connect, task networking, and cluster auto scaling. Amazon ECS and the other AWS services that it integrates with all maintain service quotas and API rate limits to ensure consistent performance and utilization. These service quotas also prevent the accidental provisioning of more resources than needed and protect against malicious actions that might increase your bill.

By familiarizing yourself with your service quotas and the AWS API rate limits, you can plan for scaling your workloads without worrying about unexpected performance degradation. For more information, see Request throttling for the Amazon ECS API.

When scaling your workloads on Amazon ECS, we recommend that you consider the following service quota.

• AWS Fargate has quotas that limit the number of concurrent running tasks in each AWS Region. There are quotas for both On-Demand and Fargate Spot tasks on Amazon ECS. Each service quota also includes any Amazon EKS pods that you run on Fargate.

• For tasks that run on Amazon EC2 instances, the maximum number of Amazon EC2 instances that you can register for each cluster is 5,000. If you use Amazon ECS cluster auto scaling with an Auto Scaling group capacity provider, or if you manage Amazon EC2 instances for your cluster on your own, this quota might become a deployment bottleneck. If you require more capacity, you can create more clusters or request a service quota increase.

• If you use Amazon ECS cluster auto scaling with an Auto Scaling group capacity provider, when scaling your services consider the Tasks in the PROVISIONING state per cluster
quota. This quota is the maximum number of tasks in the PROVISIONING state for each cluster for which capacity providers can increase capacity. When you launch a large number of tasks all at the same time, you can easily meet this quota. One example is if you simultaneously deploy tens of services, each with hundreds of tasks. When this happens, the capacity provider needs to launch new container instances to place the tasks when the cluster has insufficient capacity. While the capacity provider is launching additional Amazon EC2 instances, the Amazon ECS service scheduler likely will continue to launch tasks in parallel. However, this activity might be throttled because of insufficient cluster capacity. The Amazon ECS service scheduler implements a back-off and exponential throttling strategy for retrying task placement as new container instances are launched. As a result, you might experience slower deployment or scale-out times. To avoid this situation, you can plan your service deployments in one of the following ones. Either deploy a large number of tasks don’t require increasing cluster capacity, or keep spare cluster capacity for new task launches.

In addition to considering Amazon ECS service quota when scaling your workloads, consider also the service quota for the other AWS services that are integrated with Amazon ECS.

**Elastic Load Balancing**

You can configure your Amazon ECS services to use Elastic Load Balancing to distribute traffic evenly across the tasks. For more information and recommended best practices for how to choose a load balancer, see Distribute Amazon ECS service traffic using load balancing.

**Elastic Load Balancing service quotas**

When you scale your workloads, consider the following Elastic Load Balancing service quotas. Most Elastic Load Balancing service quotas are adjustable, and you can request an increase in the Service Quotas console.

**Application Load Balancer**

When you use an Application Load Balancer, depending on your use case, you might need to request a quota increase for:

- The Targets per Application Load Balancer quota which is the number of targets behind your Application Load Balancer.
- The Targets per Target Group per Region quota which is the number of targets behind your Target Groups.
For more information, see Quotas for your Application Load Balancers in User Guide for Application Load Balancers.

**Network Load Balancer**

There are stricter limitations on the number of targets you can register with a Network Load Balancer. When using a Network Load Balancer, you often will want to enable cross-zone support, which comes with additional scaling limitations on Targets per Availability Zone Per Network Load Balancer the maximum number of targets per Availability Zone for each Network Load Balancer. For more information, see Quotas for your Network Load Balancers in the User Guide for Network Load Balancers.

**Elastic Load Balancing API throttling**

When you configure an Amazon ECS service to use a load balancer, the target group health checks must pass before the service is considered healthy. For performing these health checks, Amazon ECS invokes Elastic Load Balancing API operations on your behalf. If you have a large number of services configured with load balancers in your account, you might slower service deployments because of potential throttling specifically for the RegisterTarget, DeregisterTarget, and DescribeTargetHealth Elastic Load Balancing API operations. When throttling occurs, throttling errors occur in your Amazon ECS service event messages.

If you experience AWS Cloud Map API throttling, you can contact AWS Support for guidance on how to increase your AWS Cloud Map API throttling limits. For more information about monitoring and troubleshooting such throttling errors, see Best practices for handling Amazon ECS throttling issues.

**Elastic network interfaces**

With your tasks use the awsvpc network mode, Amazon ECS provisions a unique elastic network interface (ENI) for each task. When your Amazon ECS services use an Elastic Load Balancing load balancer, these network interfaces are also registered as targets to the appropriate target group defined in the service.

**Elastic network interface service quotas**

When you run tasks that use the awsvpc network mode, a unique elastic network interface is attached to each task. If those tasks must be reached over the internet, assign a public IP address to the elastic network interface for those tasks. When you scale your Amazon ECS workloads, consider these two important quotas:
• The Network interfaces per Region quota which is the maximum number of network interfaces in an AWS Region for your account.

• The Elastic IP addresses per Region quota which is the maximum number of elastic IP addresses in an AWS Region.

Both of these service quotas are adjustable and you can request an increase from your Service Quotas console for these. For more information, see Amazon VPC service quotas in the Amazon Virtual Private Cloud user Guide.

For Amazon ECS workloads that are hosted on Amazon EC2 instances, when running tasks that use the awsvpc network mode consider the Maximum network interfaces service quota, the maximum number of network instances for each Amazon EC2 instance. This quota limits the number of tasks that you can place on an instance. You cannot adjust the quota and it's not available in the Service Quotas console. For more information, see IP addresses per network interface per instance type in the Amazon EC2 User Guide.

Although you can't change the number of network interfaces that can be attached to an Amazon EC2 instance, you can use the elastic network interface trunking feature to increase the number of available network interfaces. For example, by default a c5.large instance can have up to three network interfaces. The primary network interface for the instance counts as one. So, you can attach an additional two network interfaces to the instance. Because each task that uses the awsvpc network mode requires a network interface, you can typically only run two such tasks on this instance type. This can lead to under-utilization of your cluster capacity. If you enable elastic network interface trunking, you can increase the network interface density to place a larger number of tasks on each instance. With trunking turned on, a c5.large instance can have up to 12 network interfaces. The instance has the primary network interface and Amazon ECS creates and attaches a "trunk" network interface to the instance. As a result, with this configuration you can run 10 tasks on the instance instead of the default two tasks. For more information, see Elastic network interface trunking.

Elastic network interface API throttling

When you run tasks that use the awsvpc network mode, Amazon ECS relies on the following Amazon EC2 APIs. Each of these APIs have different API throttles. For more information, see Request throttling for the Amazon EC2 API in the Amazon EC2 API Reference.

• CreateNetworkInterface
• AttachNetworkInterface
If the Amazon EC2 API calls are throttled during the elastic network interface provisioning workflows, the Amazon ECS service scheduler automatically retries with exponential back-offs. These automatic retries might sometimes lead to a delay in launching tasks, which results in slower deployment speeds. When API throttling occurs, you will see the message *Operations are being throttled. Will try again later.* on your service event messages. If you consistently meet Amazon EC2 API throttles, you can contact AWS Support for guidance on how to increase your API throttling limits. For more information about monitoring and troubleshooting throttling errors, see [Handling throttling issues](#).

**AWS Cloud Map**

Amazon ECS service discovery and Service Connect use AWS Cloud Map APIs to manage namespaces for your Amazon ECS services. If your services have a large number of tasks, consider the following recommendations.

**AWS Cloud Map service quotas**

When Amazon ECS services are configured to use service discovery or Service Connect, the *Tasks per service* quota which is the maximum number of tasks for the service, is affected by the AWS Cloud Map *Instances per service* service quota which is the maximum number of instances for that service. In particular, the AWS Cloud Map service quota decreases the amount of tasks that you can run to at most 1,0000 tasks for service. You cannot change the AWS Cloud Map quota. For more information, see [AWS Cloud Map service quotas](#).

**AWS Cloud Map API throttling**

Amazon ECS calls the `ListInstances`, `GetInstancesHealthStatus`, `RegisterInstance`, and `DeregisterInstance` AWS Cloud Map APIs on your behalf. They help with service discovery and perform health checks when you launch a task. When multiple services that use service discovery
with a large number of tasks are deployed at the same time, this can result in exceeding the AWS Cloud Map API throttling limits. When this happens, you likely will see the following message:

Operations are being throttled. Will try again later in your Amazon ECS service event messages and slower deployment and task launch speed. AWS Cloud Map doesn't document throttling limits for these APIs. If you experience throttling from these, you can contact AWS Support for guidance on increasing your API throttling limits. For more recommendations about monitoring and troubleshooting such throttling errors, see Best practices for handling Amazon ECS throttling issues.
Amazon ECS API reference

In addition to the AWS Management Console and the AWS Command Line Interface (AWS CLI), Amazon ECS also provides an API. You can use the API to automate tasks for managing Amazon ECS resources.

- For a list of API operations by Amazon ECS resource, see Actions by Amazon ECS resource.
- For an alphabetical list of API operations, see Actions.
- For an alphabetical list of data types, see Data types.
- For a list of common query parameters, see Common parameters.
- For descriptions of the error codes, see Common errors.

For more information about the AWS CLI, see AWS Command Line Interface reference for Amazon ECS.
## Document history

The following table describes the major updates and new features for the *Amazon Elastic Container Service Developer Guide*. We also update the documentation frequently to address the feedback that you send us.

<table>
<thead>
<tr>
<th>Change</th>
<th>Description</th>
<th>Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>gMSA for Linux Containers on Fargate support</td>
<td>Amazon ECS supports Active Directory authentication for Linux containers on Fargate through a special kind of service account called a group Managed Service Account (gMSA). For more information, see <a href="#">Using gMSA for Linux containers on Fargate</a>.</td>
<td>March 5, 2024</td>
</tr>
<tr>
<td>CloudWatch metrics added for Amazon EBS volumes attached to tasks</td>
<td>Amazon ECS now publishes CloudWatch metrics for the Amazon EBS storage utilization for tasks that have an Amazon EBS volume attached. For more information, see <a href="#">Amazon ECS CloudWatch metrics</a>.</td>
<td>February 8, 2024</td>
</tr>
<tr>
<td>Service Connect TLS</td>
<td>You can now use <a href="#">TLS with Service Connect</a>.</td>
<td>January 22, 2024</td>
</tr>
<tr>
<td>Service Connect TLS managed policy</td>
<td>Added new <a href="#">AmazonECSInfrastructureRolePolicyForServiceConnectTransportLayerSecurity</a> policy.</td>
<td>January 22, 2024</td>
</tr>
<tr>
<td>Service Connect timeout configuration update</td>
<td>Service Connect <a href="#">timeout configuration</a> can now be updated and includes two optional parameters - <code>idleTimeout</code> and <code>perRequestTimeout</code>.</td>
<td>January 22, 2024</td>
</tr>
<tr>
<td>Amazon ECS managed instance draining</td>
<td>You can use Amazon ECS <a href="#">managed instance draining</a> to facilitate graceful termination of Amazon ECS instances.</td>
<td>January 19, 2024</td>
</tr>
<tr>
<td>Ubuntu 22 support added for ECS Anywhere</td>
<td>Support for the Ubuntu 22 operating system was added to ECS Anywhere. For more information, see <a href="#">Supported operating systems and system architectures</a>.</td>
<td>January 16, 2024</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>

<tr>
<td>New task definition sizes</td>
<td>Amazon ECS on Fargate now supports the 8 vCPU and 16 vCPU task sizes. For more information, see the section called “Task size”.</td>
<td>September 16, 2022</td>
</tr>
<tr>
<td>ECS CLI pages archived</td>
<td>The ECS CLI documentation has been archived. We recommend using AWS Copilot for your command line tool needs. For more information, see Using the AWS Copilot command line interface.</td>
<td>September 15, 2022</td>
</tr>
<tr>
<td>New Fargate quotas</td>
<td>Fargate is transitioning from task count-based quotas to vCPU-based quotas. For more information, see the section called “AWS Fargate service quotas”.</td>
<td>September 8, 2022</td>
</tr>
<tr>
<td>Support for Amazon EC2 Auto Scaling warm pools.</td>
<td>You can now use Amazon EC2 Auto Scaling warm pools to scale out your applications faster and save costs. For more information, see Using a warm pool for your Auto Scaling group.</td>
<td>March 23, 2022</td>
</tr>
<tr>
<td>Support for Windows instances in ECS Anywhere.</td>
<td>ECS Anywhere now supports Windows instances. For more information, see External instances (Amazon ECS Anywhere).</td>
<td>March 3, 2022</td>
</tr>
<tr>
<td>Added ECS Exec support for external instances</td>
<td>ECS Exec is now supported for external instances. For more information, see Monitor Amazon ECS containers with ECS Exec.</td>
<td>January 24, 2022</td>
</tr>
<tr>
<td>The new Amazon ECS console experience updated</td>
<td>The new Amazon ECS console experience supports creating and deleting a cluster, updating a task definition, and deregistering a task definition. For more information, see Creating a cluster for the Fargate and External launch type using the console, Deleting a cluster using the console, Updating a task definition using the console, and Deregistering a task definition revision using the console.</td>

<td></td>
</tr>
</tbody>
</table>
AWS Fargate platform version 1.4.0 is released, which contains the following features:

- Added support for using Amazon EFS file system volumes for persistent task storage. For more information, see Amazon EFS volumes.

- The ephemeral task storage has been increased to 20 GB. For more information, see Fargate task ephemeral storage.

- The network traffic behavior to and from tasks has been updated. Starting with platform version 1.4, all Fargate tasks receive a single elastic network interface (referred to as the task ENI) and all network traffic flows through that ENI within your VPC and will be visible to you through your VPC flow logs. For more information, see Fargate Task Networking in the Amazon Elastic Container Service User Guide for AWS Fargate.

- Task ENIs add support for jumbo frames. Network interfaces are configured with a maximum transmission unit (MTU), which is the size of the largest payload that fits within a single frame. The larger the MTU, the more application payload can fit within a single frame, which reduces per-frame overhead and increases efficiency. Supporting jumbo frames will reduce overhead when the network path between your task and the destination supports jumbo frames, such as all traffic that remains within your VPC.

- CloudWatch Container Insights will include network performance metrics for Fargate tasks. For more
<table>

| Amazon ECS service scheduler strategies added | Amazon ECS introduced the concept of service scheduler strategies. There are two service scheduler strategies available:  
  • REPLICA—The replica scheduling strategy places and maintains the desired number of tasks across your cluster. By default, the service scheduler spreads tasks across Availability Zones. You can use task placement strategies and constraints to customize task placement decisions. For more information, see Replica.  
  • DAEMON—The daemon scheduling strategy deploys exactly one task on each active container instance that meets all of the task placement constraints that you specify in your cluster. When using this strategy, there is no need to specify a desired number of tasks, a task placement strategy, or use Service Auto Scaling policies. For more information, see Daemon.  

Note  
Fargate tasks do not support the DAEMON scheduling strategy.                                                                                                                                   | June 12, 2018 |

| Amazon ECS container agent v1.18.0 | New version of the Amazon ECS container agent released, which added the following functionality:  
  - Added procedure to manually install the container agent from a S3 URL on non-Amazon Linux EC2 instance, including a PGP signature method for verifying the Amazon ECS container agent installation file. For more information, see [Installing the Amazon ECS container agent](#).  
  - Added procedure to manually install the container agent from a S3 URL on a Windows EC2 instance, including a PGP signature method for verifying the Amazon ECS container agent installation file.  
  - Added support for customizing the container agent image pull behavior using the ECS_IMAGE_PULL_BEHAVIOR parameter. For more information, see [Amazon ECS container agent configuration](#). | May 24, 2018 |
<p>| Added Support for bridge and host Network Modes When Configuring Service Discovery | Added support for configuring service discovery for Amazon ECS services using task definitions that specify the bridge or host network modes. For more information, see <a href="#">Service discovery</a>. | May 22, 2018 |</p>

<tr>
<td>Elastic Load Balancing health check initialization wait period</td>
<td>Added ability to specify a wait period for health checks.</td>
<td>December 27, 2017</td>
</tr>
<tr>
<td>Task-level CPU and memory</td>
<td>Added support for specifying CPU and memory at the task-level in task definitions. For more information, see <a href="#">TaskDefinition</a>.</td>
<td>December 12, 2017</td>
</tr>
</tbody>
</table>
| Task execution role                         | The Amazon ECS container agent makes calls to the Amazon ECS API actions on your behalf, so it requires an IAM policy and role for the service to know that the agent belongs to you. The following actions are covered by the task execution role:  
  - Calls to Amazon ECR to pull the container image  
  - Calls to CloudWatch to store container application logs  

  For more information, see [Amazon ECS task execution IAM role](#). | December 7, 2017 |
<p>| Windows containers support GA               | Added support for Windows Server 2016 containers. For more information, see <a href="#">Amazon ECS-optimized AMI variants</a>. | December 5, 2017 |
| AWS Fargate GA                              | Added support for launching Amazon ECS services using the Fargate launch type. For more information, see <a href="#">Amazon ECS launch types</a>. | November 29, 2017 |
| Amazon ECS name change                      | Amazon Elastic Container Service is renamed (previously Amazon EC2 Container Service). | November 21, 2017 |</p>
<table>

<tbody>
<tr>
<td>Task networking</td>
<td>The task networking features provided by the awsvpc network mode give Amazon ECS tasks the same networking properties as Amazon EC2 instances. When you use the awsvpc network mode in your task definitions, every task that is launched from that task definition gets its own elastic network interface, a primary private IP address, and an internal DNS hostname. The task networking feature simplifies container networking and gives you more control over how containerized applications communicate with each other and other services within your VPCs. For more information, see <a href="#">Task networking for tasks on Amazon EC2 instances</a>.</td>
<td>November 14, 2017</td>
</tr>
<tr>
<td>Amazon ECS container metadata</td>
<td>Amazon ECS containers are now able to access metadata such as their Docker container or image ID, networking configuration, or Amazon ARNs. For more information, see <a href="#">Amazon ECS container metadata file</a>.</td>
<td>November 2, 2017</td>
</tr>
<tr>
<td>Docker 17.06 support</td>
<td>Added support for Docker 17.06. For more information, see <a href="#">Amazon ECS-optimized AMI</a>.</td>
<td>November 2, 2017</td>
</tr>
<tr>
<td>Support for Docker flags:</td>
<td>Added support for Docker's device and init features in task definitions using the <code>LinuxParameters</code> parameter (devices and initProcessEnabled). For more information, see <a href="#">LinuxParameters</a>.</td>
<td>November 2, 2017</td>
</tr>
<tr>
<td>device and init</td>
<td></td>
<td>September 22, 2017</td>

<tr>
<td>RunTask overrides</td>
<td>Added support for task definition overrides when running a task. This allows you to run a task while changing a task definition without the need to create a new task definition revision. For more information, see <a href="#">Run an application as an Amazon ECS task</a>.</td>
<td>June 27, 2017</td>
</tr>
<tr>
<td>Amazon ECS scheduled tasks</td>
<td>Added support for scheduling tasks using cron.</td>
<td>June 7, 2017</td>
</tr>
<tr>
<td>Spot Instances in the Amazon ECS console</td>
<td>Added support for creating Spot Fleet container instances within the Amazon ECS console. For more information, see <a href="#">Launching an Amazon ECS Linux container instance</a>.</td>
<td>June 6, 2017</td>
</tr>
<tr>
<td>Amazon SNS notification for new Amazon ECS-optimized AMI releases</td>
<td>Added ability to subscribe to SNS notifications about new Amazon ECS-optimized AMI releases.</td>
<td>March 23, 2017</td>
</tr>
<tr>
<td>Microservices and batch jobs</td>
<td>Added documentation for two common use cases for Amazon ECS: microservices and batch jobs. For more information, see <a href="#">Related information</a>.</td>
<td>February 2017</td>
</tr>
<tr>
<td>Container instance draining</td>
<td>Added support for container instance draining, which provides a method for removing container instances from a cluster. For more information, see <a href="#">Container instance draining</a>.</td>
<td>January 24, 2017</td>
</tr>
<tr>
<td>Docker 1.12 support</td>
<td>Added support for Docker 1.12. For more information, see <a href="#">Amazon ECS-optimized AMI</a>.</td>
<td>January 24, 2017</td>
</tr>
<tr>
<td>New task placement strategies</td>
<td>Added support for task placement strategies: attribute-based placement, bin pack, Availability Zone spread, and one per host. For more information, see <a href="#">Use strategies to define Amazon ECS task placement</a>.</td>
<td>December 29, 2016</td>
</tr>
<tr>
<td>Change</td>
<td>Description</td>
<td>Date</td>
</tr>
<tr>
<td>----------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------</td>
</tr>
<tr>
<td>Windows container support in beta</td>
<td>Added support for Windows Server 2016 containers (beta). For more information, see <a href="https://aws.amazon.com/ec2/ami-support/">Amazon ECS-optimized AMI variants</a>.</td>
<td>December 20, 2016</td>
</tr>
<tr>
<td>Blox OSS support</td>
<td>Added support for Blox OSS, which allows for custom task schedulers. For more information, see <a href="https://docs.aws.amazon.com/ecs/latest/userguide/blox-oss.html">Scheduling your containers on Amazon ECS</a>.</td>
<td>December 1, 2016</td>
</tr>
<tr>
<td>Amazon ECS event stream for CloudWatch Events</td>
<td>Amazon ECS now sends container instance and task state changes to CloudWatch Events. For more information, see <a href="https://docs.aws.amazon.com/ecs/latest/userguide/eventbridge.html">Automate responses to Amazon ECS errors using EventBridge</a>.</td>
<td>November 21, 2016</td>
</tr>
<tr>
<td>Amazon ECS container logging to CloudWatch Logs</td>
<td>Added support for the awslogs driver to send container log streams to CloudWatch Logs. For more information, see <a href="https://docs.aws.amazon.com/ecs/latest/userguide/awslogs.html">Using the awslogs log driver</a>.</td>
<td>September 12, 2016</td>
</tr>
<tr>
<td>Amazon ECS services with Elastic Load Balancing support for dynamic ports</td>
<td>Added support for a load balancer to support multiple instance:port combinations per listener, which increases flexibility for containers. Now you can let Docker dynamically define the container's host port and the ECS scheduler registers the instance:port with the load balancer. For more information, see <a href="https://docs.aws.amazon.com/ecs/latest/userguide/distribute-service-traffic.html">Distribute Amazon ECS service traffic using load balancing</a>.</td>
<td>August 11, 2016</td>
</tr>
<tr>
<td>IAM roles for Amazon ECS tasks</td>
<td>Added support for associating IAM roles with a task. This provides finer-grained permissions to container instances as opposed to a single role for an entire container instance. For more information, see <a href="https://docs.aws.amazon.com/ecs/latest/userguide/iam-roles.html">Task IAM role</a>.</td>
<td>July 13, 2016</td>
</tr>
<tr>
<td>Docker 1.11 support</td>
<td>Added support for Docker 1.11. For more information, see <a href="https://aws.amazon.com/ec2/ami-support/">Amazon ECS-optimized AMI</a>.</td>
