</table>

⚠️ **Important**

These values represent the theoretical maximum amount of free storage on each DB instance. The actual local storage available to you might be lower. Aurora uses some local storage for its management processes, and the DB instance uses some local storage even before you load any data. You can monitor the temporary storage available for a specific DB instance with the `FreeLocalStorage` CloudWatch metric, described in [Amazon CloudWatch metrics for Amazon Aurora](https://docs.aws.amazon.com/AmazonAurora/latest/UserGuide/Concepts.Aurora-CloudWatch-Metrics.html). You can check the amount of free storage at the present time. You can also chart the amount of free storage over time. Monitoring the free
storage over time helps you to determine whether the value is increasing or decreasing, or to find the minimum, maximum, or average values.
(This doesn't apply to Aurora Serverless v2.)

Backtracking an Aurora DB cluster

With Amazon Aurora MySQL-Compatible Edition, you can backtrack a DB cluster to a specific time, without restoring data from a backup.

Contents

- Overview of backtracking
  - Backtrack window
  - Backtracking time
  - Backtracking limitations
- Region and version availability

- Performing a backtrack
- Monitoring backtracking
- Subscribing to a backtrack event with the console
- Retrieving existing backtracks
- Disabling backtracking for a DB cluster

Overview of backtracking

Backtracking "rewinds" the DB cluster to the time you specify. Backtracking is not a replacement for backing up your DB cluster so that you can restore it to a point in time. However, backtracking provides the following advantages over traditional backup and restore:

- You can easily undo mistakes. If you mistakenly perform a destructive action, such as a DELETE without a WHERE clause, you can backtrack the DB cluster to a time before the destructive action with minimal interruption of service.
• You can backtrack a DB cluster quickly. Restoring a DB cluster to a point in time launches a new DB cluster and restores it from backup data or a DB cluster snapshot, which can take hours. Backtracking a DB cluster doesn't require a new DB cluster and rewinds the DB cluster in minutes.

• You can explore earlier data changes. You can repeatedly backtrack a DB cluster back and forth in time to help determine when a particular data change occurred. For example, you can backtrack a DB cluster three hours and then backtrack forward in time one hour. In this case, the backtrack time is two hours before the original time.

Note
For information about restoring a DB cluster to a point in time, see Overview of backing up and restoring an Aurora DB cluster.

Backtrack window

With backtracking, there is a target backtrack window and an actual backtrack window:

• The target backtrack window is the amount of time you want to be able to backtrack your DB cluster. When you enable backtracking, you specify a target backtrack window. For example, you might specify a target backtrack window of 24 hours if you want to be able to backtrack the DB cluster one day.

• The actual backtrack window is the actual amount of time you can backtrack your DB cluster, which can be smaller than the target backtrack window. The actual backtrack window is based on your workload and the storage available for storing information about database changes, called change records.

As you make updates to your Aurora DB cluster with backtracking enabled, you generate change records. Aurora retains change records for the target backtrack window, and you pay an hourly rate for storing them. Both the target backtrack window and the workload on your DB cluster determine the number of change records you store. The workload is the number of changes you make to your DB cluster in a given amount of time. If your workload is heavy, you store more change records in your backtrack window than you do if your workload is light.

You can think of your target backtrack window as the goal for the maximum amount of time you want to be able to backtrack your DB cluster. In most cases, you can backtrack the maximum amount of time that you specified. However, in some cases, the DB cluster can't store enough
change records to backtrack the maximum amount of time, and your actual backtrack window is smaller than your target. Typically, the actual backtrack window is smaller than the target when you have extremely heavy workload on your DB cluster. When your actual backtrack window is smaller than your target, we send you a notification.

When backtracking is enabled for a DB cluster, and you delete a table stored in the DB cluster, Aurora keeps that table in the backtrack change records. It does this so that you can revert back to a time before you deleted the table. If you don't have enough space in your backtrack window to store the table, the table might be removed from the backtrack change records eventually.

Backtracking time

Aurora always backtracks to a time that is consistent for the DB cluster. Doing so eliminates the possibility of uncommitted transactions when the backtrack is complete. When you specify a time for a backtrack, Aurora automatically chooses the nearest possible consistent time. This approach means that the completed backtrack might not exactly match the time you specify, but you can determine the exact time for a backtrack by using the describe-db-cluster-backtracks AWS CLI command. For more information, see Retrieving existing backtracks.

Backtracking limitations

The following limitations apply to backtracking:

- Backtracking is only available for DB clusters that were created with the Backtrack feature enabled. You can't modify a DB cluster to enable the Backtrack feature. You can enable the Backtrack feature when you create a new DB cluster or restore a snapshot of a DB cluster.
- The limit for a backtrack window is 72 hours.
- Backtracking affects the entire DB cluster. For example, you can't selectively backtrack a single table or a single data update.
- You can't create cross-Region read replicas from a backtrack-enabled cluster, but you can still enable binary log (binlog) replication on the cluster. If you try to backtrack a DB cluster for which binary logging is enabled, an error typically occurs unless you choose to force the backtrack. Any attempts to force a backtrack will break downstream read replicas and interfere with other operations such as blue/green deployments.
- You can't backtrack a database clone to a time before that database clone was created. However, you can use the original database to backtrack to a time before the clone was created. For more information about database cloning, see Cloning a volume for an Amazon Aurora DB cluster.
• Backtracking causes a brief DB instance disruption. You must stop or pause your applications before starting a backtrack operation to ensure that there are no new read or write requests. During the backtrack operation, Aurora pauses the database, closes any open connections, and drops any uncommitted reads and writes. It then waits for the backtrack operation to complete.

• You can't restore a cross-Region snapshot of a backtrack-enabled cluster in an AWS Region that doesn't support backtracking.

• If you perform an in-place upgrade for a backtrack-enabled cluster from Aurora MySQL version 2 to version 3, you can't backtrack to a point in time before the upgrade happened.

Region and version availability

Backtrack is not available for Aurora PostgreSQL.

Following are the supported engines and Region availability for Backtrack with Aurora MySQL.

<table>
<thead>
<tr>
<th>Region</th>
<th>Aurora MySQL version 3</th>

Upgrade considerations for backtrack-enabled clusters

You can upgrade a backtrack-enabled DB cluster from Aurora MySQL version 2 to version 3, because all minor versions of Aurora MySQL version 3 are supported for Backtrack.

Configuring backtracking

To use the Backtrack feature, you must enable backtracking and specify a target backtrack window. Otherwise, backtracking is disabled.
For the target backtrack window, specify the amount of time that you want to be able to rewind your database using Backtrack. Aurora tries to retain enough change records to support that window of time.

**Console**

You can use the console to configure backtracking when you create a new DB cluster. You can also modify a DB cluster to change the backtrack window for a backtrack-enabled cluster. If you turn off backtracking entirely for a cluster by setting the backtrack window to 0, you can't enable backtrack again for that cluster.

**Topics**

- [Configuring backtracking with the console when creating a DB cluster](#)
- [Configuring backtrack with the console when modifying a DB cluster](#)

**Configuring backtracking with the console when creating a DB cluster**

When you create a new Aurora MySQL DB cluster, backtracking is configured when you choose *Enable Backtrack* and specify a *Target Backtrack window* value that is greater than zero in the *Backtrack* section.

To create a DB cluster, follow the instructions in [Creating an Amazon Aurora DB cluster](#). The following image shows the *Backtrack* section.

![Backtrack Section](image-url)
When you create a new DB cluster, Aurora has no data for the DB cluster's workload. So it can't estimate a cost specifically for the new DB cluster. Instead, the console presents a typical user cost for the specified target backtrack window based on a typical workload. The typical cost is meant to provide a general reference for the cost of the Backtrack feature.

**Important**

Your actual cost might not match the typical cost, because your actual cost is based on your DB cluster's workload.

Configuring backtrack with the console when modifying a DB cluster

You can modify backtracking for a DB cluster using the console.

**Note**

Currently, you can modify backtracking only for a DB cluster that has the Backtrack feature enabled. The Backtrack section doesn't appear for a DB cluster that was created with the Backtrack feature disabled or if the Backtrack feature has been disabled for the DB cluster.

To modify backtracking for a DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases.
3. Choose the cluster that you want to modify, and choose Modify.
4. For Target Backtrack window, modify the amount of time that you want to be able to backtrack. The limit is 72 hours.
The console shows the estimated cost for the amount of time you specified based on the DB cluster's past workload:

- If backtracking was disabled on the DB cluster, the cost estimate is based on the VolumeWriteIOPS metric for the DB cluster in Amazon CloudWatch.
- If backtracking was enabled previously on the DB cluster, the cost estimate is based on the BacktrackChangeRecordsCreationRate metric for the DB cluster in Amazon CloudWatch.

5. Choose **Continue**.

6. For **Scheduling of Modifications**, choose one of the following:

   - **Apply during the next scheduled maintenance window** – Wait to apply the Target Backtrack window modification until the next maintenance window.
   - **Apply immediately** – Apply the Target Backtrack window modification as soon as possible.

7. Choose **Modify cluster**.

**AWS CLI**

When you create a new Aurora MySQL DB cluster using the `create-db-cluster` AWS CLI command, backtracking is configured when you specify a `--backtrack-window` value that is greater than zero. The `--backtrack-window` value specifies the target backtrack window. For more information, see [Creating an Amazon Aurora DB cluster](#).

You can also specify the `--backtrack-window` value using the following AWS CLI commands:
The following procedure describes how to modify the target backtrack window for a DB cluster using the AWS CLI.

To modify the target backtrack window for a DB cluster using the AWS CLI

- Call the `modify-db-cluster` AWS CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.
  - `--backtrack-window` – The maximum number of seconds that you want to be able to backtrack the DB cluster.

The following example sets the target backtrack window for `sample-cluster` to one day (86,400 seconds).

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier sample-cluster \
  --backtrack-window 86400
```

For Windows:

```bash
aws rds modify-db-cluster ^
  --db-cluster-identifier sample-cluster ^
  --backtrack-window 86400
```
Note
Currently, you can enable backtracking only for a DB cluster that was created with the Backtrack feature enabled.

RDS API

When you create a new Aurora MySQL DB cluster using the `CreateDBCluster` Amazon RDS API operation, backtracking is configured when you specify a `BacktrackWindow` value that is greater than zero. The `BacktrackWindow` value specifies the target backtrack window for the DB cluster specified in the `DBClusterIdentifier` value. For more information, see Creating an Amazon Aurora DB cluster.

You can also specify the `BacktrackWindow` value using the following API operations:

- `ModifyDBCluster`
- `RestoreDBClusterFromS3`
- `RestoreDBClusterFromSnapshot`
- `RestoreDBClusterToPointInTime`

Note
Currently, you can enable backtracking only for a DB cluster that was created with the Backtrack feature enabled.

Performing a backtrack

You can backtrack a DB cluster to a specified backtrack time stamp. If the backtrack time stamp isn't earlier than the earliest possible backtrack time, and isn't in the future, the DB cluster is backtracked to that time stamp.

Otherwise, an error typically occurs. Also, if you try to backtrack a DB cluster for which binary logging is enabled, an error typically occurs unless you've chosen to force the backtrack to occur. Forcing a backtrack to occur can interfere with other operations that use binary logging.
**Important**

Backtracking doesn't generate binlog entries for the changes that it makes. If you have binary logging enabled for the DB cluster, backtracking might not be compatible with your binlog implementation.

**Note**

For database clones, you can't backtrack the DB cluster earlier than the date and time when the clone was created. For more information about database cloning, see [Cloning a volume for an Amazon Aurora DB cluster](#).

**Console**

The following procedure describes how to perform a backtrack operation for a DB cluster using the console.

**To perform a backtrack operation using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Instances**.
3. Choose the primary instance for the DB cluster that you want to backtrack.
4. For **Actions**, choose **Backtrack DB cluster**.
5. On the **Backtrack DB cluster** page, enter the backtrack time stamp to backtrack the DB cluster to.
6. Choose **Backtrack DB cluster**.

**AWS CLI**

The following procedure describes how to backtrack a DB cluster using the AWS CLI.

**To backtrack a DB cluster using the AWS CLI**

- Call the `backtrack-db-cluster` AWS CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.
  - `--backtrack-to` – The backtrack time stamp to backtrack the DB cluster to, specified in ISO 8601 format.

The following example backtracks the DB cluster `sample-cluster` to March 19, 2018, at 10 a.m.

For Linux, macOS, or Unix:

```bash
aws rds backtrack-db-cluster \
  --db-cluster-identifier sample-cluster \
  --backtrack-to 2018-03-19T10:00:00+00:00
```

For Windows:
```
aws rds backtrack-db-cluster ^
   --db-cluster-identifier sample-cluster ^
   --backtrack-to 2018-03-19T10:00:00+00:00
```

**RDS API**

To backtrack a DB cluster using the Amazon RDS API, use the `BacktrackDBCluster` operation. This operation backtracks the DB cluster specified in the `DBClusterIdentifier` value to the specified time.

**Monitoring backtracking**

You can view backtracking information and monitor backtracking metrics for a DB cluster.

**Console**

**To view backtracking information and monitor backtracking metrics using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. Choose **Databases**.
3. Choose the DB cluster name to open information about it.

   The backtrack information is in the **Backtrack** section.

```
Backtrack

Backtrack window
Enabled
Target window (12 hours)
Actual window (12 hours)

Earliest backtrack time
May 7, 2018 at 8:19:20 PM UTC-7 (Local)
```

When backtracking is enabled, the following information is available:
• **Target window** – The current amount of time specified for the target backtrack window. The target is the maximum amount of time that you can backtrack if there is sufficient storage.

• **Actual window** – The actual amount of time you can backtrack, which can be smaller than the target backtrack window. The actual backtrack window is based on your workload and the storage available for retaining backtrack change records.

• **Earliest backtrack time** – The earliest possible backtrack time for the DB cluster. You can't backtrack the DB cluster to a time before the displayed time.

4. Do the following to view backtracking metrics for the DB cluster:
   a. In the navigation pane, choose **Instances**.
   b. Choose the name of the primary instance for the DB cluster to display its details.
   c. In the **CloudWatch** section, type **Backtrack** into the **CloudWatch** box to show only the Backtrack metrics.
The following metrics are displayed:

- **Backtrack Change Records Creation Rate (Count)** – This metric shows the number of backtrack change records created over five minutes for your DB cluster. You can use this metric to estimate the backtrack cost for your target backtrack window.

- **[Charged] Backtrack Change Records Stored (Count)** – This metric shows the actual number of backtrack change records used by your DB cluster.

- **Backtrack Window Actual (Minutes)** – This metric shows whether there is a difference between the target backtrack window and the actual backtrack window. For example, if your target backtrack window is 2 hours (120 minutes), and this metric shows that the actual backtrack window is 100 minutes, then the actual backtrack window is smaller than the target.
• **Backtrack Window Alert (Count)** – This metric shows how often the actual backtrack window is smaller than the target backtrack window for a given period of time.

**Note**
The following metrics might lag behind the current time:

• **Backtrack Change Records Creation Rate (Count)**
• **[Billed] Backtrack Change Records Stored (Count)**

**AWS CLI**

The following procedure describes how to view backtrack information for a DB cluster using the AWS CLI.

**To view backtrack information for a DB cluster using the AWS CLI**

- Call the `describe-db-clusters` AWS CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.

The following example lists backtrack information for `sample-cluster`.

For Linux, macOS, or Unix:

```
aws rds describe-db-clusters \
  --db-cluster-identifier sample-cluster
```

For Windows:

```
aws rds describe-db-clusters ^
  --db-cluster-identifier sample-cluster
```
RDS API

To view backtrack information for a DB cluster using the Amazon RDS API, use the DescribeDBClusters operation. This operation returns backtrack information for the DB cluster specified in the DBClusterIdentifier value.

Subscribing to a backtrack event with the console

The following procedure describes how to subscribe to a backtrack event using the console. The event sends you an email or text notification when your actual backtrack window is smaller than your target backtrack window.

To view backtrack information using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Event subscriptions.
3. Choose Create event subscription.
4. In the Name box, type a name for the event subscription, and ensure that Yes is selected for Enabled.
5. In the Target section, choose New email topic.
6. For Topic name, type a name for the topic, and for With these recipients, enter the email addresses or phone numbers to receive the notifications.
7. In the Source section, choose Instances for Source type.
8. For Instances to include, choose Select specific instances, and choose your DB instance.
9. For Event categories to include, choose Select specific event categories, and choose backtrack.

Your page should look similar to the following page.
10. Choose Create.

**Retrieving existing backtracks**

You can retrieve information about existing backtracks for a DB cluster. This information includes the unique identifier of the backtrack, the date and time backtracked to and from, the date and time the backtrack was requested, and the current status of the backtrack.

**Note**

Currently, you can't retrieve existing backtracks using the console.

**AWS CLI**

The following procedure describes how to retrieve existing backtracks for a DB cluster using the AWS CLI.

**To retrieve existing backtracks using the AWS CLI**

- Call the `describe-db-cluster-backtracks` AWS CLI command and supply the following values:
  - `--db-cluster-identifier` – The name of the DB cluster.

  The following example retrieves existing backtracks for `sample-cluster`.

  For Linux, macOS, or Unix:

  ```bash
  aws rds describe-db-cluster-backtracks \n  --db-cluster-identifier sample-cluster
  ```

  For Windows:

  ```bash
  aws rds describe-db-cluster-backtracks ^
  --db-cluster-identifier sample-cluster
  ```
RDS API

To retrieve information about the backtracks for a DB cluster using the Amazon RDS API, use the DescribeDBClusterBacktracks operation. This operation returns information about backtracks for the DB cluster specified in the DBClusterIdentifier value.

Disabling backtracking for a DB cluster

You can disable the Backtrack feature for a DB cluster.

Console

You can disable backtracking for a DB cluster using the console. After you turn off backtracking entirely for a cluster, you can’t enable it again for that cluster.

To disable the Backtrack feature for a DB cluster using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases.
3. Choose the cluster you want to modify, and choose Modify.
4. In the Backtrack section, choose Disable Backtrack.
5. Choose Continue.
6. For Scheduling of Modifications, choose one of the following:
   - **Apply during the next scheduled maintenance window** – Wait to apply the modification until the next maintenance window.
   - **Apply immediately** – Apply the modification as soon as possible.
7. Choose Modify Cluster.

AWS CLI

You can disable the Backtrack feature for a DB cluster using the AWS CLI by setting the target backtrack window to 0 (zero). After you turn off backtracking entirely for a cluster, you can’t enable it again for that cluster.

To modify the target backtrack window for a DB cluster using the AWS CLI

- Call the modify-db-cluster AWS CLI command and supply the following values:
- --db-cluster-identifier – The name of the DB cluster.
- --backtrack-window – specify 0 to turn off backtracking.

The following example disables the Backtrack feature for the sample-cluster by setting --backtrack-window to 0.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster
   --db-cluster-identifier sample-cluster
   --backtrack-window 0
```

For Windows:

```bash
aws rds modify-db-cluster ^
   --db-cluster-identifier sample-cluster ^
   --backtrack-window 0
```

**RDS API**

To disable the Backtrack feature for a DB cluster using the Amazon RDS API, use the ModifyDBCluster operation. Set the BacktrackWindow value to 0 (zero), and specify the DB cluster in the DBClusterIdentifier value. After you turn off backtracking entirely for a cluster, you can't enable it again for that cluster.

**Testing Amazon Aurora MySQL using fault injection queries**

You can test the fault tolerance of your Aurora MySQL DB cluster by using fault injection queries. Fault injection queries are issued as SQL commands to an Amazon Aurora instance. They let you schedule a simulated occurrence of one of the following events:

- A crash of a writer or reader DB instance
- A failure of an Aurora Replica
- A disk failure
- Disk congestion
When a fault injection query specifies a crash, it forces a crash of the Aurora MySQL DB instance. The other fault injection queries result in simulations of failure events, but don't cause the event to occur. When you submit a fault injection query, you also specify an amount of time for the failure event simulation to occur for.

You can submit a fault injection query to one of your Aurora Replica instances by connecting to the endpoint for the Aurora Replica. For more information, see Amazon Aurora connection management.

Running fault injection queries requires all of the master user privileges. For more information, see Master user account privileges.

**Testing an instance crash**

You can force a crash of an Amazon Aurora instance using the `ALTER SYSTEM CRASH` fault injection query.

For this fault injection query, a failover will not occur. If you want to test a failover, then you can choose the Failover instance action for your DB cluster in the RDS console, or use the `failover-db-cluster` AWS CLI command or the `FailoverDBCluster` RDS API operation.

**Syntax**

```
ALTER SYSTEM CRASH [ INSTANCE | DISPATCHER | NODE ];
```

**Options**

This fault injection query takes one of the following crash types:

- **INSTANCE** — A crash of the MySQL-compatible database for the Amazon Aurora instance is simulated.

- **DISPATCHER** — A crash of the dispatcher on the writer instance for the Aurora DB cluster is simulated. The `dispatcher` writes updates to the cluster volume for an Amazon Aurora DB cluster.

- **NODE** — A crash of both the MySQL-compatible database and the dispatcher for the Amazon Aurora instance is simulated. For this fault injection simulation, the cache is also deleted.

The default crash type is INSTANCE.
Testing an Aurora replica failure

You can simulate the failure of an Aurora Replica using the ALTER SYSTEM SIMULATE READ REPLICA FAILURE fault injection query.

An Aurora Replica failure blocks all requests from the writer instance to an Aurora Replica or all Aurora Replicas in the DB cluster for a specified time interval. When the time interval completes, the affected Aurora Replicas will be automatically synced up with master instance.

Syntax

```
ALTER SYSTEM SIMULATE percentage_of_failure PERCENT READ REPLICA FAILURE
[ TO ALL | TO "replica name" ]
FOR INTERVAL quantity { YEAR | QUARTER | MONTH | WEEK | DAY | HOUR | MINUTE | SECOND };
```

Options

This fault injection query takes the following parameters:

- **percentage_of_failure** — The percentage of requests to block during the failure event. This value can be a double between 0 and 100. If you specify 0, then no requests are blocked. If you specify 100, then all requests are blocked.

- **Failure type** — The type of failure to simulate. Specify TO ALL to simulate failures for all Aurora Replicas in the DB cluster. Specify TO and the name of the Aurora Replica to simulate a failure of a single Aurora Replica. The default failure type is TO ALL.

- **quantity** — The amount of time for which to simulate the Aurora Replica failure. The interval is an amount followed by a time unit. The simulation will occur for that amount of the specified unit. For example, 20 MINUTE will result in the simulation running for 20 minutes.

⚠️ Note

Take care when specifying the time interval for your Aurora Replica failure event. If you specify too long of a time interval, and your writer instance writes a large amount of data during the failure event, then your Aurora DB cluster might assume that your Aurora Replica has crashed and replace it.
Testing a disk failure

You can simulate a disk failure for an Aurora DB cluster using the `ALTER SYSTEM SIMULATE DISK FAILURE` fault injection query.

During a disk failure simulation, the Aurora DB cluster randomly marks disk segments as faulting. Requests to those segments will be blocked for the duration of the simulation.

Syntax

```
ALTER SYSTEM SIMULATE percentage_of_failure PERCENT DISK FAILURE
    [ IN DISK index | NODE index ]
    FOR INTERVAL quantity { YEAR | QUARTER | MONTH | WEEK | DAY | HOUR | MINUTE | SECOND };
```

Options

This fault injection query takes the following parameters:

- **percentage_of_failure** — The percentage of the disk to mark as faulting during the failure event. This value can be a double between 0 and 100. If you specify 0, then none of the disk is marked as faulting. If you specify 100, then the entire disk is marked as faulting.

- **DISK index** — A specific logical block of data to simulate the failure event for. If you exceed the range of available logical blocks of data, you will receive an error that tells you the maximum index value that you can specify. For more information, see [Displaying volume status for an Aurora MySQL DB cluster](#).

- **NODE index** — A specific storage node to simulate the failure event for. If you exceed the range of available storage nodes, you will receive an error that tells you the maximum index value that you can specify. For more information, see [Displaying volume status for an Aurora MySQL DB cluster](#).

- **quantity** — The amount of time for which to simulate the disk failure. The interval is an amount followed by a time unit. The simulation will occur for that amount of the specified unit. For example, `20 MINUTE` will result in the simulation running for 20 minutes.

Testing disk congestion

You can simulate a disk failure for an Aurora DB cluster using the `ALTER SYSTEM SIMULATE DISK CONGESTION` fault injection query.
During a disk congestion simulation, the Aurora DB cluster randomly marks disk segments as congested. Requests to those segments will be delayed between the specified minimum and maximum delay time for the duration of the simulation.

Syntax

```
ALTER SYSTEM SIMULATE percentage_of_failure PERCENT DISK CONGESTION
   BETWEEN minimum AND maximum MILLISECONDS
   [ IN DISK index | NODE index ]
   FOR INTERVAL quantity { YEAR | QUARTER | MONTH | WEEK | DAY | HOUR | MINUTE | SECOND };
```

Options

This fault injection query takes the following parameters:

- **percentage_of_failure** — The percentage of the disk to mark as congested during the failure event. This value can be a double between 0 and 100. If you specify 0, then none of the disk is marked as congested. If you specify 100, then the entire disk is marked as congested.

- **DISK index Or NODE index** — A specific disk or node to simulate the failure event for. If you exceed the range of indexes for the disk or node, you will receive an error that tells you the maximum index value that you can specify.

- **minimum And maximum** — The minimum and maximum amount of congestion delay, in milliseconds. Disk segments marked as congested will be delayed for a random amount of time within the range of the minimum and maximum amount of milliseconds for the duration of the simulation.

- **quantity** — The amount of time for which to simulate the disk congestion. The interval is an amount followed by a time unit. The simulation will occur for that amount of the specified time unit. For example, 20 MINUTE will result in the simulation running for 20 minutes.

Alter tables in Amazon Aurora using Fast DDL

Amazon Aurora includes optimizations to run an ALTER TABLE operation in place, nearly instantaneously. The operation completes without requiring the table to be copied and without having a material impact on other DML statements. Because the operation doesn't consume temporary storage for a table copy, it makes DDL statements practical even for large tables on small instance classes.
Aurora MySQL version 3 is compatible with the MySQL 8.0 feature called instant DDL. Aurora MySQL version 2 uses a different implementation called Fast DDL.

**Topics**

- Instant DDL (Aurora MySQL version 3)
- Fast DDL (Aurora MySQL version 2)

**Instant DDL (Aurora MySQL version 3)**

The optimization performed by Aurora MySQL version 3 to improve the efficiency of some DDL operations is called instant DDL.

Aurora MySQL version 3 is compatible with the instant DDL from community MySQL 8.0. You perform an instant DDL operation by using the clause ALGORITHM=INSTANT with the ALTER TABLE statement. For syntax and usage details about instant DDL, see [ALTER TABLE](https://dev.mysql.com/doc/refman/8.0/en/alter-table.html) and [Online DDL Operations](https://dev.mysql.com/doc/refman/8.0/en/alter-table.html) in the MySQL documentation.

The following examples demonstrate the instant DDL feature. The ALTER TABLE statements add columns and change default column values. The examples include both regular and virtual columns, and both regular and partitioned tables. At each step, you can see the results by issuing SHOW CREATE TABLE and DESCRIBE statements.

```sql
mysql> CREATE TABLE t1 (a INT, b INT, KEY(b)) PARTITION BY KEY(b) PARTITIONS 6;
Query OK, 0 rows affected (0.02 sec)

mysql> ALTER TABLE t1 RENAME TO t2, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 ALTER COLUMN b SET DEFAULT 100, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t2 ALTER COLUMN b DROP DEFAULT, ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 ADD COLUMN c ENUM('a', 'b', 'c'), ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)

mysql> ALTER TABLE t2 MODIFY COLUMN c ENUM('a', 'b', 'c', 'd', 'e'), ALGORITHM = INSTANT;
Query OK, 0 rows affected (0.01 sec)
```
Fast DDL (Aurora MySQL version 2)

Altering tables in Amazon Aurora using Fast DDL
In MySQL, many data definition language (DDL) operations have a significant performance impact.

For example, suppose that you use an `ALTER TABLE` operation to add a column to a table. Depending on the algorithm specified for the operation, this operation can involve the following:

- Creating a full copy of the table
- Creating a temporary table to process concurrent data manipulation language (DML) operations
- Rebuilding all indexes for the table
- Applying table locks while applying concurrent DML changes
- Slowing concurrent DML throughput

The optimization performed by Aurora MySQL version 2 to improve the efficiency of some DDL operations is called Fast DDL.

In Aurora MySQL version 3, Aurora uses the MySQL 8.0 feature called instant DDL. Aurora MySQL version 2 uses a different implementation called Fast DDL.

**Important**

Currently, Aurora lab mode must be enabled to use Fast DDL for Aurora MySQL. We don't recommend using Fast DDL for production DB clusters. For information about enabling Aurora lab mode, see [Amazon Aurora MySQL lab mode](#).

**Fast DDL limitations**

Currently, Fast DDL has the following limitations:

- Fast DDL only supports adding nullable columns, without default values, to the end of an existing table.
- Fast DDL doesn't work for partitioned tables.
- Fast DDL doesn't work for InnoDB tables that use the REDUNDANT row format.
- Fast DDL doesn't work for tables with full-text search indexes.
- If the maximum possible record size for the DDL operation is too large, Fast DDL is not used. A record size is too large if it is greater than half the page size. The maximum size of a record is computed by adding the maximum sizes of all columns. For variable sized columns, according to InnoDB standards, extern bytes are not included for computation.
Fast DDL syntax

```
ALTER TABLE tbl_name ADD COLUMN col_name column_definition
```

This statement takes the following options:

- **tbl_name** — The name of the table to be modified.
- **col_name** — The name of the column to be added.
- **col_definition** — The definition of the column to be added.

**Note**

You must specify a nullable column definition without a default value. Otherwise, Fast DDL isn't used.

Fast DDL examples

The following examples demonstrate the speedup from Fast DDL operations. The first SQL example runs `ALTER TABLE` statements on a large table without using Fast DDL. This operation takes substantial time. A CLI example shows how to enable Fast DDL for the cluster. Then another SQL example runs the same `ALTER TABLE` statements on an identical table. With Fast DDL enabled, the operation is very fast.

This example uses the ORDERS table from the TPC-H benchmark, containing 150 million rows. This cluster intentionally uses a relatively small instance class, to demonstrate how long `ALTER TABLE` statements can take when you can't use Fast DDL. The example creates a clone of the original table containing identical data. Checking the `aurora.lab_mode` setting confirms that the cluster can't use Fast DDL, because lab mode isn't enabled. Then `ALTER TABLE ADD COLUMN` statements take substantial time to add new columns at the end of the table.

```
mysql> create table orders_regular_ddl like orders;
Query OK, 0 rows affected (0.06 sec)

mysql> insert into orders_regular_ddl select * from orders;
Query OK, 150000000 rows affected (1 hour 1 min 25.46 sec)

mysql> select @aurora_lab_mode;
+-------------------+
<table>
<thead>
<tr>
<th>@aurora_lab_mode</th>
</tr>
</thead>
</table>
```

Alter tables in Amazon Aurora using Fast DDL
This example does the same preparation of a large table as the previous example. However, you can't simply enable lab mode within an interactive SQL session. That setting must be enabled in a custom parameter group. Doing so requires switching out of the mysql session and running some AWS CLI commands or using the AWS Management Console.

Enabling lab mode for the cluster requires some work with a parameter group. This AWS CLI example uses a cluster parameter group, to ensure that all DB instances in the cluster use the same value for the lab mode setting.
The following example shows the remaining steps after the parameter group change takes effect. It tests the `aurora_lab_mode` setting to make sure that the cluster can use Fast DDL. Then it runs `ALTER TABLE` statements to add columns to the end of another large table. This time, the statements finish very quickly.

```
mysql> select @@aurora_lab_mode;
+-------------------+
<table>
<thead>
<tr>
<th>@@aurora_lab_mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+-------------------+
```
Displaying volume status for an Aurora MySQL DB cluster

In Amazon Aurora, a DB cluster volume consists of a collection of logical blocks. Each of these represents 10 gigabytes of allocated storage. These blocks are called *protection groups*.

The data in each protection group is replicated across six physical storage devices, called *storage nodes*. These storage nodes are allocated across three Availability Zones (AZs) in the AWS Region where the DB cluster resides. In turn, each storage node contains one or more logical blocks of data for the DB cluster volume. For more information about protection groups and storage nodes, see [Introducing the Aurora storage engine](https://aws.amazon.com/blogs/database/introducing-the-aurora-storage-engine/) on the AWS Database Blog.

You can simulate the failure of an entire storage node, or a single logical block of data within a storage node. To do so, you use the `ALTER SYSTEM SIMULATE DISK FAILURE` fault injection statement. For the statement, you specify the index value of a specific logical block of data or storage node. However, if you specify an index value greater than the number of logical blocks of data or storage nodes used by the DB cluster volume, the statement returns an error. For more information about fault injection queries, see [Testing Amazon Aurora MySQL using fault injection queries](https://aws.amazon.com/blogs/database/testing-amazon-aurora-mysql-using-fault-injection-queries/).

You can avoid that error by using the `SHOW VOLUME STATUS` statement. The statement returns two server status variables, `Disks` and `Nodes`. These variables represent the total number of logical blocks of data and storage nodes, respectively, for the DB cluster volume.

**Syntax**

```
SHOW VOLUME STATUS
```

**Example**

The following example illustrates a typical `SHOW VOLUME STATUS` result.

```
mysql> SHOW VOLUME STATUS;
```
<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disks</td>
<td>96</td>
</tr>
<tr>
<td>Nodes</td>
<td>74</td>
</tr>
</tbody>
</table>
Tuning Aurora MySQL

Wait events and thread states are important tuning tools for Aurora MySQL. If you can find out why sessions are waiting for resources and what they are doing, you are better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions.

Amazon DevOps Guru for RDS can proactively determine whether your Aurora MySQL databases are experiencing problematic conditions that might cause bigger problems later. Amazon DevOps Guru for RDS publishes an explanation and recommendations for corrective actions in a proactive insight. This section contains insights for common problems.

⚠️ Important
The wait events and thread states in this section are specific to Aurora MySQL. Use the information in this section to tune only Amazon Aurora, not Amazon RDS for MySQL. Some wait events in this section have no analogs in the open source versions of these database engines. Other wait events have the same names as events in open source engines, but behave differently. For example, Amazon Aurora storage works different from open source storage, so storage-related wait events indicate different resource conditions.

Topics
- Essential concepts for Aurora MySQL tuning
- Tuning Aurora MySQL with wait events
- Tuning Aurora MySQL with thread states
- Tuning Aurora MySQL with Amazon DevOps Guru proactive insights

Essential concepts for Aurora MySQL tuning

Before you tune your Aurora MySQL database, make sure to learn what wait events and thread states are and why they occur. Also review the basic memory and disk architecture of Aurora MySQL when using the InnoDB storage engine. For a helpful architecture diagram, see the MySQL Reference Manual.

Topics
• **Aurora MySQL wait events**
• **Aurora MySQL thread states**
• **Aurora MySQL memory**
• **Aurora MySQL processes**

**Aurora MySQL wait events**

A *wait event* indicates a resource for which a session is waiting. For example, the wait event `io/socket/sql/client_connection` indicates that a thread is in the process of handling a new connection. Typical resources that a session waits for include the following:

- Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
- A row that is currently locked by another session
- A data file read
- A log file write

For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.

A wait event doesn't by itself show a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

Large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now runs for hours, you can identify the wait events that contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.
Aurora MySQL thread states

*A general thread state* is a *State* value that is associated with general query processing. For example, the thread state *sending data* indicates that a thread is reading and filtering rows for a query to determine the correct result set.

You can use thread states to tune Aurora MySQL in a similar fashion to how you use wait events. For example, frequent occurrences of *sending data* usually indicate that a query isn't using an index. For more information about thread states, see [General Thread States](#) in the *MySQL Reference Manual*.

When you use Performance Insights, one of the following conditions is true:

- Performance Schema is turned on – Aurora MySQL shows wait events rather than the thread state.
- Performance Schema isn't turned on – Aurora MySQL shows the thread state.

We recommend that you configure the Performance Schema for automatic management. The Performance Schema provides additional insights and better tools to investigate potential performance problems. For more information, see [Turning on the Performance Schema for Performance Insights on Aurora MySQL](#).

Aurora MySQL memory

In Aurora MySQL, the most important memory areas are the buffer pool and log buffer.

Topics

- **Buffer pool**

Buffer pool

The *buffer pool* is the shared memory area where Aurora MySQL caches table and index data. Queries can access frequently used data directly from memory without reading from disk.

The buffer pool is structured as a linked list of pages. A *page* can hold multiple rows. Aurora MySQL uses a least recently used (LRU) algorithm to age pages out of the pool.

For more information, see [Buffer Pool](#) in the *MySQL Reference Manual*. 
Aurora MySQL processes

Aurora MySQL uses a process model that is very different from Aurora PostgreSQL.

Topics

- MySQL server (mysqld)
- Threads
- Thread pool

MySQL server (mysqld)

The MySQL server is a single operating-system process named mysqld. The MySQL server doesn't spawn additional processes. Thus, an Aurora MySQL database uses mysqld to perform most of its work.

When the MySQL server starts, it listens for network connections from MySQL clients. When a client connects to the database, mysqld opens a thread.

Threads

Connection manager threads associate each client connection with a dedicated thread. This thread manages authentication, runs statements, and returns results to the client. Connection manager creates new threads when necessary.

The thread cache is the set of available threads. When a connection ends, MySQL returns the thread to the thread cache if the cache isn't full. The thread_cache_size system variable determines the thread cache size.

Thread pool

The thread pool consists of a number of thread groups. Each group manages a set of client connections. When a client connects to the database, the thread pool assigns the connections to thread groups in round-robin fashion. The thread pool separates connections and threads. There is no fixed relationship between connections and the threads that run statements received from those connections.
# Tuning Aurora MySQL with wait events

The following table summarizes the Aurora MySQL wait events that most commonly indicate performance problems. The following wait events are a subset of the list in Aurora MySQL wait events.

<table>
<thead>
<tr>
<th>Wait event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cpu</td>
<td>This event occurs when a thread is active in CPU or is waiting for CPU.</td>
</tr>
<tr>
<td>io/aurora_redo_log_flush</td>
<td>This event occurs when a session is writing persistent data to Aurora storage.</td>
</tr>
<tr>
<td>io/aurora_respond_to_client</td>
<td>This event occurs when a thread is waiting to return a result set to a client.</td>
</tr>
<tr>
<td>io/redu_log_flush</td>
<td>This event occurs when a session is writing persistent data to Aurora storage.</td>
</tr>
<tr>
<td>io/socket/sql/client_connection</td>
<td>This event occurs when a thread is in the process of handling a new connection.</td>
</tr>
<tr>
<td>io/table/sql/handler</td>
<td>This event occurs when work has been delegated to a storage engine.</td>
</tr>
<tr>
<td>synch/cond/innodb/row_lock_wait</td>
<td>This event occurs when one session has locked a row for an update, and another session tries to update the same row.</td>
</tr>
<tr>
<td>synch/cond/innodb/row_lock_wait_cond</td>
<td>This event occurs when one session has locked a row for an update, and another session tries to update the same row.</td>
</tr>
<tr>
<td>synch/cond/sql/MDL_context::COND_wait_status</td>
<td>This event occurs when there are threads waiting on a table metadata lock.</td>
</tr>
<tr>
<td>Wait event</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>synch/mutex/innodb/aurora_lock_thread_slot_futex</td>
<td>This event occurs when one session has locked a row for an update, and another session tries to update the same row.</td>
</tr>
<tr>
<td>synch/mutex/innodb/buf_pool_mutex</td>
<td>This event occurs when a thread has acquired a lock on the InnoDB buffer pool to access a page in memory.</td>
</tr>
<tr>
<td>synch/mutex/innodb/fil_system_mutex</td>
<td>This event occurs when a session is waiting to access the tablespace memory cache.</td>
</tr>
<tr>
<td>synch/mutex/innodb/trx_sys_mutex</td>
<td>This event occurs when there is high database activity with a large number of transactions.</td>
</tr>
<tr>
<td>synch/sxlock/innodb/hash_table_locks</td>
<td>This event occurs when pages not found in the buffer pool must be read from a file.</td>
</tr>
</tbody>
</table>

**Synopsis**

The `cpu` wait event occurs when a thread is active in CPU or is waiting for CPU.

**Topics**

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL versions 2 and 3
Context

For every vCPU, a connection can run work on this CPU. In some situations, the number of active connections that are ready to run is higher than the number of vCPUs. This imbalance results in connections waiting for CPU resources. If the number of active connections stays consistently higher than the number of vCPUs, then your instance experiences CPU contention. The contention causes the cpu wait event to occur.

**Note**

The Performance Insights metric for CPU is DBLoadCPU. The value for DBLoadCPU can differ from the value for the CloudWatch metric CPUUtilization. The latter metric is collected from the HyperVisor for a database instance.

Performance Insights OS metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

- `os.cpuUtilization.nice.avg`
- `os.cpuUtilization.total.avg`
- `os.cpuUtilization.wait.avg`
- `os.cpuUtilization.idle.avg`

Performance Insights reports the CPU usage by the database engine as `os.cpuUtilization.nice.avg`.

**Likely causes of increased waits**

When this event occurs more than normal, possibly indicating a performance problem, typical causes include the following:

- Analytic queries
- Highly concurrent transactions
- Long-running transactions
- A sudden increase in the number of connections, known as a *login storm*
- An increase in context switching
Actions

If the cpu wait event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

Depending on the cause of the increase in CPU utilization, consider the following strategies:

- Increase the CPU capacity of the host. This approach typically gives only temporary relief.
- Identify top queries for potential optimization.
- Redirect some read-only workload to reader nodes, if applicable.

Topics

- Identify the sessions or queries that are causing the problem
- Analyze and optimize the high CPU workload

Identify the sessions or queries that are causing the problem

To find the sessions and queries, look at the Top SQL table in Performance Insights for the SQL statements that have the highest CPU load. For more information, see Analyzing metrics with the Performance Insights dashboard.

Typically, one or two SQL statements consume the majority of CPU cycles. Concentrate your efforts on these statements. Suppose that your DB instance has 2 vCPUs with a DB load of 3.1 average active sessions (AAS), all in the CPU state. In this case, your instance is CPU bound. Consider the following strategies:

- Upgrade to a larger instance class with more vCPUs.
- Tune your queries to have lower CPU load.

In this example, the top SQL queries have a DB load of 1.5 AAS, all in the CPU state. Another SQL statement has a load of 0.1 in the CPU state. In this example, if you stopped the lowest-load SQL statement, you don't significantly reduce database load. However, if you optimize the two high-load queries to be twice as efficient, you eliminate the CPU bottleneck. If you reduce the CPU load of 1.5 AAS by 50 percent, the AAS for each statement decreases to 0.75. The total DB load spent on CPU is now 1.6 AAS. This value is below the maximum vCPU line of 2.0.
For a useful overview of troubleshooting using Performance Insights, see the blog post *Analyze Amazon Aurora MySQL Workloads with Performance Insights*. Also see the AWS Support article *How can I troubleshoot and resolve high CPU utilization on my Amazon RDS for MySQL instances?*.

**Analyze and optimize the high CPU workload**

After you identify the query or queries increasing CPU usage, you can either optimize them or end the connection. The following example shows how to end a connection.

```
CALL mysql.rds_kill(processID);
```

For more information, see *mysql.rds_kill*.

If you end a session, the action might trigger a long rollback.

**Follow the guidelines for optimizing queries**

To optimize queries, consider the following guidelines:

- Run the `EXPLAIN` statement.
  
  This command shows the individual steps involved in running a query. For more information, see *Optimizing Queries with EXPLAIN* in the MySQL documentation.

- Run the `SHOW PROFILE` statement.
  
  Use this statement to review profile details that can indicate resource usage for statements that are run during the current session. For more information, see *SHOW PROFILE Statement* in the MySQL documentation.

- Run the `ANALYZE TABLE` statement.
  
  Use this statement to refresh the index statistics for the tables accessed by the high-CPU consuming query. By analyzing the statement, you can help the optimizer choose an appropriate execution plan. For more information, see *ANALYZE TABLE Statement* in the MySQL documentation.

**Follow the guidelines for improving CPU usage**

To improve CPU usage in a database instance, follow these guidelines:

- Ensure that all queries are using proper indexes.
• Find out whether you can use Aurora parallel queries. You can use this technique to reduce CPU usage on the head node by pushing down function processing, row filtering, and column projection for the WHERE clause.

• Find out whether the number of SQL executions per second meets the expected thresholds.

• Find out whether index maintenance or new index creation takes up CPU cycles needed by your production workload. Schedule maintenance activities outside of peak activity times.

• Find out whether you can use partitioning to help reduce the query data set. For more information, see the blog post How to plan and optimize Amazon Aurora with MySQL compatibility for consolidated workloads.

Check for connection storms

If the DBLoadCPU metric is not very high, but the CPUUtilization metric is high, the cause of the high CPU utilization lies outside of the database engine. A classic example is a connection storm.

Check whether the following conditions are true:

• There is an increase in both the Performance Insights CPUUtilization metric and the Amazon CloudWatch DatabaseConnections metric.

• The number of threads in the CPU is greater than the number of vCPUs.

If the preceding conditions are true, consider decreasing the number of database connections. For example, you can use a connection pool such as RDS Proxy. To learn the best practices for effective connection management and scaling, see the whitepaper Amazon Aurora MySQL DBA Handbook for Connection Management.

io/aurora_redo_log_flush

The io/aurora_redo_log_flush event occurs when a session is writing persistent data to Amazon Aurora storage.

Topics

• Supported engine versions

• Context

• Likely causes of increased waits

• Actions
Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2

Context

The `io/aurora_redo_log_flush` event is for a write input/output (I/O) operation in Aurora MySQL.

💡 Note

In Aurora MySQL version 3, this wait event is named `io/redo_log_flush`.

Likely causes of increased waits

For data persistence, commits require a durable write to stable storage. If the database is doing too many commits, there is a wait event on the write I/O operation, the `io/aurora_redo_log_flush` wait event.

In the following examples, 50,000 records are inserted into an Aurora MySQL DB cluster using the db.r5.xlarge DB instance class:

- In the first example, each session inserts 10,000 records row by row. By default, if a data manipulation language (DML) command isn't within a transaction, Aurora MySQL uses implicit commits. Autocommit is turned on. This means that for each row insertion there is a commit. Performance Insights shows that the connections spend most of their time waiting on the `io/aurora_redo_log_flush` wait event.
This is caused by the simple insert statements used.

<table>
<thead>
<tr>
<th>Top SQL</th>
<th>SQL statements</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>INSERT INTO sales.<code>customers</code> (NAME, address) VALUES(1)</td>
</tr>
<tr>
<td></td>
<td>INSERT INTO sales.<code>customers</code> (NAME, address) VALUES(1, 1)</td>
</tr>
<tr>
<td></td>
<td>SELECT * FROM customers WHERE ID = 1</td>
</tr>
</tbody>
</table>

The 50,000 records take 3.5 minutes to be inserted.

- In the second example, inserts are made in 1,000 batches, that is each connection performs 10 commits instead of 10,000. Performance Insights shows that the connections don't spend most of their time on the `io/aurora_redo_log_flush` wait event.

The 50,000 records take 4 seconds to be inserted.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Identify the problematic sessions and queries**

If your DB instance is experiencing a bottleneck, your first task is to find the sessions and queries that cause it. For a useful AWS Database Blog post, see [Analyze Amazon Aurora MySQL Workloads with Performance Insights](https://aws.amazon.com/blogs/database/analyze-amazon-aurora-mysql-workloads-with-performance-insights/).

**To identify sessions and queries causing a bottleneck**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Performance Insights**.
3. Choose your DB instance.
4. In Database load, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

The queries at the top of the list are causing the highest load on the database.

**Group your write operations**

The following examples trigger the io/aurora_redo_log_flush wait event. (Autocommit is turned on.)

```
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
....
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');

UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
....
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;

DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
....
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
```

To reduce the time spent waiting on the io/aurora_redo_log_flush wait event, group your write operations logically into a single commit to reduce persistent calls to storage.

**Turn off autocommit**

Turn off autocommit before making large changes that aren't within a transaction, as shown in the following example.

```
SET SESSION AUTOCOMMIT=OFF;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
```
Use transactions

You can use transactions, as shown in the following example.

```
BEGIN
  INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
  INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
  INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
  ....
  INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');

  DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
  DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
  DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
  ....
  DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;

  -- Other DML statements here
END
```

Use batches

You can make changes in batches, as shown in the following example. However, using batches that are too large can cause performance issues, especially in read replicas or when doing point-in-time recovery (PITR).

```
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx'),('xxxx','xxxxx'),...,('xxxx','xxxxx'),('xxxx','xxxxx');

UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1 BETWEEN xx AND xxx;

DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1<xx;
```
The `io/aurora_respond_to_client` event occurs when a thread is waiting to return a result set to a client.

**Topics**
- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

**Supported engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2

In versions before version 2.07.7, 2.09.3, and 2.10.2, this wait event erroneously includes idle time.

**Context**

The event `io/aurora_respond_to_client` indicates that a thread is waiting to return a result set to a client.

The query processing is complete, and the results are being returned back to the application client. However, because there isn't enough network bandwidth on the DB cluster, a thread is waiting to return the result set.

**Likely causes of increased waits**

When the `io/aurora_respond_to_client` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

**DB instance class insufficient for the workload**

The DB instance class used by the DB cluster doesn't have the necessary network bandwidth to process the workload efficiently.
Large result sets

There was an increase in size of the result set being returned, because the query returns higher numbers of rows. The larger result set consumes more network bandwidth.

Increased load on the client

There might be CPU pressure, memory pressure, or network saturation on the client. An increase in load on the client delays the reception of data from the Aurora MySQL DB cluster.

Increased network latency

There might be increased network latency between the Aurora MySQL DB cluster and client. Higher network latency increases the time required for the client to receive the data.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Identify the sessions and queries causing the events
- Scale the DB instance class
- Check workload for unexpected results
- Distribute workload with reader instances
- Use the SQL_BUFFER_RESULT modifier

Identify the sessions and queries causing the events

You can use Performance Insights to show queries blocked by the io/aurora_respond_to_client wait event. Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Performance Insights**.

3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.

4. In the **Database load** chart, choose **Slice by wait**.

5. At the bottom of the page, choose **Top SQL**.

   The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

**Scale the DB instance class**

Check for the increase in the value of the Amazon CloudWatch metrics related to network throughput, such as `NetworkReceiveThroughput` and `NetworkTransmitThroughput`. If the DB instance class network bandwidth is being reached, you can scale the DB instance class used by the DB cluster by modifying the DB cluster. A DB instance class with larger network bandwidth returns data to clients more efficiently.

For information about monitoring Amazon CloudWatch metrics, see [Viewing metrics in the Amazon RDS console](https://aws.amazon.com/rds/view-metrics/). For information about DB instance classes, see [Aurora DB instance classes](https://aws.amazon.com/rds/db-instance-classes/). For information about modifying a DB cluster, see [Modifying an Amazon Aurora DB cluster](https://aws.amazon.com/rds/modify-db-cluster/).

**Check workload for unexpected results**

Check the workload on the DB cluster and make sure that it isn't producing unexpected results. For example, there might be queries that are returning a higher number of rows than expected. In this case, you can use Performance Insights counter metrics such as `Innodb_rows_read`. For more information, see [Performance Insights counter metrics](https://aws.amazon.com/rds/performance-insights-counter-metrics/).

**Distribute workload with reader instances**

You can distribute read-only workload with Aurora replicas. You can scale horizontally by adding more Aurora replicas. Doing so can result in an increase in the throttling limits for network bandwidth. For more information, see [Amazon Aurora DB clusters](https://aws.amazon.com/rds/aurora-db-clusters/).

**Use the SQL_BUFFER_RESULT modifier**

You can add the `SQL_BUFFER_RESULT` modifier to `SELECT` statements to force the result into a temporary table before they are returned to the client. This modifier can help with
performance issues when InnoDB locks aren't being freed because queries are in the `io/aurora_respond_to_client` wait state. For more information, see SELECT Statement in the MySQL documentation.

**io/redo_log_flush**

The `io/redo_log_flush` event occurs when a session is writing persistent data to Amazon Aurora storage.

**Topics**

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

**Supported engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL version 3

**Context**

The `io/redo_log_flush` event is for a write input/output (I/O) operation in Aurora MySQL.

**Note**

In Aurora MySQL version 2, this wait event is named `io/aurora_redo_log_flush`.

**Likely causes of increased waits**

For data persistence, commits require a durable write to stable storage. If the database is doing too many commits, there is a wait event on the write I/O operation, the `io/redo_log_flush` wait event.

For examples of the behavior of this wait event, see `io/aurora_redo_log_flush`.
Actions

We recommend different actions depending on the causes of your wait event.

Identify the problematic sessions and queries

If your DB instance is experiencing a bottleneck, your first task is to find the sessions and queries that cause it. For a useful AWS Database Blog post, see [Analyze Amazon Aurora MySQL Workloads with Performance Insights](https://aws.amazon.com/blogs/database/analyze-amazon-aurora-mysql-workloads-with-performance-insights/).

To identify sessions and queries causing a bottleneck

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Performance Insights.
3. Choose your DB instance.
4. In Database load, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

The queries at the top of the list are causing the highest load on the database.

Group your write operations

The following examples trigger the io/redo_log_flush wait event. (Autocommit is turned on.)

```sql
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
....
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');

UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;
....
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE id=xx;

DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
```
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;

To reduce the time spent waiting on the io/redo_log_flush wait event, group your write operations logically into a single commit to reduce persistent calls to storage.

**Turn off autocommit**

Turn off autocommit before making large changes that aren't within a transaction, as shown in the following example.

```
SET SESSION AUTOCOMMIT=OFF;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
....
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1=xx;
-- Other DML statements here
COMMIT;
SET SESSION AUTOCOMMIT=ON;
```

**Use transactions**

You can use transactions, as shown in the following example.

```
BEGIN
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');
....
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx');

DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
....
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1=xx;
-- Other DML statements here
END
```
Use batches

You can make changes in batches, as shown in the following example. However, using batches that are too large can cause performance issues, especially in read replicas or when doing point-in-time recovery (PITR).

```
INSERT INTO `sampleDB`.`sampleTable` (sampleCol2, sampleCol3) VALUES ('xxxx','xxxxx'), ('xxxx','xxxxx'), ..., ('xxxx','xxxxx'), ('xxxx','xxxxx');
UPDATE `sampleDB`.`sampleTable` SET sampleCol3='xxxxx' WHERE sampleCol1 BETWEEN xx AND xxx;
DELETE FROM `sampleDB`.`sampleTable` WHERE sampleCol1<xx;
```

io/socket/sql/client_connection

The io/socket/sql/client_connection event occurs when a thread is in the process of handling a new connection.

Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

Supported engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL versions 2 and 3

Context

The event io/socket/sql/client_connection indicates that mysqld is busy creating threads to handle incoming new client connections. In this scenario, the processing of servicing new client connection requests slows down while connections wait for the thread to be assigned. For more information, see [MySQL server (mysqld)](https://dev.mysql.com/doc/mysql/).
Likely causes of increased waits

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- There is a sudden increase in new user connections from the application to your Amazon RDS instance.
- Your DB instance can't process new connections because the network, CPU, or memory is being throttled.

Actions

If io/socket/sql/client_connection dominates database activity, it doesn't necessarily indicate a performance problem. In a database that isn't idle, a wait event is always on top. Act only when performance degrades. We recommend different actions depending on the causes of your wait event.

Topics

- Identify the problematic sessions and queries
- Follow best practices for connection management
- Scale up your instance if resources are being throttled
- Check the top hosts and top users
- Query the performance_schema tables
- Check the thread states of your queries
- Audit your requests and queries
- Pool your database connections

Identify the problematic sessions and queries

If your DB instance is experiencing a bottleneck, your first task is to find the sessions and queries that cause it. For a useful blog post, see Analyze Amazon Aurora MySQL Workloads with Performance Insights.

To identify sessions and queries causing a bottleneck

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Performance Insights**.

3. Choose your DB instance.

4. In **Database load**, choose **Slice by wait**.

5. At the bottom of the page, choose **Top SQL**.

   The queries at the top of the list are causing the highest load on the database.

**Follow best practices for connection management**

To manage your connections, consider the following strategies:

- Use connection pooling.

  You can gradually increase the number of connections as required. For more information, see the whitepaper [Amazon Aurora MySQL Database Administrator's Handbook](https://aws.amazon.com/africa/aurora/mysql-db-admin-handbook/).

- Use a reader node to redistribute read-only traffic.

  For more information, see [Aurora Replicas](https://aws.amazon.com/africa/aurora/mysql-replication/) and [Amazon Aurora connection management](https://aws.amazon.com/africa/aurora/mysql-connection-management/).

**Scale up your instance if resources are being throttled**

Look for examples of throttling in the following resources:

- **CPU**

  Check your Amazon CloudWatch metrics for high CPU usage.

- **Network**

  Check for an increase in the value of the CloudWatch metrics `network_receive_throughput` and `network_transmit_throughput`. If your instance has reached the network bandwidth limit for your instance class, consider scaling up your RDS instance to a higher instance class type. For more information, see [Aurora DB instance classes](https://aws.amazon.com/africa/aurora/mysql-instance-classes/).

- **Freeable memory**

  Check for a drop in the CloudWatch metric `FreeableMemory`. Also, consider turning on Enhanced Monitoring. For more information, see [Monitoring OS metrics with Enhanced Monitoring](https://aws.amazon.com/africa/aurora/mysql-os-monitoring/).
Check the top hosts and top users

Use Performance Insights to check the top hosts and top users. For more information, see [Analyzing metrics with the Performance Insights dashboard](#).

Query the performance_schema tables

To get an accurate count of the current and total connections, query the `performance_schema` tables. With this technique, you identify the source user or host that is responsible for creating a high number of connections. For example, query the `performance_schema` tables as follows.

```sql
SELECT * FROM performance_schema.accounts;
SELECT * FROM performance_schema.users;
SELECT * FROM performance_schema.hosts;
```

Check the thread states of your queries

If your performance issue is ongoing, check the thread states of your queries. In the `mysql` client, issue the following command.

```
show processlist;
```

Audit your requests and queries

To check the nature of the requests and queries from user accounts, use Aurora MySQL Advanced Auditing. To learn how to turn on auditing, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster](#).

Pool your database connections

Consider using Amazon RDS Proxy for connection management. By using RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. For more information, see [Using Amazon RDS Proxy for Aurora](#).

**io/table/sql/handler**

The `io/table/sql/handler` event occurs when work has been delegated to a storage engine.

**Topics**
• **Supported engine versions**

• **Context**

• **Likely causes of increased waits**

• **Actions**

**Supported engine versions**

This wait event information is supported for the following engine versions:

• Aurora MySQL version 3: 3.01.0 and 3.01.1

• Aurora MySQL version 2

**Context**

The event `io/table` indicates a wait for access to a table. This event occurs regardless of whether the data is cached in the buffer pool or accessed on disk. The `io/table/sql/handler` event indicates an increase in workload activity.

A *handler* is a routine specialized in a certain type of data or focused on certain special tasks. For example, an event handler receives and digests events and signals from the operating system or from a user interface. A memory handler performs tasks related to memory. A file input handler is a function that receives file input and performs special tasks on the data, according to context.

Views such as `performance_schema.events_waits_current` often show `io/table/sql/handler` when the actual wait is a nested wait event such as a lock. When the actual wait isn't `io/table/sql/handler`, Performance Insights reports the nested wait event. When Performance Insights reports `io/table/sql/handler`, it represents InnoDB processing of the I/O request and not a hidden nested wait event. For more information, see [Performance Schema Atom and Molecule Events](https://dev.mysql.com/doc/refman/8.0/en/performance-schema-atom-molecule-events.html) in the MySQL Reference Manual.

**Note**

However, in Aurora MySQL versions 3.01.0 and 3.01.1, `synch/mutex/innodb/aurora_lock_thread_slot_futex` is reported as `io/table/sql/handler`.

The `io/table/sql/handler` event often appears in top wait events with I/O waits such as `io/aurora_redo_log_flush` and `io/file/innodb/innodb_data_file`. 
Likely causes of increased waits

In Performance Insights, sudden spikes in the io/table/sql/handler event indicate an increase in workload activity. Increased activity means increased I/O.

Performance Insights filters the nesting event IDs and doesn't report a io/table/sql/handler wait when the underlying nested event is a lock wait. For example, if the root cause event is synch/mutex/innodb/aurora_lock_thread_slot_futex, Performance Insights displays this wait in top wait events and not io/table/sql/handler.

In views such as performance_schema.events_waits_current, waits for io/table/sql/handler often appear when the actual wait is a nested wait event such as a lock. When the actual wait differs from io/table/sql/handler, Performance Insights looks up the nested wait and reports the actual wait instead of io/table/sql/handler. When Performance Insights reports io/table/sql/handler, the real wait is io/table/sql/handler and not a hidden nested wait event. For more information, see Performance Schema Atom and Molecule Events in the MySQL 5.7 Reference Manual.

Note

However, in Aurora MySQL versions 3.01.0 and 3.01.1, synch/mutex/innodb/aurora_lock_thread_slot_futex is reported as io/table/sql/handler.

Actions

If this wait event dominates database activity, it doesn't necessarily indicate a performance problem. A wait event is always on top when the database is active. You need to act only when performance degrades.

We recommend different actions depending on the other wait events that you see.

Topics

- Identify the sessions and queries causing the events
- Check for a correlation with Performance Insights counter metrics
- Check for other correlated wait events
Identify the sessions and queries causing the events

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance is not optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the Database load chart, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

Check for a correlation with Performance Insights counter metrics

Check for Performance Insights counter metrics such as Innodb_rows_changed. If counter metrics are correlated with io/table/sql/handler, follow these steps:

1. In Performance Insights, look for the SQL statements accounting for the io/table/sql/handler top wait event. If possible, optimize this statement so that it returns fewer rows.
2. Retrieve the top tables from the schema_table_statistics and x$schema_table_statistics views. These views show the amount of time spent per table. For more information, see The schema_table_statistics and x$schema_table_statistics Views in the MySQL Reference Manual.

By default, rows are sorted by descending total wait time. Tables with the most contention appear first. The output indicates whether time is spent on reads, writes, fetches, inserts, updates, or deletes. The following example was run on an Aurora MySQL 2.09.1 instance.
Check for other correlated wait events

If synch/sxlock/innodb/btr_search_latch and io/table/sql/handler contribute most to the DB load anomaly together, check whether the innodb_adaptive_hash_index variable is turned on. If it is, consider increasing the innodb_adaptive_hash_index_parts parameter value.

If the Adaptive Hash Index is turned off, consider turning it on. To learn more about the MySQL Adaptive Hash Index, see the following resources:

- The article Is Adaptive Hash Index in InnoDB right for my workload? on the Percona website
- Adaptive Hash Index in the MySQL Reference Manual
- The article Contention in MySQL InnoDB: Useful Info From the Semaphores Section on the Percona website
**Note**

The Adaptive Hash Index isn't supported on Aurora reader DB instances. In some cases, performance might be poor on a reader instance when `synch/sxlock/innodb/btr_search_latch` and `io/table/sql/handler` are dominant. If so, consider redirecting the workload temporarily to the writer DB instance and turning on the Adaptive Hash Index.

**synch/cond/innodb/row_lock_wait**

The `synch/cond/innodb/row_lock_wait` event occurs when one session has locked a row for an update, and another session tries to update the same row. For more information, see [InnoDB locking](https://dev.mysql.com/doc/refman/8.0/en/innodb-locking-mechanisms.html) in the *MySQL Reference*.

**Supported engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL version 3: 3.02.0, 3.02.1, 3.02.2

**Likely causes of increased waits**

Multiple data manipulation language (DML) statements are accessing the same row or rows simultaneously.

**Actions**

We recommend different actions depending on the other wait events that you see.

**Topics**

- [Find and respond to the SQL statements responsible for this wait event](#)
- [Find and respond to the blocking session](#)

**Find and respond to the SQL statements responsible for this wait event**

Use Performance Insights to identify the SQL statements responsible for this wait event. Consider the following strategies:
• If row locks are a persistent problem, consider rewriting the application to use optimistic locking.

• Use multirow statements.

• Spread the workload over different database objects. You can do this through partitioning.

• Check the value of the innodb_lock_wait_timeout parameter. It controls how long transactions wait before generating a timeout error.

For a useful overview of troubleshooting using Performance Insights, see the blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

Find and respond to the blocking session

Determine whether the blocking session is idle or active. Also, find out whether the session comes from an application or an active user.

To identify the session holding the lock, you can run SHOW ENGINE INNODB STATUS. The following example shows sample output.

```sql
mysql> SHOW ENGINE INNODB STATUS;
---TRANSACTION 1688153, ACTIVE 82 sec starting index read
mysql tables in use 1, locked 1
LOCK WAIT 2 lock struct(s), heap size 1136, 2 row lock(s)
MySQL thread id 4244, OS thread handle 70369524330224, query id 4020834 172.31.14.179
reinvent executing
select id1 from test.t1 where id1=1 for update
------- TRX HAS BEEN WAITING 24 SEC FOR THIS LOCK TO BE GRANTED:
RECORD LOCKS space id 11 page no 4 n bits 72 index GEN_CLUST_INDEX of table test.t1 trx
id 1688153 lock_mode X waiting
Record lock, heap no 2 PHYSICAL RECORD: n_fields 5; compact format; info bits 0
```

Or you can use the following query to extract details on current locks.

```sql
mysql> SELECT p1.id waiting_thread,
    p1.user waiting_user,
    p1.host waiting_host,
    it1.trx_query waiting_query,
    ilw.requesting_engine_transaction_id waiting_transaction,
    ilw.blocking_engine_lock_id blocking_transaction,
    il.lock_mode blocking_mode,
```
When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see Ending a session or query.
For more information about identifying blocking transactions, see Using InnoDB Transaction and Locking Information in the MySQL Reference Manual.

**synch/cond/innodb/row_lock_wait_cond**

The synch/cond/innodb/row_lock_wait_cond event occurs when one session has locked a row for an update, and another session tries to update the same row. For more information, see InnoDB locking in the MySQL Reference.

**Supported engine versions**

This wait event information is supported for the following engine versions:

- Aurora MySQL version 2

**Likely causes of increased waits**

Multiple data manipulation language (DML) statements are accessing the same row or rows simultaneously.

**Actions**

We recommend different actions depending on the other wait events that you see.

**Topics**

- Find and respond to the SQL statements responsible for this wait event
- Find and respond to the blocking session

**Find and respond to the SQL statements responsible for this wait event**

Use Performance Insights to identify the SQL statements responsible for this wait event. Consider the following strategies:

- If row locks are a persistent problem, consider rewriting the application to use optimistic locking.
- Use multirow statements.
- Spread the workload over different database objects. You can do this through partitioning.
- Check the value of the innodb_lock_wait_timeout parameter. It controls how long transactions wait before generating a timeout error.
For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](https://aws.amazon.com/blogs/database/analyze-aurora-mysql-workloads-performance-insights/).

Find and respond to the blocking session

Determine whether the blocking session is idle or active. Also, find out whether the session comes from an application or an active user.

To identify the session holding the lock, you can run `SHOW ENGINE INNODB STATUS`. The following example shows sample output.

```plaintext
mysql> SHOW ENGINE INNODB STATUS;
---TRANSACTION 2771110, ACTIVE 112 sec starting index read
mysql tables in use 1, locked 1
LOCK WAIT 2 lock struct(s), heap size 1136, 1 row lock(s)
MySQL thread id 24, OS thread handle 70369573642160, query id 13271336 172.31.14.179
  reinvent Sending data
select id1 from test.t1 where id1=1 for update
------- TRX HAS BEEN WAITING 43 SEC FOR THIS LOCK TO BE GRANTED:
RECORD LOCKS space id 11 page no 3 n bits 0 index GEN_CLUST_INDEX of table test.t1 trx id 2771110 lock_mode X waiting
Record lock, heap no 2 PHYSICAL RECORD: n_fields 5; compact format; info bits 0
```

Or you can use the following query to extract details on current locks.

```sql
mysql> SELECT p1.id waiting_thread, p1.user waiting_user, p1.host waiting_host, it1.trx_query waiting_query, ilw.requesting_trx_id waiting_transaction, ilw.blocking_lock_id blocking_lock, il.lock_mode blocking_mode, il.lock_type blocking_type, ilw.blocking_trx_id blocking_transaction, CASE it.trx_state WHEN 'LOCK WAIT' THEN it.trx_state ELSE p.state END blocker_state, il.lock_table locked_table, it.trx_mysql_thread_id blocker_thread,
```
Tuning Aurora MySQL with wait events

When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see Ending a session or query.

For more information about identifying blocking transactions, see Using InnoDB Transaction and Locking Information in the MySQL Reference Manual.
synch/cond/sql/MDL_context::COND_wait_status

The synch/cond/sql/MDL_context::COND_wait_status event occurs when there are threads waiting on a table metadata lock.

Topics

• Supported engine versions
• Context
• Likely causes of increased waits
• Actions

Supported engine versions

This wait event information is supported for the following engine versions:

• Aurora MySQL versions 2 and 3

Context

The event synch/cond/sql/MDL_context::COND_wait_status indicates that there are threads waiting on a table metadata lock. In some cases, one session holds a metadata lock on a table and another session tries to get the same lock on the same table. In such a case, the second session waits on the synch/cond/sql/MDL_context::COND_wait_status wait event.

MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. Metadata locking applies to tables, schemas, scheduled events, tablespaces, and user locks acquired with the get_lock function, and stored programs. Stored programs include procedures, functions, and triggers. For more information, see Metadata locking in the MySQL documentation.

The MySQL process list shows this session in the state waiting for metadata lock. In Performance Insights, if Performance_schema is turned on, the event synch/cond/sql/MDL_context::COND_wait_status appears.

The default timeout for a query waiting on a metadata lock is based on the value of the lock_wait_timeout parameter, which defaults to 31,536,000 seconds (365 days).

For more details on different InnoDB locks and the types of locks that can cause conflicts, see InnoDB Locking in the MySQL documentation.
Likely causes of increased waits

When the synch/cond/sql/MDL_context::COND_wait_status event appears more than normal, possibly indicating a performance problem, typical causes include the following:

**Long-running transactions**

One or more transactions are modifying a large amount of data and holding locks on tables for a very long time.

**Idle transactions**

One or more transactions remain open for a long time, without being committed or rolled back.

**DDL statements on large tables**

One or more data definition statements (DDL) statements, such as ALTER TABLE commands, were run on very large tables.

**Explicit table locks**

There are explicit locks on tables that aren't being released in a timely manner. For example, an application might run LOCK TABLE statements improperly.

**Actions**

We recommend different actions depending on the causes of your wait event and on the version of the Aurora MySQL DB cluster.

**Topics**

- Identify the sessions and queries causing the events
- Check for past events
- Run queries on Aurora MySQL version 2
- Respond to the blocking session

**Identify the sessions and queries causing the events**

You can use Performance Insights to show queries blocked by the synch/cond/sql/MDL_context::COND_wait_status wait event. However, to identify the blocking session, query metadata tables from performance_schema and information_schema on the DB cluster.
Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.

**To find SQL queries that are responsible for high load**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard for that DB instance appears.
4. In the **Database load** chart, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

   The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

**Check for past events**

You can gain insight into this wait event to check for past occurrences of it. To do so, complete the following actions:

- Check the data manipulation language (DML) and DDL throughput and latency to see if there were any changes in workload.

  You can use Performance Insights to find queries waiting on this event at the time of the issue. Also, you can view the digest of the queries run near the time of issue.

- If audit logs or general logs are turned on for the DB cluster, you can check for all queries run on the objects (schema.table) involved in the waiting transaction. You can also check for the queries that completed running before the transaction.

The information available to troubleshoot past events is limited. Performing these checks doesn't show which object is waiting for information. However, you can identify tables with heavy load at the time of the event and the set of frequently operated rows causing conflict at the time of issue.
You can then use this information to reproduce the issue in a test environment and provide insights about its cause.

Run queries on Aurora MySQL version 2

In Aurora MySQL version 2, you can identify the blocked session directly by querying performance_schema tables or sys schema views. An example can illustrate how to query tables to identify blocking queries and sessions.

In the following process list output, the connection ID 89 is waiting on a metadata lock, and it's running a TRUNCATE TABLE command. In a query on the performance_schema tables or sys schema views, the output shows that the blocking session is 76.

MySQL [(none)]> select @@version, @@aurora_version;
+-----------+------------------+
<table>
<thead>
<tr>
<th>@@version</th>
<th>@@aurora_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.7.12</td>
<td>2.09.0</td>
</tr>
</tbody>
</table>
+-----------+------------------+
1 row in set (0.01 sec)

MySQL [(none)]> show processlist;
+----+-----------------+--------------------+-----------+---------+------+
| Id | User            | Host               | db        | Command | Time |
| Info                          |                          |
+----+-----------------+--------------------+-----------+---------+------+
|  2 | rdsadmin        | localhost          | NULL      | Sleep   | 0    |
| NULL                          |                          |
|  4 | rdsadmin        | localhost          | NULL      | Sleep   | 2    |

| NULL                          |                          |
| 67 | auroramysql5712 | 172.31.21.51:52158 | sbtest123 | Sleep   | 0    |
| NULL                          |                          |

Tuning Aurora MySQL with wait events
Next, a query on the `performance_schema` tables or `sys` schema views shows that the blocking session is 76.

```
MySQL [(none)]> select * from sys.schema_table_lock_waits;
```

```
+---------------+-------------+-------------------+-------------+
| object_schema | object_name | waiting_thread_id | waiting_pid  |
| waiting_lock_type | waiting_lock_duration | waiting_query               |
| blocking_thread_id | blocking_pid | blocking_account | blocking_lock_type |
| blocking_lock_duration | sql_kill_blocking_query | sql_kill_blocking_connection |
+---------------+-------------+-------------------+-------------+
```

18 rows in set (0.00 sec)
Respond to the blocking session

When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see [Ending a session or query](#).

For more information about identifying blocking transactions, see [Using InnoDB Transaction and Locking Information](#) in the MySQL documentation.

**synch/mutex/inndodb/aurora_lock_thread_slot_futex**

The synch/mutex/inndodb/aurora_lock_thread_slot_futex event occurs when one session has locked a row for an update, and another session tries to update the same row. For more information, see [InnoDB locking](#) in the MySQL Reference.

**Supported engine versions**

This wait event information is supported for the following engine versions:
• Aurora MySQL version 2

**Note**

In Aurora MySQL versions 3.01.0 and 3.01.1, this wait event is reported as `io/table/sql/handler`.

**Likely causes of increased waits**

Multiple data manipulation language (DML) statements are accessing the same row or rows simultaneously.

**Actions**

We recommend different actions depending on the other wait events that you see.

**Topics**

- [Find and respond to the SQL statements responsible for this wait event](#)
- [Find and respond to the blocking session](#)

**Find and respond to the SQL statements responsible for this wait event**

Use Performance Insights to identify the SQL statements responsible for this wait event. Consider the following strategies:

- If row locks are a persistent problem, consider rewriting the application to use optimistic locking.
- Use multirow statements.
- Spread the workload over different database objects. You can do this through partitioning.
- Check the value of the `innodb_lock_wait_timeout` parameter. It controls how long transactions wait before generating a timeout error.

For a useful overview of troubleshooting using Performance Insights, see the blog post [Analyze Amazon Aurora MySQL Workloads with Performance Insights](#).
Find and respond to the blocking session

Determine whether the blocking session is idle or active. Also, find out whether the session comes from an application or an active user.

To identify the session holding the lock, you can run `SHOW ENGINE INNODB STATUS`. The following example shows sample output.

```
mysql> SHOW ENGINE INNODB STATUS;

---------------------TRANSACTION 302631452, ACTIVE 2 sec starting index read
mysql tables in use 1, locked 1
LOCK WAIT 2 lock struct(s), heap size 376, 1 row lock(s)
MySQL thread id 80109, OS thread handle 0x2ae915060700, query id 938819 10.0.4.12
reinvent updating
UPDATE sbtest1 SET k=k+1 WHERE id=503
------- TRX HAS BEEN WAITING 2 SEC FOR THIS LOCK TO BE GRANTED:
RECORD LOCKS space id 148 page no 11 n bits 30 index `PRIMARY` of table
`sysbench2`.`sbtest1` trx id 302631452 lock_mode X locks rec but not gap waiting
Record lock, heap no 30 PHYSICAL RECORD: n_fields 6; compact format; info bits 0
```

Or you can use the following query to extract details on current locks.

```
mysql> SELECT p1.id waiting_thread, 
    p1.user waiting_user, 
    p1.host waiting_host, 
    it1.trx_query waiting_query, 
    ilw.requesting_trx_id waiting_transaction, 
    ilw.blocking_lock_id blocking_lock, 
    il.lock_mode blocking_mode, 
    il.lock_type blocking_type, 
    ilw.blocking_trx_id blocking_transaction, 
    CASE it.trx_state 
    WHEN 'LOCK WAIT' 
    THEN it.trx_state 
    ELSE p.state 
    END blocker_state, 
    il.lock_table locked_table, 
    it.trx_mysql_thread_id blocker_thread, 
    p.user blocker_user, 
    p.host blocker_host 
FROM information_schema.innodb_lock_waits ilw 
JOIN information_schema.innodb_locks il
```
When you identify the session, your options include the following:

- Contact the application owner or the user.
- If the blocking session is idle, consider ending the blocking session. This action might trigger a long rollback. To learn how to end a session, see [Ending a session or query](#).

For more information about identifying blocking transactions, see [Using InnoDB Transaction and Locking Information](#) in the MySQL Reference Manual.

**synch/mutex/innodb/buf_pool_mutex**

The `synch/mutex/innodb/buf_pool_mutex` event occurs when a thread has acquired a lock on the InnoDB buffer pool to access a page in memory.
Topics

• Relevant engine versions
• Context
• Likely causes of increased waits
• Actions

Relevant engine versions

This wait event information is supported for the following engine versions:

• Aurora MySQL version 2

Context

The buf_pool mutex is a single mutex that protects the control data structures of the buffer pool.

For more information, see Monitoring InnoDB Mutex Waits Using Performance Schema in the MySQL documentation.

Likely causes of increased waits

This is a workload-specific wait event. Common causes for synch/mutex/innodb/buf_pool_mutex to appear among the top wait events include the following:

• The buffer pool size isn't large enough to hold the working set of data.
• The workload is more specific to certain pages from a specific table in the database, leading to contention in the buffer pool.

Actions

We recommend different actions depending on the causes of your wait event.

Identify the sessions and queries causing the events

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.
To view the Top SQL chart in the AWS Management Console

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the Database load chart, choose Slice by wait.
5. Underneath the Database load chart, choose Top SQL.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

Use Performance Insights

This event is related to workload. You can use Performance Insights to do the following:

• Identify when wait events start, and whether there's any change in the workload around that time from the application logs or related sources.
• Identify the SQL statements responsible for this wait event. Examine the execution plan of the queries to make sure that these queries are optimized and using appropriate indexes.

If the top queries responsible for the wait event are related to the same database object or table, then consider partitioning that object or table.

Create Aurora Replicas

You can create Aurora Replicas to serve read-only traffic. You can also use Aurora Auto Scaling to handle surges in read traffic. Make sure to run scheduled read-only tasks and logical backups on Aurora Replicas.

For more information, see Using Amazon Aurora Auto Scaling with Aurora Replicas.

Examine the buffer pool size

Check whether the buffer pool size is sufficient for the workload by looking at the metric innodb_buffer_pool_wait_free. If the value of this metric is high and
increasing continuously, that indicates that the size of the buffer pool isn't sufficient to handle the workload. If `innodb_buffer_pool_size` has been set properly, the value of `innodb_buffer_pool_wait_free` should be small. For more information, see `Innodb_buffer_pool_wait_free` in the MySQL documentation.

Increase the buffer pool size if the DB instance has enough memory for session buffers and operating-system tasks. If it doesn't, change the DB instance to a larger DB instance class to get additional memory that can be allocated to the buffer pool.

**Note**

Aurora MySQL automatically adjusts the value of `innodb_buffer_pool_instances` based on the configured `innodb_buffer_pool_size`.

**Monitor the global status history**

By monitoring the change rates of status variables, you can detect locking or memory issues on your DB instance. Turn on Global Status History (GoSH) if it isn't already turned on. For more information on GoSH, see [Managing the global status history](#).

You can also create custom Amazon CloudWatch metrics to monitor status variables. For more information, see [Publishing custom metrics](#).

**synch/mutex/innodb/fil_system_mutex**

The `synch/mutex/innodb/fil_system_mutex` event occurs when a session is waiting to access the tablespace memory cache.

**Topics**
- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

**Supported engine versions**

This wait event information is supported for the following engine versions:
• Aurora MySQL versions 2 and 3

Context

InnoDB uses tablespaces to manage the storage area for tables and log files. The `tablespace` memory cache is a global memory structure that maintains information about tablespaces. MySQL uses `synch/mutex/innodb/fil_system_mutex` waits to control concurrent access to the tablespace memory cache.

The event `synch/mutex/innodb/fil_system_mutex` indicates that there is currently more than one operation that needs to retrieve and manipulate information in the tablespace memory cache for the same tablespace.

Likely causes of increased waits

When the `synch/mutex/innodb/fil_system_mutex` event appears more than normal, possibly indicating a performance problem, this typically occurs when all of the following conditions are present:

- An increase in concurrent data manipulation language (DML) operations that update or delete data in the same table.
- The tablespace for this table is very large and has a lot of data pages.
- The fill factor for these data pages is low.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Identify the sessions and queries causing the events
- Reorganize large tables during off-peak hours

Identify the sessions and queries causing the events

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, examine where the database is spending the most time. Look at the wait events that contribute to the highest load, and find out whether you can optimize the database and application to reduce those events.
To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Performance Insights.
3. Choose a DB instance. The Performance Insights dashboard appears for that DB instance.
4. In the Database load chart, choose Slice by wait.
5. At the bottom of the page, choose Top SQL.

The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

For a useful overview of troubleshooting using Performance Insights, see the blog post Analyze Amazon Aurora MySQL Workloads with Performance Insights.

Another way to find out which queries are causing high numbers of synch/mutex/innodb/fil_system_mutex waits is to check performance_schema, as in the following example.

```sql
mysql> select * from performance_schema.events_waits_current where EVENT_NAME='wait/synch/mutex/innodb/fil_system_mutex'\G
*************************** 1. row ***************************
<table>

**Tuning Aurora MySQL with wait events**
Reorganize large tables during off-peak hours

Reorganize large tables that you identify as the source of high numbers of synch/mutex/innodb/fil_system_mutex wait events during a maintenance window outside of production hours. Doing so ensures that the internal tables spaces map cleanup doesn't occur when quick access to the table is critical. For information about reorganizing tables, see OPTIMIZE TABLE Statement in the MySQL Reference.

synch/mutex/innodb/trx_sys_mutex

The synch/mutex/innodb/trx_sys_mutex event occurs when there is high database activity with a large number of transactions.

Topics

- Relevant engine versions
- Context
- Likely causes of increased waits
- Actions

Relevant engine versions

This wait event information is supported for the following engine versions:

- Aurora MySQL versions 2 and 3

Context

Internally, the InnoDB database engine uses the repeatable read isolation level with snapshots to provide read consistency. This gives you a point-in-time view of the database at the time the snapshot was created.

In InnoDB, all changes are applied to the database as soon as they arrive, regardless of whether they're committed. This approach means that without multiversion concurrency control (MVCC), all users connected to the database see all of the changes and the latest rows. Therefore, InnoDB requires a way to track the changes to understand what to roll back when necessary.

To do this, InnoDB uses a transaction system (trx_sys) to track snapshots. The transaction system does the following:
• Tracks the transaction ID for each row in the undo logs.
• Uses an internal InnoDB structure called ReadView that helps to identify which transaction IDs are visible for a snapshot.

Likely causes of increased waits

Any database operation that requires the consistent and controlled handling (creating, reading, updating, and deleting) of transactions IDs generates a call fromtrx_sys to the mutex.

These calls happen inside three functions:

•trx_sys_mutex_enter – Creates the mutex.
•trx_sys_mutex_exit – Releases the mutex.
•trx_sys_mutex_own – Tests whether the mutex is owned.

The InnoDB Performance Schema instrumentation tracks alltrx_sys mutex calls. Tracking includes, but isn't limited to, management oftrx_sys on database startup or shutdown, rollback operations, undo cleanups, row read access, and buffer pool loads. High database activity with a large number of transactions results in synch/mutex/innodb/trx_sys_mutex appearing among the top wait events.

For more information, see Monitoring InnoDB Mutex Waits Using Performance Schema in the MySQL documentation.

Actions

We recommend different actions depending on the causes of your wait event.

Identify the sessions and queries causing the events

Typically, databases with moderate to significant load have wait events. The wait events might be acceptable if performance is optimal. If performance isn't optimal, then examine where the database is spending the most time. Look at the wait events that contribute to the highest load. Find out whether you can optimize the database and application to reduce those events.

To view the Top SQL chart in the AWS Management Console

1. Open the Amazon RDS console athttps://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. Under the **Database load** chart, choose **Top SQL**.

   The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

### Examine other wait events

Examine the other wait events associated with the `synch/mutex/innodb/trx_sys_mutex` wait event. Doing this can provide more information about the nature of the workload. A large number of transactions might reduce throughput, but the workload might also make this necessary.

For more information on how to optimize transactions, see [Optimizing InnoDB Transaction Management](https://docs.oracle.com/en/database/oracle/database/121/appmgmt/optimizing.html) in the MySQL documentation.

### synch/sxlock/innodb/hash_table_locks

The `synch/sxlock/innodb/hash_table_locks` event occurs when pages not found in the buffer pool must be read from storage.

### Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

### Supported engine versions

This wait event information is supported for the following versions:

- Aurora MySQL versions 2 and 3
Context

The event synch/sxlock/innodb/hash_table_locks indicates that a workload is frequently accessing data that isn't stored in the buffer pool. This wait event is associated with new page additions and old data evictions from the buffer pool. The data stored in the buffer pool aged and new data must be cached, so the aged pages are evicted to allow caching of the new pages. MySQL uses a least recently used (LRU) algorithm to evict pages from the buffer pool. The workload is trying to access data that hasn't been loaded into the buffer pool or data that has been evicted from the buffer pool.

This wait event occurs when the workload must access the data in files on disk or when blocks are freed from or added to the buffer pool's LRU list. These operations wait to obtain a shared excluded lock (SX-lock). This SX-lock is used for the synchronization over the hash table, which is a table in memory designed to improve buffer pool access performance.

For more information, see Buffer Pool in the MySQL documentation.

Likely causes of increased waits

When the synch/sxlock/innodb/hash_table_locks wait event appears more than normal, possibly indicating a performance problem, typical causes include the following:

An undersized buffer pool

The size of the buffer pool is too small to keep all of the frequently accessed pages in memory.

Heavy workload

The workload is causing frequent evictions and data pages reloads in the buffer cache.

Errors reading the pages

There are errors reading pages in the buffer pool, which might indicate data corruption.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Increase the size of the buffer pool
- Improve data access patterns
• Reduce or avoid full-table scans
• Check the error logs for page corruption

Increase the size of the buffer pool

Make sure that the buffer pool is appropriately sized for the workload. To do so, you can check the buffer pool cache hit rate. Typically, if the value drops below 95 percent, consider increasing the buffer pool size. A larger buffer pool can keep frequently accessed pages in memory longer. To increase the size of the buffer pool, modify the value of the `innodb_buffer_pool_size` parameter. The default value of this parameter is based on the DB instance class size. For more information, see [Best practices for Amazon Aurora MySQL database configuration](https://docs.aws.amazon.com/aurora/latest/user_guide/best-practices.html).

Improve data access patterns

Check the queries affected by this wait and their execution plans. Consider improving data access patterns. For example, if you are using `mysqli_result::fetch_array`, you can try increasing the array fetch size.

You can use Performance Insights to show queries and sessions that might be causing the `synch/sxlock/innodb/hash_table_locks` wait event.

To find SQL queries that are responsible for high load

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is shown for that DB instance.
4. In the **Database load** chart, choose **Slice by wait**.
5. At the bottom of the page, choose **Top SQL**.

   The chart lists the SQL queries that are responsible for the load. Those at the top of the list are most responsible. To resolve a bottleneck, focus on these statements.

Reduce or avoid full-table scans

Monitor your workload to see if it's running full-table scans, and, if it is, reduce or avoid them. For example, you can monitor status variables such as Handler_read_rnd_next. For more information, see Server Status Variables in the MySQL documentation.

Check the error logs for page corruption

You can check the mysql-error.log for corruption-related messages that were detected near the time of the issue. Messages that you can work with to resolve the issue are in the error log. You might need to recreate objects that were reported as corrupted.
Tuning Aurora MySQL with thread states

The following table summarizes the most common general thread states for Aurora MySQL.

<table>
<thead>
<tr>
<th>General thread state</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>??</td>
<td>This thread state indicates that a thread is processing a SELECT statement that requires the use of an internal temporary table to sort the data.</td>
</tr>
<tr>
<td>??</td>
<td>This thread state indicates that a thread is reading and filtering rows for a query to determine the correct result set.</td>
</tr>
</tbody>
</table>

creating sort index

The creating sort index thread state indicates that a thread is processing a SELECT statement that requires the use of an internal temporary table to sort the data.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This thread state information is supported for the following versions:

- Aurora MySQL version 2 up to 2.09.2

Context

The creating sort index state appears when a query with an ORDER BY or GROUP BY clause can't use an existing index to perform the operation. In this case, MySQL needs to perform a more
expensive filesort operation. This operation is typically performed in memory if the result set isn't too large. Otherwise, it involves creating a file on disk.

**Likely causes of increased waits**

The appearance of `creating sort index` doesn't by itself indicate a problem. If performance is poor, and you see frequent instances of `creating sort index`, the most likely cause is slow queries with `ORDER BY` or `GROUP BY` operators.

**Actions**

The general guideline is to find queries with `ORDER BY` or `GROUP BY` clauses that are associated with the increases in the `creating sort index` state. Then see whether adding an index or increasing the sort buffer size solves the problem.

**Topics**

- [Turn on the Performance Schema if it isn't turned on](#)
- [Identify the problem queries](#)
- [Examine the explain plans for filesort usage](#)
- [Increase the sort buffer size](#)

---

**Turn on the Performance Schema if it isn't turned on**

Performance Insights reports thread states only if Performance Schema instruments aren't turned on. When Performance Schema instruments are turned on, Performance Insights reports wait events instead. Performance Schema instruments provide additional insights and better tools when you investigate potential performance problems. Therefore, we recommend that you turn on the Performance Schema. For more information, see [Turning on the Performance Schema for Performance Insights on Aurora MySQL](#).

**Identify the problem queries**

To identify current queries that are causing increases in the `creating sort index` state, run `show processlist` and see if any of the queries have `ORDER BY` or `GROUP BY`. Optionally, run `explain for connection N`, where N is the process list ID of the query with filesort.

To identify past queries that are causing these increases, turn on the slow query log and find the queries with `ORDER BY`. Run `EXPLAIN` on the slow queries and look for "using filesort." For more information, see [Examine the explain plans for filesort usage](#).
Examine the explain plans for filesort usage

Identify the statements with ORDER BY or GROUP BY clauses that result in the creating sort index state.

The following example shows how to run explain on a query. The Extra column shows that this query uses filesort.

```
mysql> explain select * from mytable order by c1 limit 10
+---------+-------------+-----------+---------+------------+-------------+------+
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>partitions</th>
<th>type</th>
<th>possible_keys</th>
<th>key_len</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>mytable</td>
<td>NULL</td>
<td>ALL</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>rows:</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2064548</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>filtered:</td>
<td>100.00</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Extra:</td>
<td>Using filesort</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
1 row in set, 1 warning (0.01 sec)
```

The following example shows the result of running EXPLAIN on the same query after an index is created on column c1.

```
mysql> alter table mytable add index (c1);
mysql> explain select * from mytable order by c1 limit 10
+---------+-------------+-----------+---------+------------+-------------+------+
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>partitions</th>
<th>type</th>
<th>possible_keys</th>
<th>key_len</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>mytable</td>
<td>NULL</td>
<td>index</td>
<td>NULL</td>
<td>1023</td>
</tr>
<tr>
<td>rows:</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>10</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Tuning Aurora MySQL with thread states
For information on using indexes for sort order optimization, see [ORDER BY Optimization](#) in the MySQL documentation.

### Increase the sort buffer size

To see whether a specific query required a **filesort** process that created a file on disk, check the `sort_merge_passes` variable value after running the query. The following shows an example.

```sql
mysql> show session status like 'sort_merge_passes';
+-------------------+-------+
| Variable_name     | Value |
+-------------------+-------+
| Sort_merge_passes | 0     |
+-------------------+-------+
1 row in set (0.01 sec)

--- run query
mysql> select * from mytable order by u limit 10;
--- run status again:

mysql> show session status like 'sort_merge_passes';
+-------------------+-------+
| Variable_name     | Value |
+-------------------+-------+
| Sort_merge_passes | 0     |
+-------------------+-------+
1 row in set (0.01 sec)
```

If the value of `sort_merge_passes` is high, consider increasing the sort buffer size. Apply the increase at the session level, because increasing it globally can significantly increase the amount of RAM MySQL uses. The following example shows how to change the sort buffer size before running a query.

```sql
mysql> set session sort_buffer_size=10*1024*1024;
Query OK, 0 rows affected (0.00 sec)
-- run query
```
sending data

The sending data thread state indicates that a thread is reading and filtering rows for a query to determine the correct result set. The name is misleading because it implies the state is transferring data, not collecting and preparing data to be sent later.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This thread state information is supported for the following versions:

- Aurora MySQL version 2 up to 2.09.2

Context

Many thread states are short-lasting. Operations occurring during sending data tend to perform large numbers of disk or cache reads. Therefore, sending data is often the longest-running state over the lifetime of a given query. This state appears when Aurora MySQL is doing the following:

- Reading and processing rows for a SELECT statement
- Performing a large number of reads from either disk or memory
- Completing a full read of all data from a specific query
- Reading data from a table, an index, or the work of a stored procedure
- Sorting, grouping, or ordering data

After the sending data state finishes preparing the data, the thread state writing to net indicates the return of data to the client. Typically, writing to net is captured only when the result set is very large or severe network latency is slowing the transfer.
Likely causes of increased waits

The appearance of sending data doesn't by itself indicate a problem. If performance is poor, and you see frequent instances of sending data, the most likely causes are as follows.

Topics

- **Inefficient query**
- **Suboptimal server configuration**

Inefficient query

In most cases, what's responsible for this state is a query that isn't using an appropriate index to find the result set of a specific query. For example, consider a query reading a 10 million record table for all orders placed in California, where the state column isn't indexed or is poorly indexed. In the latter case, the index might exist, but the optimizer ignores it because of low cardinality.

Suboptimal server configuration

If several queries appear in the sending data state, the database server might be configured poorly. Specifically, the server might have the following issues:

- The database server doesn't have enough computing capacity: disk I/O, disk type and speed, CPU, or number of CPUs.
- The server is starved for allocated resources, such as the InnoDB buffer pool for InnoDB tables or the key buffer for MyIsam tables.
- Per-thread memory settings such as sort_buffer, read_buffer, and join_buffer consume more RAM than required, starving the physical server for memory resources.

Actions

The general guideline is to find queries that return large numbers of rows by checking the Performance Schema. If logging queries that don't use indexes is turned on, you can also examine the results from the slow logs.

Topics

- **Turn on the Performance Schema if it isn't turned on**
- **Examine memory settings**
- Examine the explain plans for index usage
- Check the volume of data returned
- Check for concurrency issues
- Check the structure of your queries

**Turn on the Performance Schema if it isn't turned on**

Performance Insights reports thread states only if Performance Schema instruments aren't turned on. When Performance Schema instruments are turned on, Performance Insights reports wait events instead. Performance Schema instruments provide additional insights and better tools when you investigate potential performance problems. Therefore, we recommend that you turn on the Performance Schema. For more information, see [Turning on the Performance Schema for Performance Insights on Aurora MySQL](#).

**Examine memory settings**

Examine the memory settings for the primary buffer pools. Make sure that these pools are appropriately sized for the workload. If your database uses multiple buffer pool instances, make sure that they aren't divided into many small buffer pools. Threads can only use one buffer pool at a time.

Make sure that the following memory settings used for each thread are properly sized:

- read_buffer
- read_rnd_buffer
- sort_buffer
- join_buffer
- binlog_cache

Unless you have a specific reason to modify the settings, use the default values.

**Examine the explain plans for index usage**

For queries in the sending data thread state, examine the plan to determine whether appropriate indexes are used. If a query isn't using a useful index, consider adding hints like USE INDEX or FORCE INDEX. Hints can greatly increase or decrease the time it takes to run a query, so use care before adding them.
Check the volume of data returned

Check the tables that are being queried and the amount of data that they contain. Can any of this data be archived? In many cases, the cause of poor query execution times isn't the result of the query plan, but the volume of data to be processed. Many developers are very efficient in adding data to a database but seldom consider dataset life cycle in the design and development phases.

Look for queries that perform well in low-volume databases but perform poorly in your current system. Sometimes developers who design specific queries might not realize that these queries are returning 350,000 rows. The developers might have developed the queries in a lower-volume environment with smaller datasets than production environments have.

Check for concurrency issues

Check whether multiple queries of the same type are running at the same time. Some forms of queries run efficiently when they run alone. However, if similar forms of query run together, or in high volume, they can cause concurrency issues. Often, these issues are caused when the database uses temp tables to render results. A restrictive transaction isolation level can also cause concurrency issues.

If tables are read and written to concurrently, the database might be using locks. To help identify periods of poor performance, examine the use of databases through large-scale batch processes. To see recent locks and rollbacks, examine the output of the `SHOW ENGINE INNODB STATUS` command.

Check the structure of your queries

Check whether captured queries from these states use subqueries. This type of query often leads to poor performance because the database compiles the results internally and then substitutes them back into the query to render data. This process is an extra step for the database. In many cases, this step can cause poor performance in a highly concurrent loading condition.

Also check whether your queries use large numbers of `ORDER BY` and `GROUP BY` clauses. In such operations, often the database must first form the entire dataset in memory. Then it must order or group it in a specific manner before returning it to the client.

Tuning Aurora MySQL with Amazon DevOps Guru proactive insights

DevOps Guru proactive insights detect known problematic conditions on your Aurora MySQL DB clusters before they occur. DevOps Guru can do the following:
• Prevent many common database issues by cross-checking your database configuration against common recommended settings.

• Alert you to critical issues in your fleet that, if left unchecked, can lead to larger problems later.

• Alert you to newly discovered problems.

Every proactive insight contains an analysis of the cause of the problem and recommendations for corrective actions.

**Topics**

• [The InnoDB history list length increased significantly](#)

• [Database is creating temporary tables on disk](#)

**The InnoDB history list length increased significantly**

Starting on *date*, your history list for row changes increased significantly, up to *length* on *db-instance*. This increase affects query and database shutdown performance.

**Topics**

• [Supported engine versions](#)

• [Context](#)

• [Likely causes for this issue](#)

• [Actions](#)

• [Relevant metrics](#)

**Supported engine versions**

This insight information is supported for all versions of Aurora MySQL.

**Context**

The InnoDB transaction system maintains multiversion concurrency control (MVCC). When a row is modified, the pre-modification version of the data being modified is stored as an undo record in an undo log. Every undo record has a reference to its previous redo record, forming a linked list.

The *InnoDB history list* is a global list of the undo logs for committed transactions. MySQL uses the history list to purge records and log pages when transactions no longer require the history.
The *history list length* is the total number of undo logs that contain modifications in the history list. Each log contains one or more modifications. If the InnoDB history list length grows too large, indicating a large number of old row versions, queries and database shutdowns become slower.

**Likely causes for this issue**

Typical causes of a long history list include the following:

- Long-running transactions, either read or write
- A heavy write load

**Actions**

We recommend different actions depending on the causes of your insight.

**Topics**

- Don't begin any operation involving a database shutdown until the InnoDB history list decreases
- Identify and end long-running transactions
- Identify the top hosts and top users by using Performance Insights.

**Don't begin any operation involving a database shutdown until the InnoDB history list decreases**

Because a long InnoDB history list slows database shutdowns, reduce the list size before initiating operations involving a database shutdown. These operations include major version database upgrades.

**Identify and end long-running transactions**

You can find long-running transactions by querying `information_schema.innodb_trx`.

### Note

Make sure also to look for long-running transactions on read replicas.

**To identify and end long-running transactions**

1. In your SQL client, run the following query:
```
SELECT a.trx_id,
       a.trx_state,
       a.trx_started,
       TIMESTAMPDIFF(SECOND,a.trx_started, now()) as "Seconds Transaction Has Been Open",
       a.trx_rows_modified,
       b.USER,
       b.host,
       b.db,
       b.command,
       b.time,
       b.state
FROM  information_schema.innodb_trx a,
       information_schema.processlist b
WHERE a.trx_mysql_thread_id=b.id
  AND TIMESTAMPDIFF(SECOND,a.trx_started, now()) > 10
ORDER BY trx_started
```

2. End each long-running transaction with a COMMIT or ROLLBACK command.

**Identify the top hosts and top users by using Performance Insights.**

Optimize transactions so that large numbers of modified rows are immediately committed.

**Relevant metrics**

The following metrics are related to this insight:

- `trx_rseg_history_len`

  For more information, see [InnoDB INFORMATION_SCHEMA Metrics Table](innoDB_innodb_trx_metrics.html) in the *MySQL 5.7 Reference Manual*.

**Database is creating temporary tables on disk**

Your recent on-disk temporary table usage increased significantly, up to `percentage`. The database is creating around `number` temporary tables per second. This might impact performance and increase disk operations on `db-instance`.

**Topics**
Supported engine versions

This insight information is supported for all versions of Aurora MySQL.

Context

Sometimes it’s necessary for the MySQL server to create an internal temporary table while processing a query. Aurora MySQL can hold an internal temporary table in memory, where it can be processed by the TempTable or MEMORY storage engine, or stored on disk by InnoDB. For more information, see Internal Temporary Table Use in MySQL in the MySQL Reference Manual.

Likely causes for this issue

An increase in on-disk temporary tables indicates the use of complex queries. If the configured memory is insufficient to store temporary tables in memory, Aurora MySQL creates the tables on disk. This can impact performance and increase disk operations.

Actions

We recommend different actions depending on the causes of your insight.

• For Aurora MySQL version 3, we recommend that you use the TempTable storage engine.

• Optimize your queries to return less data by selecting only necessary columns.

• Consider indexing columns that are involved in sorting and grouping operations.

• Rewrite your queries to avoid BLOB and TEXT columns. These columns always use disk.

• Tune the following database parameters: tmp_table_size and max_heap_table_size.
The default values for these parameters is 16 MiB. When using the MEMORY storage engine for in-memory temporary tables, their maximum size is defined by the tmp_table_size or max_heap_table_size value, whichever is smaller. When this maximum size is reached, MySQL automatically converts the in-memory internal temporary table to an InnoDB on-disk internal temporary table. For more information, see Use the TempTable storage engine on Amazon RDS for MySQL and Amazon Aurora MySQL.

Note

When explicitly creating MEMORY tables with CREATE TABLE, only the max_heap_table_size variable determines how large a table can grow. There is also no conversion to an on-disk format.

Relevant metrics

The following Performance Insights metrics are related to this insight:

- Created_tmp_disk_tables
- Created_tmp_tables

For more information, see Created_tmp_disk_tables in the MySQL documentation.
Working with parallel query for Amazon Aurora MySQL

This topic describes the parallel query performance optimization for Amazon Aurora MySQL-Compatible Edition. This feature uses a special processing path for certain data-intensive queries, taking advantage of the Aurora shared storage architecture. Parallel query works best with Aurora MySQL DB clusters that have tables with millions of rows and analytic queries that take minutes or hours to complete.

Overview of parallel query for Aurora MySQL

Aurora MySQL parallel query is an optimization that parallelizes some of the I/O and computation involved in processing data-intensive queries. The work that is parallelized includes retrieving rows from storage, extracting column values, and determining which rows match the conditions in the WHERE clause and join clauses. This data-intensive work is delegated (in database optimization terms, pushed down) to multiple nodes in the Aurora distributed storage layer. Without parallel query, each query brings all the scanned data to a single node within the Aurora MySQL cluster (the head node) and performs all the query processing there.
The PostgreSQL database engine also has a feature called "parallel query." That feature is unrelated to Aurora parallel query.

When the parallel query feature is turned on, the Aurora MySQL engine automatically determines when queries can benefit, without requiring SQL changes such as hints or table attributes. In the following sections, you can find an explanation of when parallel query is applied to a query. You can also find how to make sure that parallel query is applied where it provides the most benefit.

Note

The parallel query optimization provides the most benefit for long-running queries that take minutes or hours to complete. Aurora MySQL generally doesn't perform parallel query optimization for inexpensive queries. It also generally doesn't perform parallel query optimization if another optimization technique makes more sense, such as query caching, buffer pool caching, or index lookups. If you find that parallel query isn't being used when you expect it, see Verifying which statements use parallel query.

Benefits

With parallel query, you can run data-intensive analytic queries on Aurora MySQL tables. In many cases, you can get an order-of-magnitude performance improvement over the traditional division of labor for query processing.

Benefits of parallel query include the following:
• Improved I/O performance, due to parallelizing physical read requests across multiple storage nodes.

• Reduced network traffic. Aurora doesn't transmit entire data pages from storage nodes to the head node and then filter out unnecessary rows and columns afterward. Instead, Aurora transmits compact tuples containing only the column values needed for the result set.

• Reduced CPU usage on the head node, due to pushing down function processing, row filtering, and column projection for the WHERE clause.

• Reduced memory pressure on the buffer pool. The pages processed by the parallel query aren't added to the buffer pool. This approach reduces the chance of a data-intensive scan evicting frequently used data from the buffer pool.

• Potentially reduced data duplication in your extract, transform, load (ETL) pipeline, by making it practical to perform long-running analytic queries on existing data.

Architecture

The parallel query feature uses the major architectural principles of Aurora MySQL: decoupling the database engine from the storage subsystem, and reducing network traffic by streamlining communication protocols. Aurora MySQL uses these techniques to speed up write-intensive operations such as redo log processing. Parallel query applies the same principles to read operations.

Note

The architecture of Aurora MySQL parallel query differs from that of similarly named features in other database systems. Aurora MySQL parallel query doesn't involve symmetric multiprocessing (SMP) and so doesn't depend on the CPU capacity of the database server. The parallel processing happens in the storage layer, independent of the Aurora MySQL server that serves as the query coordinator.

By default, without parallel query, the processing for an Aurora query involves transmitting raw data to a single node within the Aurora cluster (the head node). Aurora then performs all further processing for that query in a single thread on that single node. With parallel query, much of this I/O-intensive and CPU-intensive work is delegated to nodes in the storage layer. Only the compact rows of the result set are transmitted back to the head node, with rows already filtered, and column values already extracted and transformed. The performance benefit comes from the
reduction in network traffic, reduction in CPU usage on the head node, and parallelizing the I/O across the storage nodes. The amount of parallel I/O, filtering, and projection is independent of the number of DB instances in the Aurora cluster that runs the query.

**Prerequisites**

To use all features of parallel query requires an Aurora MySQL DB cluster that's running version 2.09 or higher. If you already have a cluster that you want to use with parallel query, you can upgrade it to a compatible version and turn on parallel query afterward. In that case, make sure to follow the upgrade procedure in [Upgrade considerations for parallel query](#) because the configuration setting names and default values are different in these newer versions.

The DB instances in your cluster must use the `db.r*` instance classes.

Make sure that hash join optimization is turned on for your cluster. To learn how, see [Turning on hash join for parallel query clusters](#).

To customize parameters such as `aurora_parallel_query` and `aurora_disable_hash_join`, you must have a custom parameter group that you use with your cluster. You can specify these parameters individually for each DB instance by using a DB parameter group. However, we recommend that you specify them in a DB cluster parameter group. That way, all DB instances in your cluster inherit the same settings for these parameters.

**Limitations**

The following limitations apply to the parallel query feature:

- Parallel query isn't supported with the Aurora I/O-Optimized DB cluster storage configuration.
- You can't use parallel query with the `db.t2` or `db.t3` instance classes. This limitation applies even if you request parallel query using the `aurora_pq_force` session variable.
- Parallel query doesn't apply to tables using the COMPRESSED or REDUNDANT row formats. Use the COMPACT or DYNAMIC row formats for tables you plan to use with parallel query.
- Aurora uses a cost-based algorithm to determine whether to use the parallel query mechanism for each SQL statement. Using certain SQL constructs in a statement can prevent parallel query or make parallel query unlikely for that statement. For information about compatibility of SQL constructs with parallel query, see [How parallel query works with SQL constructs](#).
- Each Aurora DB instance can run only a certain number of parallel query sessions at one time. If a query has multiple parts that use parallel query, such as subqueries, joins, or UNION operators,
those phases run in sequence. The statement only counts as a single parallel query session at any one time. You can monitor the number of active sessions using the parallel query status variables. You can check the limit on concurrent sessions for a given DB instance by querying the status variable Aurora_pq_max_concurrent_requests.

- Parallel query is available in all AWS Regions that Aurora supports. For most AWS Regions, the minimum required Aurora MySQL version to use parallel query is 2.09.
- Parallel query is designed to improve the performance of data-intensive queries. It isn't designed for lightweight queries.
- We recommend that you use reader nodes for SELECT statements, especially data-intensive ones.

I/O costs with parallel query

If your Aurora MySQL cluster uses parallel query, you might see an increase in VolumeReadIOPS values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing can result in an increase in read operations and associated charges.

Parallel query I/O costs for your query are metered at the storage layer, and will be the same or larger with parallel query turned on. Your benefit is the improvement in query performance. There are two reasons for potentially higher I/O costs with parallel query:

- Even if some of the data in a table is in the buffer pool, parallel query requires all data to be scanned at the storage layer, incurring I/O costs.
- Running a parallel query doesn't warm up the buffer pool. As a result, consecutive runs of the same parallel query incur the full I/O cost.

Planning for a parallel query cluster

Planning for a DB cluster that has parallel query turned on requires making some choices. These include performing setup steps (either creating or restoring a full Aurora MySQL cluster) and deciding how broadly to turn on parallel query across your DB cluster.

Consider the following as part of planning:

- If you use Aurora MySQL that's compatible with MySQL 5.7, you must choose Aurora MySQL 2.09 or higher. In this case, you always create a provisioned cluster. Then you turn on parallel query using the aurora_parallel_query parameter.
If you have an existing Aurora MySQL cluster that's running version 2.09 or higher, you don't have to create a new cluster to use parallel query. You can associate your cluster, or specific DB instances in the cluster, with a parameter group that has the aurora_parallel_query parameter turned on. By doing so, you can reduce the time and effort to set up the relevant data to use with parallel query.

- Plan for any large tables that you need to reorganize so that you can use parallel query when accessing them. You might need to create new versions of some large tables where parallel query is useful. For example, you might need to remove full-text search indexes. For details, see Creating schema objects to take advantage of parallel query.

Checking Aurora MySQL version compatibility for parallel query

To check which Aurora MySQL versions are compatible with parallel query clusters, use the describe-db-engine-versions AWS CLI command and check the value of the SupportsParallelQuery field. The following code example shows how to check which combinations are available for parallel query clusters in a specified AWS Region. Make sure to specify the full --query parameter string on a single line.

```bash
aws rds describe-db-engine-versions --region us-east-1 --engine aurora-mysql --query '[]|?[SupportsParallelQuery == `true`].[EngineVersion]' --output text
```

The preceding commands produce output similar to the following. The output might vary depending on which Aurora MySQL versions are available in the specified AWS Region.

```
5.7.mysql_aurora.2.11.1
8.0.mysql_aurora.3.01.0
8.0.mysql_aurora.3.01.1
8.0.mysql_aurora.3.02.0
8.0.mysql_aurora.3.02.1
8.0.mysql_aurora.3.02.2
8.0.mysql_aurora.3.03.0
```

After you start using parallel query with a cluster, you can monitor performance and remove obstacles to parallel query usage. For those instructions, see Performance tuning for parallel query.
Creating a DB cluster that works with parallel query

To create an Aurora MySQL cluster with parallel query, add new instances to it, or perform other administrative operations, you use the same AWS Management Console and AWS CLI techniques that you do with other Aurora MySQL clusters. You can create a new cluster to work with parallel query. You can also create a DB cluster to work with parallel query by restoring from a snapshot of a MySQL-compatible Aurora DB cluster. If you aren't familiar with the process for creating a new Aurora MySQL cluster, you can find background information and prerequisites in Creating an Amazon Aurora DB cluster.

When you choose an Aurora MySQL engine version, we recommend that you choose the latest one available. Currently, Aurora MySQL versions 2.09 and higher support parallel query. You have more flexibility to turn parallel query on and off, or use parallel query with existing clusters, if you use Aurora MySQL 2.09 and higher.

Whether you create a new cluster or restore from a snapshot, you use the same techniques to add new DB instances that you do with other Aurora MySQL clusters.

Creating a parallel query cluster using the console

You can create a new parallel query cluster with the console as described following.

To create a parallel query cluster with the AWS Management Console

1. Follow the general AWS Management Console procedure in Creating an Amazon Aurora DB cluster.
2. On the Select engine screen, choose Aurora MySQL.

   For Engine version, choose Aurora MySQL 2.09 or higher. With these versions, you have the fewest limitations on parallel query usage. Those versions also have the most flexibility to turn parallel query on or off at any time.

   If it isn't practical to use a recent Aurora MySQL version for this cluster, choose Show versions that support the parallel query feature. Doing so filters the Version menu to show only the specific Aurora MySQL versions that are compatible with parallel query.
3. For Additional configuration, choose a parameter group that you created for DB cluster parameter group. Using such a custom parameter group is required for Aurora MySQL 2.09 and higher. In your DB cluster parameter group, specify the parameter settings aurora_parallel_query=ON and aurora_disable_hash_join=OFF. Doing so turns
on parallel query for the cluster, and turns on the hash join optimization that works in combination with parallel query.

To verify that a new cluster can use parallel query

1. Create a cluster using the preceding technique.

2. (For Aurora MySQL version 2 or 3) Check that the `aurora_parallel_query` configuration setting is true.

   ```
   mysql> select @@aurora_parallel_query;
   +-------------------------+
   | @@aurora_parallel_query |
   +-------------------------+
   |                       1 |
   +-------------------------+
   ```

3. (For Aurora MySQL version 2) Check that the `aurora_disable_hash_join` setting is false.

   ```
   mysql> select @@aurora_disable_hash_join;
   +----------------------------+
   | @@aurora_disable_hash_join |
   +----------------------------+
   |                          0 |
   +----------------------------+
   ```

4. With some large tables and data-intensive queries, check the query plans to confirm that some of your queries are using the parallel query optimization. To do so, follow the procedure in Verifying which statements use parallel query.

Creating a parallel query cluster using the CLI

You can create a new parallel query cluster with the CLI as described following.

To create a parallel query cluster with the AWS CLI

1. (Optional) Check which Aurora MySQL versions are compatible with parallel query clusters. To do so, use the `describe-db-engine-versions` command and check the value of the `SupportsParallelQuery` field. For an example, see Checking Aurora MySQL version compatibility for parallel query.
2. (Optional) Create a custom DB cluster parameter group with the settings aurora_parallel_query=ON and aurora_disable_hash_join=OFF. Use commands such as the following.

```bash
aws rds create-db-cluster-parameter-group --db-parameter-group-family aurora-mysql5.7 --db-cluster-parameter-group-name pq-enabled-57-compatible
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name pq-enabled-57-compatible --parameters ParameterName=aurora_parallel_query,ParameterValue=ON,ApplyMethod=pending-reboot
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name pq-enabled-57-compatible --parameters ParameterName=aurora_disable_hash_join,ParameterValue=OFF,ApplyMethod=pending-reboot
```

If you perform this step, specify the option `--db-cluster-parameter-group-name my_cluster_parameter_group` in the subsequent `create-db-cluster` statement. Substitute the name of your own parameter group. If you omit this step, you create the parameter group and associate it with the cluster later, as described in Turning parallel query on and off.

3. Follow the general AWS CLI procedure in Creating an Amazon Aurora DB cluster.

4. Specify the following set of options:

   - For the `--engine` option, use `aurora-mysql`. These values produce parallel query clusters that are compatible with MySQL 5.7 or 8.0.

   - For the `--db-cluster-parameter-group-name` option, specify the name of a DB cluster parameter group that you created and specified the parameter value aurora_parallel_query=ON. If you omit this option, you can create the cluster with a default parameter group and later modify it to use such a custom parameter group.

   - For the `--engine-version` option, use an Aurora MySQL version that's compatible with parallel query. Use the procedure from Planning for a parallel query cluster to get a list of versions if necessary. Use at least version 2.09.0. These versions and all higher ones contain substantial enhancements to parallel query.

   The following code example shows how. Substitute your own value for each of the environment variables such as `$CLUSTER_ID`. This example also specifies the `--manage-master-user-password` option to generate the master user password and manage it in
Secrets Manager. For more information, see Password management with Amazon Aurora and AWS Secrets Manager. Alternatively, you can use the --master-password option to specify and manage the password yourself.

```bash
aws rds create-db-cluster --db-cluster-identifier $CLUSTER_ID \
    --engine aurora-mysql --engine-version 5.7.mysql_aurora.2.11.1 \
    --master-username $MASTER_USER_ID --manage-master-user-password \
    --db-cluster-parameter-group-name $CUSTOM_CLUSTER_PARAM_GROUP

aws rds create-db-instance --db-instance-identifier ${INSTANCE_ID}-1 \
    --engine same_value_as_in_create_cluster_command \
    --db-cluster-identifier $CLUSTER_ID --db-instance-class $INSTANCE_CLASS
```

5. Verify that a cluster you created or restored has the parallel query feature available.

Check that the `aurora_parallel_query` configuration setting exists. If this setting has the value 1, parallel query is ready for you to use. If this setting has the value 0, set it to 1 before you can use parallel query. Either way, the cluster is capable of performing parallel queries.

```
mysql> select @@aurora_parallel_query;
+------------------------+
| @@aurora_parallel_query|
+------------------------+
|                      1 |
+------------------------+
```

To restore a snapshot to a parallel query cluster with the AWS CLI

1. Check which Aurora MySQL versions are compatible with parallel query clusters. To do so, use the describe-db-engine-versions command and check the value of the `SupportsParallelQuery` field. For an example, see Checking Aurora MySQL version compatibility for parallel query. Decide which version to use for the restored cluster. Choose Aurora MySQL 2.09.0 or higher for a MySQL 5.7-compatible cluster.

2. Locate an Aurora MySQL-compatible cluster snapshot.

3. Follow the general AWS CLI procedure in Restoring from a DB cluster snapshot.

```
aws rds restore-db-cluster-from-snapshot \
    --db-cluster-identifier mynewdbcluster \
    --snapshot-identifier mydbclustersnapshot
```
4. Verify that a cluster you created or restored has the parallel query feature available. Use the same verification procedure as in Creating a parallel query cluster using the CLI.

Turning parallel query on and off

When parallel query is turned on, Aurora MySQL determines whether to use it at runtime for each query. In the case of joins, unions, subqueries, and so on, Aurora MySQL determines whether to use parallel query at runtime for each query block. For details, see Verifying which statements use parallel query and How parallel query works with SQL constructs.

You can turn on and turn off parallel query dynamically at both the global and session level for a DB instance by using the aurora_parallel_query option. You can change the aurora_parallel_query setting in your DB cluster group to turn parallel query on or off by default.

```
mysql> select @@aurora_parallel_query;
+------------------------+
| @@aurora_parallel_query|
+------------------------+
|                      1 |
+------------------------+
```

To toggle the aurora_parallel_query parameter at the session level, use the standard methods to change a client configuration setting. For example, you can do so through the mysql command line or within a JDBC or ODBC application. The command on the standard MySQL client is set session aurora_parallel_query = {'ON'/'OFF'}. You can also add the session-level parameter to the JDBC configuration or within your application code to turn on or turn off parallel query dynamically.

You can permanently change the setting for the aurora_parallel_query parameter, either for a specific DB instance or for your whole cluster. If you specify the parameter value in a DB parameter group, that value only applies to specific DB instance in your cluster. If you specify the parameter value in a DB cluster parameter group, all DB instances in the cluster inherit the same setting. To toggle the aurora_parallel_query parameter, use the techniques for working with parameter groups, as described in Working with parameter groups. Follow these steps:

1. Create a custom cluster parameter group (recommended) or a custom DB parameter group.
2. In this parameter group, update `parallel_query` to the value that you want.

3. Depending on whether you created a DB cluster parameter group or a DB parameter group, attach the parameter group to your Aurora cluster or to the specific DB instances where you plan to use the parallel query feature.

**Tip**

Because `aurora_parallel_query` is a dynamic parameter, it doesn't require a cluster restart after changing this setting. However, any connections that were using parallel query before toggling the option will continue to do so until the connection is closed, or the instance is rebooted.

You can modify the parallel query parameter by using the `ModifyDBClusterParameterGroup` or `ModifyDBParameterGroup` API operation or the AWS Management Console.

### Turning on hash join for parallel query clusters

Parallel query is typically used for the kinds of resource-intensive queries that benefit from the hash join optimization. Thus, it's helpful to make sure that hash joins are turned on for clusters where you plan to use parallel query. For information about how to use hash joins effectively, see [Optimizing large Aurora MySQL join queries with hash joins](#).

### Turning on and turning off parallel query using the console

You can turn on or turn off parallel query at the DB instance level or the DB cluster level by working with parameter groups.

#### To turn on or turn off parallel query for a DB cluster with the AWS Management Console

1. Create a custom parameter group, as described in [Working with parameter groups](#).
2. Update `aurora_parallel_query` to 1 (turned on) or 0 (turned off). For clusters where the parallel query feature is available, `aurora_parallel_query` is turned off by default.
3. If you use a custom cluster parameter group, attach it to the Aurora DB cluster where you plan to use the parallel query feature. If you use a custom DB parameter group, attach it to one or more DB instances in the cluster. We recommend using a cluster parameter group. Doing so makes sure that all DB instances in the cluster have the same settings for parallel query and associated features such as hash join.
Turning on and turning off parallel query using the CLI

You can modify the parallel query parameter by using the modify-db-cluster-parameter-group or modify-db-parameter-group command. Choose the appropriate command depending on whether you specify the value of `aurora_parallel_query` through a DB cluster parameter group or a DB parameter group.

**To turn on or turn off parallel query for a DB cluster with the CLI**

- Modify the parallel query parameter by using the `modify-db-cluster-parameter-group` command. Use a command such as the following. Substitute the appropriate name for your own custom parameter group. Substitute either **ON** or **OFF** for the `ParameterValue` portion of the `--parameters` option.

```
$ aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name `cluster_param_group_name` \
   --parameters ParameterName=aurora_parallel_query,ParameterValue=ON,ApplyMethod=pending-reboot
{
   "DBClusterParameterGroupArn": "`cluster_param_group_name`"
}
```

```
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name `cluster_param_group_name` \
   --parameters ParameterName=aurora_pq,ParameterValue=ON,ApplyMethod=pending-reboot
```

You can also turn on or turn off parallel query at the session level, for example through the `mysql` command line or within a JDBC or ODBC application. To do so, use the standard methods to change a client configuration setting. For example, the command on the standard MySQL client is set `session aurora_parallel_query = {'ON'/'OFF'}` for Aurora MySQL.

You can also add the session-level parameter to the JDBC configuration or within your application code to turn on or turn off parallel query dynamically.

**Overriding the parallel query optimizer**

You can use the `aurora_pq_force` session variable to override the parallel query optimizer and request parallel query for every query. We recommend that you do this only for testing purposes. The following example shows how to use `aurora_pq_force` in a session.
set SESSION aurora_parallel_query = ON;
set SESSION aurora_pq_force = ON;

To turn off the override, do the following:

set SESSION aurora_pq_force = OFF;

### Upgrade considerations for parallel query

Depending on the original and destination versions when you upgrade a parallel query cluster, you might find enhancements in the types of queries that parallel query can optimize. You might also find that you don't need to specify a special engine mode parameter for parallel query. The following sections explain the considerations when you upgrade a cluster that has parallel query turned on.

#### Upgrading parallel query clusters to Aurora MySQL version 3

Several SQL statements, clauses, and data types have new or improved parallel query support starting in Aurora MySQL version 3. When you upgrade from a release that's earlier than version 3, check whether additional queries can benefit from parallel query optimizations. For information about these parallel query enhancements, see [Column data types](#), [Partitioned tables](#), and [Aggregate functions, GROUP BY clauses, and HAVING clauses](#).

If you're upgrading a parallel query cluster from Aurora MySQL 2.08 or lower, also learn about changes in how to turn on parallel query. To do so, read [Upgrading to Aurora MySQL 2.09 and higher](#).

In Aurora MySQL version 3, hash join optimization is turned on by default. The `aurora_disable_hash_join` configuration option from earlier versions isn't used.

#### Upgrading to Aurora MySQL 2.09 and higher

In Aurora MySQL version 2.09 and higher, parallel query works for provisioned clusters and doesn't require the `parallelquery` engine mode parameter. Thus, you don't need to create a new cluster or restore from an existing snapshot to use parallel query with these versions. You can use the upgrade procedures described in [Upgrading the minor version or patch level of an Aurora MySQL DB cluster](#) to upgrade your cluster to such a version. You can upgrade an older cluster regardless of whether it was a parallel query cluster or a provisioned cluster. To reduce the number of choices in
the **Engine version** menu, you can choose **Show versions that support the parallel query feature** to filter the entries in that menu. Then choose Aurora MySQL 2.09 or higher.

After you upgrade an earlier parallel query cluster to Aurora MySQL 2.09 or higher, you turn on parallel query in the upgraded cluster. Parallel query is turned off by default in these versions, and the procedure for enabling it is different. The hash join optimization is also turned off by default and must be turned on separately. Thus, make sure that you turn on these settings again after the upgrade. For instructions on doing so, see [Turning parallel query on and off](#) and [Turning on hash join for parallel query clusters](#).

In particular, you turn on parallel query by using the configuration parameters aurora_parallel_query=ON and aurora_disable_hash_join=OFF instead of aurora_pq_supported and aurora_pq. The aurora_pq_supported and aurora_pq parameters are deprecated in the newer Aurora MySQL versions.

In the upgraded cluster, the EngineMode attribute has the value provisioned instead of parallelquery. To check whether parallel query is available for a specified engine version, now you check the value of the SupportsParallelQuery field in the output of the describe-db-engine-versions AWS CLI command. In earlier Aurora MySQL versions, you checked for the presence of parallelquery in the SupportedEngineModes list.

After you upgrade to Aurora MySQL version 2.09 or higher, you can take advantage of the following features. These features aren't available to parallel query clusters running older Aurora MySQL versions.

- **Performance Insights.** For more information, see [Monitoring DB load with Performance Insights on Amazon Aurora](#).
- **Backtracking.** For more information, see [Backtracking an Aurora DB cluster](#).
- **Stopping and starting the cluster.** For more information, see [Stopping and starting an Amazon Aurora DB cluster](#).

**Performance tuning for parallel query**

To manage the performance of a workload with parallel query, make sure that parallel query is used for the queries where this optimization helps the most.

To do so, you can do the following:
• Make sure that your biggest tables are compatible with parallel query. You might change table properties or recreate some tables so that queries for those tables can take advantage of the parallel query optimization. To learn how, see Creating schema objects to take advantage of parallel query.

• Monitor which queries use parallel query. To learn how, see Monitoring parallel query.

• Verify that parallel query is being used for the most data-intensive and long-running queries, and with the right level of concurrency for your workload. To learn how, see Verifying which statements use parallel query.

• Fine-tune your SQL code to turn on parallel query to apply to the queries that you expect. To learn how, see How parallel query works with SQL constructs.

Creating schema objects to take advantage of parallel query

Before you create or modify tables that you plan to use for parallel query, make sure to familiarize yourself with the requirements described in Prerequisites and Limitations.

Because parallel query requires tables to use the ROW_FORMAT=Compact or ROW_FORMAT=Dynamic setting, check your Aurora configuration settings for any changes to the INNODB_FILE_FORMAT configuration option. Issue the SHOW TABLE STATUS statement to confirm the row format for all the tables in a database.

Before changing your schema to turn on parallel query to work with more tables, make sure to test. Your tests should confirm if parallel query results in a net increase in performance for those tables. Also, make sure that the schema requirements for parallel query are otherwise compatible with your goals.

For example, before switching from ROW_FORMAT=Compressed to ROW_FORMAT=Compact or ROW_FORMAT=Dynamic, test the performance of workloads for the original and new tables. Also, consider other potential effects such as increased data volume.

Verifying which statements use parallel query

In typical operation, you don't need to perform any special actions to take advantage of parallel query. After a query meets the essential requirements for parallel query, the query optimizer automatically decides whether to use parallel query for each specific query.

If you run experiments in a development or test environment, you might find that parallel query isn't used because your tables are too small in number of rows or overall data volume. The data for
the table might also be entirely in the buffer pool, especially for tables that you created recently to perform experiments.

As you monitor or tune cluster performance, make sure to decide whether parallel query is being used in the appropriate contexts. You might adjust the database schema, settings, SQL queries, or even the cluster topology and application connection settings to take advantage of this feature.

To check if a query is using parallel query, check the query plan (also known as the "explain plan") by running the `EXPLAIN` statement. For examples of how SQL statements, clauses, and expressions affect EXPLAIN output for parallel query, see [How parallel query works with SQL constructs](#).

The following example demonstrates the difference between a traditional query plan and a parallel query plan. This explain plan is from Query 3 from the TPC-H benchmark. Many of the sample queries throughout this section use the tables from the TPC-H dataset. You can get the table definitions, queries, and the `dbgen` program that generates sample data from [the TPC-h website](#).

```sql
EXPLAIN SELECT l_orderkey, 
    sum(l_extendedprice * (1 - l_discount)) AS revenue, 
    o_orderdate, 
    o_shippriority 
FROM customer, 
    orders, 
    lineitem 
WHERE c_mktsegment = 'AUTOMOBILE' 
AND c_custkey = o_custkey 
AND l_orderkey = o_orderkey 
AND o_orderdate < date '1995-03-13' 
AND l_shipdate > date '1995-03-13' 
GROUP BY l_orderkey, 
    o_orderdate, 
    o_shippriority 
ORDER BY revenue DESC, 
    o_orderdate LIMIT 10;
```

By default, the query might have a plan like the following. If you don't see hash join used in the query plan, make sure that optimization is turned on first.

```
+----+-------------+----------+------------+------+---------------+------+---------+
| id | select_type | table    | partitions | type | possible_keys | key  | key_len |
| ref | rows        | filtered | Extra      |      |              |      |         |
```

Verifying parallel query usage
For Aurora MySQL version 3, you turn on hash join at the session level by issuing the following statement.

```sql
SET optimizer_switch='block_nested_loop=on';
```

For Aurora MySQL version 2.09 and higher, you set the `aurora_disable_hash_join` DB parameter or DB cluster parameter to 0 (off). Turning off `aurora_disable_hash_join` sets the value of `optimizer_switch` to `hash_join=on`.

After you turn on hash join, try running the `EXPLAIN` statement again. For information about how to use hash joins effectively, see [Optimizing large Aurora MySQL join queries with hash joins](#).

With hash join turned on but parallel query turned off, the query might have a plan like the following, which uses hash join but not parallel query.

```sql
+----+-------------+----------+...+-----------
| id | select_type | table    |...| rows      | Extra
|    |            |          |...|           |      
+----+-------------+----------+...+-----------
|  1 | SIMPLE      | customer |...| 5798330   | Using where; Using index; Using temporary; Using filesort |
|  1 | SIMPLE      | orders   |...| 154545408 | Using where; Using join buffer (Hash Join Outer table orders) |
|  1 | SIMPLE      | lineitem |...| 606119300 | Using where; Using join buffer (Hash Join Outer table lineitem) |
```
After parallel query is turned on, two steps in this query plan can use the parallel query optimization, as shown under the Extra column in the EXPLAIN output. The I/O-intensive and CPU-intensive processing for those steps is pushed down to the storage layer.

```
+----+...|
| id |...| Extra
+----+...|
+----+...|
|  1 |...| Using where; Using index; Using temporary; Using filesort
|  1 |...| Using where; Using join buffer (Hash Join Outer table orders); Using parallel query (4 columns, 1 filters, 1 exprs; 0 extra)
|  1 |...| Using where; Using join buffer (Hash Join Outer table lineitem); Using parallel query (4 columns, 1 filters, 1 exprs; 0 extra)
+----+...
```

For information about how to interpret EXPLAIN output for a parallel query and the parts of SQL statements that parallel query can apply to, see [How parallel query works with SQL constructs](#).

The following example output shows the results of running the preceding query on a `db.r4.2xlarge` instance with a cold buffer pool. The query runs substantially faster when using parallel query.

```
-- Without parallel query
+------------+-------------+-------------+----------------+
<table>
<thead>
<tr>
<th>l_orderkey</th>
<th>revenue</th>
<th>o_orderdate</th>
<th>o_shippriority</th>
</tr>
</thead>
<tbody>
<tr>
<td>92511430</td>
<td>514726.4896</td>
<td>1995-03-06</td>
<td>0</td>
</tr>
</tbody>
</table>
```

**Note**

Because timings depend on many environmental factors, your results might be different. Always conduct your own performance tests to confirm the findings with your own environment, workload, and so on.
Many of the sample queries throughout this section use the tables from this TPC-H dataset, particularly the PART table, which has 20 million rows and the following definition.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Null</th>
<th>Key</th>
<th>Default</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_partkey</td>

<td></td>
</tr>
<tr>
<td>p_comment</td>
<td>varchar(23)</td>
<td>NO</td>
<td></td>
<td>NULL</td>
<td></td>
</tr>
</tbody>
</table>

Experiment with your workload to get a sense of whether individual SQL statements can take advantage of parallel query. Then use the following monitoring techniques to help verify how often parallel query is used in real workloads over time. For real workloads, extra factors such as concurrency limits apply.
Monitoring parallel query

If your Aurora MySQL cluster uses parallel query, you might see an increase in VolumeReadIOPS values. Parallel queries don't use the buffer pool. Thus, although the queries are fast, this optimized processing can result in an increase in read operations and associated charges.

In addition to the Amazon CloudWatch metrics described in Viewing metrics in the Amazon RDS console, Aurora provides other global status variables. You can use these global status variables to help monitor parallel query execution. They can give you insights into why the optimizer might use or not use parallel query in a given situation. To access these variables, you can use the SHOW GLOBAL STATUS command. You can also find these variables listed following.

A parallel query session isn't necessarily a one-to-one mapping with the queries performed by the database. For example, suppose that your query plan has two steps that use parallel query. In that case, the query involves two parallel sessions and the counters for requests attempted and requests successful are incremented by two.

When you experiment with parallel query by issuing EXPLAIN statements, expect to see increases in the counters designated as "not chosen" even though the queries aren't actually running. When you work with parallel query in production, you can check if the "not chosen" counters are increasing faster than you expect. At this point, you can adjust so that parallel query runs for the queries that you expect. To do so, you can change your cluster settings, query mix, DB instances where parallel query is turned on, and so on.

These counters are tracked at the DB instance level. When you connect to a different endpoint, you might see different metrics because each DB instance runs its own set of parallel queries. You might also see different metrics when the reader endpoint connects to a different DB instance for each session.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora_pq_bytes_returned</td>
<td>The number of bytes for the tuple data structures transmitted to the head node during parallel queries. Divide by 16,384 to compare against Aurora_pq_pages_pushed_down.</td>
</tr>
<tr>
<td>Aurora_pq_max_concurrent_requests</td>
<td>The maximum number of parallel query sessions that can run concurrently on this</td>

**How parallel query works with SQL constructs**

In the following section, you can find more detail about why particular SQL statements use or don't use parallel query. This section also details how Aurora MySQL features interact with parallel query. This information can help you diagnose performance issues for a cluster that uses parallel query or understand how parallel query applies for your particular workload.

The decision to use parallel query relies on many factors that occur at the moment that the statement runs. Thus, parallel query might be used for certain queries always, never, or only under certain conditions.

[Tip](#)

When you view these examples in HTML, you can use the *Copy* widget in the upper-right corner of each code listing to copy the SQL code to try yourself. Using the *Copy* widget avoids copying the extra characters around the `mysql>` prompt and `->` continuation lines.

**Topics**

- [EXPLAIN statement](#)
- [WHERE clause](#)
- [Data definition language (DDL)](#)
EXPLAIN statement

As shown in examples throughout this section, the EXPLAIN statement indicates whether each stage of a query is currently eligible for parallel query. It also indicates which aspects of a query can be pushed down to the storage layer. The most important items in the query plan are the following:

- A value other than NULL for the key column suggests that the query can be performed efficiently using index lookups, and parallel query is unlikely.
- A small value for the rows column (a value not in the millions) suggests that the query isn't accessing enough data to make parallel query worthwhile. This means that parallel query is unlikely.
- The Extra column shows you if parallel query is expected to be used. This output looks like the following example.
Using parallel query \((A\ \text{columns},\ B\ \text{filters},\ C\ \text{exprs};\ D\ \text{extra})\)

The columns number represents how many columns are referred to in the query block.

The filters number represents the number of \textit{WHERE} predicates representing a simple comparison of a column value to a constant. The comparison can be for equality, inequality, or a range. Aurora can parallelize these kinds of predicates most effectively.

The exprs number represents the number of expressions such as function calls, operators, or other expressions that can also be parallelized, though not as effectively as a filter condition.

The extra number represents how many expressions can't be pushed down and are performed by the head node.

For example, consider the following \texttt{EXPLAIN} output.

```
mysql> explain select p_name, p_mfgr from part
   -> where p_brand is not null
   -> and upper(p_type) is not null
   -> and round(p_retailprice) is not null;
+----+-------------+-------+...+----------+
| id | select_type | table |...| rows     | Extra |
+----+-------------+-------+...+----------+
+------------------------------------------------------------------------------------------------+
|  1 | SIMPLE      | part  |...| 20427936 | Using where; Using parallel query (5 columns, 1 filters, 2 exprs; 0 extra) |
+----+-------------+-------+...+----------+
+------------------------------------------------------------------------------------------------+
```

The information from the Extra column shows that five columns are extracted from each row to evaluate the query conditions and construct the result set. One \textit{WHERE} predicate involves a filter, that is, a column that is directly tested in the \textit{WHERE} clause. Two \textit{WHERE} clauses require evaluating more complicated expressions, in this case involving function calls. The 0 extra field confirms that all the operations in the \textit{WHERE} clause are pushed down to the storage layer as part of parallel query processing.
In cases where parallel query isn't chosen, you can typically deduce the reason from the other columns of the EXPLAIN output. For example, the rows value might be too small, or the possible_keys column might indicate that the query can use an index lookup instead of a data-intensive scan. The following example shows a query where the optimizer can estimate that the query will scan only a small number of rows. It does so based on the characteristics of the primary key. In this case, parallel query isn't required.

```
mysql> explain select count(*) from part where p_partkey between 1 and 100;
```

```
+----+-------------+-------+-------+---------------+---------+---------+------+------+
| id | select_type | table | type  | possible_keys | key     | key_len | ref  | rows |
|    |             | part  | range | PRIMARY      | PRIMARY | 4       | NULL | 99   |
Extra
Using where; Using index
```

The output showing whether parallel query will be used takes into account all available factors at the moment that the EXPLAIN statement is run. The optimizer might make a different choice when the query is actually run, if the situation changed in the meantime. For example, EXPLAIN might report that a statement will use parallel query. But when the query is actually run later, it might not use parallel query based on the conditions then. Such conditions can include several other parallel queries running concurrently. They can also include rows being deleted from the table, a new index being created, too much time passing within an open transaction, and so on.

**WHERE clause**

For a query to use the parallel query optimization, it must include a WHERE clause.

The parallel query optimization speeds up many kinds of expressions used in the WHERE clause:

- Simple comparisons of a column value to a constant, known as *filters*. These comparisons benefit the most from being pushed down to the storage layer. The number of filter expressions in a query is reported in the EXPLAIN output.
- Other kinds of expressions in the WHERE clause are also pushed down to the storage layer where possible. The number of such expressions in a query is reported in the EXPLAIN output. These expressions can be function calls, LIKE operators, CASE expressions, and so on.
• Certain functions and operators aren't currently pushed down by parallel query. The number of such expressions in a query is reported as the extra counter in the EXPLAIN output. The rest of the query can still use parallel query.

• While expressions in the select list aren't pushed down, queries containing such functions can still benefit from reduced network traffic for the intermediate results of parallel queries. For example, queries that call aggregation functions in the select list can benefit from parallel query, even though the aggregation functions aren't pushed down.

For example, the following query does a full-table scan and processes all the values for the P_BRAND column. However, it doesn't use parallel query because the query doesn't include any WHERE clause.

```
mysql> explain select count(*), p_brand from part group by p_brand;
```

```
+----+-------------+-------+------+---------------+------+---------+------+----------+
| id | select_type | table | type | possible_keys | key  | key_len | ref  | rows     | Extra                                   |
+----+-------------+-------+------+---------------+------+---------+------+----------+
|  1 | SIMPLE      | part  | ALL  | NULL          | NULL | NULL    | NULL | 20427936 | Using temporary; Using filesort         |
+----+-------------+-------+------+---------------+------+---------+------+----------+

In contrast, the following query includes WHERE predicates that filter the results, so parallel query can be applied:

```
mysql> explain select count(*), p_brand from part where p_name is not null
   -> and p_mfgr in ('Manufacturer#1', 'Manufacturer#3') and p_retailprice > 1000
   -> group by p_brand;
```

```
+----+-----+----------+-------------------------------+
| id | ...| rows     | Extra                         |
+----+-----+----------+-------------------------------|
|  1 | ...| 20427936 | Using where; Using temporary; Using filesort; Using parallel query (5 columns, 1 filters, 2 exprs; 0 extra) |
+----+-----+----------+-------------------------------+
If the optimizer estimates that the number of returned rows for a query block is small, parallel query isn't used for that query block. The following example shows a case where a greater-than operator on the primary key column applies to millions of rows, which causes parallel query to be used. The converse less-than test is estimated to apply to only a few rows and doesn't use parallel query.

```
mysql> explain select count(*) from part where p_partkey > 10;
+----+...+----------+-------------------------------------------------------------------------------------------------------------+
| id |...| rows     | Extra                                                                                                      |
|----|...|----------|-------------------------------------------------------------------------------------------------------------|
+----+...+----------+-------------------------------------------------------------------------------------------------------------+
|  1 |...| 20427936 | Using where; **Using parallel query (1 columns, 1 filters, 0 exprs; 0 extra)** |
+----+...+----------+-------------------------------------------------------------------------------------------------------------+
```

```
mysql> explain select count(*) from part where p_partkey < 10;
+----+...+------+--------------------------+-------------------------------------------------------------------------------------------------------------+
| id |...| rows | Extra                    |
|----|...|------|--------------------------|
+----+...+------+--------------------------+
|  1 |...|    9 | Using where; **Using index** |
+----+...+------+--------------------------+
```

**Data definition language (DDL)**

In Aurora MySQL version 2, parallel query is only available for tables for which no fast data definition language (DDL) operations are pending. In Aurora MySQL version 3, you can use parallel query on a table at the same time as an instant DDL operation.

Instant DDL in Aurora MySQL version 3 replaces the fast DDL feature in Aurora MySQL version 2. For information about instant DDL, see [Instant DDL (Aurora MySQL version 3)](https://docs.aws.amazon.com/aurora/latest/userguide/data-definition-language.html).

**Column data types**

In Aurora MySQL version 3, parallel query can work with tables containing columns with data types TEXT, BLOB, JSON, and GEOMETRY. It can also work with VARCHAR and CHAR columns with a
maximum declared length longer than 768 bytes. If your query refers to any columns containing such large object types, the additional work to retrieve them does add some overhead to query processing. In that case, check if the query can omit the references to those columns. If not, run benchmarks to confirm if such queries are faster with parallel query turned on or turned off.

In Aurora MySQL version 2, parallel query has these limitations for large object types:

- TEXT, BLOB, JSON, and GEOMETRY data types aren't supported with parallel query. A query that refers to any columns of these types can't use parallel query.
- Variable-length columns (VARCHAR and CHAR data types) are compatible with parallel query up to a maximum declared length of 768 bytes. A query that refers to any columns of the types declared with a longer maximum length can't use parallel query. For columns that use multibyte character sets, the byte limit takes into account the maximum number of bytes in the character set. For example, for the character set utf8mb4 (which has a maximum character length of 4 bytes), a VARCHAR(192) column is compatible with parallel query but a VARCHAR(193) column isn't.

### Partitioned tables

You can use partitioned tables with parallel query in Aurora MySQL version 3. Because partitioned tables are represented internally as multiple smaller tables, a query that uses parallel query on a nonpartitioned table might not use parallel query on an identical partitioned table. Aurora MySQL considers whether each partition is large enough to qualify for the parallel query optimization, instead of evaluating the size of the entire table. Check whether the Aurora_pq_request_not_chosen_small_table status variable is incremented if a query on a partitioned table doesn't use parallel query when you expect it to.

For example, consider one table partitioned with PARTITION BY HASH (column) PARTITIONS 2 and another table partitioned with PARTITION BY HASH (column) PARTITIONS 10. In the table with two partitions, the partitions are five times as large as the table with ten partitions. Thus, parallel query is more likely to be used for queries against the table with fewer partitions. In the following example, the table PART_BIG_PARTITIONS has two partitions and PART_SMALL_PARTITIONS has ten partitions. With identical data, parallel query is more likely to be used for the table with fewer big partitions.

```
mysql> explain select count(*), p_brand from part_big_partitions where p_name is not null
```
 Aggregate functions, GROUP BY clauses, and HAVING clauses

Queries involving aggregate functions are often good candidates for parallel query, because they involve scanning large numbers of rows within large tables.

In Aurora MySQL 3, parallel query can optimize aggregate function calls in the select list and the HAVING clause.

Before Aurora MySQL 3, aggregate function calls in the select list or the HAVING clause aren’t pushed down to the storage layer. However, parallel query can still improve the performance of such queries with aggregate functions. It does so by first extracting column values from the raw data pages in parallel at the storage layer. It then transmits those values back to the head node in
a compact tuple format instead of as entire data pages. As always, the query requires at least one WHERE predicate for parallel query to be activated.

The following simple examples illustrate the kinds of aggregate queries that can benefit from parallel query. They do so by returning intermediate results in compact form to the head node, filtering nonmatching rows from the intermediate results, or both.

```sql
mysql> explain select sql_no_cache count(distinct p_brand) from part where p_mfgr = 'Manufacturer#5';
+----+...+----------------------------------------------------------------------------+
| id |...| Extra                                                                      |
+----+...+----------------------------------------------------------------------------+
|  1 |...| Using where; Using parallel query (2 columns, 1 filters, 0 exprs; 0 extra) |
+----+...+----------------------------------------------------------------------------+

mysql> explain select sql_no_cache p_mfgr from part where p_retailprice > 1000 group by p_mfgr having count(*) > 100;
+----+...+-------------------------------------------------------------------------------------------------------------+
| id |...| Extra                                    |
+----+...+-------------------------------------------------------------------------------------------------------------+
|  1 |...| Using where; Using temporary; Using filesort; Using parallel query (3 columns, 0 filters, 1 exprs; 0 extra) |
+----+...+-------------------------------------------------------------------------------------------------------------+
```

**Function calls in WHERE clause**

Aurora can apply the parallel query optimization to calls to most built-in functions in the WHERE clause. Parallelizing these function calls offloads some CPU work from the head node. Evaluating the predicate functions in parallel during the earliest query stage helps Aurora minimize the amount of data transmitted and processed during later stages.

Currently, the parallelization doesn't apply to function calls in the select list. Those functions are evaluated by the head node, even if identical function calls appear in the WHERE clause. The original values from relevant columns are included in the tuples transmitted from the storage.
nodes back to the head node. The head node performs any transformations such as UPPER, CONCATENATE, and so on to produce the final values for the result set.

In the following example, parallel query parallelizes the call to LOWER because it appears in the WHERE clause. Parallel query doesn't affect the calls to SUBSTR and UPPER because they appear in the select list.

```sql
mysql> explain select sql_no_cache distinct substr(upper(p_name),1,5) from part
    -> where lower(p_name) like '%cornflower%' or lower(p_name) like '%goldenrod%';
```

The same considerations apply to other expressions, such as CASE expressions or LIKE operators. For example, the following example shows that parallel query evaluates the CASE expression and LIKE operators in the WHERE clause.

```sql
mysql> explain select p_mfgr, p_retailprice from part
    -> where p_retailprice > case p_mfgr
    -> when 'Manufacturer#1' then 1000
    -> when 'Manufacturer#2' then 1200
    -> else 950
    -> end
    -> and p_name like '%vanilla%'
    -> group by p_retailprice;
```
LIMIT clause

Currently, parallel query isn't used for any query block that includes a LIMIT clause. Parallel query might still be used for earlier query phases with GROUP by, ORDER BY, or joins.

Comparison operators

The optimizer estimates how many rows to scan to evaluate comparison operators, and determines whether to use parallel query based on that estimate.

The first example following shows that an equality comparison against the primary key column can be performed efficiently without parallel query. The second example following shows that a similar comparison against an unindexed column requires scanning millions of rows and therefore can benefit from parallel query.

```
mysql> explain select * from part where p_partkey = 10;
+----+...+------+-------+
| id |...| rows | Extra |
+----+...+------+-------+
|  1 |...|    1 | NULL  |
+----+...+------+-------+

mysql> explain select * from part where p_type = 'LARGE BRUSHED BRASS';
+----+...+----------+---------------------------------------------+
| id |...| rows     | Extra                                        |
|----|...|----------|---------------------------------------------|
|    |...|----------|---------------------------------------------|
+----+...+----------+---------------------------------------------+
|  1 |...| 20427936 | Using where; Using parallel query (9 columns, 1 filters, 0 exprs; 0 extra) |
+----+...+----------+---------------------------------------------+
```
The same considerations apply for not-equals tests and for range comparisons such as less than, greater than or equal to, or BETWEEN. The optimizer estimates the number of rows to scan, and determines whether parallel query is worthwhile based on the overall volume of I/O.

## Joins

Join queries with large tables typically involve data-intensive operations that benefit from the parallel query optimization. The comparisons of column values between multiple tables (that is, the join predicates themselves) currently aren’t parallelized. However, parallel query can push down some of the internal processing for other join phases, such as constructing the Bloom filter during a hash join. Parallel query can apply to join queries even without a WHERE clause. Therefore, a join query is an exception to the rule that a WHERE clause is required to use parallel query.

Each phase of join processing is evaluated to check if it is eligible for parallel query. If more than one phase can use parallel query, these phases are performed in sequence. Thus, each join query counts as a single parallel query session in terms of concurrency limits.

For example, when a join query includes WHERE predicates to filter the rows from one of the joined tables, that filtering option can use parallel query. As another example, suppose that a join query uses the hash join mechanism, for example to join a big table with a small table. In this case, the table scan to produce the Bloom filter data structure might be able to use parallel query.

### Note

Parallel query is typically used for the kinds of resource-intensive queries that benefit from the hash join optimization. The method for turning on the hash join optimization depends on the Aurora MySQL version. For details for each version, see [Turning on hash join for parallel query clusters](#). For information about how to use hash joins effectively, see [Optimizing large Aurora MySQL join queries with hash joins](#).

```
mysql> explain select count(*) from orders join customer where o_custkey = c_custkey;
+----+...+----------+-------+---------------+-------------+...+-----------
+-----------------------------------------------------------------------------------------------------------------
| id |...| table    | type  | possible_keys | key         |...| rows      | Extra |
+----+...+----------+-------+---------------+-------------+...+-----------
+...+-----------------------------+-----------------------------+...+-----------
|    | id |...| table     | type  | possible_keys | key         |...| rows      | Extra |
|    |    |...|           |       |              |              |...|            |       |
```

---

**Parallel query and SQL constructs**

1522
For a join query that uses the nested loop mechanism, the outermost nested loop block might use parallel query. The use of parallel query depends on the same factors as usual, such as the presence of additional filter conditions in the WHERE clause.

```
For example, the following query uses parallel query for the subquery block but not the outer block.

mysql> explain select count(*) from part where
```
Currently, correlated subqueries can't use the parallel query optimization.

**UNION**

Each query block in a UNION query can use parallel query, or not, based on the usual characteristics of the table, WHERE clause, and so on, for each part of the UNION.

```
mysql> explain select p_partkey from part where p_name like '%choco_ate%'
    -> union select p_partkey from part where p_name like '%vanil_a%';
+----+----------------+...+----------+
| id | select_type |...| rows     | Extra
|    | PRIMARY      |...| NULL     | Impossible WHERE noticed after reading const tables
|  2 | UNION        |...| 20427936 | Using where; Using parallel query (2 columns, 0 filters, 1 exprs; 0 extra)
|  NULL | UNION RESULT | <union1,2> |...| NULL | Using temporary
```

**Note**

Each UNION clause within the query is run sequentially. Even if the query includes multiple stages that all use parallel query, it only runs a single parallel query at any one time.
Therefore, even a complex multistage query only counts as 1 toward the limit of concurrent parallel queries.

Views

The optimizer rewrites any query using a view as a longer query using the underlying tables. Thus, parallel query works the same whether table references are views or real tables. All the same considerations about whether to use parallel query for a query, and which parts are pushed down, apply to the final rewritten query.

For example, the following query plan shows a view definition that usually doesn't use parallel query. When the view is queried with additional WHERE clauses, Aurora MySQL uses parallel query.

```sql
mysql> create view part_view as select * from part;
mysql> explain select count(*) from part_view where p_partkey is not null;
+----+-----+---------+-------------------+
| id |...| rows    | Extra             |
| 1  |...| 20427936 | Using where; Using parallel query (1 columns, 0 filters, 0 exprs; 1 extra) |
```

Data manipulation language (DML) statements

The INSERT statement can use parallel query for the SELECT phase of processing, if the SELECT part meets the other conditions for parallel query.

```sql
mysql> create table part_subset like part;
mysql> explain insert into part_subset select * from part where p_mfgr = 'Manufacturer#1';
+----+-----+---------+-------------------+
| id |...| rows    | Extra             |
| 1  |...|         |                  |
```

Parallel query and SQL constructs
Typically, after an INSERT statement, the data for the newly inserted rows is in the buffer pool. Therefore, a table might not be eligible for parallel query immediately after inserting a large number of rows. Later, after the data is evicted from the buffer pool during normal operation, queries against the table might begin using parallel query again.

The CREATE TABLE AS SELECT statement doesn't use parallel query, even if the SELECT portion of the statement would otherwise be eligible for parallel query. The DDL aspect of this statement makes it incompatible with parallel query processing. In contrast, in the INSERT ... SELECT statement, the SELECT portion can use parallel query.

Parallel query is never used for DELETE or UPDATE statements, regardless of the size of the table and predicates in the WHERE clause.

Transactions and locking

You can use all the isolation levels on the Aurora primary instance.

On Aurora reader DB instances, parallel query applies to statements performed under the REPEATABLE READ isolation level. Aurora MySQL version 2.09 or higher can also use the READ COMMITTED isolation level on reader DB instances. REPEATABLE READ is the default isolation level for Aurora reader DB instances. To use READ COMMITTED isolation level on reader DB instances requires setting the aurora_read_replica_read_committed configuration option at the session level. The READ COMMITTED isolation level for reader instances complies with SQL
standard behavior. However, the isolation is less strict on reader instances than when queries use READ COMMITTED isolation level on the writer instance.

For more information about Aurora isolation levels, especially the differences in READ COMMITTED between writer and reader instances, see Aurora MySQL isolation levels.

After a big transaction is finished, the table statistics might be stale. Such stale statistics might require an ANALYZE TABLE statement before Aurora can accurately estimate the number of rows. A large-scale DML statement might also bring a substantial portion of the table data into the buffer pool. Having this data in the buffer pool can lead to parallel query being chosen less frequently for that table until the data is evicted from the pool.

When your session is inside a long-running transaction (by default, 10 minutes), further queries inside that session don't use parallel query. A timeout can also occur during a single long-running query. This type of timeout might happen if the query runs for longer than the maximum interval (currently 10 minutes) before the parallel query processing starts.

You can reduce the chance of starting long-running transactions accidentally by setting autocommit=1 in mysql sessions where you perform ad hoc (one-time) queries. Even a SELECT statement against a table begins a transaction by creating a read view. A read view is a consistent set of data for subsequent queries that remains until the transaction is committed. Be aware of this restriction also when using JDBC or ODBC applications with Aurora, because such applications might run with the autocommit setting turned off.

The following example shows how, with the autocommit setting turned off, running a query against a table creates a read view that implicitly begins a transaction. Queries that are run shortly afterward can still use parallel query. However, after a pause of several minutes, queries are no longer eligible for parallel query. Ending the transaction with COMMIT or ROLLBACK restores parallel query eligibility.

```
mysql> set autocommit=0;

mysql> explain select sql_no_cache count(*) from part where p_retailprice > 10.0;
+----+...+---------+---------------------------------------------------------------+  
| id |...| rows    | Extra                                                                 |
|----|...|---------|---------------------------------------------------------------------|
|  1 |...| 2976129 | Using where; Using parallel query (1 columns, 1 filters, 0 exprs; 0 extra) |
```
mysql> select sleep(720); explain select sql_no_cache count(*) from part where p_retailprice > 10.0;
+-----------+
| sleep(720) |
+-----------+
| 0         |
+-----------+
1 row in set (12 min 0.00 sec)

mysql> commit;

mysql> explain select sql_no_cache count(*) from part where p_retailprice > 10.0;
+----+...+---------+-------------+
| id |...| rows    | Extra       |
| 1  |...| 2976129 | Using where |
+----+...+---------+-------------+

mysql> commit;

mysql> explain select sql_no_cache count(*) from part where p_retailprice > 10.0;
+----+...+---------+-------------+
| id |...| rows    | Extra       |
| 1  |...| 2976129 | Using where; Using parallel query (1 columns, 1 filters, 0 exprs; 0 extra) |
+----+...+---------+-------------+

To see how many times queries weren't eligible for parallel query because they were inside long-running transactions, check the status variable Aurora_pq_request_not_chosen_long_trx.

mysql> show global status like '%pq%trx%';
+-----------------------------+-------+
| Variable_name               | Value |
| Aurora_pq_request_not_chosen_long_trx | 4     |
+-----------------------------+-------+
Any SELECT statement that acquires locks, such as the SELECT FOR UPDATE or SELECT LOCK IN SHARE MODE syntax, can't use parallel query.

Parallel query can work for a table that is locked by a LOCK TABLES statement.

```
mysql> explain select o_orderpriority, o_shippriority from orders where o_clerk = 'Clerk#000095055';
+----+...+-----------+-------------+
| id |...| rows      | Extra       |
+----+...+-----------+-------------+
|  1 |...| 154545408 | Using where |
+----+...+-----------+-------------+

mysql> explain select o_orderpriority, o_shippriority from orders where o_clerk = 'Clerk#000095055' for update;
+----+...+-----------+-------------+
| id |...| rows      | Extra       |
+----+...+-----------+-------------+
|  1 |...| 154545408 | Using where |
+----+...+-----------+-------------+
```

B-tree indexes

The statistics gathered by the ANALYZE TABLE statement help the optimizer to decide when to use parallel query or index lookups, based on the characteristics of the data for each column. Keep statistics current by running ANALYZE TABLE after DML operations that make substantial changes to the data within a table.

If index lookups can perform a query efficiently without a data-intensive scan, Aurora might use index lookups. Doing so avoids the overhead of parallel query processing. There are also concurrency limits on the number of parallel queries that can run simultaneously on any Aurora DB cluster. Make sure to use best practices for indexing your tables, so that your most frequent and most highly concurrent queries use index lookups.
Full-text search (FTS) indexes

Currently, parallel query isn't used for tables that contain a full-text search index, regardless of whether the query refers to such indexed columns or uses the MATCH operator.

Virtual columns

Currently, parallel query isn't used for tables that contain a virtual column, regardless of whether the query refers to any virtual columns.

Built-in caching mechanisms

Aurora includes built-in caching mechanisms, namely the buffer pool and the query cache. The Aurora optimizer chooses between these caching mechanisms and parallel query depending on which one is most effective for a particular query.

When a parallel query filters rows and transforms and extracts column values, data is transmitted back to the head node as tuples rather than as data pages. Therefore, running a parallel query doesn't add any pages to the buffer pool, or evict pages that are already in the buffer pool.

Aurora checks the number of pages of table data that are present in the buffer pool, and what proportion of the table data that number represents. Aurora uses that information to determine whether it is more efficient to use parallel query (and bypass the data in the buffer pool). Alternatively, Aurora might use the nonparallel query processing path, which uses data cached in the buffer pool. Which pages are cached and how data-intensive queries affect caching and eviction depends on configuration settings related to the buffer pool. Therefore, it can be hard to predict whether any particular query uses parallel query, because the choice depends on the ever-changing data within the buffer pool.

Also, Aurora imposes concurrency limits on parallel queries. Because not every query uses parallel query, tables that are accessed by multiple queries simultaneously typically have a substantial portion of their data in the buffer pool. Therefore, Aurora often doesn't choose these tables for parallel queries.

When you run a sequence of nonparallel queries on the same table, the first query might be slow due to the data not being in the buffer pool. Then the second and subsequent queries are much faster because the buffer pool is now "warmed up". Parallel queries typically show consistent performance from the very first query against the table. When conducting performance tests, benchmark the nonparallel queries with both a cold and a warm buffer pool. In some cases, the results with a warm buffer pool can compare well to parallel query times. In these cases, consider
factors such as the frequency of queries against that table. Also consider whether it is worthwhile to keep the data for that table in the buffer pool.

The query cache avoids rerunning a query when an identical query is submitted and the underlying table data hasn't changed. Queries optimized by parallel query feature can go into the query cache, effectively making them instantaneous when run again.

### Note

When conducting performance comparisons, the query cache can produce artificially low timing numbers. Therefore, in benchmark-like situations, you can use the `sql_no_cache` hint. This hint prevents the result from being served from the query cache, even if the same query had been run previously. The hint comes immediately after the `SELECT` statement in a query. Many parallel query examples in this topic include this hint, to make query times comparable between versions of the query for which parallel query is turned on and turned off.

Make sure that you remove this hint from your source when you move to production use of parallel query.

### Optimizer hints

Another way to control the optimizer is by using optimizer hints, which can be specified within individual statements. For example, you can turn on an optimization for one table in a statement, and then turn off the optimization for a different table. For more information about these hints, see [Optimizer Hints](https://dev.mysql.com/doc/refman/8.0/en(optimizer-hints).html) in the *MySQL Reference Manual*.

You can use SQL hints with Aurora MySQL queries to fine-tune performance. You can also use hints to prevent execution plans for important queries from changing because of unpredictable conditions.

We have extended the SQL hints feature to help you control optimizer choices for your query plans. These hints apply to queries that use parallel query optimization. For more information, see [Aurora MySQL hints](https://aws.amazon.com/documentation/aurora/mysql/hints/).

### MyISAM temporary tables

The parallel query optimization only applies to InnoDB tables. Because Aurora MySQL uses MyISAM behind the scenes for temporary tables, internal query phases involving temporary tables never
use parallel query. These query phases are indicated by `Using temporary` in the EXPLAIN output.
Using Advanced Auditing with an Amazon Aurora MySQL DB cluster

You can use the high-performance Advanced Auditing feature in Amazon Aurora MySQL to audit database activity. To do so, you enable the collection of audit logs by setting several DB cluster parameters. When Advanced Auditing is enabled, you can use it to log any combination of supported events.

You can view or download the audit logs to review the audit information for one DB instance at a time. To do so, you can use the procedures in Monitoring Amazon Aurora log files.

Tip
For an Aurora DB cluster containing multiple DB instances, you might find it more convenient to examine the audit logs for all instances in the cluster. To do so, you can use CloudWatch Logs. You can turn on a setting at the cluster level to publish the Aurora MySQL audit log data to a log group in CloudWatch. Then you can view, filter, and search the audit logs through the CloudWatch interface. For more information, see Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs.

Enabling Advanced Auditing

Use the parameters described in this section to enable and configure Advanced Auditing for your DB cluster.

Use the server_audit Logging parameter to enable or disable Advanced Auditing.

Use the server_audit_events parameter to specify what events to log.

Use the server_audit_incl_users and server_audit_excl_users parameters to specify who gets audited. By default, all users are audited. For details about how these parameters work when one or both are left empty, or the same user names are specified in both, see server_audit_incl_users and server_audit_excl_users.

Configure Advanced Auditing by setting these parameters in the parameter group used by your DB cluster. You can use the procedure shown in Modifying parameters in a DB parameter group to modify DB cluster parameters using the AWS Management Console. You can use the modify-db-
cluster-parameter-group AWS CLI command or the ModifyDBClusterParameterGroup Amazon RDS API operation to modify DB cluster parameters programmatically.

Modifying these parameters doesn't require a DB cluster restart when the parameter group is already associated with your cluster. When you associate the parameter group with the cluster for the first time, a cluster restart is required.

Topics

- server_audit_logging
- server_audit_events
- server_audit_incl_users
- server_audit_excl_users

server_audit_logging

Enables or disables Advanced Auditing. This parameter defaults to OFF; set it to ON to enable Advanced Auditing.

No audit data appears in the logs unless you also define one or more types of events to audit using the server_audit_events parameter.

To confirm that audit data is logged for a DB instance, check that some log files for that instance have names of the form audit/audit.log.\_other_identifying\_information. To see the names of the log files, follow the procedure in Viewing and listing database log files.

server_audit_events

Contains the comma-delimited list of events to log. Events must be specified in all caps, and there should be no white space between the list elements, for example: CONNECT, QUERY_DDL. This parameter defaults to an empty string.

You can log any combination of the following events:

- CONNECT – Logs both successful and failed connections and also disconnections. This event includes user information.
- QUERY – Logs all queries in plain text, including queries that fail due to syntax or permission errors.
Tip

With this event type turned on, the audit data includes information about the continuous monitoring and health-checking information that Aurora does automatically. If you are only interested in particular kinds of operations, you can use the more specific kinds of events. You can also use the CloudWatch interface to search in the logs for events related to specific databases, tables, or users.

- QUERY_DCL – Similar to the QUERY event, but returns only data control language (DCL) queries (GRANT, REVOKE, and so on).
- QUERY_DDL – Similar to the QUERY event, but returns only data definition language (DDL) queries (CREATE, ALTER, and so on).
- QUERY_DML – Similar to the QUERY event, but returns only data manipulation language (DML) queries (INSERT, UPDATE, and so on, and also SELECT).
- TABLE – Logs the tables that were affected by query execution.

Note

There's no filter in Aurora that excludes certain queries from audit logs. To exclude SELECT queries, you must exclude all DML statements.
If a certain user is reporting these internal SELECT queries in the audit logs, then you can exclude that user by setting the `server_audit_excl_users` DB cluster parameter. However, if that user is also used in other activities and can't be omitted, then there is no other option for excluding SELECT queries.

server_audit_incl_users

Contains the comma-delimited list of user names for users whose activity is logged. There should be no white space between the list elements, for example: `user_3, user_4`. This parameter defaults to an empty string. The maximum length is 1024 characters. Specified user names must match corresponding values in the `User` column of the `mysql.user` table. For more information about user names, see [Account User Names and Passwords](#) in the MySQL documentation.

If `server_audit_incl_users` and `server_audit_excl_users` are both empty (the default), all users are audited.
If you add users to server_audit_incl_users and leave server_audit_excl_users empty, then only those users are audited.

If you add users to server_audit_excl_users and leave server_audit_incl_users empty, then all users are audited, except for those listed in server_audit_excl_users.

If you add the same users to both server_audit_excl_users and server_audit_incl_users, then those users are audited. When the same user is listed in both settings, server_audit_incl_users is given higher priority.

Connect and disconnect events aren't affected by this variable; they are always logged if specified. A user is logged even if that user is also specified in the server_audit_excl_users parameter, because server_audit_incl_users has higher priority.

**server_audit_excl_users**

Contains the comma-delimited list of user names for users whose activity isn't logged. There should be no white space between the list elements, for example: rdsadmin,user_1,user_2. This parameter defaults to an empty string. The maximum length is 1024 characters. Specified user names must match corresponding values in the User column of the mysql.user table. For more information about user names, see [Account User Names and Passwords](#) in the MySQL documentation.

If server_audit_incl_users and server_audit_excl_users are both empty (the default), all users are audited.

If you add users to server_audit_excl_users and leave server_audit_incl_users empty, then only those users that you list in server_audit_excl_users are not audited, and all other users are.

If you add the same users to both server_audit_excl_users and server_audit_incl_users, then those users are audited. When the same user is listed in both settings, server_audit_incl_users is given higher priority.

Connect and disconnect events aren't affected by this variable; they are always logged if specified. A user is logged if that user is also specified in the server_audit_incl_users parameter, because that setting has higher priority than server_audit_excl_users.
Viewing audit logs

You can view and download the audit logs by using the console. On the Databases page, choose the DB instance to show its details, then scroll to the Logs section. The audit logs produced by the Advanced Auditing feature have names of the form audit/audit.log.<other_identifying_information>.

To download a log file, choose that file in the Logs section and then choose Download.

You can also get a list of the log files by using the describe-db-log-files AWS CLI command. You can download the contents of a log file by using the download-db-log-file-portion AWS CLI command. For more information, see Viewing and listing database log files and Downloading a database log file.

Audit log details

Log files are represented as comma-separated variable (CSV) files in UTF-8 format. Queries are also wrapped in single quotes (').

The audit log is stored separately on the local storage of each instance. Each Aurora instance distributes writes across four log files at a time. The maximum size of the logs is 100 MB in aggregate. When this non-configurable limit is reached, Aurora rotates the files and generates four new files.

Tip

Log file entries are not in sequential order. To order the entries, use the timestamp value. To see the latest events, you might have to review all log files. For more flexibility in sorting and searching the log data, turn on the setting to upload the audit logs to CloudWatch and view them using the CloudWatch interface.

To view audit data with more types of fields and with output in JSON format, you can also use the Database Activity Streams feature. For more information, see Monitoring Amazon Aurora with Database Activity Streams.

The audit log files include the following comma-delimited information in rows, in the specified order:
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timestamp</td>
<td>The Unix time stamp for the logged event with microsecond precision.</td>
</tr>
<tr>
<td>serverhost</td>
<td>The name of the instance that the event is logged for.</td>
</tr>
<tr>
<td>username</td>
<td>The connected user name of the user.</td>
</tr>
<tr>
<td>host</td>
<td>The host that the user connected from.</td>
</tr>
<tr>
<td>connectionid</td>
<td>The connection ID number for the logged operation.</td>
</tr>
<tr>
<td>queryid</td>
<td>The query ID number, which can be used for finding the relational table events and related queries. For TABLE events, multiple lines are added.</td>
</tr>
<tr>
<td>operation</td>
<td>The recorded action type. Possible values are: CONNECT, QUERY, READ, WRITE, CREATE, ALTER, RENAME, and DROP.</td>
</tr>
<tr>
<td>database</td>
<td>The active database, as set by the USE command.</td>
</tr>
<tr>
<td>object</td>
<td>For QUERY events, this value indicates the query that the database performed. For TABLE events, it indicates the table name.</td>
</tr>
<tr>
<td>retcode</td>
<td>The return code of the logged operation.</td>
</tr>
</tbody>
</table>
Replication with Amazon Aurora MySQL

The Aurora MySQL replication features are key to the high availability and performance of your cluster. Aurora makes it easy to create or resize clusters with up to 15 Aurora Replicas.

All the replicas work from the same underlying data. If some database instances go offline, others remain available to continue processing queries or to take over as the writer if needed. Aurora automatically spreads your read-only connections across multiple database instances, helping an Aurora cluster to support query-intensive workloads.

In the following topics, you can find information about how Aurora MySQL replication works and how to fine-tune replication settings for best availability and performance.

Topics

- Using Aurora Replicas
- Replication options for Amazon Aurora MySQL
- Performance considerations for Amazon Aurora MySQL replication
- Zero-downtime restart (ZDR) for Amazon Aurora MySQL
- Configuring replication filters with Aurora MySQL
- Monitoring Amazon Aurora MySQL replication
- Using local write forwarding in an Amazon Aurora MySQL DB cluster
- Replicating Amazon Aurora MySQL DB clusters across AWS Regions
- Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)
- Using GTID-based replication

Using Aurora Replicas

Aurora Replicas are independent endpoints in an Aurora DB cluster, best used for scaling read operations and increasing availability. Up to 15 Aurora Replicas can be distributed across the Availability Zones that a DB cluster spans within an AWS Region. Although the DB cluster volume is made up of multiple copies of the data for the DB cluster, the data in the cluster volume is represented as a single, logical volume to the primary instance and to Aurora Replicas in the DB cluster. For more information about Aurora Replicas, see Aurora Replicas.
Aurora Replicas work well for read scaling because they are fully dedicated to read operations on your cluster volume. Write operations are managed by the primary instance. Because the cluster volume is shared among all instances in your Aurora MySQL DB cluster, no additional work is required to replicate a copy of the data for each Aurora Replica. In contrast, MySQL read replicas must replay, on a single thread, all write operations from the source DB instance to their local data store. This limitation can affect the ability of MySQL read replicas to support large volumes of read traffic.

With Aurora MySQL, when an Aurora Replica is deleted, its instance endpoint is removed immediately, and the Aurora Replica is removed from the reader endpoint. If there are statements running on the Aurora Replica that is being deleted, there is a three minute grace period. Existing statements can finish gracefully during the grace period. When the grace period ends, the Aurora Replica is shut down and deleted.

⚠️ Important

Aurora Replicas for Aurora MySQL always use the REPEATABLE READ default transaction isolation level for operations on InnoDB tables. You can use the SET TRANSACTION ISOLATION LEVEL command to change the transaction level only for the primary instance of an Aurora MySQL DB cluster. This restriction avoids user-level locks on Aurora Replicas, and allows Aurora Replicas to scale to support thousands of active user connections while still keeping replica lag to a minimum.

ℹ️ Note

DDL statements that run on the primary instance might interrupt database connections on the associated Aurora Replicas. If an Aurora Replica connection is actively using a database object, such as a table, and that object is modified on the primary instance using a DDL statement, the Aurora Replica connection is interrupted.

ℹ️ Note

The China (Ningxia) Region does not support cross-Region read replicas.
Replication options for Amazon Aurora MySQL

You can set up replication between any of the following options:

- Two Aurora MySQL DB clusters in different AWS Regions, by creating a cross-Region read replica of an Aurora MySQL DB cluster.
  
  For more information, see Replicating Amazon Aurora MySQL DB clusters across AWS Regions.

- Two Aurora MySQL DB clusters in the same AWS Region, by using MySQL binary log (binlog) replication.
  
  For more information, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication).

- An RDS for MySQL DB instance as the source and an Aurora MySQL DB cluster, by creating an Aurora read replica of an RDS for MySQL DB instance.
  
  You can use this approach to bring existing and ongoing data changes into Aurora MySQL during migration to Aurora. For more information, see Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica.

  You can also use this approach to increase the scalability of read queries for your data. You do so by querying the data using one or more DB instances within a read-only Aurora MySQL cluster. For more information, see Using Amazon Aurora to scale reads for your MySQL database.

- An Aurora MySQL DB cluster in one AWS Region and up to five Aurora read-only Aurora MySQL DB clusters in different Regions, by creating an Aurora global database.
  
  You can use an Aurora global database to support applications with a world-wide footprint. The primary Aurora MySQL DB cluster has a Writer instance and up to 15 Aurora Replicas. The read-only secondary Aurora MySQL DB clusters can each be made up of as many as 16 Aurora Replicas. For more information, see Using Amazon Aurora global databases.

Note

Rebooting the primary instance of an Amazon Aurora DB cluster also automatically reboots the Aurora Replicas for that DB cluster, to re-establish an entry point that guarantees read/write consistency across the DB cluster.
Performance considerations for Amazon Aurora MySQL replication

The following features help you to fine-tune the performance of Aurora MySQL replication.

The replica log compression feature automatically reduces network bandwidth for replication messages. Because each message is transmitted to all Aurora Replicas, the benefits are greater for larger clusters. This feature involves some CPU overhead on the writer node to perform the compression. It's always enabled in Aurora MySQL version 2 and version 3.

The binlog filtering feature automatically reduces network bandwidth for replication messages. Because the Aurora Replicas don't use the binlog information that is included in the replication messages, that data is omitted from the messages sent to those nodes.

In Aurora MySQL version 2, you can control this feature by changing the `aurora_enable_repl_bin_log_filtering` parameter. This parameter is on by default. Because this optimization is intended to be transparent, you might turn off this setting only during diagnosis or troubleshooting for issues related to replication. For example, you can do so to match the behavior of an older Aurora MySQL cluster where this feature was not available.

Binlog filtering is always enabled in Aurora MySQL version 3.

Zero-downtime restart (ZDR) for Amazon Aurora MySQL

The zero-downtime restart (ZDR) feature can preserve some or all of the active connections to DB instances during certain kinds of restarts. ZDR applies to restarts that Aurora performs automatically to resolve error conditions, for example when a replica begins to lag too far behind the source.

⚠️ Important

The ZDR mechanism operates on a best-effort basis. The Aurora MySQL versions, instance classes, error conditions, compatible SQL operations, and other factors that determine where ZDR applies are subject to change at any time.

ZDR for Aurora MySQL 2.x requires version 2.10 and higher. ZDR is available in all minor versions of Aurora MySQL 3.x. In Aurora MySQL version 2 and 3, the ZDR mechanism is turned on by default and Aurora doesn't use the `aurora_enable_zdr` parameter.
Aurora reports on the **Events** page activities related to zero-downtime restart. Aurora records an event when it attempts a restart using the ZDR mechanism. This event states why Aurora performs the restart. Then Aurora records another event when the restart finishes. This final event reports how long the process took, and how many connections were preserved or dropped during the restart. You can consult the database error log to see more details about what happened during the restart.

Although connections remain intact following a successful ZDR operation, some variables and features are reinitialized. The following kinds of information aren't preserved through a restart caused by zero-downtime restart:

- Global variables. Aurora restores session variables, but it doesn't restore global variables after the restart.
- Status variables. In particular, the uptime value reported by the engine status is reset.
- `LAST_INSERT_ID`.
- Diagnostic information from INFORMATION_SCHEMA and PERFORMANCE_SCHEMA tables. This diagnostic information also appears in the output of commands such as `SHOW PROFILE` and `SHOW PROFILES`.

The following table shows the versions, instance roles, and other circumstances that determine whether Aurora can use the ZDR mechanism when restarting DB instances in your cluster.

<table>
<thead>
<tr>
<th>Aurora MySQL version</th>
<th>ZDR applies to the writer?</th>
<th>ZDR applies to readers?</th>
<th>ZDR always enabled?</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.x, lower than 2.10.0</td>
<td>No</td>
<td>No</td>
<td>N/A</td>
<td>ZDR isn't available for these versions.</td>
</tr>
<tr>
<td>2.10.0–2.11.0</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Aurora rolls back any transactions that are in progress on active connections. Your application must retry the transactions.</td>
</tr>
</tbody>
</table>
### Configuring replication filters with Aurora MySQL

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

<table>
<thead>
<tr>
<th>Aurora MySQL version</th>
<th>ZDR applies to the writer?</th>
<th>ZDR applies to readers?</th>
<th>ZDR always enabled?</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2.11.1 and higher</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Aurora cancels any connections that use TLS/SSL, temporary tables, table locks, or user locks. Aurora rolls back any transactions that are in progress on active connections. Your application must retry the transactions.</td>
</tr>
<tr>
<td>3.01–3.03</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Aurora rolls back any transactions that are in progress on active connections. Your application must retry the transactions. Aurora cancels any connections that use TLS/SSL, temporary tables, table locks, or user locks.</td>
</tr>
<tr>
<td>3.04 and higher</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Aurora rolls back any transactions that are in progress on active connections. Your application must retry the transactions. Aurora cancels any connections that use temporary tables, table locks, or user locks.</td>
</tr>
</tbody>
</table>
• To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.

• To exclude databases and tables from read replicas for security reasons.

• To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.

• For a DB cluster that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.

• To specify which databases and tables are replicated with an Aurora MySQL DB cluster that is configured as a replica in an inbound replication topology. For more information about this configuration, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication).

Topics

• Setting replication filtering parameters for Aurora MySQL

• Replication filtering limitations for Aurora MySQL

• Replication filtering examples for Aurora MySQL

• Viewing the replication filters for a read replica

Setting replication filtering parameters for Aurora MySQL

To configure replication filters, set the following parameters:

• binlog-do-db – Replicate changes to the specified binary logs. When you set this parameter for a binlog source cluster, only the binary logs specified in the parameter are replicated.

• binlog-ignore-db – Don't replicate changes to the specified binary logs. When the binlog-do-db parameter is set for a binlog source cluster, this parameter isn't evaluated.

• replicate-do-db – Replicate changes to the specified databases. When you set this parameter for a binlog replica cluster, only the databases specified in the parameter are replicated.

• replicate-ignore-db – Don't replicate changes to the specified databases. When the replicate-do-db parameter is set for a binlog replica cluster, this parameter isn't evaluated.

• replicate-do-table – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the replicate-do-db or replicate-ignore-db parameter is set, make sure to include the database that includes the specified tables in replication with the binlog replica cluster.
• **replicate-ignore-table** – Don't replicate changes to the specified tables. When the `replicate-do-table` parameter is set for a binlog replica cluster, this parameter isn't evaluated.

• **replicate-wild-do-table** – Replicate tables based on the specified database and table name patterns. The `%` and `_` wildcard characters are supported. When the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the binlog replica cluster.

• **replicate-wild-ignore-table** – Don't replicate tables based on the specified database and table name patterns. The `%` and `_` wildcard characters are supported. When the `replicate-do-table` or `replicate-wild-do-table` parameter is set for a binlog replica cluster, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MySQL documentation:

• For general information, see [Replica Server Options and Variables](#).

• For information about how database replication filtering parameters are evaluated, see [Evaluation of Database-Level Replication and Binary Logging Options](#).

• For information about how table replication filtering parameters are evaluated, see [Evaluation of Table-Level Replication Options](#).

By default, each of these parameters has an empty value. On each binlog cluster, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the `%` and `_` wildcard characters in the `replicate-wild-do-table` and `replicate-wild-ignore-table` parameters. The `%` wildcard matches any number of characters, and the `_` wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the `binlog_format` parameter determines whether the replication is row-based or statement-based. For more information, see [Configuring Aurora MySQL binary logging](#).
Note

All data definition language (DDL) statements are replicated as statements, regardless of the `binlog_format` setting on the source DB instance.

Replication filtering limitations for Aurora MySQL

The following limitations apply to replication filtering for Aurora MySQL:

- Replication filters are supported only for Aurora MySQL version 3.
- Each replication filtering parameter has a 2,000-character limit.
- Commas aren't supported in replication filters.
- Replication filtering doesn't support XA transactions.

For more information, see *Restrictions on XA Transactions* in the MySQL documentation.

Replication filtering examples for Aurora MySQL

To configure replication filtering for a read replica, modify the replication filtering parameters in the DB cluster parameter group associated with the read replica.

Note

You can't modify a default DB cluster parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB cluster parameter groups, see *Working with parameter groups*.

You can set parameters in a DB cluster parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see *Modifying parameters in a DB parameter group*. When you set parameters in a DB cluster parameter group, all of the DB clusters associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a DB cluster parameter group, make sure that the parameter group is associated only with read replica clusters. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set `ApplyMethod` to `immediate` so that the parameter changes occur immediately after the CLI command.
completes. If you want a pending change to be applied after the read replica is rebooted, set ApplyMethod to pending-reboot.

The following examples set replication filters:

- **Including databases in replication**
- **Including tables in replication**
- **Including tables in replication with wildcard characters**
- **Excluding databases from replication**
- **Excluding tables from replication**
- **Excluding tables from replication using wildcard characters**

**Example Including databases in replication**

The following example includes the mydb1 and mydb2 databases in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
   --db-cluster-parameter-group-name myparametergroup \
   --parameters "ParameterName=replicate-do-db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^
   --db-cluster-parameter-group-name myparametergroup ^
   --parameters "ParameterName=replicate-do-db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"
```

**Example Including tables in replication**

The following example includes the table1 and table2 tables in database mydb1 in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^
```

Configuring replication filters
Example Including tables in replication using wildcard characters

The following example includes tables with names that begin with *order* and *return* in database *mydb* in replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-parameter-group
--db-cluster-parameter-group-name myparametergroup
--parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order %,mydb.return %',ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-cluster-parameter-group ^
--db-cluster-parameter-group-name myparametergroup ^
--parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order %,mydb.return %',ApplyMethod=immediate"
```

Example Excluding databases from replication

The following example excludes the *mydb5* and *mydb6* databases from replication.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-parameter-group
--db-cluster-parameter-group-name myparametergroup
--parameters "ParameterName=replicate-do-table,ParameterValue='mydb1.table1,mydb1.table2',ApplyMethod=immediate"
```

For Windows:

```bash
aws rds modify-db-cluster-parameter-group ^
--db-cluster-parameter-group-name myparametergroup ^
--parameters "ParameterName=replicate-do-table,ParameterValue='mydb1.table1,mydb1.table2',ApplyMethod=immediate"
```
For Windows:

```
aws rds modify-db-cluster-parameter-group
  --db-cluster-parameter-group-name myparametergroup
  --parameters "ParameterName=replicate-ignore-db,ParameterValue='mydb5,mydb6',ApplyMethod=immediate"
```

**Example Excluding tables from replication**

The following example excludes tables table1 in database mydb5 and table2 in database mydb6 from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
  --db-cluster-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-ignore-table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group
  --db-cluster-parameter-group-name myparametergroup
  --parameters "ParameterName=replicate-ignore-table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

**Example Excluding tables from replication using wildcard characters**

The following example excludes tables with names that begin with order and return in database mydb7 from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
  --db-cluster-parameter-group-name myparametergroup \
  --parameters "ParameterName=replicate-ignore-table,ParameterValue='mydb5.order*,mydb6.return*',ApplyMethod=immediate"
```
Amazon Aurora
User Guide for Aurora

--parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order%,mydb7.return%',ApplyMethod=immediate"

For Windows:

```bash
aws rds modify-db-cluster-parameter-group ^
   --db-cluster-parameter-group-name myparametergroup ^
   --parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order%,mydb7.return%',ApplyMethod=immediate"
```

**Viewing the replication filters for a read replica**

You can view the replication filters for a read replica in the following ways:

- Check the settings of the replication filtering parameters in the parameter group associated with the read replica.
  
  For instructions, see [Viewing parameter values for a DB parameter group](#).

- In a MySQL client, connect to the read replica and run the `SHOW REPLICA STATUS` statement.

  In the output, the following fields show the replication filters for the read replica:

  - `Binlog_Do_DB`
  - `Binlog_Ignore_DB`
  - `Replicate_Do_DB`
  - `Replicate_Ignore_DB`
  - `Replicate_Do_Table`
  - `Replicate_Ignore_Table`
  - `Replicate_Wild_Do_Table`
  - `Replicate_Wild_Ignore_Table`

  For more information about these fields, see [Checking Replication Status](#) in the MySQL documentation.

**Monitoring Amazon Aurora MySQL replication**

Read scaling and high availability depend on minimal lag time. You can monitor how far an Aurora Replica is lagging behind the primary instance of your Aurora MySQL DB cluster by monitoring the
Amazon CloudWatch AuroraReplicaLag metric. The AuroraReplicaLag metric is recorded in each Aurora Replica.

The primary DB instance also records the AuroraReplicaLagMaximum and AuroraReplicaLagMinimum Amazon CloudWatch metrics. The AuroraReplicaLagMaximum metric records the maximum amount of lag between the primary DB instance and each Aurora Replica in the DB cluster. The AuroraReplicaLagMinimum metric records the minimum amount of lag between the primary DB instance and each Aurora Replica in the DB cluster.

If you need the most current value for Aurora Replica lag, you can check the AuroraReplicaLag metric in Amazon CloudWatch. The Aurora Replica lag is also recorded on each Aurora Replica of your Aurora MySQL DB cluster in the information_schema.replica_host_status table. For more information on this table, see information_schema.replica_host_status.

For more information on monitoring RDS instances and CloudWatch metrics, see Monitoring metrics in an Amazon Aurora cluster.
Using local write forwarding in an Amazon Aurora MySQL DB cluster

Local (in-cluster) write forwarding allows your applications to issue read/write transactions directly on an Aurora Replica. These transactions are then forwarded to the writer DB instance to be committed. You can use local write forwarding when your applications require read-after-write consistency, which is the ability to read the latest write in a transaction.

Read replicas receive updates asynchronously from the writer. Without write forwarding, you have to transact any reads that require read-after-write consistency on the writer DB instance. Or you have to develop complex custom application logic to take advantage of multiple read replicas for scalability. Your applications must fully split all read and write traffic, maintaining two sets of database connections to send the traffic to the correct endpoint. This development overhead complicates application design when the queries are part of a single logical session, or transaction, within the application. Moreover, because replication lag can differ among read replicas, it's difficult to achieve global read consistency across all instances in the database.

Write forwarding avoids the need to split those transactions or send them exclusively to the writer, which simplifies application development. This new capability makes it easy to achieve read scale for workloads that need to read the latest write in a transaction and aren't sensitive to write latency.

Local write forwarding is different from global write forwarding, which forwards writes from a secondary DB cluster to the primary DB cluster in an Aurora global database. You can use local write forwarding in a DB cluster that is part of an Aurora global database. For more information, see Using write forwarding in an Amazon Aurora global database.

Local write forwarding requires Aurora MySQL version 3.04 or higher.

Topics

- Enabling local write forwarding
- Checking if a DB cluster has write forwarding enabled
- Application and SQL compatibility with write forwarding
- Isolation levels for write forwarding
- Read consistency for write forwarding
- Running multipart statements with write forwarding
- Transactions with write forwarding
- Configuration parameters for write forwarding
Enabling local write forwarding

By default, local write forwarding isn’t enabled for Aurora MySQL DB clusters. You enable local write forwarding at the cluster level, not at the instance level.

⚠️ Important
You can also enable local write forwarding for cross-Region read replicas that use binary logging, but write operations aren't forwarded to the source AWS Region. They're forwarded to the writer DB instance of the binlog read replica cluster. Use this method only if you have a use case for writing to the binlog read replica in the secondary AWS Region. Otherwise, you might end up with a "split-brain" scenario where replicated datasets are inconsistent with each other.

We recommend that you use global write forwarding with global databases, rather than local write forwarding on cross-Region read replicas, unless absolutely necessary. For more information, see Using write forwarding in an Amazon Aurora global database.

Console

Using the AWS Management Console, select the **Turn on local write forwarding** check box under **Read replica write forwarding** when you create or modify a DB cluster.

AWS CLI

To enable write forwarding with the AWS CLI, use the **--enable-local-write-forwarding** option. This option works when you create a new DB cluster using the create-db-cluster command. It also works when you modify an existing DB cluster using the modify-db-cluster command. You can disable write forwarding by using the **--no-enable-local-write-forwarding** option with these same CLI commands.

The following example creates an Aurora MySQL DB cluster with write forwarding enabled.

```
aws rds create-db-cluster \
  --db-cluster-identifier write-forwarding-test-cluster \
```
You then create writer and reader DB instances so that you can use write forwarding. For more information, see [Creating an Amazon Aurora DB cluster](#).

**RDS API**

To enable write forwarding using the Amazon RDS API, set the `EnableLocalWriteForwarding` parameter to `true`. This parameter works when you create a new DB cluster using the `CreateDBCluster` operation. It also works when you modify an existing DB cluster using the `ModifyDBCluster` operation. You can disable write forwarding by setting the `EnableLocalWriteForwarding` parameter to `false`.

**Enabling write forwarding for database sessions**

The `aurora_replica_read_consistency` parameter is a DB parameter and DB cluster parameter that enables write forwarding. You can specify EVENTUAL, SESSION, or GLOBAL for the read consistency level. To learn more about consistency levels, see [Read consistency for write forwarding](#).

The following rules apply to this parameter:

- The default value is " (null).
- Write forwarding is available only if you set `aurora_replica_read_consistency` to EVENTUAL, SESSION, or GLOBAL. This parameter is relevant only in reader instances of DB clusters that have write forwarding enabled.
- You can't set this parameter (when empty) or unset it (when already set) inside a multistatement transaction. You can change it from one valid value to another valid value during such a transaction, but we don't recommend this action.

**Checking if a DB cluster has write forwarding enabled**

To determine that you can use write forwarding in a DB cluster, confirm that the cluster has the attribute `LocalWriteForwardingStatus` set to enabled.

```
--enable-local-write-forwarding \
--engine aurora-mysql \
--engine-version 8.0.mysql_aurora.3.04.0 \
--master-username myuser \
--master-user-password mypassword \
--backup-retention 1
```

You then create writer and reader DB instances so that you can use write forwarding. For more information, see [Creating an Amazon Aurora DB cluster](#).
In the AWS Management Console, on the **Configuration** tab of the details page for the cluster, you see the status **Enabled** for **Local read replica write forwarding**.

To see the status of the write forwarding setting for all of your clusters, run the following AWS CLI command.

**Example**

```bash
aws rds describe-db-clusters \
--query '*[].
{DBClusterIdentifier:DBClusterIdentifier,LocalWriteForwardingStatus:LocalWriteForwardingStatus}

[
  {
    "LocalWriteForwardingStatus": "enabled",
    "DBClusterIdentifier": "write-forwarding-test-cluster-1"
  },
  {
    "LocalWriteForwardingStatus": "disabled",
    "DBClusterIdentifier": "write-forwarding-test-cluster-2"
  },
  {
    "LocalWriteForwardingStatus": "requested",
    "DBClusterIdentifier": "test-global-cluster-2"
  },
  {
    "LocalWriteForwardingStatus": "null",
    "DBClusterIdentifier": "aurora-mysql-v2-cluster"
  }
]
```

A DB cluster can have the following values for **LocalWriteForwardingStatus**:

- **disabled** – Write forwarding is disabled.
- **disabling** – Write forwarding is in the process of being disabled.
- **enabled** – Write forwarding is enabled.
- **enabling** – Write forwarding is in the process of being enabled.
- **null** – Write forwarding isn't available for this DB cluster.
- **requested** – Write forwarding has been requested, but is not yet active.
Application and SQL compatibility with write forwarding

You can use the following kinds of SQL statements with write forwarding:

- Data manipulation language (DML) statements, such as INSERT, DELETE, and UPDATE. There are some restrictions on the properties of these statements that you can use with write forwarding, as described following.
- SELECT ... LOCK IN SHARE MODE and SELECT FOR UPDATE statements.
- PREPARE and EXECUTE statements.

Certain statements aren't allowed or can produce stale results when you use them in a DB cluster with write forwarding. Thus, the EnableLocalWriteForwarding setting is disabled by default for DB clusters. Before enabling it, check to make sure that your application code isn't affected by any of these restrictions.

The following restrictions apply to the SQL statements you use with write forwarding. In some cases, you can use the statements on DB clusters with write forwarding enabled. This approach works if write forwarding isn't enabled within the session by the aurora_replica_read_consistency configuration parameter. If you try to use a statement when it's not allowed because of write forwarding, then you will see an error message similar to the following:

```
ERROR 1235 (42000): This version of MySQL doesn't yet support 'operation' with write forwarding'.
```

Data definition language (DDL)

Connect to the writer DB instance to run DDL statements. You can't run them from reader DB instances.

Updating a permanent table using data from a temporary table

You can use temporary tables on DB clusters with write forwarding enabled. However, you can't use a DML statement to modify a permanent table if the statement refers to a temporary table. For example, you can't use an INSERT ... SELECT statement that takes the data from a temporary table.
XA transactions

You can’t use the following statements on a DB cluster when write forwarding is enabled within the session. You can use these statements on DB clusters that don’t have write forwarding enabled, or within sessions where the `aurora_replica_read_consistency` setting is empty. Before enabling write forwarding within a session, check if your code uses these statements.

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER [CONVERT XID]
```

LOAD statements for permanent tables

You can’t use the following statements on a DB cluster with write forwarding enabled.

```
LOAD DATA INFILE 'data.txt' INTO TABLE t1;
LOAD XML LOCAL INFILE 'test.xml' INTO TABLE t1;
```

Plugin statements

You can’t use the following statements on a DB cluster with write forwarding enabled.

```
INSTALL PLUGIN example SONAME 'ha_example.so';
UNINSTALL PLUGIN example;
```

SAVEPOINT statements

You can’t use the following statements on a DB cluster when write forwarding is enabled within the session. You can use these statements on DB clusters that don’t have write forwarding enabled, or within sessions where the `aurora_replica_read_consistency` setting is blank. Check if your code uses these statements before enabling write forwarding within a session.

```
SAVEPOINT t1_save;
ROLLBACK TO SAVEPOINT t1_save;
RELEASE SAVEPOINT t1_save;
```
Isolation levels for write forwarding

In sessions that use write forwarding, you can only use the REPEATABLE READ isolation level. Although you can also use the READ COMMITTED isolation level with Aurora Replicas, that isolation level doesn't work with write forwarding. For information about the REPEATABLE READ and READ COMMITTED isolation levels, see Aurora MySQL isolation levels.

Read consistency for write forwarding

You can control the degree of read consistency on a DB cluster. The read consistency level determines how long the DB cluster waits before each read operation to ensure that some or all changes are replicated from the writer. You can adjust the read consistency level to make sure that all forwarded write operations from your session are visible in the DB cluster before any subsequent queries. You can also use this setting to make sure that queries on the DB cluster always see the most current updates from the writer. This setting also applies to queries submitted by other sessions or other clusters. To specify this type of behavior for your application, choose a value for the aurora_replica_read_consistency DB parameter or DB cluster parameter.

⚠️ Important

Always set the aurora_replica_read_consistency DB parameter or DB cluster parameter when you want to forward writes. If you don't, then Aurora doesn't forward writes. This parameter has an empty value by default, so choose a specific value when you use this parameter. The aurora_replica_read_consistency parameter only affects DB clusters or instances that have write forwarding enabled.

As you increase the consistency level, your application spends more time waiting for changes to be propagated between DB instances. You can choose the balance between fast response time and making sure that changes made in other DB instances are fully available before your queries run.

You can specify the following values for the aurora_replica_read_consistency parameter:

- EVENTUAL – Results of write operations in the same session aren't visible until the write operation is performed on the writer DB instance. The query doesn't wait for the updated results to be available. Thus it might retrieve the older data or the updated data, depending on the timing of the statements and the amount of replication lag. This is the same consistency as for Aurora MySQL DB clusters that don't use write forwarding.
• SESSION – All queries that use write forwarding see the results of all changes made in that session. The changes are visible regardless of whether the transaction is committed. If necessary, the query waits for the results of forwarded write operations to be replicated.

• GLOBAL – A session sees all committed changes across all sessions and instances in the DB cluster. Each query might wait for a period that varies depending on the amount of session lag. The query proceeds when the DB cluster is up-to-date with all committed data from the writer, as of the time that the query began.

For information about the configuration parameters involved in write forwarding, see Configuration parameters for write forwarding.

Note

You can also use aurora_replica_read_consistency as a session variable, for example:

```sql
mysql> set aurora_replica_read_consistency = 'session';
```

Examples of using write forwarding

The following examples show the effects of the aurora_replica_read_consistency parameter on running INSERT statements followed by SELECT statements. The results can differ, depending on the value of aurora_replica_read_consistency and the timing of the statements.

To achieve higher consistency, you might wait briefly before issuing the SELECT statement. Or Aurora can automatically wait until the results finish replicating before proceeding with SELECT.

For information on setting DB parameters, see Working with parameter groups.

Example with aurora_replica_read_consistency set to EVENTUAL

Running an INSERT statement, immediately followed by a SELECT statement, returns a value for COUNT(*) with the number of rows before the new row is inserted. Running the SELECT again a short time later returns the updated row count. The SELECT statements don't wait.

```sql
mysql> select count(*) from t1;
+----------+
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1560</td>
</tr>
</tbody>
</table>
+----------+
```
Example with **aurora_replica_read_consistency** set to **SESSION**

A SELECT statement immediately after an INSERT waits until the changes from the INSERT statement are visible. Subsequent SELECT statements don't wait.
With the read consistency setting still set to SESSION, introducing a brief wait after performing an INSERT statement makes the updated row count available by the time the next SELECT statement runs.

```sql
mysql> insert into t1 values (6); select sleep(2); select count(*) from t1;
Query OK, 1 row affected (0.07 sec)
+----------+
| sleep(2) |
+----------+
|        0 |
+----------+
1 row in set (2.01 sec)
```

Example with `aurora_replica_read_consistency` set to GLOBAL

Each SELECT statement waits for all data changes, as of the start time of the statement, to be visible before performing the query. The wait time for each SELECT statement varies, depending on the amount of replication lag.

```sql
mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|        8 |
+----------+
1 row in set (0.75 sec)
```

mysql> select count(*) from t1;
+----------+
| count(*) |
+----------+
|        8 |
+----------+
1 row in set (0.00 sec)
Running multipart statements with write forwarding

A DML statement might consist of multiple parts, such as an INSERT ... SELECT statement or a DELETE ... WHERE statement. In this case, the entire statement is forwarded to the writer DB instance and run there.

Transactions with write forwarding

If the transaction access mode is set to read only, write forwarding isn't used. You can specify the access mode for the transaction by using the SET TRANSACTION statement or the START TRANSACTION statement. You can also specify the transaction access mode by changing the value of the transaction_read_only session variable. You can change this session value only while you're connected to a DB cluster that has write forwarding enabled.

If a long-running transaction doesn't issue any statement for a substantial period of time, it might exceed the idle timeout period. This period has a default of one minute. You can set the aurora_fwd_writer_idle_timeout parameter to increase it up to one day. A transaction that exceeds the idle timeout is canceled by the writer instance. The next subsequent statement you submit receives a timeout error. Then Aurora rolls back the transaction.

This type of error can occur in other cases when write forwarding becomes unavailable. For example, Aurora cancels any transactions that use write forwarding if you restart the DB cluster or if you disable write forwarding.

When a writer instance in a cluster using local write forwarding is restarted, any active, forwarded transactions and queries on reader instances using local write forwarding are automatically closed. After the writer instance is available again, you can retry these transactions.
Configuration parameters for write forwarding

The Aurora DB parameter groups include settings for the write forwarding feature. Details about these parameters are summarized in the following table, with usage notes after the table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Scope</th>
<th>Type</th>
<th>Default value</th>
<th>Valid values</th>
</tr>
</thead>
<tbody>
<tr>
<td>aurora_fwd_writer_idle_timeout</td>
<td>Cluster</td>
<td>Unsigned integer</td>
<td>60</td>
<td>1–86,400</td>
</tr>
<tr>
<td>aurora_fwd_writer_max_connections_pct</td>
<td>Cluster</td>
<td>Unsigned long integer</td>
<td>10</td>
<td>0–90</td>
</tr>
<tr>
<td>aurora_replica_read_consistency</td>
<td>Cluster or instance</td>
<td>Enum</td>
<td>&quot; (null)</td>
<td>EVENTUAL, SESSION, GLOBAL</td>
</tr>
</tbody>
</table>

To control incoming write requests, use these settings:

- **aurora_fwd_writer_idle_timeout** – The number of seconds the writer DB instance waits for activity on a connection that's forwarded from a reader instance before closing it. If the session remains idle beyond this period, Aurora cancels the session.

- **aurora_fwd_writer_max_connections_pct** – The upper limit on database connections that can be used on a writer DB instance to handle queries forwarded from reader instances. It's expressed as a percentage of the max_connections setting for the writer. For example, if max_connections is 800 and aurora_fwd_master_max_connections_pct or aurora_fwd_writer_max_connections_pct is 10, then the writer allows a maximum of 80 simultaneous forwarded sessions. These connections come from the same connection pool managed by the max_connections setting.

This setting applies only on the writer when it has write forwarding enabled. If you decrease the value, existing connections aren't affected. Aurora takes the new value of the setting into account when attempting to create a new connection from a DB cluster. The default value is 10, representing 10% of the max_connections value.
Note

Because `aurora_fwd_writer_idle_timeout` and `aurora_fwd_writer_max_connections_pct` are DB cluster parameters, all DB instances in each cluster have the same values for these parameters.

For more information about `aurora_replica_read_consistency`, see [Read consistency for write forwarding](#).

For more information on DB parameter groups, see [Working with parameter groups](#).

### Amazon CloudWatch metrics and Aurora MySQL status variables for write forwarding

The following Amazon CloudWatch metrics and Aurora MySQL status variables apply when you use write forwarding on one or more DB clusters. These metrics and status variables are all measured on the writer DB instance.

<table>
<thead>
<tr>
<th>CloudWatch metric</th>
<th>Aurora MySQL status variable</th>
<th>Unit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ForwardingWriterDMLLatency</td>
<td>–</td>
<td>Milliseconds</td>
<td>Average time to process each forwarded DML statement on the writer DB instance. It doesn't include the time for the DB cluster to forward the write request, or the time to replicate changes back to the writer.</td>
</tr>
<tr>
<td>CloudWatch metric</td>
<td>Aurora MySQL status variable</td>
<td>Unit</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ForwardingWriterDM</td>
<td>–</td>
<td>Count per second</td>
<td>Number of forwarded DML statements processed each second by this writer DB instance.</td>
</tr>
<tr>
<td>LThroughput</td>
<td>Aurora_fw_d_writer_open_sessions</td>
<td>Count</td>
<td>Number of forwarded sessions on the writer DB instance.</td>
</tr>
<tr>
<td></td>
<td>Aurora_fw_d_writer_dml_stmt_count</td>
<td>Count</td>
<td>Total number of DML statements forwarded to this writer DB instance.</td>
</tr>
<tr>
<td></td>
<td>Aurora_fw_d_writer_dml_stmt_duration</td>
<td>Microseconds</td>
<td>Total duration of DML statements forwarded to this writer DB instance.</td>
</tr>
<tr>
<td></td>
<td>Aurora_fw_d_writer_select_stmt_count</td>
<td>Count</td>
<td>Total number of SELECT statements forwarded to this writer DB instance.</td>
</tr>
<tr>
<td></td>
<td>Aurora_fw_d_writer_select_stmt_duration</td>
<td>Microseconds</td>
<td>Total duration of SELECT statements forwarded to this writer DB instance.</td>
</tr>
</tbody>
</table>

The following CloudWatch metrics and Aurora MySQL status variables are measured on each reader DB instance in a DB cluster with write forwarding enabled.
<table>
<thead>
<tr>
<th>CloudWatch metric</th>
<th>Aurora MySQL status variable</th>
<th>Unit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ForwardingReplicaDMLLatency</td>
<td></td>

</table>
Identifying forwarded transactions and queries

You can use the `information_schema.aurora_forwarding_processlist` table to identify forwarded transactions and queries. For more information on this table, see `information_schema.aurora_forwarding_processlist`.

The following example shows all forwarded connections on a writer DB instance.

```sql
mysql> select * from information_schema.AURORA_FORWARDING_PROCESSLIST where IS_FORWARDED=1 order by REPLICA_SESSION_ID;
```

```
+-----+----------+--------------------+----------+---------+------+--------------
| ID  | USER     | HOST               | DB       | COMMAND | TIME | STATE        |
| INFO                                       | IS_FORWARDED | REPLICA_SESSION_ID |
| REPLICA_INSTANCE_IDENTIFIER     | REPLICA_CLUSTER_NAME | REPLICA_REGION |
|-----------------------------------+-----------------------------------------------+--------------|
| 648 | myuser   | IP_address:port1   | sysbench | Query   | 0    | async commit |
| UPDATE sbtest58 SET k=k+1 WHERE id=4802579 | 1 | 637 | my-db-cluster-instance-2 | my-db-cluster | us-west-2 |
| 650 | myuser   | IP_address:port2   | sysbench | Query   | 0    | async commit |
| UPDATE sbtest54 SET k=k+1 WHERE id=2503953 | 1 | 639 | my-db-cluster-instance-2 | my-db-cluster | us-west-2 |
```

On the forwarding reader DB instance, you can see the threads associated with these writer DB connections by running `SHOW PROCESSLIST`. The REPLICA_SESSION_ID values on the writer, 637 and 639, are the same as the Id values on the reader.

```sql
mysql> select @@aurora_server_id;
```

```
+---------------------------------+------------------+
| @@aurora_server_id              | my-db-cluster-instance-2 |
```

Using local write forwarding
mysql> show processlist;

Replicating Amazon Aurora MySQL DB clusters across AWS Regions

You can create an Amazon Aurora MySQL DB cluster as a read replica in a different AWS Region than the source DB cluster. Taking this approach can improve your disaster recovery capabilities, let you scale read operations into an AWS Region that is closer to your users, and make it easier to migrate from one AWS Region to another.

You can create read replicas of both encrypted and unencrypted DB clusters. The read replica must be encrypted if the source DB cluster is encrypted.

For each source DB cluster, you can have up to five cross-Region DB clusters that are read replicas.

### Note

As an alternative to cross-Region read replicas, you can scale read operations with minimal lag time by using an Aurora global database. An Aurora global database has a primary Aurora DB cluster in one AWS Region and up to five secondary read-only DB clusters in different Regions. Each secondary DB cluster can include up to 16 (rather than 15) Aurora Replicas. Replication from the primary DB cluster to all secondaries is handled by the Aurora storage layer rather than by the database engine, so lag time for replicating changes is minimal—typically, less than 1 second. Keeping the database engine out of the replication process means that the database engine is dedicated to processing workloads. It also means that you don't need to configure or manage the Aurora MySQL binlog (binary logging) replication. To learn more, see [Using Amazon Aurora global databases](#).

When you create an Aurora MySQL DB cluster read replica in another AWS Region, you should be aware of the following:

- Both your source DB cluster and your cross-Region read replica DB cluster can have up to 15 Aurora Replicas, along with the primary instance for the DB cluster. By using this functionality, you can scale read operations for both your source AWS Region and your replication target AWS Region.
- In a cross-Region scenario, there is more lag time between the source DB cluster and the read replica due to the longer network channels between AWS Regions.
- Data transferred for cross-Region replication incurs Amazon RDS data transfer charges. The following cross-Region replication actions generate charges for the data transferred out of the source AWS Region:
• When you create the read replica, Amazon RDS takes a snapshot of the source cluster and transfers the snapshot to the AWS Region that holds the read replica.

• For each data modification made in the source databases, Amazon RDS transfers data from the source region to the AWS Region that holds the read replica.

For more information about Amazon RDS data transfer pricing, see Amazon Aurora pricing.

• You can run multiple concurrent create or delete actions for read replicas that reference the same source DB cluster. However, you must stay within the limit of five read replicas for each source DB cluster.

• For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB cluster. If you scale the source DB cluster, you should also scale the read replicas.

Topics

• Before you begin
• Creating an Amazon Aurora MySQL DB cluster that is a cross-Region read replica
• Viewing Amazon Aurora MySQL cross-Region replicas
• Promoting a read replica to be a DB cluster
• Troubleshooting Amazon Aurora MySQL cross Region replicas

Before you begin

Before you can create an Aurora MySQL DB cluster that is a cross-Region read replica, you must turn on binary logging on your source Aurora MySQL DB cluster. Cross-region replication for Aurora MySQL uses MySQL binary replication to replay changes on the cross-Region read replica DB cluster.

To turn on binary logging on an Aurora MySQL DB cluster, update the `binlog_format` parameter for your source DB cluster. The `binlog_format` parameter is a cluster-level parameter that is in the default cluster parameter group. If your DB cluster uses the default DB cluster parameter group, create a new DB cluster parameter group to modify `binlog_format` settings. We recommend that you set the `binlog_format` to MIXED. However, you can also set `binlog_format` to ROW or STATEMENT if you need a specific binlog format. Reboot your Aurora DB cluster for the change to take effect.
For more information about using binary logging with Aurora MySQL, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication). For more information about modifying Aurora MySQL configuration parameters, see Amazon Aurora DB cluster and DB instance parameters and Working with parameter groups.

Creating an Amazon Aurora MySQL DB cluster that is a cross-Region read replica

You can create an Aurora DB cluster that is a cross-Region read replica by using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the Amazon RDS API. You can create cross-Region read replicas from both encrypted and unencrypted DB clusters.

When you create a cross-Region read replica for Aurora MySQL by using the AWS Management Console, Amazon RDS creates a DB cluster in the target AWS Region, and then automatically creates a DB instance that is the primary instance for that DB cluster.

When you create a cross-Region read replica using the AWS CLI or RDS API, you first create the DB cluster in the target AWS Region and wait for it to become active. Once it is active, you then create a DB instance that is the primary instance for that DB cluster.

Replication begins when the primary instance of the read replica DB cluster becomes available.

Use the following procedures to create a cross-Region read replica from an Aurora MySQL DB cluster. These procedures work for creating read replicas from either encrypted or unencrypted DB clusters.

Console

To create an Aurora MySQL DB cluster that is a cross-Region read replica with the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the top-right corner of the AWS Management Console, select the AWS Region that hosts your source DB cluster.
3. In the navigation pane, choose Databases.
4. Choose the DB cluster for which you want to create a cross-Region read replica.
5. For Actions, choose Create cross-Region read replica.
6. On the Create cross region read replica page, choose the option settings for your cross-Region read replica DB cluster, as described in the following table.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Destination region</td>
<td>Choose the AWS Region to host the new cross-Region read replica DB cluster.</td>
</tr>
<tr>
<td>Destination DB subnet group</td>
<td>Choose the DB subnet group to use for the cross-Region read replica DB cluster.</td>
</tr>
<tr>
<td>Publicly accessible</td>
<td>Choose Yes to give the cross-Region read replica DB cluster a public IP address; otherwise, select No.</td>
</tr>
<tr>
<td>Encryption</td>
<td>Select <strong>Enable Encryption</strong> to turn on encryption at rest for this DB cluster. For more information, see <a href="#">Encrypting Amazon Aurora resources</a>.</td>
</tr>
<tr>
<td>AWS KMS key</td>
<td>Only available if Encryption is set to <strong>Enable Encryption</strong>. Select the AWS KMS key to use for encrypting this DB cluster. For more information, see <a href="#">Encrypting Amazon Aurora resources</a>.</td>
</tr>
<tr>
<td>DB instance class</td>
<td>Choose a DB instance class that defines the processing and memory requirements for the primary instance in the DB cluster. For more information about DB instance class options, see <a href="#">Aurora DB instance classes</a>.</td>
</tr>
<tr>
<td>Multi-AZ deployment</td>
<td>Choose Yes to create a read replica of the new DB cluster in another Availability Zone in the target AWS Region for failover support. For more information about multiple Availability Zones, see <a href="#">Regions and Availability Zones</a>.</td>
</tr>
<tr>
<td>Read replica source</td>
<td>Choose the source DB cluster to create a cross-Region read replica for.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| DB instance identifier | Type a name for the primary instance in your cross-Region read replica DB cluster. This identifier is used in the endpoint address for the primary instance of the new DB cluster.  

The DB instance identifier has the following constraints:  

- It must contain from 1 to 63 alphanumeric characters or hyphens.  
- Its first character must be a letter.  
- It cannot end with a hyphen or contain two consecutive hyphens.  
- It must be unique for all DB instances for each AWS account, for each AWS Region.  

Because the cross-Region read replica DB cluster is created from a snapshot of the source DB cluster, the master user name and master password for the read replica are the same as the master user name and master password for the source DB cluster. |
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| DB cluster identifier   | Type a name for your cross-Region read replica DB cluster that is unique for your account in the target AWS Region for your replica. This identifier is used in the cluster endpoint address for your DB cluster. For information on the cluster endpoint, see Amazon Aurora connection management.

The DB cluster identifier has the following constraints:

- It must contain from 1 to 63 alphanumeric characters or hyphens.
- Its first character must be a letter.
- It cannot end with a hyphen or contain two consecutive hyphens.
- It must be unique for all DB clusters for each AWS account, for each AWS Region. |
<p>| Priority                | Choose a failover priority for the primary instance of the new DB cluster. This priority determines the order in which Aurora Replicas are promoted when recovering from a primary instance failure. If you don't select a value, the default is tier-1. For more information, see Fault tolerance for an Aurora DB cluster. |
| Database port           | Specify the port for applications and utilities to use to access the database. Aurora DB clusters default to the default MySQL port, 3306. Firewalls at some companies block connections to this port. If your company firewall blocks the default port, choose another port for the new DB cluster. |</p>
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>

<td>This setting doesn't apply to Aurora MySQL DB clusters.</td>
</tr>
</tbody>
</table>

For more information about engine updates for Aurora MySQL, see [Database engine updates for Amazon Aurora MySQL](#).  

7. Choose **Create** to create your cross-Region read replica for Aurora.

**AWS CLI**

**To create an Aurora MySQL DB cluster that is a cross-Region read replica with the CLI**

1. Call the AWS CLI **create-db-cluster** command in the AWS Region where you want to create the read replica DB cluster. Include the **--replication-source-identifier** option and specify the Amazon Resource Name (ARN) of the source DB cluster to create a read replica for.
For cross-Region replication where the DB cluster identified by `--replication-source-identifier` is encrypted, specify the `--kms-key-id` option and the `--storage-encrypted` option.

**Note**

You can set up cross-Region replication from an unencrypted DB cluster to an encrypted read replica by specifying `--storage-encrypted` and providing a value for `--kms-key-id`.

You can't specify the `--master-username` and `--master-user-password` parameters. Those values are taken from the source DB cluster.

The following code example creates a read replica in the us-east-1 Region from an unencrypted DB cluster snapshot in the us-west-2 Region. The command is called in the us-east-1 Region. This example specifies the `--manage-master-user-password` option to generate the master user password and manage it in Secrets Manager. For more information, see [Password management with Amazon Aurora and AWS Secrets Manager](#). Alternatively, you can use the `--master-password` option to specify and manage the password yourself.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
  --db-cluster-identifier sample-replica-cluster \
  --engine aurora \
```

For Windows:

```
aws rds create-db-cluster ^
  --db-cluster-identifier sample-replica-cluster ^
  --engine aurora ^
```
The following code example creates a read replica in the us-east-1 Region from an encrypted DB cluster snapshot in the us-west-2 Region. The command is called in the us-east-1 Region.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster \
  --db-cluster-identifier sample-replica-cluster \
  --engine aurora \
  --kms-key-id my-us-east-1-key \
  --storage-encrypted
```

For Windows:

```bash
aws rds create-db-cluster ^
  --db-cluster-identifier sample-replica-cluster ^
  --engine aurora ^
  --kms-key-id my-us-east-1-key ^
  --storage-encrypted
```

The `--source-region` option is required for cross-Region replication between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions, where the DB cluster identified by `--replication-source-identifier` is encrypted. For `--source-region`, specify the AWS Region of the source DB cluster.

If `--source-region` isn't specified, specify a `--pre-signed-url` value. A presigned URL is a URL that contains a Signature Version 4 signed request for the create-db-cluster command that is called in the source AWS Region. To learn more about the `--pre-signed-url` option, see `create-db-cluster` in the AWS CLI Command Reference.

2. Check that the DB cluster has become available to use by using the AWS CLI `describe-db-clusters` command, as shown in the following example.

```bash
aws rds describe-db-clusters --db-cluster-identifier sample-replica-cluster
```
When the `describe-db-clusters` results show a status of available, create the primary instance for the DB cluster so that replication can begin. To do so, use the AWS CLI `create-db-instance` command as shown in the following example.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-cluster-identifier sample-replica-cluster \
  --db-instance-class db.r3.large \
  --db-instance-identifier sample-replica-instance \
  --engine aurora
```

For Windows:

```
aws rds create-db-instance ^
  --db-cluster-identifier sample-replica-cluster ^
  --db-instance-class db.r3.large ^
  --db-instance-identifier sample-replica-instance ^
  --engine aurora
```

When the DB instance is created and available, replication begins. You can determine if the DB instance is available by calling the AWS CLI `describe-db-instances` command.

**RDS API**

**To create an Aurora MySQL DB cluster that is a cross-Region read replica with the API**

1. Call the RDS API `CreateDBCluster` operation in the AWS Region where you want to create the read replica DB cluster. Include the `ReplicationSourceIdentifier` parameter and specify the Amazon Resource Name (ARN) of the source DB cluster to create a read replica for.

   For cross-Region replication where the DB cluster identified by `ReplicationSourceIdentifier` is encrypted, specify the `KmsKeyId` parameter and set the `StorageEncrypted` parameter to `true`.
Note

You can set up cross-Region replication from an unencrypted DB cluster to an encrypted read replica by specifying StorageEncrypted as `true` and providing a value for KmsKeyId. In this case, you don't need to specify PreSignedUrl.

You don't need to include the MasterUsername and MasterUserPassword parameters, because those values are taken from the source DB cluster.

The following code example creates a read replica in the us-east-1 Region from an unencrypted DB cluster snapshot in the us-west-2 Region. The action is called in the us-east-1 Region.

```https://rds.us-east-1.amazonaws.com/
?Action=CreateDBCluster
&DBClusterIdentifier=sample-replica-cluster
&Engine=aurora
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20161117/us-east-1/rds/aws4_request
&X-Amz-Date=20160201T001547Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=a04c831a0b54b5e4cd236a90dcb9f5fab7185eb3b72b5ebe9a70a4e95790c8b7```

The following code example creates a read replica in the us-east-1 Region from an encrypted DB cluster snapshot in the us-west-2 Region. The action is called in the us-east-1 Region.

```https://rds.us-east-1.amazonaws.com/
?Action=CreateDBCluster
&KmsKeyId=my-us-east-1-key
&StorageEncrypted=true
&PreSignedUrl=https%253A%252F%252Frd.s.us-west-2.amazonaws.com%252F%252FAction%252FcreateDBCluster%252F%2526DestinationRegion%252Fus-east-1%252FKmsKeyId%252F%252F%252Fmy-us-east-1-key```
For cross-Region replication between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions, where the DB cluster identified by ReplicationSourceIdentifier is encrypted, also specify the PreSignedUrl parameter. The presigned URL must be a valid request for the CreateDBCluster API operation that can be performed in the source AWS Region that contains the encrypted DB cluster to be replicated. The KMS key identifier is used to encrypt the read replica, and must be a KMS key valid for the destination AWS Region. To automatically rather than manually generate a presigned URL, use the AWS CLI `create-db-cluster` command with the `--source-region` option instead.

2. Check that the DB cluster has become available to use by using the RDS API `DescribeDBClusters` operation, as shown in the following example.

```
https://rds.us-east-1.amazonaws.com/
  ?Action=DescribeDBClusters
  &DBClusterIdentifier=sample-replica-cluster
```
When DescribeDBClusters results show a status of available, create the primary instance for the DB cluster so that replication can begin. To do so, use the RDS API CreateDBInstance action as shown in the following example.

```
https://rds.us-east-1.amazonaws.com/
?Action=CreateDBInstance
&DBClusterIdentifier=sample-replica-cluster
&DBInstanceClass=db.r3.large
&DBInstanceIdentifier=sample-replica-instance
&Engine=aurora
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&Version=2014-10-31
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20161117/us-east-1/rds/aws4_request
&X-Amz-Date=20160201T003808Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=125fe575959f5bbcebd53f2365f907179757a08b5d7a16a378dfa59387f58cdb
```

When the DB instance is created and available, replication begins. You can determine if the DB instance is available by calling the AWS CLI DescribeDBInstances command.

**Viewing Amazon Aurora MySQL cross-Region replicas**

You can view the cross-Region replication relationships for your Amazon Aurora MySQL DB clusters by calling the describe-db-clusters AWS CLI command or the DescribeDBClusters RDS API operation. In the response, refer to the ReadReplicaIdentifiers field for the DB cluster identifiers of any cross-Region read replica DB clusters. Refer to the ReplicationSourceIdentifier element for the ARN of the source DB cluster that is the replication source.
Promoting a read replica to be a DB cluster

You can promote an Aurora MySQL read replica to a standalone DB cluster. When you promote an Aurora MySQL read replica, its DB instances are rebooted before they become available.

Typically, you promote an Aurora MySQL read replica to a standalone DB cluster as a data recovery scheme if the source DB cluster fails.

To do this, first create a read replica and then monitor the source DB cluster for failures. In the event of a failure, do the following:

1. Promote the read replica.
2. Direct database traffic to the promoted DB cluster.
3. Create a replacement read replica with the promoted DB cluster as its source.

When you promote a read replica, the read replica becomes a standalone Aurora DB cluster. The promotion process can take several minutes or longer to complete, depending on the size of the read replica. After you promote the read replica to a new DB cluster, it’s just like any other DB cluster. For example, you can create read replicas from it and perform point-in-time restore operations. You can also create Aurora Replicas for the DB cluster.

Because the promoted DB cluster is no longer a read replica, you can't use it as a replication target.

The following steps show the general process for promoting a read replica to a DB cluster:

1. Stop any transactions from being written to the read replica source DB cluster, and then wait for all updates to be made to the read replica. Database updates occur on the read replica after they have occurred on the source DB cluster, and this replication lag can vary significantly. Use the ReplicaLag metric to determine when all updates have been made to the read replica. The ReplicaLag metric records the amount of time a read replica DB instance lags behind the source DB instance. When the ReplicaLag metric reaches 0, the read replica has caught up to the source DB instance.

2. Promote the read replica by using the Promote option on the Amazon RDS console, the AWS CLI command `promote-read-replica-db-cluster`, or the `PromoteReadReplicaDBCluster` Amazon RDS API operation.

You choose an Aurora MySQL DB instance to promote the read replica. After the read replica is promoted, the Aurora MySQL DB cluster is promoted to a standalone DB cluster. The DB instance
with the highest failover priority is promoted to the primary DB instance for the DB cluster. The other DB instances become Aurora Replicas.

**Note**

The promotion process takes a few minutes to complete. When you promote a read replica, replication is stopped and the DB instances are rebooted. When the reboot is complete, the read replica is available as a new DB cluster.

**Console**

To promote an Aurora MySQL read replica to a DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. On the console, choose **Instances**.
   
   The **Instance** pane appears.
3. In the **Instances** pane, choose the read replica that you want to promote.
   
   The read replicas appear as Aurora MySQL DB instances.
4. For **Actions**, choose **Promote read replica**.
5. On the acknowledgment page, choose **Promote read replica**.

**AWS CLI**

To promote a read replica to a DB cluster, use the AWS CLI `promote-read-replica-db-cluster` command.

**Example**

For Linux, macOS, or Unix:

```
aws rds promote-read-replica-db-cluster \  
    --db-cluster-identifier mydbcluster
```

For Windows:
aws rds promote-read-replica-db-cluster ^
   --db-cluster-identifier mydbcluster

RDS API

To promote a read replica to a DB cluster, call `PromoteReadReplicaDBCluster`.

Troubleshooting Amazon Aurora MySQL cross Region replicas

Following you can find a list of common error messages that you might encounter when creating an Amazon Aurora cross-Region read replica, and how to resolve the specified errors.

Source cluster [DB cluster ARN] doesn't have binlogs enabled

To resolve this issue, turn on binary logging on the source DB cluster. For more information, see Before you begin.

Source cluster [DB cluster ARN] doesn't have cluster parameter group in sync on writer

You receive this error if you have updated the `binlog_format` DB cluster parameter, but have not rebooted the primary instance for the DB cluster. Reboot the primary instance (that is, the writer) for the DB cluster and try again.

Source cluster [DB cluster ARN] already has a read replica in this region

You can have up to five cross-Region DB clusters that are read replicas for each source DB cluster in any AWS Region. If you already have the maximum number of read replicas for a DB cluster in a particular AWS Region, you must delete an existing one before you can create a new cross-Region DB cluster in that Region.

DB cluster [DB cluster ARN] requires a database engine upgrade for cross-Region replication support

To resolve this issue, upgrade the database engine version for all of the instances in the source DB cluster to the most recent database engine version, and then try creating a cross-Region read replica DB again.

Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication)

Because Amazon Aurora MySQL is compatible with MySQL, you can set up replication between a MySQL database and an Amazon Aurora MySQL DB cluster. This type of replication uses the MySQL
binary log replication, also referred to as **binlog replication**. If you use binary log replication with Aurora, we recommend that your MySQL database run MySQL version 5.5 or later. You can set up replication where your Aurora MySQL DB cluster is the replication source or the replica. You can replicate with an Amazon RDS MySQL DB instance, a MySQL database external to Amazon RDS, or another Aurora MySQL DB cluster.

### Note

You can't use binlog replication to or from certain types of Aurora DB clusters. In particular, binlog replication isn't available for Aurora Serverless v1 clusters. If the `SHOW MASTER STATUS` and `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) statement returns no output, check that the cluster you're using supports binlog replication.

In Aurora MySQL version 3, binary log replication doesn't replicate to the `mysql` system database. Passwords and accounts aren't replicated by binlog replication in Aurora MySQL version 3. Therefore, Data Control Language (DCL) statements such as `CREATE USER`, `GRANT`, and `REVOKE` aren't replicated.

You can also replicate with an RDS for MySQL DB instance or Aurora MySQL DB cluster in another AWS Region. When you're performing replication across AWS Regions, make sure that your DB clusters and DB instances are publicly accessible. If the Aurora MySQL DB clusters are in private subnets in your VPC, use VPC peering between the AWS Regions. For more information, see [A DB cluster in a VPC accessed by an EC2 instance in a different VPC](#).

If you want to configure replication between an Aurora MySQL DB cluster and an Aurora MySQL DB cluster in another AWS Region, you can create an Aurora MySQL DB cluster as a read replica in a different AWS Region from the source DB cluster. For more information, see [Replicating Amazon Aurora MySQL DB clusters across AWS Regions](#).

With Aurora MySQL version 2 and 3, you can replicate between Aurora MySQL and an external source or target that uses global transaction identifiers (GTIDs) for replication. Ensure that the GTID-related parameters in the Aurora MySQL DB cluster have settings that are compatible with the GTID status of the external database. To learn how to do this, see [Using GTID-based replication](#).

In Aurora MySQL version 3.01 and higher, you can choose how to assign GTIDs to transactions that are replicated from a source that doesn't use GTIDs. For information about the stored procedure that controls that setting, see [mysql.rds_assign_gtids_to_anonymous_transactions (Aurora MySQL version 3)](#).
Warning

When you replicate between Aurora MySQL and MySQL, make sure that you use only InnoDB tables. If you have MyISAM tables that you want to replicate, you can convert them to InnoDB before setting up replication with the following command.

```
alter table <schema>.<table_name> engine=innodb, algorithm=copy;
```

Setting up replication with MySQL or another Aurora DB cluster

Setting up MySQL replication with Aurora MySQL involves the following steps, which are discussed in detail:

1. **Turn on binary logging on the replication source**
2. **Retain binary logs on the replication source until no longer needed**
3. **Create a snapshot or dump of your replication source**
4. **Load the snapshot or dump into your replica target**
5. **Create a replication user on your replication source**
6. **Turn on replication on your replica target**
7. **Monitor your replica**

1. **Turn on binary logging on the replication source**

   Find instructions on how to turn on binary logging on the replication source for your database engine following.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL</td>
<td><strong>To turn on binary logging on an Aurora MySQL DB cluster</strong></td>
</tr>
</tbody>
</table>

   Set the `binlog_format` DB cluster parameter to `ROW`, `STATEMENT`, or `MIXED`. `MIXED` is recommended unless you have a need for a specific binlog format. (The default value is `OFF`.)
To change the `binlog_format` parameter, create a custom DB cluster parameter group and associate that custom parameter group with your DB cluster. You can't change parameters in the default DB cluster parameter group.

If you're changing the `binlog_format` parameter from `OFF` to another value, reboot your Aurora DB cluster for the change to take effect.

For more information, see Amazon Aurora DB cluster and DB instance parameters and Working with parameter groups.

### RDS for MySQL

**To turn on binary logging on an Amazon RDS DB instance**

You can't turn on binary logging directly for an Amazon RDS DB instance, but you can turn it on by doing one of the following:

- Turn on automated backups for the DB instance. You can turn on automated backups when you create a DB instance, or you can turn on backups by modifying an existing DB instance. For more information, see Creating a DB instance in the Amazon RDS User Guide.

- Create a read replica for the DB instance. For more information, see Working with read replicas in the Amazon RDS User Guide.
<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL (external)</td>
<td><strong>To set up encrypted replication</strong></td>
</tr>
</tbody>
</table>

To replicate data securely with Aurora MySQL version 2, you can use encrypted replication.

**Note**

If you don't need to use encrypted replication, you can skip these steps.

The following are prerequisites for using encrypted replication:

- Secure Sockets Layer (SSL) must be enabled on the external MySQL source database.
- A client key and client certificate must be prepared for the Aurora MySQL DB cluster.

During encrypted replication, the Aurora MySQL DB cluster acts a client to the MySQL database server. The certificates and keys for the Aurora MySQL client are in files in .pem format.

1. Ensure that you are prepared for encrypted replication:

   - If you don't have SSL enabled on the external MySQL source database and don't have a client key and client certificate prepared, turn on SSL on the MySQL database server and generate the required client key and client certificate.
   - If SSL is enabled on the external source, supply a client key and certificate for the Aurora MySQL DB cluster. If you don't have these, generate a new key and certificate for the Aurora MySQL DB cluster. To sign the client certificate, you must have the certificate authority key that you used to configure SSL on the external MySQL source database.
<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>For more information, see <a href="#">Creating SSL certificates and keys using openssl</a> in the MySQL documentation. You need the certificate authority certificate, the client key, and the client certificate.</td>
</tr>
<tr>
<td></td>
<td>2. Connect to the Aurora MySQL DB cluster as the master user using SSL. For information about connecting to an Aurora MySQL DB cluster with SSL, see <a href="#">Using TLS with Aurora MySQL DB clusters</a>.</td>
</tr>
<tr>
<td></td>
<td>3. Run the <code>mysql.rds_import_binlog_ssl_material</code> stored procedure to import the SSL information into the Aurora MySQL DB cluster. For the <code>ssl_material_value</code> parameter, insert the information from the <code>.pem</code> format files for the Aurora MySQL DB cluster in the correct JSON payload. The following example imports SSL information into an Aurora MySQL DB cluster. In <code>.pem</code> format files, the body code typically is longer than the body code shown in the example.</td>
</tr>
</tbody>
</table>

```sql
CALL mysql.rds_import_binlog_ssl_material(
    '{"ssl_ca":"-----BEGIN CERTIFICATE-----
    AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eYhCe53pcj
    qP3maAhDFcvBS706V
    hz2ItxCi+h+PnDSUaw+wNQn/mZphTk/a/gU8jEzoOWbkm4xyyb/wB96
    xbiFveSfJuo/p/d6RfJh0IiBXR
    lsLnBItntckiJ7FbtxJMXLvvwJryDUilBMTjYtwB+QhYXUMozce5Pjz5/
    i8SeJtjnV3iAoG/cQk+0FzZ
    qae3AHHco+CY/5WzUBkrHmFJz6HcXkvJdWPkYQS3xqC0+FmUZofZ22
    1Cbt5MucxcXPkX4wi+z7Wb3Rb
    BQoQzd8v7Yebe70z1PnW0yN0qFU0XA246RA8QFYiCNYwI3f05p6KLxEXAMPLE
    -----END CERTIFICATE-----\n"},
    "ssl_cert":"-----BEGIN CERTIFICATE-----
    AAAAB3NzaC1yc2EAAAADAQABAAABAQClKsfkNkuSevGj3eYhCe53pcj
    qP3maAhDFcvBS706V
    -----END CERTIFICATE-----\n"
);```
For more information, see `mysql.rds_import_binlog_ssl_material` and [Using TLS with Aurora MySQL DB clusters](#).

**Note**

After running the procedure, the secrets are stored in files. To erase the files later, you can run the `mysql.rds_remove_binlog_ssl_material` stored procedure.

### To turn on binary logging on an external MySQL database

1. From a command shell, stop the mysql service.

   ```bash
   sudo service mysqld stop
   ```

2. Edit the `my.cnf` file (this file is usually under `/etc`).
### Database engine

<table>
<thead>
<tr>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sudo vi /etc/my.cnf</code></td>
</tr>
</tbody>
</table>

Add the `log_bin` and `server_id` options to the `[mysqld]` section. The `log_bin` option provides a file name identifier for binary log files. The `server_id` option provides a unique identifier for the server in source-replica relationships.

If encrypted replication isn't required, ensure that the external MySQL database is started with binlogs enabled and SSL is turned off.

The following are the relevant entries in the `/etc/my.cnf` file for unencrypted data.

```ini
log-bin=mysql-bin
server-id=2133421
innodb_flush_log_at_trx_commit=1
sync_binlog=1
```

If encrypted replication is required, ensure that the external MySQL database is started with SSL and binlogs enabled.

The entries in the `/etc/my.cnf` file include the `.pem` file locations for the MySQL database server.

```ini
log-bin=mysql-bin
server-id=2133421
innodb_flush_log_at_trx_commit=1
sync_binlog=1

# Setup SSL.
ssl-ca=/home/sslcerts/ca.pem
ssl-cert=/home/sslcerts/server-cert.pem
ssl-key=/home/sslcerts/server-key.pem
```

Additionally, the `sql_mode` option for your MySQL DB instance must be set to 0, or must not be included in your `my.cnf` file.
<table>
<thead>
<tr>
<th><strong>Database engine</strong></th>
<th><strong>Instructions</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>While connected to the external MySQL database, record the external MySQL database's binary log position.</td>
</tr>
<tr>
<td></td>
<td>mysql&gt; SHOW MASTER STATUS;</td>
</tr>
<tr>
<td></td>
<td>Your output should be similar to the following:</td>
</tr>
<tr>
<td></td>
<td>+------------------+----------+--------------+------------------</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>+------------------+----------+--------------+------------------</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>+------------------+----------+--------------+------------------</td>
</tr>
<tr>
<td></td>
<td>1 row in set (0.00 sec)</td>
</tr>
<tr>
<td></td>
<td>For more information, see <a href="#">Setting the replication source configuration</a> in the MySQL documentation.</td>
</tr>
<tr>
<td></td>
<td>3. Start the mysql service.</td>
</tr>
<tr>
<td></td>
<td>sudo service mysqld start</td>
</tr>
</tbody>
</table>

### 2. Retain binary logs on the replication source until no longer needed

When you use MySQL binary log replication, Amazon RDS doesn't manage the replication process. As a result, you need to ensure that the binlog files on your replication source are retained until after the changes have been applied to the replica. This maintenance helps you to restore your source database in the event of a failure.

Use the following instructions to retain binary logs for your database engine.
Amazon Aurora

Database engine | Instructions
---|---
Aurora MySQL | **To retain binary logs on an Aurora MySQL DB cluster**

You don't have access to the binlog files for an Aurora MySQL DB cluster. As a result, you must choose a time frame to retain the binlog files on your replication source long enough to ensure that the changes have been applied to your replica before the binlog file is deleted by Amazon RDS. You can retain binlog files on an Aurora MySQL DB cluster for up to 90 days.

If you're setting up replication with a MySQL database or RDS for MySQL DB instance as the replica, and the database that you are creating a replica for is very large, choose a large time frame to retain binlog files until the initial copy of the database to the replica is complete and the replica lag has reached 0.

To set the binary log retention time frame, use the `mysql.rds_set_configuration` procedure and specify a configuration parameter of 'binlog retention hours' along with the number of hours to retain binlog files on the DB cluster. The maximum value for Aurora MySQL version 2.11.0 and higher and version 3 is 2160 (90 days).

The following example sets the retention period for binlog files to 6 days:

```
CALL mysql.rds_set_configuration('binlog retention hours', 144);
```

After replication has been started, you can verify that changes have been applied to your replica by running the `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command on your replica and checking the Seconds behind master field. If the Seconds behind master field is 0, then there is no replica lag. When there is no replica lag, reduce the length of time that binlog files are retained by setting the `binlog retention hours` configuration parameter to a smaller time frame.

If this setting isn't specified, the default for Aurora MySQL is 24 (1 day).

If you specify a value for 'binlog retention hours' that is higher than the maximum value, then Aurora MySQL uses the maximum.
### Database engine

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
</table>
| RDS for MySQL   | **To retain binary logs on an Amazon RDS DB instance**  
You can retain binary log files on an Amazon RDS DB instance by setting the binlog retention hours just as with an Aurora MySQL DB cluster, described in the previous row.  
You can also retain binlog files on an Amazon RDS DB instance by creating a read replica for the DB instance. This read replica is temporary and solely for the purpose of retaining binlog files. After the read replica has been created, call the `mysql.rds_stop_replication` procedure on the read replica. While replication is stopped, Amazon RDS doesn't delete any of the binlog files on the replication source. After you have set up replication with your permanent replica, you can delete the read replica when the replica lag (Seconds behind master field) between your replication source and your permanent replica reaches 0. |
| MySQL (external)| **To retain binary logs on an external MySQL database**  
Because binlog files on an external MySQL database are not managed by Amazon RDS, they are retained until you delete them.  
After replication has been started, you can verify that changes have been applied to your replica by running the `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command on your replica and checking the Seconds behind master field. If the Seconds behind master field is 0, then there is no replica lag. When there is no replica lag, you can delete old binlog files. |

### 3. Create a snapshot or dump of your replication source

You use a snapshot or dump of your replication source to load a baseline copy of your data onto your replica and then start replicating from that point on.

Use the following instructions to create a snapshot or dump of the replication source for your database engine.
### Aurora MySQL

#### To create a snapshot of an Aurora MySQL DB cluster

1. Create a DB cluster snapshot of your Amazon Aurora DB cluster. For more information, see [Creating a DB cluster snapshot](#).

2. Create a new Aurora DB cluster by restoring from the DB cluster snapshot that you just created. Be sure to retain the same DB parameter group for your restored DB cluster as your original DB cluster. Doing this ensures that the copy of your DB cluster has binary logging enabled. For more information, see [Restoring from a DB cluster snapshot](#).

3. In the console, choose **Databases** and choose the primary instance (writer) for your restored Aurora DB cluster to show its details. Scroll to **Recent Events**. An event message shows that includes the binlog file name and position. The event message is in the following format.

   ```plaintext
   Binlog position from crash recovery is binlog-file-name binlog-position
   ```

   Save the binlog file name and position values for when you start replication.

   You can also get the binlog file name and position by calling the `describe-events` command from the AWS CLI. The following shows an example `describe-events` command with example output.

   ```bash
   PROMPT> aws rds describe-events
   ```

   ```json
   {
     "Events": [
       {
         "EventCategories": [],
         "SourceType": "db-instance",
         "Date": "2016-10-28T19:43:46.862Z",
         "Message": "Binlog position from crash recovery is mysql-bin-changelog.000003 4278",
       }
   ```
You can also get the binlog file name and position by checking the MySQL error log for the last MySQL binlog file position.

4. If your replica target is an external MySQL database or an RDS for MySQL DB instance, then you can't load the data from an Amazon Aurora DB cluster snapshot. Instead, create a dump of your Aurora DB cluster by connecting to your DB cluster using a MySQL client and issuing the `mysqldump` command. Be sure to run the `mysqldump` command against the copy of your Aurora DB cluster that you created. The following is an example.

```
PROMPT> mysqldump --databases <database_name> --single-transaction --order-by-primary -r backup.sql -u <local_user> -p
```

5. When you have finished creating the dump of your data from the newly created Aurora DB cluster, delete that DB cluster as it is no longer needed.
To create a snapshot of an Amazon RDS DB instance

Create a read replica of your Amazon RDS DB instance. For more information, see Creating a read replica in the Amazon Relational Database Service User Guide.

1. Connect to your read replica and stop replication by running the `mysql.rds_stop_replication` procedure.

2. While the read replica is Stopped, Connect to the read replica and run the `SHOW_SLAVE_STATUS` (Aurora MySQL version 2) or `SHOW_REPLICA_STATUS` (Aurora MySQL version 3) command. Retrieve the current binary log file name from the `Relay_Master_Log_File` field and the log file position from the `Exec_Master_Log_Pos` field. Save these values for when you start replication.

3. While the read replica remains Stopped, create a DB snapshot of the read replica. For more information, see Creating a DB snapshot in the Amazon Relational Database Service User Guide.

4. Delete the read replica.
To create a dump of an external MySQL database

1. Before you create a dump, you need to ensure that the binlog location for the dump is current with the data in your source instance. To do this, you must first stop any write operations to the instance with the following command:

   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   ```

2. Create a dump of your MySQL database using the `mysqldump` command as shown following:

   ```
PROMPT> sudo mysqldump --databases <database_name> --master-data=2 --single-transaction --order-by-primary -r backup.sql -u <local_user> -p
   ```

3. After you have created the dump, unlock the tables in your MySQL database with the following command:

   ```
   mysql> UNLOCK TABLES;
   ```

4. Load the snapshot or dump into your replica target

   If you plan to load data from a dump of a MySQL database that is external to Amazon RDS, then you might want to create an EC2 instance to copy the dump files to, and then load the data into your DB cluster or DB instance from that EC2 instance. Using this approach, you can compress the dump file(s) before copying them to the EC2 instance in order to reduce the network costs associated with copying data to Amazon RDS. You can also encrypt the dump file or files to secure the data as it is being transferred across the network.

   Use the following instructions to load the snapshot or dump of your replication source into your replica target for your database engine.
<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
</table>
| Aurora MySQL    | **To load a snapshot or dump into an Aurora MySQL DB cluster**  
|                 | • If the snapshot of your replication source is a DB cluster snapshot, then you can restore from the DB cluster snapshot to create a new Aurora MySQL DB cluster as your replica target. For more information, see [Restoring from a DB cluster snapshot](#).  
|                 | • If the snapshot of your replication source is a DB snapshot, then you can migrate the data from your DB snapshot into a new Aurora MySQL DB cluster. For more information, see [Migrating data to an Amazon Aurora MySQL DB cluster](#).  
|                 | • If the data from your replication source is the output from the `mysqldump` command, then follow these steps:  
|                 | 1. Copy the output of the `mysqldump` command from your replication source to a location that can also connect to your Aurora MySQL DB cluster.  
|                 | 2. Connect to your Aurora MySQL DB cluster using the `mysql` command. The following is an example.  
|                 | ```  
PROMPT> mysql -h <host_name> -port=3306 -u <db_master_user> -p  
```  
|                 | 3. At the `mysql` prompt, run the `source` command and pass it the name of your database dump file to load the data into the Aurora MySQL DB cluster, for example:  
|                 | ```  
mysql> source backup.sql;  
```  
| RDS for MySQL   | **To load a dump into an Amazon RDS DB instance**  
|                 | 1. Copy the output of the `mysqldump` command from your replication source to a location that can also connect to your MySQL DB instance.  
|                 | 2. Connect to your MySQL DB instance using the `mysql` command. The following is an example.  
|                 | ```  
PROMPT> mysql -h <host_name> -port=3306 -u <db_master_user> -p  
```
### Database engine | Instructions
--- | ---
| **MySQL (external)** | 3. At the mysql prompt, run the `source` command and pass it the name of your database dump file to load the data into the MySQL DB instance, for example:  

```bash
code
mysql> source backup.sql;
```

| **To load a dump into an external MySQL database** |  
| You can't load a DB snapshot or a DB cluster snapshot into an external MySQL database. Instead, you must use the output from the `mysqldump` command.  

1. Copy the output of the `mysqldump` command from your replication source to a location that can also connect to your MySQL database.  

2. Connect to your MySQL database using the `mysql` command. The following is an example.  

```bash
code
PROMPT> mysql -h <host_name> -port=3306 -u <db_master_user> -p
```

3. At the mysql prompt, run the `source` command and pass it the name of your database dump file to load the data into your MySQL database. The following is an example.  

```bash
code
mysql> source backup.sql;
```

| 5. **Create a replication user on your replication source** |  
| Create a user ID on the source that is used solely for replication. The following example is for RDS for MySQL or external MySQL source databases.  

```bash
code
mysql> CREATE USER 'repl_user'@'domain_name' IDENTIFIED BY 'password';
```

For Aurora MySQL source databases, the `skip_name_resolve` DB cluster parameter is set to 1 (ON) and can't be modified, so you must use an IP address for the host instead of a domain name. For more information, see [skip_name_resolve](#) in the MySQL documentation.
mysql> CREATE USER 'repl_user'@'IP_address' IDENTIFIED BY 'password';

The user requires the REPLICATION CLIENT and REPLICATION SLAVE privileges. Grant these privileges to the user.

If you need to use encrypted replication, require SSL connections for the replication user. For example, you can use one of the following statements to require SSL connections on the user account repl_user.

GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'IP_address';

GRANT USAGE ON *.* TO 'repl_user'@'IP_address' REQUIRE SSL;

 <!--[Note]--> Note
 If REQUIRE SSL isn't included, the replication connection might silently fall back to an unencrypted connection.

### 6. Turn on replication on your replica target

Before you turn on replication, we recommend that you take a manual snapshot of the Aurora MySQL DB cluster or RDS for MySQL DB instance replica target. If a problem arises and you need to re-establish replication with the DB cluster or DB instance replica target, you can restore the DB cluster or DB instance from this snapshot instead of having to import the data into your replica target again.

Use the following instructions to turn on replication for your database engine.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL</td>
<td><strong>To turn on replication from an Aurora MySQL DB cluster</strong></td>
</tr>
<tr>
<td></td>
<td>1. Find the starting place for replication. You need the binlog file name and binlog position.</td>
</tr>
<tr>
<td></td>
<td>If your DB cluster replica target was created from the following:</td>
</tr>
</tbody>
</table>
- **DB cluster snapshot** – Retrieve the binlog file name and position from the recent events for your restored DB cluster, as shown in 3. Create a snapshot or dump of your replication source.

- **DB snapshot** – You retrieved the binlog file name and position from the SHOW SLAVE STATUS (Aurora MySQL version 2) or SHOW REPLICA STATUS (Aurora MySQL version 3) command when you created the snapshot of your replication source.

2. Connect to the DB cluster and call the following procedures to start replication with your replication source using the binary log file name and location from the previous step:

   - `mysql.rds_set_external_source` (Aurora MySQL version 3)
   - `mysql.rds_set_external_master` (Aurora MySQL version 2)
   - `mysql.rds_start_replication` (all versions)

   The following example is for Aurora MySQL version 3.

   ```sql
   CALL mysql.rds_set_external_source ('mydbinstance.123456789012.us-east-1.rds.amazonaws.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
   CALL mysql.rds_start_replication;
   ```

   To use SSL encryption, set the final value to 1 instead of 0.
### To turn on replication from an Amazon RDS DB instance

1. If your DB instance replica target was created from a DB snapshot, then you need the binlog file and binlog position that are the starting place for replication. You retrieved these values from the `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command when you created the snapshot of your replication source.

2. Connect to the DB instance and call the `mysql.rds_set_external_master` (Aurora MySQL version 2) or `mysql.rds_set_external_source` (Aurora MySQL version 3) and `mysql.rds_start_replication` procedures to start replication with your replication source. Use the binary log file name and location from the previous step. The following is an example.

```sql
CALL mysql.rds_set_external_master ('mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
CALL mysql.rds_start_replication;
```

To use SSL encryption, set the final value to 1 instead of 0.
### To turn on replication from an external MySQL database

1. Retrieve the binlog file and binlog position that are the starting place for replication. You retrieved these values from the `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command when you created the snapshot of your replication source. If your external MySQL replica target was populated from the output of the `mysqldump` command with the `--master-data=2` option, then the binlog file and binlog position are included in the output. The following is an example.

```
--
-- Position to start replication or point-in-time recovery from
--

-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031',
    MASTER_LOG_POS=107;
```

2. Connect to the external MySQL replica target, and issue `CHANGE MASTER TO` and `START SLAVE` (Aurora MySQL version 2) or `START REPLICA` (Aurora MySQL version 3) to start replication with your replication source using the binary log file name and location from the previous step, for example:

```
CHANGE MASTER TO
    MASTER_HOST = 'mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com',
    MASTER_PORT = 3306,
    MASTER_USER = 'repl_user',
    MASTER_PASSWORD = 'password',
    MASTER_LOG_FILE = 'mysql-bin-changelog.000031',
    MASTER_LOG_POS = 107;
-- And one of these statements depending on your engine version:
START SLAVE; -- Aurora MySQL version 2
START REPLICA; -- Aurora MySQL version 3
```

If replication fails, it can result in a large increase in unintentional I/O on the replica, which can degrade performance. If replication fails or is no longer needed, you can run the
mysql.rds_reset_external_master (Aurora MySQL version 2) or mysql.rds_reset_external_source (Aurora MySQL version 3) stored procedure to remove the replication configuration.

**Setting a location to stop replication to a read replica**

In Aurora MySQL version 3.04 and higher, you can start replication and then stop it at a specified binary log file location using the mysql.rds_start_replication_until (Aurora MySQL version 3) stored procedure.

**To start replication to a read replica and stop replication at a specific location**

1. Using a MySQL client, connect to the replica Aurora MySQL DB cluster as the master user.
2. Run the mysql.rds_start_replication_until (Aurora MySQL version 3) stored procedure.

    The following example initiates replication and replicates changes until it reaches location 120 in the mysql-bin-changelog.000777 binary log file. In a disaster recovery scenario, assume that location 120 is just before the disaster.

    ```
    call mysql.rds_start_replication_until(
        'mysql-bin-changelog.000777',
        120);
    ```

    Replication stops automatically when the stop point is reached. The following RDS event is generated: Replication has been stopped since the replica reached the stop point specified by the rds_start_replication_until stored procedure.

    If you use GTID-based replication, use the mysql.rds_start_replication_until_gtid (Aurora MySQL version 3) stored procedure instead of the mysql.rds_start_replication_until (Aurora MySQL version 3) stored procedure. For more information about GTID-based replication, see Using GTID-based replication.

**7. Monitor your replica**

When you set up MySQL replication with an Aurora MySQL DB cluster, you must monitor failover events for the Aurora MySQL DB cluster when it is the replica target. If a failover occurs, then the DB cluster that is your replica target might be recreated on a new host with a different network address. For information on how to monitor failover events, see Working with Amazon RDS event notification.
You can also monitor how far the replica target is behind the replication source by connecting to the replica target and running the `SHOW SLAVE STATUS` (Aurora MySQL version 2) or `SHOW REPLICA STATUS` (Aurora MySQL version 3) command. In the command output, the `Seconds Behind Master` field tells you how far the replica target is behind the source.

**Synchronizing passwords between replication source and target**

When you change user accounts and passwords on the replication source using SQL statements, those changes are replicated to the replication target automatically.

If you use the AWS Management Console, the AWS CLI, or the RDS API to change the master password on the replication source, those changes are not automatically replicated to the replication target. If you want to synchronize the master user and master password between the source and target systems, you must make the same change on the replication target yourself.

**Stopping replication between Aurora and MySQL or between Aurora and another Aurora DB cluster**

To stop binary log replication with a MySQL DB instance, external MySQL database, or another Aurora DB cluster, follow these steps, discussed in detail following in this topic.

1. Stop binary log replication on the replica target
2. Turn off binary logging on the replication source

**1. Stop binary log replication on the replica target**

Use the following instructions to stop binary log replication for your database engine.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL</td>
<td><strong>To stop binary log replication on an Aurora MySQL DB cluster replica target</strong></td>
</tr>
<tr>
<td></td>
<td>Connect to the Aurora DB cluster that is the replica target, and call the <code>mysql.rds_stop_replication</code> procedure.</td>
</tr>
<tr>
<td>RDS for MySQL</td>
<td><strong>To stop binary log replication on an Amazon RDS DB instance</strong></td>
</tr>
<tr>
<td></td>
<td>Connect to the RDS DB instance that is the replica target and call the <code>mysql.rds_stop_replication</code> procedure.</td>
</tr>
</tbody>
</table>
2. Turn off binary logging on the replication source

Use the instructions in the following table to turn off binary logging on the replication source for your database engine.

<table>
<thead>
<tr>
<th>Database engine</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL</td>
<td><strong>To turn off binary logging on an Amazon Aurora DB cluster</strong></td>
</tr>
<tr>
<td></td>
<td>1. Connect to the Aurora DB cluster that is the replication source.</td>
</tr>
<tr>
<td></td>
<td>2. Use the <code>mysql.rds_set_configuration</code> procedure and specify the configuration parameter <code>binlog retention hours</code>, with the value NULL, as shown in the following example.</td>
</tr>
</tbody>
</table>
|                 | ```
|                 | CALL mysql.rds_set_configuration('binlog retention hours', NULL);
<p>|                 | ``` |
|                 | <strong>Note</strong> |
|                 | You can't use the value 0 for <code>binlog retention hours</code>. |
|                 | 3. Set the <code>binlog_format</code> parameter to OFF on the replication source. The <code>binlog_format</code> parameter is in the custom DB cluster parameter group associated with your DB cluster. |
|                 | After you've changed the <code>binlog_format</code> parameter value, reboot your DB cluster for the change to take effect. |</p>
<table>
<thead>
<tr>
<th>Database engine</th>

</tr>
<tr>
<td><strong>MySQL (external)</strong></td>
<td><strong>To turn off binary logging on an external MySQL database</strong></td>
</tr>
<tr>
<td>Connect to the MySQL database and call the STOP REPLICATION command.</td>
<td></td>
</tr>
<tr>
<td>1. From a command shell, stop the mysqld service,</td>
<td></td>
</tr>
</tbody>
</table>
| ```
sudo service mysqld stop
```
| 2. Edit the my.cnf file (this file is usually under /etc). |
| ```
sudo vi /etc/my.cnf
```
| Delete the log_bin and server_id options from the [mysqld] section. |
| For more information, see [Setting the replication source configuration](#) in the MySQL documentation. |
| 3. Start the mysql service. |
| ```
sudo service mysqld start
```
Using Amazon Aurora to scale reads for your MySQL database

You can use Amazon Aurora with your MySQL DB instance to take advantage of the read scaling capabilities of Amazon Aurora and expand the read workload for your MySQL DB instance. To use Aurora to scale reads for your MySQL DB instance, create an Amazon Aurora MySQL DB cluster and make it a read replica of your MySQL DB instance. This applies to an RDS for MySQL DB instance, or a MySQL database running external to Amazon RDS.

For information on creating an Amazon Aurora DB cluster, see Creating an Amazon Aurora DB cluster.

When you set up replication between your MySQL DB instance and your Amazon Aurora DB cluster, be sure to follow these guidelines:

- Use the Amazon Aurora DB cluster endpoint address when you reference your Amazon Aurora MySQL DB cluster. If a failover occurs, then the Aurora Replica that is promoted to the primary instance for the Aurora MySQL DB cluster continues to use the DB cluster endpoint address.

- Maintain the binlogs on your writer instance until you have verified that they have been applied to the Aurora Replica. This maintenance ensures that you can restore your writer instance in the event of a failure.

⚠️ Important

When using self-managed replication, you're responsible for monitoring and resolving any replication issues that may occur. For more information, see Diagnosing and resolving lag between read replicas.

🔍 Note

The permissions required to start replication on an Aurora MySQL DB cluster are restricted and not available to your Amazon RDS master user. Therefore, you must use the mysql.rds_set_external_master (Aurora MySQL version 2) or mysql.rds_set_external_source (Aurora MySQL version 3) and mysql.rds_start_replication procedures to set up replication between your Aurora MySQL DB cluster and your MySQL DB instance.
**Start replication between an external source instance and an Aurora MySQL DB cluster**

1. Make the source MySQL DB instance read-only:

   ```sql
   mysql> FLUSH TABLES WITH READ LOCK;
   mysql> SET GLOBAL read_only = ON;
   ```

2. Run the SHOW MASTER STATUS command on the source MySQL DB instance to determine the binlog location. You receive output similar to the following example:

   ```plaintext
   +-------------------+----------+
   | File              | Position |
   +-------------------+----------+
   | mysql-bin-changelog.000031 | 107      |
   +-------------------+----------+
   ```

3. Copy the database from the external MySQL DB instance to the Amazon Aurora MySQL DB cluster using `mysqldump`. For very large databases, you might want to use the procedure in *Importing data to a MySQL or MariaDB DB instance with reduced downtime* in the *Amazon Relational Database Service User Guide*.

   **For Linux, macOS, or Unix:**

   ```bash
   mysqldump \
     --databases <database_name> \
     --single-transaction \
     --compress \
     --order-by-primary \
     -u local_user \
     -p local_password | mysql \
     --host aurora_cluster_endpoint_address \
     --port 3306 \
     -u RDS_user_name \
     -p RDS_password
   ```

   **For Windows:**

   ```bash
   mysqldump ^
     --databases <database_name> ^
     --single-transaction ^
     --compress ^
     --order-by-primary ^
   ```
```
-u local_user ^
-p local_password ^
--host aurora_cluster_endpoint_address ^
--port 3306 ^
-u RDS_user_name ^
-p RDS_password
```

**Note**

Make sure that there is not a space between the `-p` option and the entered password.

Use the `--host`, `--user (-u)`, `--port` and `-p` options in the `mysql` command to specify the hostname, user name, port, and password to connect to your Aurora DB cluster. The host name is the DNS name from the Amazon Aurora DB cluster endpoint, for example, `mydbcluster.cluster-123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the cluster details in the Amazon RDS Management Console.

4. Make the source MySQL DB instance writeable again:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see [Backing up a source or replica by making it read only](#) in the MySQL documentation.

5. In the Amazon RDS Management Console, add the IP address of the server that hosts the source MySQL database to the VPC security group for the Amazon Aurora DB cluster. For more information on modifying a VPC security group, see [Security groups for your VPC](#) in the Amazon Virtual Private Cloud User Guide.

You might also need to configure your local network to permit connections from the IP address of your Amazon Aurora DB cluster, so that it can communicate with your source MySQL instance. To find the IP address of the Amazon Aurora DB cluster, use the `host` command.

```
host aurora_endpoint_address
```

The host name is the DNS name from the Amazon Aurora DB cluster endpoint.
6. Using the client of your choice, connect to the external MySQL instance and create a MySQL user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

7. For the external MySQL instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
IDENTIFIED BY 'password';
```

8. Take a manual snapshot of the Aurora MySQL DB cluster to be the read replica before setting up replication. If you need to reestablish replication with the DB cluster as a read replica, you can restore the Aurora MySQL DB cluster from this snapshot instead of having to import the data from your MySQL DB instance into a new Aurora MySQL DB cluster.

9. Make the Amazon Aurora DB cluster the replica. Connect to the Amazon Aurora DB cluster as the master user and identify the source MySQL database as the replication master by using the `mysql.rds_set_external_master` (Aurora MySQL version 2) or `mysql.rds_set_external_source` (Aurora MySQL version 3) and `mysql.rds_start_replication` procedures.

Use the master log file name and master log position that you determined in Step 2. The following is an example.

```
For Aurora MySQL version 2:
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);

For Aurora MySQL version 3:
CALL mysql.rds_set_external_source ('mymasterserver.mydomain.com', 3306, 'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

10. On the Amazon Aurora DB cluster, call the `mysql.rds_start_replication` procedure to start replication.

```
CALL mysql.rds_start_replication;
```
After you have established replication between your source MySQL DB instance and your Amazon Aurora DB cluster, you can add Aurora Replicas to your Amazon Aurora DB cluster. You can then connect to the Aurora Replicas to read scale your data. For information on creating an Aurora Replica, see Adding Aurora Replicas to a DB cluster.

Optimizing binary log replication

Following, you can learn how to optimize binary log replication performance and troubleshoot related issues in Aurora MySQL.

Tip

This discussion presumes that you are familiar with the MySQL binary log replication mechanism and how it works. For background information, see Replication Implementation in the MySQL documentation.

Multithreaded binary log replication

With multithreaded binary log replication, a SQL thread reads events from the relay log and queues them up for SQL worker threads to apply. The SQL worker threads are managed by a coordinator thread. The binary log events are applied in parallel when possible.

Multithreaded binary log replication is supported in Aurora MySQL version 3, and in Aurora MySQL version 2.12.1 and higher.

When an Aurora MySQL DB instance is configured to use binary log replication, by default the replica instance uses single-threaded replication for Aurora MySQL versions lower than 3.04. To enable multithreaded replication, you update the replica_parallel_workers parameter to a value greater than zero in your custom parameter group.

For Aurora MySQL version 3.04 and higher, replication is multithreaded by default, with replica_parallel_workers set to 4. You can modify this parameter in your custom parameter group.

The following configuration options help you to fine-tune multithreaded replication. For usage information, see Replication and Binary Logging Options and Variables in the MySQL Reference Manual.

Optimal configuration depends on several factors. For example, performance for binary log replication is influenced by your database workload characteristics and the DB instance class.
the replica is running on. Thus, we recommend that you thoroughly test all changes to these configuration parameters before applying new parameter settings to a production instance:

- `binlog_group_commit_sync_delay`
- `binlog_group_commit_sync_no_delay_count`
- `binlog_transaction_dependency_history_size`
- `binlog_transaction_dependency_tracking`
- `replica_preserve_commit_order`
- `replica_parallel_type`
- `replica_parallel_workers`

In Aurora MySQL version 3.06 and higher, you can improve performance for binary log replicas when replicating transactions for large tables with more than one secondary index. This feature introduces a thread pool to apply secondary index changes in parallel on a binlog replica. The feature is controlled by the `aurora_binlog_replication_sec_index_parallel_workers` DB cluster parameter, which controls the total number of parallel threads available to apply the secondary index changes. The parameter is set to 0 (disabled) by default. Enabling this feature doesn't require an instance restart. To enable this feature, stop ongoing replication, set the desired number of parallel worker threads, and then start replication again.

You can also use this parameter as a global variable, where \( n \) is the number of parallel worker threads:

```
SET global aurora_binlog_replication_sec_index_parallel_workers=n;
```

### Optimizing binlog replication (Aurora MySQL 2.10 and higher)

In Aurora MySQL 2.10 and higher, Aurora automatically applies an optimization known as the binlog I/O cache to binary log replication. By caching the most recently committed binlog events, this optimization is designed to improve binlog dump thread performance while limiting the impact to foreground transactions on the binlog source instance.

**Note**

This memory used for this feature is independent of the MySQL `binlog_cache` setting.
This feature doesn't apply to Aurora DB instances that use the db.t2 and db.t3 instance classes.

You don't need to adjust any configuration parameters to turn on this optimization. In particular, if you adjust the configuration parameter `aurora_binlog_replication_max_yield_seconds` to a nonzero value in earlier Aurora MySQL versions, set it back to zero for Aurora MySQL 2.10 and higher.

The status variables `aurora_binlog_io_cache_reads` and `aurora_binlog_io_cache_read_requests` are available in Aurora MySQL 2.10 and higher. These status variables help you to monitor how often the data is read from the binlog I/O cache.

- `aurora_binlog_io_cache_read_requests` shows the number of binlog I/O read requests from the cache.
- `aurora_binlog_io_cache_reads` shows the number of binlog I/O reads that retrieve information from the cache.

The following SQL query computes the percentage of binlog read requests that take advantage of the cached information. In this case, the closer the ratio is to 100, the better it is.

```
mysql> SELECT
    (SELECT VARIABLE_VALUE FROM INFORMATION_SCHEMA.GLOBAL_STATUS
     WHERE VARIABLE_NAME='aurora_binlog_io_cache_reads')
/ (SELECT VARIABLE_VALUE FROM INFORMATION_SCHEMA.GLOBAL_STATUS
  WHERE VARIABLE_NAME='aurora_binlog_io_cache_read_requests')
* 100
  as binlog_io_cache_hit_ratio;
```

<table>
<thead>
<tr>
<th>binlog_io_cache_hit_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>99.99847949080622</td>
</tr>
</tbody>
</table>

The binlog I/O cache feature also includes new metrics related to the binlog dump threads. Dump threads are the threads that are created when new binlog replicas are connected to the binlog source instance.
The dump thread metrics are printed to the database log every 60 seconds with the prefix [Dump thread metrics]. The metrics include information for each binlog replica such as Secondary_id, Secondary_uuid, binlog file name, and the position that each replica is reading. The metrics also include Bytes_behind_primary representing the distance in bytes between replication source and replica. This metric measures the lag of the replica I/O thread. That figure is different from the lag of the replica SQL applier thread, which is represented by the seconds_behind_master metric on the binlog replica. You can determine whether binlog replicas are catching up to the source or falling behind by checking whether the distance decreases or increases.

**Optimizing binlog replication (Aurora MySQL version 2 through 2.09)**

To optimize binary log replication for Aurora MySQL, you adjust the following cluster-level optimization parameters. These parameters help you to specify the right balance between latency on the binlog source instance and replication lag.

- aurora_binlog_use_large_read_buffer
- aurora_binlog_read_buffer_size
- aurora_binlog_replication_max_yield_seconds

**Note**

For MySQL 5.7-compatible clusters, you can use these parameters in Aurora MySQL version 2 through 2.09.*. In Aurora MySQL 2.10.0 and higher, these parameters are superseded by the binlog I/O cache optimization and you don't need to use them.

**Topics**

- [Overview of the large read buffer and max-yield optimizations](#)

Overview of the large read buffer and max-yield optimizations

You might experience reduced binary log replication performance when the binary log dump thread accesses the Aurora cluster volume while the cluster processes a high number of transactions. You can use the parameters `aurora_binlog_use_large_read_buffer`, `aurora_binlog_replication_max_yield_seconds`, and `aurora_binlog_read_buffer_size` to help minimize this type of contention.

Suppose that you have a situation where `aurora_binlog_replication_max_yield_seconds` is set to greater than 0 and the current binlog file of the dump thread is active. In this case, the binary log dump thread waits up to a specified number of seconds for the current binlog file to be filled by transactions. This wait period avoids contention that can arise from replicating each binlog event individually. However, doing so increases the replica lag for binary log replicas. Those replicas can fall behind the source by the same number of seconds as the `aurora_binlog_replication_max_yield_seconds` setting.

The current binlog file means the binlog file that the dump thread is currently reading to perform replication. We consider that a binlog file is active when the binlog file is updating or open to be updated by incoming transactions. After Aurora MySQL fills up the active binlog file, MySQL creates and switches to a new binlog file. The old binlog file becomes inactive. It isn’t updated by incoming transactions any longer.

⚠️ Note

Before adjusting these parameters, measure your transaction latency and throughput over time. You might find that binary log replication performance is stable and has low latency even if there is occasional contention.

`aurora_binlog_use_large_read_buffer`

If this parameter is set to 1, Aurora MySQL optimizes binary log replication based on the settings of the parameters `aurora_binlog_read_buffer_size` and `aurora_binlog_replication_max_yield_seconds`. If `aurora_binlog_use_large_read_buffer` is 0, Aurora MySQL ignores the values of the `aurora_binlog_read_buffer_size` and `aurora_binlog_replication_max_yield_seconds` parameters.
**aurora_binlog_read_buffer_size**

Binary log dump threads with larger read buffer minimize the number of read I/O operations by reading more events for each I/O. The parameter `aurora_binlog_read_buffer_size` sets the read buffer size. The large read buffer can reduce binary log contention for workloads that generate a large amount of binlog data.

**Note**

This parameter only has an effect when the cluster also has the setting `aurora_binlog_use_large_read_buffer=1`. Increasing the size of the read buffer doesn't affect the performance of binary log replication. Binary log dump threads don't wait for updating transactions to fill up the read buffer.

**aurora_binlog_replication_max_yield_seconds**

If your workload requires low transaction latency, and you can tolerate some replication lag, you can increase the `aurora_binlog_replication_max_yield_seconds` parameter. This parameter controls the maximum yield property of binary log replication in your cluster.

**Note**

This parameter only has an effect when the cluster also has the setting `aurora_binlog_use_large_read_buffer=1`.

Aurora MySQL recognizes any change to the `aurora_binlog_replication_max_yield_seconds` parameter value immediately. You don't need to restart the DB instance. However, when you turn on this setting, the dump thread only starts to yield when the current binlog file reaches its maximum size of 128 MB and is rotated to a new file.

**Related parameters**

Use the following DB cluster parameters to turn on binlog optimization.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Valid Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>aurora_binlog_use_large_read_buffer</code></td>
<td>1</td>
<td>0, 1</td>
<td>Switch for turning on the feature of replication improvement. When its value is 1, the binary log dump thread uses <code>aurora_binlog_read_buffer_size</code> for binary log replication; otherwise default buffer size (8K) is used. Not used in Aurora MySQL version 3.</td>
</tr>
<tr>
<td><code>aurora_binlog_read_buffer_size</code></td>
<td>5242880</td>
<td>8192-536870912</td>
<td>Read buffer size used by binary log dump thread when the parameter <code>aurora_binlog_use_large_read_buffer</code> is set to 1. Not used in Aurora MySQL version 3.</td>
</tr>
<tr>
<td><code>aurora_binlog_repllication_max_yield_seconds</code></td>
<td>0</td>
<td>0-36000</td>
<td>For Aurora MySQL version 2.07.*, the maximum accepted value is 45. You can tune it to a higher value on 2.09 and later versions.</td>
</tr>
</tbody>
</table>
Enabling the max-yield mechanism for binary log replication

You can turn on the binary log replication max-yield optimization as follows. Doing so minimizes latency for transactions on the binlog source instance. However, you might experience higher replication lag.

**To turn on the max-yield binlog optimization for an Aurora MySQL cluster**

1. Create or edit a DB cluster parameter group using the following parameter settings:
   - `aurora_binlog_use_large_read_buffer`: turn on with a value of `ON` or 1.
   - `aurora_binlog_replication_max_yield_seconds`: specify a value greater than 0.
2. Associate the DB cluster parameter group with the Aurora MySQL cluster that works as the binlog source. To do so, follow the procedures in [Working with parameter groups](#).
3. Confirm that the parameter change takes effect. To do so, run the following query on the binlog source instance.

   ```sql
   SELECT @@aurora_binlog_use_large_read_buffer,
   @@aurora_binlog_replication_max_yield_seconds;
   ```

   Your output should be similar to the following.

   | @aurora_binlog_use_large_read_buffer | @aurora_binlog_replication_max_yield_seconds |
   +-------------------------------------------------+-----------------------------------------------+
Turning off the binary log replication max-yield optimization

You can turn off the binary log replication max-yield optimization as follows. Doing so minimizes replication lag. However, you might experience higher latency for transactions on the binlog source instance.

To turn off the max-yield optimization for an Aurora MySQL cluster

1. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `aurora_binlog_replication_max_yield_seconds` set to 0. For more information about setting configuration parameters using parameter groups, see Working with parameter groups.

2. Confirm that the parameter change takes effect. To do so, run the following query on the binlog source instance.

   ```sql
   SELECT @@aurora_binlog_replication_max_yield_seconds;
   ```

   Your output should be similar to the following.

   ```plaintext
   +-----------------------------------------------+
   | @@aurora_binlog_replication_max_yield_seconds |
   +-----------------------------------------------+
   |                                             0 |
   +-----------------------------------------------+
   ```

Turning off the large read buffer

You can turn off the entire large read buffer feature as follows.

To turn off the large binary log read buffer for an Aurora MySQL cluster

1. Reset the `aurora_binlog_use_large_read_buffer` to OFF or 0.
Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `aurora_binlog_use_large_read_buffer` set to 0. For more information about setting configuration parameters using parameter groups, see Working with parameter groups.

2. On the binlog source instance, run the following query.

```sql
SELECT @@ aurora_binlog_use_large_read_buffer;
```

Your output should be similar to the following.

```
+----------------------------------------+
| @@aurora_binlog_use_large_read_buffer |
+----------------------------------------+
|                                      0 |
+----------------------------------------+
```

## Setting up enhanced binlog

Enhanced binlog reduces the compute performance overhead caused by turning on binlog, which can reach up to 50% in certain cases. With enhanced binlog, this overhead can be reduced to about 13%. To reduce overhead, enhanced binlog writes the binary and transactions logs to storage in parallel, which minimizes the data written at the transaction commit time.

Using enhanced binlog also improves database recovery time after restarts and failovers by up to 99% compared to community MySQL binlog. The enhanced binlog is compatible with existing binlog-based workloads, and you interact with it the same way you interact with the community MySQL binlog.

Enhanced binlog is available on Aurora MySQL version 3.03.1 and higher.

- [Enhanced binlog limitations](#)
## Configuring enhanced binlog parameters

You can switch between community MySQL binlog and enhanced binlog by turning on/off the enhanced binlog parameters. The existing binlog consumers can continue to read and consume the binlog files without any gaps in the binlog file sequence.

### To turn on enhanced binlog

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>binlog_format</td>
<td>-</td>
<td>Set the <code>binlog_format</code> parameter to the binary logging format of your choice to turn on enhanced binlog. Make sure the <code>binlog_format</code> parameter isn't set to OFF. For more information, see <a href="#">Configuring Aurora MySQL binary logging</a>.</td>
</tr>
<tr>
<td>aurora_enhanced_binlog</td>
<td>0</td>
<td>Set the value of this parameter to 1 in the DB cluster parameter group associated with the Aurora MySQL cluster. To turn off the enhanced binlog

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aurora_enhanced_binlog</td>
<td>Set the value of this parameter to 0 in the DB cluster parameter group associated with the Aurora MySQL cluster. Whenever you change the value of this parameter, you must reboot the writer instance when the DBCluster ParameterGroupStatus value is shown as pending-reboot.</td>
</tr>
<tr>
<td>binlog_backup</td>
<td>Turn on this parameter when you turn off enhanced binlog. To do so, set the value of this parameter to 1.</td>
</tr>
<tr>
<td>binlog_replication_globaldb</td>
<td>Turn on this parameter when you turn off enhanced binlog. To do so, set the value of this parameter to 1.</td>
</tr>
</tbody>
</table>

To check whether enhanced binlog is turned on, use the following command in the MySQL client:

```
mysql> show status like 'aurora_enhanced_binlog';
```

+---------------------------------------------+--------+
| Variable_name                               | Value  |
+---------------------------------------------+--------+
When enhanced binlog is turned on, the output shows ACTIVE for aurora_enhanced_binlog.

**Other related parameters**

When you turn on the enhanced binlog, the following parameters are affected:

- The max_binlog_size parameter is visible but not modifiable. It's default value 134217728 is automatically adjusted to 268435456 when enhanced binlog is turned on.
- Unlike in community MySQL binlog, the binlog_checksum doesn't act as a dynamic parameter when the enhanced binlog is turned on. For the change to this parameter to take effect, you must manually reboot the DB cluster even when the ApplyMethod is immediate.
- The value you set on the binlog_order_commits parameter has no effect on the order of the commits when enhanced binlog is turned on. The commits are always ordered without any further performance implications.

**Differences between enhanced binlog and community MySQL binlog**

Enhanced binlog interacts differently with clones, backups, and Aurora global database when compared to community MySQL binlog. We recommend that you understand the following differences before using enhanced binlog.

- Enhanced binlog files from the source DB cluster aren't available on a cloned DB cluster.
- Enhanced binlog files aren't included in Aurora backups. Therefore, enhanced binlog files from the source DB cluster aren't available after restoring a DB cluster despite any retention period set on it.
- When used with an Aurora global database, the enhanced binlog files of the primary DB cluster aren't replicated to the DB cluster in the secondary regions.

**Examples**

The following examples illustrate the differences between enhanced binlog and community MySQL binlog.

**On a restored or cloned DB cluster**
When enhanced binlog is turned on, the historical binlog files aren't available in the restored or cloned DB cluster. After a restore or clone operation, if binlog is turned on, the new DB cluster starts writing its own sequence of binlog files, starting from 1 (mysql-bin-changelog.000001).

To turn on enhanced binlog after a restore or clone operation, set the required DB cluster parameters on the restored or cloned DB cluster. For more information, see [Configuring enhanced binlog parameters](#).

**Example Clone or restore operation performed when enhanced binlog is turned on**

**Source DB Cluster:**

```sql
mysql> show binary logs;
+----------------------------+-----------+-----------+
| Log_name                   | File_size | Encrypted |
+----------------------------+-----------+-----------+
| mysql-bin-changelog.000001 | 156       | No        | --> Enhanced Binlog turned on
| mysql-bin-changelog.000002 | 156       | No        | --> Enhanced Binlog turned on
| mysql-bin-changelog.000003 | 156       | No        | --> Enhanced Binlog turned on
| mysql-bin-changelog.000004 | 156       | No        | --> Enhanced Binlog turned on
| mysql-bin-changelog.000005 | 156       | No        | --> Enhanced Binlog turned on
| mysql-bin-changelog.000006 | 156       | No        | --> Enhanced Binlog turned on
+----------------------------+-----------+-----------+
6 rows in set (0.00 sec)
```

On a restored or cloned DB cluster, binlog files aren't backed up when enhanced binlog is turned on. To avoid discontinuity in the binlog data, the binlog files written before turning on the enhanced binlog are also not available.

```sql
mysql> show binary logs;
+----------------------------+-----------+-----------+
| Log_name                   | File_size | Encrypted |
+----------------------------+-----------+-----------+
| mysql-bin-changelog.000001 | 156       | No        | --> New sequence of Binlog files
+----------------------------+-----------+-----------+
1 row in set (0.00 sec)
```
Example Clone or restore operation performed when enhanced binlog is turned off

Source DB cluster:

```
mysql> show binary logs;
+--------------------------+-----------+-----------+
| Log_name                 | File_size | Encrypted |
+--------------------------+-----------+-----------+
| mysql-bin-changelog.000001 |       156 | No        | --> Enhanced Binlog enabled
| mysql-bin-changelog.000002 |       156 | No        | --> Enhanced Binlog enabled
| mysql-bin-changelog.000003 |       156 | No        |
| mysql-bin-changelog.000004 |       156 | No        |
| mysql-bin-changelog.000005 |       156 | No        |
| mysql-bin-changelog.000006 |       156 | No        |
+--------------------------+-----------+-----------+
6 rows in set (0.00 sec)
```

On a restored or cloned DB cluster, binlog files written after turning off the enhanced binlog are available.

```
mysql> show binary logs;
+--------------------------+-----------+-----------+
| Log_name                 | File_size | Encrypted |
+--------------------------+-----------+-----------+
| mysql-bin-changelog.000004 |       156 | No        |
| mysql-bin-changelog.000005 |       156 | No        |
| mysql-bin-changelog.000006 |       156 | No        |
+--------------------------+-----------+-----------+
1 row in set (0.00 sec)
```

On an Amazon Aurora global database

On an Amazon Aurora global database, the binlog data of the primary DB cluster isn't replicated to the secondary DB clusters. After a cross-Region failover process, the binlog data isn't available in the newly promoted primary DB cluster. If binlog is turned on, the newly promoted DB cluster starts its own sequence of binlog files, starting from 1 (mysql-bin-changelog.000001).
To turn on enhanced binlog after failover, you must set the required DB cluster parameters on the secondary DB cluster. For more information, see Configuring enhanced binlog parameters.

Example Global database failover operation is performed when enhanced binlog is turned on

Old primary DB Cluster (before failover):

```sql
mysql> show binary logs;
+----------------------------+-----------+-----------+
| Log_name                   | File_size | Encrypted |
+----------------------------+-----------+-----------+
| mysql-bin-changelog.000001 |       156 | No        | --> Enhanced Binlog enabled
| mysql-bin-changelog.000002 |       156 | No        | --> Enhanced Binlog enabled
| mysql-bin-changelog.000003 |       156 | No        | --> Enhanced Binlog enabled
| mysql-bin-changelog.000004 |       156 | No        | --> Enhanced Binlog enabled
| mysql-bin-changelog.000005 |       156 | No        | --> Enhanced Binlog enabled
| mysql-bin-changelog.000006 |       156 | No        | --> Enhanced Binlog enabled
+----------------------------+-----------+-----------+
6 rows in set (0.00 sec)
```

New primary DB cluster (after failover):

Binlog files aren't replicated to secondary regions when enhanced binlog is turned on. To avoid discontinuity in the binlog data, the binlog files written before turning on the enhanced binlog aren't available.

```sql
mysql> show binary logs;
+----------------------------+-----------+-----------+
| Log_name                   | File_size | Encrypted |
+----------------------------+-----------+-----------+
| mysql-bin-changelog.000001 |       156 | No        | --> Fresh sequence of Binlog files
+----------------------------+-----------+-----------+
1 row in set (0.00 sec)
```

Example Global database failover operation is performed when enhanced binlog is turned off

Source DB Cluster:
```sql
mysql> show binary logs;

+----------------------------+-----------+-----------+
| Log_name                   | File_size | Encrypted |
+----------------------------+-----------+-----------+
| mysql-bin-changelog.000001 | 156       | No        |
| mysql-bin-changelog.000002 | 156       | No        | --> Enhanced Binlog enabled |
| mysql-bin-changelog.000003 | 156       | No        | --> Enhanced Binlog enabled |
| mysql-bin-changelog.000004 | 156       | No        |
| mysql-bin-changelog.000005 | 156       | No        |
| mysql-bin-changelog.000006 | 156       | No        |
+----------------------------+-----------+-----------+
6 rows in set (0.00 sec)
```

**Restored or cloned DB cluster:**

Binlog files that are written after turning off the enhanced binlog are replicated and are available in the newly promoted DB cluster.

```sql
mysql> show binary logs;

+----------------------------+-----------+-----------+
| Log_name                   | File_size | Encrypted |
+----------------------------+-----------+-----------+
| mysql-bin-changelog.000004 | 156       | No        |
| mysql-bin-changelog.000005 | 156       | No        |
| mysql-bin-changelog.000006 | 156       | No        |
+----------------------------+-----------+-----------+
3 rows in set (0.00 sec)
```

**Amazon CloudWatch metrics for enhanced binlog**

The following Amazon CloudWatch metrics are published only when enhanced binlog is turned on.

<table>
<thead>
<tr>
<th>CloudWatch metric</th>
<th>Description</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>ChangeLogBytesUsed</td>
<td>The amount of storage used by the enhanced binlog.</td>
<td>Bytes</td>
</tr>
<tr>
<td>CloudWatch metric</td>
<td>Description</td>
<td>Units</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------</td>
</tr>
<tr>
<td>ChangeLogReadIOPs</td>
<td>The number of read I/O operations performed in the enhanced binlog within a 5-minute interval.</td>
<td>Count per 5 minutes</td>
</tr>
<tr>
<td>ChangeLogWriteIOPs</td>
<td>The number of write disk I/O operations performed in the enhanced binlog within a 5-minute interval.</td>
<td>Count per 5 minutes</td>
</tr>
</tbody>
</table>

**Enhanced binlog limitations**

The following limitations apply to Amazon Aurora DB clusters when enhanced binlog is turned on.

- Enhanced binlog is only supported on Aurora MySQL version 3.03.1 and higher.
- The enhanced binlog files written on the primary DB cluster aren't copied to the cloned or restored DB clusters.
- When used with Amazon Aurora global database, the enhanced binlog files of the primary DB cluster aren't replicated to the secondary DB clusters. Therefore, after the failover process, the historical binlog data isn't available in the new primary DB cluster.
- The following binlog configuration parameters are ignored:
  - binlog_group_commit_sync_delay
  - binlog_group_commit_sync_no_delay_count
  - binlog_max_flush_queue_time
- You can't drop or rename a corrupted table in a database. To drop these tables, you can contact AWS Support.
- The binlog I/O cache is disabled when enhanced binlog is turned on. For more information, see [Optimizing binary log replication](#).

**Note**

Enhanced binlog provides similar read performance improvements as binlog I/O cache and better write performance improvements.
• The backtrack feature is not supported. Enhanced binlog can't be turned on in a DB cluster under the following conditions:
  • DB cluster with the backtrack feature currently enabled.
  • DB cluster where the backtrack feature was previously enabled, but is now disabled.
  • DB cluster restored from a source DB cluster or a snapshot with the backtrack feature enabled.

Using GTID-based replication

The following content explains how to use global transaction identifiers (GTIDs) with binary log (binlog) replication between an Aurora MySQL cluster and an external source.

ℹ️ **Note**
For Aurora, you can use this feature only with Aurora MySQL clusters that use binlog replication to or from an external MySQL database. The other database might be an Amazon RDS MySQL instance, an on-premises MySQL database, or an Aurora DB cluster in a different AWS Region. To learn how to configure that kind of replication, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication).

If you use binlog replication and aren't familiar with GTID-based replication with MySQL, see Replication with global transaction identifiers in the MySQL documentation.

GTID-based replication is supported for Aurora MySQL version 2 and 3.

**Topics**
• Overview of global transaction identifiers (GTIDs)
• Parameters for GTID-based replication
• Configuring GTID-based replication for an Aurora MySQL cluster
• Disabling GTID-based replication for an Aurora MySQL DB cluster

**Overview of global transaction identifiers (GTIDs)**

*Global transaction identifiers (GTIDs)* are unique identifiers generated for committed MySQL transactions. You can use GTIDs to make binlog replication simpler and easier to troubleshoot.
Note
When Aurora synchronizes data among the DB instances in a cluster, that replication mechanism doesn't involve the binary log (binlog). For Aurora MySQL, GTID-based replication only applies when you also use binlog replication to replicate into or out of an Aurora MySQL DB cluster from an external MySQL-compatible database.

MySQL uses two different types of transactions for binlog replication:

- **GTID transactions** – Transactions that are identified by a GTID.
- **Anonymous transactions** – Transactions that don't have a GTID assigned.

In a replication configuration, GTIDs are unique across all DB instances. GTIDs simplify replication configuration because when you use them, you don't have to refer to log file positions. GTIDs also make it easier to track replicated transactions and determine whether the source instance and replicas are consistent.

You typically use GTID-based replication with Aurora when replicating from an external MySQL-compatible database into an Aurora cluster. You can set up this replication configuration as part of a migration from an on-premises or Amazon RDS database into Aurora MySQL. If the external database already uses GTIDs, enabling GTID-based replication for the Aurora cluster simplifies the replication process.

You configure GTID-based replication for an Aurora MySQL cluster by first setting the relevant configuration parameters in a DB cluster parameter group. You then associate that parameter group with the cluster.

**Parameters for GTID-based replication**

Use the following parameters to configure GTID-based replication.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gtid_mode</td>
<td>OFF, OFF_PERMISSIVE,</td>
<td>0FF specifies that new transactions are anonymous transactions (that is,</td>
</tr>
<tr>
<td></td>
<td>ON_PERMISSIVE, ON</td>
<td>don't have GTIDs), and a transaction must be anonymous to be replicated.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Valid values</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>OFF_PERMISSIVE specifies that new transactions are anonymous transactions,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>but all transactions can be replicated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ON_PERMISSIVE specifies that new transactions are GTID transactions, but</td>
</tr>
<tr>
<td></td>
<td></td>
<td>all transactions can be replicated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ON specifies that new transactions are GTID transactions, and a transaction</td>
</tr>
<tr>
<td></td>
<td></td>
<td>must be a GTID transaction to be replicated.</td>
</tr>
<tr>
<td>enforce_gtid_consistency</td>
<td>OFF, ON, WARN</td>
<td>OFF allows transactions to violate GTID consistency.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ON prevents transactions from violating GTID consistency.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>WARN allows transactions to violate GTID consistency but generates a</td>
</tr>
<tr>
<td></td>
<td></td>
<td>warning when a violation occurs.</td>
</tr>
</tbody>
</table>

**Note**

In the AWS Management Console, the `gtid_mode` parameter appears as `gtid-mode`.

For GTID-based replication, use these settings for the DB cluster parameter group for your Aurora MySQL DB cluster:

- **ON** and **ON_PERMISSIVE** apply only to outgoing replication from an Aurora MySQL cluster. Both of these values cause your Aurora DB cluster to use GTIDs for transactions that are replicated to an external database. **ON** requires that the external database also use GTID-based replication. **ON_PERMISSIVE** makes GTID-based replication optional on the external database.
OFF_PERMISSIVE, if set, means that your Aurora DB cluster can accept incoming replication from an external database. It can do this whether the external database uses GTID-based replication or not.

OFF, if set, means that your Aurora DB cluster only accepts incoming replication from external databases that don't use GTID-based replication.

Tip

Incoming replication is the most common binlog replication scenario for Aurora MySQL clusters. For incoming replication, we recommend that you set the GTID mode to OFF_PERMISSIVE. That setting allows incoming replication from external databases regardless of the GTID settings at the replication source.

For more information about parameter groups, see Working with parameter groups.

Configuring GTID-based replication for an Aurora MySQL cluster

When GTID-based replication is enabled for an Aurora MySQL DB cluster, the GTID settings apply to both inbound and outbound binlog replication.

To enable GTID-based replication for an Aurora MySQL cluster

1. Create or edit a DB cluster parameter group using the following parameter settings:
   - gtid_mode – ON or ON_PERMISSIVE
   - enforce_gtid_consistency – ON
2. Associate the DB cluster parameter group with the Aurora MySQL cluster. To do so, follow the procedures in Working with parameter groups.
3. (Optional) Specify how to assign GTIDs to transactions that don't include them. To do so, call the stored procedure in mysql.rds_assign_gtids_to_anonymous_transactions (Aurora MySQL version 3).
Disabling GTID-based replication for an Aurora MySQL DB cluster

You can disable GTID-based replication for an Aurora MySQL DB cluster. Doing so means that the Aurora cluster can't perform inbound or outbound binlog replication with external databases that use GTID-based replication.

Note

In the following procedure, read replica means the replication target in an Aurora configuration with binlog replication to or from an external database. It doesn't mean the read-only Aurora Replica DB instances. For example, when an Aurora cluster accepts incoming replication from an external source, the Aurora primary instance acts as the read replica for binlog replication.

For more details about the stored procedures mentioned in this section, see Aurora MySQL stored procedures.

To disable GTID-based replication for an Aurora MySQL DB cluster

1. On the Aurora replicas, run the following procedure:

   For version 3
   
   ```
   CALL mysql.rds_set_source_auto_position(0);
   ```

   For version 2
   
   ```
   CALL mysql.rds_set_master_auto_position(0);
   ```

2. Reset the gtid_mode to ON_PERMISSIVE.

   a. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has gtid_mode set to ON_PERMISSIVE.

      For more information about setting configuration parameters using parameter groups, see Working with parameter groups.

   b. Restart the Aurora MySQL DB cluster.

3. Reset the gtid_mode to OFF_PERMISSIVE.
a. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has `gtid_mode` set to `OFF_PERMISSIVE`.

b. Restart the Aurora MySQL DB cluster.

4. Wait for all of the GTID transactions to be applied on the Aurora primary instance. To check that these are applied, do the following steps:

a. On the Aurora primary instance, run the `SHOW MASTER STATUS` command.

Your output should be similar to the following output.

<table>
<thead>
<tr>
<th>File</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-bin-changelog.000031</td>
<td>107</td>
</tr>
</tbody>
</table>

Note the file and position in your output.

b. On each read replica, use the file and position information from its source instance in the previous step to run the following query:

For version 3

```sql
SELECT SOURCE_POS_WAIT('file', position);
```

For version 2

```sql
SELECT MASTER_POS_WAIT('file', position);
```

For example, if the file name is `mysql-bin-changelog.000031` and the position is `107`, run the following statement:

For version 3

```sql
SELECT SOURCE_POS_WAIT('mysql-bin-changelog.000031', 107);
```

For version 2

```sql
SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
```
5. Reset the GTID parameters to disable GTID-based replication.
   a. Make sure that the DB cluster parameter group associated with the Aurora MySQL cluster has the following parameter settings:
      - `gtid_mode` – OFF
      - `enforce_gtid_consistency` – OFF
   b. Restart the Aurora MySQL DB cluster.
Integrating Amazon Aurora MySQL with other AWS services

Amazon Aurora MySQL integrates with other AWS services so that you can extend your Aurora MySQL DB cluster to use additional capabilities in the AWS Cloud. Your Aurora MySQL DB cluster can use AWS services to do the following:

- Synchronously or asynchronously invoke an AWS Lambda function using the native functions `lambda_sync` or `lambda_async`. For more information, see [Invoking a Lambda function from an Amazon Aurora MySQL DB cluster](#).

- Load data from text or XML files stored in an Amazon Simple Storage Service (Amazon S3) bucket into your DB cluster using the `LOAD DATA FROM S3` or `LOAD XML FROM S3` command. For more information, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](#).

- Save data to text files stored in an Amazon S3 bucket from your DB cluster using the `SELECT INTO OUTFILE S3` command. For more information, see [Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket](#).

- Automatically add or remove Aurora Replicas with Application Auto Scaling. For more information, see [Using Amazon Aurora Auto Scaling with Aurora Replicas](#).

- Perform sentiment analysis with Amazon Comprehend, or a wide variety of machine learning algorithms with SageMaker. For more information, see [Using Amazon Aurora machine learning](#).

Aurora secures the ability to access other AWS services by using AWS Identity and Access Management (IAM). You grant permission to access other AWS services by creating an IAM role with the necessary permissions, and then associating the role with your DB cluster. For details and instructions on how to permit your Aurora MySQL DB cluster to access other AWS services on your behalf, see [Authorizing Amazon Aurora MySQL to access other AWS services on your behalf](#).

**Authorizing Amazon Aurora MySQL to access other AWS services on your behalf**

For your Aurora MySQL DB cluster to access other services on your behalf, create and configure an AWS Identity and Access Management (IAM) role. This role authorizes database users in your DB cluster to access other AWS services. For more information, see [Setting up IAM roles to access AWS services](#).
You must also configure your Aurora DB cluster to allow outbound connections to the target AWS service. For more information, see [Enabling network communication from Amazon Aurora MySQL to other AWS services](#).

If you do so, your database users can perform these actions using other AWS services:

- Synchronously or asynchronously invoke an AWS Lambda function using the native functions `lambda_sync` or `lambda_async`. Or, asynchronously invoke an AWS Lambda function using the `mysql.lambda_async` procedure. For more information, see [Invoking a Lambda function with an Aurora MySQL native function](#).
- Load data from text or XML files stored in an Amazon S3 bucket into your DB cluster by using the `LOAD DATA FROM S3` or `LOAD XML FROM S3` statement. For more information, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](#).
- Save data from your DB cluster into text files stored in an Amazon S3 bucket by using the `SELECT INTO OUTFILE S3` statement. For more information, see [Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket](#).
- Export log data to Amazon CloudWatch Logs MySQL. For more information, see [Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs](#).
- Automatically add or remove Aurora Replicas with Application Auto Scaling. For more information, see [Using Amazon Aurora Auto Scaling with Aurora Replicas](#).

### Setting up IAM roles to access AWS services

To permit your Aurora DB cluster to access another AWS service, do the following:

1. Create an IAM policy that grants permission to the AWS service. For more information, see:
   - [Creating an IAM policy to access Amazon S3 resources](#)
   - [Creating an IAM policy to access AWS Lambda resources](#)
   - [Creating an IAM policy to access CloudWatch Logs resources](#)
   - [Creating an IAM policy to access AWS KMS resources](#)

2. Create an IAM role and attach the policy that you created. For more information, see [Creating an IAM role to allow Amazon Aurora to access AWS services](#).

3. Associate that IAM role with your Aurora DB cluster. For more information, see [Associating an IAM role with an Amazon Aurora MySQL DB cluster](#).
Creating an IAM policy to access Amazon S3 resources

Aurora can access Amazon S3 resources to either load data to or save data from an Aurora DB cluster. However, you must first create an IAM policy that provides the bucket and object permissions that allow Aurora to access Amazon S3.

The following table lists the Aurora features that can access an Amazon S3 bucket on your behalf, and the minimum required bucket and object permissions required by each feature.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Bucket permissions</th>
<th>Object permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOAD DATA FROM S3</td>
<td>ListBucket</td>
<td>GetObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GetObjectVersion</td>
</tr>
<tr>
<td>LOAD XML FROM S3</td>
<td>ListBucket</td>
<td>GetObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GetObjectVersion</td>
</tr>
<tr>
<td>SELECT INTO OUTFILE S3</td>
<td>ListBucket</td>
<td>AbortMultipartUpload</td>
</tr>
<tr>
<td></td>
<td></td>
<td>DeleteObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>GetObject</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ListMultipartUploadParts</td>
</tr>
<tr>
<td></td>
<td></td>
<td>PutObject</td>
</tr>
</tbody>
</table>

The following policy adds the permissions that might be required by Aurora to access an Amazon S3 bucket on your behalf.

```json
{
   "Version": "2012-10-17",
   "Statement": [
    {
        "Sid": "AllowAuroraToExampleBucket",
        "Effect": "Allow",
        "Action": [
```
Amazon Aurora User Guide for Aurora

```
"s3:PutObject",
"s3:GetObject",
"s3:AbortMultipartUpload",
"s3:ListBucket",
"s3:DeleteObject",
"s3:GetObjectVersion",
"s3:ListMultipartUploadParts"
],
"Resource": [
    "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*",
    "arn:aws:s3:::DOC-EXAMPLE-BUCKET",
]
]
```

⚠️ **Note**

Make sure to include both entries for the `Resource` value. Aurora needs the permissions on both the bucket itself and all the objects inside the bucket.

Based on your use case, you might not need to add all of the permissions in the sample policy. Also, other permissions might be required. For example, if your Amazon S3 bucket is encrypted, you need to add `kms:Decrypt` permissions.

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access an Amazon S3 bucket on your behalf. To allow Aurora to access all of your Amazon S3 buckets, you can skip these steps and use either the `AmazonS3ReadOnlyAccess` or `AmazonS3FullAccess` predefined IAM policy instead of creating your own.

**To create an IAM policy to grant access to your Amazon S3 resources**

1. Open the [IAM Management Console](https:// معظمك ليلاً،*).  
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose S3.
5. For Actions, choose Expand all, and then choose the bucket permissions and object permissions needed for the IAM policy.
Object permissions are permissions for object operations in Amazon S3, and need to be granted for objects in a bucket, not the bucket itself. For more information about permissions for object operations in Amazon S3, see Permissions for object operations.

6. Choose Resources, and choose Add ARN for bucket.

7. In the Add ARN(s) dialog box, provide the details about your resource, and choose Add.

   Specify the Amazon S3 bucket to allow access to. For instance, if you want to allow Aurora to access the Amazon S3 bucket named DOC-EXAMPLE-BUCKET, then set the Amazon Resource Name (ARN) value to arn:aws:s3:::DOC-EXAMPLE-BUCKET.

8. If the object resource is listed, choose Add ARN for object.

9. In the Add ARN(s) dialog box, provide the details about your resource.

   For the Amazon S3 bucket, specify the Amazon S3 bucket to allow access to. For the object, you can choose Any to grant permissions to any object in the bucket.

   **Note**
   
   You can set Amazon Resource Name (ARN) to a more specific ARN value in order to allow Aurora to access only specific files or folders in an Amazon S3 bucket. For more information about how to define an access policy for Amazon S3, see Managing access permissions to your Amazon S3 resources.

10. (Optional) Choose Add ARN for bucket to add another Amazon S3 bucket to the policy, and repeat the previous steps for the bucket.

   **Note**
   
   You can repeat this to add corresponding bucket permission statements to your policy for each Amazon S3 bucket that you want Aurora to access. Optionally, you can also grant access to all buckets and objects in Amazon S3.

12. For Name, enter a name for your IAM policy, for example AllowAuroraToExampleBucket. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional Description value.

13. Choose Create policy.
14. Complete the steps in Creating an IAM role to allow Amazon Aurora to access AWS services.

Creating an IAM policy to access AWS Lambda resources

You can create an IAM policy that provides the minimum required permissions for Aurora to invoke an AWS Lambda function on your behalf.

The following policy adds the permissions required by Aurora to invoke an AWS Lambda function on your behalf.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowAuroraToExampleFunction",
            "Effect": "Allow",
            "Action": "lambda:InvokeFunction",
            "Resource": "arn:aws:lambda:<region>:<123456789012>:function:<example_function>"
        }
    ]
}
```

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to invoke an AWS Lambda function on your behalf. To allow Aurora to invoke all of your AWS Lambda functions, you can skip these steps and use the predefined AWSLambdaRole policy instead of creating your own.

To create an IAM policy to grant invoke to your AWS Lambda functions

1. Open the IAM console.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose Lambda.
5. For Actions, choose Expand all, and then choose the AWS Lambda permissions needed for the IAM policy.

   Ensure that InvokeFunction is selected. It is the minimum required permission to enable Amazon Aurora to invoke an AWS Lambda function.
6. Choose **Resources** and choose **Add ARN for function**.

7. In the **Add ARN(s)** dialog box, provide the details about your resource.

   Specify the Lambda function to allow access to. For instance, if you want to allow Aurora to access a Lambda function named `example_function`, then set the ARN value to `arn:aws:lambda:::function:example_function`.

   For more information on how to define an access policy for AWS Lambda, see [Authentication and access control for AWS Lambda](#).

8. Optionally, choose **Add additional permissions** to add another AWS Lambda function to the policy, and repeat the previous steps for the function.

   **Note**
   
   You can repeat this to add corresponding function permission statements to your policy for each AWS Lambda function that you want Aurora to access.

9. Choose **Review policy**.

10. Set **Name** to a name for your IAM policy, for example `AllowAuroraToExampleFunction`. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.

11. Choose **Create policy**.

12. Complete the steps in [Creating an IAM role to allow Amazon Aurora to access AWS services](#).

### Creating an IAM policy to access CloudWatch Logs resources

Aurora can access CloudWatch Logs to export audit log data from an Aurora DB cluster. However, you must first create an IAM policy that provides the log group and log stream permissions that allow Aurora to access CloudWatch Logs.

The following policy adds the permissions required by Aurora to access Amazon CloudWatch Logs on your behalf, and the minimum required permissions to create log groups and export data.

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "EnableCreationAndManagementOfRDSCloudwatchLogEvents",
```
"Effect": "Allow",
"Action": [
    "logs:GetLogEvents",
    "logs:PutLogEvents"
],
"Resource": "arn:aws:logs:*:*:log-group:/aws/rds/*:log-stream:*"
},
{
    "Sid": "EnableCreationAndManagementOfRDSCloudwatchLogGroupsAndStreams",
    "Effect": "Allow",
    "Action": [
        "logs:CreateLogStream",
        "logs:DescribeLogStreams",
        "logs:PutRetentionPolicy",
        "logs:CreateLogGroup"
    ],
    "Resource": "arn:aws:logs:*:*:log-group:/aws/rds/*"
}

You can modify the ARNs in the policy to restrict access to a specific AWS Region and account.

You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access CloudWatch Logs on your behalf. To allow Aurora full access to CloudWatch Logs, you can skip these steps and use the CloudWatchLogsFullAccess predefined IAM policy instead of creating your own. For more information, see Using identity-based policies (IAM policies) for CloudWatch Logs in the Amazon CloudWatch User Guide.

To create an IAM policy to grant access to your CloudWatch Logs resources

1. Open the IAM console.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose CloudWatch Logs.
5. For Actions, choose Expand all (on the right), and then choose the Amazon CloudWatch Logs permissions needed for the IAM policy.

   Ensure that the following permissions are selected:

   • CreateLogGroup
- CreateLogStream
- DescribeLogStreams
- GetLogEvents
- PutLogEvents
- PutRetentionPolicy

6. Choose **Resources** and choose **Add ARN** for **log-group**.

7. In the **Add ARN(s)** dialog box, enter the following values:
   - **Region** – An AWS Region or *
   - **Account** – An account number or *
   - **Log Group Name** – /aws/rds/*

8. In the **Add ARN(s)** dialog box, choose **Add**.

9. Choose **Add ARN** for **log-stream**.

10. In the **Add ARN(s)** dialog box, enter the following values:
    - **Region** – An AWS Region or *
    - **Account** – An account number or *
    - **Log Group Name** – /aws/rds/*
    - **Log Stream Name** – *

11. In the **Add ARN(s)** dialog box, choose **Add**.

12. Choose **Review policy**.

13. Set **Name** to a name for your IAM policy, for example AmazonRDSCloudWatchLogs. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional **Description** value.

14. Choose **Create policy**.

15. Complete the steps in **Creating an IAM role to allow Amazon Aurora to access AWS services**.

#### Creating an IAM policy to access AWS KMS resources

Aurora can access the AWS KMS keys used for encrypting their database backups. However, you must first create an IAM policy that provides the permissions that allow Aurora to access KMS keys.

The following policy adds the permissions required by Aurora to access KMS keys on your behalf.
You can use the following steps to create an IAM policy that provides the minimum required permissions for Aurora to access KMS keys on your behalf.

To create an IAM policy to grant access to your KMS keys

1. Open the IAM console.
2. In the navigation pane, choose Policies.
3. Choose Create policy.
4. On the Visual editor tab, choose Choose a service, and then choose KMS.
5. For Actions, choose Write, and then choose Decrypt.
6. Choose Resources, and choose Add ARN.
7. In the Add ARN(s) dialog box, enter the following values:
   - Region – Type the AWS Region, such as us-west-2.
   - Account – Type the user account number.
   - Log Stream Name – Type the KMS key identifier.
8. In the Add ARN(s) dialog box, choose Add.
10. Set Name to a name for your IAM policy, for example AmazonRDSKMSKey. You use this name when you create an IAM role to associate with your Aurora DB cluster. You can also add an optional Description value.
11. Choose Create policy.
12. Complete the steps in Creating an IAM role to allow Amazon Aurora to access AWS services.
Creating an IAM role to allow Amazon Aurora to access AWS services

After creating an IAM policy to allow Aurora to access AWS resources, you must create an IAM role and attach the IAM policy to the new IAM role.

To create an IAM role to permit your Amazon RDS cluster to communicate with other AWS services on your behalf, take the following steps.

To create an IAM role to allow Amazon RDS to access AWS services

1. Open the IAM console.
2. In the navigation pane, choose Roles.
3. Choose Create role.
4. Under AWS service, choose RDS.
5. Under Select your use case, choose RDS – Add Role to Database.
6. Choose Next.
7. On the Permissions policies page, enter the name of your policy in the Search field.
8. When it appears in the list, select the policy that you defined earlier using the instructions in one of the following sections:
   - Creating an IAM policy to access Amazon S3 resources
   - Creating an IAM policy to access AWS Lambda resources
   - Creating an IAM policy to access CloudWatch Logs resources
   - Creating an IAM policy to access AWS KMS resources
9. Choose Next.
10. In Role name, enter a name for your IAM role, for example RDSLoadFromS3. You can also add an optional Description value.
11. Choose Create Role.
12. Complete the steps in Associating an IAM role with an Amazon Aurora MySQL DB cluster.

Associating an IAM role with an Amazon Aurora MySQL DB cluster

To permit database users in an Amazon Aurora DB cluster to access other AWS services, you associate the IAM role that you created in Creating an IAM role to allow Amazon Aurora to access
**AWS services** with that DB cluster. You can also have AWS create a new IAM role by associating the service directly.

### Note

You can't associate an IAM role with an Aurora Serverless v1 DB cluster. For more information, see [Using Amazon Aurora Serverless v1](#).

You can associate an IAM role with an Aurora Serverless v2 DB cluster.

To associate an IAM role with a DB cluster you do two things:

1. Add the role to the list of associated roles for a DB cluster by using the RDS console, the `add-role-to-db-cluster` AWS CLI command, or the `AddRoleToDBCluster` RDS API operation.

   You can add a maximum of five IAM roles for each Aurora DB cluster.

2. Set the cluster-level parameter for the related AWS service to the ARN for the associated IAM role.

The following table describes the cluster-level parameter names for the IAM roles used to access other AWS services.

<table>
<thead>
<tr>
<th>Cluster-level parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>aws_default.lambda_role</code></td>
<td>Used when invoking a Lambda function from your DB cluster.</td>
</tr>
<tr>
<td><code>aws_default.logs_role</code></td>
<td>This parameter is no longer required for exporting log data from your DB cluster to Amazon CloudWatch Logs. Aurora MySQL now uses a service-linked role for the required permissions. For more information about service-linked roles, see <a href="#">Using service-linked roles for Amazon Aurora</a>.</td>
</tr>
<tr>
<td><code>aws_default.s3_role</code></td>
<td>Used when invoking the <code>LOAD DATA FROM S3</code>, <code>LOAD XML FROM S3</code>, or <code>SELECT INTO</code> commands.</td>
</tr>
<tr>
<td>Cluster-level parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| **OUTFILE S3** statement from your DB cluster.  

In Aurora MySQL version 2, the IAM role specified in this parameter is used if an IAM role isn't specified for `aurora_load_from_s3_role` or `aurora_select_into_s3_role` for the appropriate statement.  

In Aurora MySQL version 3, the IAM role specified for this parameter is always used.  

| `aurora_load_from_s3_role` | Used when invoking the `LOAD DATA FROM S3` or `LOAD XML FROM S3` statement from your DB cluster. If an IAM role is not specified for this parameter, the IAM role specified in `aws_default_s3_role` is used.  

In Aurora MySQL version 3, this parameter isn't available. |
|--------------------------|-------------|
| `aurora_select_into_s3_role` | Used when invoking the `SELECT INTO OUTFILE S3` statement from your DB cluster. If an IAM role is not specified for this parameter, the IAM role specified in `aws_default_s3_role` is used.  

In Aurora MySQL version 3, this parameter isn't available. |

To associate an IAM role to permit your Amazon RDS cluster to communicate with other AWS services on your behalf, take the following steps.
To associate an IAM role with an Aurora DB cluster using the console

1. Open the RDS console at https://console.aws.amazon.com/rds/.
2. Choose Databases.
3. Choose the name of the Aurora DB cluster that you want to associate an IAM role with to show its details.
4. On the Connectivity & security tab, in the Manage IAM roles section, do one of the following:
   - Select IAM roles to add to this cluster (default)
   - Select a service to connect to this cluster

5. To use an existing IAM role, choose it from the menu, then choose Add role.
   
   If adding the role is successful, its status shows as Pending, then Available.
6. To connect a service directly:
   a. Choose Select a service to connect to this cluster.
   b. Choose the service from the menu, then choose Connect service.
   c. For Connect cluster to Service Name, enter the Amazon Resource Name (ARN) to use to connect to the service, then choose Connect service.

   AWS creates a new IAM role for connecting to the service. Its status shows as Pending, then Available.
7. (Optional) To stop associating an IAM role with a DB cluster and remove the related permission, choose the role and then choose Delete.
To set the cluster-level parameter for the associated IAM role

1. In the RDS console, choose **Parameter groups** in the navigation pane.

2. If you are already using a custom DB parameter group, you can select that group to use instead of creating a new DB cluster parameter group. If you are using the default DB cluster parameter group, create a new DB cluster parameter group, as described in the following steps:
   a. Choose **Create parameter group**.
   b. For **Parameter group family**, choose `aurora-mysql8.0` for an Aurora MySQL 8.0-compatible DB cluster, or `aurora-mysql5.7` for an Aurora MySQL 5.7-compatible DB cluster.
   c. For **Type**, choose **DB Cluster Parameter Group**.
   d. For **Group name**, type the name of your new DB cluster parameter group.
   e. For **Description**, type a description for your new DB cluster parameter group.
   f. Choose **Create**.

3. On the **Parameter groups** page, select your DB cluster parameter group and choose **Edit** for **Parameter group actions**.

4. Set the appropriate cluster-level **parameters** to the related IAM role ARN values.
   
   For example, you can set just the `aws_default_s3_role` parameter to `arn:aws:iam::123456789012:role/AllowS3Access`.

5. Choose **Save changes**.
6. To change the DB cluster parameter group for your DB cluster, complete the following steps:

   a. Choose **Databases**, and then choose your Aurora DB cluster.
   b. Choose **Modify**.
   c. Scroll to **Database options** and set **DB cluster parameter group** to the DB cluster parameter group.
   d. Choose **Continue**.
   e. Verify your changes and then choose **Apply immediately**.
   f. Choose **Modify cluster**.
   g. Choose **Databases**, and then choose the primary instance for your DB cluster.
   h. For **Actions**, choose **Reboot**.

   When the instance has rebooted, your IAM role is associated with your DB cluster.

   For more information about cluster parameter groups, see [Aurora MySQL configuration parameters](#).

**CLI**

To associate an IAM role with a DB cluster by using the AWS CLI

1. Call the `add-role-to-db-cluster` command from the AWS CLI to add the ARNs for your IAM roles to the DB cluster, as shown following.

   ```bash
   PROMPT> aws rds add-role-to-db-cluster --db-cluster-identifier my-cluster --role-arn arn:aws:iam::123456789012:role/AllowAuroraS3Role
   PROMPT> aws rds add-role-to-db-cluster --db-cluster-identifier my-cluster --role-arn arn:aws:iam::123456789012:role/AllowAuroraLambdaRole
   ```

2. If you are using the default DB cluster parameter group, create a new DB cluster parameter group. If you are already using a custom DB parameter group, you can use that group instead of creating a new DB cluster parameter group.

   To create a new DB cluster parameter group, call the `create-db-cluster-parameter-group` command from the AWS CLI, as shown following.

   ```bash
   PROMPT> aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name AllowAWSAccess \
   ```
For an Aurora MySQL 5.7-compatible DB cluster, specify `aurora-mysql5.7` for `--db-parameter-group-family`. For an Aurora MySQL 8.0-compatible DB cluster, specify `aurora-mysql8.0` for `--db-parameter-group-family`.

3. Set the appropriate cluster-level parameter or parameters and the related IAM role ARN values in your DB cluster parameter group, as shown following.

```
PROMPT> aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name AllowAWSAccess \
    --parameters "ParameterName=aws_default_s3_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAuroraS3Role,method=pending-reboot" \
    --parameters "ParameterName=aws_default_lambda_role,ParameterValue=arn:aws:iam::123456789012:role/AllowAurora LambdaRole,method=pending-reboot"
```

4. Modify the DB cluster to use the new DB cluster parameter group and then reboot the cluster, as shown following.

```
PROMPT> aws rds modify-db-cluster --db-cluster-identifier my-cluster --db-cluster-parameter-group-name AllowAWSAccess
PROMPT> aws rds reboot-db-instance --db-instance-identifier my-cluster-primary
```

When the instance has rebooted, your IAM roles are associated with your DB cluster.

For more information about cluster parameter groups, see [Aurora MySQL configuration parameters](#).

### Enabling network communication from Amazon Aurora MySQL to other AWS services

To use certain other AWS services with Amazon Aurora, the network configuration of your Aurora DB cluster must allow outbound connections to endpoints for those services. The following operations require this network configuration.

- Invoking AWS Lambda functions. To learn about this feature, see [Invoking a Lambda function with an Aurora MySQL native function](#).
• Accessing files from Amazon S3. To learn about this feature, see [Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket](#) and [Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket](#).

• Accessing AWS KMS endpoints. AWS KMS access is required to use database activity streams with Aurora MySQL. To learn about this feature, see [Monitoring Amazon Aurora with Database Activity Streams](#).

• Accessing SageMaker endpoints. SageMaker access is required to use SageMaker machine learning with Aurora MySQL. To learn about this feature, see [Using Amazon Aurora machine learning with Aurora MySQL](#).

Aurora returns the following error messages if it can't connect to a service endpoint.

- **ERROR 1871 (HY000):** S3 API returned error: Network Connection

- **ERROR 1873 (HY000):** Lambda API returned error: Network Connection. Unable to connect to endpoint

- **ERROR 1815 (HY000):** Internal error: Unable to initialize S3Stream

For database activity streams using Aurora MySQL, the activity stream stops functioning if the DB cluster can't access the AWS KMS endpoint. Aurora notifies you about this issue using RDS Events.

If you encounter these messages while using the corresponding AWS services, check if your Aurora DB cluster is public or private. If your Aurora DB cluster is private, you must configure it to enable connections.

For an Aurora DB cluster to be public, it must be marked as publicly accessible. If you look at the details for the DB cluster in the AWS Management Console, Publicly Accessible is Yes if this is the case. The DB cluster must also be in an Amazon VPC public subnet. For more information about publicly accessible DB instances, see [Working with a DB cluster in a VPC](#). For more information about public Amazon VPC subnets, see [Your VPC and subnets](#).

If your Aurora DB cluster isn't publicly accessible and in a VPC public subnet, it is private. You might have a DB cluster that is private and want to use one of the features that requires this network configuration. If so, configure the cluster so that it can connect to Internet addresses through Network Address Translation (NAT). As an alternative for Amazon S3, Amazon SageMaker, and AWS...
Lambda, you can instead configure the VPC to have a VPC endpoint for the other service associated with the DB cluster's route table, see Working with a DB cluster in a VPC. For more information about configuring NAT in your VPC, see NAT gateways. For more information about configuring VPC endpoints, see VPC endpoints. You can also create an S3 gateway endpoint to access your S3 bucket. For more information, see Gateway endpoints for Amazon S3.

You might also have to open the ephemeral ports for your network access control lists (ACLs) in the outbound rules for your VPC security group. For more information on ephemeral ports for network ACLs, see Ephemeral ports in the Amazon Virtual Private Cloud User Guide.

### Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket

You can use the LOAD DATA FROM S3 or LOAD XML FROM S3 statement to load data from files stored in an Amazon S3 bucket. In Aurora MySQL, the files are first stored on the local disk, and then imported to the database. After the imports to the database are done, the local files are deleted.

**Note**

Loading data into a table from text files isn't supported for Aurora Serverless v1. It is supported for Aurora Serverless v2.

• Examples
• LOAD XML FROM S3
  • Syntax
  • Parameters

Giving Aurora access to Amazon S3

Before you can load data from an Amazon S3 bucket, you must first give your Aurora MySQL DB cluster permission to access Amazon S3.

To give Aurora MySQL access to Amazon S3

1. Create an AWS Identity and Access Management (IAM) policy that provides the bucket and object permissions that allow your Aurora MySQL DB cluster to access Amazon S3. For instructions, see Creating an IAM policy to access Amazon S3 resources.

   Note
   In Aurora MySQL version 3.05 and higher, you can load objects that are encrypted using customer-managed AWS KMS keys. To do so, include the kms:Decrypt permission in your IAM policy. For more information, see Creating an IAM policy to access AWS KMS resources.
   You don't need this permission to load objects that are encrypted using AWS managed keys or Amazon S3 managed keys (SSE-S3).

2. Create an IAM role, and attach the IAM policy you created in Creating an IAM policy to access Amazon S3 resources to the new IAM role. For instructions, see Creating an IAM role to allow Amazon Aurora to access AWS services.

3. Make sure the DB cluster is using a custom DB cluster parameter group.

   For more information about creating a custom DB cluster parameter group, see Creating a DB cluster parameter group.

4. For Aurora MySQL version 2, set either the aurora_load_from_s3_role or aws_default_s3_role DB cluster parameter to the Amazon Resource Name (ARN) of the
new IAM role. If an IAM role isn't specified for aurora_load_from_s3_role, Aurora uses the IAM role specified in aws_default_s3_role.

For Aurora MySQL version 3, use aws_default_s3_role.

If the cluster is part of an Aurora global database, set this parameter for each Aurora cluster in the global database. Although only the primary cluster in an Aurora global database can load data, another cluster might be promoted by the failover mechanism and become the primary cluster.

For more information about DB cluster parameters, see Amazon Aurora DB cluster and DB instance parameters.

5. To permit database users in an Aurora MySQL DB cluster to access Amazon S3, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services with the DB cluster. For an Aurora global database, associate the role with each Aurora cluster in the global database. For information about associating an IAM role with a DB cluster, see Associating an IAM role with an Amazon Aurora MySQL DB cluster.

6. Configure your Aurora MySQL DB cluster to allow outbound connections to Amazon S3. For instructions, see Enabling network communication from Amazon Aurora MySQL to other AWS services.

If your DB cluster isn't publicly accessible and in a VPC public subnet, it is private. You can create an S3 gateway endpoint to access your S3 bucket. For more information, see Gateway endpoints for Amazon S3.

For an Aurora global database, enable outbound connections for each Aurora cluster in the global database.

Granting privileges to load data in Amazon Aurora MySQL

The database user that issues the LOAD DATA FROM S3 or LOAD XML FROM S3 statement must have a specific role or privilege to issue either statement. In Aurora MySQL version 3, you grant the AWS_LOAD_S3_ACCESS role. In Aurora MySQL version 2, you grant the LOAD FROM S3 privilege.

The administrative user for a DB cluster is granted the appropriate role or privilege by default. You can grant the privilege to another user by using one of the following statements.

Use the following statement for Aurora MySQL version 3:
Grant the AWS_LOAD_S3_ACCESS role to a user:

```
GRANT AWS_LOAD_S3_ACCESS TO 'user'@'domain-or-ip-address'
```

**Tip**

When you use the role technique in Aurora MySQL version 3, you can also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in [Role-based privilege model](#). For more details, see [Using roles](#) in the MySQL Reference Manual.

This only applies to the current active session. When you reconnect, you must run the `SET ROLE` statement again to grant privileges. For more information, see [SET ROLE statement](#) in the MySQL Reference Manual.

You can use the `activate_all_roles_on_login` DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you generally don't have to call the `SET ROLE` statement explicitly to activate a role. For more information, see [activate_all_roles_on_login](#) in the MySQL Reference Manual.

However, you must call `SET ROLE ALL` explicitly at the beginning of a stored procedure to activate the role, when the stored procedure is called by a different user.

Use the following statement for Aurora MySQL version 2:

```
GRANT LOAD FROM S3 ON *.* TO 'user'@'domain-or-ip-address'
```

The AWS_LOAD_S3_ACCESS role and `LOAD FROM S3` privilege are specific to Amazon Aurora and are not available for external MySQL databases or RDS for MySQL DB instances. If you have set up replication between an Aurora DB cluster as the replication master and a MySQL database as the replication client, then the `GRANT` statement for the role or privilege causes replication to stop with an error. You can safely skip the error to resume replication. To skip the error on an RDS for MySQL instance, use the `mysql_rds_skip_repl_error` procedure. To skip the error on an external MySQL database, use the `slave_skip_errors` system variable (Aurora MySQL version 2) or `replica_skip_errors` system variable (Aurora MySQL version 3).

**Note**

The database user must have `INSERT` privileges for the database into which it’s loading data.
Specifying the path (URI) to an Amazon S3 bucket

The syntax for specifying the path (URI) to files stored on an Amazon S3 bucket is as follows.

```
s3-region://DOC-EXAMPLE-BUCKET/file-name-or-prefix
```

The path includes the following values:

- **region** (optional) – The AWS Region that contains the Amazon S3 bucket to load from. This value is optional. If you don't specify a region value, then Aurora loads your file from Amazon S3 in the same region as your DB cluster.

- **bucket-name** – The name of the Amazon S3 bucket that contains the data to load. Object prefixes that identify a virtual folder path are supported.

- **file-name-or-prefix** – The name of the Amazon S3 text file or XML file, or a prefix that identifies one or more text or XML files to load. You can also specify a manifest file that identifies one or more text files to load. For more information about using a manifest file to load text files from Amazon S3, see Using a manifest to specify data files to load.

To copy the URI for files in an S3 bucket

1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.

2. In the navigation pane, choose **Buckets**, and then choose the bucket whose URI you want to copy.

3. Select the prefix or file that you want to load from S3.

4. Choose **Copy S3 URI**.

LOAD DATA FROM S3

You can use the `LOAD DATA FROM S3` statement to load data from any text file format that is supported by the MySQL `LOAD DATA INFILE` statement, such as text data that is comma-delimited. Compressed files are not supported.
Note
Make sure that your Aurora MySQL DB cluster allows outbound connections to S3. For more information, see Enabling network communication from Amazon Aurora MySQL to other AWS services.

Syntax

LOAD DATA [FROM] S3 [FILE | PREFIX | MANIFEST] 'S3-URI'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[PARTITION (partition_name,...)]
[CHARACTER SET charset_name]
[{$FIELDS | COLUMNS}
  [TERMINATED BY 'string']
  [[OPTIONALLY] ENCLOSED BY 'char']
  [ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
[IGNORE number {LINES | ROWS}]
[({col_name_or_user_var,...})]
[SET col_name = expr,...]

Note
In Aurora MySQL version 3.05 and higher, the keyword FROM is optional.

Parameters

The LOAD DATA FROM S3 statement uses the following required and optional parameters. You can find more details about some of these parameters in LOAD DATA Statement in the MySQL documentation.
FILE | PREFIX | MANIFEST

Identifies whether to load the data from a single file, from all files that match a given prefix, or from all files in a specified manifest. FILE is the default.

S3-URI

Specifies the URI for a text or manifest file to load, or an Amazon S3 prefix to use. Specify the URI using the syntax described in Specifying the path (URI) to an Amazon S3 bucket.

REPLACE | IGNORE

Determines what action to take if an input row has the same unique key values as an existing row in the database table.

• Specify REPLACE if you want the input row to replace the existing row in the table.
• Specify IGNORE if you want to discard the input row.

INTO TABLE

Identifies the name of the database table to load the input rows into.

PARTITION

Requires that all input rows be inserted into the partitions identified by the specified list of comma-separated partition names. If an input row cannot be inserted into one of the specified partitions, then the statement fails and an error is returned.

CHARACTER SET

Identifies the character set of the data in the input file.

FIELDS | COLUMNS

Identifies how the fields or columns in the input file are delimited. Fields are tab-delimited by default.

LINES

Identifies how the lines in the input file are delimited. Lines are delimited by a newline character ("\n") by default.

IGNORE number LINES | ROWS

Specifies to ignore a certain number of lines or rows at the start of the input file. For example, you can use IGNORE 1 LINES to skip over an initial header line containing column names, or
IGNORE 2 ROWS to skip over the first two rows of data in the input file. If you also use PREFIX, IGNORE skips a certain number of lines or rows at the start of the first input file.

**col_name_or_user_var, ...**

Specifies a comma-separated list of one or more column names or user variables that identify which columns to load by name. The name of a user variable used for this purpose must match the name of an element from the text file, prefixed with @. You can employ user variables to store the corresponding field values for subsequent reuse.

For example, the following statement loads the first column from the input file into the first column of `table1`, and sets the value of the `table_column2` column in `table1` to the input value of the second column divided by 100.

```sql
LOAD DATA FROM S3 's3://DOC-EXAMPLE-BUCKET/data.txt'
    INTO TABLE table1
    (column1, @var1)
    SET table_column2 = @var1/100;
```

**SET**

Specifies a comma-separated list of assignment operations that set the values of columns in the table to values not included in the input file.

For example, the following statement sets the first two columns of `table1` to the values in the first two columns from the input file, and then sets the value of the `column3` in `table1` to the current time stamp.

```sql
LOAD DATA FROM S3 's3://DOC-EXAMPLE-BUCKET/data.txt'
    INTO TABLE table1
    (column1, column2)
    SET column3 = CURRENT_TIMESTAMP;
```

You can use subqueries in the right side of SET assignments. For a subquery that returns a value to be assigned to a column, you can use only a scalar subquery. Also, you cannot use a subquery to select from the table that is being loaded.

You can't use the LOCAL keyword of the LOAD DATA FROM S3 statement if you're loading data from an Amazon S3 bucket.
Using a manifest to specify data files to load

You can use the LOAD DATA FROM S3 statement with the MANIFEST keyword to specify a manifest file in JSON format that lists the text files to be loaded into a table in your DB cluster.

The following JSON schema describes the format and content of a manifest file.

```json
{
   "$schema": "http://json-schema.org/draft-04/schema#",
   "additionalProperties": false,
   "definitions": {},
   "id": "Aurora_LoadFromS3_Manifest",
   "properties": {
      "entries": {
         "additionalItems": false,
         "id": "/properties/entries",
         "items": {
            "additionalProperties": false,
            "id": "/properties/entries/items",
            "properties": {
               "mandatory": {
                  "default": "false",
                  "id": "/properties/entries/items/properties/mandatory",
                  "type": "boolean"
               },
               "url": {
                  "id": "/properties/entries/items/properties/url",
                  "maxLength": 1024,
                  "minLength": 1,
                  "type": "string"
               }
            },
            "required": ["url"],
            "type": "object"
         },
         "type": "array",
         "uniqueItems": true
      }
   },
   "required": ["entries"],
}
```
Each URL in the manifest must specify a URL with the bucket name and full object path for the file, not just a prefix. You can use a manifest to load files from different buckets, different regions, or files that do not share the same prefix. If a region is not specified in the URL, the region of the target Aurora DB cluster is used. The following example shows a manifest file that loads four files from different buckets.

```json
{
    "entries": [
        {
            "url":"s3://aurora-bucket/2013-10-04-customerdata",
            "mandatory":true
        },
        {
            "url":"s3-us-west-2://aurora-bucket-usw2/2013-10-05-customerdata",
            "mandatory":true
        },
        {
            "url":"s3://aurora-bucket/2013-10-04-customerdata",
            "mandatory":false
        },
        {
            "url":"s3://aurora-bucket/2013-10-05-customerdata"
        }
    ]
}
```

The optional `mandatory` flag specifies whether `LOAD DATA FROM S3` should return an error if the file is not found. The `mandatory` flag defaults to `false`. Regardless of how `mandatory` is set, `LOAD DATA FROM S3` terminates if no files are found.

Manifest files can have any extension. The following example runs the `LOAD DATA FROM S3` statement with the manifest in the previous example, which is named `customer.manifest`.

```
LOAD DATA FROM S3 MANIFEST 's3-us-west-2://aurora-bucket/customer.manifest'
    INTO TABLE CUSTOMER
    FIELDS TERMINATED BY ','
    LINES TERMINATED BY '\n'
    (ID, FIRSTNAME, LASTNAME, EMAIL);
```

Loading data from text files in Amazon S3
After the statement completes, an entry for each successfully loaded file is written to the `aurora_s3_load_history` table.

### Verifying loaded files using the `aurora_s3_load_history` table

Every successful `LOAD DATA FROM S3` statement updates the `aurora_s3_load_history` table in the `mysql` schema with an entry for each file that was loaded.

After you run the `LOAD DATA FROM S3` statement, you can verify which files were loaded by querying the `aurora_s3_load_history` table. To see the files that were loaded from one iteration of the statement, use the `WHERE` clause to filter the records on the Amazon S3 URI for the manifest file used in the statement. If you have used the same manifest file before, filter the results using the `timestamp` field.

```sql
select * from mysql.aurora_s3_load_history where load_prefix = 'S3_URI';
```

The following table describes the fields in the `aurora_s3_load_history` table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>load_prefix</td>
<td>The URI that was specified in the load statement. This URI can map to any of the following:</td>
</tr>
<tr>
<td></td>
<td>• A single data file for a <code>LOAD DATA FROM S3 FILE</code> statement</td>
</tr>
<tr>
<td></td>
<td>• An Amazon S3 prefix that maps to multiple data files for a <code>LOAD DATA FROM S3 PREFIX</code> statement</td>
</tr>
<tr>
<td></td>
<td>• A single manifest file that contains the names of files to be loaded for a <code>LOAD DATA FROM S3 MANIFEST</code> statement</td>
</tr>
<tr>
<td>file_name</td>
<td>The name of a file that was loaded into Aurora from Amazon S3 using the URI identified in the <code>load_prefix</code> field.</td>
</tr>
<tr>
<td>version_number</td>
<td>The version number of the file identified by the <code>file_name</code> field that was loaded, if the Amazon S3 bucket has a version number.</td>
</tr>
<tr>
<td>bytes_loaded</td>
<td>The size of the file loaded, in bytes.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>load_timestamp</td>
<td>The timestamp when the LOAD DATA FROM S3 statement completed.</td>
</tr>
</tbody>
</table>

### Examples

The following statement loads data from an Amazon S3 bucket that is in the same region as the Aurora DB cluster. The statement reads the comma-delimited data in the file `customerdata.txt` that is in the `DOC-EXAMPLE-BUCKET` Amazon S3 bucket, and then loads the data into the table `store-schema.customer-table`.

```sql
LOAD DATA FROM S3 's3://DOC-EXAMPLE-BUCKET/customerdata.csv'
INTO TABLE store-schema.customer-table
FIELDS TERMINATED BY ','
LINES TERMINATED BY '\n'
(ID, FIRSTNAME, LASTNAME, ADDRESS, EMAIL, PHONE);
```

The following statement loads data from an Amazon S3 bucket that is in a different region from the Aurora DB cluster. The statement reads the comma-delimited data from all files that match the `employee-data` object prefix in the `DOC-EXAMPLE-BUCKET` Amazon S3 bucket in the `us-west-2` region, and then loads the data into the `employees` table.

```sql
LOAD DATA FROM S3 PREFIX 's3-us-west-2://DOC-EXAMPLE-BUCKET/employee_data'
INTO TABLE employees
FIELDS TERMINATED BY ','
LINES TERMINATED BY '\n'
(ID, FIRSTNAME, LASTNAME, EMAIL, SALARY);
```

The following statement loads data from the files specified in a JSON manifest file named `q1_sales.json` into the `sales` table.

```sql
LOAD DATA FROM S3 MANIFEST 's3-us-west-2://DOC-EXAMPLE-BUCKET1/q1_sales.json'
INTO TABLE sales
FIELDS TERMINATED BY ','
LINES TERMINATED BY '\n'
(MONTH, STORE, GROSS, NET);
```
LOAD XML FROM S3

You can use the LOAD XML FROM S3 statement to load data from XML files stored on an Amazon S3 bucket in one of three different XML formats:

- Column names as attributes of a `<row>` element. The attribute value identifies the contents of the table field.

```xml
<row column1="value1" column2="value2" .../>
```

- Column names as child elements of a `<row>` element. The value of the child element identifies the contents of the table field.

```xml
<row>
    <column1>value1</column1>
    <column2>value2</column2>
</row>
```

- Column names in the name attribute of `<field>` elements in a `<row>` element. The value of the `<field>` element identifies the contents of the table field.

```xml
<row>
    <field name='column1'>value1</field>
    <field name='column2'>value2</field>
</row>
```

Syntax

```
LOAD XML FROM S3 'S3-URI'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[PARTITION (partition_name,...)]
[CHARACTER SET charset_name]
[ROWS IDENTIFIED BY '<element-name>']
[IGNORE number {LINES | ROWS}]
[(field_name_or_user_var,...)]
[SET col_name = expr,...]
```
Parameters

The LOAD XML FROM S3 statement uses the following required and optional parameters. You can find more details about some of these parameters in LOAD XML Statement in the MySQL documentation.

FILE | PREFIX

Identifies whether to load the data from a single file, or from all files that match a given prefix. FILE is the default.

REPLACE | IGNORE

Determines what action to take if an input row has the same unique key values as an existing row in the database table.

- Specify REPLACE if you want the input row to replace the existing row in the table.
- Specify IGNORE if you want to discard the input row. IGNORE is the default.

INTO TABLE

Identifies the name of the database table to load the input rows into.

PARTITION

Requires that all input rows be inserted into the partitions identified by the specified list of comma-separated partition names. If an input row cannot be inserted into one of the specified partitions, then the statement fails and an error is returned.

CHARACTER SET

Identifies the character set of the data in the input file.

ROWS IDENTIFIED BY

Identifies the element name that identifies a row in the input file. The default is <row>.

IGNORE number LINES | ROWS

Specifies to ignore a certain number of lines or rows at the start of the input file. For example, you can use IGNORE 1 LINES to skip over the first line in the text file, or IGNORE 2 ROWS to skip over the first two rows of data in the input XML.

field_name_or_user_var, ...

Specifies a comma-separated list of one or more XML element names or user variables that identify which elements to load by name. The name of a user variable used for this purpose
must match the name of an element from the XML file, prefixed with @. You can employ user variables to store the corresponding field values for subsequent reuse.

For example, the following statement loads the first column from the input file into the first column of table1, and sets the value of the table_column2 column in table1 to the input value of the second column divided by 100.

```
LOAD XML FROM S3 's3://DOC-EXAMPLE-BUCKET/data.xml'
    INTO TABLE table1
    (column1, @var1)
    SET table_column2 = @var1/100;
```

**SET**

Specifies a comma-separated list of assignment operations that set the values of columns in the table to values not included in the input file.

For example, the following statement sets the first two columns of table1 to the values in the first two columns from the input file, and then sets the value of the column3 in table1 to the current time stamp.

```
LOAD XML FROM S3 's3://DOC-EXAMPLE-BUCKET/data.xml'
    INTO TABLE table1
    (column1, column2)
    SET column3 = CURRENT_TIMESTAMP;
```

You can use subqueries in the right side of SET assignments. For a subquery that returns a value to be assigned to a column, you can use only a scalar subquery. Also, you can't use a subquery to select from the table that's being loaded.

**Saving data from an Amazon Aurora MySQL DB cluster into text files in an Amazon S3 bucket**

You can use the SELECT INTO OUTFILE S3 statement to query data from an Amazon Aurora MySQL DB cluster and save it into text files stored in an Amazon S3 bucket. In Aurora MySQL, the files are first stored on the local disk, and then exported to S3. After the exports are done, the local files are deleted.
You can encrypt the Amazon S3 bucket using an Amazon S3 managed key (SSE-S3) or AWS KMS key (SSE-KMS: AWS managed key or customer managed key).

The `LOAD DATA FROM S3` statement can use files created by the `SELECT INTO OUTFILE S3` statement to load data into an Aurora DB cluster. For more information, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket.

**Note**

This feature isn't supported for Aurora Serverless v1 DB clusters. It is supported for Aurora Serverless v2 DB clusters.

You can also save DB cluster data and DB cluster snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see Exporting DB cluster data to Amazon S3 and Exporting DB cluster snapshot data to Amazon S3.

- Creating a manifest to list data files
- `SELECT INTO OUTFILE S3`
  - Syntax
  - Parameters
  - Considerations
  - Examples

### Giving Aurora MySQL access to Amazon S3

Before you can save data into an Amazon S3 bucket, you must first give your Aurora MySQL DB cluster permission to access Amazon S3.
To give Aurora MySQL access to Amazon S3

1. Create an AWS Identity and Access Management (IAM) policy that provides the bucket and object permissions that allow your Aurora MySQL DB cluster to access Amazon S3. For instructions, see Creating an IAM policy to access Amazon S3 resources.

   **Note**
   In Aurora MySQL version 3.05 and higher, you can encrypt objects using AWS KMS customer managed keys. To do so, include the \( \text{kms:GenerateDataKey} \) permission in your IAM policy. For more information, see Creating an IAM policy to access AWS KMS resources. You don't need this permission to encrypt objects using AWS managed keys or Amazon S3 managed keys (SSE-S3).

2. Create an IAM role, and attach the IAM policy you created in Creating an IAM policy to access Amazon S3 resources to the new IAM role. For instructions, see Creating an IAM role to allow Amazon Aurora to access AWS services.

3. For Aurora MySQL version 2, set either the `aurora_select_into_s3_role` or `aws_default_s3_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role. If an IAM role isn't specified for `aurora_select_into_s3_role`, Aurora uses the IAM role specified in `aws_default_s3_role`. For Aurora MySQL version 3, use `aws_default_s3_role`.

   If the cluster is part of an Aurora global database, set this parameter for each Aurora cluster in the global database.

   For more information about DB cluster parameters, see Amazon Aurora DB cluster and DB instance parameters.

4. To permit database users in an Aurora MySQL DB cluster to access Amazon S3, associate the role that you created in Creating an IAM role to allow Amazon Aurora to access AWS services with the DB cluster.

   For an Aurora global database, associate the role with each Aurora cluster in the global database.
For information about associating an IAM role with a DB cluster, see [Associating an IAM role with an Amazon Aurora MySQL DB cluster](#).

5. Configure your Aurora MySQL DB cluster to allow outbound connections to Amazon S3. For instructions, see [Enabling network communication from Amazon Aurora MySQL to other AWS services](#).

For an Aurora global database, enable outbound connections for each Aurora cluster in the global database.

### Granting privileges to save data in Aurora MySQL

The database user that issues the `SELECT INTO OUTFILE S3` statement must have a specific role or privilege. In Aurora MySQL version 3, you grant the `AWS_SELECT_S3_ACCESS` role. In Aurora MySQL version 2, you grant the `SELECT INTO S3` privilege. The administrative user for a DB cluster is granted the appropriate role or privilege by default. You can grant the privilege to another user by using one of the following statements.

Use the following statement for Aurora MySQL version 3:

```sql
GRANT AWS_SELECT_S3_ACCESS TO 'user'@'domain-or-ip-address'
```

**Tip**

When you use the role technique in Aurora MySQL version 3, you can also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in [Role-based privilege model](#). For more details, see [Using roles](#) in the *MySQL Reference Manual*.

This only applies to the current active session. When you reconnect, you must run the `SET ROLE` statement again to grant privileges. For more information, see [SET ROLE statement](#) in the *MySQL Reference Manual*.

You can use the `activate_all_roles_on_login` DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you generally don't have to call the `SET ROLE` statement explicitly to activate a role. For more information, see [activate_all_roles_on_login](#) in the *MySQL Reference Manual*.

However, you must call `SET ROLE ALL` explicitly at the beginning of a stored procedure to activate the role, when the stored procedure is called by a different user.
Use the following statement for Aurora MySQL version 2:

```sql
GRANT SELECT INTO S3 ON *:* TO 'user'@'domain-or-ip-address'
```

The AWS_SELECT_S3_ACCESS role and SELECT INTO S3 privilege are specific to Amazon Aurora MySQL and are not available for MySQL databases or RDS for MySQL DB instances. If you have set up replication between an Aurora MySQL DB cluster as the replication master and a MySQL database as the replication client, then the GRANT statement for the role or privilege causes replication to stop with an error. You can safely skip the error to resume replication. To skip the error on an RDS for MySQL DB instance, use the `mysql_rds_skip_repl_error` procedure. To skip the error on an external MySQL database, use the `slave_skip_errors` system variable (Aurora MySQL version 2) or `replica_skip_errors` system variable (Aurora MySQL version 3).

### Specifying a path to an Amazon S3 bucket

The syntax for specifying a path to store the data and manifest files on an Amazon S3 bucket is similar to that used in the `LOAD DATA FROM S3 PREFIX` statement, as shown following.

```plaintext
s3-region://bucket-name/file-prefix
```

The path includes the following values:

- **region (optional)** – The AWS Region that contains the Amazon S3 bucket to save the data into. This value is optional. If you don't specify a `region` value, then Aurora saves your files into Amazon S3 in the same region as your DB cluster.
- **bucket-name** – The name of the Amazon S3 bucket to save the data into. Object prefixes that identify a virtual folder path are supported.
- **file-prefix** – The Amazon S3 object prefix that identifies the files to be saved in Amazon S3.

The data files created by the `SELECT INTO OUTFILE S3` statement use the following path, in which `00000` represents a 5-digit, zero-based integer number.

```plaintext
s3-region://bucket-name/file-prefix.part_00000
```

For example, suppose that a `SELECT INTO OUTFILE S3` statement specifies `s3-us-west-2://bucket/prefix` as the path in which to store data files and creates three data files. The specified Amazon S3 bucket contains the following data files.
Creating a manifest to list data files

You can use the `SELECT INTO OUTFILE S3` statement with the `MANIFEST ON` option to create a manifest file in JSON format that lists the text files created by the statement. The `LOAD DATA FROM S3` statement can use the manifest file to load the data files back into an Aurora MySQL DB cluster. For more information about using a manifest to load data files from Amazon S3 into an Aurora MySQL DB cluster, see Using a manifest to specify data files to load.

The data files included in the manifest created by the `SELECT INTO OUTFILE S3` statement are listed in the order that they're created by the statement. For example, suppose that a `SELECT INTO OUTFILE S3` statement specified `s3-us-west-2://bucket/prefix` as the path in which to store data files and creates three data files and a manifest file. The specified Amazon S3 bucket contains a manifest file named `s3-us-west-2://bucket/prefix.manifest`, that contains the following information.

```
{
    "entries": [
        {
            "url":"s3-us-west-2://bucket/prefix.part_00000"
        },
        {
            "url":"s3-us-west-2://bucket/prefix.part_00001"
        },
        {
            "url":"s3-us-west-2://bucket/prefix.part_00002"
        }
    ]
}
```

**SELECT INTO OUTFILE S3**

You can use the `SELECT INTO OUTFILE S3` statement to query data from a DB cluster and save it directly into delimited text files stored in an Amazon S3 bucket.
Compressed files aren't supported. Encrypted files are supported starting in Aurora MySQL version 2.09.0.

Syntax

```
SELECT
  [ALL | DISTINCT | DISTINCTROW]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
  select_expr [, select_expr ...]
  [FROM table_references
   [PARTITION partition_list]]
  [WHERE where_condition]
  [GROUP BY {col_name | expr | position}
    [ASC | DESC], ... [WITH ROLLUP]]
  [HAVING where_condition]
  [ORDER BY {col_name | expr | position}
    [ASC | DESC], ...]
  [LIMIT {{offset,} row_count | row_count OFFSET offset}]
  INTO OUTFILE S3 's3_uri'
  [CHARACTER SET charset_name]
  [export_options]
  [MANIFEST {ON | OFF}]
  [OVERWRITE {ON | OFF}]
  [ENCRYPTION {ON | OFF | SSE_S3 | SSE_KMS ['cmk_id']}]}

export_options:
  [FORMAT {CSV|TEXT} [HEADER]]
  [FIELDS | COLUMNS]
    [TERMINATED BY 'string']
    [[OPTIONALLY] ENCLOSED BY 'char']
    [ESCAPED BY 'char']
  [LINES]
    [STARTING BY 'string']
    [TERMINATED BY 'string']
```
Parameters

The SELECT INTO OUTFILE S3 statement uses the following required and optional parameters that are specific to Aurora.

**s3-uri**

Specifies the URI for an Amazon S3 prefix to use. Use the syntax described in Specifying a path to an Amazon S3 bucket.

**FORMAT {CSV|TEXT} [HEADER]**

Optionally saves the data in CSV format.

The TEXT option is the default and produces the existing MySQL export format.

The CSV option produces comma-separated data values. The CSV format follows the specification in RFC-4180. If you specify the optional keyword HEADER, the output file contains one header line. The labels in the header line correspond to the column names from the SELECT statement. You can use the CSV files for training data models for use with AWS ML services. For more information about using exported Aurora data with AWS ML services, see Exporting data to Amazon S3 for SageMaker model training (Advanced).

**MANIFEST {ON | OFF}**

Indicates whether a manifest file is created in Amazon S3. The manifest file is a JavaScript Object Notation (JSON) file that can be used to load data into an Aurora DB cluster with the LOAD DATA FROM S3 MANIFEST statement. For more information about LOAD DATA FROM S3 MANIFEST, see Loading data into an Amazon Aurora MySQL DB cluster from text files in an Amazon S3 bucket.

If MANIFEST ON is specified in the query, the manifest file is created in Amazon S3 after all data files have been created and uploaded. The manifest file is created using the following path:

```
s3-region://bucket-name/file-prefix.manifest
```

For more information about the format of the manifest file's contents, see Creating a manifest to list data files.
OVERWRITE {ON | OFF}

Indicates whether existing files in the specified Amazon S3 bucket are overwritten. If OVERWRITE ON is specified, existing files that match the file prefix in the URI specified in s3-uri are overwritten. Otherwise, an error occurs.

ENCRIPTION {ON | OFF | SSE_S3 | SSE_KMS ['cmk_id']}

Indicates whether to use server-side encryption with Amazon S3 managed keys (SSE-S3) or AWS KMS keys (SSE-KMS, including AWS managed keys and customer managed keys). The SSE_S3 and SSE_KMS settings are available in Aurora MySQL version 3.05 and higher.

You can also use the aurora_select_into_s3_encryption_default session variable instead of the ENCRYPTION clause, as shown in the following example. Use either the SQL clause or the session variable, but not both.

```sql
set session aurora_select_into_s3_encryption_default={ON | OFF | SSE_S3 | SSE_KMS};
```

The SSE_S3 and SSE_KMS settings are available in Aurora MySQL version 3.05 and higher.

When you set aurora_select_into_s3_encryption_default to the following value:

- OFF – The default encryption policy of the S3 bucket is followed. The default value of aurora_select_into_s3_encryption_default is OFF.
- ON or SSE_S3 – The S3 object is encrypted using Amazon S3 managed keys (SSE-S3).
- SSE_KMS – The S3 object is encrypted using an AWS KMS key.

In this case, you also include the session variable aurora_s3_default_cmk_id, for example:

```sql
set session aurora_select_into_s3_encryption_default={SSE_KMS};
set session aurora_s3_default_cmk_id={NULL | 'cmk_id'};
```

- When aurora_s3_default_cmk_id is NULL, the S3 object is encrypted using an AWS managed key.
- When aurora_s3_default_cmk_id is a nonempty string cmk_id, the S3 object is encrypted using a customer managed key.

The value of cmk_id can't be an empty string.
When you use the `SELECT INTO OUTFILE S3` command, Aurora determines the encryption as follows:

- If the `ENCRYPTION` clause is present in the SQL command, Aurora relies only on the value of `ENCRYPTION`, and doesn't use a session variable.
- If the `ENCRYPTION` clause isn't present, Aurora relies on the value of the session variable.

**Considerations**

The number of files written to the Amazon S3 bucket depends on the amount of data selected by the `SELECT INTO OUTFILE S3` statement and the file size threshold for Aurora MySQL. The default file size threshold is 6 gigabytes (GB). If the data selected by the statement is less than the file size threshold, a single file is created; otherwise, multiple files are created. Other considerations for files created by this statement include the following:

- Aurora MySQL guarantees that rows in data files are not split across file boundaries. For multiple files, the size of every data file except the last is typically close to the file size threshold. However, occasionally staying under the file size threshold results in a row being split across two data files. In this case, Aurora MySQL creates a data file that keeps the row intact, but might be larger than the file size threshold.

- Because each `SELECT` statement in Aurora MySQL runs as an atomic transaction, a `SELECT INTO OUTFILE S3` statement that selects a large data set might run for some time. If the statement fails for any reason, you might need to start over and issue the statement again. If the statement fails, however, files already uploaded to Amazon S3 remain in the specified Amazon S3 bucket. You can use another statement to upload the remaining data instead of starting over again.

- If the amount of data to be selected is large (more than 25 GB), we recommend that you use multiple `SELECT INTO OUTFILE S3` statements to save the data to Amazon S3. Each statement should select a different portion of the data to be saved, and also specify a different `file_prefix` in the `s3-uri` parameter to use when saving the data files. Partitioning the data to be selected with multiple statements makes it easier to recover from an error in one.
statement. If an error occurs for one statement, only a portion of data needs to be re-selected and uploaded to Amazon S3. Using multiple statements also helps to avoid a single long-running transaction, which can improve performance.

- If multiple SELECT INTO OUTFILE S3 statements that use the same file_prefix in the s3-uri parameter run in parallel to select data into Amazon S3, the behavior is undefined.
- Metadata, such as table schema or file metadata, is not uploaded by Aurora MySQL to Amazon S3.
- In some cases, you might re-run a SELECT INTO OUTFILE S3 query, such as to recover from a failure. In these cases, you must either remove any existing data files in the Amazon S3 bucket with the same file prefix specified in s3-uri, or include OVERWRITE ON in the SELECT INTO OUTFILE S3 query.

The SELECT INTO OUTFILE S3 statement returns a typical MySQL error number and response on success or failure. If you don't have access to the MySQL error number and response, the easiest way to determine when it's done is by specifying MANIFEST ON in the statement. The manifest file is the last file written by the statement. In other words, if you have a manifest file, the statement has completed.

Currently, there's no way to directly monitor the progress of the SELECT INTO OUTFILE S3 statement while it runs. However, suppose that you're writing a large amount of data from Aurora MySQL to Amazon S3 using this statement, and you know the size of the data selected by the statement. In this case, you can estimate progress by monitoring the creation of data files in Amazon S3.

To do so, you can use the fact that a data file is created in the specified Amazon S3 bucket for about every 6 GB of data selected by the statement. Divide the size of the data selected by 6 GB to get the estimated number of data files to create. You can then estimate the progress of the statement by monitoring the number of files uploaded to Amazon S3 while the statement runs.

**Examples**

The following statement selects all of the data in the employees table and saves the data into an Amazon S3 bucket that is in a different region from the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character. The statement returns an error if files that match the sample_employee_data file prefix exist in the specified Amazon S3 bucket.
The following statement selects all of the data in the employees table and saves the data into an Amazon S3 bucket that is in the same region as the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character, and also a manifest file. The statement returns an error if files that match the sample_employee_data file prefix exist in the specified Amazon S3 bucket.

```
SELECT * FROM employees INTO OUTFILE S3 's3-us-west-2://aurora-select-into-s3-pdx/sample_employee_data'
    FIELDS TERMINATED BY ','
    LINES TERMINATED BY '\n';
```

The following statement selects all of the data in the employees table and saves the data into an Amazon S3 bucket that is in a different region from the Aurora DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character. The statement overwrites any existing files that match the sample_employee_data file prefix in the specified Amazon S3 bucket.

```
SELECT * FROM employees INTO OUTFILE S3 's3://aurora-select-into-s3-pdx/sample_employee_data'
    FIELDS TERMINATED BY ','
    LINES TERMINATED BY '\n'
    MANIFEST ON;
```

The following statement selects all of the data in the employees table and saves the data into an Amazon S3 bucket that is in the same region as the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character, and also a manifest file. The statement overwrites any existing files that match the sample_employee_data file prefix in the specified Amazon S3 bucket.

```
SELECT * FROM employees INTO OUTFILE S3 's3-us-west-2://aurora-select-into-s3-pdx/sample_employee_data'
    FIELDS TERMINATED BY ','
    LINES TERMINATED BY '\n'
    OVERWRITE ON;
```

The following statement selects all of the data in the employees table and saves the data into an Amazon S3 bucket that is in the same region as the Aurora MySQL DB cluster. The statement creates data files in which each field is terminated by a comma (,) character and each row is terminated by a newline (\n) character, and also a manifest file. The statement overwrites any existing files that match the sample_employee_data file prefix in the specified Amazon S3 bucket.

```
SELECT * FROM employees INTO OUTFILE S3 's3://aurora-select-into-s3-pdx/sample_employee_data'
```
Invoking a Lambda function from an Amazon Aurora MySQL DB cluster

You can invoke an AWS Lambda function from an Amazon Aurora MySQL-Compatible Edition DB cluster with the native function `lambda_sync` or `lambda_async`. Before invoking a Lambda function from an Aurora MySQL, the Aurora DB cluster must have access to Lambda. For details about granting access to Aurora MySQL, see Giving Aurora access to Lambda. For information about the `lambda_sync` and `lambda_async` stored functions, see Invoking a Lambda function with an Aurora MySQL native function.

You can also call an AWS Lambda function by using a stored procedure. However, using a stored procedure is deprecated. We strongly recommend using an Aurora MySQL native function if you are using one of the following Aurora MySQL versions:

- Aurora MySQL version 2, for MySQL 5.7-compatible clusters.
- Aurora MySQL version 3.01 and higher, for MySQL 8.0-compatible clusters. The stored procedure isn't available in Aurora MySQL version 3.

Topics

- Giving Aurora access to Lambda
- Invoking a Lambda function with an Aurora MySQL native function
- Invoking a Lambda function with an Aurora MySQL stored procedure (deprecated)

Giving Aurora access to Lambda

Before you can invoke Lambda functions from an Aurora MySQL DB cluster, make sure to first give your cluster permission to access Lambda.

To give Aurora MySQL access to Lambda

1. Create an AWS Identity and Access Management (IAM) policy that provides the permissions that allow your Aurora MySQL DB cluster to invoke Lambda functions. For instructions, see Creating an IAM policy to access AWS Lambda resources.
2. Create an IAM role, and attach the IAM policy you created in [Creating an IAM policy to access AWS Lambda resources](#) to the new IAM role. For instructions, see [Creating an IAM role to allow Amazon Aurora to access AWS services](#).

3. Set the `aws_default_lambda_role` DB cluster parameter to the Amazon Resource Name (ARN) of the new IAM role.

   If the cluster is part of an Aurora global database, apply the same setting for each Aurora cluster in the global database.

   For more information about DB cluster parameters, see [Amazon Aurora DB cluster and DB instance parameters](#).

4. To permit database users in an Aurora MySQL DB cluster to invoke Lambda functions, associate the role that you created in [Creating an IAM role to allow Amazon Aurora to access AWS services](#) with the DB cluster. For information about associating an IAM role with a DB cluster, see [Associating an IAM role with an Amazon Aurora MySQL DB cluster](#).

   If the cluster is part of an Aurora global database, associate the role with each Aurora cluster in the global database.

5. Configure your Aurora MySQL DB cluster to allow outbound connections to Lambda. For instructions, see [Enabling network communication from Amazon Aurora MySQL to other AWS services](#).

   If the cluster is part of an Aurora global database, enable outbound connections for each Aurora cluster in the global database.

### Invoking a Lambda function with an Aurora MySQL native function

**Note**

You can call the native functions `lambda_sync` and `lambda_async` when you use Aurora MySQL version 2, or Aurora MySQL version 3.01 and higher. For more information about Aurora MySQL versions, see [Database engine updates for Amazon Aurora MySQL](#).

You can invoke an AWS Lambda function from an Aurora MySQL DB cluster by calling the native functions `lambda_sync` and `lambda_async`. This approach can be useful when you want to integrate your database running on Aurora MySQL with other AWS services. For example, you
might want to send a notification using Amazon Simple Notification Service (Amazon SNS) whenever a row is inserted into a specific table in your database.

  - Syntax for the lambda_async function
  - Parameters for the lambda_async function
  - Example for the lambda_async function
  - Invoking a Lambda function within a trigger

Working with native functions to invoke a Lambda function

The `lambda_sync` and `lambda_async` functions are built-in, native functions that invoke a Lambda function synchronously or asynchronously. When you must know the result of the Lambda function before moving on to another action, use the synchronous function `lambda_sync`. When you don't need to know the result of the Lambda function before moving on to another action, use the asynchronous function `lambda_async`.

Granting the role in Aurora MySQL version 3

In Aurora MySQL version 3, the user invoking a native function must be granted the `AWS_LAMBDA_ACCESS` role. To grant this role to a user, connect to the DB instance as the administrative user, and run the following statement.

```
GRANT AWS_LAMBDA_ACCESS TO user@domain-or-ip-address
```

You can revoke this role by running the following statement.

```
REVOKE AWS_LAMBDA_ACCESS FROM user@domain-or-ip-address
```
When you use the role technique in Aurora MySQL version 3, you can also activate the role by using the SET ROLE role_name or SET ROLE ALL statement. If you aren't familiar with the MySQL 8.0 role system, you can learn more in Role-based privilege model. For more details, see Using roles in the MySQL Reference Manual.

This only applies to the current active session. When you reconnect, you must run the SET ROLE statement again to grant privileges. For more information, see SET ROLE statement in the MySQL Reference Manual.

You can use the activate_all_roles_on_login DB cluster parameter to automatically activate all roles when a user connects to a DB instance. When this parameter is set, you generally don't have to call the SET ROLE statement explicitly to activate a role. For more information, see activate_all_roles_on_login in the MySQL Reference Manual.

However, you must call SET ROLE ALL explicitly at the beginning of a stored procedure to activate the role, when the stored procedure is called by a different user.

If you get an error such as the following when you try to invoke a Lambda function, then run a SET ROLE statement.

SQL Error [1227] [42000]: Access denied; you need (at least one of) the Invoke Lambda privilege(s) for this operation

Granting the privilege in Aurora MySQL version 2

In Aurora MySQL version 2, the user invoking a native function must be granted the INVOKE LAMBDA privilege. To grant this privilege to a user, connect to the DB instance as the administrative user, and run the following statement.

GRANT INVOKE LAMBDA ON *.* TO user@domain-or-ip-address

You can revoke this privilege by running the following statement.

REVOKE INVOKE LAMBDA ON *.* FROM user@domain-or-ip-address
Syntax for the lambda_sync function

You invoke the lambda_sync function synchronously with the RequestResponse invocation type. The function returns the result of the Lambda invocation in a JSON payload. The function has the following syntax.

```sql
lambda_sync(
    lambda_function_ARN,
    JSON_payload
)
```

Parameters for the lambda_sync function

The lambda_sync function has the following parameters.

**lambda_function_ARN**

The Amazon Resource Name (ARN) of the Lambda function to invoke.

**JSON_payload**

The payload for the invoked Lambda function, in JSON format.

**Note**

Aurora MySQL version 3 supports the JSON parsing functions from MySQL 8.0. However, Aurora MySQL version 2 doesn't include those functions. JSON parsing isn't required when a Lambda function returns an atomic value, such as a number or a string.

Example for the lambda_sync function

The following query based on lambda_sync invokes the Lambda function BasicTestLambda synchronously using the function ARN. The payload for the function is {"operation": "ping"}.

```sql
SELECT lambda_sync(
    'arn:aws:lambda:us-east-1:123456789012:function:BasicTestLambda',
    '{"operation": "ping"}');
```
Syntax for the lambda_async function

You invoke the lambda_async function asynchronously with the Event invocation type. The function returns the result of the Lambda invocation in a JSON payload. The function has the following syntax.

```sql
lambda_async (lambda_function_ARN, JSON_payload)
```

Parameters for the lambda_async function

The lambda_async function has the following parameters.

**lambda_function_ARN**

The Amazon Resource Name (ARN) of the Lambda function to invoke.

**JSON_payload**

The payload for the invoked Lambda function, in JSON format.

Note

Aurora MySQL version 3 supports the JSON parsing functions from MySQL 8.0. However, Aurora MySQL version 2 doesn't include those functions. JSON parsing isn't required when a Lambda function returns an atomic value, such as a number or a string.

Example for the lambda_async function

The following query based on lambda_async invokes the Lambda function BasicTestLambda asynchronously using the function ARN. The payload for the function is {"operation": "ping"}.

```sql
SELECT lambda_async('arn:aws:lambda:us-east-1:123456789012:function:BasicTestLambda', '{"operation": "ping"}');
```
Invoking a Lambda function within a trigger

You can use triggers to call Lambda on data-modifying statements. The following example uses the `lambda_async` native function and stores the result in a variable.

```sql
mysql> SET @result=0;
mysql> DELIMITER //
mysql> CREATE TRIGGER myFirstTrigger
    AFTER INSERT
    ON Test_trigger FOR EACH ROW
    BEGIN
    SELECT lambda_async('arn:aws:lambda:us-east-1:123456789012:function:BasicTestLambda',
        '{"operation": "ping"}')
    INTO @result;
    END; //
mysql> DELIMITER ;
```

**Note**
Triggers aren't run once per SQL statement, but once per row modified, one row at a time. When a trigger runs, the process is synchronous. The data-modifying statement only returns when the trigger completes. Be careful when invoking an AWS Lambda function from triggers on tables that experience high write traffic. INSERT, UPDATE, and DELETE triggers are activated per row. A write-heavy workload on a table with INSERT, UPDATE, or DELETE triggers results in a large number of calls to your AWS Lambda function.

Invoking a Lambda function with an Aurora MySQL stored procedure (deprecated)

You can invoke an AWS Lambda function from an Aurora MySQL DB cluster by calling the `mysql.lambda_async` procedure. This approach can be useful when you want to integrate your database running on Aurora MySQL with other AWS services. For example, you might want to send a notification using Amazon Simple Notification Service (Amazon SNS) whenever a row is inserted into a specific table in your database.
Aurora MySQL version considerations

Starting in Aurora MySQL version 2, you can use the native function method instead of these stored procedures to invoke a Lambda function. For more information about the native functions, see Working with native functions to invoke a Lambda function.

In Aurora MySQL version 2, the stored procedure `mysql.lambda_async` is no longer supported. We strongly recommend that you work with native Lambda functions instead.

In Aurora MySQL version 3, the stored procedure isn't available.

Working with the `mysql.lambda_async` procedure to invoke a Lambda function (deprecated)

The `mysql.lambda_async` procedure is a built-in stored procedure that invokes a Lambda function asynchronously. To use this procedure, your database user must have EXECUTE privilege on the `mysql.lambda_async` stored procedure.

Syntax

The `mysql.lambda_async` procedure has the following syntax.

```sql
CALL mysql.lambda_async (lambda_function_ARN,
                          lambda_function_input )
```

Parameters

The `mysql.lambda_async` procedure has the following parameters.

`lambda_function_ARN`

The Amazon Resource Name (ARN) of the Lambda function to invoke.
**lambda_function_input**

The input string, in JSON format, for the invoked Lambda function.

**Examples**

As a best practice, we recommend that you wrap calls to the `mysql.lambda_async` procedure in a stored procedure that can be called from different sources such as triggers or client code. This approach can help to avoid impedance mismatch issues and make it easier to invoke Lambda functions.

**Note**

Be careful when invoking an AWS Lambda function from triggers on tables that experience high write traffic. INSERT, UPDATE, and DELETE triggers are activated per row. A write-heavy workload on a table with INSERT, UPDATE, or DELETE triggers results in a large number of calls to your AWS Lambda function. Although calls to the `mysql.lambda_async` procedure are asynchronous, triggers are synchronous. A statement that results in a large number of trigger activations doesn't wait for the call to the AWS Lambda function to complete, but it does wait for the triggers to complete before returning control to the client.

**Example Example: Invoke an AWS Lambda function to send email**

The following example creates a stored procedure that you can call in your database code to send an email using a Lambda function.

**AWS Lambda Function**

```python
import boto3

es = boto3.client('ses')

def SES_send_email(event, context):
    return ses.send_email(
        Source=event['email_from'],
        Destination={
            'ToAddresses': [event['email_to'] ]
        },
        Body={
            'Subject': {'Data': 'Example Email Subject'},
            'Text': {'Data': 'Example Email Body'}
        }
    )
```
ToAddresses: [ 
    event['email_to'], 
], 

Message={ 
    'Subject': { 
        'Data': event['email_subject'] 
    }, 
    'Body': { 
        'Text': { 
            'Data': event['email_body'] 
        } 
    } 
} 
);

Call the Stored Procedure to Invoke the AWS Lambda Function

mysql> call SES_send_email('example_from@amazon.com', 'example_to@amazon.com', 'Email subject', 'Email content');
Example Example: Invoke an AWS Lambda function to publish an event from a trigger

The following example creates a stored procedure that publishes an event by using Amazon SNS. The code calls the procedure from a trigger when a row is added to a table.

AWS Lambda Function

```python
import boto3

sns = boto3.client('sns')

def SNS_publish_message(event, context):
    return sns.publish(
        Message=event['message'],
        Subject=event['subject'],
        MessageStructure='string'
    )
```

Stored Procedure

```sql
DROP PROCEDURE IF EXISTS SNS_Publish_Message;
DELIMITER ;;
CREATE PROCEDURE SNS_Publish_Message (IN subject VARCHAR(255),
    IN message TEXT) LANGUAGE SQL
BEGIN
    CALL mysql.lambda_async('arn:aws:lambda:us-
west-2:123456789012:function:SNS_publish_message',
        CONCAT('{ "subject" : "]", subject,
            "message" : "]", message, "] }')
    );
END
;;
DELIMITER ;
```

Table

```sql
CREATE TABLE 'Customer_Feedback' (  
    'id' int(11) NOT NULL AUTO_INCREMENT,  
    'customer_name' varchar(255) NOT NULL,  
    'customer_feedback' varchar(1024) NOT NULL,  
```
Trigger

DELIMITER ;;
CREATE TRIGGER TR_Customer_Feedback_AI
AFTER INSERT ON Customer_Feedback
FOR EACH ROW
BEGIN
    SELECT CONCAT('New customer feedback from ', NEW.customer_name),
    NEW.customer_feedback INTO @subject, @feedback;
    CALL SNS_Publish_Message(@subject, @feedback);
END ;;
DELIMITER ;

Insert a Row into the Table to Trigger the Notification

mysql> insert into Customer_Feedback (customer_name, customer_feedback) VALUES ('Sample Customer', 'Good job guys!');

Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs

You can configure your Aurora MySQL DB cluster to publish general, slow, audit, and error log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

To publish logs to CloudWatch Logs, the respective logs must be enabled. Error logs are enabled by default, but you must enable the other types of logs explicitly. For information about enabling logs in MySQL, see Selecting general query and slow query log output destinations in the MySQL documentation. For more information about enabling Aurora MySQL audit logs, see Enabling Advanced Auditing.

Note

- If exporting log data is disabled, Aurora doesn't delete existing log groups or log streams. If exporting log data is disabled, existing log data remains available in CloudWatch Logs,
depending on log retention, and you still incur charges for stored audit log data. You can delete log streams and log groups using the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API.

- An alternative way to publish audit logs to CloudWatch Logs is by enabling Advanced Auditing, then creating a custom DB cluster parameter group and setting the `server_audit_logs_upload` parameter to 1. The default for the `server_audit_logs_upload` DB cluster parameter is 0. For information on enabling Advanced Auditing, see Using Advanced Auditing with an Amazon Aurora MySQL DB cluster.

If you use this alternative method, you must have an IAM role to access CloudWatch Logs and set the `aws_default_logs_role` cluster-level parameter to the ARN for this role. For information about creating the role, see Setting up IAM roles to access AWS services. However, if you have the `AWSServiceRoleForRDS` service-linked role, it provides access to CloudWatch Logs and overrides any custom-defined roles. For information about service-linked roles for Amazon RDS, see Using service-linked roles for Amazon Aurora.

- If you don't want to export audit logs to CloudWatch Logs, make sure that all methods of exporting audit logs are disabled. These methods are the AWS Management Console, the AWS CLI, the RDS API, and the `server_audit_logs_upload` parameter.

- The procedure is slightly different for Aurora Serverless v1 DB clusters than for DB clusters with provisioned or Aurora Serverless v2 DB instances. Aurora Serverless v1 clusters automatically upload all of the logs that you enable through configuration parameters.

Therefore, you turn on or turn off log upload for Aurora Serverless v1 DB clusters by turning different log types on and off in the DB cluster parameter group. You don't modify the settings of the cluster itself through the AWS Management Console, AWS CLI, or RDS API. For information about turning on and off MySQL logs for Aurora Serverless v1 clusters, see Parameter groups for Aurora Serverless v1.

**Console**

You can publish Aurora MySQL logs for provisioned clusters to CloudWatch Logs with the console.

**To publish Aurora MySQL logs from the console**

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose **Databases**.

3. Choose the Aurora MySQL DB cluster that you want to publish the log data for.

4. Choose **Modify**.

5. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.

6. Choose **Continue**, and then choose **Modify DB Cluster** on the summary page.

### AWS CLI

You can publish Aurora MySQL logs for provisioned clusters with the AWS CLI. To do so, you run the **modify-db-cluster** AWS CLI command with the following options:

- **--db-cluster-identifier**—The DB cluster identifier.
- **--cloudwatch-logs-export-configuration**—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora MySQL logs by running one of the following AWS CLI commands:

- **create-db-cluster**
- **restore-db-cluster-from-s3**
- **restore-db-cluster-from-snapshot**
- **restore-db-cluster-to-point-in-time**

Run one of these AWS CLI commands with the following options:

- **--db-cluster-identifier**—The DB cluster identifier.
- **--engine**—The database engine.
- **--enable-cloudwatch-logs-exports**—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other options might be required depending on the AWS CLI command that you run.
Example

The following command modifies an existing Aurora MySQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster \
   --db-cluster-identifier mydbcluster \
   --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["error","general","slowquery","audit"]}'
```

For Windows:

```
aws rds modify-db-cluster ^
   --db-cluster-identifier mydbcluster ^
   --cloudwatch-logs-export-configuration '{"EnableLogTypes": ["error","general","slowquery","audit"]}'
```

Example

The following command creates an Aurora MySQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:

```
aws rds create-db-cluster \
   --db-cluster-identifier mydbcluster \
   --engine aurora \
   --enable-cloudwatch-logs-exports '["error","general","slowquery","audit"]'
```

For Windows:

```
aws rds create-db-cluster ^
   --db-cluster-identifier mydbcluster ^
   --engine aurora ^
   --enable-cloudwatch-logs-exports '["error","general","slowquery","audit"]'
```
RDS API

You can publish Aurora MySQL logs for provisioned clusters with the RDS API. To do so, you run the ModifyDBCluster operation with the following options:

- `DBClusterIdentifier`—The DB cluster identifier.
- `CloudwatchLogsExportConfiguration`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora MySQL logs with the RDS API by running one of the following RDS API operations:

- `CreateDBCluster`
- `RestoreDBClusterFromS3`
- `RestoreDBClusterFromSnapshot`
- `RestoreDBClusterToPointInTime`

Run the RDS API operation with the following parameters:

- `DBClusterIdentifier`—The DB cluster identifier.
- `Engine`—The database engine.
- `EnableCloudwatchLogsExports`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other parameters might be required depending on the AWS CLI command that you run.

Monitoring log events in Amazon CloudWatch

After enabling Aurora MySQL log events, you can monitor the events in Amazon CloudWatch Logs. A new log group is automatically created for the Aurora DB cluster under the following prefix, in which `cluster-name` represents the DB cluster name, and `log_type` represents the log type.

```
/aws/rds/cluster/cluster-name/log_type
```

For example, if you configure the export function to include the slow query log for a DB cluster named `mydbcluster`, slow query data is stored in the `/aws/rds/cluster/mydbcluster/slowquery` log group.
The events from all instances in your cluster are pushed to a log group using different log streams. The behavior depends on which of the following conditions is true:

- A log group with the specified name exists.

  Aurora uses the existing log group to export log data for the cluster. To create log groups with predefined log retention periods, metric filters, and customer access, you can use automated configuration, such as AWS CloudFormation.

- A log group with the specified name doesn't exist.

  When a matching log entry is detected in the log file for the instance, Aurora MySQL creates a new log group in CloudWatch Logs automatically. The log group uses the default log retention period of **Never Expire**.

  To change the log retention period, use the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API. For more information about changing log retention periods in CloudWatch Logs, see [Change log data retention in CloudWatch Logs](#).

To search for information within the log events for a DB cluster, use the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API. For more information about searching and filtering log data, see [Searching and filtering log data](#).
Amazon Aurora MySQL lab mode

Aurora lab mode is used to enable Aurora features that are available in the current Aurora database version, but are not enabled by default. While Aurora lab mode features are not recommended for use in production DB clusters, you can use Aurora lab mode to enable these features for DB clusters in your development and test environments. For more information about Aurora features available when Aurora lab mode is enabled, see Aurora lab mode features.

The `aurora_lab_mode` parameter is an instance-level parameter that is in the default parameter group. The parameter is set to 0 (disabled) in the default parameter group. To enable Aurora lab mode, create a custom parameter group, set the `aurora_lab_mode` parameter to 1 (enabled) in the custom parameter group, and modify one or more DB instances in your Aurora cluster to use the custom parameter group. Then connect to the appropriate instance endpoint to try the lab mode features. For information on modifying a DB parameter group, see Modifying parameters in a DB parameter group. For information on parameter groups and Amazon Aurora, see Aurora MySQL configuration parameters.

### Aurora lab mode features

The following table lists the Aurora features currently available when Aurora lab mode is enabled. You must enable Aurora lab mode before any of these features can be used.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scan Batching</td>
<td>Aurora MySQL scan batching speeds up in-memory, scan-oriented queries significantly. The feature boosts the performance of table full scans, index full scans, and index range scans by batch processing.</td>
</tr>
<tr>
<td>Hash Joins</td>
<td>This feature can improve query performance when you need to join a large amount of data by using an equijoin. You can use this feature without lab mode in Aurora MySQL version 2. For more information about using this feature, see Optimizing large Aurora MySQL join queries with hash joins.</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Fast DDL</td>
<td>This feature allows you to run an ALTER TABLE <code>tbl_name</code> ADD COLUMN <code>col_name</code> <code>column_definition</code> operation nearly instantaneously. The operation completes without requiring the table to be copied and without materially impacting other DML statements. Since it does not consume temporary storage for a table copy, it makes DDL statements practical even for large tables on small instance classes. Fast DDL is currently only supported for adding a nullable column, without a default value, at the end of a table. For more information about using this feature, see <a href="#">Altering tables in Amazon Aurora using Fast DDL</a>.</td>
</tr>
</tbody>
</table>
Best practices with Amazon Aurora MySQL

This topic includes information on best practices and options for using or migrating data to an Amazon Aurora MySQL DB cluster. The information in this topic summarizes and reiterates some of the guidelines and procedures that you can find in Managing an Amazon Aurora DB cluster.

Contents

• Determining which DB instance you are connected to

• Best practices for Aurora MySQL performance and scaling
  • Using T instance classes for development and testing
  • Optimizing Aurora MySQL indexed join queries with asynchronous key prefetch
    • Enabling asynchronous key prefetch
    • Optimizing queries for asynchronous key prefetch
  • Optimizing large Aurora MySQL join queries with hash joins
    • Enabling hash joins
    • Optimizing queries for hash joins
  • Using Amazon Aurora to scale reads for your MySQL database
  • Optimizing timestamp operations

• Best practices for Aurora MySQL high availability
  • Using Amazon Aurora for Disaster Recovery with your MySQL databases
  • Migrating from MySQL to Amazon Aurora MySQL with reduced downtime
  • Avoiding slow performance, automatic restart, and failover for Aurora MySQL DB instances

• Recommendations for Aurora MySQL
  • Using multithreaded replication in Aurora MySQL
  • Invoking AWS Lambda functions using native MySQL functions
  • Avoiding XA transactions with Amazon Aurora MySQL
  • Keeping foreign keys turned on during DML statements
  • Configuring how frequently the log buffer is flushed
  • Minimizing and troubleshooting Aurora MySQL deadlocks
    • Minimizing InnoDB deadlocks
      • Monitoring InnoDB deadlocks
Determining which DB instance you are connected to

To determine which DB instance in an Aurora MySQL DB cluster a connection is connected to, check the `innodb_read_only` global variable, as shown in the following example.

```
SHOW GLOBAL VARIABLES LIKE 'innodb_read_only';
```

The `innodb_read_only` variable is set to ON if you are connected to a reader DB instance. This setting is OFF if you are connected to a writer DB instance, such as primary instance in a provisioned cluster.

This approach can be helpful if you want to add logic to your application code to balance the workload or to ensure that a write operation is using the correct connection.

Best practices for Aurora MySQL performance and scaling

You can apply the following best practices to improve the performance and scalability of your Aurora MySQL clusters.

Topics

- Using T instance classes for development and testing
- Optimizing Aurora MySQL indexed join queries with asynchronous key prefetch
- Optimizing large Aurora MySQL join queries with hash joins
- Using Amazon Aurora to scale reads for your MySQL database
- Optimizing timestamp operations

Using T instance classes for development and testing

Amazon Aurora MySQL instances that use the db.t2, db.t3, or db.t4g DB instance classes are best suited for applications that do not support a high workload for an extended amount of time. The T instances are designed to provide moderate baseline performance and the capability to burst to significantly higher performance as required by your workload. They are intended for workloads that don't use the full CPU often or consistently, but occasionally need to burst. We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see Burstable performance instances.
If your Aurora cluster is larger than 40 TB, don’t use the T instance classes. When your database has a large volume of data, the memory overhead for managing schema objects can exceed the capacity of a T instance.

Don’t enable the MySQL Performance Schema on Amazon Aurora MySQL T instances. If the Performance Schema is enabled, the instance might run out of memory.

**Tip**

If your database is sometimes idle but at other times has a substantial workload, you can use Aurora Serverless v2 as an alternative to T instances. With Aurora Serverless v2, you define a capacity range and Aurora automatically scales your database up or down depending on the current workload. For usage details, see [Using Aurora Serverless v2](#). For the database engine versions that you can use with Aurora Serverless v2, see [Requirements and limitations for Aurora Serverless v2](#).

When you use a T instance as a DB instance in an Aurora MySQL DB cluster, we recommend the following:

- Use the same DB instance class for all instances in your DB cluster. For example, if you use `db.t2.medium` for your writer instance, then we recommend that you use `db.t2.medium` for your reader instances also.

- Don’t adjust any memory-related configuration settings, such as `innodb_buffer_pool_size`. Aurora uses a highly tuned set of default values for memory buffers on T instances. These special defaults are needed for Aurora to run on memory-constrained instances. If you change any memory-related settings on a T instance, you are much more likely to encounter out-of-memory conditions, even if your change is intended to increase buffer sizes.

- Monitor your CPU Credit Balance (**CPUCreditBalance**) to ensure that it is at a sustainable level. That is, CPU credits are being accumulated at the same rate as they are being used.

  When you have exhausted the CPU credits for an instance, you see an immediate drop in the available CPU and an increase in the read and write latency for the instance. This situation results in a severe decrease in the overall performance of the instance.

  If your CPU credit balance is not at a sustainable level, then we recommend that you modify your DB instance to use a one of the supported R DB instance classes (scale compute).
For more information on monitoring metrics, see View metrics in the Amazon RDS console.

- Monitor the replica lag (AuroraReplicaLag) between the writer instance and the reader instances.

  If a reader instance runs out of CPU credits before the writer instance does, the resulting lag can cause the reader instance to restart frequently. This result is common when an application has a heavy load of read operations distributed among reader instances, at the same time that the writer instance has a minimal load of write operations.

  If you see a sustained increase in replica lag, make sure that your CPU credit balance for the reader instances in your DB cluster is not being exhausted.

  If your CPU credit balance is not at a sustainable level, then we recommend that you modify your DB instance to use one of the supported R DB instance classes (scale compute).

- Keep the number of inserts per transaction below 1 million for DB clusters that have binary logging enabled.

  If the DB cluster parameter group for your DB cluster has the binlog_format parameter set to a value other than OFF, then your DB cluster might experience out-of-memory conditions if the DB cluster receives transactions that contain over 1 million rows to insert. You can monitor the freeable memory (FreeableMemory) metric to determine if your DB cluster is running out of available memory. You then check the write operations (VolumeWriteIOPS) metric to see if a writer instance is receiving a heavy load of write operations. If this is the case, then we recommend that you update your application to limit the number of inserts in a transaction to less than 1 million. Alternatively, you can modify your instance to use one of the supported R DB instance classes (scale compute).

**Optimizing Aurora MySQL indexed join queries with asynchronous key prefetch**

Aurora MySQL can use the asynchronous key prefetch (AKP) feature to improve the performance of queries that join tables across indexes. This feature improves performance by anticipating the rows needed to run queries in which a JOIN query requires use of the Batched Key Access (BKA) Join algorithm and Multi-Range Read (MRR) optimization features. For more information about BKA and MRR, see Block nested-loop and batched key access joins and Multi-range read optimization in the MySQL documentation.
To take advantage of the AKP feature, a query must use both BKA and MRR. Typically, such a query occurs when the JOIN clause of a query uses a secondary index, but also needs some columns from the primary index. For example, you can use AKP when a JOIN clause represents an equijoin on index values between a small outer and large inner table, and the index is highly selective on the larger table. AKP works in concert with BKA and MRR to perform a secondary to primary index lookup during the evaluation of the JOIN clause. AKP identifies the rows required to run the query during the evaluation of the JOIN clause. It then uses a background thread to asynchronously load the pages containing those rows into memory before running the query.

AKP is available for Aurora MySQL version 2.10 and higher, and version 3. For more information about Aurora MySQL versions, see Database engine updates for Amazon Aurora MySQL.

Enabling asynchronous key prefetch

You can enable the AKP feature by setting aurora_use_key_prefetch, a MySQL server variable, to on. By default, this value is set to on. However, AKP can't be enabled until you also enable the BKA Join algorithm and disable cost-based MRR functionality. To do so, you must set the following values for optimizer_switch, a MySQL server variable:

- Set batched_key_access to on. This value controls the use of the BKA Join algorithm. By default, this value is set to off.
- Set mrr_cost_based to off. This value controls the use of cost-based MRR functionality. By default, this value is set to on.

Currently, you can set these values only at the session level. The following example illustrates how to set these values to enable AKP for the current session by executing SET statements.

```sql
mysql> set @@session.aurora_use_key_prefetch=on;
mysql> set @@session.optimizer_switch='batched_key_access=on,mrr_cost_based=off';
```

Similarly, you can use SET statements to disable AKP and the BKA Join algorithm and re-enable cost-based MRR functionality for the current session, as shown in the following example.

```sql
mysql> set @@session.aurora_use_key_prefetch=off;
mysql> set @@session.optimizer_switch='batched_key_access=off,mrr_cost_based=on';
```
For more information about the **batched_key_access** and **mrr_cost_based** optimizer switches, see [Switchable optimizations](#) in the MySQL documentation.

**Optimizing queries for asynchronous key prefetch**

You can confirm whether a query can take advantage of the AKP feature. To do so, use the EXPLAIN statement to profile the query before running it. The EXPLAIN statement provides information about the execution plan to use for a specified query.

In the output for the EXPLAIN statement, the `Extra` column describes additional information included with the execution plan. If the AKP feature applies to a table used in the query, this column includes one of the following values:

- Using Key Prefetching
- Using join buffer (Batched Key Access with Key Prefetching)

The following example shows the use of EXPLAIN to view the execution plan for a query that can take advantage of AKP.

```sql
mysql> explain select sql_no_cache
    | ps_partkey,
    | sum(ps_supplycost * ps_availqty) as value
    | from
    | partsupp,
    | supplier,
    | nation
    | where
    | ps_suppkey = s_suppkey
    | and s_nationkey = n_nationkey
    | and n_name = 'ETHIOPIA'
    | group by
    | ps_partkey having
    | sum(ps_supplycost * ps_availqty) > (select
    |     sum(ps_supplycost * ps_availqty) * 0.0000003333
    |     from
    |     partsupp,
    |     supplier,
    |     nation
    |     where
```
```sql
-> ps_suppkey = s_suppkey
-> and s_nationkey = n_nationkey
-> and n_name = 'ETHIOPIA'
-> )
-> order by
-> value desc;

+----+-------------+----------+------+-----------------------+---------------
| id | select_type | table    | type | possible_keys         | key           | key_len |
| ref |              | rows | filtered | Extra |
+----+-------------+----------+------+-----------------------+---------------

| 1 | PRIMARY     | nation   | ALL  | PRIMARY               | NULL          | NULL |
| ref |              | 25 | 100.00 | Using where; Using temporary; Using filesort |
| 1 | PRIMARY     | supplier | ref  | PRIMARY,i_s_nationkey | i_s_nationkey | 5 |
| dbt3_scale_10.nation.n_nationkey | 2057 | 100.00 | Using index |
| 1 | PRIMARY     | partsupp | ref  | i_ps_suppkey          | i_ps_suppkey  | 4 |
| dbt3_scale_10.supplier.s_suppkey | 42 | 100.00 | Using join buffer (Batched Key Access with Key Prefetching) |
| 2 | SUBQUERY    | nation   | ALL  | PRIMARY               | NULL          | NULL |
| NULL |              | 25 | 100.00 | Using where |
| 2 | SUBQUERY    | supplier | ref  | PRIMARY,i_s_nationkey | i_s_nationkey | 5 |
| dbt3_scale_10.nation.n_nationkey | 2057 | 100.00 | Using index |
| 2 | SUBQUERY    | partsupp | ref  | i_ps_suppkey          | i_ps_suppkey  | 4 |
| dbt3_scale_10.supplier.s_suppkey | 42 | 100.00 | Using join buffer (Batched Key Access with Key Prefetching) |

+----+-------------+----------+------+-----------------------+---------------+
| 6 rows in set, 1 warning (0.00 sec) |
```

For more information about the EXPLAIN output format, see [Extended EXPLAIN output format](#) in the MySQL documentation.
Optimizing large Aurora MySQL join queries with hash joins

When you need to join a large amount of data by using an equijoin, a hash join can improve query performance. You can enable hash joins for Aurora MySQL.

A hash join column can be any complex expression. In a hash join column, you can compare across data types in the following ways:

- You can compare anything across the category of precise numeric data types, such as int, bigint, numeric, and bit.
- You can compare anything across the category of approximate numeric data types, such as float and double.
- You can compare items across string types if the string types have the same character set and collation.
- You can compare items with date and timestamp data types if the types are the same.

⚠️ Note
You can't compare data types in different categories.

The following restrictions apply to hash joins for Aurora MySQL:

- Left-right outer joins aren't supported for Aurora MySQL version 2, but are supported for version 3.
- Semijoins such as subqueries aren't supported, unless the subqueries are materialized first.
- Multiple-table updates or deletes aren't supported.

⚠️ Note
Single-table updates or deletes are supported.

- BLOB and spatial data type columns can't be join columns in a hash join.

Enabling hash joins

To enable hash joins:
• Aurora MySQL version 2 – Set the DB parameter or DB cluster parameter aurora_disable_hash_join to 0. Turning off aurora_disable_hash_join sets the value of optimizer_switch to hash_join=on.

• Aurora MySQL version 3 – Set the MySQL server parameter optimizer_switch to block_nested_loop=on.

Hash joins are turned on by default in Aurora MySQL version 3 and turned off by default in Aurora MySQL version 2. The following example illustrates how to enable hash joins for Aurora MySQL version 3. You can issue the statement select @@optimizer_switch first to see what other settings are present in the SET parameter string. Updating one setting in the optimizer_switch parameter doesn't erase or modify the other settings.

```sql
mysql> SET optimizer_switch='block_nested_loop=on';
```

⚠️ **Note**
For Aurora MySQL version 3, hash join support is available in all minor versions and is turned on by default.
For Aurora MySQL version 2, hash join support is available in all minor versions.
In Aurora MySQL version 2, the hash join feature is always controlled by the aurora_disable_hash_join value.

With this setting, the optimizer chooses to use a hash join based on cost, query characteristics, and resource availability. If the cost estimation is incorrect, you can force the optimizer to choose a hash join. You do so by setting hash_join_cost_based, a MySQL server variable, to off. The following example illustrates how to force the optimizer to choose a hash join.

```sql
mysql> SET optimizer_switch='hash_join_cost_based=off';
```

⚠️ **Note**
This setting overrides the decisions of the cost-based optimizer. While the setting can be useful for testing and development, we recommend that you not use it in production.
Optimizing queries for hash joins

To find out whether a query can take advantage of a hash join, use the EXPLAIN statement to profile the query first. The EXPLAIN statement provides information about the execution plan to use for a specified query.

In the output for the EXPLAIN statement, the Extra column describes additional information included with the execution plan. If a hash join applies to the tables used in the query, this column includes values similar to the following:

- Using where; Using join buffer (Hash Join Outer table `table1_name`)
- Using where; Using join buffer (Hash Join Inner table `table2_name`)

The following example shows the use of EXPLAIN to view the execution plan for a hash join query.

```sql
mysql> explain SELECT sql_no_cache * FROM hj_small, hj_big, hj_big2
  ->  WHERE hj_small.col1 = hj_big.col1 and hj_big.col1=hj_big2.col1 ORDER BY 1;
+----+-------------+----------+------+---------------+------+---------+------+------+
| id | select_type | table    | type | possible_keys | key  | key_len | ref  | rows |
Extra                                                                     |
|----|-------------|----------|------|---------------|------|---------|------|------|
+----+-------------+----------+------|---------------|------|---------+------|------|
|  1 | SIMPLE      | hj_small | ALL  | NULL          | NULL | NULL    | NULL |  6   |
  |  1 | SIMPLE      | hj_big   | ALL  | NULL          | NULL | NULL    | NULL | 10   |
  |  1 | SIMPLE      | hj_big2  | ALL  | NULL          | NULL | NULL    | NULL | 15   |
```  

In the output, the Hash Join Inner table is the table used to build hash table, and the Hash Join Outer table is the table that is used to probe the hash table.

For more information about the extended EXPLAIN output format, see [Extended EXPLAIN Output Format](#) in the MySQL product documentation.
In Aurora MySQL 2.08 and higher, you can use SQL hints to influence whether a query uses hash join or not, and which tables to use for the build and probe sides of the join. For details, see Aurora MySQL hints.

**Using Amazon Aurora to scale reads for your MySQL database**

You can use Amazon Aurora with your MySQL DB instance to take advantage of the read scaling capabilities of Amazon Aurora and expand the read workload for your MySQL DB instance. To use Aurora to read scale your MySQL DB instance, create an Aurora MySQL DB cluster and make it a read replica of your MySQL DB instance. Then connect to the Aurora MySQL cluster to process the read queries. The source database can be an RDS for MySQL DB instance, or a MySQL database running external to Amazon RDS. For more information, see Using Amazon Aurora to scale reads for your MySQL database.

**Optimizing timestamp operations**

When the value of the system variable `time_zone` is set to `SYSTEM`, each MySQL function call that requires a time zone calculation makes a system library call. When you run SQL statements that return or change such `TIMESTAMP` values at high concurrency, you might experience increased latency, lock contention, and CPU usage. For more information, see `time_zone` in the MySQL documentation.

To avoid this behavior, we recommend that you change the value of the `time_zone` DB cluster parameter to UTC. For more information, see Modifying parameters in a DB cluster parameter group.

While the `time_zone` parameter is dynamic (doesn't require a database server restart), the new value is used only for new connections. To make sure that all connections are updated to use the new `time_zone` value, we recommend that you recycle your application connections after updating the DB cluster parameter.

**Best practices for Aurora MySQL high availability**

You can apply the following best practices to improve the availability of your Aurora MySQL clusters.

**Topics**

- Using Amazon Aurora for Disaster Recovery with your MySQL databases
• Migrating from MySQL to Amazon Aurora MySQL with reduced downtime

• Avoiding slow performance, automatic restart, and failover for Aurora MySQL DB instances

Using Amazon Aurora for Disaster Recovery with your MySQL databases

You can use Amazon Aurora with your MySQL DB instance to create an offsite backup for disaster recovery. To use Aurora for disaster recovery of your MySQL DB instance, create an Amazon Aurora DB cluster and make it a read replica of your MySQL DB instance. This applies to an RDS for MySQL DB instance, or a MySQL database running external to Amazon RDS.

⚠️ Important

When you set up replication between a MySQL DB instance and an Amazon Aurora MySQL DB cluster, you should monitor the replication to ensure that it remains healthy and repair it if necessary.

For instructions on how to create an Amazon Aurora MySQL DB cluster and make it a read replica of your MySQL DB instance, follow the procedure in Using Amazon Aurora to scale reads for your MySQL database.

For more information on disaster recovery models, see How to choose the best disaster recovery option for your Amazon Aurora MySQL cluster.

Migrating from MySQL to Amazon Aurora MySQL with reduced downtime

When importing data from a MySQL database that supports a live application to an Amazon Aurora MySQL DB cluster, you might want to reduce the time that service is interrupted while you migrate. To do so, you can use the procedure documented in Importing data to a MySQL or MariaDB DB instance with reduced downtime in the Amazon Relational Database Service User Guide. This procedure can especially help if you are working with a very large database. You can use the procedure to reduce the cost of the import by minimizing the amount of data that is passed across the network to AWS.

The procedure lists steps to transfer a copy of your database data to an Amazon EC2 instance and import the data into a new RDS for MySQL DB instance. Because Amazon Aurora is compatible with MySQL, you can instead use an Amazon Aurora DB cluster for the target Amazon RDS MySQL DB instance.
Avoiding slow performance, automatic restart, and failover for Aurora MySQL DB instances

If you're running a heavy workload or workloads that spike beyond the allocated resources of your DB instance, you can exhaust the resources on which you're running your application and Aurora database. To get metrics on your database instance such as CPU utilization, memory usage, and number of database connections used, you can refer to the metrics provided by Amazon CloudWatch, Performance Insights, and Enhanced Monitoring. For more information on monitoring your DB instance, see Monitoring metrics in an Amazon Aurora cluster.

If your workload exhausts the resources you're using, your DB instance might slow down, restart, or even fail over to another DB instance. To avoid this, monitor your resource utilization, examine the workload running on your DB instance, and make optimizations where necessary. If optimizations don't improve the instance metrics and mitigate the resource exhaustion, consider scaling up your DB instance before you reach its limits. For more information on available DB instance classes and their specifications, see Aurora DB instance classes.

Recommendations for Aurora MySQL

The following features are available in Aurora MySQL for MySQL compatibility. However, they have performance, scalability, stability, or compatibility issues in the Aurora environment. Thus, we recommend that you follow certain guidelines in your use of these features. For example, we recommend that you don't use certain features for production Aurora deployments.

Topics

- Using multithreaded replication in Aurora MySQL
- Invoking AWS Lambda functions using native MySQL functions
- Avoiding XA transactions with Amazon Aurora MySQL
- Keeping foreign keys turned on during DML statements
- Configuring how frequently the log buffer is flushed
- Minimizing and troubleshooting Aurora MySQL deadlocks

Using multithreaded replication in Aurora MySQL

With multithreaded binary log replication, a SQL thread reads events from the relay log and queues them up for SQL worker threads to apply. The SQL worker threads are managed by a coordinator thread. The binary log events are applied in parallel when possible.
Multithreaded replication is supported in Aurora MySQL version 3, and in Aurora MySQL version 2.12.1 and higher.

For Aurora MySQL versions lower than 3.04, Aurora uses single-threaded replication by default when an Aurora MySQL DB cluster is used as a read replica for binary log replication.

Earlier versions of Aurora MySQL version 2 inherited several issues regarding multithreaded replication from MySQL Community Edition. For those versions, we recommend that you not use multithreaded replication in production.

If you do use multithreaded replication, we recommend that you test it thoroughly.

For more information about using replication in Amazon Aurora, see Replication with Amazon Aurora. For more information about multithreaded replication in Aurora MySQL, see Multithreaded binary log replication.

**Invoking AWS Lambda functions using native MySQL functions**

We recommend using the native MySQL functions `lambda_sync` and `lambda_async` to invoke Lambda functions.

If you are using the deprecated `mysql.lambda_async` procedure, we recommend that you wrap calls to the `mysql.lambda_async` procedure in a stored procedure. You can call this stored procedure from different sources, such as triggers or client code. This approach can help to avoid impedance mismatch issues and make it easier for your database programmers to invoke Lambda functions.

For more information on invoking Lambda functions from Amazon Aurora, see Invoking a Lambda function from an Amazon Aurora MySQL DB cluster.

**Avoiding XA transactions with Amazon Aurora MySQL**

We recommend that you don't use eXtended Architecture (XA) transactions with Aurora MySQL, because they can cause long recovery times if the XA was in the PREPARED state. If you must use XA transactions with Aurora MySQL, follow these best practices:

- Don't leave an XA transaction open in the PREPARED state.
- Keep XA transactions as small as possible.

For more information about using XA transactions with MySQL, see XA transactions in the MySQL documentation.
Keeping foreign keys turned on during DML statements

We strongly recommend that you don't run any data definition language (DDL) statements when the foreign_key_checks variable is set to 0 (off).

If you need to insert or update rows that require a transient violation of foreign keys, follow these steps:

1. Set foreign_key_checks to 0.
2. Make your data manipulation language (DML) changes.
3. Make sure that your completed changes don't violate any foreign key constraints.
4. Set foreign_key_checks to 1 (on).

In addition, follow these other best practices for foreign key constraints:

- Make sure that your client applications don't set the foreign_key_checks variable to 0 as a part of the init_connect variable.

- If a restore from a logical backup such as mysqldump fails or is incomplete, make sure that foreign_key_checks is set to 1 before starting any other operations in the same session. A logical backup sets foreign_key_checks to 0 when it starts.

Configuring how frequently the log buffer is flushed

In MySQL Community Edition, to make transactions durable, the InnoDB log buffer must be flushed to durable storage. You use theinnodb_flush_log_at_trx_commit parameter to configure how frequently the log buffer is flushed to disk.

When you set the innodb_flush_log_at_trx_commit parameter to the default value of 1, the log buffer is flushed at each transaction commit. This setting helps to keep the database ACID compliant. We recommend that you keep the default setting of 1.

Changing innodb_flush_log_at_trx_commit to a nondefault value can help reduce data manipulation language (DML) latency, but sacrifices the durability of the log records. This lack of durability makes the database ACID noncompliant. We recommend that your databases be ACID compliant to avoid the risk of data loss in the event of a server restart. For more information on this parameter, see innodb_flush_log_at_trx_commit in the MySQL documentation.
In Aurora MySQL, redo log processing is offloaded to the storage layer, so no flushing to log files occurs on the DB instance. When a write is issued, redo logs are sent from the writer DB instance directly to the Aurora cluster volume. The only writes that cross the network are redo log records. No pages are ever written from the database tier.

By default, each thread committing a transaction waits for confirmation from the Aurora cluster volume. This confirmation indicates that this record and all previous redo log records are written and have achieved quorum. Persisting the log records and achieving quorum make the transaction durable, whether through autocommit or explicit commit. For more information on the Aurora storage architecture, see Amazon Aurora storage demystified.

Aurora MySQL doesn't flush logs to data files as MySQL Community Edition does. However, you can use the innodb_flush_log_at_trx_commit parameter to relax durability constraints when writing redo log records to the Aurora cluster volume.

For Aurora MySQL version 2:

- **innodb_flush_log_at_trx_commit = 0 or 2** – The database doesn't wait for confirmation that the redo log records are written to the Aurora cluster volume.
- **innodb_flush_log_at_trx_commit = 1** – The database waits for confirmation that the redo log records are written to the Aurora cluster volume.

For Aurora MySQL version 3:

- **innodb_flush_log_at_trx_commit = 0** – The database doesn't wait for confirmation that the redo log records are written to the Aurora cluster volume.
- **innodb_flush_log_at_trx_commit = 1 or 2** – The database waits for confirmation that the redo log records are written to the Aurora cluster volume.

Therefore, to obtain the same nondefault behavior in Aurora MySQL version 3 that you would with the value set to 0 or 2 in Aurora MySQL version 2, set the parameter to 0.

While these settings can lower DML latency to the client, they can also result in data loss in the event of a failover or restart. Therefore, we recommend that you keep the innodb_flush_log_at_trx_commit parameter set to the default value of 1.

While data loss can occur in both MySQL Community Edition and Aurora MySQL, behavior differs in each database because of their different architectures. These architectural differences can lead
to varying degrees of data loss. To make sure that your database is ACID compliant, always set `innodb_flush_log_at_trx_commit` to 1.

**Note**

In Aurora MySQL version 3, before you can change `innodb_flush_log_at_trx_commit` to a value other than 1, you must first change the value of `innodb_trx_commit_allow_data_loss` to 1. By doing so, you acknowledge the risk of data loss.

**Minimizing and troubleshooting Aurora MySQL deadlocks**

Users running workloads that regularly experience constraint violations on unique secondary indexes or foreign keys, when modifying records on the same data page concurrently, might experience increased deadlocks and lock wait timeouts. These deadlocks and timeouts are because of a MySQL Community Edition bug fix.

This fix is included in MySQL Community Edition versions 5.7.26 and higher, and was backported into Aurora MySQL versions 2.10.3 and higher. The fix is necessary for enforcing *serializability*, by implementing additional locking for these types of data manipulation language (DML) operations, on changes made to records in an InnoDB table. This issue was uncovered as part of an investigation into deadlock issues introduced by a previous MySQL Community Edition bug fix.

The fix changed the internal handling for the *partial rollback* of a tuple (row) update in the InnoDB storage engine. Operations that generate constraint violations on foreign keys or unique secondary indexes cause partial rollback. This includes, but isn't limited to, concurrent `INSERT...ON DUPLICATE KEY UPDATE`, `REPLACE INTO`, and `INSERT IGNORE` statements (*upserts*).

In this context, partial rollback doesn't refer to the rollback of application-level transactions, but rather an internal InnoDB rollback of changes to a clustered index, when a constraint violation is encountered. For example, a duplicate key value is found during an upsert operation.

In a normal insert operation, InnoDB atomically creates clustered and secondary index entries for each index. If InnoDB detects a duplicate value on a unique secondary index during an upsert operation, the inserted entry in the clustered index has to be reverted (partial rollback), and the update then has to be applied to the existing duplicate row. During this internal partial rollback step, InnoDB must lock each record seen as part of the operation. The fix ensures transaction serializability by introducing additional locking after the partial rollback.
Minimizing InnoDB deadlocks

You can take the following approaches to reduce the frequency of deadlocks in your database instance. More examples can be found in the MySQL documentation.

1. To reduce the chances of deadlocks, commit transactions immediately after making a related set of changes. You can do this by breaking up large transactions (multiple row updates between commits) into smaller ones. If you're batch inserting rows, then try to reduce batch insert sizes, especially when using the upsert operations mentioned previously.

To reduce the number of possible partial rollbacks, you can try some of the following approaches:

a. Replace batch insert operations with inserting one row at a time. This can reduce the amount of time where locks are held by transactions that might have conflicts.

b. Instead of using REPLACE INTO, rewrite the SQL statement as a multistatement transaction such as the following:

```
BEGIN;
DELETE conflicting rows;
INSERT new rows;
COMMIT;
```

c. Instead of using INSERT...ON DUPLICATE KEY UPDATE, rewrite the SQL statement as a multistatement transaction such as the following:

```
BEGIN;
SELECT rows that conflict on secondary indexes;
UPDATE conflicting rows;
INSERT new rows;
COMMIT;
```

2. Avoid long-running transactions, active or idle, that might hold onto locks. This includes interactive MySQL client sessions that might be open for an extended period with an uncommitted transaction. When optimizing transaction sizes or batch sizes, the impact can vary depending on a number of factors such as concurrency, number of duplicates, and table structure. Any changes should be implemented and tested based on your workload.

3. In some situations, deadlocks can occur when two transactions attempt to access the same datasets, either in one or multiple tables, in different orders. To prevent this, you can modify the transactions to access the data in the same order, thereby serializing the access. For example,
create a queue of transactions to be completed. This approach can help to avoid deadlocks when multiple transactions occur concurrently.

4. Adding carefully chosen indexes to your tables can improve selectivity and reduce the need to access rows, which leads to less locking.

5. If you encounter gap locking, you can modify the transaction isolation level to READ COMMITTED for the session or transaction to prevent it. For more information on InnoDB isolation levels and their behaviors, see Transaction isolation levels in the MySQL documentation.

**Note**

While you can take precautions to reduce the possibility of deadlocks occurring, deadlocks are an expected database behavior and can still occur. Applications should have the necessary logic to handle deadlocks when they are encountered. For example, implement retry and backing-off logic in the application. It’s best to address the root cause of the issue but if a deadlock does occur, the application has the option to wait and retry.

### Monitoring InnoDB deadlocks

**Deadlocks** can occur in MySQL when application transactions try to take table-level and row-level locks in a way that results in circular waiting. An occasional InnoDB deadlock isn't necessarily an issue, because the InnoDB storage engine detects the condition immediately and rolls back one of the transactions automatically. If you encounter deadlocks frequently, we recommend reviewing and modifying your application to alleviate performance issues and avoid deadlocks. When deadlock detection is turned on (the default), InnoDB automatically detects transaction deadlocks and rolls back a transaction or transactions to break the deadlock. InnoDB tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

- **SHOW ENGINE statement** – The SHOW ENGINE INNODB STATUS \G statement contains details of the most recent deadlock encountered on the database since the last restart.
- **MySQL error log** – If you encounter frequent deadlocks where the output of the SHOW ENGINE statement is inadequate, you can turn on the innodb_print_all_deadlocks DB cluster parameter. When this parameter is turned on, information about all deadlocks in InnoDB user transactions is recorded in the Aurora MySQL error log.
• Amazon CloudWatch metrics – We also recommend that you proactively monitor deadlocks using the CloudWatch metric Deadlocks. For more information, see Instance-level metrics for Amazon Aurora.

• Amazon CloudWatch Logs – With CloudWatch Logs, you can view metrics, analyze log data, and create real-time alarms. For more information, see Monitor errors in Amazon Aurora MySQL and Amazon RDS for MySQL using Amazon CloudWatch and send notifications using Amazon SNS.

Using CloudWatch Logs with innodb_print_all_deadlocks turned on, you can configure alarms to notify you when the number of deadlocks exceeds a given threshold. To define a threshold, we recommend that you observe your trends and use a value based on your normal workload.

• Performance Insights – When you use Performance Insights, you can monitor the innodb_deadlocks and innodb_lock_wait_timeout metrics. For more information on these metrics, see Non-native counters for Aurora MySQL.
Troubleshooting Amazon Aurora MySQL database performance

This topic focuses on some common Aurora MySQL DB performance issues, and how to troubleshoot or collect information to remediate these issues quickly. We divide database performance into two categories:

- Server performance – The entire database server runs slower.
- Query performance – One or more queries take longer to run.

AWS monitoring options

We recommend that you use the following AWS monitoring options to help with troubleshooting:

- Amazon CloudWatch – Amazon CloudWatch monitors your AWS resources and the applications you run on AWS in real time. You can use CloudWatch to collect and track metrics, which are variables you can measure for your resources and applications. For more information, see What is Amazon CloudWatch?. You can view all of the system metrics and process information for your DB instances on the AWS Management Console. You can configure your Aurora MySQL DB cluster to publish general, slow, audit, and error log data to a log group in Amazon CloudWatch Logs. This allows you to view trends, maintain logs if a host is impacted, and create a baseline for "normal" performance to easily identify anomalies or changes. For more information, see Publishing Amazon Aurora MySQL logs to Amazon CloudWatch Logs.

- Enhanced Monitoring – To enable additional Amazon CloudWatch metrics for an Aurora MySQL database, turn on Enhanced Monitoring. When you create or modify an Aurora DB cluster, select Enable Enhanced Monitoring. This allows Aurora to publish performance metrics to CloudWatch. Some of the key metrics available include CPU usage, database connections, storage usage, and query latency. These can help identify performance bottlenecks.

The amount of information transferred for a DB instance is directly proportional to the defined granularity for Enhanced Monitoring. A smaller monitoring interval results in more frequent reporting of OS metrics and increases your monitoring cost. To manage costs, set different granularities for different instances in your AWS accounts. The default granularity at creation of an instance is 60 seconds. For more information, see Cost of Enhanced Monitoring.

- Performance Insights – You can view all of the database call metrics. This includes DB locks, waits, and the number of rows processed, all of which you can use for troubleshooting. When
you create or modify an Aurora DB cluster, select **Turn on Performance Insights**. By default, Performance Insights has a 7-day data retention period, but can be customized to analyze longer-term performance trends. For longer than 7-day retention, you need to upgrade to the paid tier. For more information, see **Performance Insights pricing**. You can set the data retention period for each Aurora DB instance separately. For more information, see **Monitoring DB load with Performance Insights on Amazon Aurora**.

**Most common reasons for Aurora MySQL database performance issues**

You can use the following steps to troubleshoot performance issues in your Aurora MySQL database. We list these steps in the logical order of investigation, but they’re not intended to be linear. One discovery could jump across steps, which allow for a series of investigative paths.

1. **Workload** – Understand your database workload.
2. **Logging** – Review all of the database logs.
3. **Query performance** – Examine your query execution plans to see if they’ve changed. Code changes can cause plans to change.

**Troubleshooting workload issues for Aurora MySQL databases**

Database workload can be viewed as reads and writes. With an understanding of "normal" database workload, you can tune queries and the database server to meet demand as it changes. There are a number of different reasons why performance can change, so the first step is to understand what has changed.

- Has there been a major or minor version upgrade?

  A major version upgrade includes changes to the engine code, particularly in the optimizer, that can change the query execution plan. When upgrading database versions, especially major versions, it's very important that you analyze the database workload and tune accordingly. Tuning can involve optimizing and rewriting queries, or adding and updating parameter settings, depending on the results of testing. Understanding what is causing the impact will allow you to start focusing on that specific area.

  For more information, see **What is new in MySQL 8.0** and **Server and status variables and options added, deprecated, or removed in MySQL 8.0** in the MySQL documentation, and **Comparison of Aurora MySQL version 2 and Aurora MySQL version 3**.
• Has there been an increase in data being processed (row counts)?
• Are there more queries running concurrently?
• Are there schema or database changes?
• Have there been code defects or fixes?

  • Troubleshooting memory usage issues for Aurora MySQL databases
    • Example 1: Continuous high memory usage
    • Example 2: Transient memory spikes
  • Troubleshooting out-of-memory issues for Aurora MySQL databases

Instance host metrics

Monitor instance host metrics such as CPU, memory, and network activity to help understand whether there has been a workload change. There are two main concepts for understanding workload changes:

• Utilization – The usage of a device, such as CPU or disk. It can be time-based or capacity-based.
  • Time-based – The amount of time that a resource is busy over a particular observation period.
  • Capacity-based – The amount of throughput that a system or component can deliver, as a percentage of its capacity.
• Saturation – The degree to which more work is required of a resource than it can process. When capacity-based usage reaches 100%, the extra work can't be processed and must be queued.

CPU usage

You can use the following tools to identify CPU usage and saturation:
CloudWatch provides the CPUUtilization metric. If this reaches 100%, then the instance is saturated. However, CloudWatch metrics are averaged over 1 minute, and lack granularity.

For more information on CloudWatch metrics, see Instance-level metrics for Amazon Aurora.

Enhanced Monitoring provides metrics returned by the operating system top command. It shows load averages and the following CPU states, with 1-second granularity:

- **Idle (%)** = Idle time
- **IRQ (%)** = Software interrupts
- **Nice (%)** = Nice time for processes with a *niced* priority.
- **Steal (%)** = Time spent serving other tenants (virtualization related)
- **System (%)** = System time
- **User (%)** = User time
- **Wait (%)** = I/O wait

For more information on Enhanced Monitoring metrics, see OS metrics for Aurora.

**Memory usage**

If the system is under memory pressure, and resource consumption is reaching saturation, you should be observing a high degree of page scanning, paging, swapping, and out-of-memory errors.

You can use the following tools to identify memory usage and saturation:

CloudWatch provides the FreeableMemory metric, that shows how much memory can be reclaimed by flushing some of the OS caches and the current free memory.

For more information on CloudWatch metrics, see Instance-level metrics for Amazon Aurora.

Enhanced Monitoring provides the following metrics that can help you identify memory usage issues:

- **Buffers (KB)** – The amount of memory used for buffering I/O requests before writing to the storage device, in kilobytes.
- **Cached (KB)** – The amount of memory used for caching file system–based I/O.
- **Free (KB)** – The amount of unassigned memory, in kilobytes.
- **Swap** – Cached, Free, and Total.
For example, if you see that your DB instance uses Swap memory, then the total amount of memory for your workload is larger than your instance currently has available. We recommend increasing the size of your DB instance or tuning your workload to use less memory.

For more information on Enhanced Monitoring metrics, see [OS metrics for Aurora](#).

For more detailed information on using the Performance Schema and sys schema to determine which connections and components are using memory, see [Troubleshooting memory usage issues for Aurora MySQL databases](#).

**Network throughput**

CloudWatch provides the following metrics for total network throughput, all averaged over 1 minute:

- `NetworkReceiveThroughput` – The amount of network throughput received from clients by each instance in the Aurora DB cluster.
- `NetworkTransmitThroughput` – The amount of network throughput sent to clients by each instance in the Aurora DB cluster.
- `NetworkThroughput` – The amount of network throughput both received from and transmitted to clients by each instance in the Aurora DB cluster.
- `StorageNetworkReceiveThroughput` – The amount of network throughput received from the Aurora storage subsystem by each instance in the DB cluster.
- `StorageNetworkTransmitThroughput` – The amount of network throughput sent to the Aurora storage subsystem by each instance in the Aurora DB cluster.
- `StorageNetworkThroughput` – The amount of network throughput received from and sent to the Aurora storage subsystem by each instance in the Aurora DB cluster.

For more information on CloudWatch metrics, see [Instance-level metrics for Amazon Aurora](#).

Enhanced Monitoring provides the network received (RX) and transmitted (TX) graphs, with up to 1-second granularity.

For more information on Enhanced Monitoring metrics, see [OS metrics for Aurora](#).

**Database metrics**

Examine the following CloudWatch metrics for workload changes:
• **BlockedTransactions** – The average number of transactions in the database that are blocked per second.
• **BufferCacheHitRatio** – The percentage of requests that are served by the buffer cache.
• **CommitThroughput** – The average number of commit operations per second.
• **DatabaseConnections** – The number of client network connections to the database instance.
• **Deadlocks** – The average number of deadlocks in the database per second.
• **DMLThroughput** – The average number of inserts, updates, and deletes per second.
• **ResultSetCacheHitRatio** – The percentage of requests that are served by the query cache.
• **RollbackSegmentHistoryListLength** – The undo logs that record committed transactions with delete-marked records.
• **RowLockTime** – The total time spent acquiring row locks for InnoDB tables.
• **SelectThroughput** – The average number of select queries per second.

For more information on CloudWatch metrics, see [Instance-level metrics for Amazon Aurora](#).

Consider the following questions when examining the workload:

1. Were there recent changes in DB instance class, for example reducing the instance size from 8xlarge to 4xlarge, or changing from db.r5 to db.r6?
2. Can you create a clone and reproduce the issue, or is it happening only on that one instance?
3. Is there server resource exhaustion, high CPU or memory exhaustion? If yes, this could mean that additional hardware is required.
4. Are one or more queries taking longer?
5. Are the changes caused by an upgrade, especially a major version upgrade? If yes, then compare the pre- and post-upgrade metrics.
6. Are there changes in the number of reader DB instances?
7. Have you enabled general, audit, or binary logging? For more information, see [Logging for Aurora MySQL databases](#).
8. Did you enable, disable, or change your use of binary log (binlog) replication?
9. Are there any long-running transactions holding large numbers of row locks? Examine the InnoDB history list length (HLL) for indications of long-running transactions.

For more information, see [The InnoDB history list length increased significantly](#) and the blog post [Why is my SELECT query running slowly on my Amazon Aurora MySQL DB cluster?](#).
a. If a large HLL is caused by a write transaction, it means that UNDO logs are accumulating (not being cleaned regularly). In a large write transaction, this accumulation can grow quickly. In MySQL, UNDO is stored in the SYSTEM tablespace. The SYSTEM tablespace is not shrinkable. The UNDO log might cause the SYSTEM tablespace to grow to several GB, or even TB. After the purge, release the allocated space by taking a logical backup (dump) of the data, then import the dump to a new DB instance.

b. If a large HLL is caused by a read transaction (long-running query), it can mean that the query is using a large amount of temporary space. Release the temporary space by rebooting. Examine Performance Insights DB metrics for any changes in the Temp section, such as created_tmp_tables. For more information, see Monitoring DB load with Performance Insights on Amazon Aurora.

10 Can you split long-running transactions into smaller ones that modify fewer rows?

11 Are there any changes in blocked transactions or increases in deadlocks? Examine Performance Insights DB metrics for any changes in status variables in the Locks section, such as innodb_row_lock_time, innodb_row_lock_wait, and innodb_dead_locks. Use 1-minute or 5-minute intervals.

12 Are there increased wait events? Examine Performance Insights wait events and wait types using 1-minute or 5-minute intervals. Analyze the top wait events and see whether they are correlated to workload changes or database contention. For example, buf_pool_mutex indicates buffer pool contention. For more information, see Tuning Aurora MySQL with wait events.

Troubleshooting memory usage issues for Aurora MySQL databases

While CloudWatch, Enhanced Monitoring, and Performance Insights provide a good overview of memory usage at the operating system level, such as how much memory the database process is using, they don't allow you to break down what connections or components within the engine might be causing this memory usage.

To troubleshoot this, you can use the Performance Schema and sys schema. In Aurora MySQL version 3, memory instrumentation is enabled by default when the Performance Schema is enabled. In Aurora MySQL version 2, only memory instrumentation for Performance Schema memory usage is enabled by default. For information on tables available in the Performance Schema to track memory usage and enabling Performance Schema memory instrumentation, see Memory summary tables in the MySQL documentation. For more information on using the Performance Schema with Performance Insights, see Turning on the Performance Schema for Performance Insights on Aurora MySQL.
While detailed information is available in the Performance Schema to track current memory usage, the MySQL `sys schema` has views on top of Performance Schema tables that you can use to quickly pinpoint where memory is being used.

In the `sys` schema, the following views are available to track memory usage by connection, component, and query.

<table>
<thead>
<tr>
<th>View</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>memory_by_host_by_current_bytes</code></td>
<td>Provides information on engine memory usage by host. This can be useful for identifying which application servers or client hosts are consuming memory.</td>
</tr>
<tr>
<td><code>memory_by_thread_by_current_bytes</code></td>
<td>Provides information on engine memory usage by thread ID. The thread ID in MySQL can be a client connection or a background thread. You can map thread IDs to MySQL connection IDs by using the <code>sys.processlist</code> view or <code>performance_schema.threads</code> table.</td>
</tr>
<tr>
<td><code>memory_by_user_by_current_bytes</code></td>
<td>Provides information on engine memory usage by user. This can be useful for identifying which user accounts or clients are consuming memory.</td>
</tr>
<tr>
<td><code>memory_global_by_current_bytes</code></td>
<td>Provides information on engine memory usage by engine component. This can be useful for identifying memory usage globally by engine buffers or components. For example, you might see the <code>memory/innodb/buf_buf_pool</code> event for the InnoDB buffer pool, or the <code>memory/sql/Prepare::main_mem_root</code> event for prepared statements.</td>
</tr>
<tr>
<td><code>memory_global_total</code></td>
<td>Provides an overview of total tracked memory usage in the database engine.</td>
</tr>
</tbody>
</table>
In Aurora MySQL version 3.05 and higher, you can also track maximum memory usage by statement digest in the Performance Schema statement summary tables. The statement summary tables contain normalized statement digests and aggregated statistics on their execution. The MAX_TOTAL_MEMORY column can help you identify maximum memory used by query digest since the statistics were last reset, or since the database instance was restarted. This can be useful in identifying specific queries that might be consuming a lot of memory.

### Note

The Performance Schema and sys schema show you the current memory usage on the server, and the high-water marks for memory consumed per connection and engine component. Because the Performance Schema is maintained in memory, information is reset when the DB instance restarts. To maintain a history over time, we recommend that you configure retrieval and storage of this data outside of the Performance Schema.

### Topics

- **Example 1: Continuous high memory usage**
- **Example 2: Transient memory spikes**

### Example 1: Continuous high memory usage

Looking globally at FreeableMemory in CloudWatch, we can see that memory usage greatly increased at 2024-03-26 02:59 UTC.
This doesn't tell us the whole picture. To determine which component is using the most memory, you can log into the database and look at `sys.memory_global_by_current_bytes`. This table contains a list of memory events that MySQL tracks, along with information on memory allocation per event. Each memory tracking event starts with `memory/%`, followed by other information on which engine component/feature the event is associated with.

For example, `memory/performance_schema/%` is for memory events related to the Performance Schema, `memory/innodb/%` is for InnoDB, and so on. For more information on event naming conventions, see [Performance Schema instrument naming conventions](#) in the MySQL documentation.

From the following query, we can find the likely culprit based on `current_alloc`, but we can also see many `memory/performance_schema/%` events.

```
mysql> SELECT * FROM sys.memory_global_by_current_bytes LIMIT 10;
```

```
+---------------------------------------------------------------------------------------------------------+--------------------------+-----------+-------------------------------------+--------------------------+--------------------------|
| event_name                                                                                             | current_count | current_alloc | current_avg_alloc | high_count   | high_alloc   |
| memory/sql/Prepared_statement::main_mem_root                                                         | 512817        | 4.91 GiB      | 10.04 KiB         | 512823       | 4.91 GiB     |
| memory/performance_schema/prepared_statements_instances                                               | 252           | 488.25 MiB    | 1.94 MiB          | 252          | 488.25 MiB   |
| memory/innodb/hash0hash                                                                                | 4             | 79.07 MiB     | 19.77 MiB         | 4            | 79.07 MiB    |
| memory/performance_schema/events_errors_summary_by_thread_by_error                                     | 1028          | 52.27 MiB     | 52.06 KiB         | 1028         | 52.27 MiB    |
| memory/performance_schema/events_statements_summary_by_digest_by_event_name                           | 4             | 47.25 MiB     | 11.81 MiB         | 4            | 47.25 MiB    |
| memory/performance_schema/events_statements_summary_by_digest                                         | 1             | 40.28 MiB     | 40.28 MiB         | 1            | 40.28 MiB    |
| memory/performance_schema/memory_summary_by_thread_by_event_name                                      | 4             | 31.64 MiB     | 7.91 MiB          | 4            | 31.64 MiB    |
| memory/innodb/memory                                                                                  | 15227         | 27.44 MiB     | 1.85 KiB          | 20619        | 33.33 MiB    |
```
We mentioned previously that the Performance Schema is stored in memory, which means that it's also tracked in the `performance_schema` memory instrumentation.

Note

If you find that the Performance Schema is using a lot of memory, and want to limit its memory usage, you can tune database parameters based on your requirements. For more information, see The Performance Schema memory-allocation model in the MySQL documentation.

For readability, you can rerun the same query but exclude Performance Schema events. The output shows the following:

- The main memory consumer is `memory/sql/Prepared_statement::main_mem_root`.
- The `current_alloc` column tells us that MySQL has 4.91 GiB currently allocated to this event.
- The `high_alloc` column tells us that 4.91 GiB is the high-water mark of `current_alloc` since the stats were last reset or since the server restarted. This means that `memory/sql/Prepared_statement::main_mem_root` is at its highest value.

```
mysql> SELECT * FROM sys.memory_global_by_current_bytes WHERE event_name NOT LIKE 'memory/performance_schema/%' LIMIT 10;
```

```plaintext
+-----------------------------------------------+---------------+---------------+----------------+
| event_name                                    | current_count | current_alloc | current_avg_alloc | high_count | high_alloc | high_avg_alloc |
+-----------------------------------------------+---------------+---------------+-------------------+------------+------------+----------------+
+-----------------------------------------------+---------------+---------------+-------------------+------------+------------+----------------+
10 rows in set (0.02 sec)
```
From the name of the event, we can tell that this memory is being used for prepared statements. If you want to see which connections are using this memory, you can check memory_by_thread_by_current_bytes.

In the following example, each connection has approximately 7 MiB allocated, with a high-water mark of approximately 6.29 MiB (current_max_alloc). This makes sense, because the example is using sysbench with 80 tables and 800 connections with prepared statements. If you want to reduce memory usage in this scenario, you can optimize your application's usage of prepared statements to reduce memory consumption.

As mentioned earlier, the thread ID (thd_id) value here can refer to server background threads or database connections. If you want to map thread ID values to database connection IDs, you can use the performance_schema.threads table or the sys.processlist view, where conn_id is the connection ID.

mysql> SELECT thd_id,conn_id,user,db,command,state,time,last_wait FROM sys.processlist
WHERE user='reinvent@10.0.4.4';

Troubleshooting workload issues
Now we stop the sysbench workload, which closes the connections and released the memory. Checking the events again, we can confirm that memory is released, but high_alloc still tells us what the high-water mark is. The high_alloc column can be very useful in identifying short spikes in memory usage, where you might not be able to immediately identify usage from current_alloc, which shows only currently allocated memory.

```
mysql> SELECT * FROM sys.memory_global_by_current_bytes WHERE event_name='memory/sql/Prepared_statement::main_mem_root' LIMIT 10;
```

```
+----------------------------------------------+---------------+---------------+
| event_name                                   | current_count | current_alloc |
| current_avg_alloc | high_count | high_alloc | high_avg_alloc |
+----------------------------------------------+---------------+---------------+
| memory/sql/Prepared_statement::main_mem_root |            17 | 253.80 KiB    | 14.93 KiB     |
+----------------------------------------------+---------------+---------------+
1 row in set (0.00 sec)
```

If you want to reset high_alloc, you can truncate the performance_schema memory summary tables, but this resets all memory instrumentation. For more information, see Performance Schema general table characteristics in the MySQL documentation.

In the following example, we can see that high_alloc is reset after truncation.

```
mysql> TRUNCATE `performance_schema`.`memory_summary_global_by_event_name`;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM sys.memory_global_by_current_bytes WHERE event_name='memory/sql/Prepared_statement::main_mem_root' LIMIT 10;
```

Troubleshooting workload issues
Example 2: Transient memory spikes

Another common occurrence is short spikes in memory usage on a database server. These can be periodic drops in freeable memory that are difficult to troubleshoot using `current_alloc` in `sys.memory_global_by_current_bytes`, because the memory has already been freed.

Note

If Performance Schema statistics have been reset, or the database instance has been restarted, this information won't be available in `sys` or `performance_schema`. To retain this information, we recommend that you configure external metrics collection.

The following graph of the `os.memory.free` metric in Enhanced Monitoring shows brief 7-second spikes in memory usage. Enhanced Monitoring allows you to monitor at intervals as short as 1 second, which is perfect for catching transient spikes like these.
To help diagnose the cause of the memory usage here, we can use a combination of `high_alloc` in the sys memory summary views and `Performance Schema statement summary tables` to try to identify offending sessions and connections.

As expected, because memory usage isn't currently high, we can't see any major offenders in the sys schema view under `current_alloc`.

```sql
mysql> SELECT * FROM sys.memory_global_by_current_bytes LIMIT 10;
+-----------------------------------------------------------------------+------------------+
| event_name                                                                  |
| current_count | current_alloc | current_avg_alloc | high_count | high_alloc | high_avg_alloc |
|-----------------------------------------------------------------------|
| memory/innodb/hash0hash                                                  | 4 | 79.07 MiB | 19.77 MiB | 4 | 79.07 MiB | 19.77 MiB      |
| memory/innodb/os0event                                                  | 439372 | 60.34 MiB | 144 bytes | 439372 | 60.34 MiB | 144 bytes    |
| memory/performance_schema/events_statements_summary_by_digest            | 1 | 40.28 MiB | 40.28 MiB | 1 | 40.28 MiB | 40.28 MiB      |
| memory/mysys/KEY_CACHE                                                  | 3 | 16.00 MiB | 5.33 MiB  | 3 | 16.00 MiB | 5.33 MiB       |
| memory/performance_schema/events_statements_history_long                 | 1 | 14.34 MiB | 14.34 MiB | 1 | 14.34 MiB | 14.34 MiB      |
| memory/performance_schema/events_errors_summary_by_thread_by_error       | 257 | 13.07 MiB | 52.06 KiB | 257 | 13.07 MiB | 52.06 KiB      |
| memory/performance_schema/events_statements_summary_by_thread_by_event_name | 1 | 11.81 MiB | 11.81 MiB | 1 | 11.81 MiB | 11.81 MiB      |
| memory/performance_schema/events_statements_summary_by_digest.digest_text | 1 | 9.77 MiB  | 9.77 MiB  | 1 | 9.77 MiB  | 9.77 MiB       |
| memory/performance_schema/events_statements_history_long.digest_text     | 1 | 9.77 MiB  | 9.77 MiB  | 1 | 9.77 MiB  | 9.77 MiB       |
| memory/performance_schema/events_statements_history_long.sql_text        | 1 | 9.77 MiB  | 9.77 MiB  | 1 | 9.77 MiB  | 9.77 MiB       |
+-----------------------------------------------------------------------+
10 rows in set (0.01 sec)
Expanding the view to order by high_alloc, we can now see that the memory/temptable/physical_ram component is a very good candidate here. At its highest, it consumed 515.00 MiB.

As its name suggests, memory/temptable/physical_ram instruments memory usage for the TEMP storage engine in MySQL, which was introduced in MySQL 8.0. For more information on how MySQL uses temporary tables, see Internal temporary table use in MySQL in the MySQL documentation.

**Note**

We're using the sys.x$memory_global_by_current_bytes view in this example.

```sql
mysql> SELECT event_name, format_bytes(current_alloc) AS "currently allocated",
    sys.format_bytes(high_alloc) AS "high-water mark"
FROM sys.x$memory_global_by_current_bytes ORDER BY high_alloc DESC LIMIT 10;
```

```
+-----------------------------------------------------------------------------
| event_name                                                                  |
 currently allocated | high-water mark |
+-----------------------------------------------------------------------------
| memory/temptable/physical_ram                                               | 4.00 MiB        |
| memory/innodb/hash0hash                                                     | 79.07 MiB       |
| memory/innodb/os0event                                                      | 63.95 MiB       |
| memory/performance_schema/events_statements_summary_by_digest               | 40.28 MiB       |
| memory/performance_schema/events_statements_history_long                    | 14.34 MiB       |
| memory/performance_schema/events_errors_summary_by_thread_by_error          | 13.07 MiB       |
| memory/performance_schema/events_statements_summary_by_thread_by_event_name | 11.81 MiB       |
| memory/performance_schema/events_statements_summary_by_digest.digest_text   | 9.77 MiB        |
```
In Example 1: Continuous high memory usage, we checked the current memory usage for each connection to determine which connection is responsible for using the memory in question. In this example, the memory is already freed, so checking the memory usage for current connections isn't useful.

To dig deeper and find the offending statements, users, and hosts, we use the Performance Schema. The Performance Schema contains multiple statement summary tables that are sliced by different dimensions such as event name, statement digest, host, thread, and user. Each view will allow you dig deeper into where certain statements are being run and what they are doing. This section is focused on MAX_TOTAL_MEMORY, but you can find more information on all of the columns available in the Performance Schema statement summary tables documentation.

First we check `events_statements_summary_by_digest` to see MAX_TOTAL_MEMORY.

From this we can see the following:

- The query with digest `20676ce4a690592ff05debcfc26faeb76f22005e7628364d7a498769d0c4a` seems to be a good candidate for this memory usage. The MAX_TOTAL_MEMORY is 537450710, which
matches the high-water mark we saw for the memory/temptable/physical_ram event in sys.x$memory_global_by_current_bytes.

- It has been run four times (COUNT_STAR), first at 2024-03-26 04:08:34.943256, and last at 2024-03-26 04:43:06.998310.

```sql
mysql> SELECT SCHEMA_NAME,DIGEST,COUNT_STAR,MAX_TOTAL_MEMORY,FIRST_SEEN,LAST_SEEN
    FROM performance_schema.events_statements_summary_by_digest ORDER BY MAX_TOTAL_MEMORY DESC LIMIT 5;
```

```
+-------------+------------------------------------------------------------------+
| SCHEMA_NAME | DIGEST                                                           |
| COUNT_STAR  | MAX_TOTAL_MEMORY | FIRST_SEEN             | LAST_SEEN |

+-------------+------------------------------------------------------------------+
5 rows in set (0.00 sec)
```

Now that we know the offending digest, we can get more details such as the query text, the user who ran it, and where it was run. Based on the digest text returned, we can see that this is a common table expression (CTE) that creates four temporary tables and performs four table scans, which is very inefficient.

```sql
mysql> SELECT
    SCHEMA_NAME,DIGEST_TEXT,QUERY_SAMPLE_TEXT,MAX_TOTAL_MEMORY,SUM_ROWS_SENT,SUM_ROWS_EXAMINED,SUM_CREATED_TMP_TABLES,SUM_NO_INDEX_USED
    FROM performance_schema.events_statements_summary_by_digest
```

Now that we know the offending digest, we can get more details such as the query text, the user who ran it, and where it was run. Based on the digest text returned, we can see that this is a common table expression (CTE) that creates four temporary tables and performs four table scans, which is very inefficient.
WHERE DIGEST='20676ce4a690592ff05debcffcbc26faeb76f22005e7628364d7a498769d0c4a'\G;

**Troubleshooting out-of-memory issues for Aurora MySQL databases**

The Aurora MySQL `aurora_oom_response` instance-level parameter can enable the DB instance to monitor the system memory and estimate the memory consumed by various statements and connections. If the system runs low on memory, it can perform a list of actions to attempt to release that memory. It does so in an attempt to avoid a database restart due to out-of-memory (OOM) issues. The instance-level parameter takes a string of comma-separated actions that a DB instance performs when its memory is low. The `aurora_oom_response` parameter is supported for Aurora MySQL versions 2 and 3.
The following values, and combinations of them, can be used for the `aurora_oom_response` parameter. An empty string means that no action is taken, and effectively turns off the feature, leaving the database prone to OOM restarts.

- **decline** – Declines new queries when the DB instance is low on memory.
- **kill_connect** – Closes database connections that are consuming a large amount of memory, and ends current transactions and Data Definition Language (DDL) statements. This response isn't supported for Aurora MySQL version 2.

For more information, see [KILL statement](https://dev.mysql.com/doc/refman/8.0/en/kill.html) in the MySQL documentation.

- **kill_query** – Ends queries in descending order of memory consumption until the instance memory surfaces above the low threshold. DDL statements aren't ended.

For more information, see [KILL statement](https://dev.mysql.com/doc/refman/8.0/en/kill.html) in the MySQL documentation.

- **print** – Only prints the queries that are consuming a large amount of memory.
- **tune** – Tunes the internal table caches to release some memory back to the system. Aurora MySQL decreases the memory used for caches such as `table_open_cache` and `table_definition_cache` in low-memory conditions. Eventually, Aurora MySQL sets their memory usage back to normal when the system is no longer low on memory.

For more information, see [table_open_cache](https://dev.mysql.com/doc/refman/8.0/en/innodb-parameters.html#sysvar_table_open_cache) and [table_definition_cache](https://dev.mysql.com/doc/refman/8.0/en/innodb-parameters.html#sysvar_table_definition_cache) in the MySQL documentation.

- **tune_buffer_pool** – Decreases the size of the buffer pool to release some memory and make it available for the database server to process connections. This response is supported for Aurora MySQL version 3.06 and higher.

You must pair `tune_buffer_pool` with either `kill_query` or `kill_connect` in the `aurora_oom_response` parameter value. If not, buffer pool resizing won't happen, even when you include `tune_buffer_pool` in the parameter value.

In Aurora MySQL versions lower than 3.06, for DB instance classes with memory less than or equal to 4 GiB, when the instance is under memory pressure, the default actions include `print`, `tune`, `decline`, and `kill_query`. For DB instance classes with memory greater than 4 GiB, the parameter value is empty by default (disabled).
In Aurora MySQL version 3.06 and higher, for DB instance classes with memory less than or equal to 4 GiB, Aurora MySQL also closes the top memory-consuming connections (kill_connect). For DB instance classes with memory greater than 4 GiB, the default parameter value is print.

If you frequently run into out-of-memory issues, memory usage can be monitored using memory summary tables when performance_schema is enabled.

Logging for Aurora MySQL databases

Aurora MySQL logs provide essential information about database activity and errors. By enabling these logs, you can identify and troubleshoot issues, understand database performance, and audit database activity. We recommend that you enable these logs for all of your Aurora MySQL DB instances to ensure optimal performance and availability of the databases. The following types of logging can be enabled. Each log contains specific information that can lead to uncovering impacts to database processing.

• Error – Aurora MySQL writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server didn't encounter an error that would result in a log entry. Error logging is enabled by default. For more information, see Aurora MySQL error logs.

• General – The general log provides detailed information about database activity, including all SQL statements executed by the database engine. For more information on enabling general logging and setting logging parameters, see Aurora MySQL slow query and general logs, and The general query log in the MySQL documentation.

Note
General logs can grow to be very large and consume your storage. For more information, see Log rotation and retention for Aurora MySQL.

• Slow query – The slow query log consists of SQL statements that take more than long_query_time seconds to run and require at least min_examined_row_limit rows to be examined. You can use the slow query log to find queries that take a long time to run and are therefore candidates for optimization.

The default value for long_query_time is 10 seconds. We recommend that you start with a high value to identify the slowest queries, then work your way down for fine tuning.
You can also use related parameters, such as `log_slow_admin_statements` and `log_queries_not_using_indexes`. Compare `rows_examined` with `rows_returned`. If `rows_examined` is much greater than `rows_returned`, then those queries can potentially be blocking.

In Aurora MySQL version 3, you can enable `log_slow_extra` to obtain more details. For more information, see [Slow query log contents](#) in the MySQL documentation. You can also modify `long_query_time` at the session level for debugging query execution interactively, which is especially useful if `log_slow_extra` is enabled globally.

For more information on enabling slow query logging and setting logging parameters, see [Aurora MySQL slow query and general logs](#) and [The slow query log](#) in the MySQL documentation.

- **Audit** – The audit log monitors and logs database activity. Audit logging for Aurora MySQL is called Advanced Auditing. To enable Advanced Auditing, you set certain DB cluster parameters. For more information, see [Using Advanced Auditing with an Amazon Aurora MySQL DB cluster](#).

- **Binary** – The binary log (binlog) contains events that describe database changes, such as table creation operations and changes to table data. It also contains events for statements that potentially could have made changes (for example, a `DELETE` that matched no rows), unless row-based logging is used. The binary log also contains information about how long each statement took that updated data.

Running a server with binary logging enabled makes performance slightly slower. However, the benefits of the binary log in enabling you to set up replication and for restore operations generally outweigh this minor performance decrease.

---

**Note**

Aurora MySQL doesn't require binary logging for restore operations.

---

For more information on enabling binary logging and setting the binlog format, see [Configuring Aurora MySQL binary logging](#), and [The binary log](#) in the MySQL documentation.

You can publish the error, general, slow, query, and audit logs to Amazon CloudWatch Logs. For more information, see [Publishing database logs to Amazon CloudWatch Logs](#).
Another useful tool for summarizing slow, general, and binary log files is `pt-query-digest`.

### Troubleshooting query performance for Aurora MySQL databases

MySQL provides [query optimizer control](#) through system variables that affect how query plans are evaluated, switchable optimizations, optimizer and index hints, and the optimizer cost model. These data points can be helpful not only while comparing different MySQL environments, but also to compare previous query execution plans with current execution plans, and to understand the overall execution of a MySQL query at any point.

Query performance depends on many factors, including the execution plan, table schema and size, statistics, resources, indexes, and parameter configuration. Query tuning requires identifying bottlenecks and optimizing the execution path.

- Find the execution plan for the query and check whether the query is using appropriate indexes. You can optimize your query by using `EXPLAIN` and reviewing the details of each plan.
- Aurora MySQL version 3 (compatible with MySQL 8.0 Community Edition) uses an `EXPLAIN ANALYZE` statement. The `EXPLAIN ANALYZE` statement is a profiling tool that shows where MySQL spends time on your query and why. With `EXPLAIN ANALYZE`, Aurora MySQL plans, prepares, and runs the query while counting rows and measuring the time spent at various points of the execution plan. When the query completes, `EXPLAIN ANALYZE` prints the plan and its measurements instead of the query result.
- Keep your schema statistics updated by using the `ANALYZE` statement. The query optimizer can sometimes choose poor execution plans because of outdated statistics. This can lead to poor performance of a query because of inaccurate cardinality estimates of both tables and indexes. The `last_update` column of the `innodb_table_stats` table shows the last time your schema statistics were updated, which is a good indicator of "staleness."
- Other issues can occur, such as distribution skew of data, that aren't taken into account for table cardinality. For more information, see [Estimating ANALYZE TABLE complexity for InnoDB tables](#) and [Histogram statistics in MySQL](#) in the MySQL documentation.

### Understanding the time spent by queries

The following are ways to determine the time spent by queries:

- **Profiling**
- **Performance Schema**
Profiling

By default, profiling is disabled. Enable profiling, then run the slow query and review its profile.

```
SET profiling = 1;
Run your query.
SHOW PROFILE;
```

1. Identify the stage where the most time is spent. According to General thread states in the MySQL documentation, reading and processing rows for a SELECT statement is often the longest-running state over the lifetime of a given query. You can use the EXPLAIN statement to understand how MySQL runs this query.

2. Review the slow query log to evaluate `rows_examined` and `rows_sent` to make sure that the workload is similar in each environment. For more information, see Logging for Aurora MySQL databases.

3. Run the following command for tables that are part of the identified query:

```
SHOW TABLE STATUS\G;
```

4. Capture the following outputs before and after running the query on each environment:

```
SHOW GLOBAL STATUS;
```

5. Run the following commands on each environment to see if there are any other query/session influencing the performance of this sample query.

```
SHOW FULL PROCESSLIST;
SHOW ENGINE INNODB STATUS\G;
```

Sometimes, when resources on the server are busy, it impacts every other operation on the server, including queries. You can also capture information periodically when queries are run or set up a cron job to capture information at useful intervals.
Performance Schema

The Performance Schema provides useful information about server runtime performance, while having minimal impact on that performance. This is different from the information_schema, which provides schema information about the DB instance. For more information, see Turning on the Performance Schema for Performance Insights on Aurora MySQL.

Query optimizer trace

To understand why a particular query plan was chosen for execution, you can set up optimizer_trace to access the MySQL query optimizer.

Run an optimizer trace to show extensive information on all the paths available to the optimizer and its choice.

```
SET SESSION OPTIMIZER_TRACE="enabled=on";
SET optimizer_trace_offset=-5, optimizer_trace_limit=5;

-- Run your query.
SELECT * FROM table WHERE x = 1 AND y = 'A';

-- After the query completes:
SELECT * FROM information_schema.OPTIMIZER_TRACE;
SET SESSION OPTIMIZER_TRACE="enabled=off";
```

Reviewing query optimizer settings

Aurora MySQL version 3 (compatible with MySQL 8.0 Community Edition) has many optimizer-related changes compared with Aurora MySQL version 2 (compatible with MySQL 5.7 Community Edition). If you have some custom values for the optimizer_switch, we recommend that you review the differences in the defaults and set optimizer_switch values that work best for your workload. We also recommend that you test the options available for Aurora MySQL version 3 to examine how your queries perform.

Note

Aurora MySQL version 3 uses the community default value of 20 for the innodb_stats_persistent_sample_pages parameter.
You can use the following command to show the optimizer_switch values:

```
SELECT @@optimizer_switch\G;
```

The following table shows the default optimizer_switch values for Aurora MySQL versions 2 and 3.

<table>

For more information, see [Switchable optimizations (MySQL 5.7)](https://dev.mysql.com/doc/refman/5.7/en) and [Switchable optimizations (MySQL 8.0)](https://dev.mysql.com/doc/refman/8.0/en) in the MySQL documentation.
Amazon Aurora MySQL reference

This reference includes information about Aurora MySQL parameters, status variables, and general SQL extensions or differences from the community MySQL database engine.

Topics

- Aurora MySQL configuration parameters
- Aurora MySQL wait events
- Aurora MySQL thread states
- Aurora MySQL isolation levels
- Aurora MySQL hints
- Aurora MySQL stored procedures
- Aurora MySQL–specific information_schema tables

Aurora MySQL configuration parameters

You manage your Amazon Aurora MySQL DB cluster in the same way that you manage other Amazon RDS DB instances, by using parameters in a DB parameter group. Amazon Aurora differs from other DB engines in that you have a DB cluster that contains multiple DB instances. As a result, some of the parameters that you use to manage your Aurora MySQL DB cluster apply to the entire cluster. Other parameters apply only to a particular DB instance in the DB cluster.

To manage cluster-level parameters, use DB cluster parameter groups. To manage instance-level parameters, use DB parameter groups. Each DB instance in an Aurora MySQL DB cluster is compatible with the MySQL database engine. However, you apply some of the MySQL database engine parameters at the cluster level, and you manage these parameters using DB cluster parameter groups. You can't find cluster-level parameters in the DB parameter group for an instance in an Aurora DB cluster. A list of cluster-level parameters appears later in this topic.

You can manage both cluster-level and instance-level parameters using the AWS Management Console, the AWS CLI, or the Amazon RDS API. You use separate commands for managing cluster-level parameters and instance-level parameters. For example, you can use the `modify-db-cluster-parameter-group` CLI command to manage cluster-level parameters in a DB cluster parameter group. You can use the `modify-db-parameter-group` CLI command to manage instance-level parameters in a DB parameter group for a DB instance in a DB cluster.
You can view both cluster-level and instance-level parameters in the console, or by using the CLI or RDS API. For example, you can use the `describe-db-cluster-parameters` AWS CLI command to view cluster-level parameters in a DB cluster parameter group. You can use the `describe-db-parameters` CLI command to view instance-level parameters in a DB parameter group for a DB instance in a DB cluster.

### Note

Each [default parameter group](#) contains the default values for all parameters in the parameter group. If the parameter has "engine default" for this value, see the version-specific MySQL or PostgreSQL documentation for the actual default value. Unless otherwise noted, parameters listed in the following tables are valid for Aurora MySQL versions 2 and 3.

For more information about DB parameter groups, see [Working with parameter groups](#). For rules and restrictions for Aurora Serverless v1 clusters, see [Parameter groups for Aurora Serverless v1](#).

| `init_connect`              | Yes        | The command to be run by the server for each client that connects. Use double quotes (") for settings to avoid connection failures, for example:  
|                             |            | ``` SET optimizer_switch="hash_join=off" ```                                                                                         |
|                             |            | In Aurora MySQL version 3, this parameter doesn't apply for users who have the CONNECTION_ADMIN privilege. This includes the Aurora master user. For more information, see [Role-based privilege model](#). |
| `innodb_adaptive_hash_index`| Yes        | You can modify this parameter at the DB cluster level in Aurora MySQL versions 2 and 3.                                                      |
|                             |            | The Adaptive Hash Index isn't supported on reader DB instances.                                                                       |
### Parameter name | Modifiable | Notes
--- | --- | ---
innodb_aurora_instant_alter_column_allowed | Yes | Controls whether the INSTANT algorithm can be used for ALTER COLUMN operations at the global level. The allowed values are the following:
- 0 – The INSTANT algorithm isn't allowed for ALTER COLUMN operations (OFF). Reverts to other algorithms.
- 1 – The INSTANT algorithm is allowed for ALTER COLUMN operations (ON). This is the default value.
For more information, see [Column Operations](#) in the MySQL documentation.
This parameter applies to Aurora MySQL version 3.05 and higher.

innodb_autoinc_lock_mode | Yes |  

innodb_checksums | No | Removed from Aurora MySQL version 3.

innodb_cmp_per_index_enabled | Yes |  

innodb_commit_concurrency | Yes |  

innodb_data_home_dir | No | Aurora MySQL uses managed instances where you don't access the file system directly.

</tbody>
</table>
### Parameter name | Modifiable | Notes
--- | --- | ---
innodb_aurora_max_partitions_for_range | Yes | In some cases where persisted statistics aren’t available, you can use this parameter to improve the performance of row count estimations on partitioned tables. You can set it to a value from 0–8192, where the value determines the number of partitions to check during row count estimation. The default value is 0, which estimates using all of the partitions, consistent with default MySQL behavior. This parameter is available for Aurora MySQL version 3.03.1 and higher.

innodb_autoextend_increment | Yes

innodb_buffer_pool_dump_at_shutdown | No

innodb_buffer_pool_dump_now | No

innodb_buffer_pool_filename | No

innodb_buffer_pool_load_abort | No

innodb_buffer_pool_load_at_startup | No

innodb_buffer_pool_load_now | No

<tr>
<td>read_only</td>
<td>Yes</td>
<td>When this parameter is turned on, the server permits no updates except from those performed by replica threads. For Aurora MySQL version 2, valid values are the following: • 0 – OFF • 1 – ON • {TrueIfReplica} – ON for read replicas. This is the default value. • {TrueIfClusterReplica} – ON for instances in replica clusters such as cross-Region read replicas, secondary clusters in an Aurora global database, and blue/green deployments. We recommend that you use the DB cluster parameter group in Aurora MySQL version 2 to make sure that the read_only parameter is applied to new writer instances on failover.</td>
</tr>
</tbody>
</table>

**Note**
Reader instances are always read only, because Aurora MySQL sets innodb_read_only to 1 on all readers. Therefore, read_only is redundant on reader instances.

<td>Yes</td>
<td></td>
</tr>
</tbody>
</table>
### Parameter name | Modifiable | Notes
--- | --- | ---
tx_isolation | Yes | Removed from Aurora MySQL version 3. It is replaced by transaction_isolation.
updatable_views_with_limit | Yes |
validate-password | No |
validate_password_dictionary_file | No |
validate_password_length | No |
validate_password_mixed_case_count | No |
validate_password_number_count | No |
validate_password_policy | No |
validate_password_special_character_count | No |
wait_timeout | Yes | Aurora evaluates the minimum value of interactive_timeout and wait_timeout. It then uses that minimum as the timeout to end all idle sessions, both interactive and noninteractive.

**MySQL parameters that don't apply to Aurora MySQL**

Because of architectural differences between Aurora MySQL and MySQL, some MySQL parameters don't apply to Aurora MySQL.

The following MySQL parameters don't apply to Aurora MySQL. This list isn't exhaustive.
- activate_all_roles_on_login – This parameter doesn't apply to Aurora MySQL version 2. It is available in Aurora MySQL version 3.
- big_tables
- bind_address
- character_sets_dir
- innodb_adaptive_flushing
- innodb_adaptive_flushing_lwm
- innodb_buffer_pool_chunk_size
- innodb_buffer_pool_instances
- innodb_change_buffering
- innodb_checksum_algorithm
- innodb_data_file_path
- innodb_dedicated_server
- innodb_doublewrite
- innodb_flush_log_at_timeout – This parameter doesn't apply to Aurora MySQL. For more information, see Configuring how frequently the log buffer is flushed.
- innodb_flush_method
- innodb_flush_neighbors
- innodb_io_capacity
- innodb_io_capacity_max
- innodb_log_buffer_size
- innodb_log_file_size
- innodb_log_files_in_group
- innodb_log_spin_cpu_abs_lwm
- innodb_log_spin_cpu_pct_hwm
- innodb_log_writer_threads
- innodb_max_dirty_pages_pct
- innodb_numa_interleave
- innodb_page_size
- innodb_redo_log_capacity
- innodb_redo_log_encrypt
- innodb_undo_log_encrypt
- innodb_undo_log_truncate
- innodb_undo_logs
- innodb_undo_tablespaces
- innodb_use_native_aio
- innodb_write_io_threads

Aurora MySQL global status variables

You can find the current values for Aurora MySQL global status variables by using a statement such as the following:

```sql
show global status like '%aurora%';
```

The following table describes the global status variables that Aurora MySQL uses.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AuroraDb_commits</td>
<td>The total number of commits since the last restart.</td>
</tr>
<tr>
<td>AuroraDb_commit_latency</td>
<td>The aggregate commit latency since the last restart.</td>
</tr>
<tr>
<td>AuroraDb_ddl_stmt_duration</td>
<td>The aggregate DDL latency since the last restart.</td>
</tr>
<tr>
<td>AuroraDb_select_stmt_duration</td>
<td>The aggregate SELECT statement latency since the last restart.</td>
</tr>
<tr>
<td>AuroraDb_insert_stmt_duration</td>
<td>The aggregate INSERT statement latency since the last restart.</td>
</tr>
<tr>
<td>AuroraDb_update_stmt_duration</td>
<td>The aggregate UPDATE statement latency since the last restart.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>AuroraDb_delete_stmt_duration</td>
<td>The aggregate DELETE statement latency since the last restart.</td>
</tr>
<tr>
<td>Aurora_binlog_io_cache_allocated</td>
<td>The number of bytes allocated to the binlog I/O cache.</td>
</tr>
<tr>
<td>Aurora_binlog_io_cache_read_requests</td>
<td>The number of read requests made to the binlog I/O cache.</td>
</tr>
<tr>
<td>Aurora_binlog_io_cache_reads</td>
<td>The number of read requests that were served from the binlog I/O cache.</td>
</tr>
<tr>
<td>Aurora_enhanced_binlog</td>
<td>Indicates whether enhanced binlog is enabled or disabled for this DB instance. For more information, see <a href="#">Setting up enhanced binlog</a>.</td>
</tr>
<tr>
<td>Aurora_external_connection_count</td>
<td>The number of database connections to the DB instance, excluding RDS service connections used for database health checks.</td>
</tr>
<tr>
<td>Aurora_fast_insert_cache_hits</td>
<td>A counter that's incremented when the cached cursor is successfully retrieved and verified. For more information on the fast insert cache, see <a href="#">Amazon Aurora MySQL performance enhancements</a>.</td>
</tr>
<tr>
<td>Aurora_fast_insert_cache_misses</td>
<td>A counter that's incremented when the cached cursor is no longer valid and Aurora performs a normal index traversal. For more information on the fast insert cache, see <a href="#">Amazon Aurora MySQL performance enhancements</a>.</td>
</tr>
<tr>
<td>Aurora_fts_cache_memory_used</td>
<td>The amount of memory in bytes that the InnoDB full-text search system is using. This variable applies to Aurora MySQL version 3.07 and higher.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>Aurora_fwd_master_dml_stmt_count</code></td>
<td>The total number of DML statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 2.</td>
</tr>
<tr>
<td><code>Aurora_fwd_master_dml_stmt_duration</code></td>
<td>The total duration of DML statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 2.</td>
</tr>
<tr>
<td><code>Aurora_fwd_master_errors_rpc_timeout</code></td>
<td>The number of times a forwarded connection failed to be established on the writer.</td>
</tr>
<tr>
<td><code>Aurora_fwd_master_errors_session_limit</code></td>
<td>The number of forwarded queries that get rejected due to session full on the writer.</td>
</tr>
<tr>
<td><code>Aurora_fwd_master_errors_session_timeout</code></td>
<td>The number of times a forwarding session is ended due to a timeout on the writer.</td>
</tr>
<tr>
<td><code>Aurora_fwd_master_open_sessions</code></td>
<td>The number of forwarded sessions on the writer DB instance. This variable applies to Aurora MySQL version 2.</td>
</tr>
<tr>
<td><code>Aurora_fwd_master_select_stmt_count</code></td>
<td>The total number of SELECT statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 2.</td>
</tr>
<tr>
<td><code>Aurora_fwd_master_select_stmt_duration</code></td>
<td>The total duration of SELECT statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 2.</td>
</tr>
<tr>
<td><code>Aurora_fwd_writer_dml_stmt_count</code></td>
<td>The total number of DML statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 3.</td>
</tr>
<tr>
<td><code>Aurora_fwd_writer_dml_stmt_duration</code></td>
<td>The total duration of DML statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 3.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Aurora_fwd_writer_errors_crc_timeout</td>
<td>The number of times a forwarded connection failed to be established on the writer.</td>
</tr>
<tr>
<td>Aurora_fwd_writer_errors_session_limit</td>
<td>The number of forwarded queries that get rejected due to session full on the writer.</td>
</tr>
<tr>
<td>Aurora_fwd_writer_errors_session_timeout</td>
<td>The number of times a forwarding session is ended due to a timeout on the writer.</td>
</tr>
<tr>
<td>Aurora_fwd_writer_open_sessions</td>
<td>The number of forwarded sessions on the writer DB instance. This variable applies to Aurora MySQL version 3.</td>
</tr>
<tr>
<td>Aurora_fwd_writer_select_stmt_count</td>
<td>The total number of SELECT statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 3.</td>
</tr>
<tr>
<td>Aurora_fwd_writer_select_stmt_duration</td>
<td>The total duration of SELECT statements forwarded to this writer DB instance. This variable applies to Aurora MySQL version 3.</td>
</tr>
<tr>
<td>Aurora_lockmgr_buffer_pool_memory_used</td>
<td>The amount of buffer pool memory in bytes that the Aurora MySQL lock manager is using.</td>
</tr>
<tr>
<td>Aurora_lockmgr_memory_used</td>
<td>The amount of memory in bytes that the Aurora MySQL lock manager is using.</td>
</tr>
<tr>
<td>Aurora_ml_actual_request_cnt</td>
<td>The aggregate request count that Aurora MySQL makes to the Aurora machine learning services across all queries run by users of the DB instance. For more information, see Using Amazon Aurora machine learning with Aurora MySQL.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Aurora_ml_actual_response_cnt</td>
<td>The aggregate response count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance. For more information, see <a href="#">Using Amazon Aurora machine learning with Aurora MySQL</a>.</td>
</tr>
<tr>
<td>Aurora_ml_cache_hit_cnt</td>
<td>The aggregate internal cache hit count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance. For more information, see <a href="#">Using Amazon Aurora machine learning with Aurora MySQL</a>.</td>
</tr>
<tr>
<td>Aurora_ml_logical_request_cnt</td>
<td>The number of logical requests that the DB instance has evaluated to be sent to the Aurora machine learning services since the last status reset. Depending on whether batching has been used, this value can be higher than Aurora_ml_actual_request_cnt. For more information, see <a href="#">Using Amazon Aurora machine learning with Aurora MySQL</a>.</td>
</tr>
<tr>
<td>Aurora_ml_logical_response_cnt</td>
<td>The aggregate response count that Aurora MySQL receives from the Aurora machine learning services across all queries run by users of the DB instance. For more information, see <a href="#">Using Amazon Aurora machine learning with Aurora MySQL</a>.</td>
</tr>
<tr>
<td>Aurora_ml_retry_request_cnt</td>
<td>The number of retried requests that the DB instance has sent to the Aurora machine learning services since the last status reset. For more information, see <a href="#">Using Amazon Aurora machine learning with Aurora MySQL</a>.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Aurora_ml_single_request_cnt</strong></td>
<td>The aggregate count of Aurora machine learning functions that are evaluated by non-batch mode across all queries run by users of the DB instance. For more information, see <a href="https://example.com">Using Amazon Aurora machine learning with Aurora MySQL</a>.</td>
</tr>
<tr>
<td><strong>aurora_oom_avoidance_recovery_state</strong></td>
<td>Indicates whether Aurora out-of-memory (OOM) avoidance recovery is in the ACTIVE or INACTIVE state for this DB instance.</td>
</tr>
<tr>
<td><strong>aurora_oom_reserved_mem_enter_kb</strong></td>
<td>Represents the threshold for entering the RESERVED state in Aurora's OOM handling mechanism.</td>
</tr>
<tr>
<td></td>
<td>When the available memory on the server falls below this threshold, <code>aurora_oom_status</code> changes to RESERVED, indicating that the server is approaching a critical level of memory usage.</td>
</tr>
<tr>
<td><strong>aurora_oom_reserved_mem_exit_kb</strong></td>
<td>Represents the threshold for exiting the RESERVED state in Aurora's OOM handling mechanism.</td>
</tr>
<tr>
<td></td>
<td>When the available memory on the server rises above this threshold, <code>aurora_oom_status</code> reverts to NORMAL, indicating that the server has returned to a more stable state with sufficient memory resources.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>aurora_oom_status</td>
<td>Represents the current OOM status of this DB instance. When the value is NORMAL, it indicates that there are sufficient memory resources. If the value changes to RESERVED, it signifies that the server has entered an OOM state, indicating critically low available memory.</td>
</tr>
<tr>
<td>Aurora_pq_bytes_returned</td>
<td>The number of bytes for the tuple data structures transmitted to the head node during parallel queries. Divide by 16,384 to compare against Aurora_pq_pages_pushed_down.</td>
</tr>
<tr>
<td>Aurora_pq_max_concurrent_requests</td>
<td>The maximum number of parallel query sessions that can run concurrently on this Aurora DB instance. This is a fixed number that depends on the AWS DB instance class.</td>
</tr>
<tr>
<td>Aurora_pq_pages_pushed_down</td>
<td>The number of data pages (each with a fixed size of 16 KiB) where parallel query avoided a network transmission to the head node.</td>
</tr>
<tr>
<td>Aurora_pq_request_attempted</td>
<td>The number of parallel query sessions requested. This value might represent more than one session per query, depending on SQL constructs such as subqueries and joins.</td>
</tr>
<tr>
<td>Aurora_pq_request_executed</td>
<td>The number of parallel query sessions run successfully.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Aurora_pq_request_failed</strong></td>
<td>The number of parallel query sessions that returned an error to the client. In some cases, a request for a parallel query might fail, for example due to a problem in the storage layer. In these cases, the query part that failed is retried using the nonparallel query mechanism. If the retried query also fails, an error is returned to the client and this counter is incremented.</td>
</tr>
<tr>
<td><strong>Aurora_pq_request_in_progress</strong></td>
<td>The number of parallel query sessions currently in progress. This number applies to the particular Aurora DB instance that you are connected to, not the entire Aurora DB cluster. To see if a DB instance is close to its concurrency limit, compare this value to <strong>Aurora_pq_max_concurrent_requests</strong>.</td>
</tr>
<tr>
<td><strong>Aurora_pq_request_not_chosen</strong></td>
<td>The number of times parallel query wasn't chosen to satisfy a query. This value is the sum of several other more granular counters. An EXPLAIN statement can increment this counter even though the query isn't actually performed.</td>
</tr>
<tr>
<td><strong>Aurora_pq_request_not_chosen_below_min_rows</strong></td>
<td>The number of times parallel query wasn't chosen due to the number of rows in the table. An EXPLAIN statement can increment this counter even though the query isn't actually performed.</td>
</tr>
<tr>
<td><strong>Aurora_pq_request_not_chosen_column_bit</strong></td>
<td>The number of parallel query requests that use the nonparallel query processing path because of an unsupported data type in the list of projected columns.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_column_geometry</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the table has columns with the GEOMETRY data type. For information about Aurora MySQL versions that remove this limitation, see <a href="#">Upgrading parallel query clusters to Aurora MySQL version 3</a>.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_column_lob</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the table has columns with a LOB data type, or VARCHAR columns that are stored externally due to the declared length. For information about Aurora MySQL versions that remove this limitation, see <a href="#">Upgrading parallel query clusters to Aurora MySQL version 3</a>.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_column_virtual</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the table contains a virtual column.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_custom_charset</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the table has columns with a custom character set.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_fast_ddl</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the table is currently being altered by a fast DDL ALTER statement.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_few_pages_outside_buffer_pool</td>
<td>The number of times parallel query wasn't chosen, even though less than 95 percent of the table data was in the buffer pool, because there wasn't enough unbuffered table data to make parallel query worthwhile.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_full_text_index</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the table has full-text indexes.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_high_buffer_pool_pct</td>
<td>The number of times parallel query wasn't chosen because a high percentage of the table data (currently, greater than 95 percent) was already in the buffer pool. In these cases, the optimizer determines that reading the data from the buffer pool is more efficient. An EXPLAIN statement can increment this counter even though the query isn't actually performed.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_index_hint</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the query includes an index hint.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_innodb_table_format</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the table uses an unsupported InnoDB row format. Aurora parallel query only applies to the COMPACT, REDUNDANT, and DYNAMIC row formats.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_long_trx</td>
<td>The number of parallel query requests that used the nonparallel query processing path, due to the query being started inside a long-running transaction. An EXPLAIN statement can increment this counter even though the query isn't actually performed.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_no_where_clause</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the query doesn't include any WHERE clause.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_range_scan</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the query uses a range scan on an index.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_row_length_too_long</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the total combined length of all the columns is too long.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_small_table</td>
<td>The number of times parallel query wasn't chosen due to the overall size of the table, as determined by number of rows and average row length. An EXPLAIN statement can increment this counter even though the query isn't actually performed.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_temporary_table</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the query refers to temporary tables that use the unsupported MyISAM or memory table types.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_tx_isolation</td>
<td>The number of parallel query requests that use the nonparallel query processing path because query uses an unsupported transaction isolation level. On reader DB instances, parallel query only applies to the REPEATABLE READ and READ COMMITTED isolation levels.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_update_delete_stmts</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the query is part of an UPDATE or DELETE statement.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_unsupported_access</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the WHERE clause doesn't meet the criteria for parallel query. This result can occur if the query doesn't require a data-intensive scan, or if the query is a DELETE or UPDATE statement.</td>
</tr>
<tr>
<td>Aurora_pq_request_not_chosen_n_unsupported_storage_type</td>
<td>The number of parallel query requests that use the nonparallel query processing path because the Aurora MySQL DB cluster isn't using a supported Aurora cluster storage configuration. For more information, see Limitations.</td>
</tr>
<tr>
<td>Aurora_pq_request_throttled</td>
<td>The number of times parallel query wasn't chosen due to the maximum number of concurrent parallel queries already running on a particular Aurora DB instance.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Aurora_repl_bytes_received</td>
<td>Number of bytes replicated to an Aurora MySQL reader database instance since the last restart. For more information, see <a href="https://aws.amazon.com">Replication with Amazon Aurora MySQL</a>.</td>
</tr>
<tr>
<td>Aurora_reserved_mem_exceeded_incidents</td>
<td>The number of times since the last restart that the engine has exceeded reserved memory limits. If <code>aurora_oom_response</code> is configured, this threshold defines when out-of-memory (OOM) avoidance activities are triggered. For more information on the Aurora MySQL OOM response, see <a href="https://aws.amazon.com">Troubleshooting out-of-memory issues for Aurora MySQL databases</a>.</td>
</tr>
<tr>
<td>Aurora_thread_pool_thread_count</td>
<td>The current number of threads in the Aurora thread pool. For more information on the thread pool in Aurora MySQL, see <a href="https://aws.amazon.com">Thread pool</a>.</td>
</tr>
<tr>
<td>Aurora_tmz_version</td>
<td>Denotes the current version of the time zone information used by the DB cluster. The values follow the Internet Assigned Numbers Authority (IANA) format: YYYYsuffix, for example 2022a and 2023c. This parameter applies to Aurora MySQL version 2.12 and higher, and version 3.04 and higher.</td>
</tr>
<tr>
<td>Aurora_zdr_oom_threshold</td>
<td>Represents the memory threshold, in kilobytes (KB), for an Aurora DB instance to initiate a zero downtime restart (ZDR) to recover from potential memory-related issues.</td>
</tr>
</tbody>
</table>
### Name | Description
--- | ---
server_aurora_das_running | Indicates whether Database Activity Streams (DAS) are enabled or disabled on this DB instance. For more information, see [Monitoring Amazon Aurora with Database Activity Streams](https).

### MySQL status variables that don’t apply to Aurora MySQL

Because of architectural differences between Aurora MySQL and MySQL, some MySQL status variables don’t apply to Aurora MySQL.

The following MySQL status variables don’t apply to Aurora MySQL. This list isn’t exhaustive:

- innodb_buffer_pool_bytes_dirty
- innodb_buffer_pool_pages_dirty
- innodb_buffer_pool_pages_flushed

Aurora MySQL version 3 removes the following status variables that were in Aurora MySQL version 2:

- AuroraDb_lockmgr_bitmaps0_in_use
- AuroraDb_lockmgr_bitmaps1_in_use
- AuroraDb_lockmgr_bitmaps_mem_used
- AuroraDb_thread_deadlocks
- available_alter_table_log_entries
- Aurora_lockmgr_memory_used
- Aurora_missing_history_on_replica_incidents
- Aurora_new_lock_manager_lock_release_cnt
- Aurora_new_lock_manager_lock_release_total_duration_micro
- Aurora_new_lock_manager_lock_timeout_cnt
- Aurora_total_op_memory
• Aurora_total_op_temp_space
• Aurora_used_alter_table_log_entries
• Aurora_using_new_lock_manager
• Aurora_volume_bytes_allocated
• Aurora_volume_bytes_left_extent
• Aurora_volume_bytes_left_total
• Com_alter_db_upgrade
• Compression
• External_threads_connected
• Innodb_available undo_logs
• Last_query_cost
• Last_query_partial_plans
• Slave_heartbeat_period
• Slave_last_heartbeat
• Slave_received_heartbeats
• Slave_retried_transactions
• Slave_running
• Time_since_zero_connections

These MySQL status variables are available in Aurora MySQL version 2, but they aren't available in
Aurora MySQL version 3:

• Innodb_redo_log_enabled
• Innodb_undo_tablespaces_total
• Innodb_undo_tablespaces_implicit
• Innodb_undo_tablespaces_explicit
• Innodb_undo_tablespaces_active

**Aurora MySQL wait events**

The following are some common wait events for Aurora MySQL.
Note

For information on tuning Aurora MySQL performance using wait events, see Tuning Aurora MySQL with wait events.
For information about the naming conventions used in MySQL wait events, see Performance Schema instrument naming conventions in the MySQL documentation.

cpu

The number of active connections that are ready to run is consistently higher than the number of vCPUs. For more information, see cpu.

io/aurora_redo_log_flush

A session is persisting data to Aurora storage. Typically, this wait event is for a write I/O operation in Aurora MySQL. For more information, see io/aurora_redo_log_flush.

io/aurora_respond_to_client

Query processing has completed and results are being returned to the application client for the following Aurora MySQL versions: 2.10.2 and higher 2.10 versions, 2.09.3 and higher 2.09 versions, and 2.07.7 and higher 2.07 versions. Compare the network bandwidth of the DB instance class with the size of the result set being returned. Also, check client-side response times. If the client is unresponsive and can't process the TCP packets, packet drops and TCP retransmissions can occur. This situation negatively affects network bandwidth. In versions lower than 2.10.2, 2.09.3, and 2.07.7, the wait event erroneously includes idle time. To learn how to tune your database when this wait is prominent, see io/aurora_respond_to_client.

io/file/csv/data

Threads are writing to tables in comma-separated value (CSV) format. Check your CSV table usage. A typical cause of this event is setting log_output on a table.

io/file/sql/binlog

A thread is waiting on a binary log (binlog) file that is being written to disk.

io/redo_log_flush

A session is persisting data to Aurora storage. Typically, this wait event is for a write I/O operation in Aurora MySQL. For more information, see io/redo_log_flush.
io/socket/sql/client_connection

The `mysqld` program is busy creating threads to handle incoming new client connections. For more information, see `io/socket/sql/client_connection`.

io/table/sql/handler

The engine is waiting for access to a table. This event occurs regardless of whether the data is cached in the buffer pool or accessed on disk. For more information, see `io/table/sql/handler`.

lock/table/sql/handler

This wait event is a table lock wait event handler. For more information about atom and molecule events in the Performance Schema, see `Performance Schema atom and molecule events` in the MySQL documentation.

synch/cond/innodb/row_lock_wait

Multiple data manipulation language (DML) statements are accessing the same database rows at the same time. For more information, see `synch/cond/innodb/row_lock_wait`.

synch/cond/innodb/row_lock_wait_cond

Multiple DML statements are accessing the same database rows at the same time. For more information, see `synch/cond/innodb/row_lock_wait_cond`.

synch/cond/sql/MDL_context::COND_wait_status

Threads are waiting on a table metadata lock. The engine uses this type of lock to manage concurrent access to a database schema and to ensure data consistency. For more information, see `Optimizing locking operations` in the MySQL documentation. To learn how to tune your database when this event is prominent, see `synch/cond/sql/MDL_context::COND_wait_status`.

synch/cond/sql/MYSQL_BIN_LOG::COND_done

You have turned on binary logging. There might be a high commit throughput, large number transactions committing, or replicas reading binlogs. Consider using multirow statements or bundling statements into one transaction. In Aurora, use global databases instead of binary log replication, or use the `aurora_binlog_*` parameters.

synch/mutex/innodb/aurora_lock_thread_slot_futex

Multiple DML statements are accessing the same database rows at the same time. For more information, see `synch/mutex/innodb/aurora_lock_thread_slot_futex`.
synch/mutex/innodb/buf_pool_mutex

The buffer pool isn't large enough to hold the working data set. Or the workload accesses pages from a specific table, which leads to contention in the buffer pool. For more information, see synch/mutex/innodb/buf_pool_mutex.

synch/mutex/innodb/fil_system_mutex

The process is waiting for access to the tablespace memory cache. For more information, see synch/mutex/innodb/fil_system_mutex.

synch/mutex/innodb/trx_sys_mutex

Operations are checking, updating, deleting, or adding transaction IDs in InnoDB in a consistent or controlled manner. These operations require a trx_sys mutex call, which is tracked by Performance Schema instrumentation. Operations include management of the transaction system when the database starts or shuts down, rollbacks, undo cleanups, row read access, and buffer pool loads. High database load with a large number of transactions results in the frequent appearance of this wait event. For more information, see synch/mutex/innodb/trx_sys_mutex.

synch/mutex/mysys/KEY_CACHE::cache_lock

The keycache->cache_lock mutex controls access to the key cache for MyISAM tables. While Aurora MySQL doesn't allow usage of MyISAM tables to store persistent data, they are used to store internal temporary tables. Consider checking the created_tmp_tables or created_tmp_disk_tables status counters, because in certain situations, temporary tables are written to disk when they no longer fit in memory.

synch/mutex/sql/FILE_AS_TABLE::LOCK_offsets

The engine acquires this mutex when opening or creating a table metadata file. When this wait event occurs with excessive frequency, the number of tables being created or opened has spiked.

synch/mutex/sql/FILE_AS_TABLE::LOCK_shim_lists

The engine acquires this mutex while performing operations such as reset_size, detach_contents, or add_contents on the internal structure that keeps track of opened tables. The mutex synchronizes access to the list contents. When this wait event occurs with high frequency, it indicates a sudden change in the set of tables that were previously accessed. The engine needs to access new tables or let go of the context related to previously accessed tables.
**synch/mutex/sql/LOCK_open**

The number of tables that your sessions are opening exceeds the size of the table definition cache or the table open cache. Increase the size of these caches. For more information, see How MySQL opens and closes tables.

**synch/mutex/sql/LOCK_table_cache**

The number of tables that your sessions are opening exceeds the size of the table definition cache or the table open cache. Increase the size of these caches. For more information, see How MySQL opens and closes tables.

**synch/mutex/sql/LOG**

In this wait event, there are threads waiting on a log lock. For example, a thread might wait for a lock to write to the slow query log file.

**synch/mutex/sql/MYSQL_BIN_LOG::LOCK_commit**

In this wait event, there is a thread that is waiting to acquire a lock with the intention of committing to the binary log. Binary logging contention can occur on databases with a very high change rate. Depending on your version of MySQL, there are certain locks being used to protect the consistency and durability of the binary log. In RDS for MySQL, binary logs are used for replication and the automated backup process. In Aurora MySQL, binary logs are not needed for native replication or backups. They are disabled by default but can be enabled and used for external replication or change data capture. For more information, see The binary log in the MySQL documentation.

**sync/mutex/sql/MYSQL_BIN_LOG::LOCK_dump_thread_metrics_collection**

If binary logging is turned on, the engine acquires this mutex when it prints active dump threads metrics to the engine error log and to the internal operations map.

**sync/mutex/sql/MYSQL_BIN_LOG::LOCK_inactive_binlogs_map**

If binary logging is turned on, the engine acquires this mutex when it adds to, deletes from, or searches through the list of binlog files behind the latest one.

**sync/mutex/sql/MYSQL_BIN_LOG::LOCK_io_cache**

If binary logging is turned on, the engine acquires this mutex during Aurora binlog IO cache operations: allocate, resize, free, write, read, purge, and access cache info. If this event occurs frequently, the engine is accessing the cache where binlog events are stored. To reduce wait times, reduce commits. Try grouping multiple statements into a single transaction.
**synch/mutex/sql/MYSQL_BIN_LOG::LOCK_log**

You have turned on binary logging. There might be high commit throughput, many transactions committing, or replicas reading binlogs. Consider using multirow statements or bundling statements into one transaction. In Aurora, use global databases instead of binary log replication or use the `aurora_binlog_*` parameters.

**synch/mutex/sql/SERVER_THREAD::LOCK_sync**

The mutex `SERVER_THREAD::LOCK_sync` is acquired during the scheduling, processing, or launching of threads for file writes. The excessive occurrence of this wait event indicates increased write activity in the database.

**synch/mutex/sql/TABLESPACES:lock**

The engine acquires the `TABLESPACES:lock` mutex during the following tablespace operations: create, delete, truncate, and extend. The excessive occurrence of this wait event indicates a high frequency of tablespace operations. An example is loading a large amount of data into the database.

**synch/rwlock/innodb/dict**

In this wait event, there are threads waiting on an rwlock held on the InnoDB data dictionary.

**synch/rwlock/innodb/dict_operation_lock**

In this wait event, there are threads holding locks on InnoDB data dictionary operations.

**synch/rwlock/innodb/dict sys RW lock**

A high number of concurrent data control language statements (DCLs) in data definition language code (DDLs) are triggered at the same time. Reduce the application's dependency on DDLs during regular application activity.

**synch/rwlock/innodb/index_tree_rw_lock**

A large number of similar data manipulation language (DML) statements are accessing the same database object at the same time. Try using multirow statements. Also, spread the workload over different database objects. For example, implement partitioning.

**synch/sxlock/innodb/dict_operation_lock**

A high number of concurrent data control language statements (DCLs) in data definition language code (DDLs) are triggered at the same time. Reduce the application's dependency on DDLs during regular application activity.
A high number of concurrent data control language statements (DCLs) in data definition language code (DDLs) are triggered at the same time. Reduce the application's dependency on DDLs during regular application activity.

The session couldn't find pages in the buffer pool. The engine either needs to read a file or modify the least-recently used (LRU) list for the buffer pool. Consider increasing the buffer cache size and improving access paths for the relevant queries.

Many similar data manipulation language (DML) statements are accessing the same database object at the same time. Try using multirow statements. Also, spread the workload over different database objects. For example, implement partitioning.

For more information on troubleshooting synch wait events, see Why is my MySQL DB instance showing a high number of active sessions waiting on SYNCH wait events in Performance Insights?

### Aurora MySQL thread states

The following are some common thread states for Aurora MySQL.

**checking permissions**

The thread is checking whether the server has the required privileges to run the statement.

**checking query cache for query**

The server is checking whether the current query is present in the query cache.

**cleaned up**

This is the final state of a connection whose work is complete but which hasn't been closed by the client. The best solution is to explicitly close the connection in code. Or you can set a lower value for `wait_timeout` in your parameter group.

**closing tables**

The thread is flushing the changed table data to disk and closing the used tables. If this isn't a fast operation, verify the network bandwidth consumption metrics against the instance class network bandwidth. Also, check that the parameter values for `table_open_cache` and
table_definition_cache parameter allow for enough tables to be simultaneously open so that the engine doesn't need to open and close tables frequently. These parameters influence the memory consumption on the instance.

**converting HEAP to MyISAM**

The query is converting a temporary table from in-memory to on-disk. This conversion is necessary because the temporary tables created by MySQL in the intermediate steps of query processing grew too big for memory. Check the values of `tmp_table_size` and `max_heap_table_size`. In later versions, this thread state name is **converting HEAP to ondisk**.

**converting HEAP to ondisk**

The thread is converting an internal temporary table from an in-memory table to an on-disk table.

**copy to tmp table**

The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it. For a thread in this state, you can use the Performance Schema to obtain information about the progress of the copy operation.

**creating sort index**

Aurora MySQL is performing a sort because it can't use an existing index to satisfy the `ORDER BY` or `GROUP BY` clause of a query. For more information, see [creating sort index](#).

**creating table**

The thread is creating a permanent or temporary table.

**delayed commit ok done**

An asynchronous commit in Aurora MySQL has received an acknowledgement and is complete.

**delayed commit ok initiated**

The Aurora MySQL thread has started the async commit process but is waiting for acknowledgement. This is usually the genuine commit time of a transaction.

**delayed send ok done**

An Aurora MySQL worker thread that is tied to a connection can be freed while a response is sent to the client. The thread can begin other work. The state **delayed send ok done** means that the asynchronous acknowledgement to the client completed.
**delayed send ok initiated**

An Aurora MySQL worker thread has sent a response asynchronously to a client and is now free to do work for other connections. The transaction has started an async commit process that hasn't yet been acknowledged.

**executing**

The thread has begun running a statement.

**freeing items**

The thread has run a command. Some freeing of items done during this state involves the query cache. This state is usually followed by cleaning up.

**init**

This state occurs before the initialization of ALTER TABLE, DELETE, INSERT, SELECT, or UPDATE statements. Actions in this state include flushing the binary log or InnoDB log, and some cleanup of the query cache.

**master has sent all binlog to slave**

The primary node has finished its part of the replication. The thread is waiting for more queries to run so that it can write to the binary log (binlog).

**opening tables**

The thread is trying to open a table. This operation is fast unless an ALTER TABLE or a LOCK TABLE statement needs to finish, or it exceeds the value of table_open_cache.

**optimizing**

The server is performing initial optimizations for a query.

**preparing**

This state occurs during query optimization.

**query end**

This state occurs after processing a query but before the freeing items state.

**removing duplicates**

Aurora MySQL couldn't optimize a DISTINCT operation in the early stage of a query. Aurora MySQL must remove all duplicated rows before sending the result to the client.
searching rows for update

The thread is finding all matching rows before updating them. This stage is necessary if the UPDATE is changing the index that the engine uses to find the rows.

sending binlog event to slave

The thread read an event from the binary log and is sending it to the replica.

sending cached result to client

The server is taking the result of a query from the query cache and sending it to the client.

sending data

The thread is reading and processing rows for a SELECT statement but hasn't yet started sending data to the client. The process is identifying which pages contain the results necessary to satisfy the query. For more information, see sending data.

sending to client

The server is writing a packet to the client. In earlier MySQL versions, this wait event was labeled writing to net.

starting

This is the first stage at the beginning of statement execution.

statistics

The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound while performing other work.

storing result in query cache

The server is storing the result of a query in the query cache.

system lock

The thread has called mysql_lock_tables, but the thread state hasn't been updated since the call. This general state occurs for many reasons.

update

The thread is preparing to start updating the table.
**updating**

The thread is searching for rows and is updating them.

**user lock**

The thread issued a GET_LOCK call. The thread either requested an advisory lock and is waiting for it, or is planning to request it.

**waiting for more updates**

The primary node has finished its part of the replication. The thread is waiting for more queries to run so that it can write to the binary log (binlog).

**waiting for schema metadata lock**

This is a wait for a metadata lock.

**waiting for stored function metadata lock**

This is a wait for a metadata lock.

**waiting for stored procedure metadata lock**

This is a wait for a metadata lock.

**waiting for table flush**

The thread is executing FLUSH TABLES and is waiting for all threads to close their tables. Or the thread received notification that the underlying structure for a table changed, so it must reopen the table to get the new structure. To reopen the table, the thread must wait until all other threads have closed the table. This notification takes place if another thread has used one of the following statements on the table: FLUSH TABLES, ALTER TABLE, RENAME TABLE, REPAIR TABLE, ANALYZE TABLE, or OPTIMIZE TABLE.

**waiting for table level lock**

One session is holding a lock on a table while another session tries to acquire the same lock on the same table.

**waiting for table metadata lock**

Aurora MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. In this wait event, one session is holding a metadata lock on a table while another session tries to acquire the same lock on the same table. When the
Performance Schema is enabled, this thread state is reported as the wait event synch/cond/sql/MDL_context::COND_wait_status.

**writing to net**

The server is writing a packet to the network. In later MySQL versions, this wait event is labeled Sending to client.

**Aurora MySQL isolation levels**

Learn how DB instances in an Aurora MySQL cluster implement the database property of isolation. This topic explains how the Aurora MySQL default behavior balances between strict consistency and high performance. You can use this information to help you decide when to change the default settings based on the traits of your workload.

**Available isolation levels for writer instances**

You can use the isolation levels REPEATABLE READ, READ COMMITTED, READ UNCOMMITTED, and SERIALIZABLE on the primary instance of an Aurora MySQL DB cluster. These isolation levels work the same in Aurora MySQL as in RDS for MySQL.

**REPEATABLE READ isolation level for reader instances**

By default, Aurora MySQL DB instances that are configured as read-only Aurora Replicas always use the REPEATABLE READ isolation level. These DB instances ignore any SET TRANSACTION ISOLATION LEVEL statements and continue using the REPEATABLE READ isolation level.

You can't set the isolation level for reader DB instances using DB parameters or DB cluster parameters.

**READ COMMITTED isolation level for reader instances**

If your application includes a write-intensive workload on the primary instance and long-running queries on the Aurora Replicas, you might experience substantial purge lag. Purge lag happens when internal garbage collection is blocked by long-running queries. The symptom that you see is a high value for history list length in the output from the SHOW ENGINE INNODB STATUS command. You can monitor this value using the RollbackSegmentHistoryListLength metric in CloudWatch. Substantial purge lag can reduce the effectiveness of secondary indexes, decrease overall query performance, and lead to wasted storage space.
If you experience such issues, you can set an Aurora MySQL session-level configuration setting, `aurora_read_replica_read_committed`, to use the READ COMMITTED isolation level on Aurora Replicas. When you apply this setting, you can help reduce slowdowns and wasted space that can result from performing long-running queries at the same time as transactions that modify your tables.

We recommend making sure that you understand the specific Aurora MySQL behavior of the READ COMMITTED isolation before using this setting. The Aurora Replica READ COMMITTED behavior complies with the ANSI SQL standard. However, the isolation is less strict than typical MySQL READ COMMITTED behavior that you might be familiar with. Therefore, you might see different query results under READ COMMITTED on an Aurora MySQL read replica than you might see for the same query under READ COMMITTED on the Aurora MySQL primary instance or on RDS for MySQL. You might consider using the `aurora_read_replica_read_committed` setting for such cases as a comprehensive report that scans a very large database. In contrast, you might avoid it for short queries with small result sets, where precision and repeatability are important.

The READ COMMITTED isolation level isn't available for sessions within a secondary cluster in an Aurora global database that use the write forwarding feature. For information about write forwarding, see [Using write forwarding in an Amazon Aurora global database](#).

### Using READ COMMITTED for readers

To use the READ COMMITTED isolation level for Aurora Replicas, set the `aurora_read_replica_read_committed` configuration setting to ON. Use this setting at the session level while connected to a specific Aurora Replica. To do so, run the following SQL commands.

```sql
set session aurora_read_replica_read_committed = ON;
set session transaction isolation level read committed;
```

You might use this configuration setting temporarily to perform interactive, one-time queries. You might also want to run a reporting or data analysis application that benefits from the READ COMMITTED isolation level, while leaving the default setting unchanged for other applications.

When the `aurora_read_replica_read_committed` setting is turned on, use the `SET TRANSACTION ISOLATION LEVEL` command to specify the isolation level for the appropriate transactions.

```sql
set transaction isolation level read committed;
```
Differences in READ COMMITTED behavior on Aurora replicas

The `aurora_read_replica_read_committed` setting makes the READ COMMITTED isolation level available for an Aurora Replica, with consistency behavior that is optimized for long-running transactions. The READ COMMITTED isolation level on Aurora Replicas has less strict isolation than on Aurora primary instances. For that reason, enable this setting only on Aurora Replicas where you know that your queries can accept the possibility of certain types of inconsistent results.

Your queries can experience certain kinds of read anomalies when the `aurora_read_replica_read_committed` setting is turned on. Two kinds of anomalies are especially important to understand and handle in your application code. A *non-repeatable read* occurs when another transaction commits while your query is running. A long-running query can see different data at the start of the query than it sees at the end. A *phantom read* occurs when other transactions cause existing rows to be reorganized while your query is running, and one or more rows are read twice by your query.

Your queries might experience inconsistent row counts as a result of phantom reads. Your queries might also return incomplete or inconsistent results due to non-repeatable reads. For example, suppose that a join operation refers to tables that are concurrently modified by SQL statements such as INSERT or DELETE. In this case, the join query might read a row from one table but not the corresponding row from another table.

The ANSI SQL standard allows both of these behaviors for the READ COMMITTED isolation level. However, those behaviors are different than the typical MySQL implementation of READ COMMITTED. Thus, before enabling the `aurora_read_replica_read_committed` setting, check any existing SQL code to verify if it operates as expected under the looser consistency model.

Row counts and other results might not be strongly consistent under the READ COMMITTED isolation level while this setting is enabled. Thus, you typically enable the setting only while running analytic queries that aggregate large amounts of data and don't require absolute precision. If you don't have these kinds of long-running queries alongside a write-intensive workload, you probably don't need the `aurora_read_replica_read_committed` setting. Without the combination of long-running queries and a write-intensive workload, you're unlikely to encounter issues with the length of the history list.

**Example Queries showing isolation behavior for READ COMMITTED on Aurora Replicas**

The following example shows how READ COMMITTED queries on an Aurora Replica might return non-repeatable results if transactions modify the associated tables at the same time. The table
BIG_TABLE contains 1 million rows before any queries start. Other data manipulation language (DML) statements add, remove, or change rows while they are running.

The queries on the Aurora primary instance under the READ COMMITTED isolation level produce predictable results. However, the overhead of keeping the consistent read view for the lifetime of every long-running query can lead to expensive garbage collection later.

The queries on the Aurora Replica under the READ COMMITTED isolation level are optimized to minimize this garbage collection overhead. The tradeoff is that the results might vary depending on whether the queries retrieve rows that are added, removed, or reorganized by transactions that are committed while the query is running. The queries are allowed to consider these rows, but aren’t required to. For demonstration purposes, the queries check only the number of rows in the table by using the COUNT(*) function.

<table>
<thead>
<tr>
<th>Time</th>
<th>DML statement on Aurora primary instance</th>
<th>Query on Aurora primary instance with READ COMMITTED</th>
<th>Query on Aurora Replica with READ COMMITTED</th>
</tr>
</thead>
<tbody>
<tr>
<td>T1</td>
<td>INSERT INTO big_table SELECT * FROM other_table LIMIT 1000000; COMMIT;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>T2</td>
<td>Q1: SELECT COUNT(*) FROM big_table;</td>
<td>Q2: SELECT COUNT(*) FROM big_table;</td>
<td></td>
</tr>
<tr>
<td>T3</td>
<td>INSERT INTO big_table (c1, c2) VALUES (1, 'one more row'); COMMIT;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>T4</td>
<td>If Q1 finishes now, result is 1,000,000.</td>
<td>If Q2 finishes now, result is 1,000,000 or 1,000,001.</td>
<td></td>
</tr>
<tr>
<td>Time</td>
<td>DML statement on Aurora primary instance</td>
<td>Query on Aurora primary instance with READ COMMITTED</td>
<td>Query on Aurora Replica with READ COMMITTED</td>
</tr>
<tr>
<td>------</td>
<td>------------------------------------------</td>
<td>---------------------------------------------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>T5</td>
<td>DELETE FROM big_table LIMIT 2; COMMIT;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>T6</td>
<td></td>
<td>If Q1 finishes now, result is 1,000,000.</td>
<td>If Q2 finishes now, result is 1,000,000 or 1,000,001 or 999,999 or 999,998.</td>
</tr>
<tr>
<td>T7</td>
<td>UPDATE big_table SET c2 = CONCAT(c2 ,c2,c2); COMMIT;</td>
<td>If Q1 finishes now, result is 1,000,000.</td>
<td>If Q2 finishes now, result is 1,000,000 or 1,000,001 or 999,999, or possibly some higher number.</td>
</tr>
<tr>
<td>T8</td>
<td></td>
<td>If Q1 finishes now, result is 1,000,000.</td>
<td>If Q2 finishes now, result is 1,000,000 or 1,000,001 or 999,999, or possibly some higher number.</td>
</tr>
<tr>
<td>T9</td>
<td></td>
<td><strong>Q3:</strong> SELECT COUNT(*) FROM big_table;</td>
<td><strong>Q4:</strong> SELECT COUNT(*) FROM big_table;</td>
</tr>
<tr>
<td>T10</td>
<td></td>
<td>If Q3 finishes now, result is 999,999.</td>
<td>If Q4 finishes now, result is 999,999.</td>
</tr>
</tbody>
</table>
If the queries finish quickly, before any other transactions perform DML statements and commit, the results are predictable and the same between the primary instance and the Aurora Replica. Let's examine the differences in behavior in detail, starting with the first query.

The results for Q1 are highly predictable because READ COMMITTED on the primary instance uses a strong consistency model similar to the REPEATABLE READ isolation level.

The results for Q2 might vary depending on what transactions are committed while that query is running. For example, suppose that other transactions perform DML statements and commit while the queries are running. In this case, the query on the Aurora Replica with the READ COMMITTED isolation level might or might not take the changes into account. The row counts aren't predictable.
in the same way as under the REPEATABLE READ isolation level. They also aren't as predictable as queries running under the READ COMMITTED isolation level on the primary instance, or on an RDS for MySQL instance.

The UPDATE statement at T7 doesn't actually change the number of rows in the table. However, by changing the length of a variable-length column, this statement can cause rows to be reorganized internally. A long-running READ COMMITTED transaction might see the old version of a row, and later within the same query see the new version of the same row. The query can also skip both the old and new versions of the row, so the row count might be different than expected.

The results of Q5 and Q6 might be identical or slightly different. Query Q6 on the Aurora Replica under READ COMMITTED is able to see, but is not required to see, the new rows that are committed while the query is running. It might also see the row from one table, but not from the other table. If the join query doesn't find a matching row in both tables, it returns a count of zero. If the query does find both the new rows in PARENT_TABLE and CHILD_TABLE, the query returns a count of one. In a long-running query, the lookups from the joined tables might happen at widely separated times.

Note
These differences in behavior depend on the timing of when transactions are committed and when the queries process the underlying table rows. Thus, you're most likely to see such differences in report queries that take minutes or hours and that run on Aurora clusters processing OLTP transactions at the same time. These are the kinds of mixed workloads that benefit the most from the READ COMMITTED isolation level on Aurora Replicas.

Aurora MySQL hints

You can use SQL hints with Aurora MySQL queries to fine-tune performance. You can also use hints to prevent execution plans for important queries from changing because of unpredictable conditions.

Tip
To verify the effect that a hint has on a query, examine the query plan produced by the EXPLAIN statement. Compare the query plans with and without the hint.
In Aurora MySQL version 3, you can use all the hints that are available in MySQL Community Edition 8.0. For more information about these hints, see Optimizer Hints in the MySQL Reference Manual.

The following hints are available in Aurora MySQL version 2. These hints apply to queries that use the hash join feature in Aurora MySQL version 2, especially queries that use parallel query optimization.

**PQ, NO_PQ**

Specifies whether to force the optimizer to use parallel query on a per-table or per-query basis.

PQ forces the optimizer to use parallel query for specified tables or the whole query (block). NO_PQ prevents the optimizer from using parallel query for specified tables or the whole query (block).

This hint is available in Aurora MySQL version 2.11 and higher. The following examples show you how to use this hint.

**Note**

Specifying a table name forces the optimizer to apply the PQ/NO_PQ hint only on those select tables. Not specifying a table name forces the PQ/NO_PQ hint on all tables affected by the query block.

```
EXPLAIN SELECT /*+ PQ() */ f1, f2
    FROM num1 t1 WHERE f1 > 10 and f2 < 100;

EXPLAIN SELECT /*+ PQ(t1) */ f1, f2
    FROM num1 t1 WHERE f1 > 10 and f2 < 100;

EXPLAIN SELECT /*+ PQ(t1,t2) */ f1, f2
    FROM num1 t1, num1 t2 WHERE t1.f1 = t2.f21;

EXPLAIN SELECT /*+ NO_PQ() */ f1, f2
    FROM num1 t1 WHERE f1 > 10 and f2 < 100;

EXPLAIN SELECT /*+ NO_PQ(t1) */ f1, f2
    FROM num1 t1 WHERE f1 > 10 and f2 < 100;
```
EXPLAIN SELECT /*+ NO_PQ(t1,t2) */ f1, f2
FROM num1 t1, num1 t2 WHERE t1.f1 = t2.f21;

**HASH_JOIN, NO_HASH_JOIN**

Turns on or off the ability of the parallel query optimizer to choose whether to use the hash join optimization method for a query. HASH_JOIN lets the optimizer use hash join if that mechanism is more efficient. NO_HASH_JOIN prevents the optimizer from using hash join for the query. This hint is available in Aurora MySQL version 2.08 and higher. It has no effect in Aurora MySQL version 3.

The following examples show you how to use this hint.

EXPLAIN SELECT /*+ HASH_JOIN(t2) */ f1, f2
FROM t1, t2 WHERE t1.f1 = t2.f1;

EXPLAIN SELECT /*+ NO_HASH_JOIN(t2) */ f1, f2
FROM t1, t2 WHERE t1.f1 = t2.f1;

**HASH_JOIN_PROBING, NO_HASH_JOIN_PROBING**

In a hash join query, specifies whether to use the specified table for the probe side of the join. The query tests if column values from the build table exist in the probe table, instead of reading the entire contents of the probe table. You can use HASH_JOIN_PROBING and HASH_JOIN_BUILDING to specify how hash join queries are processed without reordering the tables within the query text. This hint is available in Aurora MySQL version 2.08 and higher. It has no effect in Aurora MySQL version 3.

The following examples show how to use this hint. Specifying the HASH_JOIN_PROBING hint for the table T2 has the same effect as specifying NO_HASH_JOIN_PROBING for the table T1.

EXPLAIN SELECT /*+ HASH_JOIN(t2) HASH_JOIN_PROBING(t2) */ f1, f2
FROM t1, t2 WHERE t1.f1 = t2.f1;

EXPLAIN SELECT /*+ HASH_JOIN(t2) NO_HASH_JOIN_PROBING(t1) */ f1, f2
FROM t1, t2 WHERE t1.f1 = t2.f1;

**HASH_JOIN_BUILDING, NO_HASH_JOIN_BUILDING**

In a hash join query, specifies whether to use the specified table for the build side of the join. The query processes all the rows from this table to build the list of column values to cross-
reference with the other table. You can use HASH_JOIN_PROBING and HASH_JOIN_BUILDING to specify how hash join queries are processed without reordering the tables within the query text. This hint is available in Aurora MySQL version 2.08 and higher. It has no effect in Aurora MySQL version 3.

The following example shows you how to use this hint. Specifying the HASH_JOIN_BUILDING hint for the table T2 has the same effect as specifying NO_HASH_JOIN_BUILDING for the table T1.

```
EXPLAIN SELECT /*+ HASH_JOIN(t2) HASH_JOIN_BUILDING(t2) */ f1, f2
   FROM t1, t2 WHERE t1.f1 = t2.f1;

EXPLAIN SELECT /*+ HASH_JOIN(t2) NO_HASH_JOIN_BUILDING(t1) */ f1, f2
   FROM t1, t2 WHERE t1.f1 = t2.f1;
```

**JOIN_FIXED_ORDER**

Specifies that tables in the query are joined based on the order they are listed in the query. It is useful with queries involving three or more tables. It is intended as a replacement for the MySQL STRAIGHT_JOIN hint and is equivalent to the MySQL JOIN_FIXED_ORDER hint. This hint is available in Aurora MySQL version 2.08 and higher.

The following example shows you how to use this hint.

```
EXPLAIN SELECT /*+ JOIN_FIXED_ORDER() */ f1, f2
   FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

**JOIN_ORDER**

Specifies the join order for the tables in the query. It is useful with queries involving three or more tables. It is equivalent to the MySQL JOIN_ORDER hint. This hint is available in Aurora MySQL version 2.08 and higher.

The following example shows you how to use this hint.

```
EXPLAIN SELECT /*+ JOIN_ORDER (t4, t2, t1, t3) */ f1, f2
   FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```
JOIN_PREFIX

Specifies the tables to put first in the join order. It is useful with queries involving three or more tables. It is equivalent to the MySQL `JOIN_PREFIX` hint. This hint is available in Aurora MySQL version 2.08 and higher.

The following example shows you how to use this hint.

```sql
EXPLAIN SELECT /*+ JOIN_PREFIX (t4, t2) */ f1, f2
    FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

JOIN_SUFFIX

Specifies the tables to put last in the join order. It is useful with queries involving three or more tables. It is equivalent to the MySQL `JOIN_SUFFIX` hint. This hint is available in Aurora MySQL version 2.08 and higher.

The following example shows you how to use this hint.

```sql
EXPLAIN SELECT /*+ JOIN_SUFFIX (t1) */ f1, f2
    FROM t1 JOIN t2 USING (id) JOIN t3 USING (id) JOIN t4 USING (id);
```

For information about using hash join queries, see Optimizing large Aurora MySQL join queries with hash joins.

Aurora MySQL stored procedures

You can manage your Aurora MySQL DB cluster by calling built-in stored procedures.

Topics

- Configuring
- Ending a session or query
- Logging
- Managing the Global Status History
- Replicating
Configuring

The following stored procedures set and show configuration parameters, such as for binary log file retention.

Topics

- `mysql.rds_set_configuration`
- `mysql.rds_show_configuration`

mysql.rds_set_configuration

Specifies the number of hours to retain binary logs or the number of seconds to delay replication.

Syntax

```
CALL mysql.rds_set_configuration(name, value);
```

Parameters

```
name
```

The name of the configuration parameter to set.

```
value
```

The value of the configuration parameter.

Usage notes

The `mysql.rds_set_configuration` procedure supports the following configuration parameters:

- `binlog retention hours`

The configuration parameters are stored permanently and survive any DB instance reboot or failover.
binlog retention hours

The binlog retention hours parameter is used to specify the number of hours to retain binary log files. Amazon Aurora normally purges a binary log as soon as possible, but the binary log might still be required for replication with a MySQL database external to Aurora.

The default value of binlog retention hours is NULL. For Aurora MySQL, NULL means binary logs are cleaned up lazily. Aurora MySQL binary logs might remain in the system for a certain period, which is usually not longer than a day.

To specify the number of hours to retain binary logs on a DB cluster, use the mysql.rds_set_configuration stored procedure and specify a period with enough time for replication to occur, as shown in the following example.

call mysql.rds_set_configuration('binlog retention hours', 24);

Note

You can't use the value 0 for binlog retention hours.

For Aurora MySQL version 2.11.0 and higher and version 3 DB clusters, the maximum binlog retention hours value is 2160 (90 days).

After you set the retention period, monitor storage usage for the DB instance to make sure that the retained binary logs don't take up too much storage.

mysql.rds_show_configuration

The number of hours that binary logs are retained.

Syntax

CALL mysql.rds_show_configuration;

Usage notes

To verify the number of hours that Amazon RDS retains binary logs, use the mysql.rds_show_configuration stored procedure.
Examples

The following example displays the retention period:

```sql
call mysql.rds_show_configuration;

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>binlog retention hours</td>
<td>24</td>
<td>binlog retention hours specifies the duration in hours before binary logs are automatically deleted.</td>
</tr>
</tbody>
</table>
```
Ending a session or query

The following stored procedures end a session or query.

Topics

- `mysql.rds_kill`
- `mysql.rds_kill_query`

mysql.rds_kill

Ends a connection to the MySQL server.

Syntax

```
CALL mysql.rds_kill(processID);
```

Parameters

`processID`

The identity of the connection thread to be ended.

Usage notes

Each connection to the MySQL server runs in a separate thread. To end a connection, use the `mysql.rds_kill` procedure and pass in the thread ID of that connection. To obtain the thread ID, use the MySQL `SHOW PROCESSLIST` command.

Examples

The following example ends a connection with a thread ID of 4243:

```
CALL mysql.rds_kill(4243);
```

mysql.rds_kill_query

Ends a query running against the MySQL server.
Syntax

```
CALL mysql.rds_kill_query(processID);
```

Parameters

`processID`

The identity of the process or thread that is running the query to be ended.

Usage notes

To stop a query running against the MySQL server, use the `mysql_rds_kill_query` procedure and pass in the connection ID of the thread that is running the query. The procedure then terminates the connection.

To obtain the ID, query the MySQL `INFORMATION_SCHEMA.PROCESSLIST` table or use the MySQL `SHOW PROCESSLIST` command. The value in the ID column from `SHOW PROCESSLIST` or `SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST` is the `processID`.

Examples

The following example stops a query with a query thread ID of 230040:

```
CALL mysql.rds_kill_query(230040);
```
Logging

The following stored procedures rotate MySQL logs to backup tables. For more information, see Aurora MySQL database log files.

Topics

- `mysql.rds_rotate_general_log`
- `mysql.rds_rotate_slow_log`

`mysql.rds_rotate_general_log`

Rotates the `mysql.general_log` table to a backup table.

Syntax

```sql
CALL mysql.rds_rotate_general_log;
```

Usage notes

You can rotate the `mysql.general_log` table to a backup table by calling the `mysql.rds_rotate_general_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`.

You can run this procedure only when the `log_output` parameter is set to `TABLE`.

`mysql.rds_rotate_slow_log`

Rotates the `mysql.slow_log` table to a backup table.

Syntax

```sql
CALL mysql.rds_rotate_slow_log;
```
Usage notes

You can rotate the mysql.slow_log table to a backup table by calling the mysql.rds_rotate_slow_log procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup.

You can query the backup log table if needed. The backup log table for the mysql.slow_log table is named mysql.slow_log_backup.
Managing the Global Status History

Amazon RDS provides a set of procedures that take snapshots of the values of status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure is called Global Status History. For more information, see Managing the Global Status History.

The following stored procedures manage how the Global Status History is collected and maintained.

Topics

- `mysql.rds_collect_global_status_history`
- `mysql.rds_disable_gsh_collector`
- `mysql.rds_disable_gsh_rotation`
- `mysql.rds_enable_gsh_collector`
- `mysql.rds_enable_gsh_rotation`
- `mysql.rds_rotate_global_status_history`
- `mysql.rds_set_gsh_collector`
- `mysql.rds_set_gsh_rotation`

`mysql.rds_collect_global_status_history`

Takes a snapshot on demand for the Global Status History.

Syntax

```
CALL mysql.rds_collect_global_status_history;
```

`mysql.rds_disable_gsh_collector`

Turns off snapshots taken by the Global Status History.

Syntax

```
CALL mysql.rds_disable_gsh_collector;
```
**mysql.rds_disable_gsh_rotation**

Turns off rotation of the `mysql.global_status_history` table.

**Syntax**

```sql
CALL mysql.rds_disable_gsh_rotation;
```

**mysql.rds_enable_gsh_collector**

Turns on the Global Status History to take default snapshots at intervals specified by `rds_set_gsh_collector`.

**Syntax**

```sql
CALL mysql.rds_enable_gsh_collector;
```

**mysql.rds_enable_gsh_rotation**

Turns on rotation of the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` at intervals specified by `rds_set_gsh_rotation`.

**Syntax**

```sql
CALL mysql.rds_enable_gsh_rotation;
```

**mysql.rds_rotate_global_status_history**

Rotates the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` on demand.

**Syntax**

```sql
CALL mysql.rds_rotate_global_status_history;
```

**mysql.rds_set_gsh_collector**

Specifies the interval, in minutes, between snapshots taken by the Global Status History.
Syntax

CALL mysql.rds_set_gsh_collector(intervalPeriod);

Parameters

intervalPeriod

The interval, in minutes, between snapshots. Default value is 5.

mysql.rds_set_gsh_rotation

Specifies the interval, in days, between rotations of the mysql.global_status_history table.

Syntax

CALL mysql.rds_set_gsh_rotation(intervalPeriod);

Parameters

intervalPeriod

The interval, in days, between table rotations. Default value is 7.
Replicating

You can call the following stored procedures while connected to the primary instance in an Aurora MySQL cluster. These procedures control how transactions are replicated from an external database into Aurora MySQL, or from Aurora MySQL to an external database. To learn how to use replication based on global transaction identifiers (GTIDs) with Aurora MySQL, see Using GTID-based replication.

Topics

- `mysql.rds_assign_gtids_to_anonymous_transactions` (Aurora MySQL version 3)
- `mysql.rds_disable_session_binlog` (Aurora MySQL version 2)
- `mysql.rds_enable_session_binlog` (Aurora MySQL version 2)
- `mysql.rds_gtid_purged` (Aurora MySQL version 3)
- `mysql.rds_import_binlog_ssl_material`
- `mysql.rds_next_master_log` (Aurora MySQL version 2)
- `mysql.rds_next_source_log` (Aurora MySQL version 3)
- `mysql.rds_remove_binlog_ssl_material`
- `mysql.rds_reset_external_master` (Aurora MySQL version 2)
- `mysql.rds_reset_external_source` (Aurora MySQL version 3)
- `mysql.rds_set_binlog_source_ssl` (Aurora MySQL version 3)
- `mysql.rds_set_external_master` (Aurora MySQL version 2)
- `mysql.rds_set_external_master_with_auto_position` (Aurora MySQL version 2)
- `mysql.rds_set_external_source` (Aurora MySQL version 3)
- `mysql.rds_set_external_source_with_auto_position` (Aurora MySQL version 3)
- `mysql.rds_set_master_auto_position` (Aurora MySQL version 2)
- `mysql.rds_set_read_only` (Aurora MySQL version 3)
- `mysql.rds_set_session_binlog_format` (Aurora MySQL version 2)
- `mysql.rds_set_source_auto_position` (Aurora MySQL version 3)
- `mysql.rds_skip_transaction_with_gtid` (Aurora MySQL version 2 and 3)
- `mysql.rds_skip_repl_error`
- `mysql.rds_start_replication`
- `mysql.rds_start_replication_until` (Aurora MySQL version 3)
• `mysql.rds_start_replication_until_gtid` (Aurora MySQL version 3)
• `mysql.rds_stop_replication`

`mysql.rds_assign_gtids_to_anonymous_transactions` (Aurora MySQL version 3)

Configures the `ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS` option of the `CHANGE REPLICATION SOURCE TO` statement. It makes the replication channel assign a GTID to replicated transactions that don't have one. That way, you can perform binary log replication from a source that doesn't use GTID-based replication to a replica that does. For more information, see `CHANGE REPLICATION SOURCE TO Statement` and `Replication From a Source Without GTIDs to a Replica With GTIDs` in the `MySQL Reference Manual`.

**Syntax**

```sql
CALL mysql.rds_assign_gtids_to_anonymous_transactions('gtid_option');
```

**Parameters**

*gtid_option*

String value. The allowed values are OFF, LOCAL, or a specified UUID.

**Usage notes**

This procedure has the same effect as issuing the statement `CHANGE REPLICATION SOURCE TO ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS = gtid_option` in community MySQL.

GTID must be turned to ON for `gtid_option` to be set to LOCAL or a specific UUID.

The default is OFF, meaning that the feature isn't used.

LOCAL assigns a GTID including the replica's own UUID (the `server_uuid` setting).

Passing a parameter that is a UUID assigns a GTID that includes the specified UUID, such as the `server_uuid` setting for the replication source server.

**Examples**

To turn off this feature:

```sql
mysql> call mysql.rds_assign_gtids_to_anonymous_transactions('OFF');
```
<table>
<thead>
<tr>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS has been set to: OFF</td>
</tr>
<tr>
<td>-------------------------------------------------------------</td>
</tr>
</tbody>
</table>
1 row in set (0.07 sec)

To use the replica's own UUID:

```sql
mysql> call mysql.rds_assign_gtids_to_anonymous_transactions('LOCAL');
+---------------------------------------------------------------+
| Message  |
+---------------------------------------------------------------+
| ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS has been set to: LOCAL |
+---------------------------------------------------------------+
1 row in set (0.07 sec)
```

To use a specified UUID:

```sql
mysql> call mysql.rds_assign_gtids_to_anonymous_transactions('317a4760-f3dd-3b74-8e45-0615ed29de0e');
+-----------------------------------------------------------------------------------------------+
| Message |
+-----------------------------------------------------------------------------------------------+
| ASSIGN_GTIDS_TO_ANONYMOUS_TRANSACTIONS has been set to: 317a4760-f3dd-3b74-8e45-0615ed29de0e   |
+-----------------------------------------------------------------------------------------------+
1 row in set (0.07 sec)
```

**mysql.rds_disable_session_binlog (Aurora MySQL version 2)**

Turns off binary logging for the current session by setting the `sql_log_bin` variable to OFF.

**Syntax**

```
CALL mysql.rds_disable_session_binlog;
```

**Parameters**

None
Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

For Aurora, this procedure is supported for Aurora MySQL version 2.12 and higher MySQL 5.7–compatible versions.

Note

In Aurora MySQL version 3, you can use the following command to disable binary logging for the current session if you have the SESSION_VARIABLES_ADMIN privilege:

```
SET SESSION sql_log_bin = OFF;
```

mysql.rds_enable_session_binlog (Aurora MySQL version 2)

Turns on binary logging for the current session by setting the sql_log_bin variable to ON.

Syntax

```
CALL mysql.rds_enable_session_binlog;
```

Parameters

None

Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

For Aurora, this procedure is supported for Aurora MySQL version 2.12 and higher MySQL 5.7–compatible versions.

Note

In Aurora MySQL version 3, you can use the following command to enable binary logging for the current session if you have the SESSION_VARIABLES_ADMIN privilege:
**mysql.rds_gtid_purged (Aurora MySQL version 3)**

Sets the global value of the system variable `gtid_purged` to a given global transaction identifier (GTID) set. The `gtid_purged` system variable is a GTID set that consists of the GTIDs of all transactions that have been committed on the server, but don't exist in any binary log file on the server.

To allow compatibility with MySQL 8.0, there are two ways to set the value of `gtid_purged`:

- Replace the value of `gtid_purged` with your specified GTID set.
- Append your specified GTID set to the GTID set that `gtid_purged` already contains.

**Syntax**

To replace the value of `gtid_purged` with your specified GTID set:

```
CALL mysql.rds_gtid_purged (gtid_set);
```

To append the value of `gtid_purged` to your specified GTID set:

```
CALL mysql.rds_gtid_purged (+gtid_set);
```

**Parameters**

`gtid_set`

The value of `gtid_set` must be a superset of the current value of `gtid_purged`, and can't intersect with `gtid_subtract(gtid_executed,gtid_purged)`. That is, the new GTID set must include any GTIDs that were already in `gtid_purged`, and can't include any GTIDs in `gtid_executed` that haven't yet been purged. The `gtid_set` parameter also can't include any GTIDs that are in the global `gtid_owned` set, the GTIDs for transactions that are currently being processed on the server.
Usage notes

The master user must run the mysql.rds_gtid_purged procedure.

This procedure is supported for Aurora MySQL version 3.04 and higher.

Examples

The following example assigns the GTID 3E11FA47-71CA-11E1-9E33-C80AA9429562:23 to the gtid_purged global variable.

```
CALL mysql.rds_gtid_purged('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

mysql.rds_import_binlog_ssl_material

Imports the certificate authority certificate, client certificate, and client key into an Aurora MySQL DB cluster. The information is required for SSL communication and encrypted replication.

Note

Currently, this procedure is supported for Aurora MySQL version 2: 2.09.2, 2.10.0, 2.10.1, and 2.11.0; and version 3: 3.01.1 and higher.

Syntax

```
CALL mysql.rds_import_binlog_ssl_material (ssl_material);
```

Parameters

**ssl_material**

JSON payload that contains the contents of the following .pem format files for a MySQL client:

- "ssl_ca": "Certificate authority certificate"
- "ssl_cert": "Client certificate"
- "ssl_key": "Client key"
Usage notes

Prepare for encrypted replication before you run this procedure:

- If you don't have SSL enabled on the external MySQL source database instance and don't have a client key and client certificate prepared, enable SSL on the MySQL database server and generate the required client key and client certificate.

- If SSL is enabled on the external source database instance, supply a client key and certificate for the Aurora MySQL DB cluster. If you don't have these, generate a new key and certificate for the Aurora MySQL DB cluster. To sign the client certificate, you must have the certificate authority key you used to configure SSL on the external MySQL source database instance.

For more information, see Creating SSL certificates and keys using openssl in the MySQL documentation.

⚠️ Important

After you prepare for encrypted replication, use an SSL connection to run this procedure. The client key must not be transferred across an insecure connection.

This procedure imports SSL information from an external MySQL database into an Aurora MySQL DB cluster. The SSL information is in .pem format files that contain the SSL information for the Aurora MySQL DB cluster. During encrypted replication, the Aurora MySQL DB cluster acts a client to the MySQL database server. The certificates and keys for the Aurora MySQL client are in files in .pem format.

You can copy the information from these files into the ssl_material parameter in the correct JSON payload. To support encrypted replication, import this SSL information into the Aurora MySQL DB cluster.

The JSON payload must be in the following format.

```
{"ssl_ca":"-----BEGIN CERTIFICATE-----
ssl_ca_pem_body_code
-----END CERTIFICATE-----
","ssl_cert":"-----BEGIN CERTIFICATE-----
ssl_cert_pem_body_code
-----END CERTIFICATE-----
","ssl_key":"-----BEGIN RSA PRIVATE KEY-----
```
ssl_key_pem_body_code
-----END RSA PRIVATE KEY-----

Examples

The following example imports SSL information into an Aurora MySQL. In .pem format files, the body code typically is longer than the body code shown in the example.

call mysql.rds_import_binlog_ssl_material(‘{"ssl_ca":"-----BEGIN CERTIFICATE-----

-----END RSA PRIVATE KEY-----

mysql.rds_next_master_log (Aurora MySQL version 2)

Changes the source database instance log position to the start of the next binary log on the source
database instance. Use this procedure only if you are receiving replication I/O error 1236 on a read
replica.

Syntax

CALL mysql.rds_next_master_log(
curr_master_log
);

Stored procedures 1865
Parameters

curr_master_log

The index of the current master log file. For example, if the current file is named mysql-bin-changelog.012345, then the index is 12345. To determine the current master log file name, run the `SHOW REPLICA STATUS` command and view the `Master_Log_File` field.

### Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

Usage notes

The master user must run the `mysql.rds_next_master_log` procedure.

### Warning

Call `mysql.rds_next_master_log` only if replication fails after a failover of a Multi-AZ DB instance that is the replication source, and the `Last_IO_Errno` field of `SHOW REPLICA STATUS` reports I/O error 1236.

Calling `mysql.rds_next_master_log` can result in data loss in the read replica if transactions in the source instance were not written to the binary log on disk before the failover event occurred.

Examples

Assume replication fails on an Aurora MySQL read replica. Running `SHOW REPLICA STATUS\G` on the read replica returns the following result:

```
*************************** 1. row ***************************
Replica_IO_State:
  Source_Host: myhost.XXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com
  Source_User: MasterUser
  Source_Port: 3306
```
The `Last_IO_Errno` field shows that the instance is receiving I/O error 1236. The `Master_Log_File` field shows that the file name is `mysql-bin-changelog.012345`. The last error from master when reading data from binary log: 'Client requested master to start replication from impossible position; the first event 'mysql-bin-changelog.013406' at 1219393, the last event read from '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4, the last byte read from '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4.'
which means that the log file index is 12345. To resolve the error, you can call mysql.rds_next_master_log with the following parameter:

```
CALL mysql.rds_next_master_log(12345);
```

>Note

Previous versions of MySQL used SHOW SLAVE STATUS instead of SHOW REPLICA STATUS. If you are using a MySQL version before 8.0.23, then use SHOW SLAVE STATUS.

**mysql.rds_next_source_log (Aurora MySQL version 3)**

Changes the source database instance log position to the start of the next binary log on the source database instance. Use this procedure only if you are receiving replication I/O error 1236 on a read replica.

**Syntax**

```
CALL mysql.rds_next_source_log(
    curr_source_log
);
```

**Parameters**

*curr_source_log*

The index of the current source log file. For example, if the current file is named mysql-bin-changelog.012345, then the index is 12345. To determine the current source log file name, run the SHOW REPLICA STATUS command and view the Source_Log_File field.

**Usage notes**

The master user must run the mysql.rds_next_source_log procedure.
**Warning**

Call `mysql.rds_next_source_log` only if replication fails after a failover of a Multi-AZ DB instance that is the replication source, and the `Last_IO_Errno` field of `SHOW REPLICA STATUS` reports I/O error 1236.

Calling `mysql.rds_next_source_log` can result in data loss in the read replica if transactions in the source instance were not written to the binary log on disk before the failover event occurred.

**Examples**

Assume replication fails on an Aurora MySQL read replica. Running `SHOW REPLICA STATUS\G` on the read replica returns the following result:

```
*************************** 1. row ***************************
Replica_IO_State: Replica_SQL_Running: Yes
Source_Host: myhost.XXXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com Source_User: MasterUser

</tr>
</tbody>
</table>

The `Last_IO_Errno` field shows that the instance is receiving I/O error 1236. The `Source_Log_File` field shows that the file name is `mysql-bin-changelog.012345`, which means that the log file index is 12345. To resolve the error, you can call `mysql.rds_next_source_log` with the following parameter:

```
CALL mysql.rds_next_source_log(12345);
```

**mysql.rds_remove_binlog_ssl_material**

Removes the certificate authority certificate, client certificate, and client key for SSL communication and encrypted replication. This information is imported by using `mysql.rds_import_binlog_ssl_material`.

**Syntax**

```
CALL mysql.rds_remove_binlog_ssl_material;
```

**mysql.rds_reset_external_master (Aurora MySQL version 2)**

Reconfigures an Aurora MySQL DB instance to no longer be a read replica of an instance of MySQL running external to Amazon RDS.
Important

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group.

Syntax

CALL mysql.rds_reset_external_master;

Usage notes

The master user must run the mysql.rds_reset_external_master procedure. This procedure must be run on the MySQL DB instance to be removed as a read replica of a MySQL instance running external to Amazon RDS.

Note

We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. We recommend that you use Aurora Replicas to manage replication within an Aurora MySQL DB cluster when possible. For information about managing replication in Aurora MySQL DB clusters, see Using Aurora Replicas.

For more information about using replication to import data from an instance of MySQL running external to Aurora MySQL, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication).

mysql.rds_reset_external_source (Aurora MySQL version 3)

Reconfigures an Aurora MySQL DB instance to no longer be a read replica of an instance of MySQL running external to Amazon RDS.
**Important**

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group](#).

**Syntax**

```sql
CALL mysql.rds_reset_external_source;
```

**Usage notes**

The master user must run the `mysql.rds_reset_external_source` procedure. This procedure must be run on the MySQL DB instance to be removed as a read replica of a MySQL instance running external to Amazon RDS.

**Note**

We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. We recommend that you use Aurora Replicas to manage replication within an Aurora MySQL DB cluster when possible. For information about managing replication in Aurora MySQL DB clusters, see [Using Aurora Replicas](#).

---

### `mysql.rds_set_binlog_source_ssl (Aurora MySQL version 3)`

Enables SOURCE_SSL encryption for binlog replication. For more information, see [CHANGE REPLICATION SOURCE TO statement](#) in the MySQL documentation.

**Syntax**

```sql
CALL mysql.rds_set_binlog_source_ssl(mode);
```

**Parameters**

`mode`

A value that indicates whether SOURCE_SSL encryption is enabled:
• 0 – SOURCE_SSL encryption is disabled. The default is 0.
• 1 – SOURCE_SSL encryption is enabled. You can configure encryption using SSL or TLS.

Usage notes

This procedure is supported for Aurora MySQL version 3.06 and higher.

mysql.rds_set_external_master (Aurora MySQL version 2)

Configures an Aurora MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

The mysql.rds_set_external_master procedure is deprecated and will be removed in a future release. Use mysql.rds_set_external_source instead.

⚠️ Important

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see Modifying parameters in a DB parameter group.

Syntax

CALL mysql.rds_set_external_master (  
  host_name  
  , host_port  
  , replication_user_name  
  , replication_user_password  
  , mysql_binary_log_file_name  
  , mysql_binary_log_file_location  
  , ssl_encryption  
);  

Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.
host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with REPLICATION_CLIENT and REPLICATION_SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in replication_user_name.

mysql_binary_log_file_name

The name of the binary log on the source database instance that contains the replication information.

mysql_binary_log_file_location

The location in the mysql_binary_log_file_name binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running SHOW MASTER STATUS on the source database instance.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

Usage notes

The master user must run the mysql.rds_set_external_master procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.
Before you run `mysql.rds_set_external_master`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify `replication_user_name` and `replication_user_password` values that indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   **MySQL 5.7**

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   **MySQL 8.0**

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
   ```

   **Note**

   Specify a password other than the prompt shown here as a security best practice.

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain.

   **MySQL 5.7**

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   IDENTIFIED BY 'password';
   ```

   **MySQL 8.0**

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
   ```
To use encrypted replication, configure source database instance to use SSL connections. Also, import the certificate authority certificate, client certificate, and client key into the DB instance or DB cluster using the `mysql.rds_import_binlog_ssl_material` procedure.

**Note**

We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. We recommend that you use Aurora Replicas to manage replication within an Aurora MySQL DB cluster when possible. For information about managing replication in Aurora MySQL DB clusters, see [Using Aurora Replicas](#).

After calling `mysql.rds_set_external_master` to configure an Amazon RDS DB instance as a read replica, you can call `mysql.rds_start_replication` on the read replica to start the replication process. You can call `mysql.rds_reset_external_master (Aurora MySQL version 2)` to remove the read replica configuration.

When `mysql.rds_set_external_master` is called, Amazon RDS records the time, user, and an action of set master in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

**Examples**

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

```sql
call mysql.rds_set_external_master(
    'Externaldb.some.com',
    3306,
    'repl_user',
    'password',
    'mysql-bin-changelog.0777',
    120,
    0);
```

**mysql.rds_set_external_master_with_auto_position (Aurora MySQL version 2)**

Configures an Aurora MySQL primary instance to accept incoming replication from an external MySQL instance. This procedure also configures replication based on global transaction identifiers (GTIDs).
This procedure doesn't configure delayed replication, because Aurora MySQL doesn't support delayed replication.

Syntax

```sql
CALL mysql.rds_set_external_master_with_auto_position (  
    host_name,
    host_port,
    replication_user_name,
    replication_user_password,
    ssl_encryption
);
```

Parameters

**host_name**

The host name or IP address of the MySQL instance running external to Aurora to become the replication master.

**host_port**

The port used by the MySQL instance running external to Aurora to be configured as the replication master. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

**replication_user_name**

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Aurora. We recommend that you provide an account that is used solely for replication with the external instance.

**replication_user_password**

The password of the user ID specified in `replication_user_name`.

**ssl_encryption**

This option isn't currently implemented. The default is 0.

Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.
The master user must run the `mysql.rds_set_external_master_with_auto_position` procedure. The master user runs this procedure on the primary instance of an Aurora MySQL DB cluster that acts as a replication target. This can be the replication target of an external MySQL DB instance or an Aurora MySQL DB cluster.

This procedure is supported for Aurora MySQL version 2. For Aurora MySQL version 3, use the procedure `mysql.rds_set_external_source_with_auto_position (Aurora MySQL version 3)` instead.

Before you run `mysql.rds_set_external_master_with_auto_position`, configure the external MySQL DB instance to be a replication master. To connect to the external MySQL instance, specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external MySQL instance.

**To configure an external MySQL instance as a replication master**

1. Using the MySQL client of your choice, connect to the external MySQL instance and create a user account to be used for replication. The following is an example.

   ```sql
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
   ```

2. On the external MySQL instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain.

   ```sql
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   IDENTIFIED BY 'SomePassW0rd'
   ```

When you call `mysql.rds_set_external_master_with_auto_position`, Amazon RDS records certain information. This information is the time, the user, and an action of "set master" in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

To skip a specific GTID-based transaction that is known to cause a problem, you can use the `mysql.rds_skip_transaction_with_gtid` stored procedure. For more information about working with GTID-based replication, see [Using GTID-based replication](#).
Examples

When run on an Aurora primary instance, the following example configures the Aurora cluster to act as a read replica of an instance of MySQL running external to Aurora.

```sql
call mysql.rds_set_external_master_with_auto_position(
    'Externaldb.some.com',
    3306,
    'repl_user@'mydomain.com',
    'SomePassW0rd');
```

**mysql.rds_set_external_source (Aurora MySQL version 3)**

Configures an Aurora MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

⚠️ Important

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group](#).

Syntax

```sql
CALL mysql.rds_set_external_source (host_name, host_port, replication_user_name, replication_user_password, mysql_binary_log_file_name, mysql_binary_log_file_location, ssl_encryption);
```

Parameters

**host_name**

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.
**host_port**

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

**replication_user_name**

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

**replication_user_password**

The password of the user ID specified in replication_user_name.

**mysql_binary_log_file_name**

The name of the binary log on the source database instance that contains the replication information.

**mysql_binary_log_file_location**

The location in the mysql_binary_log_file_name binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running SHOW MASTER STATUS on the source database instance.

**ssl_encryption**

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

---

**Note**

You must have imported a custom SSL certificate using [mysql.rds_import_binlog_ssl_material](https://aws.amazon.com) to enable this option. If you haven't imported an custom SSL certificate, then set this parameter to 0 and use [mysql.rds_set_binlog_source_ssl](https://aws.amazon.com) (Aurora MySQL version 3) to enable SSL for binary log replication.

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.
Usage notes

The master user must run the mysql.rds_set_external_source procedure. This procedure must be run on the Aurora MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run mysql.rds_set_external_source, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify replication_user_name and replication_user_password values that indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

   MySQL 5.7

   ```sql
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   MySQL 8.0

   ```sql
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
   ```

   ⚠️ Note

   Specify a password other than the prompt shown here as a security best practice.

2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

   MySQL 5.7

   ```sql
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
   ```

   Stored procedures

   1881
To use encrypted replication, configure source database instance to use SSL connections. Also, import the certificate authority certificate, client certificate, and client key into the DB instance or DB cluster using the `mysql.rds_import_binlog_ssl_material` procedure.

**Note**

We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. We recommend that you use Aurora Replicas to manage replication within an Aurora MySQL DB cluster when possible. For information about managing replication in Aurora MySQL DB clusters, see Using Aurora Replicas.

After calling `mysql.rds_set_external_source` to configure an Aurora MySQL DB instance as a read replica, you can call `mysql.rds_start_replication` on the read replica to start the replication process. You can call `mysql.rds_reset_external_source` to remove the read replica configuration.

When `mysql.rds_set_external_source` is called, Amazon RDS records the time, user, and an action of set master in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

**Examples**

When run on an Aurora MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

```sql
CALL mysql.rds_set_external_source(
   'Externaldb.some.com',
   3306,
   'repl_user',
   'password',
   'mysql-bin-changelog.0777',
   120,
   0)
```
mysql.rds_set_external_source_with_auto_position (Aurora MySQL version 3)

Configures an Aurora MySQL primary instance to accept incoming replication from an external MySQL instance. This procedure also configures replication based on global transaction identifiers (GTIDs).

Syntax

```
CALL mysql.rds_set_external_source_with_auto_position (
    host_name,
    host_port,
    replication_user_name,
    replication_user_password,
    ssl_encryption
);
```

Parameters

**host_name**

The host name or IP address of the MySQL instance running external to Aurora to become the replication source.

**host_port**

The port used by the MySQL instance running external to Aurora to be configured as the replication source. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

**replication_user_name**

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Aurora. We recommend that you provide an account that is used solely for replication with the external instance.

**replication_user_password**

The password of the user ID specified in replication_user_name.

**ssl_encryption**

This option isn't currently implemented. The default is 0.
Note
Use `mysql.rds_set_binlog_source_ssl (Aurora MySQL version 3)` to enable SSL for binary log replication.

Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

The administrative user must run the `mysql.rds_set_external_source_with_auto_position` procedure. The administrative user runs this procedure on the primary instance of an Aurora MySQL DB cluster that acts as a replication target. This can be the replication target of an external MySQL DB instance or an Aurora MySQL DB cluster.

This procedure is supported for Aurora MySQL version 3. This procedure doesn't configure delayed replication, because Aurora MySQL doesn't support delayed replication.

Before you run `mysql.rds_set_external_source_with_auto_position`, configure the external MySQL DB instance to be a replication source. To connect to the external MySQL instance, specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has REPLICATION CLIENT and REPLICATION SLAVE permissions on the external MySQL instance.

To configure an external MySQL instance as a replication source

1. Using the MySQL client of your choice, connect to the external MySQL instance and create a user account to be used for replication. The following is an example.

   ```
   CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
   ```

2. On the external MySQL instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the `repl_user` user for your domain.

   ```
   GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'
   IDENTIFIED BY 'SomePassW0rd'
   ```
When you call `mysql.rds_set_external_source_with_auto_position`, Amazon RDS records certain information. This information is the time, the user, and an action of "set master" in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

To skip a specific GTID-based transaction that is known to cause a problem, you can use the `mysql.rds_skip_transaction_with_gtid` stored procedure. For more information about working with GTID-based replication, see Using GTID-based replication.

**Examples**

When run on an Aurora primary instance, the following example configures the Aurora cluster to act as a read replica of an instance of MySQL running external to Aurora.

```
call mysql.rds_set_external_source_with_auto_position(
   'Externaldb.some.com',
   3306,
   'repl_user'@'mydomain.com',
   'SomePassW0rd');
```

`mysql.rds_set_master_auto_position (Aurora MySQL version 2)`

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

**Syntax**

```
CALL mysql.rds_set_master_auto_position (auto_position_mode);
```

**Parameters**

`auto_position_mode`

A value that indicates whether to use log file position replication or GTID-based replication:

- 0 – Use the replication method based on binary log file position. The default is 0.
- 1 – Use the GTID-based replication method.
Usage notes

The master user must run the mysql.rds_set_master_auto_position procedure.

This procedure is supported for Aurora MySQL version 2.

mysql.rds_set_read_only (Aurora MySQL version 3)

Turns read_only mode on or off globally for the DB instance.

Syntax

CALL mysql.rds_set_read_only(mode);

Parameters

mode

A value that indicates whether read_only mode is on or off globally for the DB instance:

- 0 – OFF. The default is 0.
- 1 – ON

Usage notes

The mysql.rds_set_read_only stored procedure modifies only the read_only parameter. The innodb_read_only parameter can't be changed on reader DB instances.

The read_only parameter change doesn't persist on rebooting. To make permanent changes to read_only, you must use the read_only DB cluster parameter.

This procedure is supported for Aurora MySQL version 3.06 and higher.

mysql.rds_set_session_binlog_format (Aurora MySQL version 2)

Sets the binary log format for the current session.

Syntax

CALL mysql.rds_set_session_binlog_format(format);
Parameters

format

A value that indicates the binary log format for the current session:

- **STATEMENT** – The replication source writes events to the binary log based on SQL statements.
- **ROW** – The replication source writes events to the binary log that indicate changes to individual table rows.
- **MIXED** – Logging is generally based on SQL statements, but switches to rows under certain conditions. For more information, see [Mixed Binary Logging Format](#) in the MySQL documentation.

Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

To use this stored procedure, you must have binary logging configured for the current session.

For Aurora, this procedure is supported for Aurora MySQL version 2.12 and higher MySQL 5.7–compatible versions.

**mysql.rds_set_source_auto_position (Aurora MySQL version 3)**

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

Syntax

```sql
CALL mysql.rds_set_source_auto_position (auto_position_mode);
```

Parameters

**auto_position_mode**

A value that indicates whether to use log file position replication or GTID-based replication:

- 0 – Use the replication method based on binary log file position. The default is 0.
- 1 – Use the GTID-based replication method.
Usage notes

For an Aurora MySQL DB cluster, you call this stored procedure while connected to the primary instance.

The administrative user must run the `mysql.rds_set_source_auto_position` procedure.

`mysql.rds_skip_transaction_with_gtid` (Aurora MySQL version 2 and 3)

Skips replication of a transaction with the specified global transaction identifier (GTID) on an Aurora primary instance.

You can use this procedure for disaster recovery when a specific GTID transaction is known to cause a problem. Use this stored procedure to skip the problematic transaction. Examples of problematic transactions include transactions that disable replication, delete important data, or cause the DB instance to become unavailable.

Syntax

```
CALL mysql.rds_skip_transaction_with_gtid (gtid_to_skip);
```

Parameters

`gtid_to_skip`

The GTID of the replication transaction to skip.

Usage notes

The master user must run the `mysql.rds_skip_transaction_with_gtid` procedure.

This procedure is supported for Aurora MySQL version 2 and 3.

Examples

The following example skips replication of the transaction with the GTID `3E11FA47-71CA-11E1-9E33-C80AA9429562:23`.

```
CALL mysql.rds_skip_transaction_with_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```
mysql.rds_skip_repl_error

Skips and deletes a replication error on a MySQL DB read replica.

Syntax

CALL mysql.rds_skip_repl_error;

Usage notes

The master user must run the `mysql.rds_skip_repl_error` procedure on a read replica. For more information about this procedure, see Skipping the current replication error.

To determine if there are errors, run the MySQL `SHOW REPLICA STATUS\G` command. If a replication error isn't critical, you can run `mysql.rds_skip_repl_error` to skip the error. If there are multiple errors, `mysql.rds_skip_repl_error` deletes the first error, then warns that others are present. You can then use `SHOW REPLICA STATUS\G` to determine the correct course of action for the next error. For information about the values returned, see `SHOW REPLICA STATUS` statement in the MySQL documentation.

Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

For more information about addressing replication errors with Aurora MySQL, see Diagnosing and resolving a MySQL read replication failure.

Replication stopped error

When you call the `mysql.rds_skip_repl_error` procedure, you might receive an error message stating that the replica is down or disabled.

This error message appears if you run the procedure on the primary instance instead of the read replica. You must run this procedure on the read replica for the procedure to work.

This error message might also appear if you run the procedure on the read replica, but replication can't be restarted successfully.
If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log (binlog) files. In this case, you might encounter a fatal error due to binlog files being purged before they have been replayed on the read replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binlog files are retained on your source database instance. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the `mysql.rds_set_configuration` procedure and specify a configuration parameter of `'binlog retention hours'` along with the number of hours to retain binlog files on the DB cluster. The following example sets the retention period for binlog files to 48 hours.

```
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

### `mysql.rds_start_replication`

Initiates replication from an Aurora MySQL DB cluster.

#### Note

You can use the `mysql.rds_start_replication_until (Aurora MySQL version 3)` or `mysql.rds_start_replication_until_gtid (Aurora MySQL version 3)` stored procedure to initiate replication from an Aurora MySQL DB instance and stop replication at the specified binary log file location.

#### Syntax

```
CALL mysql.rds_start_replication;
```

#### Usage notes

The master user must run the `mysql.rds_start_replication` procedure.

To import data from an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` on the read replica to start the replication process after you
call `mysql.rds_set_external_master` or `mysql.rds_set_external_source` to build the replication configuration. For more information, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication).

To export data to an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication).

You can also call `mysql.rds_start_replication` on the read replica to restart any replication process that you previously stopped by calling `mysql.rds_stop_replication`. For more information, see Replication stopped error.

**mysql.rds_start_replication_until (Aurora MySQL version 3)**

Initiates replication from an Aurora MySQL DB cluster and stops replication at the specified binary log file location.

**Syntax**

```sql
CALL mysql.rds_start_replication_until (
    replication_log_file,
    replication_stop_point
);
```

**Parameters**

*replication_log_file*

The name of the binary log on the source database instance that contains the replication information.

*replication_stop_point*

The location in the replication_log_file binary log at which replication will stop.

**Usage notes**

The master user must run the `mysql.rds_start_replication_until` procedure.

This procedure is supported for Aurora MySQL version 3.04 and higher.
The `mysql.rds_start_replication_until` stored procedure isn't supported for managed replication, which includes the following:

- Replicating Amazon Aurora MySQL DB clusters across AWS Regions
- Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica

The file name specified for the `replication_log_file` parameter must match the source database instance binlog file name.

When the `replication_stop_point` parameter specifies a stop location that is in the past, replication is stopped immediately.

**Examples**

The following example initiates replication and replicates changes until it reaches location 120 in the `mysql-bin-changelog.000777` binary log file.

```sql
call mysql.rds_start_replication_until('mysql-bin-changelog.000777', 120);
```

**mysql.rds_start_replication_until_gtid (Aurora MySQL version 3)**

Initiates replication from an Aurora MySQL DB cluster and stops replication immediately after the specified global transaction identifier (GTID).

**Syntax**

```sql
CALL mysql.rds_start_replication_until_gtid(gtid);
```

**Parameters**

`gtid`

The GTID after which replication is to stop.

**Usage notes**

The master user must run the `mysql.rds_start_replication_until_gtid` procedure.
This procedure is supported for Aurora MySQL version 3.04 and higher.

The `mysql.rds_start_replication_until_gtid` stored procedure isn't supported for managed replication, which includes the following:

- Replicating Amazon Aurora MySQL DB clusters across AWS Regions
- Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica

When the `gtid` parameter specifies a transaction that has already been run by the replica, replication is stopped immediately.

**Examples**

The following example initiates replication and replicates changes until it reaches GTID 3E11FA47-71CA-11E1-9E33-C80AA9429562:23.

```sql
call mysql.rds_start_replication_until_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

**mysql.rds_stop_replication**

Stops replication from a MySQL DB instance.

**Syntax**

```sql
CALL mysql.rds_stop_replication;
```

**Usage notes**

The master user must run the `mysql.rds_stop_replication` procedure.

If you are configuring replication to import data from an instance of MySQL running external to Amazon RDS, you call `mysql.rds_stop_replication` on the read replica to stop the replication process after the import has completed. For more information, see Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication).

If you are configuring replication to export data to an instance of MySQL external to Amazon RDS, you call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see...
Replication between Aurora and MySQL or between Aurora and another Aurora DB cluster (binary log replication).

The `mysql.rds_stop_replication` stored procedure isn't supported for managed replication, which includes the following:

- Replicating Amazon Aurora MySQL DB clusters across AWS Regions
- Migrating data from an RDS for MySQL DB instance to an Amazon Aurora MySQL DB cluster by using an Aurora read replica

**Aurora MySQL–specific information_schema tables**

Aurora MySQL has certain `information_schema` tables that are specific to Aurora.

**`information_schema.aurora_global_db_instance_status`**

The `information_schema.aurora_global_db_instance_status` table contains information about the status of all DB instances in a global database's primary and secondary DB clusters. The following table shows the columns that you can use. The remaining columns are for Aurora internal use only.

> **Note**

This information schema table is only available with Aurora MySQL version 3.04.0 and higher global databases.

<table>
<thead>
<tr>
<th>Column</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERVER_ID</td>
<td>varchar(100)</td>
<td>The identifier of the DB instance.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>varchar(100)</td>
<td>A unique identifier for the current session. A value of MASTER_SESSION_ID identifies the Writer (primary) DB instance.</td>
</tr>
<tr>
<td>Column</td>
<td>Data type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>AWS_REGION</td>
<td>varchar(100)</td>
<td>The AWS Region in which this global database instance runs. For a list of Regions, see Region availability.</td>
</tr>
<tr>
<td>DURABLE_LSN</td>
<td>bigint unsigned</td>
<td>The log sequence number (LSN) made durable in storage. A log sequence number (LSN) is a unique sequential number that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.</td>
</tr>
<tr>
<td>HIGHEST_LSN_RCVD</td>
<td>bigint unsigned</td>
<td>The highest LSN received by the DB instance from the writer DB instance.</td>
</tr>
<tr>
<td>OLDEST_READ_VIEW_TRX_ID</td>
<td>bigint unsigned</td>
<td>The ID of the oldest transaction that the writer DB instance can purge to.</td>
</tr>
<tr>
<td>OLDEST_READ_VIEW_LSN</td>
<td>bigint unsigned</td>
<td>The oldest LSN used by the DB instance to read from storage.</td>
</tr>
<tr>
<td>Column</td>
<td>Data type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>VISIBILITY_LAG_IN_MSEC</td>
<td>float(10,0) unsigned</td>
<td>For readers in the primary DB cluster, how far this DB instance is lagging behind the writer DB instance in milliseconds. For readers in a secondary DB cluster, how far this DB instance is lagging behind the secondary volume in milliseconds.</td>
</tr>
</tbody>
</table>

**information_schema.aurora_global_db_status**

The `information_schema.aurora_global_db_status` table contains information about various aspects of Aurora global database lag, specifically, lag of the underlying Aurora storage (so called durability lag) and lag between the recovery point objective (RPO). The following table shows the columns that you can use. The remaining columns are for Aurora internal use only.

⚠️ **Note**

This information schema table is only available with Aurora MySQL version 3.04.0 and higher global databases.

<table>
<thead>
<tr>
<th>Column</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS_REGION</td>
<td>varchar(100)</td>
<td>The AWS Region in which this global database instance runs. For a list of Regions, see Region availability.</td>
</tr>
<tr>
<td>HIGHEST_LSN_WRITTEN</td>
<td>bigint unsigned</td>
<td>The highest log sequence number (LSN) that currently exists on this DB cluster. A log sequence number (LSN) is a unique sequential number</td>
</tr>
<tr>
<td>Column</td>
<td>Data type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>that identifies a record in the database transaction log. LSNs are ordered such that a larger LSN represents a later transaction.</td>
</tr>
<tr>
<td>DURABILITY_LAG_IN_MILLISECONDS</td>
<td>float(10,0) unsigned</td>
<td>The difference in the timestamp values between the HIGHEST_LSN_WRITTEN on a secondary DB cluster and the HIGHEST_LSN_WRITTEN on the primary DB cluster. This value is always 0 on the primary DB cluster of the Aurora global database.</td>
</tr>
<tr>
<td>Column</td>
<td>Data type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RPO_LAG_IN_MILLISECONDS</td>
<td>float(10,0) unsigned</td>
<td>The recovery point objective (RPO) lag. The RPO lag is the time it takes for the most recent user transaction COMMIT to be stored on a secondary DB cluster after it's been stored on the primary DB cluster of the Aurora global database. This value is always 0 on the primary DB cluster of the Aurora global database. In simple terms, this metric calculates the recovery point objective for each Aurora MySQL DB cluster in the Aurora global database, that is, how much data might be lost if there were an outage. As with lag, RPO is measured in time.</td>
</tr>
<tr>
<td>LAST_LAG_CALCULATION_TIMESTAMP</td>
<td>datetime</td>
<td>The timestamp that specifies when values were last calculated for DURABILITY_LAG_IN_MILLISECONDS and RPO_LAG_IN_MILLISECONDS. A time value such as 1970-01-01 00:00:00+00 means this is the primary DB cluster.</td>
</tr>
<tr>
<td>Column</td>
<td>Data type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>OLDEST_READ_VIEW_TRX_ID</td>
<td>bigint unsigned</td>
<td>The ID of the oldest transaction that the writer DB instance can purge to.</td>
</tr>
</tbody>
</table>

### information_schema.replica_host_status

The `information_schema.replica_host_status` table contains replication information. The columns that you can use are shown in the following table. The remaining columns are for Aurora internal use only.

<table>
<thead>
<tr>
<th>Column</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU</td>
<td>double</td>
<td>The CPU percentage usage of the replica host.</td>
</tr>
<tr>
<td>IS_CURRENT</td>
<td>tinyint</td>
<td>Whether the replica is current.</td>
</tr>
<tr>
<td>LAST_UPDATE_TIMESTAMP</td>
<td>datetime(6)</td>
<td>The time the last update occurred. Used to determine whether a record is stale.</td>
</tr>
<tr>
<td>REPLICA_LAG_IN_MILLISECONDS</td>
<td>double</td>
<td>The replica lag in milliseconds.</td>
</tr>
<tr>
<td>SERVER_ID</td>
<td>varchar(100)</td>
<td>The ID of the database server.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>varchar(100)</td>
<td>The ID of the database session. Used to determine whether a DB instance is a writer or reader instance.</td>
</tr>
</tbody>
</table>
Note

When a replica instance falls behind, the information queried from its `information_schema.replica_host_status` table might be outdated. In this situation, we recommend that you query from the writer instance instead. While the `mysql.ro_replica_status` table has similar information, we don't recommend that you use it.

information_schema.aurora_forwarding_processlist

The `information_schema.aurora_forwarding_processlist` table contains information about processes involved in write forwarding.

The contents of this table are visible only on the writer DB instance for a DB cluster with global or in-cluster write forwarding turned on. An empty result set is returned on reader DB instances.

<table>
<thead>
<tr>
<th>Field</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>bigint</td>
<td>The identifier of the connection on the writer DB instance. This identifier is the same value displayed in the Id column of the <code>SHOW PROCESSLIST</code> statement and returned by the <code>CONNECTION_ID()</code> function within the thread.</td>
</tr>
<tr>
<td>USER</td>
<td>varchar(32)</td>
<td>The MySQL user that issued the statement.</td>
</tr>
<tr>
<td>HOST</td>
<td>varchar(255)</td>
<td>The MySQL client that issued the statement. For forwarded statements, this field shows the application client host address that established the connection on the forwarding reader DB instance.</td>
</tr>
<tr>
<td>DB</td>
<td>varchar(64)</td>
<td>The default database for the thread.</td>
</tr>
<tr>
<td>COMMAND</td>
<td>varchar(16)</td>
<td>The type of command the thread is executing on behalf of the client, or <code>Sleep</code> if the session is idle. For descriptions</td>
</tr>
<tr>
<td>Field</td>
<td>Data type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>of thread commands, see the MySQL documentation on <strong>Thread Command Values</strong> in the MySQL documentation.</td>
</tr>
<tr>
<td>TIME</td>
<td>int</td>
<td>The time in seconds that the thread has been in its current state.</td>
</tr>
<tr>
<td>STATE</td>
<td>varchar(64)</td>
<td>An action, event, or state that indicates what the thread is doing. For descriptions of state values, see <strong>General Thread States</strong> in the MySQL documentation.</td>
</tr>
<tr>
<td>INFO</td>
<td>longtext</td>
<td>The statement that the thread is executing, or NULL if it isn't executing a statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements.</td>
</tr>
<tr>
<td>IS_FORWARDED</td>
<td>bigint</td>
<td>Indicates whether the thread is forwarded from a reader DB instance.</td>
</tr>
<tr>
<td>REPLICA_SESSION_ID</td>
<td>bigint</td>
<td>The connection identifier on the Aurora Replica. This identifier is the same value displayed in the Id column of the <strong>SHOW PROCESSLIST</strong> statement on the forwarding Aurora reader DB instance.</td>
</tr>
<tr>
<td>REPLICA_INSTANCE_ID</td>
<td>varchar(64)</td>
<td>The DB instance identifier of the forwarding thread.</td>
</tr>
<tr>
<td>REPLICA_CLUSTER_NAME</td>
<td>varchar(64)</td>
<td>The DB cluster identifier of the forwarding thread. For in-cluster write forwarding, this identifier is the same DB cluster as the writer DB instance.</td>
</tr>
<tr>
<td>REPLICA_REGION</td>
<td>varchar(64)</td>
<td>The AWS Region from which the forwarding thread originates. For in-cluster write forwarding, this Region is the same AWS Region as the writer DB instance.</td>
</tr>
</tbody>
</table>
Database engine updates for Amazon Aurora MySQL

Amazon Aurora releases updates regularly. Updates are applied to Aurora DB clusters during system maintenance windows. The timing when updates are applied depends on the region and maintenance window setting for the DB cluster, as well as the type of update.

Amazon Aurora releases are made available to all AWS Regions over the course of multiple days. Some Regions might temporarily show an engine version that isn't available in a different Region yet.

Updates are applied to all instances in a DB cluster at the same time. An update requires a database restart on all instances in a DB cluster, so you experience 20 to 30 seconds of downtime, after which you can resume using your DB cluster or clusters. You can view or change your maintenance window settings from the AWS Management Console.

For details about the Aurora MySQL versions that are supported by Amazon Aurora, see the Release Notes for Aurora MySQL.

Following, you can learn how to choose the right Aurora MySQL version for your cluster, how to specify the version when you create or upgrade a cluster, and the procedures to upgrade a cluster from one version to another with minimal interruption.

Topics
- Aurora MySQL version numbers and special versions
- Preparing for Amazon Aurora MySQL-Compatible Edition version 2 end of standard support
- Preparing for Amazon Aurora MySQL-Compatible Edition version 1 end of life
- Upgrading Amazon Aurora MySQL DB clusters
- Database engine updates and fixes for Amazon Aurora MySQL

Aurora MySQL version numbers and special versions

Although Aurora MySQL-Compatible Edition is compatible with the MySQL database engines, Aurora MySQL includes features and bug fixes that are specific to particular Aurora MySQL versions. Application developers can check the Aurora MySQL version in their applications by using SQL. Database administrators can check and specify Aurora MySQL versions when creating or upgrading Aurora MySQL DB clusters and DB instances.

Topics
Checking or specifying Aurora MySQL engine versions through AWS

When you perform administrative tasks using the AWS Management Console, AWS CLI, or RDS API, you specify the Aurora MySQL version in a descriptive alphanumeric format.

Starting with Aurora MySQL version 2, Aurora engine versions have the following syntax.

```
mysql-major-version.mysql_aurora.aurora-mysql-version
```

The `mysql-major-version` portion is 5.7 or 8.0. This value represents the version of the client protocol and general level of MySQL feature support for the corresponding Aurora MySQL version.

The `aurora-mysql-version` is a dotted value with three parts: the Aurora MySQL major version, the Aurora MySQL minor version, and the patch level. The major version is 2 or 3. Those values represent Aurora MySQL compatible with MySQL 5.7 or 8.0, respectively. The minor version represents the feature release within the 2.x or 3.x series. The patch level begins at 0 for each minor version, and represents the set of subsequent bug fixes that apply to the minor version. Occasionally, a new feature is incorporated into a minor version but not made visible immediately. In these cases, the feature undergoes fine-tuning and is made public in a later patch level.

All 2.x Aurora MySQL engine versions are wire-compatible with Community MySQL 5.7.12. All 3.x Aurora MySQL engine versions are wire-compatible with MySQL 8.0.23 onwards. You can refer to release notes of the specific 3.x version to find the corresponding MySQL compatible version.

For example, the engine versions for Aurora MySQL 3.02.0 and 2.11.2 are the following.

```
8.0.mysql_aurora.3.02.0
5.7.mysql_aurora.2.11.2
```

**Note**

There isn't a one-to-one correspondence between community MySQL versions and the Aurora MySQL 2.x versions. For Aurora MySQL version 3, there is a more direct mapping.
To check which bug fixes and new features are in a particular Aurora MySQL release, see Database engine updates for Amazon Aurora MySQL version 3 and Database engine updates for Amazon Aurora MySQL version 2 in the Release Notes for Aurora MySQL. For a chronological list of new features and releases, see Document history. To check the minimum version required for a security-related fix, see Security vulnerabilities fixed in Aurora MySQL in the Release Notes for Aurora MySQL.

You specify the Aurora MySQL engine version in some AWS CLI commands and RDS API operations. For example, you specify the --engine-version option when you run the AWS CLI commands create-db-cluster and modify-db-cluster. You specify the EngineVersion parameter when you run the RDS API operations CreateDBCluster and ModifyDBCluster.

In Aurora MySQL version 2 and higher, the engine version in the AWS Management Console also includes the Aurora version. Upgrading the cluster changes the displayed value. This change helps you to specify and check the precise Aurora MySQL versions, without the need to connect to the cluster or run any SQL commands.

Tip
For Aurora clusters managed through AWS CloudFormation, this change in the EngineVersion setting can trigger actions by AWS CloudFormation. For information about how AWS CloudFormation treats changes to the EngineVersion setting, see the AWS CloudFormation documentation.

Checking Aurora MySQL versions using SQL

The Aurora version numbers that you can retrieve in your application using SQL queries use the format `<major version>`.`<minor version>`.`<patch version>`. You can get this version number for any DB instance in your Aurora MySQL cluster by querying the AURORA_VERSION system variable. To get this version number, use one of the following queries.

```
select aurora_version();
select @@aurora_version;
```

Those queries produce output similar to the following.
The version numbers that the console, CLI, and RDS API return by using the techniques described in [Checking or specifying Aurora MySQL engine versions through AWS](#) are typically more descriptive.

### Aurora MySQL long-term support (LTS) releases

Each new Aurora MySQL version remains available for a certain amount of time for you to use when you create or upgrade a DB cluster. After this period, you must upgrade any clusters that use that version. You can manually upgrade your cluster before the support period ends, or Aurora can automatically upgrade it for you when its Aurora MySQL version is no longer supported.

Aurora designates certain Aurora MySQL versions as long-term support (LTS) releases. DB clusters that use LTS releases can stay on the same version longer and undergo fewer upgrade cycles than clusters that use non-LTS releases. Aurora supports each LTS release for at least three years after that release becomes available. When a DB cluster that's on an LTS release is required to upgrade, Aurora upgrades it to the next LTS release. That way, the cluster doesn't need to be upgraded again for a long time.

During the lifetime of an Aurora MySQL LTS release, new patch levels introduce fixes to important issues. The patch levels don't include any new features. You can choose whether to apply such patches to DB clusters running the LTS release. For certain critical fixes, Amazon might perform a managed upgrade to a patch level within the same LTS release. Such managed upgrades are performed automatically within the cluster maintenance window.

We recommend that you upgrade to the latest release, instead of using the LTS release, for most of your Aurora MySQL clusters. Doing so takes advantage of Aurora as a managed service and gives you access to the latest features and bug fixes. The LTS releases are intended for clusters with the following characteristics:

- You can't afford downtime on your Aurora MySQL application for upgrades outside of rare occurrences for critical patches.
- The testing cycle for the cluster and associated applications takes a long time for each update to the Aurora MySQL database engine.
The database version for your Aurora MySQL cluster has all the DB engine features and bug fixes that your application needs.

The current LTS release for Aurora MySQL is the following:

- Aurora MySQL version 3.04.*. For more details about the LTS version, see [Database engine updates for Amazon Aurora MySQL version 3](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-mysql-release-notes.html) in the *Release Notes for Aurora MySQL*.

**Note**

We recommend that you don't set the `AutoMinorVersionUpgrade` parameter to `true` (or enable **Auto minor version upgrade** in the AWS Management Console) for LTS versions. Doing so could lead to your DB cluster being upgraded to a non-LTS version such as 3.05.2.

**Aurora MySQL beta releases**

An Aurora MySQL beta release is an early, security fix-only release in a limited number of AWS Regions. These fixes are later deployed more broadly across all Regions with the next patch release.

The numbering for a beta release is similar to an Aurora MySQL minor version, but with an extra fourth digit, for example 2.12.0.1 or 3.05.0.1.

For more information, see [Database engine updates for Amazon Aurora MySQL version 2](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-mysql-release-notes.html) and [Database engine updates for Amazon Aurora MySQL version 3](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-mysql-release-notes.html) in the *Release Notes for Aurora MySQL*.

**Preparing for Amazon Aurora MySQL-Compatible Edition version 2 end of standard support**

Amazon Aurora MySQL-Compatible Edition version 2 (with MySQL 5.7 compatibility) is planned to reach the end of standard support on October 31, 2024. We recommend that you upgrade all clusters running Aurora MySQL version 2 to the default Aurora MySQL version 3 (with MySQL 8.0 compatibility) or higher before Aurora MySQL version 2 reaches the end of its standard support period. On October 31, 2024, Amazon RDS will automatically enroll your databases into [Amazon RDS Extended Support](https://aws.amazon.com/rds/extended-support/). If you're running Amazon Aurora MySQL version 2 (with MySQL 5.7 compatibility) in an Aurora Serverless version 1 cluster, this doesn't apply to you. If you want to
upgrade your Aurora Serverless version 1 clusters to Aurora MySQL version 3, see Upgrade path for Aurora Serverless v1 DB clusters.

You can find upcoming end-of-support dates for Aurora major versions in Amazon Aurora versions.

If you have clusters running Aurora MySQL version 2, you will receive periodic notices with the latest information about how to conduct an upgrade as we get closer to the end of standard support date. We will update this page periodically with the latest information.

**End of standard support timeline**

1. Now through October 31, 2024 – You can upgrade clusters from Aurora MySQL version 2 (with MySQL 5.7 compatibility) to Aurora MySQL version 3 (with MySQL 8.0 compatibility).
2. October 31, 2024 – On this date, Aurora MySQL version 2 will reach the end of standard support and Amazon RDS automatically enrolls your clusters into Amazon RDS Extended Support.

We will automatically enroll you in RDS Extended Support. For more information, see Using Amazon RDS Extended Support.

**Finding clusters affected by this end-of-life process**

To find clusters affected by this end-of-life process, use the following procedures.

⚠️ **Important**

Be sure to perform these instructions in every AWS Region and for each AWS account where your resources are located.

**Console**

**To find an Aurora MySQL version 2 cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. In the Filter by databases box, enter 5.7.
4. Check for Aurora MySQL in the engine column.
AWS CLI

To find clusters affected by this end-of-life process using the AWS CLI, call the `describe-db-clusters` command. You can use the sample script following.

Example

```
aws rds describe-db-clusters --include-share --query 'DBClusters[?(Engine==`aurora-mysql` && contains(EngineVersion,`5.7.mysql_aurora`))].{EngineVersion:EngineVersion, 
DBClusterIdentifier:DBClusterIdentifier, EngineMode:EngineMode}' --output table 
--region us-east-1
```

+---------------------------------------------------------------+  
|                      DescribeDBClusters                       |  
+---------------------+---------------+-------------------------+  
|         DBCI        |      EM       |          EV             |  
+---------------------+---------------+-------------------------+  
|    aurora-mysql2    |  provisioned  | 5.7.mysql_aurora.2.11.3 |  
| aurora-serverlessv1 |   serverless  | 5.7.mysql_aurora.2.11.3 |  
+---------------------+---------------+-------------------------+  

RDS API

To find Aurora MySQL DB clusters running Aurora MySQL version 2, use the RDS `DescribeDBClusters` API operation with the following required parameters:

- DescribeDBClusters
  - Filters.Filter.N
    - Name
      - engine
    - Values.Value.N
      - ['aurora']

Amazon RDS Extended Support

You can use Amazon RDS Extended Support over community MySQL 5.7 at no charge until the end of support date, October 31, 2024. On October 31, 2024, Amazon RDS automatically enrolls your databases into RDS Extended Support for Aurora MySQL version 2. RDS Extended Support
for Aurora is a paid service that provides up to 28 additional months of support for Aurora MySQL version 2 until the end of RDS Extended Support in February 2027. RDS Extended Support will only be offered for Aurora MySQL minor versions 2.11 and 2.12. To use Amazon Aurora MySQL version 2 past the end of standard support, plan to run your databases on one of these minor versions before October 31, 2024.

For more information about RDS Extended Support, such as charges and other considerations, see Using Amazon RDS Extended Support.

Performing an upgrade

Upgrading between major versions requires more extensive planning and testing than for a minor version. The process can take substantial time. We want to look at the upgrade as a three-step process, with activities before the upgrade, for the upgrade, and after the upgrade.

Before the upgrade:

Before the upgrade, we recommend that you check for application compatibility, performance, maintenance procedures, and similar considerations for the upgraded cluster, thereby confirming that post-upgrade your applications will work as expected. Here are five recommendations that will help provide you a better upgrade experience.

- First, it's critical to understand How the Aurora MySQL in-place major version upgrade works.
- Next, explore the upgrade techniques that are available when Upgrading from Aurora MySQL version 2 to version 3.
- To help you decide the right time and approach to upgrade, you can learn the differences between Aurora MySQL version 3 and your current environment with Comparison of Aurora MySQL version 2 and Aurora MySQL version 3.
- After you've decided on the option that's convenient and works best, try a mock in-place upgrade on a cloned cluster, using Planning a major version upgrade for an Aurora MySQL cluster. The pre-checker can run and determine if your database can be upgraded successfully, and if there is any application incompatibility issue post-upgrade as well as performance, maintenance procedures, and similar considerations.
- Review the upgrade checklist blog part 1 and part 2.
- Not all kinds or versions of Aurora MySQL clusters can use the in-place upgrade mechanism. For more information, see Aurora MySQL major version upgrade paths.
If you have any questions or concerns, the AWS Support Team is available on the community forums and Premium Support.

Doing the upgrade:

You can use one of the following upgrade techniques. The amount of downtime your system will experience depends on the technique chosen.

- **Blue/Green Deployments** – For situations where the top priority is to reduce application downtime, you can use Amazon RDS Blue/Green Deployments for performing the major version upgrade in provisioned Amazon Aurora DB clusters. A blue/green deployment creates a staging environment that copies the production environment. You can make certain changes to the Aurora DB cluster in the green (staging) environment without affecting production workloads. The switchover typically takes under a minute with no data loss. For more information, see Overview of Amazon RDS Blue/Green Deployments for Aurora. This minimizes downtime, but requires you to run additional resources while performing the upgrade.

- **In-place upgrades** – You can perform an in-place upgrade where Aurora automatically performs a precheck process for you, takes the cluster offline, backs up your cluster, performs the upgrade, and puts your cluster back online. An in-place major version upgrade can be performed in a few clicks, and doesn't involve other coordination or failovers with other clusters, but does involve downtime. For more information, see How to perform an in-place upgrade.

- **Snapshot restore** – You can upgrade your Aurora MySQL version 2 cluster by restoring from an Aurora MySQL version 2 snapshot into an Aurora MySQL version 3 cluster. To do this, you should follow the process for taking a snapshot and restoring from it. This process involves database interruption because you're restoring from a snapshot.

After the upgrade:

After the upgrade, you need to closely monitor your system (application and database) and make fine-tuning changes if necessary. Following the pre-upgrade steps closely will minimize the required changes needed. For more information, see Troubleshooting Amazon Aurora MySQL database performance.

To learn more about the methods, planning, testing, and troubleshooting of Aurora MySQL major version upgrades, be sure to thoroughly read Upgrading the major version of an Amazon Aurora MySQL DB cluster, including Troubleshooting for Aurora MySQL in-place upgrade. Also, note that some instance types aren't supported for Aurora MySQL version 3. For more information, see Aurora DB instance classes.
Upgrade path for Aurora Serverless v1 DB clusters

Upgrading between major versions requires more extensive planning and testing than for a minor version. The process can take substantial time. We want to look at the upgrade as a three-step process, with activities before the upgrade, for the upgrade, and after the upgrade.

Aurora MySQL version 2 (with MySQL 5.7 compatibility) will continue to receive standard support for Aurora Serverless v1 clusters.

If you want to upgrade to Amazon Aurora MySQL 3 (with MySQL 8.0 compatibility) and continue running Aurora Serverless, you can use Amazon Aurora Serverless v2. To understand the differences between Aurora Serverless v1 and Aurora Serverless v2, see Comparison of Aurora Serverless v2 and Aurora Serverless v1.

Upgrade to Aurora Serverless v2: You can upgrade an Aurora Serverless v1 cluster to Aurora Serverless v2. For more information, see Upgrading from an Aurora Serverless v1 cluster to Aurora Serverless v2.

Preparing for Amazon Aurora MySQL-Compatible Edition version 1 end of life

Amazon Aurora MySQL-Compatible Edition version 1 (with MySQL 5.6 compatibility) is planned to reach end of life on February 28, 2023. Amazon advises that you upgrade all clusters (provisioned and Aurora Serverless) running Aurora MySQL version 1 to Aurora MySQL version 2 (with MySQL 5.7 compatibility) or Aurora MySQL version 3 (with MySQL 8.0 compatibility). Do this before Aurora MySQL version 1 reaches the end of its support period.

For Aurora provisioned DB clusters, you can complete upgrades from Aurora MySQL version 1 to Aurora MySQL version 2 by several methods. You can find instructions for the in-place upgrade mechanism in How to perform an in-place upgrade. Another way to complete the upgrade is to take a snapshot of an Aurora MySQL version 1 cluster and restore the snapshot to an Aurora MySQL version 2 cluster. Or you can follow a multistep process that runs the old and new clusters side by side. For more details about each method, see Upgrading the major version of an Amazon Aurora MySQL DB cluster.

For Aurora Serverless v1 DB clusters, you can perform an in-place upgrade from Aurora MySQL version 1 to Aurora MySQL version 2. For more details about this method, see Modifying an Aurora Serverless v1 DB cluster.
For Aurora provisioned DB clusters, you can complete upgrades from Aurora MySQL version 1 to Aurora MySQL version 3 by using a two-stage upgrade process:

1. Upgrade from Aurora MySQL version 1 to Aurora MySQL version 2 using the methods described preceding.
2. Upgrade from Aurora MySQL version 2 to Aurora MySQL version 3 using the same methods as for upgrading from version 1 to version 2. For more details, see Upgrading from Aurora MySQL version 2 to version 3. Note the Feature differences between Aurora MySQL version 2 and 3.

You can find upcoming end-of-life dates for Aurora major versions in Amazon Aurora versions. Amazon automatically upgrades any clusters that you don't upgrade yourself before the end-of-life date. After the end-of-life date, these automatic upgrades to the subsequent major version occur during a scheduled maintenance window for clusters.

The following are additional milestones for upgrading Aurora MySQL version 1 clusters (provisioned and Aurora Serverless) that are reaching end of life. For each, the start time is 00:00 Universal Coordinated Time (UTC).

1. Now through February 28, 2023 – You can at any time start upgrades of Aurora MySQL version 1 (with MySQL 5.6 compatibility) clusters to Aurora MySQL version 2 (with MySQL 5.7 compatibility). From Aurora MySQL version 2, you can do a further upgrade to Aurora MySQL version 3 (with MySQL 8.0 compatibility) for Aurora provisioned DB clusters.

2. January 16, 2023 – After this time, you can't create new Aurora MySQL version 1 clusters or instances from either the AWS Management Console or the AWS Command Line Interface (AWS CLI). You also can't add new secondary Regions to an Aurora global database. This might affect your ability to recover from an unplanned outage as outlined in Recovering an Amazon Aurora global database from an unplanned outage, because you can't complete steps 5 and 6 after this time. You will also be unable to create a new cross-Region read replica running Aurora MySQL version 1. You can still do the following for existing Aurora MySQL version 1 clusters until February 28, 2023:
   - Restore a snapshot taken of an Aurora MySQL version 1 cluster to the same version as the original snapshot cluster.
   - Add read replicas (not applicable for Aurora Serverless DB clusters).
   - Change instance configuration.
   - Perform point-in-time restore.
   - Create clones of existing version 1 clusters.
• Create a new cross-Region read replica running Aurora MySQL version 2 or higher.

3. February 28, 2023 – After this time, we plan to automatically upgrade Aurora MySQL version 1 clusters to the default version of Aurora MySQL version 2 within a scheduled maintenance window that follows. Restoring Aurora MySQL version 1 DB snapshots results in an automatic upgrade of the restored cluster to the default version of Aurora MySQL version 2 at that time.

Upgrading between major versions requires more extensive planning and testing than for a minor version. The process can take substantial time.

For situations where the top priority is to reduce downtime, you can also use blue/green deployments for performing the major version upgrade in provisioned Amazon Aurora DB clusters. A blue/green deployment creates a staging environment that copies the production environment. You can make changes to the Aurora DB cluster in the green (staging) environment without affecting production workloads. The switchover typically takes under a minute with no data loss and no need for application changes. For more information, see Overview of Amazon RDS Blue/Green Deployments for Aurora.

After the upgrade is finished, you also might have follow-up work to do. For example, you might need to follow up due to differences in SQL compatibility, the way certain MySQL-related features work, or parameter settings between the old and new versions.

To learn more about the methods, planning, testing, and troubleshooting of Aurora MySQL major version upgrades, be sure to thoroughly read Upgrading the major version of an Amazon Aurora MySQL DB cluster.

Finding clusters affected by this end-of-life process

To find clusters affected by this end-of-life process, use the following procedures.

⚠️ Important

Be sure to perform these instructions in every AWS Region and for each AWS account where your resources are located.
Console

To find an Aurora MySQL version 1 cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. In the Filter by databases box, enter 5.6.
4. Check for Aurora MySQL in the engine column.

AWS CLI

To find clusters affected by this end-of-life process using the AWS CLI, call the describe-db-clusters command. You can use the sample script following.

Example

```
aws rds describe-db-clusters --include-share --query 'DBClusters[?Engine==`aurora`].
{EV:EngineVersion, DBCI:DBClusterIdentifier, EM:EngineMode}' --output table --region us-east-1
```

| DescribeDBClusters | | |
| +-------------------+--------------+-----------+|
| DBCI              | EM           | EV        |
| my-database-1     | serverless   | 5.6.10a   |

RDS API

To find Aurora MySQL DB clusters running Aurora MySQL version 1, use the RDS DescribeDBClusters API operation with the following required parameters:

- DescribeDBClusters
  - Filters.Filter.N
    - Name
    - engine
Upgrading Amazon Aurora MySQL DB clusters

You can upgrade an Aurora MySQL DB cluster to get bug fixes, new Aurora MySQL features, or to change to an entirely new version of the underlying database engine. The following sections show how.

Note

The type of upgrade that you do depends on how much downtime you can afford for your cluster, how much verification testing you plan to do, how important the specific bug fixes or new features are for your use case, and whether you plan to do frequent small upgrades or occasional upgrades that skip several intermediate versions. For each upgrade, you can change the major version, the minor version, and the patch level for your cluster. If you aren’t familiar with the distinction between Aurora MySQL major versions, minor versions, and patch levels, you can read the background information at Aurora MySQL version numbers and special versions.

Tip

You can minimize the downtime required for a DB cluster upgrade by using a blue/green deployment. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

Topics

- Upgrading the minor version or patch level of an Aurora MySQL DB cluster
- Upgrading the major version of an Amazon Aurora MySQL DB cluster

Upgrading the minor version or patch level of an Aurora MySQL DB cluster

You can use the following methods to upgrade the minor version of a DB cluster or to patch a DB cluster:
Upgrading Aurora MySQL by modifying the engine version (for Aurora MySQL version 2 and 3)

Enabling automatic upgrades between minor Aurora MySQL versions

For information about how zero-downtime patching can reduce interruptions during the upgrade process, see Using zero-downtime patching.

Before performing a minor version upgrade

We recommend that you perform the following actions to reduce the downtime during a minor version upgrade:

- The Aurora DB cluster maintenance should be performed during a period of low traffic. Use Performance Insights to identify these time periods in order to configure the maintenance windows correctly. For more information on Performance Insights, see Monitoring DB load with Performance Insights on Amazon RDS. For more information on DB cluster maintenance window, Adjusting the preferred DB cluster maintenance window.

- Use AWS SDKs that support exponential backoff and jitter as a best practice. For more information, see Exponential Backoff And Jitter.

Minor version upgrade prechecks for Aurora MySQL

When you start a minor version upgrade, Amazon Aurora runs prechecks automatically.

These prechecks are mandatory. You can't choose to skip them. The prechecks provide the following benefits:

- They enable you to avoid unplanned downtime during the upgrade.

- If there are incompatibilities, Amazon Aurora prevents the upgrade and provides a log for you to learn about them. You can then use the log to prepare your database for the upgrade by reducing the incompatibilities. For detailed information about removing incompatibilities, see Preparing your installation for upgrade in the MySQL documentation.

The prechecks run before the DB instance is stopped for the upgrade, meaning that they don't cause any downtime when they run. If the prechecks find an incompatibility, Aurora automatically cancels the upgrade before the DB instance is stopped. Aurora also generates an event for the incompatibility. For more information about Amazon Aurora events, see Working with Amazon RDS event notification.
Amazon Aurora

Aurora records detailed information about each incompatibility in the log file `PrePatchCompatibility.log`. In most cases, the log entry includes a link to the MySQL documentation for correcting the incompatibility. For more information about viewing log files, see Viewing and listing database log files.

Due to the nature of the prechecks, they analyze the objects in your database. This analysis results in resource consumption and increases the time for the upgrade to complete.

**Upgrading Aurora MySQL by modifying the engine version**

Upgrading the minor version of an Aurora MySQL DB cluster applies additional fixes and new features to an existing cluster.

This kind of upgrade applies to Aurora MySQL clusters where the original version and the upgraded version both have the same Aurora MySQL major version, either 2 or 3. The process is fast and straightforward because it doesn't involve any conversion for the Aurora MySQL metadata or reorganization of your table data.

You perform this kind of upgrade by modifying the engine version of the DB cluster using the AWS Management Console, AWS CLI, or the RDS API. For example, if your cluster is running Aurora MySQL 2.x, choose a higher 2.x version.

If you're performing a minor upgrade on an Aurora global database, upgrade all of the secondary clusters before you upgrade the primary cluster.

**Note**

To perform a minor version upgrade to Aurora MySQL version 3.03.* or higher, or version 2.12.*, use the following process:

1. Remove all secondary Regions from the global cluster. Follow the steps in Removing a cluster from an Amazon Aurora global database.
2. Upgrade the engine version of the primary Region to version 3.03.* or higher, or version 2.12.*, as applicable. Follow the steps in To modify the engine version of a DB cluster.
3. Add secondary Regions to the global cluster. Follow the steps in Adding an AWS Region to an Amazon Aurora global database.

**To modify the engine version of a DB cluster**

Upgrading Amazon Aurora MySQL DB clusters
• **By using the console** – Modify the properties of your cluster. In the **Modify DB cluster** window, change the Aurora MySQL engine version in the **DB engine version** box. If you aren't familiar with the general procedure for modifying a cluster, follow the instructions at [Modifying the DB cluster by using the console, CLI, and API](https://aws.amazon.com/).  

• **By using the AWS CLI** – Call the `modify-db-cluster` AWS CLI command, and specify the name of your DB cluster for the `--db-cluster-identifier` option and the engine version for the `--engine-version` option.

For example, to upgrade to Aurora MySQL version 2.12.1, set the `--engine-version` option to `5.7.mysql_aurora.2.12.1`. Specify the `--apply-immediately` option to immediately update the engine version for your DB cluster.

• **By using the RDS API** – Call the `ModifyDBCluster` API operation, and specify the name of your DB cluster for the `DBClusterIdentifier` parameter and the engine version for the `EngineVersion` parameter. Set the `ApplyImmediately` parameter to `true` to immediately update the engine version for your DB cluster.

**Enabling automatic upgrades between minor Aurora MySQL versions**

For an Amazon Aurora MySQL DB cluster, you can specify that Aurora upgrades the DB cluster automatically to new minor versions. You do so by setting the `AutoMinorVersionUpgrade` property (**Auto minor version upgrade** in the AWS Management Console) of the DB cluster.

Automatic upgrades occur during the maintenance window. If the individual DB instances in the DB cluster have different maintenance windows from the cluster maintenance window, then the cluster maintenance window takes precedence.

Automatic minor version upgrade doesn't apply to the following kinds of Aurora MySQL clusters:

• Clusters that are part of an Aurora global database  
• Clusters that have cross-Region replicas

The outage duration varies depending on workload, cluster size, the amount of binary log data, and if Aurora can use the zero-downtime patching (ZDP) feature. Aurora restarts the database cluster, so you might experience a short period of unavailability before resuming use of your cluster. In particular, the amount of binary log data affects recovery time. The DB instance processes the binary log data during recovery. Thus, a high volume of binary log data increases recovery time.
Aurora only performs automatic upgrades if all DB instances in your DB cluster have the AutoMinorVersionUpgrade setting enabled. For information on how to set it, and how it works when applied at the cluster and instance levels, see Automatic minor version upgrades for Aurora DB clusters.

Then if an upgrade path exists for the DB cluster's instances to a minor DB engine version that has AutoUpgrade set to true, the upgrade will take place. The AutoUpgrade setting is dynamic, and is set by RDS.

Auto minor version upgrades are performed to the default minor version.

You can use a CLI command such as the following to check the status of the AutoMinorVersionUpgrade setting for all of the DB instances in your Aurora MySQL clusters.

```bash
aws rds describe-db-instances 
  --query '[][].{DBClusterIdentifier:DBClusterIdentifier,DBInstanceIdentifier:DBInstanceIdentifier,AutoMinorVersionUpgrade:AutoMinorVersionUpgrade}'
```

That command produces output similar to the following:

```
[
  {
    "DBInstanceIdentifier": "db-t2-medium-instance",
    "DBClusterIdentifier": "cluster-57-2020-06-03-6411",
    "AutoMinorVersionUpgrade": true
  },
  {
    "DBInstanceIdentifier": "db-t2-small-original-size",
    "DBClusterIdentifier": "cluster-57-2020-06-03-6411",
    "AutoMinorVersionUpgrade": false
  },
  {
    "DBInstanceIdentifier": "instance-2020-05-01-2332",
    "DBClusterIdentifier": "cluster-57-2020-05-01-4615",
    "AutoMinorVersionUpgrade": true
  }
]
```

... output omitted ...
In this example, **Enable auto minor version upgrade** is turned off for the DB cluster `cluster-57-2020-06-03-6411`, because it's turned off for one of the DB instances in the cluster.

**Using zero-downtime patching**

Performing upgrades for Aurora MySQL DB clusters involves the possibility of an outage when the database is shut down and while it's being upgraded. By default, if you start the upgrade while the database is busy, you lose all the connections and transactions that the DB cluster is processing. If you wait until the database is idle to perform the upgrade, you might have to wait a long time.

The zero-downtime patching (ZDP) feature attempts, on a best-effort basis, to preserve client connections through an Aurora MySQL upgrade. If ZDP completes successfully, application sessions are preserved and the database engine restarts while the upgrade is in progress. The database engine restart can cause a drop in throughput lasting for a few seconds to approximately one minute.

ZDP doesn't apply to the following:

- Operating system (OS) patches and upgrades
- Major version upgrades

ZDP is available for all supported Aurora MySQL versions and DB instance classes.

ZDP isn't supported for Aurora Serverless v1 or Aurora global databases.

**Note**

We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see Using T instance classes for development and testing.

You can see metrics of important attributes during ZDP in the MySQL error log. You can also see information about when Aurora MySQL uses ZDP or chooses not to use ZDP on the **Events** page in the AWS Management Console.

In Aurora MySQL version 2.10 and higher and version 3, Aurora can perform a zero-downtime patch whether or not binary log replication is enabled. If binary log replication is enabled, Aurora MySQL automatically drops the connection to the binlog target during a ZDP operation. Aurora
MySQL automatically reconnects to the binlog target and resumes replication after the restart finishes.

ZDP also works in combination with the reboot enhancements in Aurora MySQL 2.10 and higher. Patching the writer DB instance automatically patches readers at the same time. After performing the patch, Aurora restores the connections on both the writer and reader DB instances. Before Aurora MySQL 2.10, ZDP applies only to the writer DB instance of a cluster.

ZDP might not complete successfully under the following conditions:

- Long-running queries or transactions are in progress. If Aurora can perform ZDP in this case, any open transactions are canceled.
- Temporary tables or table locks are in use, for example while data definition language (DDL) statements run. If Aurora can perform ZDP in this case, any open transactions are canceled.
- Pending parameter changes exist.

If no suitable time window for performing ZDP becomes available because of one or more of these conditions, patching reverts to the standard behavior.

---

**Note**

For Aurora MySQL version 2 lower than 2.11.0 and version 3 lower than 3.04.0, ZDP might not complete successfully when there are open Secure Socket Layer (SSL) or Transport Layer Security (TLS) connections.

---

Although connections remain intact following a successful ZDP operation, some variables and features are reinitialized. The following kinds of information aren't preserved through a restart caused by zero-downtime patching:

- Global variables. Aurora restores session variables, but it doesn't restore global variables after the restart.
- Status variables. In particular, the uptime value reported by the engine status is reset after a restart that uses the ZDR or ZDP mechanisms.
- LAST_INSERT_ID.
- In-memory auto_increment state for tables. The in-memory auto-increment state is reinitialized. For more information about auto-increment values, see [MySQL Reference Manual](https://dev.mysql.com/doc/refman/8.0/en/).
• Diagnostic information from INFORMATION_SCHEMA and PERFORMANCE_SCHEMA tables. This diagnostic information also appears in the output of commands such as SHOW PROFILE and SHOW PROFILES.

The following activities related to zero-downtime restart are reported on the Events page:

• Attempting to upgrade the database with zero downtime.
• Attempting to upgrade the database with zero downtime finished. The event reports how long the process took. The event also reports how many connections were preserved during the restart and how many connections were dropped. You can consult the database error log to see more details about what happened during the restart.

Alternative blue/green upgrade technique

In some situations, your top priority is to perform an immediate switchover from the old cluster to an upgraded one. In such situations, you can use a multistep process that runs the old and new clusters side-by-side. Here, you replicate data from the old cluster to the new one until you are ready for the new cluster to take over. For details, see Using Amazon RDS Blue/Green Deployments for database updates.

Upgrading the major version of an Amazon Aurora MySQL DB cluster

In an Aurora MySQL version number such as 2.12.1, the 2 represents the major version. Aurora MySQL version 2 is compatible with MySQL 5.7. Aurora MySQL version 3 is compatible with MySQL 8.0.

Upgrading between major versions requires more extensive planning and testing than for a minor version. The process can take substantial time. After the upgrade is finished, you also might have followup work to do. For example, this might occur because of differences in SQL compatibility or the way certain MySQL-related features work. Or it might occur because of differing parameter settings between the old and new versions.

Contents

• Upgrading from Aurora MySQL version 2 to version 3
• Planning a major version upgrade for an Aurora MySQL cluster
  • Simulating the upgrade by cloning your DB cluster
  • Using the blue-green upgrade technique
Upgrading from Aurora MySQL version 2 to version 3

If you have a MySQL 5.7–compatible cluster and want to upgrade it to a MySQL–8.0 compatible cluster, you can do so by running an upgrade process on the cluster itself. This kind of upgrade is an *in-place upgrade*, in contrast to upgrades that you do by creating a new cluster. This technique keeps the same endpoint and other characteristics of the cluster. The upgrade is relatively fast because it doesn't require copying all your data to a new cluster volume. This stability helps to minimize any configuration changes in your applications. It also helps to reduce the amount of testing for the upgraded cluster. This is because the number of DB instances and their instance classes all stay the same.

The in-place upgrade mechanism involves shutting down your DB cluster while the operation takes place. Aurora performs a clean shutdown and completes outstanding operations such as transaction rollback and undo purge. For more information, see [How the Aurora MySQL in-place major version upgrade works](#).

The in-place upgrade method is convenient, because it is simple to perform and minimizes configuration changes to associated applications. For example, an in-place upgrade preserves
the endpoints and set of DB instances for your cluster. However, the time needed for an in-place upgrade can vary depending on the properties of your schema and how busy the cluster is. Thus, depending on the needs for your cluster, you can choose among the upgrade techniques:

- In-place upgrade
- Blue/Green Deployment
- Snapshot restore

**Note**

If you use the AWS CLI or RDS API for the snapshot restore upgrade method, you must run a subsequent operation to create a writer DB instance in the restored DB cluster.

For general information about Aurora MySQL version 3 and its new features, see [Aurora MySQL version 3 compatible with MySQL 8.0](https://aws.amazon.com/documentation/aurora/mysql/). For details about planning an upgrade, see [Planning a major version upgrade for an Aurora MySQL cluster](https://aws.amazon.com/documentation/aurora/mysql/) and [How to perform an in-place upgrade](https://aws.amazon.com/documentation/aurora/mysql/).

**Planning a major version upgrade for an Aurora MySQL cluster**

To help you decide the right time and approach to upgrade, you can learn the differences between Aurora MySQL version 3 and your current environment:

- If you're converting from RDS for MySQL 8.0 or MySQL 8.0 Community Edition, see [Comparison of Aurora MySQL version 3 and MySQL 8.0 Community Edition](https://aws.amazon.com/documentation/aurora/mysql/).
- If you're upgrading from Aurora MySQL version 2, RDS for MySQL 5.7, or community MySQL 5.7, see [Comparison of Aurora MySQL version 2 and Aurora MySQL version 3](https://aws.amazon.com/documentation/aurora/mysql/).
- Create new MySQL 8.0-compatible versions of any custom parameter groups. Apply any necessary custom parameter values to the new parameter groups. Consult [Parameter changes for Aurora MySQL version 3](https://aws.amazon.com/documentation/aurora/mysql/) to learn about parameter changes.
- Review your Aurora MySQL version 2 database schema and object definitions for the usage of new reserved keywords introduced in MySQL 8.0 Community Edition. Do so before you upgrade. For more information, see [MySQL 8.0 New Keywords and Reserved Words](https://aws.amazon.com/documentation/aurora/mysql/) in the MySQL documentation.
You can also find more MySQL-specific upgrade considerations and tips in *Changes in MySQL 8.0* in the *MySQL Reference Manual*. For example, you can use the command `mysqlcheck --check-upgrade` to analyze your existing Aurora MySQL databases and identify potential upgrade issues.

**Note**

We recommend using larger DB instance classes when upgrading to Aurora MySQL version 3 using the in-place upgrade or snapshot restore technique. Examples are `db.r5.24xlarge` and `db.r6g.16xlarge`. This helps the upgrade process to complete faster by using the majority of available CPU capacity on the DB instance. You can change to the DB instance class that you want after the major version upgrade is complete.

After you finish the upgrade itself, you can follow the post-upgrade procedures in *Post-upgrade cleanup for Aurora MySQL version 3*. Finally, test your application's functionality and performance.

If you’re converting from RDS from MySQL or community MySQL, follow the migration procedure explained in *Migrating data to an Amazon Aurora MySQL DB cluster*. In some cases, you might use binary log replication to synchronize your data with an Aurora MySQL version 3 cluster as part of the migration. If so, the source system must run a version that's compatible with your target DB cluster.

To make sure that your applications and administration procedures work smoothly after upgrading a cluster between major versions, do some advance planning and preparation. To see what sorts of management code to update for your AWS CLI scripts or RDS API–based applications, see *How in-place upgrades affect the parameter groups for a cluster*. Also see *Changes to cluster properties between Aurora MySQL versions*.

To learn what issues that you might encounter during the upgrade, see *Troubleshooting for Aurora MySQL in-place upgrade*. For issues that might cause the upgrade to take a long time, you can test those conditions in advance and correct them.

**Note**

An in-place upgrade involves shutting down your DB cluster while the operation takes place. Aurora MySQL performs a clean shutdown and completes outstanding operations such as undo purge. An upgrade might take a long time if there many undo records to purge. We recommend performing the upgrade only after the history list length (HLL) is
Simulating the upgrade by cloning your DB cluster

You can check application compatibility, performance, maintenance procedures, and similar considerations for the upgraded cluster. To do so, you can perform a simulation of the upgrade before doing the real upgrade. This technique can be especially useful for production clusters. Here, it's important to minimize downtime and have the upgraded cluster ready to go as soon as the upgrade has finished.

Use the following steps:

1. Create a clone of the original cluster. Follow the procedure in [Cloning a volume for an Amazon Aurora DB cluster](#).
2. Set up a similar set of writer and reader DB instances as in the original cluster.
3. Perform an in-place upgrade of the cloned cluster. Follow the procedure in [How to perform an in-place upgrade](#).

Start the upgrade immediately after creating the clone. That way, the cluster volume is still identical to the state of the original cluster. If the clone sits idle before you do the upgrade, Aurora performs database cleanup processes in the background. In that case, the upgrade of the clone isn't an accurate simulation of upgrading the original cluster.

4. Test application compatibility, performance, administration procedures, and so on, using the cloned cluster.
5. If you encounter any issues, adjust your upgrade plans to account for them. For example, adapt any application code to be compatible with the feature set of the higher version. Estimate how long the upgrade is likely to take based on the amount of data in your cluster. You might also choose to schedule the upgrade for a time when the cluster isn't busy.
6. After you're satisfied that your applications and workload work properly with the test cluster, you can perform the in-place upgrade for your production cluster.
7. Work to minimize the total downtime of your cluster during a major version upgrade. To do so, make sure that the workload on the cluster is low or zero at the time of the upgrade. In particular, make sure that there are no long running transactions in progress when you start the upgrade.
Using the blue-green upgrade technique

You can also create a blue/green deployment that runs the old and new clusters side-by-side. Here, you replicate data from the old cluster to the new one until you are ready for the new cluster to take over. For details, see Using Amazon RDS Blue/Green Deployments for database updates.

Major version upgrade prechecks for Aurora MySQL

MySQL 8.0 includes a number of incompatibilities with MySQL 5.7. These incompatibilities can cause problems during an upgrade from Aurora MySQL version 2 to version 3. Some preparation might be required on your database for the upgrade to be successful.

When you start an upgrade from Aurora MySQL version 2 to version 3, Amazon Aurora runs prechecks automatically to detect these incompatibilities.

These prechecks are mandatory. You can't choose to skip them. The prechecks provide the following benefits:

- They enable you to avoid unplanned downtime during the upgrade.
- If there are incompatibilities, Amazon Aurora prevents the upgrade and provides a log for you to learn about them. You can then use the log to prepare your database for the upgrade to version 3 by reducing the incompatibilities. For detailed information about removing incompatibilities, see Preparing your installation for upgrade in the MySQL documentation and Upgrading to MySQL 8.0? Here is what you need to know... on the MySQL Server Blog.

For more information about upgrading to MySQL 8.0, see Upgrading MySQL in the MySQL documentation.

The prechecks include some that are included with MySQL and some that were created specifically by the Aurora team. For information about the prechecks provided by MySQL, see Upgrade checker utility.

The prechecks run before the DB instance is stopped for the upgrade, meaning that they don't cause any downtime when they run. If the prechecks find an incompatibility, Aurora automatically cancels the upgrade before the DB instance is stopped. Aurora also generates an event for the incompatibility. For more information about Amazon Aurora events, see Working with Amazon RDS event notification.

Aurora records detailed information about each incompatibility in the log file PrePatchCompatibility.log. In most cases, the log entry includes a link to the MySQL
documentation for correcting the incompatibility. For more information about viewing log files, see Viewing and listing database log files.

Due to the nature of the prechecks, they analyze the objects in your database. This analysis results in resource consumption and increases the time for the upgrade to complete.

**Community MySQL upgrade prechecks**

The following is a general list of incompatibilities between MySQL 5.7 and 8.0:

- Your MySQL 5.7–compatible DB cluster must not use features that aren't supported in MySQL 8.0.

  For more information, see [Features removed in MySQL 8.0](#) in the MySQL documentation.

- There must be no keyword or reserved word violations. Some keywords might be reserved in MySQL 8.0 that were not reserved previously.

  For more information, see [Keywords and reserved words](#) in the MySQL documentation.

- For improved Unicode support, consider converting objects that use the `utf8mb3` charset to use the `utf8mb4` charset. The `utf8mb3` character set is deprecated. Also, consider using `utf8mb4` for character set references instead of `utf8`, because currently `utf8` is an alias for the `utf8mb3` charset.

  For more information, see [The utf8mb3 character set (3-byte UTF-8 unicode encoding)](#) in the MySQL documentation.

- There must be no InnoDB tables with a nondefault row format.

- There must be no ZEROFILL or display length type attributes.

- There must be no partitioned table that uses a storage engine that does not have native partitioning support.

- There must be no tables in the MySQL 5.7 `mysql` system database that have the same name as a table used by the MySQL 8.0 data dictionary.

- There must be no tables that use obsolete data types or functions.

- There must be no foreign key constraint names longer than 64 characters.

- There must be no obsolete SQL modes defined in your `sql_mode` system variable setting.

- There must be no tables or stored procedures with individual `ENUM` or `SET` column elements that exceed 255 characters in length.
There must be no table partitions that reside in shared InnoDB tablespaces.

There must be no circular references in tablespace data file paths.

There must be no queries and stored program definitions that use ASC or DESC qualifiers for GROUP BY clauses.

There must be no removed system variables, and system variables must use the new default values for MySQL 8.0.

There must be no zero (0) date, datetime, or timestamp values.

There must be no schema inconsistencies resulting from file removal or corruption.

There must be no table names that contain the FTS character string.

There must be no InnoDB tables that belong to a different engine.

There must be no table or schema names that are invalid for MySQL 5.7.

For more information about upgrading to MySQL 8.0, see Upgrading MySQL in the MySQL documentation.

**Aurora MySQL upgrade prechecks**

Aurora MySQL has its own specific requirements when upgrading from version 2 to version 3:

- There must be no deprecated SQL syntax, such as SQL_CACHE, SQL_NO_CACHE, and QUERY_CACHE, in views, routines, triggers, and events.

- There must be no FTS_DOC_ID column present on any table without the FTS index.

- There must be no column definition mismatch between the InnoDB data dictionary and the actual table definition.

- All database and table names must be lowercase when the lower_case_table_names parameter is set to 1.

- Events and triggers must not have a missing or empty definer or an invalid creation context.

- All trigger names in a database must be unique.

- DDL recovery and Fast DDL aren't supported in Aurora MySQL version 3. There must be no artifacts in databases related to these features.

- Tables with the REDUNDANT or COMPACT row format can't have indexes larger than 767 bytes.

- The prefix length of indexes defined on tiny text columns can't exceed 255 bytes. With the utf8mb4 character set, this limits the prefix length supported to 63 characters.
A larger prefix length was allowed in MySQL 5.7 using the `innodb_large_prefix` parameter. This parameter is deprecated in MySQL 8.0.

- There must be no InnoDB metadata inconsistency in the `mysql.host` table.
- There must be no column data type mismatch in system tables.
- There must be no XA transactions in the `prepared` state.
- Column names in views can't be longer than 64 characters.
- Special characters in stored procedures can't be inconsistent.
- Tables can't have data file path inconsistency.

**Aurora MySQL major version upgrade paths**

Not all kinds or versions of Aurora MySQL clusters can use the in-place upgrade mechanism. You can learn the appropriate upgrade path for each Aurora MySQL cluster by consulting the following table.

<table>
<thead>
<tr>
<th>Type of Aurora MySQL DB cluster</th>
<th>Can it use in-place upgrade?</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aurora MySQL provisioned cluster, 2.0 or higher</td>
<td>Yes</td>
<td>In-place upgrade is supported for 5.7-compatible Aurora MySQL clusters. For information about upgrading to Aurora MySQL version 3, see <a href="#">Planning a major version upgrade for an Aurora MySQL cluster</a> and <a href="#">How to perform an in-place upgrade</a>.</td>
</tr>
<tr>
<td>Aurora MySQL provisioned cluster, 3.01.0 or higher</td>
<td>N/A</td>
<td>Use a minor version upgrade procedure to upgrade between Aurora MySQL version 3 versions.</td>
</tr>
<tr>
<td>Aurora Serverless v1 cluster</td>
<td>N/A</td>
<td>Currently, Aurora Serverless v1 is supported for Aurora MySQL only on version 2.</td>
</tr>
<tr>
<td>Type of Aurora MySQL DB cluster</td>
<td>Can it use in-place upgrade?</td>
<td>Action</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Aurora Serverless v2 cluster</td>
<td>N/A</td>
<td>Currently, Aurora Serverless v2 is supported for Aurora MySQL only on version 3.</td>
</tr>
<tr>
<td>Cluster in an Aurora global database</td>
<td>Yes</td>
<td>To upgrade Aurora MySQL from version 2 to version 3, follow the <a href="#">procedure for doing an in-place upgrade</a> for clusters in an Aurora global database. Perform the upgrade on the global cluster. Aurora upgrades the primary cluster and all the secondary clusters in the global database at the same time. If you use the AWS CLI or RDS API, call the modify-global-cluster command or ModifyGlobalCluster operation instead of modify-db-cluster or ModifyDBCluster. You can't perform an in-place upgrade from Aurora MySQL version 2 to version 3 if the <code>lower_case_table_names</code> parameter is turned on. For more information, see <a href="#">Major version upgrades</a>.</td>
</tr>
<tr>
<td>Parallel query cluster</td>
<td>Yes</td>
<td>You can perform an in-place upgrade. In this case, choose 2.09.1 or higher for the Aurora MySQL version.</td>
</tr>
<tr>
<td>Cluster that is the target of binary log replication</td>
<td>Maybe</td>
<td>If the binary log replication is from an Aurora MySQL cluster, you can perform an in-place upgrade. You can't perform the upgrade if the binary log replication is from an RDS for MySQL or an on-premises MySQL DB instance. In that case, you can upgrade using the snapshot restore mechanism.</td>
</tr>
<tr>
<td>Type of Aurora MySQL DB cluster</td>
<td>Can it use in-place upgrade?</td>
<td>Action</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------</td>
<td>--------</td>
</tr>
<tr>
<td>Cluster with zero DB instances</td>
<td>No</td>
<td>Using the AWS CLI or the RDS API, you can create an Aurora MySQL cluster without any attached DB instances. In the same way, you can also remove all DB instances from an Aurora MySQL cluster while leaving the data in the cluster volume intact. While a cluster has zero DB instances, you can't perform an in-place upgrade. The upgrade mechanism requires a writer instance in the cluster to perform conversions on the system tables, data files, and so on. In this case, use the AWS CLI or the RDS API to create a writer instance for the cluster. Then you can perform an in-place upgrade.</td>
</tr>
<tr>
<td>Cluster with backtrack enabled</td>
<td>Yes</td>
<td>You can perform an in-place upgrade for an Aurora MySQL cluster that uses the backtrack feature. However, after the upgrade, you can't backtrack the cluster to a time before the upgrade.</td>
</tr>
</tbody>
</table>

**How the Aurora MySQL in-place major version upgrade works**

Aurora MySQL performs a major version upgrade as a multistage process. You can check the current status of an upgrade. Some of the upgrade steps also provide progress information. As each stage begins, Aurora MySQL records an event. You can examine events as they occur on the **Events** page in the RDS console. For more information about working with events, see [Working with Amazon RDS event notification](#).

⚠️ **Important**

Once the process begins, it runs until the upgrade either succeeds or fails. You can't cancel the upgrade while it's underway. If the upgrade fails, Aurora rolls back all the changes and your cluster has the same engine version, metadata, and so on as before.
The upgrade process consists of these stages:

1. Aurora performs a series of **prechecks** before beginning the upgrade process. Your cluster keeps running while Aurora does these checks. For example, the cluster can't have any XA transactions in the prepared state or be processing any data definition language (DDL) statements. For example, you might need to shut down applications that are submitting certain kinds of SQL statements. Or you might simply wait until certain long-running statements are finished. Then try the upgrade again. Some checks test for conditions that don't prevent the upgrade but might make the upgrade take a long time.

   If Aurora detects that any required conditions aren't met, modify the conditions identified in the event details. Follow the guidance in **Troubleshooting for Aurora MySQL in-place upgrade**. If Aurora detects conditions that might cause a slow upgrade, plan to monitor the upgrade over an extended period.

2. Aurora takes your cluster offline. Then Aurora performs a similar set of tests as in the previous stage, to confirm that no new issues arose during the shutdown process. If Aurora detects any conditions at this point that would prevent the upgrade, Aurora cancels the upgrade and brings the cluster back online. In this case, confirm when the conditions no longer apply and start the upgrade again.

3. Aurora creates a snapshot of your cluster volume. Suppose that you discover compatibility or other kinds of issues after the upgrade is finished. Or suppose that you want to perform testing using both the original and upgraded clusters. In such cases, you can restore from this snapshot to create a new cluster with the original engine version and the original data.

   **Tip**
   
   This snapshot is a manual snapshot. However, Aurora can create it and continue with the upgrade process even if you have reached your quota for manual snapshots. This snapshot remains permanently (if needed) until you delete it. After you finish all post-upgrade testing, you can delete this snapshot to minimize storage charges.

4. Aurora clones your cluster volume. Cloning is a fast operation that doesn't involve copying the actual table data. If Aurora encounters an issue during the upgrade, it reverts to the original data from the cloned cluster volume and brings the cluster back online. The temporary cloned volume during the upgrade isn't subject to the usual limit on the number of clones for a single cluster volume.
5. Aurora performs a clean shutdown for the writer DB instance. During the clean shutdown, progress events are recorded every 15 minutes for the following operations. You can examine events as they occur on the Events page in the RDS console.

- Aurora purges the undo records for old versions of rows.
- Aurora rolls back any uncommitted transactions.

6. Aurora upgrades the engine version on the writer DB instance:

- Aurora installs the binary for the new engine version on the writer DB instance.
- Aurora uses the writer DB instance to upgrade your data to MySQL 5.7-compatible format. During this stage, Aurora modifies the system tables and performs other conversions that affect the data in your cluster volume. In particular, Aurora upgrades the partition metadata in the system tables to be compatible with the MySQL 5.7 partition format. This stage can take a long time if the tables in your cluster have a large number of partitions.

    If any errors occur during this stage, you can find the details in the MySQL error logs. After this stage starts, if the upgrade process fails for any reason, Aurora restores the original data from the cloned cluster volume.

7. Aurora upgrades the engine version on the reader DB instances.

8. The upgrade process is completed. Aurora records a final event to indicate that the upgrade process completed successfully. Now your DB cluster is running the new major version.

**Blue/Green Deployments**

In some situations, your top priority is to perform an immediate switchover from the old cluster to an upgraded one. In such situations, you can use a multistep process that runs the old and new clusters side-by-side. Here, you replicate data from the old cluster to the new one until you are ready for the new cluster to take over. For details, see Using Amazon RDS Blue/Green Deployments for database updates.

**How to perform an in-place upgrade**

We recommend that you review the background material in How the Aurora MySQL in-place major version upgrade works.

Perform any preupgrade planning and testing, as described in Planning a major version upgrade for an Aurora MySQL cluster.
The following example upgrades the mydbcluster-cluster DB cluster to Aurora MySQL version 3.04.1.

**To upgrade the major version of an Aurora MySQL DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

2. If you used a custom parameter group for the original DB cluster, create a corresponding parameter group compatible with the new major version. Make any necessary adjustments to the configuration parameters in that new parameter group. For more information, see [How in-place upgrades affect the parameter groups for a cluster](#).

3. In the navigation pane, choose **Databases**.

4. In the list, choose the DB cluster that you want to modify.

5. Choose **Modify**.

6. For **Version**, choose a new Aurora MySQL major version.

   We generally recommend using the latest minor version of the major version. Here, we choose the current default version.
7. Choose **Continue**.

8. On the next page, specify when to perform the upgrade. Choose **During the next scheduled maintenance window** or **Immediately**.

9. (Optional) Periodically examine the **Events** page in the RDS console during the upgrade. Doing so helps you to monitor the progress of the upgrade and identify any issues. If the upgrade encounters any issues, consult [Troubleshooting for Aurora MySQL in-place upgrade](#) for the steps to take.

10. If you created a new parameter group at the start of this procedure, associate the custom parameter group with your upgraded cluster. For more information, see [How in-place upgrades affect the parameter groups for a cluster](#).
11. (Optional) After you complete any post-upgrade testing, delete the manual snapshot that Aurora created at the beginning of the upgrade.

AWS CLI

To upgrade the major version of an Aurora MySQL DB cluster, use the AWS CLI `modify-db-cluster` command with the following required parameters:

- `--db-cluster-identifier`
- `--engine-version`
- `--allow-major-version-upgrade`
- `--apply-immediately` or `--no-apply-immediately`

If your cluster uses any custom parameter groups, also include one or both of the following options:

- `--db-cluster-parameter-group-name`, if the cluster uses a custom cluster parameter group
- `--db-instance-parameter-group-name`, if any instances in the cluster use a custom DB parameter group

The following example upgrades the `sample-cluster` DB cluster to Aurora MySQL version 3.04.1. The upgrade happens immediately, instead of waiting for the next maintenance window.

Example

For Linux, macOS, or Unix:

```sh
aws rds modify-db-cluster \
  --db-cluster-identifier sample-cluster \
  --engine-version 8.0.mysql_aurora.3.04.1 \
  --allow-major-version-upgrade \
  --apply-immediately
```
For Windows:

```
aws rds modify-db-cluster ^
   --db-cluster-identifier sample-cluster ^
   --engine-version 8.0.mysql_aurora.3.04.1 ^
   --allow-major-version-upgrade ^
   --apply-immediately
```

You can combine other CLI commands with `modify-db-cluster` to create an automated end-to-end process for performing and verifying upgrades. For more information and examples, see [Aurora MySQL in-place upgrade tutorial](#).

**Note**

If your cluster is part of an Aurora global database, the in-place upgrade procedure is slightly different. You call the `modify-global-cluster` command operation instead of `modify-db-cluster`. For more information, see [In-place major upgrades for global databases](#).

**RDS API**

To upgrade the major version of an Aurora MySQL DB cluster, use the RDS API operation `ModifyDBCluster` with the following required parameters:

- **DBClusterIdentifier**
- **Engine**
- **EngineVersion**
- **AllowMajorVersionUpgrade**
- **ApplyImmediately** (set to true or false)

**Note**

If your cluster is part of an Aurora global database, the in-place upgrade procedure is slightly different. You call the `ModifyGlobalCluster` operation instead of `ModifyDBCluster`. For more information, see [In-place major upgrades for global databases](#).
How in-place upgrades affect the parameter groups for a cluster

Aurora parameter groups have different sets of configuration settings for clusters that are compatible with MySQL 5.7 or 8.0. When you perform an in-place upgrade, the upgraded cluster and all its instances must use the corresponding cluster and instance parameter groups:

Your cluster and instances might use the default 5.7-compatible parameter groups. If so, the upgraded cluster and instance start with the default 8.0-compatible parameter groups. If your cluster and instances use any custom parameter groups, make sure to create corresponding or 8.0-compatible parameter groups. Also make sure to specify those during the upgrade process.

Note

For most parameter settings, you can choose the custom parameter group at two points. These are when you create the cluster or associate the parameter group with the cluster later.

However, if you use a nondefault setting for the `lower_case_table_names` parameter, you must set up the custom parameter group with this setting in advance. Then specify the parameter group when you perform the snapshot restore to create the cluster. Any change to the `lower_case_table_names` parameter has no effect after the cluster is created. We recommend that you use the same setting for `lower_case_table_names` when you upgrade from Aurora MySQL version 2 to version 3.

With an Aurora global database based on Aurora MySQL, you can't perform an in-place upgrade from Aurora MySQL version 2 to version 3 if the `lower_case_table_names` parameter is turned on. For more information on the methods that you can use, see Major version upgrades.

Important

If you specify any custom parameter group during the upgrade process, make sure to manually reboot the cluster after the upgrade finishes. Doing so makes the cluster begin using your custom parameter settings.

Changes to cluster properties between Aurora MySQL versions

When you upgrade from Aurora MySQL version 2 to version 3, make sure to check any applications or scripts that you use to set up or manage Aurora MySQL clusters and DB instances.
Also, change your code that manipulates parameter groups to account for the fact that the default parameter group names are different for 5.7- and 8.0-compatible clusters. The default parameter group names for Aurora MySQL version 2 and 3 clusters are `default.aurora-mysql5.7` and `default.aurora-mysql8.0`, respectively.

For example, you might have code like the following that applies to your cluster before an upgrade.

```bash
# Check the default parameter values for MySQL 5.7-compatible clusters.
aws rds describe-db-parameters --db-parameter-group-name default.aurora-mysql5.7 --region us-east-1
```

After upgrading the major version of the cluster, modify that code as follows.

```bash
# Check the default parameter values for MySQL 8.0-compatible clusters.
aws rds describe-db-parameters --db-parameter-group-name default.aurora-mysql8.0 --region us-east-1
```

**In-place major upgrades for global databases**

For an Aurora global database, you upgrade the global database cluster. Aurora automatically upgrades all of the clusters at the same time and makes sure that they all run the same engine version. This requirement is because any changes to system tables, data file formats, and so on, are automatically replicated to all the secondary clusters.

Follow the instructions in [How the Aurora MySQL in-place major version upgrade works](#). When you specify what to upgrade, make sure to choose the global database cluster instead of one of the clusters it contains.

If you use the AWS Management Console, choose the item with the role **Global database**.

<table>
<thead>
<tr>
<th>DB identifier</th>
<th>Role</th>
<th>Engine</th>
<th>Engine version</th>
</tr>
</thead>
<tbody>
<tr>
<td>global-cluster</td>
<td>Global database</td>
<td>Aurora MySQL</td>
<td>5.7.mysql_aurora.209.2</td>
</tr>
<tr>
<td>cluster1</td>
<td>Primary cluster</td>
<td>Aurora MySQL</td>
<td>5.7.mysql_aurora.209.2</td>
</tr>
<tr>
<td>dbinstance-1</td>
<td>Writer instance</td>
<td>Aurora MySQL</td>
<td>5.7.mysql_aurora.209.2</td>
</tr>
<tr>
<td>cluster-2</td>
<td>Secondary cluster</td>
<td>Aurora MySQL</td>
<td>5.7.mysql_aurora.209.2</td>
</tr>
<tr>
<td>dbinstance-2</td>
<td>Reader instance</td>
<td>Aurora MySQL</td>
<td>5.7.mysql_aurora.209.2</td>
</tr>
</tbody>
</table>
If you use the AWS CLI or RDS API, start the upgrade process by calling the `modify-global-cluster` command or `ModifyGlobalCluster` operation. You use one of these instead of `modify-db-cluster` or `ModifyDBCluster`.

**Note**
You can't specify a custom parameter group for the global database cluster while you're performing a major version upgrade of that Aurora global database. Create your custom parameter groups in each Region of the global cluster. Then apply them manually to the Regional clusters after the upgrade.

To upgrade the major version of an Aurora MySQL global database cluster by using the AWS CLI, use the `modify-global-cluster` command with the following required parameters:

- `--global-cluster-identifier`
- `--engine aurora-mysql`
- `--engine-version`
- `--allow-major-version-upgrade`

The following example upgrades the global database cluster to Aurora MySQL version 2.10.2.

**Example**

For Linux, macOS, or Unix:
```
aws rds modify-global-cluster \
   --global-cluster-identifier global_cluster_identifier \
   --engine aurora-mysql \
   --engine-version 5.7.mysql_aurora.2.10.2 \
   --allow-major-version-upgrade
```

For Windows:
```
aws rds modify-global-cluster ^
   --global-cluster-identifier global_cluster_identifier ^
   --engine aurora-mysql ^
   --engine-version 5.7.mysql_aurora.2.10.2 ^
```
Backtrack considerations

If the cluster that you upgraded had the Backtrack feature enabled, you can’t backtrack the upgraded cluster to a time that’s before the upgrade.

Aurora MySQL in-place upgrade tutorial

The following Linux examples show how you might perform the general steps of the in-place upgrade procedure using the AWS CLI.

This first example creates an Aurora DB cluster that’s running a 2.x version of Aurora MySQL. The cluster includes a writer DB instance and a reader DB instance. The wait db-instance-available command pauses until the writer DB instance is available. That’s the point when the cluster is ready to be upgraded.

```
aws rds create-db-cluster --db-cluster-identifier mynewdbcluster --engine aurora-mysql \
  --db-cluster-version 5.7.mysql_aurora.2.10.2
...
aws rds create-db-instance --db-instance-identifier mynewdbcluster-instance1 \
  --db-cluster-identifier mynewdbcluster --db-instance-class db.t4g.medium --engine
aurora-mysql
...
aws rds wait db-instance-available --db-instance-identifier mynewdbcluster-instance1
```

The Aurora MySQL 3.x versions that you can upgrade the cluster to depend on the 2.x version that the cluster is currently running and on the AWS Region where the cluster is located. The first command, with --output text, just shows the available target version. The second command shows the full JSON output of the response. In that response, you can see details such as the aurora-mysql value that you use for the engine parameter. You can also see the fact that upgrading to 3.02.0 represents a major version upgrade.

```
aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster \
  --query '*[].{EngineVersion:EngineVersion}' --output text
5.7.mysql_aurora.2.10.2
aws rds describe-db-engine-versions --engine aurora-mysql --engine-version
5.7.mysql_aurora.2.10.2
```
This example shows how if you enter a target version number that isn't a valid upgrade target for the cluster, Aurora doesn't perform the upgrade. Aurora also doesn't perform a major version upgrade unless you include the `--allow-major-version-upgrade` parameter. That way, you can't accidentally perform an upgrade that has the potential to require extensive testing and changes to your application code.

```bash
aws rds modify-db-cluster --db-cluster-identifier mynewdbcluster \
    --engine-version 5.7.mysql_aurora.2.10.2 --apply-immediately
An error occurred (InvalidParameterCombination) when calling the ModifyDBCluster operation: Cannot find upgrade target from 5.7.mysql_aurora.2.10.2 with requested version 5.7.mysql_aurora.2.09.2.

aws rds modify-db-cluster --db-cluster-identifier mynewdbcluster \
    --engine-version 8.0.mysql_aurora.3.02.0 --region us-east-1 --apply-immediately
An error occurred (InvalidParameterCombination) when calling the ModifyDBCluster operation: The AllowMajorVersionUpgrade flag must be present when upgrading to a new major version.

aws rds modify-db-cluster --db-cluster-identifier mynewdbcluster \
    --engine-version 8.0.mysql_aurora.3.02.0 --apply-immediately --allow-major-version-upgrade
{
    "DBClusterIdentifier": "mynewdbcluster",
    "Status": "available",
    "Engine": "aurora-mysql",
    "EngineVersion": "5.7.mysql_aurora.2.10.2"
}
```
It takes a few moments for the status of the cluster and associated DB instances to change to upgrading. The version numbers for the cluster and DB instances only change when the upgrade is finished. Again, you can use the `wait db-instance-available` command for the writer DB instance to wait until the upgrade is finished before proceeding.

```bash
aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster \
   --query '[].[Status,EngineVersion]' --output text
upgrading 5.7.mysql_aurora.2.10.2

aws rds describe-db-instances --db-instance-identifier mynewdbcluster-instance1 \
   --query '[].
   {DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceStatus:DBInstanceStatus} | [0]' 
   {
   "DBInstanceIdentifier": "mynewdbcluster-instance1",
   "DBInstanceStatus": "upgrading"
   }

aws rds wait db-instance-available --db-instance-identifier mynewdbcluster-instance1
```

At this point, the version number for the cluster matches the one that was specified for the upgrade.

```bash
aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster \
   --query '[].[EngineVersion]' --output text
8.0.mysql_aurora.3.02.0
```

The preceding example did an immediate upgrade by specifying the `--apply-immediately` parameter. To let the upgrade happen at a convenient time when the cluster isn't expected to be busy, you can specify the `--no-apply-immediately` parameter. Doing so makes the upgrade start during the next maintenance window for the cluster. The maintenance window defines the period during which maintenance operations can start. A long-running operation might not finish during the maintenance window. Thus, you don't need to define a larger maintenance window even if you expect that the upgrade might take a long time.

The following example upgrades a cluster that's initially running Aurora MySQL version 2.10.2. In the `describe-db-engine-versions` output, the `False` and `True` values represent the `IsMajorVersionUpgrade` property. From version 2.10.2, you can upgrade to some other 2.*
versions. Those upgrades aren't considered major version upgrades and so don't require an in-place upgrade. In-place upgrade is only available for upgrades to the 3.* versions that are shown in the list.

```
aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster \
   --query '*[].{EngineVersion:EngineVersion}' --output text
5.7.mysql_aurora.2.10.2

aws rds describe-db-engine-versions --engine aurora-mysql --engine-version
5.7.mysql_aurora.2.10.2 \
   --query '*[].[ValidUpgradeTarget][0][0][*].[EngineVersion,IsMajorVersionUpgrade]' --output text
5.7.mysql_aurora.2.10.3 False
5.7.mysql_aurora.2.11.0 False
5.7.mysql_aurora.2.11.1 False
8.0.mysql_aurora.3.01.1 True
8.0.mysql_aurora.3.02.0 True
8.0.mysql_aurora.3.02.2 True

aws rds modify-db-cluster --db-cluster-identifier mynewdbcluster \
   --engine-version 8.0.mysql_aurora.3.02.0 --no-apply-immediately --allow-major-
   version-upgrade
...`

When a cluster is created without a specified maintenance window, Aurora picks a random day of the week. In this case, the modify-db-cluster command is submitted on a Monday. Thus, we change the maintenance window to be Tuesday morning. All times are represented in the UTC time zone. The `tue:10:00-tue:10:30` window corresponds to 2:00-2:30 AM Pacific time. The change in the maintenance window takes effect immediately.

```
aws rds describe-db-clusters --db-cluster-identifier mynewdbcluster --query '*[].
   [PreferredMaintenanceWindow]'
  
  [  
   "sat:08:20-sat:08:50"
  ]

aws rds modify-db-cluster --db-cluster-identifier mynewdbcluster --preferred-
   maintenance-window tue:10:00-tue:10:30`

Upgrading Amazon Aurora MySQL DB clusters
The following example shows how to get a report of the events generated by the upgrade. The `--duration` argument represents the number of minutes to retrieve the event information. This argument is needed, because by default `describe-events` only returns events from the last hour.

```bash
aws rds describe-events --source-type db-cluster --source-identifier mynewdbcluster --duration 20160
{
    "Events": [
    {
        "SourceIdentifier": "mynewdbcluster",
        "SourceType": "db-cluster",
        "Message": "DB cluster created",
        "EventCategories": [
            "creation"
        ],
        "Date": "2022-11-17T01:24:11.093000+00:00",
        "SourceArn": "arn:aws:rds:us-east-1:123456789012:cluster:mynewdbcluster"
    },
    {
        "SourceIdentifier": "mynewdbcluster",
        "SourceType": "db-cluster",
        "Message": "Upgrade in progress: Performing online pre-upgrade checks.",
        "EventCategories": [
            "maintenance"
        ],
        "Date": "2022-11-18T22:57:08.450000+00:00",
        "SourceArn": "arn:aws:rds:us-east-1:123456789012:cluster:mynewdbcluster"
    },
    {
        "SourceIdentifier": "mynewdbcluster",
        "SourceType": "db-cluster",
        "Message": "Upgrade in progress: Performing offline pre-upgrade checks.",
        "EventCategories": [
            "maintenance"
        ],
```

Finding the reasons for upgrade failures

In the previous tutorial, the upgrade from Aurora MySQL version 2 to version 3 succeeded. But if the upgrade had failed, you would want to know why.

You can start by using the `describe-events` AWS CLI command to look at the DB cluster events. This example shows the events for `mydbcluster` for the last 10 hours.

```
aws rds describe-events \
    --source-type db-cluster \n    --source-identifier mydbcluster \n    --duration 600
```

In this case, we had an upgrade precheck failure.

```json
{
    "Events": [
        {
```

To diagnose the exact cause of the problem, examine the database logs for the writer DB instance. When an upgrade to Aurora MySQL version 3 fails, the writer instance contains a log file with the name `upgrade-prechecks.log`. This example shows how to detect the presence of that log and then download it to a local file for examination.

```bash
aws rds describe-db-log-files --db-instance-identifier mydbcluster-instance \
   --query '*[].[LogFileName]' --output text
```

error/mysql-error-running.log
error/mysql-error-running.log.2024-04-11.20
error/mysql-error-running.log.2024-04-11.21
error/mysql-error.log
external/mysql-external.log
upgrade-prechecks.log

```bash
aws rds download-db-log-file-portion --db-instance-identifier mydbcluster-instance \
   --log-file-name upgrade-prechecks.log
```
The upgrade-prechecks.log file is in JSON format. We download it using the --output text option to avoid encoding JSON output within another JSON wrapper. For Aurora MySQL version 3 upgrades, this log always includes certain informational and warning messages. It only includes error messages if the upgrade fails. If the upgrade succeeds, the log file isn't produced at all.

To summarize all of the errors and display the associated object and description fields, you can run the command `grep -A 2 "level": "Error"` on the contents of the upgrade-prechecks.log file. Doing so displays each error line and the two lines after it. These contain the name of the corresponding database object and guidance about how to correct the problem.

```
$ cat upgrade-prechecks.log | grep -A 2 "level": "Error"
```

In this example, you can run the following SQL command on the offending table to try to fix the issue, or you can re-create the table without the dangling index.

```
OPTIMIZE TABLE problematic_upgrade.dangling_fulltext_index;
```

Then retry the upgrade.

**Troubleshooting for Aurora MySQL in-place upgrade**

Use the following tips to help troubleshoot problems with Aurora MySQL in-place upgrades. These tips don't apply to Aurora Serverless DB clusters.

<table>
<thead>
<tr>
<th>Reason for in-place upgrade being canceled or slow</th>
<th>Effect</th>
<th>Solution to allow in-place upgrade to complete within maintenance window</th>
</tr>
</thead>
<tbody>
<tr>
<td>Associated Aurora cross-Region replica isn't patched yet</td>
<td>Aurora cancels the upgrade.</td>
<td>Upgrade the Aurora cross-Region replica and try again.</td>
</tr>
<tr>
<td>Reason for in-place upgrade being canceled or slow</td>
<td>Effect</td>
<td>Solution to allow in-place upgrade to complete within maintenance window</td>
</tr>
<tr>
<td>--------------------------------------------------</td>
<td>--------</td>
<td>--------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Cluster has XA transactions in the prepared state</td>
<td>Aurora cancels the upgrade.</td>
<td>Commit or roll back all prepared XA transactions.</td>
</tr>
<tr>
<td>Cluster is processing any data definition language (DDL) statements</td>
<td>Aurora cancels the upgrade.</td>
<td>Consider waiting and performing the upgrade after all DDL statements are finished.</td>
</tr>
<tr>
<td>Cluster has uncommitted changes for many rows</td>
<td>Upgrade might take a long time.</td>
<td>The upgrade process rolls back the uncommitted changes. The indicator for this condition is the value of TRX_ROWS_MODIFIED in the INFORMATION_SCHEMA.INNODB_TRX table. Consider performing the upgrade only after all large transactions are committed or rolled back.</td>
</tr>
<tr>
<td>Reason for in-place upgrade being canceled or slow</td>
<td>Effect</td>
<td>Solution to allow in-place upgrade to complete within maintenance window</td>
</tr>
<tr>
<td>--------------------------------------------------</td>
<td>--------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Cluster has high number of undo records</td>
<td>Upgrade might take a long time.</td>
<td>Even if the uncommitted transactions don't affect a large number of rows, they might involve a large volume of data. For example, you might be inserting large BLOBs. Aurora doesn't automatically detect or generate an event for this kind of transaction activity. The indicator for this condition is the history list length (HLL). The upgrade process rolls back the uncommitted changes. You can check the HLL in the output from the <code>SHOW ENGINE INNODB STATUS</code> SQL command, or directly by using the following SQL query:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>SELECT count FROM information_schema.innodb_metrics WHERE name = 'trx_rseg_history_len';</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td>You can also monitor the RollbackSegmentHistoryListLength metric in Amazon CloudWatch.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Consider performing the upgrade only after the HLL is smaller.</td>
</tr>
<tr>
<td>Reason for in-place upgrade being canceled or slow</td>
<td>Effect</td>
<td>Solution to allow in-place upgrade to complete within maintenance window</td>
</tr>
<tr>
<td>-------------------------------------------------</td>
<td>--------</td>
<td>---------------------------------------------------------------------</td>
</tr>
<tr>
<td>Cluster is in the process of committing a large binary log transaction</td>
<td>Upgrade might take a long time.</td>
<td>The upgrade process waits until the binary log changes are applied. More transactions or DDL statements could start during this period, further slowing down the upgrade process. Schedule the upgrade process when the cluster isn't busy with generating binary log replication changes. Aurora doesn't automatically detect or generate an event for this condition.</td>
</tr>
</tbody>
</table>
| Schema inconsistencies resulting from file removal or corruption | Aurora cancels the upgrade. | Change the default storage engine for temporary tables from MyISAM to InnoDB. Perform the following steps:  
1. Modify the `default_tmp_storage_engine` DB parameter to InnoDB.  
2. Reboot the DB cluster.  
3. After rebooting, confirm that the `default_tmp_storage_engine` DB parameter is set to InnoDB. Use the following command:  
   ```sql  
   show global variables like 'default_tmp_storage_engine';  
   ```  
4. Make sure not to create any temporary tables that use the MyISAM storage engine. We recommend that you pause any database workload and not create any new database connections, because you're upgrading soon.  
5. Try the in-place upgrade again. |
<table>
<thead>
<tr>
<th>Reason for in-place upgrade being canceled or slow</th>
<th>Effect</th>
<th>Solution to allow in-place upgrade to complete within maintenance window</th>
</tr>
</thead>
</table>
| Master user was deleted                         | Aurora cancels the upgrade. | **Important**
Don't delete the master user.  

However, if for some reason you should happen to delete the master user, restore it using the following SQL commands:

```
CREATE USER 'master_username'@'%' IDENTIFIED BY 'master_user_password' REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK;
GRANT SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES, INDEX, ALTER, SHOW DATABASES, CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION SLAVE, REPLICATION CLIENT, CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, LOAD FROM S3, SELECT INTO S3, INVOKE LAMBDA, INVOKE SAGEMAKER, INVOKE COMPREHEND ON *.* TO 'master_username'@'%' WITH GRANT OPTION;
```  

For more details on troubleshooting issues that cause upgrade prechecks to fail, see the following blogs:

- [Amazon Aurora MySQL version 2 (with MySQL 5.7 compatibility) to version 3 (with MySQL 8.0 compatibility) upgrade checklist, Part 1](#)
- [Amazon Aurora MySQL version 2 (with MySQL 5.7 compatibility) to version 3 (with MySQL 8.0 compatibility) upgrade checklist, Part 2](#)
You can use the following steps to perform your own checks for some of the conditions in the preceding table. That way, you can schedule the upgrade at a time when you know the database is in a state where the upgrade can complete successfully and quickly.

- You can check for open XA transactions by executing the `XA RECOVER` statement. You can then commit or roll back the XA transactions before starting the upgrade.

- You can check for DDL statements by executing a `SHOW PROCESSLIST` statement and looking for `CREATE`, `DROP`, `ALTER`, `RENAME`, and `TRUNCATE` statements in the output. Allow all DDL statements to finish before starting the upgrade.

- You can check the total number of uncommitted rows by querying the `INFORMATION_SCHEMA.INNODB_TRX` table. The table contains one row for each transaction. The `TRX_ROWS_MODIFIED` column contains the number of rows modified or inserted by the transaction.

- You can check the length of the InnoDB history list by executing the `SHOW ENGINE INNODB STATUS SQL` statement and looking for the `History list length` in the output. You can also check the value directly by running the following query:

  ```sql
  SELECT count FROM information_schema.innodb_metrics WHERE name = 'trx_rseg_history_len';
  ```

  The length of the history list corresponds to the amount of undo information stored by the database to implement multi-version concurrency control (MVCC).

**Post-upgrade cleanup for Aurora MySQL version 3**

After you finish upgrading any Aurora MySQL version 2 clusters to Aurora MySQL version 3, you can perform these other cleanup actions:

- Create new MySQL 8.0–compatible versions of any custom parameter groups. Apply any necessary custom parameter values to the new parameter groups.

- Update any CloudWatch alarms, setup scripts, and so on to use the new names for any metrics whose names were affected by inclusive language changes. For a list of such metrics, see [Inclusive language changes for Aurora MySQL version 3](#).

- Update any AWS CloudFormation templates to use the new names for any configuration parameters whose names were affected by inclusive language changes. For a list of such parameters, see [Inclusive language changes for Aurora MySQL version 3](#).
Spatial indexes

After upgrading to Aurora MySQL version 3, check if you need to drop or recreate objects and indexes related to spatial indexes. Before MySQL 8.0, Aurora could optimize spatial queries using indexes that didn’t contain a spatial resource identifier (SRID). Aurora MySQL version 3 only uses spatial indexes containing SRIDs. During an upgrade, Aurora automatically drops any spatial indexes without SRIDs and prints warning messages in the database log. If you observe such warning messages, create new spatial indexes with SRIDs after the upgrade. For more information about changes to spatial functions and data types in MySQL 8.0, see Changes in MySQL 8.0 in the MySQL Reference Manual.

Database engine updates and fixes for Amazon Aurora MySQL

You can find the following information in the Release notes for Amazon Aurora MySQL-Compatible Edition:

- Database engine updates for Amazon Aurora MySQL version 3
- Database engine updates for Amazon Aurora MySQL version 2
- Database engine updates for Amazon Aurora MySQL version 1 (Deprecated)
- MySQL bugs fixed by Aurora MySQL database engine updates
- Security vulnerabilities fixed in Amazon Aurora MySQL
Working with Amazon Aurora PostgreSQL

Amazon Aurora PostgreSQL is a fully managed, PostgreSQL-compatible, and ACID-compliant relational database engine that combines the speed, reliability, and manageability of Amazon Aurora with the simplicity and cost-effectiveness of open-source databases. Aurora PostgreSQL is a drop-in replacement for PostgreSQL and makes it simple and cost-effective to set up, operate, and scale your new and existing PostgreSQL deployments, thus freeing you to focus on your business and applications. To learn more about Aurora in general, see What is Amazon Aurora?.

In addition to the benefits of Aurora, Aurora PostgreSQL offers a convenient migration pathway from Amazon RDS into Aurora, with push-button migration tools that convert your existing RDS for PostgreSQL applications to Aurora PostgreSQL. Routine database tasks such as provisioning, patching, backup, recovery, failure detection, and repair are also easy to manage with Aurora PostgreSQL.

Aurora PostgreSQL can work with many industry standards. For example, you can use Aurora PostgreSQL databases to build HIPAA-compliant applications and to store healthcare related information, including protected health information (PHI), under a completed Business Associate Agreement (BAA) with AWS.

Aurora PostgreSQL is FedRAMP HIGH eligible. For details about AWS and compliance efforts, see AWS services in scope by compliance program.

Working with the database preview environment

The PostgreSQL community releases new major version of PostgreSQL annually. Similarly, Amazon Aurora makes PostgreSQL major versions available as Preview releases. This allows you to create DB cluster using the Preview version and test out its features in the Database Preview Environment.

Aurora PostgreSQL DB clusters in the Database Preview Environment are functionally similar to other Aurora PostgreSQL DB clusters. However, you can't use a Preview version for production.

Keep in mind the following important limitations:

- All DB instances and DB clusters are deleted 60 days after you create them, along with any backups and snapshots.
- You can only create a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service.
- You can't copy a snapshot of a DB instance to a production environment.

The following options are supported by the Preview.

- You can create DB instances using r5, r6g, r6i, r7g, x2g, t3 and t4g instance types only. For more information about instance classes, see [Aurora DB instance classes](#).
- You can use both single-AZ and multi-AZ deployments.
- You can use standard PostgreSQL dump and load functions to export databases from or import databases to the Database Preview Environment.
Supported DB instance class types

Amazon Aurora PostgreSQL supports the following DB instance classes in the preview region:

Memory Optimized Classes

- db.r5 – memory-optimized instance classes
- db.r6g – memory-optimized instance classes powered by AWS Graviton2 processors
- db.r6i – memory-optimized instance classes
- db.x2g – memory-optimized instance classes powered by AWS Graviton2 processors

Note

For more information on the list of instance classes, see DB instance class types.

Burstable classes

- db.t3.medium
- db.t3.large
- db.t4g.medium
- db.t4g.large

Unsupported features in the preview environment

The following features aren't available in the preview environment:

- Aurora Serverless v1 and v2
- Major version upgrades (MVU)
- No new minor versions will be released in preview region
- RDS for PostgreSQL to Aurora PostgreSQL inbound replication
- Amazon RDS Blue/Green deployment
- Cross-Region snapshot copy
- Aurora global database
- Database activity streams (DAS), RDS Proxy, and AWS DMS
• Auto scaling read replicas
• AWS Bedrock
• RDS export
• Performance Insights
• Global write forwarding
• Optimized Reads
• Babelfish
• Custom endpoints
• Snapshot copy

Creating a new DB cluster in the preview environment

Use the following procedure to create a DB cluster in the preview environment.

To create a DB cluster in the preview environment

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Dashboard from the navigation pane.
3. In the Dashboard page, locate the Database Preview Environment section on the Dashboard page, as shown in the following image.
You can navigate directly to the Database preview environment. Before you can proceed, you must acknowledge and accept the limitations.
4. To create the Aurora PostgreSQL DB cluster, follow the same process as that for creating any Aurora DB cluster. For more information, see Creating an Amazon Aurora DB cluster.

To create an instance in the Database Preview Environment using the Aurora API or the AWS CLI, use the following endpoint.

rds-preview.us-east-2.amazonaws.com

**PostgreSQL version 16 in the Database Preview environment**

⚠️ *This is preview documentation for Aurora PostgreSQL version 16. It is subject to change.*

PostgreSQL version 16.0 is now available in the Amazon RDS Database Preview environment. PostgreSQL version 16 contains several improvements that are described in the following PostgreSQL documentation:

- [PostgreSQL 16 Released](#)
For information on the Database Preview Environment, see Working with the database preview environment. To access the Preview Environment from the console, select https://console.aws.amazon.com/rds-preview/.

---

Note

It is not recommend to use PostgreSQL version 16.0 in the Database Preview environment as Aurora PostgreSQL version 16.1 is now generally available. For more information, see Amazon Aurora PostgreSQL updates.

---

Security with Amazon Aurora PostgreSQL

For a general overview of Aurora security, see Security in Amazon Aurora. You can manage security for Amazon Aurora PostgreSQL at a few different levels:

- To control who can perform Amazon RDS management actions on Aurora PostgreSQL DB clusters and DB instances, use AWS Identity and Access Management (IAM). IAM handles the authentication of user identity before the user can access the service. It also handles authorization, that is, whether the user is allowed to do what they're trying to do. IAM database authentication is an additional authentication method that you can choose when you create your Aurora PostgreSQL DB cluster. For more information, see Identity and access management for Amazon Aurora.

  If you do use IAM with your Aurora PostgreSQL DB cluster, sign in to the AWS Management Console with your IAM credentials first, before opening the Amazon RDS console at https://console.aws.amazon.com/rds/.

- Make sure to create Aurora DB clusters in a virtual private cloud (VPC) based on the Amazon VPC service. To control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance for Aurora DB clusters in a VPC, use a VPC security group. You can make these endpoint and port connections by using Secure Sockets Layer (SSL). In addition, firewall rules at your company can control whether devices running at your company can open connections to a DB instance. For more information on VPCs, see Amazon VPC VPCs and Amazon Aurora.

  The supported VPC tenancy depends on the DB instance class used by your Aurora PostgreSQL DB clusters. With default VPC tenancy, the DB cluster runs on shared hardware. With dedicated VPC tenancy, the DB cluster runs on a dedicated hardware instance. The burstable
performance DB instance classes support default VPC tenancy only. The burstable performance DB instance classes include the db.t3 and db.t4g DB instance classes. All other Aurora PostgreSQL DB instance classes support both default and dedicated VPC tenancy.

For more information about instance classes, see Aurora DB instance classes. For more information about default and dedicated VPC tenancy, see Dedicated instances in the Amazon Elastic Compute Cloud User Guide.

- To grant permissions to the PostgreSQL databases running on your Amazon Aurora DB cluster, you can take the same general approach as with stand-alone instances of PostgreSQL. Commands such as CREATE ROLE, ALTER ROLE, GRANT, and REVOKE work just as they do in on-premises databases, as does directly modifying databases, schemas, and tables.

PostgreSQL manages privileges by using roles. The rds_superuser role is the most privileged role on an Aurora PostgreSQL DB cluster. This role is created automatically, and it's granted to the user that creates the DB cluster (the master user account, postgres by default). To learn more, see Understanding PostgreSQL roles and permissions.

All available Aurora PostgreSQL versions, including versions 10, 11, 12, 13, 14, and higher releases support the Salted Challenge Response Authentication Mechanism (SCRAM) for passwords as an alternative to message digest (MD5). We recommend that you use SCRAM because it's more secure than MD5. For more information, including how to migrate database user passwords from MD5 to SCRAM, see Using SCRAM for PostgreSQL password encryption.

**Understanding PostgreSQL roles and permissions**

When you create an Aurora PostgreSQL DB cluster using the AWS Management Console, an administrator account is created at the same time. By default, its name is postgres, as shown in the following screenshot:
You can choose another name rather than accept the default (postgres). If you do, the name you choose must start with a letter and be between 1 and 16 alphanumeric characters. For simplicity's sake, we refer to this main user account by its default value (postgres) throughout this guide.

If you use the create-db-cluster AWS CLI rather than the AWS Management Console, you create the user name by passing it with the master-username parameter. For more information, see Step 2: Create an Aurora PostgreSQL DB cluster.

Whether you use the AWS Management Console, the AWS CLI, or the Amazon RDS API, and whether you use the default postgres name or choose a different name, this first database user account is a member of the rds_superuser group and has rds_superuser privileges.

Topics

- Understanding the rds_superuser role
- Controlling user access to the PostgreSQL database
- Delegating and controlling user password management
- Using SCRAM for PostgreSQL password encryption

Understanding the rds_superuser role

In PostgreSQL, a role can define a user, a group, or a set of specific permissions granted to a group or user for various objects in the database. PostgreSQL commands to CREATE USER and CREATE GROUP have been replaced by the more general, CREATE ROLE with specific properties to distinguish database users. A database user can be thought of as a role with the LOGIN privilege.
The `postgres` user is the most highly privileged database user on your Aurora PostgreSQL DB cluster. It has the characteristics defined by the following `CREATE ROLE` statement.

```
CREATE ROLE postgres WITH LOGIN NOSUPERUSER INHERIT CREATEDB CREATEROLE NOREPLICATION VALID UNTIL 'infinity'
```

The properties `NOSUPERUSER`, `NOREPLICATION`, `INHERIT`, and `VALID UNTIL 'infinity'` are the default options for `CREATE ROLE`, unless otherwise specified.

By default, `postgres` has privileges granted to the `rds_superuser` role, and permissions to create roles and databases. The `rds_superuser` role allows the `postgres` user to do the following:

- Add extensions that are available for use with Aurora PostgreSQL. For more information, see [Working with extensions and foreign data wrappers](#).
- Create roles for users and grant privileges to users. For more information, see [CREATE ROLE](#) and [GRANT](#) in the PostgreSQL documentation.
- Create databases. For more information, see [CREATE DATABASE](#) in the PostgreSQL documentation.
- Grant `rds_superuser` privileges to user roles that don't have these privileges, and revoke privileges as needed. We recommend that you grant this role only to those users who perform superuser tasks. In other words, you can grant this role to database administrators (DBAs) or system administrators.
- Grant (and revoke) the `rds_replication` role to database users that don't have the `rds_superuser` role.
- Grant (and revoke) the `rds_password` role to database users that don't have the `rds_superuser` role.
- Obtain status information about all database connections by using the `pg_stat_activity` view. When needed, `rds_superuser` can stop any connections by using `pg_terminate_backend` or `pg_cancel_backend`. 

**Note**

The `CREATE USER` and `CREATE GROUP` commands can still be used. For more information, see [Database Roles](#) in the PostgreSQL documentation.
In the CREATE ROLE postgres... statement, you can see that the postgres user role specifically disallows PostgreSQL superuser permissions. Aurora PostgreSQL is a managed service, so you can't access the host OS, and you can't connect using the PostgreSQL superuser account. Many of the tasks that require superuser access on a stand-alone PostgreSQL are managed automatically by Aurora.

For more information about granting privileges, see GRANT in the PostgreSQL documentation.

The rds_superuser role is one of several predefined roles in an Aurora PostgreSQL DB cluster.

Note

In PostgreSQL 13 and earlier releases, predefined roles are known as default roles.

In the following list, you find some of the other predefined roles that are created automatically for a new Aurora PostgreSQL DB cluster. Predefined roles and their privileges can't be changed. You can't drop, rename, or modify privileges for these predefined roles. Attempting to do so results in an error.

- **rds_password** – A role that can change passwords and set up password constraints for database users. The rds_superuser role is granted with this role by default, and can grant the role to database users. For more information, see Controlling user access to the PostgreSQL database.

  • For RDS for PostgreSQL versions older than 14, rds_password role can change passwords and set up password constraints for database users and users with rds_superuser role. From RDS for PostgreSQL version 14 and later, rds_password role can change passwords and set up password constraints only for database users. Only users with rds_superuser role can perform these actions on other users with rds_superuser role.

- **rdsadmin** – A role that's created to handle many of the management tasks that the administrator with superuser privileges would perform on a standalone PostgreSQL database. This role is used internally by Aurora PostgreSQL for many management tasks.

To see all predefined roles, you can connect to the primary instance of your Aurora PostgreSQL DB cluster and use the psql \du metacommand. The output looks as follows:

<table>
<thead>
<tr>
<th>Role name</th>
<th>Attributes</th>
<th>Member of</th>
</tr>
</thead>
</table>

Understanding PostgreSQL roles and permissions 1967
In the output, you can see that `rds_superuser` isn't a database user role (it can't login), but it has the privileges of many other roles. You can also see that database user `postgres` is a member of the `rds_superuser` role. As mentioned previously, `postgres` is the default value in the Amazon RDS console's **Create database** page. If you chose another name, that name is shown in the list of roles instead.

**Note**

Aurora PostgreSQL versions 15.2 and 14.7 introduced restrictive behavior of the `rds_superuser` role. An Aurora PostgreSQL user needs to be granted the **CONNECT** privilege on the corresponding database to connect even if the user is granted the `rds_superuser` role. Prior to Aurora PostgreSQL versions 14.7 and 15.2, a user was able to connect to any database and system table if the user was granted the `rds_superuser` role. This restrictive behavior aligns with the AWS and Amazon Aurora commitments to the continuous improvement of security.

Please update the respective logic in your applications if the above enhancement has an impact.

**Controlling user access to the PostgreSQL database**

New databases in PostgreSQL are always created with a default set of privileges in the database's public schema that allow all database users and roles to create objects. These privileges allow database users to connect to the database, for example, and create temporary tables while connected.

To better control user access to the databases instances that you create on your Aurora PostgreSQL DB cluster primary node, we recommend that you revoke these default public privileges. After doing so, you then grant specific privileges for database users on a more granular basis, as shown in the following procedure.
To set up roles and privileges for a new database instance

Suppose you're setting up a database on a newly created Aurora PostgreSQL DB cluster for use by several researchers, all of whom need read-write access to the database.

1. Use psql (or pgAdmin) to connect to the primary DB instance on your Aurora PostgreSQL DB cluster:

```bash
psql --host=your-cluster-instance-1.6666666666666666.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```

When prompted, enter your password. The `psql` client connects and displays the default administrative connection database, `postgres=>`, as the prompt.

2. To prevent database users from creating objects in the `public` schema, do the following:

```sql
postgres=> REVOKE CREATE ON SCHEMA public FROM PUBLIC;
```

3. Next, you create a new database instance:

```sql
postgres=> CREATE DATABASE lab_db;
```

4. Revoke all privileges from the `PUBLIC` schema on this new database.

```sql
postgres=> REVOKE ALL ON DATABASE lab_db FROM public;
```

5. Create a role for database users.

```sql
postgres=> CREATE ROLE lab_tech;
```

6. Give database users that have this role the ability to connect to the database.

```sql
postgres=> GRANT CONNECT ON DATABASE lab_db TO lab_tech;
```

7. Grant all users with the `lab_tech` role all privileges on this database.

```sql
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_db TO lab_tech;
```
8. Create database users, as follows:

```
postgres=> CREATE ROLE lab_user1 LOGIN PASSWORD 'change_me';
CREATE ROLE
postgres=> CREATE ROLE lab_user2 LOGIN PASSWORD 'change_me';
CREATE ROLE
```

9. Grant these two users the privileges associated with the lab_tech role:

```
postgres=> GRANT lab_tech TO lab_user1;
GRANT ROLE
postgres=> GRANT lab_tech TO lab_user2;
GRANT ROLE
```

At this point, `lab_user1` and `lab_user2` can connect to the `lab_db` database. This example doesn't follow best practices for enterprise usage, which might include creating multiple database instances, different schemas, and granting limited permissions. For more complete information and additional scenarios, see [Managing PostgreSQL Users and Roles](#).

For more information about privileges in PostgreSQL databases, see the `GRANT` command in the PostgreSQL documentation.

### Delegating and controlling user password management

As a DBA, you might want to delegate the management of user passwords. Or, you might want to prevent database users from changing their passwords or reconfiguring password constraints, such as password lifetime. To ensure that only the database users that you choose can change password settings, you can turn on the restricted password management feature. When you activate this feature, only those database users that have been granted the `rds_password` role can manage passwords.

**Note**

To use restricted password management, your Aurora PostgreSQL DB cluster must be running Amazon Aurora PostgreSQL 10.6 or higher.

By default, this feature is off, as shown in the following:
postgres=> SHOW rds.restrict_password_commands;
     rds.restrict_password_commands
-----------------------------
      off
(1 row)

To turn on this feature, you use a custom parameter group and change the setting for `rds.restrict_password_commands` to 1. Be sure to reboot your Aurora PostgreSQL's primary DB instance so that the setting takes effect.

With this feature active, `rds_password` privileges are needed for the following SQL commands:

```
CREATE ROLE myrole WITH PASSWORD 'mypassword';
CREATE ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
ALTER ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
ALTER ROLE myrole WITH PASSWORD 'mypassword';
ALTER ROLE myrole VALID UNTIL '2023-01-01';
ALTER ROLE myrole RENAME TO myrole2;
```

Renaming a role (ALTER ROLE myrole RENAME TO newname) is also restricted if the password uses the MD5 hashing algorithm.

With this feature active, attempting any of these SQL commands without the `rds_password` role permissions generates the following error:

```
ERROR: must be a member of rds_password to alter passwords
```

We recommend that you grant the `rds_password` to only a few roles that you use solely for password management. If you grant `rds_password` privileges to database users that don't have `rds_superuser` privileges, you need to also grant them the `CREATEROLE` attribute.

Make sure that you verify password requirements such as expiration and needed complexity on the client side. If you use your own client-side utility for password related changes, the utility needs to be a member of `rds_password` and have `CREATE ROLE` privileges.

**Using SCRAM for PostgreSQL password encryption**

The *Salted Challenge Response Authentication Mechanism (SCRAM)* is an alternative to PostgreSQL's default message digest (MD5) algorithm for encrypting passwords. The SCRAM authentication
mechanism is considered more secure than MD5. To learn more about these two different approaches to securing passwords, see Password Authentication in the PostgreSQL documentation.

We recommend that you use SCRAM rather than MD5 as the password encryption scheme for your Aurora PostgreSQL DB cluster. As of the Aurora PostgreSQL 14 release, SCRAM is supported in all available Aurora PostgreSQL versions, including versions 10, 11, 12, 13, and 14. It's a cryptographic challenge-response mechanism that uses the scram-sha-256 algorithm for password authentication and encryption.

You might need to update libraries for your client applications to support SCRAM. For example, JDBC versions before 42.2.0 don't support SCRAM. For more information, see PostgreSQL JDBC Driver in the PostgreSQL JDBC Driver documentation. For a list of other PostgreSQL drivers and SCRAM support, see List of drivers in the PostgreSQL documentation.

**Note**

Aurora PostgreSQL version 14 and higher support scram-sha-256 for password encryption by default for new DB clusters. That is, the default DB cluster parameter group (default.aurora-postgresql14) has its password_encryption value set to scram-sha-256.

**Setting up Aurora PostgreSQL DB cluster to require SCRAM**

For Aurora PostgreSQL 14.3 and higher versions, you can require the Aurora PostgreSQL DB cluster to accept only passwords that use the scram-sha-256 algorithm.

**Important**

For existing RDS Proxies with PostgreSQL databases, if you modify the database authentication to use SCRAM only, the proxy becomes unavailable for up to 60 seconds. To avoid the issue, do one of the following:

- Ensure that the database allows both SCRAM and MD5 authentication.
- To use only SCRAM authentication, create a new proxy, migrate your application traffic to the new proxy, then delete the proxy previously associated with the database.

Before making changes to your system, be sure you understand the complete process, as follows:
Get information about all roles and password encryption for all database users.

Double-check the parameter settings for your Aurora PostgreSQL DB cluster for the parameters that control password encryption.

If your Aurora PostgreSQL DB cluster uses a default parameter group, you need to create a custom DB cluster parameter group and apply it to your Aurora PostgreSQL DB cluster so that you can modify parameters when needed. If your Aurora PostgreSQL DB cluster uses a custom parameter group, you can modify the necessary parameters later in the process, as needed.

Change the password_encryption parameter to scram-sha-256.

Notify all database users that they need to update their passwords. Do the same for your postgres account. The new passwords are encrypted and stored using the scram-sha-256 algorithm.

Verify that all passwords are encrypted using as the type of encryption.

If all passwords use scram-sha-256, you can change the rds.accepted_password_auth_method parameter from md5+scram to scram-sha-256.

**Warning**

After you change rds.accepted_password_auth_method to scram-sha-256 alone, any users (roles) with md5–encrypted passwords can't connect.

### Getting ready to require SCRAM for your Aurora PostgreSQL DB cluster

Before making any changes to your Aurora PostgreSQL DB cluster, check all existing database user accounts. Also, check the type of encryption used for passwords. You can do these tasks by using the rds_tools extension. This extension is supported on Aurora PostgreSQL 13.1 and higher releases.

### To get a list of database users (roles) and password encryption methods

1. Use psql to connect to the primary instance of your Aurora PostgreSQL DB cluster, as shown in the following.

   ```
   psql --host=cluster-name-instance-1.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. Install the rds_tools extension.
postgres=> CREATE EXTENSION rds_tools;
CREATE EXTENSION

3. Get a listing of roles and encryption.

postgres=> SELECT * FROM
            rds_tools.role_password_encryption_type();

You see output similar to the following.

<table>
<thead>
<tr>
<th>rolname</th>
<th>encryption_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>pg_monitor</td>
<td></td>
</tr>
<tr>
<td>pg_read_all_settings</td>
<td></td>
</tr>
<tr>
<td>pg_read_all_stats</td>
<td></td>
</tr>
<tr>
<td>pg_stat_scan_tables</td>
<td></td>
</tr>
<tr>
<td>pg_signal_backend</td>
<td></td>
</tr>
<tr>
<td>lab_tester</td>
<td>md5</td>
</tr>
<tr>
<td>user_465</td>
<td>md5</td>
</tr>
<tr>
<td>postgres</td>
<td>md5</td>
</tr>
<tr>
<td>(8 rows)</td>
<td></td>
</tr>
</tbody>
</table>

Creating a custom DB cluster parameter group

Note

If your Aurora PostgreSQL DB cluster already uses a custom parameter group, you don't need to create a new one.

For an overview of parameter groups for Aurora, see Creating a DB cluster parameter group.

The password encryption type used for passwords is set in one parameter, password_encryption. The encryption that the Aurora PostgreSQL DB cluster allows is set in another parameter, rds.accepted_password_auth_method. Changing either of these from the default values requires that you create a custom DB cluster parameter group and apply it to your cluster.
You can also use the AWS Management Console or the RDS API to create a custom DB cluster parameter group. For more information, see Creating a DB cluster parameter group.

You can now associate the custom parameter group with your DB instance.

**To create a custom DB cluster parameter group**

1. Use the `create-db-cluster-parameter-group` CLI command to create the custom parameter group for the cluster. The following example uses `aurora-postgresql13` as the source for this custom parameter group.

   For Linux, macOS, or Unix:

   ```bash
   aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name 'docs-lab-scram-passwords' \
   --db-parameter-group-family aurora-postgresql13 --description 'Custom DB cluster parameter group for SCRAM'
   ```

   For Windows:

   ```bash
   aws rds create-db-cluster-parameter-group --db-cluster-parameter-group-name "docs-lab-scram-passwords" ^
   --db-parameter-group-family aurora-postgresql13 --description "Custom DB cluster parameter group for SCRAM"
   ```

   You can now associate the custom parameter group with your cluster.

2. Use the `modify-db-cluster` CLI command to apply this custom parameter group to your Aurora PostgreSQL DB cluster.

   For Linux, macOS, or Unix:

   ```bash
   aws rds modify-db-cluster --db-cluster-identifier 'your-instance-name' \
   --db-cluster-parameter-group-name "docs-lab-scram-passwords"
   ```

   For Windows:

   ```bash
   aws rds modify-db-cluster --db-cluster-identifier "your-instance-name" ^
   --db-cluster-parameter-group-name "docs-lab-scram-passwords"
   ```
To resynchronize your Aurora PostgreSQL DB cluster with your custom DB cluster parameter group, reboot the primary and all other instances of the cluster.

Configuring password encryption to use SCRAM

The password encryption mechanism used by an Aurora PostgreSQL DB cluster is set in the DB cluster parameter group in the password_encryption parameter. Allowed values are unset, md5, or scram-sha-256. The default value depends on the Aurora PostgreSQL version, as follows:

- Aurora PostgreSQL 14 – Default is scram-sha-256
- Aurora PostgreSQL 13 – Default is md5

With a custom DB cluster parameter group attached to your Aurora PostgreSQL DB cluster, you can modify values for the password encryption parameter.

<table>
<thead>
<tr>
<th>Name</th>
<th>Values</th>
<th>Allowed values</th>
<th>Modifiable</th>
<th>Source</th>
<th>Apply type</th>
</tr>
</thead>
<tbody>
<tr>
<td>password_encryption</td>
<td>scram-sha-256</td>
<td>md5, scram-sha-256</td>
<td>true</td>
<td>system</td>
<td>dynamic</td>
</tr>
<tr>
<td>rds.accepted_password_auth_method</td>
<td>md5+scram</td>
<td>md5+scram, scram</td>
<td>true</td>
<td>system</td>
<td>dynamic</td>
</tr>
</tbody>
</table>

To change password encryption setting to scram-sha-256

- Change the value of the password encryption to scram-sha-256, as shown following. The change can be applied immediately because the parameter is dynamic, so a restart isn't required for the change to take effect.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name 'docs-lab-scram-passwords' --parameters 'ParameterName=password_encryption,ParameterValue=scram-sha-256,ApplyMethod=immediate'
```

For Windows:
Migrating passwords for user roles to SCRAM

You can migrate passwords for user roles to SCRAM as described following.

To migrate database user (role) passwords from MD5 to SCRAM

1. Log in as the administrator user (default user name, postgres) as shown following.

   ```
   psql --host=cluster-name-instance-1.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. Check the setting of the password_encryption parameter on your RDS for PostgreSQL DB instance by using the following command.

   ```
   postgres=> SHOW password_encryption;
   password_encryption
   ---------------
   md5
   (1 row)
   ```

3. Change the value of this parameter to scram-sha-256. This is a dynamic parameter, so you don't need to reboot the instance after making this change. Check the value again to make sure that it's now set to scram-sha-256, as follows.

   ```
   postgres=> SHOW password_encryption;
   password_encryption
   ---------------
   scram-sha-256
   (1 row)
   ```

4. Notify all database users to change their passwords. Be sure to also change your own password for account postgres (the database user with rds_superuser privileges).

   ```
   labdb=> ALTER ROLE postgres WITH LOGIN PASSWORD 'change_me';
   ```
5. Repeat the process for all databases on your Aurora PostgreSQL DB cluster.

Changing parameter to require SCRAM

This is the final step in the process. After you make the change in the following procedure, any user accounts (roles) that still use md5 encryption for passwords can't log in to the Aurora PostgreSQL DB cluster.

The `rds.accepted_password_auth_method` specifies the encryption method that the Aurora PostgreSQL DB cluster accepts for a user password during the login process. The default value is `md5+scram`, meaning that either method is accepted. In the following image, you can find the default setting for this parameter.

The allowed values for this parameter are `md5+scram` or `scram` alone. Changing this parameter value to `scram` makes this a requirement.

To change the parameter value to require SCRAM authentication for passwords

1. Verify that all database user passwords for all databases on your Aurora PostgreSQL DB cluster use `scram-sha-256` for password encryption. To do so, query `rds_tools` for the role (user) and encryption type, as follows.

```sql
postgres=> SELECT * FROM rds_tools.role_password_encryption_type();
rolname        | encryption_type
---------------+-----------------
pg_monitor     | scram-sha-256    
pg_read_all_settings |          
pg_read_all_stats |          
pg_stat_scan_tables |          
pg_signal_backend |          
lab_tester     | scram-sha-256    
```
2. Repeat the query across all DB instances in your Aurora PostgreSQL DB cluster.

   If all passwords use scram-sha-256, you can proceed.

3. Change the value of the accepted password authentication to scram-sha-256, as follows.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name 'docs-lab-scram-passwords' \
   --parameters
   'ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediate'
```

For Windows:

```bash
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name "docs-lab-scram-passwords" ^
   --parameters
   "ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediate"
```

Securing Aurora PostgreSQL data with SSL/TLS

Amazon RDS supports Secure Socket Layer (SSL) and Transport Layer Security (TLS) encryption for Aurora PostgreSQL DB clusters. Using SSL/TLS, you can encrypt a connection between your applications and your Aurora PostgreSQL DB clusters. You can also force all connections to your Aurora PostgreSQL DB cluster to use SSL/TLS. Amazon Aurora PostgreSQL supports Transport Layer Security (TLS) versions 1.1 and 1.2. We recommend using TLS 1.2 for encrypted connections. We have added support for TLSv1.3 from the following versions of Aurora PostgreSQL:

- 15.3 and all higher versions
- 14.8 and higher 14 versions
- 13.11 and higher 13 versions
- 12.15 and higher 12 versions
- 11.20 and higher 11 versions
For general information about SSL/TLS support and PostgreSQL databases, see SSL support in the PostgreSQL documentation. For information about using an SSL/TLS connection over JDBC, see Configuring the client in the PostgreSQL documentation.

Topics

- Requiring an SSL/TLS connection to an Aurora PostgreSQL DB cluster
- Determining the SSL/TLS connection status
- Configuring cipher suites for connections to Aurora PostgreSQL DB clusters

SSL/TLS support is available in all AWS Regions for Aurora PostgreSQL. Amazon RDS creates an SSL/TLS certificate for your Aurora PostgreSQL DB cluster when the DB cluster is created. If you enable SSL/TLS certificate verification, then the SSL/TLS certificate includes the DB cluster endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.

To connect to an Aurora PostgreSQL DB cluster over SSL/TLS

1. Download the certificate.

   For information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB cluster.

2. Import the certificate into your operating system.

3. Connect to your Aurora PostgreSQL DB cluster over SSL/TLS.

   When you connect using SSL/TLS, your client can choose to verify the certificate chain or not. If your connection parameters specify `sslmode=verify-ca` or `sslmode=verify-full`, then your client requires the RDS CA certificates to be in their trust store or referenced in the connection URL. This requirement is to verify the certificate chain that signs your database certificate.

   When a client, such as psql or JDBC, is configured with SSL/TLS support, the client first tries to connect to the database with SSL/TLS by default. If the client can't connect with SSL/TLS, it reverts to connecting without SSL/TLS. By default, the `sslmode` option for JDBC and libpq-based clients is set to `prefer`.

   Use the `sslrootcert` parameter to reference the certificate, for example `sslrootcert=rds-ssl-ca-cert.pem`. 
The following is an example of using psql to connect to an Aurora PostgreSQL DB cluster.

```bash
$ psql -h testpg.cdhmufqifdpib.us-east-1.rds.amazonaws.com -p 5432 \
"dbname=testpg user=testuser sslrootcert=rds-ca-2015-root.pem sslmode=verify-full"
```

### Requiring an SSL/TLS connection to an Aurora PostgreSQL DB cluster

You can require that connections to your Aurora PostgreSQL DB cluster use SSL/TLS by using the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). You can set the `rds.force_ssl` parameter to 1 (on) to require SSL/TLS for connections to your DB cluster. Updating the `rds.force_ssl` parameter also sets the PostgreSQL `ssl` parameter to 1 (on) and modifies your DB cluster's `pg_hba.conf` file to support the new SSL/TLS configuration.

You can set the `rds.force_ssl` parameter value by updating the DB cluster parameter group for your DB cluster. If the DB cluster parameter group isn't the default one, and the `ssl` parameter is already set to 1 when you set `rds.force_ssl` to 1, you don't need to reboot your DB cluster. Otherwise, you must reboot your DB cluster for the change to take effect. For more information on parameter groups, see [Working with parameter groups](https://aws.amazon.com/premier-support/docs/powertogether/working-with-parameter-groups.html).

When the `rds.force_ssl` parameter is set to 1 for a DB cluster, you see output similar to the following when you connect, indicating that SSL/TLS is now required:

```bash
$ psql postgres -h SOMEHOST.amazonaws.com -p 8192 -U someuser
psql (9.3.12, server 9.4.4)
Some psql features might not work.
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.

postgres=>
```

### Determining the SSL/TLS connection status

The encrypted status of your connection is shown in the logon banner when you connect to the DB cluster.

Password for user master:

```
psql (9.3.12)
```
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.

postgres=>

You can also load the sslinfo extension and then call the ssl_is_used() function to determine if SSL/TLS is being used. The function returns t if the connection is using SSL/TLS, otherwise it returns f.

postgres=> create extension sslinfo;
CREATE EXTENSION

postgres=> select ssl_is_used();
ssl_is_used
---------
t
(1 row)

You can use the select ssl_cipher() command to determine the SSL/TLS cipher:

postgres=> select ssl_cipher();
ssl_cipher
-------------------
DHE-RSA-AES256-SHA
(1 row)

If you enable set rds.force_ssl and restart your DB cluster, non-SSL connections are refused with the following message:

$ export PGSSLMODE=disable
$ psql postgres -h SOMEHOST.amazonaws.com -p 8192 -U someuser
psql: FATAL: no pg_hba.conf entry for host "host.ip", user "someuser", database "postgres", SSL off
$

For information about the sslmode option, see Database connection control functions in the PostgreSQL documentation.
Configuring cipher suites for connections to Aurora PostgreSQL DB clusters

By using configurable cipher suites, you can have more control over the security of your database connections. You can specify a list of cipher suites that you want to allow to secure client SSL/TLS connections to your database. With configurable cipher suites, you can control the connection encryption that your database server accepts. Doing this helps prevent the use of insecure or deprecated ciphers.

Configurable cipher suites is supported in Aurora PostgreSQL versions 11.8 and higher.

To specify the list of permissible ciphers for encrypting connections, modify the `ssl_ciphers` cluster parameter. Set the `ssl_ciphers` parameter to a string of comma-separated cipher values in a cluster parameter group using the AWS Management Console, the AWS CLI, or the RDS API. To set cluster parameters, see [Modifying parameters in a DB cluster parameter group](#).

The following table shows the supported ciphers for the valid Aurora PostgreSQL engine versions.

<table>
<thead>
<tr>

You can also use the `describe-engine-default-cluster-parameters` CLI command to determine which cipher suites are currently supported for a specific parameter group family. The following example shows how to get the allowed values for the `ssl_cipher` cluster parameter for Aurora PostgreSQL 11.

```bash
aws rds describe-engine-default-cluster-parameters --db-parameter-group-family aurora-postgresql11
```

...some output truncated...

```json
{
  "ParameterName": "ssl_ciphers",
  "Description": "Sets the list of allowed TLS ciphers to be used on secure connections.",
  "Source": "engine-default",
  "ApplyType": "dynamic",
  "DataType": "list",
}
The `ssl_ciphers` parameter defaults to all allowed cipher suites. For more information about ciphers, see the `ssl_ciphers` variable in the PostgreSQL documentation.

### Updating applications to connect to Aurora PostgreSQL DB clusters using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your Aurora DB clusters using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB clusters. If they do, you can further check whether those applications require certificate verification to connect.

**Note**

Some applications are configured to connect to Aurora PostgreSQL DB clusters only if they can successfully verify the certificate on the server.

For such applications, you must update your client application trust stores to include the new CA certificates.
After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB clusters. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see Rotating your SSL/TLS certificate. For more information about downloading certificates, see Using SSL/TLS to encrypt a connection to a DB cluster. For information about using SSL/TLS with PostgreSQL DB clusters, see Securing Aurora PostgreSQL data with SSL/TLS.

Topics

- Determining whether applications are connecting to Aurora PostgreSQL DB clusters using SSL
- Determining whether a client requires certificate verification in order to connect
- Updating your application trust store
- Using SSL/TLS connections for different types of applications

Determining whether applications are connecting to Aurora PostgreSQL DB clusters using SSL

Check the DB cluster configuration for the value of the rds.force_ssl parameter. By default, the rds.force_ssl parameter is set to 0 (off). If the rds.force_ssl parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see Working with parameter groups.

If rds.force_ssl isn't set to 1 (on), query the pg_stat_ssl view to check connections using SSL. For example, the following query returns only SSL connections and information about the clients using SSL.

```
select datname, usename, ssl, client_addr from pg_stat_ssl inner join pg_stat_activity on pg_stat_ssl.pid = pg_stat_activity.pid where ssl is true and usename<>'rdsadmin';
```

Only rows using SSL/TLS connections are displayed with information about the connection. The following is sample output.

```
datname  | usename | ssl | client_addr
----------+---------+-----+-------------
benchdb  | pgadmin | t   | 53.95.6.13
postgres | pgadmin | t   | 53.95.6.13
```
The preceding query displays only the current connections at the time of the query. The absence of results doesn't indicate that no applications are using SSL connections. Other SSL connections might be established at a different time.

**Determining whether a client requires certificate verification in order to connect**

When a client, such as `psql` or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used is different between libpq-based clients (such as `psql`) and JDBC. The libpq-based clients default to `prefer`, where JDBC clients default to `verify-full`. The certificate on the server is verified only when `sslrootcert` is provided with `sslmode` set to `verify-ca` or `verify-full`. An error is thrown if the certificate is invalid.

Use `PGSSLROOTCERT` to verify the certificate with the `PGSSLMODE` environment variable, with `PGSSLMODE` set to `verify-ca` or `verify-full`.

```
PGSSLMODE=verify-full PGSSLROOTCERT=/fullpath/ssl-cert.pem psql -h pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com -U primaryuser -d postgres
```

Use the `sslrootcert` argument to verify the certificate with `sslmode` in connection string format, with `sslmode` set to `verify-ca` or `verify-full`.

```
psql "host=pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com sslmode=verify-full sslrootcert=/full/path/ssl-cert.pem user=primaryuser dbname=postgres"
```

For example, in the preceding case, if you use an invalid root certificate, you see an error similar to the following on your client.

```
psql: SSL error: certificate verify failed
```

**Updating your application trust store**

For information about updating the trust store for PostgreSQL applications, see [Secure TCP/IP connections with SSL](#) in the PostgreSQL documentation.
Note

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for SSL/TLS connections.

For information about downloading the root certificate, see Using SSL/TLS to encrypt a connection to a DB cluster.

For sample scripts that import certificates, see Sample script for importing certificates into your trust store.

Using SSL/TLS connections for different types of applications

The following provides information about using SSL/TLS connections for different types of applications:

- **psql**

  The client is invoked from the command line by specifying options either as a connection string or as environment variables. For SSL/TLS connections, the relevant options are `sslmode` (environment variable `PGSSLMODE`), `sslrootcert` (environment variable `PGSSLROOTCERT`).

  For the complete list of options, see Parameter key words in the PostgreSQL documentation. For the complete list of environment variables, see Environment variables in the PostgreSQL documentation.

- **pgAdmin**

  This browser-based client is a more user-friendly interface for connecting to a PostgreSQL database.

  For information about configuring connections, see the pgAdmin documentation.

- **JDBC**

  JDBC enables database connections with Java applications.
For general information about connecting to a PostgreSQL database with JDBC, see Connecting to the database in the PostgreSQL documentation. For information about connecting with SSL/TLS, see Configuring the client in the PostgreSQL documentation.

- Python

A popular Python library for connecting to PostgreSQL databases is psycopg2.

For information about using psycopg2, see the psycopg2 documentation. For a short tutorial on how to connect to a PostgreSQL database, see Psycopg2 tutorial. You can find information about the options the connect command accepts in The psycopg2 module content.

⚠️ Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-rsa2048-g1 certificates. For instructions, see step 3 in Updating your CA certificate by modifying your DB instance.

Using Kerberos authentication with Aurora PostgreSQL

You can use Kerberos to authenticate users when they connect to your DB cluster running PostgreSQL. To do so, configure your DB cluster to use AWS Directory Service for Microsoft Active Directory for Kerberos authentication. AWS Directory Service for Microsoft Active Directory is also called AWS Managed Microsoft AD. It's a feature available with AWS Directory Service. To learn more, see What is AWS Directory Service? in the AWS Directory Service Administration Guide.

To start, create an AWS Managed Microsoft AD directory to store user credentials. Then, provide to your PostgreSQL DB cluster the Active Directory's domain and other information. When users authenticate with the PostgreSQL DB cluster, authentication requests are forwarded to the AWS Managed Microsoft AD directory.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized location for storing and managing credentials for multiple DB clusters. Using a directory can also improve your overall security profile.
In addition, you can access credentials from your own on-premises Microsoft Active Directory. To do so, create a trusting domain relationship so that the AWS Managed Microsoft AD directory trusts your on-premises Microsoft Active Directory. In this way, your users can access your PostgreSQL clusters with the same Windows single sign-on (SSO) experience as when they access workloads in your on-premises network.

A database can use Kerberos, AWS Identity and Access Management (IAM), or both Kerberos and IAM authentication. However, because Kerberos and IAM authentication provide different authentication methods, a specific database user can log in to a database using only one or the other authentication method but not both. For more information about IAM authentication, see IAM database authentication.

Topics

- Region and version availability
- Overview of Kerberos authentication for PostgreSQL DB clusters
- Setting up Kerberos authentication for PostgreSQL DB clusters
- Managing a DB cluster in a Domain
- Connecting to PostgreSQL with Kerberos authentication
- Using AD security groups for Aurora PostgreSQL access control

Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Aurora PostgreSQL with Kerberos authentication, see Kerberos authentication with Aurora PostgreSQL.

Overview of Kerberos authentication for PostgreSQL DB clusters

To set up Kerberos authentication for a PostgreSQL DB cluster, take the following steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service API to create the directory. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the cluster.
2. Create a role that provides Amazon Aurora access to make calls to your AWS Managed Microsoft AD directory. To do so, create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.

For the IAM role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see Activating and deactivating AWS STS in an AWS Region in the IAM User Guide.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see Manage users and groups in AWS Managed Microsoft AD in the AWS Directory Service Administration Guide.

4. If you plan to locate the directory and the DB instance in different AWS accounts or virtual private clouds (VPCs), configure VPC peering. For more information, see What is VPC peering? in the Amazon VPC Peering Guide.

5. Create or modify a PostgreSQL DB cluster either from the console, CLI, or RDS API using one of the following methods:
   - Creating and connecting to an Aurora PostgreSQL DB cluster
   - Modifying an Amazon Aurora DB cluster
   - Restoring from a DB cluster snapshot
   - Restoring a DB cluster to a specified time

You can locate the cluster in the same Amazon Virtual Private Cloud (VPC) as the directory or in a different AWS account or VPC. When you create or modify the PostgreSQL DB cluster, do the following:

   • Provide the domain identifier (d-* identifier) that was generated when you created your directory.
   • Provide the name of the IAM role that you created.
   • Ensure that the DB instance security group can receive inbound traffic from the directory security group.

6. Use the RDS master user credentials to connect to the PostgreSQL DB cluster. Create the user in PostgreSQL to be identified externally. Externally identified users can log in to the PostgreSQL DB cluster using Kerberos authentication.
Setting up Kerberos authentication for PostgreSQL DB clusters

You use AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to set up Kerberos authentication for a PostgreSQL DB cluster. To set up Kerberos authentication, take the following steps.

Topics

• Step 1: Create a directory using AWS Managed Microsoft AD
• Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and AWS Directory Service
• Step 3: Create an IAM role for Amazon Aurora to access the AWS Directory Service
• Step 4: Create and configure users
• Step 5: Enable cross-VPC traffic between the directory and the DB instance
• Step 6: Create or modify a PostgreSQL DB cluster
• Step 7: Create PostgreSQL users for your Kerberos principals
• Step 8: Configure a PostgreSQL client

Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and DNS servers for you. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

• Sets up an Active Directory within your VPC.
• Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

⚠️ Important

Make sure to save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.
• Creates a security group for the directory controllers. The security group must permit communication with the PostgreSQL DB cluster.

When you launch AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU, which has the NetBIOS name that you entered when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

• Create, update, or delete users
• Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
• Create additional OUs and containers
• Delegate authority
• Restore deleted objects from the Active Directory Recycle Bin
• Run Active Directory and Domain Name Service (DNS) modules for Windows PowerShell on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

• Manage DNS configurations (add, remove, or update records, zones, and forwarders)
• View DNS event logs
• View security event logs

To create a directory with AWS Managed Microsoft AD

1. In the AWS Directory Service console navigation pane, choose Directories, and then choose Set up directory.
2. Choose AWS Managed Microsoft AD. AWS Managed Microsoft AD is the only option currently supported for use with Amazon Aurora.
3. Choose Next.
4. On the Enter directory information page, provide the following information:
Choose the edition that meets your requirements.

Directory DNS name

The fully qualified name for the directory, such as corp.example.com.

Directory NetBIOS name

An optional short name for the directory, such as CORP.

Directory description

An optional description for the directory.

Admin password

The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Nonalphanumeric characters (~@#$%^&*_-+=`|(){}[]:"<>?,./)

Confirm password

Retype the administrator password.

⚠️ Important

Make sure that you save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

5. Choose Next.

6. On the Choose VPC and subnets page, provide the following information:
VPC

Choose the VPC for the directory. You can create the PostgreSQL DB cluster in this same VPC or in a different VPC.

Subnets

Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose Next.

8. Review the directory information. If changes are needed, choose Previous and make the changes. When the information is correct, choose Create directory.

![Review & create](image)

---

Setting up 2001
It takes several minutes for the directory to be created. When it has been successfully created, the Status value changes to Active.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the Directory ID value. You need this value when you create or modify your PostgreSQL DB instance.
Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and AWS Directory Service

If you don't plan to use your own on-premises Microsoft Active Directory, skip to Step 3: Create an IAM role for Amazon Aurora to access the AWS Directory Service.

To get Kerberos authentication using your on-premises Active Directory, you need to create a trusting domain relationship using a forest trust between your on-premises Microsoft Active Directory and the AWS Managed Microsoft AD directory (created in Step 1: Create a directory using AWS Managed Microsoft AD). The trust can be one-way, where the AWS Managed Microsoft AD directory trusts the on-premises Microsoft Active Directory. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up trusts using AWS Directory Service, see When to create a trust relationship in the AWS Directory Service Administration Guide.

Note

If you use an on-premises Microsoft Active Directory:

- Windows clients must connect using the domain name of the AWS Directory Service in the endpoint rather than rds.amazonaws.com. For more information, see Connecting to PostgreSQL with Kerberos authentication.
- Windows clients can't connect using Aurora custom endpoints. To learn more, see Amazon Aurora connection management.
- For global databases:
  - Windows clients can connect using instance endpoints or cluster endpoints in the primary AWS Region of the global database only.
  - Windows clients can't connect using cluster endpoints in secondary AWS Regions.

Make sure that your on-premises Microsoft Active Directory domain name includes a DNS suffix routing that corresponds to the newly created trust relationship. The following screenshot shows an example.
Step 3: Create an IAM role for Amazon Aurora to access the AWS Directory Service

For Amazon Aurora to call AWS Directory Service for you, your AWS account needs an IAM role that uses the managed IAM policy AmazonRDSDirectoryServiceAccess. This role allows Amazon Aurora to make calls to AWS Directory Service. (Note that this IAM role to access the AWS Directory Service is different than the IAM role used for IAM database authentication.)

When you create a DB instance using the AWS Management Console and your console user account has the iam:CreateRole permission, the console creates the needed IAM role automatically. In this case, the role name is rds-directoryservice-kerberos-access-role. Otherwise, you must create the IAM role manually. When you create this IAM role, choose Directory Service, and attach the AWS managed policy AmazonRDSDirectoryServiceAccess to it.

For more information about creating IAM roles for a service, see Creating a role to delegate permissions to an AWS service in the IAM User Guide.

>Note

The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for Amazon Aurora.

As an alternative to using the AmazonRDSDirectoryServiceAccess managed policy, you can create policies with the required permissions. In this case, the IAM role must have the following IAM trust policy.
The role must also have the following IAM role policy.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "directoryservice.rds.amazonaws.com",
                    "rds.amazonaws.com"
                ],
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

**Step 4: Create and configure users**

You can create users by using the Active Directory Users and Computers tool. This is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. For more information, see [Add Users and Computers to the Active Directory domain](https://docs.microsoft.com/en-us/windows-server/administration/add-users-and-computers-to-the-active-directory-domain) in the Microsoft documentation. In this case, users are individuals or other entities, such as their computers that are part of the domain and whose identities are being maintained in the directory.
To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that's a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information, see Create a user in the AWS Directory Service Administration Guide.

**Step 5: Enable cross-VPC traffic between the directory and the DB instance**

If you plan to locate the directory and the DB cluster in the same VPC, skip this step and move on to Step 6: Create or modify a PostgreSQL DB cluster.

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or AWS Transit Gateway.

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in What is VPC peering? in the Amazon Virtual Private Cloud Peering Guide.

**To enable cross-VPC traffic using VPC peering**

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance security group can receive inbound traffic from the directory security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

**To share the directory between AWS accounts**

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join in the AWS Directory Service Administration Guide.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the Directory ID value. You use this directory ID to join the DB instance to the domain.
Step 6: Create or modify a PostgreSQL DB cluster

Create or modify a PostgreSQL DB cluster for use with your directory. You can use the console, CLI, or RDS API to associate a DB cluster with a directory. You can do this in one of the following ways:

- Create a new PostgreSQL DB cluster using the console, the create-db-cluster CLI command, or the CreateDBCluster RDS API operation. For instructions, see Creating and connecting to an Aurora PostgreSQL DB cluster.
- Modify an existing PostgreSQL DB cluster using the console, the modify-db-cluster CLI command, or the ModifyDBCluster RDS API operation. For instructions, see Modifying an Amazon Aurora DB cluster.
- Restore a PostgreSQL DB cluster from a DB snapshot using the console, the restore-db-cluster-from-db-snapshot CLI command, or the RestoreDBClusterFromDBSnapshot RDS API operation. For instructions, see Restoring from a DB cluster snapshot.
- Restore a PostgreSQL DB cluster to a point-in-time using the console, the restore-db-instance-to-point-in-time CLI command, or the RestoreDBClusterToPointInTime RDS API operation. For instructions, see Restoring a DB cluster to a specified time.

Kerberos authentication is only supported for PostgreSQL DB clusters in a VPC. The DB cluster can be in the same VPC as the directory, or in a different VPC. The DB cluster must use a security group that allows ingress and egress within the directory's VPC so the DB cluster can communicate with the directory.

Note
Enabling Kerberos authentication isn't currently supported on Aurora PostgreSQL DB cluster during migration from RDS for PostgreSQL. You can enable Kerberos authentication only on a standalone Aurora PostgreSQL DB cluster.

Console

When you use the console to create, modify, or restore a DB cluster, choose Kerberos authentication in the Database authentication section. Then choose Browse Directory. Select the directory or choose Create a new directory to use the Directory Service.
AWS CLI

When you use the AWS CLI, the following parameters are required for the DB cluster to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy AmazonRDSDirectoryServiceAccess.

For example, the following CLI command modifies a DB cluster to use a directory.

```
aws rds modify-db-cluster --db-cluster-identifier mydbinstance --domain d-Directory-ID --domain-iam-role-name role-name
```

**Important**

If you modify a DB cluster to enable Kerberos authentication, reboot the DB cluster after making the change.

**Step 7: Create PostgreSQL users for your Kerberos principals**

At this point, your Aurora PostgreSQL DB cluster is joined to the AWS Managed Microsoft AD domain. The users that you created in the directory in [Step 4: Create and configure users](#) need
to be set up as PostgreSQL database users and granted privileges to login to the database. You do that by signing in as the database user with `rds_superuser` privileges. For example, if you accepted the defaults when you created your Aurora PostgreSQL DB cluster, you use `postgres`, as shown in the following steps.

**To create PostgreSQL database users for Kerberos principals**

1. Use `psql` to connect to your Aurora PostgreSQL DB cluster's DB instance endpoint using `psql`. The following example uses the default `postgres` account for the `rds_superuser` role.

   ```bash
   psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   
   postgres=>
   ```

2. Create a database user name for each Kerberos principal (Active Directory username) that you want to have access to the database. Use the canonical username (identity) as defined in the Active Directory instance, that is, a lower-case alias (username in Active Directory) and the upper-case name of the Active Directory domain for that user name. The Active Directory user name is an externally authenticated user, so use quotes around the name as shown following.

   ```bash
   postgres=> CREATE USER "username@CORP.EXAMPLE.COM" WITH LOGIN;
   CREATE ROLE
   
   postgres=> GRANT rds_ad TO "username@CORP.EXAMPLE.COM";
   GRANT ROLE
   ```

After you finish creating all the PostgreSQL users for your Active Directory user identities, users can access the Aurora PostgreSQL DB cluster by using their Kerberos credentials.

It's required that the database users who authenticate using Kerberos are doing so from client machines that are members of the Active Directory domain.

Database users that have been granted the `rds_ad` role can't also have the `rds_iam` role. This also applies to nested memberships. For more information, see [IAM database authentication](#).

**Configuring your Aurora PostgreSQL DB cluster for case-insensitive user names**

Aurora PostgreSQL versions 14.5, 13.8, 12.12, and 11.17 support the `krb_caseins_users` PostgreSQL parameter. This parameter supports case-insensitive Active Directory user names. By
default, this parameter is set to false, so user names are interpreted case-sensitively by Aurora PostgreSQL. That's the default behavior in all older versions of Aurora PostgreSQL. However, you can set this parameter to true in your custom DB cluster parameter group and allow your Aurora PostgreSQL DB cluster to interpret user names, case-insensitively. Consider doing this as a convenience for your database users, who might sometimes mis-type the casing of their user name when authenticating using Active Directory.

To change the `krb_caseins_users` parameter, your Aurora PostgreSQL DB cluster must be using a custom DB cluster parameter group. For information about working with a custom DB cluster parameter group, see [Working with parameter groups](#).

You can use the AWS CLI or the AWS Management Console to change the setting. For more information, see [Modifying parameters in a DB cluster parameter group](#).

### Step 8: Configure a PostgreSQL client

To configure a PostgreSQL client, take the following steps:

- Create a krb5.conf file (or equivalent) to point to the domain.
- Verify that traffic can flow between the client host and AWS Directory Service. Use a network utility such as Netcat for the following:
  - Verify traffic over DNS for port 53.
  - Verify traffic over TCP/UDP for port 53 and for Kerberos, which includes ports 88 and 464 for AWS Directory Service.
- Verify that traffic can flow between the client host and the DB instance over the database port. For example, use psql to connect and access the database.

The following is sample krb5.conf content for AWS Managed Microsoft AD.

```ini
[libdefaults]
default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
    kdc = example.com
    admin_server = example.com
}
[domain_realm]
.example.com = EXAMPLE.COM
```
example.com = EXAMPLE.COM

The following is sample krb5.conf content for an on-premises Microsoft Active Directory.

```conf
[libdefaults]
default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
    kdc = example.com
    admin_server = example.com
}
ONPREM.COM = {
    kdc = onprem.com
    admin_server = onprem.com
}
[domain_realm]
.example.com = EXAMPLE.COM
example.com = EXAMPLE.COM
.onprem.com = ONPREM.COM
.onprem.com = ONPREM.COM
.rds.amazonaws.com = EXAMPLE.COM
.amazonaws.com.cn = EXAMPLE.COM
.amazonaws.com = EXAMPLE.COM
```

Managing a DB cluster in a Domain

You can use the console, the CLI, or the RDS API to manage your DB cluster and its relationship with your Microsoft Active Directory. For example, you can associate an Active Directory to enable Kerberos authentication. You can also remove the association for an Active Directory to disable Kerberos authentication. You can also move a DB cluster to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the `modify-db-cluster` CLI command. Specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the `modify-db-cluster` CLI command. Specify `none` for the `--domain` option.
- To move a DB instance from one domain to another, use the `modify-db-cluster` CLI command. Specify the domain identifier of the new domain for the `--domain` option.
Understanding Domain membership

After you create or modify your DB cluster, the DB instances become members of the domain. You can view the status of the domain membership in the console or by running the `describe-db-instances` CLI command. The status of the DB instance can be one of the following:

- **kerberos-enabled** – The DB instance has Kerberos authentication enabled.
- **enabling-kerberos** – AWS is in the process of enabling Kerberos authentication on this DB instance.
- **pending-enable-kerberos** – Enabling Kerberos authentication is pending on this DB instance.
- **pending-maintenance-enable-kerberos** – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- **pending-disable-kerberos** – Disabling Kerberos authentication is pending on this DB instance.
- **pending-maintenance-disable-kerberos** – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- **enable-kerberos-failed** – A configuration problem prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
- **disabling-kerberos** – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. In some cases, the attempt to enable Kerberos authentication might fail when you create or modify a DB cluster. If so, make sure that you are using the correct IAM role, then modify the DB cluster to join the domain.

Connecting to PostgreSQL with Kerberos authentication

You can connect to PostgreSQL with Kerberos authentication with the pgAdmin interface or with a command-line interface such as psql. For more information about connecting, see [Connecting to an Amazon Aurora PostgreSQL DB cluster](#). For information about obtaining the endpoint, port number, and other details needed for connection, see [Viewing the endpoints for an Aurora cluster](#).
pgAdmin

To use pgAdmin to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. Launch the pgAdmin application on your client computer.
3. In the Create - Server dialog box, enter a name on the General tab to identify the server in pgAdmin.
4. On the Connection tab, enter the following information from your Aurora PostgreSQL database.
   - For Host, enter the endpoint for the Writer instance of your Aurora PostgreSQL DB cluster. An endpoint looks similar to the following:
     
     AUR-cluster-instance.111122223333.aws-region.rds.amazonaws.com

     To connect to an on-premises Microsoft Active Directory from a Windows client, you use the domain name of the AWS Managed Active Directory instead of rds.amazonaws.com in the host endpoint. For example, suppose that the domain name for the AWS Managed Active Directory is corp.example.com. Then for Host, the endpoint would be specified as follows:
     
     AUR-cluster-instance.111122223333.aws-region.corp.example.com
   - For Port, enter the assigned port.
   - For Maintenance database, enter the name of the initial database to which the client will connect.
   - For Username, enter the user name that you entered for Kerberos authentication in Step 7: Create PostgreSQL users for your Kerberos principals.
5. Choose Save.

Psq1

To use psql to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. At a command prompt, run the following command.

   kinit username
Replace `username` with the user name. At the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. If the PostgreSQL DB cluster is using a publicly accessible VPC, put IP address for your DB cluster endpoint in your `/etc/hosts` file on the EC2 client. For example, the following commands obtain the IP address and then put it in the `/etc/hosts` file.

```
% dig +short PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com
;; Truncated, retrying in TCP mode.
ec2-34-210-197-118.AWS-Region.compute.amazonaws.com.
34.210.197.118

% echo " 34.210.197.118 PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com" >> /etc/hosts
```

If you're using an on-premises Microsoft Active Directory from a Windows client, then you need to connect using a specialized endpoint. Instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint, use the domain name of the AWS Managed Active Directory.

For example, suppose that the domain name for your AWS Managed Active Directory is `corp.example.com`. Then use the format `PostgreSQL-endpoint.AWS-Region.corp.example.com` for the endpoint and put it in the `/etc/hosts` file.

```
% echo " 34.210.197.118 PostgreSQL-endpoint.AWS-Region.corp.example.com" >> /etc/hosts
```

3. Use the following `psql` command to log in to a PostgreSQL DB cluster that is integrated with Active Directory. Use a cluster or instance endpoint.

```
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com postgres
```

To log in to the PostgreSQL DB cluster from a Windows client using an on-premises Active Directory, use the following `psql` command with the domain name from the previous step (`corp.example.com`):

```
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.corp.example.com postgres
```
Using AD security groups for Aurora PostgreSQL access control

From Aurora PostgreSQL 14.10 and 15.5 versions, Aurora PostgreSQL access control can be managed using AWS Directory Service for Microsoft Active Directory (AD) security groups. Earlier versions of Aurora PostgreSQL support Kerberos based authentication with AD only for individual users. Each AD user had to be explicitly provisioned to DB cluster to get access.

Instead of explicitly provisioning each AD user to DB cluster based on business needs, you can leverage AD security groups as explained below:

• AD users are members of various AD security groups in an Active Directory. These are not dictated by DB cluster administrator, but are based on business requirements, and are handled by an AD administrator.

• DB cluster administrators create DB roles in DB instances based on business requirements. These DB roles may have different permissions or privileges.

• DB cluster administrators configure a mapping from AD security groups to DB roles on a per DB cluster basis.

• DB users can access DB clusters using their AD credentials. Access is based on AD security group membership. AD users gain or lose access automatically based on their AD group memberships.

Prerequisites

Ensure that you have the following before setting up the extension for AD Security groups:

• Setup Kerberos authentication for PostgreSQL DB clusters. For more information, see Setting up Kerberos authentication for PostgreSQL DB clusters.

Note

For AD security groups, skip Step 7: Create PostgreSQL users for your Kerberos principals in this setup procedure.

• Managing a DB cluster in a Domain. For more information, see Managing a DB cluster in a Domain.
Setting up the `pg_ad_mapping` extension

Aurora PostgreSQL is now providing `pg_ad_mapping` extension to manage the mapping between AD security groups and DB roles in Aurora PostgreSQL cluster. For more information about the functions provided by `pg_ad_mapping`, see Using functions from the `pg_ad_mapping` extension.

To set up the `pg_ad_mapping` extension on your Aurora PostgreSQL DB cluster, you first add `pg_ad_mapping` to the shared libraries on the custom DB cluster parameter group for your Aurora PostgreSQL DB cluster. For information about creating a custom DB cluster parameter group, see Working with parameter groups. Next, you install the `pg_ad_mapping` extension. The procedures in this section show you how. You can use the AWS Management Console or the AWS CLI.

You must have permissions as the `rds_superuser` role to perform all these tasks.

The steps following assume that your Aurora PostgreSQL DB cluster is associated with a custom DB cluster parameter group.

**Console**

**To set up the `pg_ad_mapping` extension**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your Aurora PostgreSQL DB cluster's Writer instance.
3. Open the **Configuration** tab for your Aurora PostgreSQL DB cluster writer instance. Among the Instance details, find the **Parameter group** link.
4. Choose the link to open the custom parameters associated with your Aurora PostgreSQL DB cluster.
5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose **Edit parameters** to access the property values.
7. Add `pg_ad_mapping` to the list in the **Values** field. Use a comma to separate items in the list of values.
8. Reboot the writer instance of your Aurora PostgreSQL DB cluster so that your change to the 
   shared_preload_libraries parameter takes effect.

9. When the instance is available, verify that pg_ad_mapping has been initialized. Use psql to 
   connect to the writer instance of your Aurora PostgreSQL DB cluster, and then run the 
   following command.

   ```sql
   SHOW shared_preload_libraries;
   shared_preload_libraries
   --------------------
   rdsutils,pg_ad_mapping
   (1 row)
   ```

10. With pg_ad_mapping initialized, you can now create the extension. You need to create 
    the extension after initializing the library to start using the functions provided by this 
    extension.

    ```sql
    CREATE EXTENSION pg_ad_mapping;
    ```

11. Close the psql session.

    ```sql
    labdb=> \q
    ```

**AWS CLI**

**To setup pg_ad_mapping**

To setup pg_ad_mapping using the AWS CLI, you call the `modify-db-parameter-group` operation to 
add this parameter in your custom parameter group, as shown in the following procedure.
1. Use the following AWS CLI command to add `pg_ad_mapping` to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \
  --db-parameter-group-name custom-param-group-name \
  --parameters "ParameterName=shared_preload_libraries,ParameterValue=pg_ad_mapping,ApplyMethod=pending-reboot" \
  --region aws-region
```

2. Use the following AWS CLI command to reboot the writer instance of your Aurora PostgreSQL DB cluster so that the `pg_ad_mapping` is initialized.

```
aws rds reboot-db-instance \
  --db-instance-identifier writer-instance \
  --region aws-region
```

3. When the instance is available, you can verify that `pg_ad_mapping` has been initialized. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pg_ad_mapping     
(1 row)
```

With `pg_ad_mapping` initialized, you can now create the extension.

```
CREATE EXTENSION pg_ad_mapping;
```

4. Close the `psql` session so that you can use the AWS CLI.

```
labdb=> \q
```

**Retrieving Active Directory Group SID in PowerShell**

A security identifier (SID) is used to uniquely identify a security principal or security group. Whenever a security group or account is created in Active Directory a SID is assigned to it. To fetch
the AD security group SID from the active directory, you can use the Get-ADGroup cmdlet from windows client machine which is joined with that Active Directory domain. The Identity parameter specifies the Active Directory group name to get the corresponding SID.

The following example returns the SID of AD group *adgroup1*.

```powershell
C:\Users\Admin> Get-ADGroup -Identity adgroup1 | select SID
SID
-----------------------------------------------
S-1-5-21-3168537779-1985441202-1799118680-1612
```

**Mapping DB role with AD security group**

You need to explicitly provision the AD security groups in the database as a PostgreSQL DB role. An AD user, who is part of at least one provisioned AD security group will get access to the database. You shouldn’t grant `rds_ad` role to AD group security based DB role. Kerberos authentication for security group will get triggered by using the domain name suffix like `user1@example.com`. This DB role can’t use Password or IAM authentication to gain access to database.

**Note**

AD users who have a corresponding DB role in the database with `rds_ad` role granted to them, can’t login as part of the AD security group. They will get access through DB role as an individual user.

For example, accounts-group is a security group in AD where you would like to provision this security group in the Aurora PostgreSQL as accounts-role.

<table>
<thead>
<tr>
<th>AD Security Group</th>
<th>PostgreSQL DB role</th>
</tr>
</thead>
<tbody>
<tr>
<td>accounts-group</td>
<td>accounts-role</td>
</tr>
</tbody>
</table>

When mapping the DB role with the AD security group, you must ensure that DB role has the LOGIN attribute set and it has CONNECT privilege to the required login database.
Admin can now proceed to create the mapping between AD security group and PostgreSQL DB role.

```
admin=> select pgadmap_set_mapping('accounts-group', 'accounts-role', <SID>, <Weight>);
```

For information on retrieving SID of AD security group, see [Retrieving Active Directory Group SID in PowerShell](#).

There might be cases where an AD user belongs to multiple groups, in that case, AD user will inherit the privileges of the DB role, which was provisioned with the highest weight. If the two roles have the same weight, AD user will inherit the privileges of the DB role corresponding to the mapping that was added recently. The recommendation is to specify weights that reflect the relative permissions/privileges of individual DB roles. Higher the permissions or privileges of a DB role, higher the weight that should be associated with the mapping entry. This will avoid the ambiguity of two mappings having the same weight.

The following table shows a sample mapping from AD security groups to Aurora PostgreSQL DB roles.

<table>
<thead>
<tr>
<th>AD Security Group</th>
<th>PostgreSQL DB role</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>accounts-group</td>
<td>accounts-role</td>
<td>7</td>
</tr>
<tr>
<td>sales-group</td>
<td>sales-role</td>
<td>10</td>
</tr>
<tr>
<td>dev-group</td>
<td>dev-role</td>
<td>7</td>
</tr>
</tbody>
</table>

In the following example, user1 will inherit the privileges of sales-role since it has the higher weight while user2 will inherit the privileges of dev-role as the mapping for this role was created after accounts-role, which share the same weight as accounts-role.
The psql commands to establish, list, and clear the mappings are shown below. Currently, it isn't possible to modify a single mapping entry. The existing entry needs to be deleted and the mapping recreated.

```
admin=> select pgadmap_set_mapping('accounts-group', 'accounts-role', 'S-1-5-67-890', 7);
admin=> select pgadmap_set_mapping('sales-group', 'sales-role', 'S-1-2-34-560', 10);
admin=> select pgadmap_set_mapping('dev-group', 'dev-role', 'S-1-8-43-612', 7);
```

```
admin=> select * from pgadmap_read_mapping();
```

```
ad_sid       | pg_role        | weight | ad_grp
-------------+----------------+--------+---------------
 S-1-5-67-890 | accounts-role  | 7      | accounts-group
 S-1-2-34-560 | sales-role     | 10     | sales-group
 S-1-8-43-612 | dev-role       | 7      | dev-group
```

(3 rows)

**AD user identity logging/auditing**

Use the following command to determine the database role inherited by current or session user:

```
postgres=> select session_user, current_user;
```

```
session_user | current_user
-------------+--------------
dev-role     | dev-role
```

(1 row)
To determine the AD security principal identity, use the following command:

```sql
postgres=> select principal from pg_stat_gssapi where pid = pg_backend_pid();

<table>
<thead>
<tr>
<th>principal</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="mailto:user1@example.com">user1@example.com</a></td>
</tr>
</tbody>
</table>
```

Currently, AD user identity isn't visible in the audit logs. The `log_connections` parameter can be enabled to log DB session establishment. For more information, see `log_connections`. The output for this includes the AD user identity, as shown below. The backend PID associated with this output can then help attribute actions back to the actual AD user.

```
pgrole1@postgres:[615]:LOG: connection authorized: user=pgrole1
database=postgres application_name=psql GSS (authenticated=yes, encrypted=yes, principal=Admin@EXAMPLE.COM)
```

**Limitations**

- Microsoft Entra ID known as Azure Active Directory isn't supported.

**Using functions from the `pg_ad_mapping` extension**

`pg_ad_mapping` extension provided support to the following functions:

- `pgadmap_set_mapping`

This function establishes the mapping between AD security group and Database role with an associated weight.

**Syntax**

```
pgadmap_set_mapping(  
ad_group,  
$db_role,$
)
Arguments

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ad_group</td>
<td>Name of AD Group. Value cannot be null or empty string.</td>
</tr>
<tr>
<td>db_role</td>
<td>Database role to be mapped to the specified AD Group. Value cannot be null or empty string.</td>
</tr>
<tr>
<td>ad_group_sid</td>
<td>Security identifier that is used to uniquely identify the AD group. Value starts with 'S-1-' and cannot be null or empty string. For more information, see <a href="#">Retrieving Active Directory Group SID in PowerShell</a>.</td>
</tr>
<tr>
<td>weight</td>
<td>Weight associated with the database role. The role with highest weight gets precedence when user is a member of multiple groups. Default value of weight is 1.</td>
</tr>
</tbody>
</table>

Return type

None

Usage notes

This function adds a new mapping from AD security group to database role. It can only be executed on the primary DB instance of the DB cluster by a user having rds_superuser privilege.

Examples

```
postgres=> select pgadmap_set_mapping('accounts-group','accounts-role','S-1-2-33-12345-67890-12345-678',10);
pgadmap_set_mapping
(1 row)
```
pgadmap_read_mapping

This function lists the mappings between AD security group and DB role that were set using pgadmap_set_mapping function.

Syntax

```sql
pgadmap_read_mapping()
```

Arguments

None

Return type

None

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ad_group_sid</td>
<td>Security identifier that is used to uniquely identify the AD group. Value starts with 'S-1-' and cannot be null or empty string. For more information, see <a href="accounts-role@example.com">Retrieving Active Directory Group SID in PowerShell</a></td>
</tr>
<tr>
<td>db_role</td>
<td>Database role to be mapped to the specified AD Group. Value cannot be null or empty string.</td>
</tr>
<tr>
<td>weight</td>
<td>Weight associated with the database role. The role with highest weight gets precedence when user is a member of multiple groups. Default value of weight is 1.</td>
</tr>
<tr>
<td>ad_group</td>
<td>Name of AD Group. Value cannot be null or empty string.</td>
</tr>
</tbody>
</table>

Usage notes

Call this function to list all the available mappings between AD security group and DB role.

Examples

```sql
postgres=> select * from pgadmap_read_mapping();

<table>
<thead>
<tr>
<th>ad_sid</th>
<th>pg_role</th>
<th>weight</th>
<th>ad_grp</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
pgadmap_reset_mapping

This function resets one or all the mappings that were set using pgadmap_set_mapping function.

Syntax

```
pgadmap_reset_mapping(
ad_group_sid,
db_role,
weight)
```

Arguments

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ad_group_sid</td>
<td>Security identifier that is used to uniquely identify the AD group.</td>
</tr>
<tr>
<td>db_role</td>
<td>Database role to be mapped to the specified AD Group.</td>
</tr>
<tr>
<td>weight</td>
<td>Weight associated with the database role.</td>
</tr>
</tbody>
</table>

If no arguments are provided, all AD group to DB role mappings are reset. Either all arguments need to be provided or none.

Return type

None

Usage notes

Call this function to delete a specific AD group to DB role mapping or to reset all mappings. This function can only be executed on the primary DB instance of the DB cluster by a user having rds_superuser privilege.
Examples

postgres=> select * from pgadmap_read_mapping();

<table>
<thead>
<tr>
<th>ad_sid</th>
<th>pg_role</th>
<th>weight</th>
<th>ad_grp</th>
</tr>
</thead>
<tbody>
<tr>
<td>S-1-2-33-12345-67890-12345-678</td>
<td>accounts-role</td>
<td>10</td>
<td>accounts-group</td>
</tr>
<tr>
<td>S-1-2-33-12345-67890-12345-666</td>
<td>sales-role</td>
<td>10</td>
<td>sales-group</td>
</tr>
</tbody>
</table>

(2 rows)

postgres=> select pgadmap_reset_mapping('S-1-2-33-12345-67890-12345-678', 'accounts-role', 10);

pgadmap_reset_mapping

(1 row)

postgres=> select * from pgadmap_read_mapping();

<table>
<thead>
<tr>
<th>ad_sid</th>
<th>pg_role</th>
<th>weight</th>
<th>ad_grp</th>
</tr>
</thead>
<tbody>
<tr>
<td>S-1-2-33-12345-67890-12345-666</td>
<td>sales-role</td>
<td>10</td>
<td>sales-group</td>
</tr>
</tbody>
</table>

(1 row)

postgres=> select pgadmap_reset_mapping();

pgadmap_reset_mapping

(1 row)

postgres=> select * from pgadmap_read_mapping();

<table>
<thead>
<tr>
<th>ad_sid</th>
<th>pg_role</th>
<th>weight</th>
<th>ad_grp</th>
</tr>
</thead>
</table>

Migrating data to Amazon Aurora with PostgreSQL compatibility

You have several options for migrating data from your existing database to an Amazon Aurora PostgreSQL-Compatible Edition DB cluster. Your migration options also depend on the database
that you are migrating from and the size of the data that you are migrating. Following are your options:

**Migrating an RDS for PostgreSQL DB instance using a snapshot**

You can migrate data directly from an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL DB cluster.

**Migrating an RDS for PostgreSQL DB instance using an Aurora read replica**

You can also migrate from an RDS for PostgreSQL DB instance by creating an Aurora PostgreSQL read replica of an RDS for PostgreSQL DB instance. When the replica lag between the RDS for PostgreSQL DB instance and the Aurora PostgreSQL read replica is zero, you can stop replication. At this point, you can make the Aurora read replica a standalone Aurora PostgreSQL DB cluster for reading and writing.

**Importing data from Amazon S3 into Aurora PostgreSQL**

You can migrate data by importing it from Amazon S3 into a table belonging to an Aurora PostgreSQL DB cluster.

**Migrating from a database that is not PostgreSQL-compatible**

You can use AWS Database Migration Service (AWS DMS) to migrate data from a database that is not PostgreSQL-compatible. For more information on AWS DMS, see [What is AWS Database Migration Service?](#) in the [AWS Database Migration Service User Guide](#).

---

**Note**

Enabling Kerberos authentication isn't currently supported on Aurora PostgreSQL DB cluster during migration from RDS for PostgreSQL. You can enable Kerberos authentication only on a standalone Aurora PostgreSQL DB cluster.

---

For a list of AWS Regions where Aurora is available, see [Amazon Aurora](#) in the [AWS General Reference](#).

---

**Important**

If you plan to migrate an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster in the near future, we strongly recommend that you turn off auto minor version
upgrades for the DB instance early in the migration planning phase. Migration to Aurora PostgreSQL might be delayed if the RDS for PostgreSQL version isn't yet supported by Aurora PostgreSQL.

For information about Aurora PostgreSQL versions, see [Engine versions for Amazon Aurora PostgreSQL](#).

---

**Migrating a snapshot of an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster**

To create an Aurora PostgreSQL DB cluster, you can migrate a DB snapshot of an RDS for PostgreSQL DB instance. The new Aurora PostgreSQL DB cluster is populated with the data from the original RDS for PostgreSQL DB instance. For information about creating a DB snapshot, see [Creating a DB snapshot](#).

In some cases, the DB snapshot might not be in the AWS Region where you want to locate your data. If so, use the Amazon RDS console to copy the DB snapshot to that AWS Region. For information about copying a DB snapshot, see [Copying a DB snapshot](#).

You can migrate RDS for PostgreSQL snapshots that are compatible with the Aurora PostgreSQL versions available in the given AWS Region. For example, you can migrate a snapshot from an RDS for PostgreSQL 11.1 DB instance to Aurora PostgreSQL version 11.4, 11.7, 11.8, or 11.9 in the US West (N. California) Region. You can migrate RDS for PostgreSQL 10.11 snapshot to Aurora PostgreSQL 10.11, 10.12, 10.13, and 10.14. In other words, the RDS for PostgreSQL snapshot must use the same or a lower minor version as the Aurora PostgreSQL.

You can also choose for your new Aurora PostgreSQL DB cluster to be encrypted at rest by using an AWS KMS key. This option is available only for unencrypted DB snapshots.

To migrate an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL DB cluster, you can use the AWS Management Console, the AWS CLI, or the RDS API. When you use the AWS Management Console, the console takes the actions necessary to create both the DB cluster and the primary instance.
Console

To migrate a PostgreSQL DB snapshot by using the RDS console

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. Choose Snapshots.

3. On the Snapshots page, choose the RDS for PostgreSQL snapshot that you want to migrate into an Aurora PostgreSQL DB cluster.

4. Choose Actions then choose Migrate snapshot.

5. Set the following values on the Migrate database page:

   - **DB engine version**: Choose a DB engine version you want to use for the new migrated instance.
   - **DB instance identifier**: Enter a name for the DB cluster that is unique for your account in the AWS Region that you chose. This identifier is used in the endpoint addresses for the instances in your DB cluster. You might choose to add some intelligence to the name, such as including the AWS Region and DB engine that you chose, for example `aurora-cluster1`. The DB instance identifier has the following constraints:
     - It must contain 1–63 alphanumeric characters or hyphens.
     - Its first character must be a letter.
     - It can't end with a hyphen or contain two consecutive hyphens.
     - It must be unique for all DB instances per AWS account, per AWS Region.
   - **DB instance class**: Choose a DB instance class that has the required storage and capacity for your database, for example `db.r6g.large`. Aurora cluster volumes automatically grow as the amount of data in your database increases. So you only need to choose a DB instance class that meets your current storage requirements. For more information, see Overview of Amazon Aurora storage.
   - **Virtual private cloud (VPC)**: If you have an existing VPC, then you can use that VPC with your Aurora PostgreSQL DB cluster by choosing your VPC identifier, for example `vpc-a464d1c1`. For information about creating a VPC, see Tutorial: Create a VPC for use with a DB cluster (IPv4 only).

   Otherwise, you can choose to have Amazon RDS create a VPC for you by choosing Create new VPC.
• **DB subnet group**: If you have an existing subnet group, then you can use that subnet group with your Aurora PostgreSQL DB cluster by choosing your subnet group identifier, for example gs-subnet-group1.

• **Public access**: Choose No to specify that instances in your DB cluster can only be accessed by resources inside of your VPC. Choose Yes to specify that instances in your DB cluster can be accessed by resources on the public network.

  **Note**
  Your production DB cluster might not need to be in a public subnet, because only your application servers require access to your DB cluster. If your DB cluster doesn't need to be in a public subnet, set **Public access** to No.

• **VPC security group**: Choose a VPC security group to allow access to your database.

• **Availability Zone**: Choose the Availability Zone to host the primary instance for your Aurora PostgreSQL DB cluster. To have Amazon RDS choose an Availability Zone for you, choose No preference.

• **Database port**: Enter the default port to be used when connecting to instances in the Aurora PostgreSQL DB cluster. The default is 5432.

  **Note**
  You might be behind a corporate firewall that doesn't allow access to default ports such as the PostgreSQL default port, 5432. In this case, provide a port value that your corporate firewall allows. Remember that port value later when you connect to the Aurora PostgreSQL DB cluster.

• **Enable Encryption**: Choose Enable Encryption for your new Aurora PostgreSQL DB cluster to be encrypted at rest. Also choose a KMS key as the **AWS KMS key** value.

• **Auto minor version upgrade**: Choose Enable auto minor version upgrade to enable your Aurora PostgreSQL DB cluster to receive minor PostgreSQL DB engine version upgrades automatically when they become available.

  The **Auto minor version upgrade** option only applies to upgrades to PostgreSQL minor engine versions for your Aurora PostgreSQL DB cluster. It doesn't apply to regular patches applied to maintain system stability.

6. Choose **Migrate** to migrate your DB snapshot.
Choose **Databases** to see the new DB cluster. Choose the new DB cluster to monitor the progress of the migration. When the migration completes, the Status for the cluster is **Available**. On the **Connectivity & security** tab, you can find the cluster endpoint to use for connecting to the primary writer instance of the DB cluster. For more information on connecting to an Aurora PostgreSQL DB cluster, see [Connecting to an Amazon Aurora DB cluster](#).

**AWS CLI**

Using the AWS CLI to migrate an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL involves two separate AWS CLI commands. First, you use the `restore-db-cluster-from-snapshot` command to create a new Aurora PostgreSQL DB cluster. You then use the `create-db-instance` command to create the primary DB instance in the new cluster to complete the migration. The following procedure creates an Aurora PostgreSQL DB cluster with primary DB instance that has the same configuration as the DB instance used to create the snapshot.

**To migrate an RDS for PostgreSQL DB snapshot to an Aurora PostgreSQL DB cluster**

1. Use the `describe-db-snapshots` command to obtain information about the DB snapshot you want to migrate. You can specify either the `--db-instance-identifier` parameter or the `--db-snapshot-identifier` in the command. If you don't specify one of these parameters, you get all snapshots.

   ```
   aws rds describe-db-snapshots --db-instance-identifier <your-db-instance-name>
   ```

2. The command returns all configuration details for any snapshots created from the DB instance specified. In the output, find the snapshot that you want to migrate and locate its Amazon Resource Name (ARN). To learn more about Amazon RDS ARNs, see [Amazon Relational Database Service (Amazon RDS)](#). An ARN looks similar to the output following.

   ```
   "DBSnapshotArn": "arn:aws:rds:aws-region:111122223333:snapshot:<snapshot_name>"
   ```

   Also in the output you can find configuration details for the RDS for PostgreSQL DB instance, such as the engine version, allocated storage, whether or not the DB instance is encrypted, and so on.

3. Use the `restore-db-cluster-from-snapshot` command to start the migration. Specify the following parameters:
- `--db-cluster-identifier` – The name that you want to give to the Aurora PostgreSQL DB cluster. This Aurora DB cluster is the target for your DB snapshot migration.

- `--snapshot-identifier` – The Amazon Resource Name (ARN) of the DB snapshot to migrate.

- `--engine` – Specify `aurora-postgresql` for the Aurora DB cluster engine.

- `--kms-key-id` – This optional parameter lets you create an encrypted Aurora PostgreSQL DB cluster from an unencrypted DB snapshot. It also lets you choose a different encryption key for the DB cluster than the key used for the DB snapshot.

**Note**

You can't create an unencrypted Aurora PostgreSQL DB cluster from an encrypted DB snapshot.

Without the `--kms-key-id` parameter specified as shown following, the `restore-db-cluster-from-snapshot` AWS CLI command creates an empty Aurora PostgreSQL DB cluster that's either encrypted using the same key as the DB snapshot or is unencrypted if the source DB snapshot isn't encrypted.

For Linux, macOS, or Unix:

```bash
aws rds restore-db-cluster-from-snapshot \
  --db-cluster-identifier cluster-name \
  --engine aurora-postgresql
```

For Windows:

```bash
aws rds restore-db-cluster-from-snapshot ^
  --db-cluster-identifier new_cluster ^
  --engine aurora-postgresql
```
4. The command returns details about the Aurora PostgreSQL DB cluster that's being created for the migration. You can check the status of the Aurora PostgreSQL DB cluster by using the `describe-db-clusters` AWS CLI command.

   ```bash/aws rds describe-db-clusters --db-cluster-identifier cluster-name
   ```

5. When the DB cluster becomes "available", you use `create-db-instance` command to populate the Aurora PostgreSQL DB cluster with the DB instance based on your Amazon RDS DB snapshot. Specify the following parameters:

   - `--db-cluster-identifier` – The name of the new Aurora PostgreSQL DB cluster that you created in the previous step.
   - `--db-instance-identifier` – The name you want to give to the DB instance. This instance becomes the primary node in your Aurora PostgreSQL DB cluster.
   - `--db-instance-class` – Specify the DB instance class to use. Choose from among the DB instance classes supported by the Aurora PostgreSQL version to which you're migrating. For more information, see [DB instance class types](#) and [Supported DB engines for DB instance classes](#).
   - `--engine` – Specify `aurora-postgresql` for the DB instance.

   You can also create the DB instance with a different configuration than the source DB snapshot, by passing in the appropriate options in the `create-db-instance` AWS CLI command. For more information, see the [create-db-instance](#) command.

   **For Linux, macOS, or Unix:**

   ```bash
/aws rds create-db-instance \
   --db-cluster-identifier cluster-name \
   --db-instance-identifier --db-instance-class db.instance.class \
   --engine aurora-postgresql
   
   For Windows:

   ```bash
/aws rds create-db-instance ^
   --db-cluster-identifier cluster-name ^
   --db-instance-identifier --db-instance-class db.instance.class ^
   --engine aurora-postgresql
   ```
When the migration process completes, the Aurora PostgreSQL cluster has a populated primary DB instance.
Migrating data from an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster using an Aurora read replica

You can use an RDS for PostgreSQL DB instance as the basis for a new Aurora PostgreSQL DB cluster by using an Aurora read replica for the migration process. The Aurora read replica option is available only for migrating within the same AWS Region and account, and it's available only if the Region offers a compatible version of Aurora PostgreSQL for your RDS for PostgreSQL DB instance. By compatible, we mean that the Aurora PostgreSQL version is the same as the RDS for PostgreSQL version, or that it is a higher minor version in the same major version family.

For example, to use this technique to migrate an RDS for PostgreSQL 11.14 DB instance, the Region must offer Aurora PostgreSQL version 11.14 or a higher minor version in the PostgreSQL version 11 family.

- Overview of migrating data by using an Aurora read replica
- Preparing to migrate data by using an Aurora read replica
- Creating an Aurora read replica
- Promoting an Aurora read replica

Overview of migrating data by using an Aurora read replica

Migrating from an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster is a multistep procedure. First, you create an Aurora read replica of your source RDS for PostgreSQL DB instance. That starts a replication process from your RDS for PostgreSQL DB instance to a special-purpose DB cluster known as a Replica cluster. The Replica cluster consists solely of an Aurora read replica (a reader instance).

Once the Replica cluster exists, you monitor the lag between it and the source RDS for PostgreSQL DB instance. When the replica lag is zero (0), you can promote the Replica cluster. Replication stops, the Replica cluster is promoted to a standalone Aurora DB cluster, and the reader is promoted to writer instance for the cluster. You can then add instances to the Aurora PostgreSQL DB cluster to size your Aurora PostgreSQL DB cluster for your use case. You can also delete the RDS for PostgreSQL DB instance if you have no further need of it.
Amazon Aurora

User Guide for Aurora

Note
It can take several hours per terabyte of data for the migration to complete.

You can't create an Aurora read replica if your RDS for PostgreSQL DB instance already has an Aurora read replica or if it has a cross-Region read replica.

Preparing to migrate data by using an Aurora read replica

During the migration process using Aurora read replica, updates made to the source RDS for PostgreSQL DB instance are asynchronously replicated to the Aurora read replica of the Replica cluster. The process uses PostgreSQL's native streaming replication functionality which stores write-ahead logs (WAL) segments on the source instance. Before starting this migration process, make sure that your instance has sufficient storage capacity by checking values for the metrics listed in the table.

<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FreeStorageSpace</td>
<td>The available storage space.</td>
</tr>
<tr>
<td></td>
<td>Units: Bytes</td>

<td>OldestReplicationSlotLag</td>
<td>The size of the lag for WAL data in the replica that is lagging the most.</td>
</tr>
<tr>
<td></td>
<td>Units: Megabytes</td>
</tr>
<tr>
<td>RDSToAuroraPostgreSQLReplicaLag</td>
<td>The amount of time in seconds that an Aurora PostgreSQL DB cluster lags behind the source RDS DB instance.</td>
</tr>
<tr>
<td>TransactionLogsDiskUsage</td>
<td>The disk space used by the transaction logs.</td>
</tr>
<tr>
<td></td>
<td>Units: Megabytes</td>
</tr>
</tbody>
</table>

For more information about monitoring your RDS instance, see Monitoring in the Amazon RDS User Guide.
Creating an Aurora read replica

You can create an Aurora read replica for an RDS for PostgreSQL DB instance by using the AWS Management Console or the AWS CLI. The option to create an Aurora read replica using the AWS Management Console is available only if the AWS Region offers a compatible Aurora PostgreSQL version. That is, it's available only if there's an Aurora PostgreSQL version that is the same as the RDS for PostgreSQL version or a higher minor version in the same major version family.

Console

To create an Aurora read replica from a source PostgreSQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the RDS for PostgreSQL DB instance that you want to use as the source for your Aurora read replica. For Actions, choose Create Aurora read replica. If this choice doesn't display, it means that a compatible Aurora PostgreSQL version isn't available in the Region.

4. On the Create Aurora read replica settings page, you configure the properties for the Aurora PostgreSQL DB cluster as shown in the following table. The Replica DB cluster is created from a snapshot of the source DB instance using the same 'master' user name and password as the source, so you can't change these at this time.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB instance class</td>
<td>Choose a DB instance class that meets the processing and memory requirements primary instance in the DB cluster. For more information, see Aurora DB instance classes.</td>
</tr>
<tr>
<td>Multi-AZ deployment</td>
<td>Not available during the migration</td>
</tr>
</tbody>
</table>
| DB instance identifier | Enter the name that you want to give to the DB instance. This identifier is used in the endpoint address for the primary instance of the new DB cluster.  

The DB instance identifier has the following constraints:  
  - It must contain 1–63 alphanumeric characters or hyphens.  
  - Its first character must be a letter.  
  - It can't end with a hyphen or contain two consecutive hyphens.  
  - It must be unique for all DB instances for each AWS account, for each AWS Region. |
<p>| Virtual Private Cloud (VPC) | Choose the VPC to host the DB cluster. Choose Create new VPC to have Amazon RDS create a VPC for you. For more information, see DB cluster prerequisites. |

</tr>
<tr>
<td>Maintenance window</td>
<td>Choose the weekly time range during which system maintenance can occur.</td>
</tr>
</tbody>
</table>

5. Choose **Create read replica**.

**AWS CLI**

To create an Aurora read replica from a source RDS for PostgreSQL DB instance by using the AWS CLI, you first use the **create-db-cluster** CLI command to create an empty Aurora DB cluster. Once the DB cluster exists, you then use the **create-db-instance** command to create the primary instance for your DB cluster. The primary instance is the first instance that's created in an Aurora DB cluster. In this case, it's created initially as an Aurora read replica of your RDS for PostgreSQL DB instance. When the process concludes, your RDS for PostgreSQL DB instance has effectively been migrated to an Aurora PostgreSQL DB cluster.

You don't need to specify the main user account (typically, `postgres`), its password, or the database name. The Aurora read replica obtains these automatically from the source RDS for PostgreSQL DB instance that you identify when you invoke the AWS CLI commands.

You do need to specify the engine version to use for the Aurora PostgreSQL DB cluster and the DB instance. The version you specify should match the source RDS for PostgreSQL DB instance. If the source RDS for PostgreSQL DB instance is encrypted, you need to also specify encryption...
for the Aurora PostgreSQL DB cluster primary instance. Migrating an encrypted instance to an unencrypted Aurora DB cluster isn't supported.

The following examples create an Aurora PostgreSQL DB cluster named my-new-aurora-cluster that's going to use an unencrypted RDS DB source instance. You first create the Aurora PostgreSQL DB cluster by calling the `create-db-cluster` CLI command. The example shows how to use the optional `--storage-encrypted` parameter to specify that the DB cluster should be encrypted. Because the source DB isn't encrypted, the `--kms-key-id` is used to specify the key to use. For more information about required and optional parameters, see the list following the example.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster  
  --db-cluster-identifier my-new-aurora-cluster  
  --db-subnet-group-name my-db-subnet  
  --vpc-security-group-ids sg-11111111  
  --engine aurora-postgresql  
  --engine-version same-as-your-rds-instance-version  
  --storage-encrypted  
  --kms-key-id arn:aws:kms:aws-region:111122223333:key/11111111-2222-3333-444444444444
```

For Windows:

```bash
aws rds create-db-cluster  
  --db-cluster-identifier my-new-aurora-cluster  
  --db-subnet-group-name my-db-subnet  
  --vpc-security-group-ids sg-11111111  
  --engine aurora-postgresql  
  --engine-version same-as-your-rds-instance-version  
  --storage-encrypted  
  --kms-key-id arn:aws:kms:aws-region:111122223333:key/11111111-2222-3333-444444444444
```

In the following list you can find more information about some of the options shown in the example. Unless otherwise specified, these parameters are required.
• --db-cluster-identifier – You need to give your new Aurora PostgreSQL DB cluster a name.

• --db-subnet-group-name – Create your Aurora PostgreSQL DB cluster in the same DB subnet as the source DB instance.

• --vpc-security-group-ids – Specify the security group for your Aurora PostgreSQL DB cluster.

• --engine-version – Specify the version to use for the Aurora PostgreSQL DB cluster. This should be the same as the version used by your source RDS for PostgreSQL DB instance.

• --replication-source-identifier – Identify your RDS for PostgreSQL DB instance using its Amazon Resource Name (ARN). For more information about Amazon RDS ARNs, see Amazon Relational Database Service (Amazon RDS) in the AWS General Reference. of your DB cluster.

• --storage-encrypted – Optional. Use only when needed to specify encryption as follows:
  • Use this parameter when the source DB instance has encrypted storage. The call to create-db-cluster fails if you don't use this parameter with a source DB instance that has encrypted storage. If you want to use a different key for the Aurora PostgreSQL DB cluster than the key used by the source DB instance, you need to also specify the --kms-key-id.
  • Use if the source DB instance's storage is unencrypted but you want the Aurora PostgreSQL DB cluster to use encryption. If so, you also need to identify the encryption key to use with the --kms-key-id parameter.

• --kms-key-id – Optional. When used, you can specify the key to use for storage encryption (--storage-encrypted) by using the key's ARN, ID, alias ARN, or its alias name. This parameter is needed only for the following situations:
  • To choose a different key for the Aurora PostgreSQL DB cluster than that used by the source DB instance.
  • To create an encrypted cluster from an unencrypted source. In this case, you need to specify the key that Aurora PostgreSQL should use for encryption.

After creating the Aurora PostgreSQL DB cluster, you then create the primary instance by using the create-db-instance CLI command, as shown in the following:

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-cluster-identifier my-new-aurora-cluster \
  --db-instance-class db.x2g.16xlarge \
```
For Windows:

```
aws rds create-db-instance ^
  --db-cluster-identifier my-new-aurora-cluster ^
  --db-instance-class db.x2g.16xlarge ^
  --db-instance-identifier rpg-for-migration ^
  --engine aurora-postgresql
```

In the following list, you can find more information about some of the options shown in the example.

- `--db-cluster-identifier` – Specify the name of the Aurora PostgreSQL DB cluster that you created with the `create-db-instance` command in the previous steps.
- `--db-instance-class` – The name of the DB instance class to use for your primary instance, such as `db.r4.xlarge`, `db.t4g.medium`, `db.x2g.16xlarge`, and so on. For a list of available DB instance classes, see [DB instance class types](#).
- `--db-instance-identifier` – Specify the name to give your primary instance.
- `--engine aurora-postgresql` – Specify `aurora-postgresql` for the engine.

**RDS API**

To create an Aurora read replica from a source RDS for PostgreSQL DB instance, first use the RDS API operation [CreateDBCluster](#) to create a new Aurora DB cluster for the Aurora read replica that gets created from your source RDS for PostgreSQL DB instance. When the Aurora PostgreSQL DB cluster is available, you then use the [CreateDBInstance](#) to create the primary instance for the Aurora DB cluster.

You don't need to specify the main user account (typically, `postgres`), its password, or the database name. The Aurora read replica obtains these automatically from the source RDS for PostgreSQL DB instance specified with [ReplicationSourceIdentifier](#).

You do need to specify the engine version to use for the Aurora PostgreSQL DB cluster and the DB instance. The version you specify should match the source RDS for PostgreSQL DB instance. If the source RDS for PostgreSQL DB instance is encrypted, you need to also specify encryption...
for the Aurora PostgreSQL DB cluster primary instance. Migrating an encrypted instance to an unencrypted Aurora DB cluster isn't supported.

To create the Aurora DB cluster for the Aurora read replica, use the RDS API operation `CreateDBCluster` with the following parameters:

- `DBClusterIdentifier` – The name of the DB cluster to create.
- `DBSubnetGroupName` – The name of the DB subnet group to associate with this DB cluster.
- `Engine=aurora-postgresql` – The name of the engine to use.
- `ReplicationSourceIdentifier` – The Amazon Resource Name (ARN) for the source PostgreSQL DB instance. For more information about Amazon RDS ARNs, see Amazon Relational Database Service (Amazon RDS) in the Amazon Web Services General Reference. If `ReplicationSourceIdentifier` identifies an encrypted source, Amazon RDS uses your default KMS key unless you specify a different key using the `KmsKeyId` option.
- `VpcSecurityGroupIds` – The list of Amazon EC2 VPC security groups to associate with this DB cluster.
- `StorageEncrypted` – Indicates that the DB cluster is encrypted. When you use this parameter without also specifying the `ReplicationSourceIdentifier`, Amazon RDS uses your default KMS key.
- `KmsKeyId` – The key for an encrypted cluster. When used, you can specify the key to use for storage encryption by using the key's ARN, ID, alias ARN, or its alias name.

For more information, see CreateDBCluster in the Amazon RDS API Reference.

Once the Aurora DB cluster is available, you can then create a primary instance for it by using the RDS API operation `CreateDBInstance` with the following parameters:

- `DBClusterIdentifier` – The name of your DB cluster.
- `DBInstanceClass` – The name of the DB instance class to use for your primary instance.
- `DBInstanceIdentifier` – The name of your primary instance.
- `Engine=aurora-postgresql` – The name of the engine to use.

For more information, see CreateDBInstance in the Amazon RDS API Reference.
Promoting an Aurora read replica

The migration to Aurora PostgreSQL isn't complete until you promote the Replica cluster, so don't delete the RDS for PostgreSQL source DB instance just yet.

Before promoting the Replica cluster, make sure that the RDS for PostgreSQL DB instance doesn't have any in-process transactions or other activity writing to the database. When the replica lag on the Aurora read replica reaches zero (0), you can promote the Replica cluster. For more information about monitoring replica lag, see Monitoring Aurora PostgreSQL replication and Instance-level metrics for Amazon Aurora.

Console

To promote an Aurora read replica to an Aurora DB cluster

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose Databases.
3. Choose the Replica cluster.

   ![Database cluster management interface](https://via.placeholder.com/150x150)

4. For Actions, choose Promote. This may take a few minutes and can cause downtime.

When the process completes, the Aurora Replica cluster is a Regional Aurora PostgreSQL DB cluster, with a Writer instance containing the data from the RDS for PostgreSQL DB instance.
AWS CLI

To promote an Aurora read replica to a stand-alone DB cluster, use the `promote-read-replica-db-cluster` AWS CLI command.

Example

For Linux, macOS, or Unix:

```bash
aws rds promote-read-replica-db-cluster \
   --db-cluster-identifier myreadreplicacluster
```

For Windows:

```bash
aws rds promote-read-replica-db-cluster ^
   --db-cluster-identifier myreadreplicacluster
```

RDS API

To promote an Aurora read replica to a stand-alone DB cluster, use the RDS API operation `PromoteReadReplicaDBCluster`.

After you promote the Replica cluster, you can confirm that the promotion has completed by checking the event log, as follows.

To confirm that the Aurora Replica cluster was promoted

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Events**.
3. On the **Events** page, find the name of your cluster in the **Source** list. Each event has a source, type, time, and message. You can see all events that have occurred in your AWS Region for your account. A successful promotion generates the following message.

   Promoted Read Replica cluster to a stand-alone database cluster.

After promotion is complete, the source RDS for PostgreSQL DB instance and the Aurora PostgreSQL DB cluster are unlinked. You can direct your client applications to the endpoint for the
Aurora read replica. For more information on the Aurora endpoints, see Amazon Aurora connection management. At this point, you can safely delete the DB instance.

**Improving query performance for Aurora PostgreSQL with Aurora Optimized Reads**

You can achieve faster query processing for Aurora PostgreSQL with Aurora Optimized Reads. An Aurora PostgreSQL DB instance that uses Aurora Optimized Reads delivers up to 8x improved query latency and up to 30% cost savings for applications with large datasets, that exceed the memory capacity of a DB instance.

**Topics**

- Overview of Aurora Optimized Reads in PostgreSQL
- Using Aurora Optimized Reads
- Use cases for Aurora Optimized Reads
- Monitoring DB instances that use Aurora Optimized Reads
- Best practices for Aurora Optimized Reads

**Overview of Aurora Optimized Reads in PostgreSQL**

Aurora Optimized Reads is available by default when you create a DB cluster that uses Graviton-based R6gd and Intel-based R6id instances with non-volatile memory express (NVMe) storage. It is available from the following PostgreSQL versions:

- 16.1 and all higher versions
- 15.4 and higher versions
- 14.9 and higher versions

Aurora Optimized Reads supports two capabilities: tiered cache and temporary objects.

**Optimized Reads-enabled tiered cache** - Using tiered cache, you can extend your DB instance caching capacity by up to 5x the instance memory. This automatically maintains the cache to contain the most recent, transactionally consistent data, freeing applications from the overhead of managing the data currency of external result-set based caching solutions. It offers up to 8x better latency for queries that were previously fetching data from Aurora storage.
In Aurora, the value for `shared_buffers` in the default parameter group is usually set to around 75% of the available memory. However, for the r6gd and r6id instance types, Aurora will reduce the `shared_buffers` space by 4.5% to host the metadata for the Optimized Reads cache.

**Optimized Reads-enabled temporary objects** - Using temporary objects, you can achieve faster query processing by placing the temporary files that are generated by PostgreSQL on the local NVMe storage. This reduces the traffic to Elastic Block Storage (EBS) over the network. It offers up to 2x better latency and throughput for advanced queries that sort, join, or merge large volumes of data that do not fit within the memory capacity available on a DB instance.

On an Aurora I/O-Optimized cluster, Optimized Reads makes use of both tiered cache and temporary objects on NVMe storage. With Optimized Reads-enabled tiered cache capability, Aurora allocates 2x the instance memory for temporary objects, approximately 10% of the storage for internal operations and the remaining storage as tiered cache. On an Aurora Standard cluster, Optimized Reads makes use of only temporary objects.

<table>

</tbody>
</table>

**Note**
A switch between IO-Optimized and Standard clusters on a NVMe-based DB instance class causes an immediate database engine restart.
In Aurora PostgreSQL, use the `temp_tablespaces` parameter to configure the table space where the temporary objects are stored.

To check whether the temporary objects are configured, use the following command:

```sql
postgres=> show temp_tablespaces;
```
```
temp_tablespaces
---------------------
aurora_temp_tablespace
(1 row)
```

The `aurora_temp_tablespace` is a tablespace configured by Aurora that points to the NVMe local storage. You can't modify this parameter or switch back to Amazon EBS storage.

To check whether optimized reads cache is turned on, use the following command:

```sql
postgres=> show shared_preload_libraries;
```
```
shared_preload_libraries
--------------------------------------------------------
rdsutils,pg_stat_statements,aurora_optimized_reads_cache
```

### Using Aurora Optimized Reads

When you provision an Aurora PostgreSQL DB instance with one of the NVMe-based DB instances, the DB instance automatically uses Aurora Optimized Reads.

To turn on Aurora Optimized Reads, do one of the following:

- Create an Aurora PostgreSQL DB cluster using one of the NVMe-based DB instance classes. For more information, see [Creating an Amazon Aurora DB cluster](#).
- Modify an existing Aurora PostgreSQL DB cluster to use one of the NVMe-based DB instance classes. For more information, see [Modifying an Amazon Aurora DB cluster](#).

Aurora Optimized Reads is available in all AWS Regions where one or more of the DB instance classes with local NVMe SSD storage are supported. For more information, see [Aurora DB instance classes](#).

To switch back to a non-optimized reads Aurora instance, modify the DB instance class of your Aurora instance to the similar instance class without NVMe ephemeral storage for your database.
workloads. For example, if the current DB instance class is db.r6gd.4xlarge, choose db.r6g.4xlarge to switch back. For more information, see [Modifying an Aurora DB instance](#).

**Use cases for Aurora Optimized Reads**

**Optimized Reads-enabled tiered cache**

The following are some use cases that can benefit from Optimized Reads with tiered cache:

- Internet scale applications such as payments processing, billing, e-commerce with strict performance SLAs.
- Real-time reporting dashboards that run hundreds of point queries for metrics/data collection.
- Generative AI applications with the pgvector extension to search exact or nearest neighbors across millions of vector embeddings.

**Optimized Reads-enabled temporary objects**

The following are some use cases that can benefit from Optimized Reads with temporary objects:

- Analytical queries that include Common Table Expressions (CTEs), derived tables, and grouping operations.
- Read replicas that handle the unoptimized queries for an application.
- On-demand or dynamic reporting queries with complex operations such as GROUP BY and ORDER BY that can't always use appropriate indexes.
- CREATE INDEX or REINDEX operations for sorting.
- Other workloads that use internal temporary tables.

**Monitoring DB instances that use Aurora Optimized Reads**

You can monitor your queries that use Optimized Reads-enabled tiered cache with the EXPLAIN command as shown in the following example:

```sql
Postgres=> EXPLAIN (ANALYZE, BUFFERS) SELECT c FROM sbtest15 WHERE id=100000000
```

**QUERY PLAN**

```
------------------------------------------------------------------
```
Index Scan using sbtest15_pkey on sbtest15 (cost=0.57..8.59 rows=1 width=121) (actual time=0.287..0.288 rows=1 loops=1)
  Index Cond: (id = 100000000)
  Buffers: shared hit=3 read=2 aurora_orcache_hit=2
  I/O Timings: shared/local read=0.264
Planning:
  Buffers: shared hit=33 read=6 aurora_orcache_hit=6
  I/O Timings: shared/local read=0.607
Planning Time: 0.929 ms
Execution Time: 0.303 ms
(9 rows)
Time: 2.028 ms

Note

aurora_orcache_hit and aurora_storage_read fields in the Buffers section of the explain plan are shown only when Optimized Reads is turned on and their values are greater than zero. The read field is the total of the aurora_orcache_hit and aurora_storage_read fields.

You can monitor DB instances that use Aurora Optimized Reads using the following CloudWatch metrics:

- AuroraOptimizedReadsCacheHitRatio
- FreeEphemeralStorage
- ReadIOPSEphemeralStorage
- ReadLatencyEphemeralStorage
- ReadThroughputEphemeralStorage
- WriteIOPSEphemeralStorage
- WriteLatencyEphemeralStorage
- WriteThroughputEphemeralStorage

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see Instance-level metrics for Amazon Aurora.
You can also use the `pg_proctab` extension to monitor NVMe storage.

```
postgres=> select * from pg_diskusage();
```

```
major | minor | devname       | reads_completed | reads_merged | sectors_read | readtime | writes_completed | writes_merged | sectors_written | writetime | current_io
| iotime | totaliotime
------+-------+---------------------+-----------------+--------------+--------------+-------+------------------+---------------+---------------+------------+-----------+----------
+----------+------------------+---------------+-----------------+--------------+--------------+-------+------------------+---------------+---------------+------------+-----------+----------
|       | rdstemp             |           23264 |            0 |       191450 |    11670 |          1750892 |             0 |        24540576 |    819350 |          0 |      1750892 |

(2 rows)
```

### Best practices for Aurora Optimized Reads

Use the following best practices for Aurora Optimized Reads:

- Monitor the storage space available on the instance store with the CloudWatch metric `FreeEphemeralStorage`. If the instance store is reaching its limit because of the workload on the DB instance, tune the concurrency and queries which heavily use temporary objects or modify it to use a larger DB instance class.

- Monitor the CloudWatch metric for the Optimized Reads cache hit rate. Operations like VACUUM modify large numbers of blocks very quickly. This can cause a temporary drop in the hit ratio. The `pg_prewarm` extension can be used to load data into the buffer cache that allows Aurora to proactively write some of those blocks to the Optimized Reads cache.

- You can enable cluster cache management (CCM) to warm up the buffer cache and tiered cache on a tier-0 reader, which will be used as a failover target. When CCM is enabled, the buffer cache is periodically scanned to write pages eligible for eviction in tiered cache. For more information on CCM, see [Fast recovery after failover with cluster cache management for Aurora PostgreSQL](https://docs.aws.amazon.com/aurora/latest/userguide/Aurora-PostgreSQL.CCM.html).
Using Babelfish for Aurora PostgreSQL

Babelfish for Aurora PostgreSQL extends your Aurora PostgreSQL DB cluster with the ability to accept database connections from SQL Server clients. With Babelfish, applications that were originally built for SQL Server can work directly with Aurora PostgreSQL with few code changes compared to a traditional migration and without changing database drivers. For more information about migrating, see [Migrating a SQL Server database to Babelfish for Aurora PostgreSQL](https://docs.aws.amazon.com/aurora/latest/userguide/using-babelfish.html).

Babelfish provides an additional endpoint for an Aurora PostgreSQL database cluster that allows it to understand the SQL Server wire-level protocol and commonly used SQL Server statements. Client applications that use the Tabular Data Stream (TDS) wire protocol can connect natively to the TDS listener port on Aurora PostgreSQL. To learn more about TDS, see [MS-TDS]: Tabular Data Stream Protocol on the Microsoft website.

**Note**  
Babelfish for Aurora PostgreSQL supports TDS versions 7.1 through 7.4.

Babelfish also provides access to data using the PostgreSQL connection. By default, both SQL dialects supported by Babelfish are available through their native wire protocols at the following ports:

- SQL Server dialect (T-SQL), clients connect to port 1433.
- PostgreSQL dialect (PL/pgSQL), clients connect to port 5432.

Babelfish runs the Transact-SQL (T-SQL) language with some differences. For more information, see [Differences between Babelfish for Aurora PostgreSQL and SQL Server](https://docs.aws.amazon.com/aurora/latest/userguide/using-babelfish.html).

In the following sections, you can find information about setting up and using a Babelfish for Aurora PostgreSQL DB cluster.

**Topics**

- Babelfish limitations

• Babelfish version updates
• Babelfish for Aurora PostgreSQL reference
Babelfish limitations

The following limitations currently apply to Babelfish for Aurora PostgreSQL:

- Babelfish currently doesn't support the following Aurora features:
  - Amazon RDS Blue/Green Deployments
  - AWS Identity and Access Management
  - Database Activity Streams (DAS)
  - PostgreSQL logical replication
  - RDS Data API with Aurora PostgreSQL Serverless v2 and provisioned
  - RDS Proxy with RDS for SQL Server
  - Salted challenge response authentication mechanism (SCRAM)
  - Query editor

- Babelfish currently doesn't support Kerberos based authentication for Active Directory groups.

- Babelfish doesn't provide the following client driver API support:
  - API requests with the connection attributes related to Microsoft Distributed Transaction Coordinator (MSDTC) aren't supported. These include XA calls by the SQLServerXAResource class in the SQL server JDBC driver.
  - Babelfish supports connection pooling with drivers that use the latest versions of the TDS protocol. With older drivers, API requests with the connection attributes and methods related to connection pooling aren't supported.

- Babelfish currently doesn't support the following Aurora PostgreSQL extensions:
  - bloom
  - btrees_gin
  - btrees_gist
  - citext
  - cube
  - hstore
  - hypopg
  - Logical replication using pglogical
  - ltree
  - pgcrypto
• Query plan management using `apg_plan_mgmt`

To learn more about PostgreSQL extensions, see Working with extensions and foreign data wrappers.

• The open source jTDS driver that is designed as an alternative to the Microsoft JDBC driver is not supported.

**Understanding Babelfish architecture and configuration**

You manage the Aurora PostgreSQL-Compatible Edition DB cluster running Babelfish much as you would any Aurora DB cluster. That is, you benefit from the scalability, high-availability with failover support, and built-in replication provided by an Aurora DB cluster. To learn more about these capabilities, see Managing performance and scaling for Aurora DB clusters, High availability for Amazon Aurora, and Replication with Amazon Aurora. You also have access to many other AWS tools and utilities, including the following:

• Amazon CloudWatch is a monitoring and observability service that provides you with data and actionable insights. For more information, see Monitoring Amazon Aurora metrics with Amazon CloudWatch.

• Performance Insights is a database performance tuning and monitoring feature that helps you quickly assess the load on your database. To learn more, see Monitoring DB load with Performance Insights on Amazon Aurora.

• Aurora global databases span multiple AWS Regions, enabling low latency global reads and providing fast recovery from the rare outage that might affect an entire AWS Region. For more information, see Using Amazon Aurora global databases.

• Automatic software patching keeps your database up-to-date with the latest security and feature patches when they become available.

• Amazon RDS events notify you by email or SMS message of important database events, such as an automated failover. For more information, see Monitoring Amazon Aurora events.

Following, you can learn about Babelfish architecture and how the SQL Server databases that you migrate are handled by Babelfish. When you create your Babelfish DB cluster, you need to make some decisions up front about single database or multiple databases, collations, and other details.

**Topics**

• Babelfish architecture
Babelfish architecture

When you create an Aurora PostgreSQL cluster with Babelfish turned on, Aurora provisions the cluster with a PostgreSQL database named babelfish_db. This database is where all migrated SQL Server objects and structures reside.

**Note**
In an Aurora PostgreSQL cluster, the babelfish_db database name is reserved for Babelfish. Creating your own "babelfish_db" database on a Babelfish DB cluster prevents Aurora from successfully provisioning Babelfish.

When you connect to the TDS port, the session is placed in the babelfish_db database. From T-SQL, the structure looks similar to being connected to a SQL Server instance. You can see the master, msdb, and tempdb databases, and the sys.databases catalog. You can create additional user databases and switch between databases with the USE statement. When you create a SQL Server user database, it's flattened into the babelfish_db PostgreSQL database. Your database retains cross-database syntax and semantics equal to or similar to those provided by SQL Server.

**Using Babelfish with a single database or multiple databases**

When you create an Aurora PostgreSQL cluster to use with Babelfish, you choose between using a single SQL Server database on its own or multiple SQL Server databases together. Your choice affects how the names of SQL Server schemas inside the babelfish_db database appear from Aurora PostgreSQL. The migration mode is stored in the migration_mode parameter. You must not change this parameter after creating your cluster as you could lose access to all your previously created SQL objects.

In single-db mode, the schema names of the SQL Server database remain the same in the babelfish_db database of the PostgreSQL. If you choose to migrate only a single database, the schema names of the migrated user database can be referenced in PostgreSQL with the same names used in SQL Server. For example, the dbo and smith schemas reside inside the dbA database.
When connecting through TDS, you can run `USE dba` to see schemas `dbo` and `dev` from T-SQL, as you would in SQL Server. The unchanged schema names are also visible from PostgreSQL.

In multiple-database mode, the schema names of user databases become `dbname_schemaname` when accessed from PostgreSQL. The schema names remain the same when accessed from T-SQL.
As shown in the image, multiple-database mode and single-database mode are the same as SQL Server when connecting through the TDS port and using T-SQL. For example, `USE dbA` lists schemas `dbo` and `dev` just as it does in SQL Server. The mapped schema names, such as `dba_dbo` and `dba_dev`, are visible from PostgreSQL.

Each database still contains your schemas. The name of each database is prepended to the name of the SQL Server schema, using an underscore as a delimiter, for example:

- `dba` contains `dba_dbo` and `dba_dev`.
- `dbb` contains `dbb_dbo` and `dbb_test`.
- `dbc` contains `dbc_dbo` and `dbc_prod`.

Inside the `babelfish_db` database, the T-SQL user still needs to run `USE dbname` to change database context, so the look and feel remains similar to SQL Server.

**Choosing a migration mode**

Each migration mode has advantages and disadvantages. Choose your migration mode based on the number of user databases you have, and your migration plans. After you create a cluster for use with Babelfish, you must not change the migration mode as you might lose access to all your
previously created SQL objects. When choosing a migration mode, consider the requirements of your user databases and clients.

When you create a cluster for use with Babelfish, Aurora PostgreSQL creates the system databases, `master` and `tempdb`. If you created or modified objects in the system databases (`master` or `tempdb`), make sure to recreate those objects in your new cluster. Unlike SQL Server, Babelfish doesn't reinitialize `tempdb` after a cluster reboot.

Use single database migration mode in the following cases:

- If you are migrating a single SQL Server database. In single database mode, migrated schema names when accessed from PostgreSQL are identical to those in original SQL Server schema names. This reduces code changes to existing SQL queries if you want to optimize them to run with a PostgreSQL connection.
- If your end goal is a complete migration to native Aurora PostgreSQL. Before migrating, consolidate your schemas into a single schema (dbo) and then migrate into a single cluster to lessen required changes.

Use multiple database migration mode in the following cases:

- If you want the default SQL Server experience with multiple user databases in the same instance.
- If multiple user databases need to be migrated together.
DB cluster parameter group settings for Babelfish

When you create an Aurora PostgreSQL DB cluster and choose Turn on Babelfish, a DB cluster parameter group is created for you automatically if you choose Create new. This DB cluster parameter group is based on the Aurora PostgreSQL DB cluster parameter group for the Aurora PostgreSQL version chosen for the install, for example, Aurora PostgreSQL version 14. It's named using the following general pattern:

custom-aurora-postgresql14-babelfish-compat-3

You can change the following settings during the cluster creation process but some of these can't be changed once they're stored in the custom parameter group, so choose carefully:

- Single database or Multiple databases
- Default collation locale
- Collation name
- DB parameter group

To use an existing Aurora PostgreSQL DB cluster version 13 or higher parameter group, edit the group and set the babelfish_status parameter to on. Specify any Babelfish options before creating your Aurora PostgreSQL cluster. To learn more, see Working with parameter groups.

The following parameters control Babelfish preferences. Unless otherwise stated in the Description, parameters are modifiable. The default value is included in the description. To see the allowable values for any parameter, do as follows:

Note

When you associate a new DB parameter group with a DB instance, the modified static and dynamic parameters are applied only after the DB instance is rebooted. However, if you modify dynamic parameters in the DB parameter group after you associate it with the DB instance, these changes are applied immediately without a reboot.

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose Parameter groups from the navigation menu.
3. Choose the default.aurora-postgresql14 DB cluster parameter group from the list.

4. Enter the name of a parameter in the search field. For example, enter `babelfishpg_tsql.default_locale` in the search field to display this parameter and its default value and allowable settings.

<table>

<td>false</td>
</tr>
</tbody>
</table>
Babelfish SSL settings and client connections

When a client connects to the TDS port (default 1433), Babelfish compares the Secure Sockets Layer (SSL) setting sent during the client handshake to the Babelfish SSL parameter setting (tds_ssl_encrypt). Babelfish then determines if a connection is allowed. If a connection is allowed, encryption behavior is either enforced or not, depending on your parameter settings and the support for encryption offered by the client.

The table following shows how Babelfish behaves for each combination.

<table>
<thead>
<tr>
<th>Client SSL setting</th>
<th>Babelfish SSL setting</th>
<th>Connection allowed?</th>
<th>Value returned to client</th>
</tr>
</thead>

</tbody>
</table>
Collations supported by Babelfish

When you create an Aurora PostgreSQL DB cluster with Babelfish, you choose a collation for your data. A *collation* specifies the sort order and bit patterns that produce the text or characters in a given written human language. A collation includes rules comparing data for a given set of bit patterns. Collation is related to localization. Different locales affect character mapping, sort order, and the like. Collation attributes are reflected in the names of various collations. For information about attributes, see the Babelfish collation attributes table.

Babelfish maps SQL Server collations to comparable collations provided by Babelfish. Babelfish predefines Unicode collations with culturally sensitive string comparisons and sort orders. Babelfish also provides a way to translate the collations in your SQL Server DB to the closest-matching Babelfish collation. Locale-specific collations are provided for different languages and regions.

Some collations specify a code page that corresponds to a client-side encoding. Babelfish automatically translates from the server encoding to the client encoding depending on the collation of each output column.

Babelfish supports the collations listed in the Babelfish supported collations table. Babelfish maps SQL Server collations to comparable collations provided by Babelfish.

Babelfish uses version 153.80 of the International Components for Unicode (ICU) collation library. For more information about ICU collations, see Collation in the ICU documentation. To learn more about PostgreSQL and collation, see Collation Support in the the PostgreSQL documentation.

Topics

- DB cluster parameters that control collation and locale
- Deterministic and nondeterministic collations and Babelfish
- Collations supported by Babelfish
- Default Collation in Babelfish
- Managing collations
- Collation limitations and behavior differences

DB cluster parameters that control collation and locale

The following parameters affect collation behavior.
babelfishpg_tsql.default_locale

This parameter specifies the default locale used by the collation. This parameter is used in combination with attributes listed in the Babelfish collation attributes table to customize collations for a specific language and region. The default value for this parameter is en-US.

The default locale applies to all Babelfish collation names that start with "BBF" and to all SQL Server collations that are mapped to Babelfish collations. Changing the setting for this parameter on an existing Babelfish DB cluster doesn't affect the locale of existing collations. For the list of collations, see the Babelfish supported collations table.

babelfishpg_tsql.server_collation_name

This parameter specifies the default collation for the server (Aurora PostgreSQL DB cluster instance) and the database. The default value is sql_latin1_general_cp1_ci_as. The server_collation_name has to be a CI_AS collation because in T-SQL, the server collation determines how identifiers are compared.

When you create your Babelfish DB cluster, you choose the Collation name from the selectable list. These include the collations listed in the Babelfish supported collations table. Don't modify the server_collation_name after the Babelfish database is created.

The settings you choose when you create your Babelfish for Aurora PostgreSQL DB cluster are stored in the DB cluster parameter group associated with the cluster for these parameters and set its collation behavior.

Deterministic and nondeterministic collations and Babelfish

Babelfish supports deterministic and nondeterministic collations:

- A deterministic collation evaluates characters that have identical byte sequences as equal. That means that x and X aren't equal in a deterministic collation. Deterministic collations can be case-sensitive (CS) and accent-sensitive (AS).
- A nondeterministic collation doesn't need an identical match. A nondeterministic collation evaluates x and X as equal. Nondeterministic collations are case-insensitive (CI) and accent-insensitive (AI).

In the table following, you can find some behavior differences between Babelfish and PostgreSQL when using nondeterministic collations.
Babelfish | PostgreSQL
---|---
Supports the LIKE clause for CI_AS collations. | Doesn't support the LIKE clause on nondeterministic collations.

<table>
<thead>
<tr>
<th>Babelfish</th>
<th>PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Doesn't support the LIKE clause on AI collations.</td>
<td></td>
</tr>
<tr>
<td>Don't support pattern-matching operations on nondeterministic collations.</td>
<td></td>
</tr>
</tbody>
</table>

For a list of other limitations and behavior differences for Babelfish compared to SQL Server and PostgreSQL, see [Collation limitations and behavior differences](#).

Babelfish and SQL Server follow a naming convention for collations that describe the collation attributes, as shown in the table following.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AI</td>
<td>Accent-insensitive.</td>
</tr>
<tr>
<td>AS</td>
<td>Accent-sensitive.</td>
</tr>
<tr>
<td>BIN2</td>
<td>BIN2 requests data to be sorted in code point order. Unicode code point order is the same character order for UTF-8, UTF-16, and UCS-2 encodings. Code point order is a fast deterministic collation.</td>
</tr>
<tr>
<td>CI</td>
<td>Case-insensitive.</td>
</tr>
<tr>
<td>CS</td>
<td>Case-sensitive.</td>
</tr>
<tr>
<td>PREF</td>
<td>To sort uppercase letters before lowercase letters, use a PREF collation. If comparison is case-insensitive, the uppercase version of a letter sorts before the lowercase version, if there is no other distinction. The ICU library supports uppercase preference with colCaseFirst=upper, but not for CI_AS collations. PREF can be applied only to CS_AS deterministic collations.</td>
</tr>
</tbody>
</table>
# Collations supported by Babelfish

Use the following collations as a server collation or an object collation.

<table>
<thead>
<tr>
<th>Collation ID</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bbf_unicode_general_ci_as</code></td>
<td>Supports case-insensitive comparison and the LIKE operator.</td>
</tr>
<tr>
<td><code>bbf_unicode_cp1_ci_as</code></td>
<td><strong>Nondeterministic collation</strong> also known as CP1252.</td>
</tr>
<tr>
<td><code>bbf_unicode_CP1250_ci_as</code></td>
<td><strong>Nondeterministic collation</strong> used to represent texts in Central European and Eastern European languages that use Latin script.</td>
</tr>
<tr>
<td><code>bbf_unicode_CP1251_ci_as</code></td>
<td><strong>Nondeterministic collation</strong> for languages that use the Cyrillic script.</td>
</tr>
<tr>
<td><code>bbf_unicode_cp1253_ci_as</code></td>
<td><strong>Nondeterministic collation</strong> used to represent modern Greek.</td>

</table>
### Default Collation in Babelfish

Earlier, the default collation of the collatable datatypes was `pg_catalog.default`. The datatypes and the objects that depend on these datatypes follow cases-sensitive collation. This condition potentially impacts the T-SQL objects of the data set with case-insensitive collation. Starting with Babelfish 2.3.0, the default collation for the collatable data types (except TEXT and NTEXT) is the same as the collation in the `babelfishpg_tsql.server_collation_name` parameter. When you upgrade to Babelfish 2.3.0, the default collation is picked automatically at the time of DB cluster creation, which doesn't create any visible impact.

### Managing collations

The ICU library provides collation version tracking to ensure that indexes that depend on collations can be reindexed when a new version of ICU becomes available. To see if your current database has collations that need refreshing, you can use the following query after connecting using psql or pgAdmin:

```
SELECT pg_describe_object(refclassid, refobjid,
                           refoid, refrelid, "pg_collation"),
```
This query returns output such as the following:

<table>
<thead>
<tr>
<th>Collation</th>
<th>Object</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>(0 rows)</td>
</tr>
</tbody>
</table>

In this example, no collations need to be updated.

To get a listing of the predefined collations in your Babelfish database, you can use psql or pgAdmin with the following query:

```
SELECT * FROM pg_collation;
```

Predefined collations are stored in the `sys.fn_helpcollations` table. You can use the following command to display information about a collation (such as its lcid, style, and collate flags). To get a listing of all collations by using sqlcmd, connect to the T-SQL port (1433, by default) and run the following query:

```
1> :setvar SQLCMDMAXVARTYPEWIDTH 40
2> :setvar SQLCMDMAXFIXEDTYPEWIDTH 40
3> SELECT * FROM fn_helpcollations()
4> GO
```

<table>
<thead>
<tr>
<th>name</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arabic_cs_as</td>
<td>Arabic, case-sensitive, accent-sensitive</td>
</tr>
<tr>
<td>arabic_ci_ai</td>
<td>Arabic, case-insensitive, accent-insensitive</td>
</tr>
<tr>
<td>arabic_ci_as</td>
<td>Arabic, case-insensitive, accent-sensitive</td>
</tr>
<tr>
<td>bbf_unicode_bin2</td>
<td>Unicode-General, case-sensitive, accent-sensitive</td>
</tr>
<tr>
<td>bbf_unicode_cp1250_ci_ai</td>
<td>Default locale, code page 1250, case-ins</td>
</tr>
<tr>
<td>bbf_unicode_cp1250_ci_as</td>
<td>Default locale, code page 1250, case-ins</td>
</tr>
<tr>
<td>bbf_unicode_cp1250_cs_ai</td>
<td>Default locale, code page 1250, case-sen</td>
</tr>
<tr>
<td>bbf_unicode_cp1250_cs_as</td>
<td>Default locale, code page 1250, case-sen</td>
</tr>
<tr>
<td>bbf_unicode_pref_cp1250_cs_as</td>
<td>Default locale, code page 1250, case-sen</td>
</tr>
<tr>
<td>bbf_unicode_cp1251_ci_ai</td>
<td>Default locale, code page 1251, case-ins</td>
</tr>
<tr>
<td>bbf_unicode_cp1251_ci_as</td>
<td>Default locale, code page 1251, case-ins</td>
</tr>
<tr>
<td>bbf_unicode_cp1254_ci_ai</td>
<td>Default locale, code page 1254, case-ins</td>
</tr>
</tbody>
</table>
Lines 1 and 2 shown in the example narrow the output for documentation readability purposes only.

```sql
1> SELECT SERVERPROPERTY('COLLATION')
2> GO
serverproperty
---------------------------------------------------------------------------
sql_latin1_general_cp1_ci_as
(1 rows affected)
1>
```

**Collation limitations and behavior differences**

Babelfish uses the ICU library for collation support. PostgreSQL is built with a specific version of ICU and can match at most one version of a collation. Variations across versions are unavoidable, as are minor variations across time as languages evolve. In the following list you can find known limitations and behavior variations of Babelfish collations:

- **Indexes and collation type dependency** – An index on a user-defined type that depends on the International Components for Unicode (ICU) collation library (the library used by Babelfish) isn't invalidated when the library version changes.

- **COLLATIONPROPERTY function** – Collation properties are implemented only for the supported Babelfish BBF collations. For more information, see the Babelfish supported collations table.

- **Unicode sorting rule differences** – SQL collations for SQL Server sort Unicode-encoded data (nchar and nvarchar) differently than data that's not Unicode-encoded (char and varchar). Babelfish databases are always UTF-8 encoded and always apply Unicode sorting rules consistently, regardless of data type, so the sort order for char or varchar is the same as it is for nchar or nvarchar.

- **Secondary-equal collations and sorting behavior** – The default ICU Unicode secondary-equal (CI_AS) collation sorts punctuation marks and other nonalphanumeric characters before numeric characters, and numeric characters before alphabetic characters. However, the order of punctuation and other special characters is different.

- **Tertiary collations, workaround for ORDER BY** – SQL collations, such as SQL_Latin1_General_Pref_CP1_CI_AS, support the TERTIARY_WEIGHTS function and the
ability to sort strings that compare equally in a CI_AS collation to be sorted uppercase first: ABC, AbC, Abc, aBC, aBc, abC, and finally abc. Thus, the DENSE_RANK OVER (ORDER BY column) analytic function assesses these strings as having the same rank but orders them uppercase first within a partition.

You can get a similar result with Babelfish by adding a COLLATE clause to the ORDER BY clause that specifies a tertiary CS_AS collation that specifies @colCaseFirst=upper. However, the colCaseFirst modifier applies only to strings that are tertiary-equal (rather than secondary-equal such as with CI_AS collation). Thus, you can't emulate tertiary SQL collations using a single ICU collation.

As a workaround, we recommend that you modify applications that use the SQL_Latin1_General_Pref_CP1_CI_AS collation to use the BBF_SQL_Latin1_General_CP1_CI_AS collation first. Then add COLLATE BBF_SQL_Latin1_General_Pref_CP1_CS_AS to any ORDER BY clause for this column.

• **Character expansion** – A character expansion treats a single character as equal to a sequence of characters at the primary level. SQL Server's default CI_AS collation supports character expansion. ICU collations support character expansion for accent-insensitive collations only.

   When character expansion is required, then use a AI collation for comparisons. However, such collations aren't currently supported by the LIKE operator.

• **char and varchar encoding** – When SQL collations are used for char or varchar data types, the sort order for characters preceding ASCII 127 is determined by the specific code page for that SQL collation. For SQL collations, strings declared as char or varchar might sort differently than strings declared as nchar or nvarchar.

   PostgreSQL encodes all strings with the database encoding, so all characters are converted to UTF-8 and sorted using Unicode rules.

   Because SQL collations sort nchar and nvarchar data types using Unicode rules, Babelfish encodes all strings on the server using UTF-8. Babelfish sorts nchar and nvarchar strings the same way it sorts char and varchar strings, using Unicode rules.

• **Supplementary character** – The SQL Server functions NCHAR, UNICODE, and LEN support characters for code-points outside the Unicode Basic Multilingual Plane (BMP). In contrast, non-SC collations use surrogate pair characters to handle supplementary characters. For Unicode data types, SQL Server can represent up to 65,535 characters using UCS-2, or the full Unicode range (1,114,114 characters) if supplementary characters are used.
• **Kana-sensitive (KS) collations** – A Kana-sensitive (KS) collation is one that treats Hiragana and Katakana Japanese Kana characters differently. ICU supports the Japanese collation standard JIS X 4061. The now deprecated colhiraganaQ [on | off] locale modifier might provide the same functionality as KS collations. However, KS collations of the same name as SQL Server aren't currently supported by Babelfish.

• **Width-sensitive (WS) collations** – When a single-byte character (half-width) and the same character represented as a double-byte character (full-width) are treated differently, the collation is called *width-sensitive (WS)*. WS collations with the same name as SQL Server aren't currently supported by Babelfish.

• **Variation-selector sensitive (VSS) collations** – Variation-selector sensitive (VSS) collations distinguish between ideographic variation selectors in Japanese collations Japanese_Bushu_Kakusu_140 and Japanese_XJIS_140. A variation sequence is made up of a base character plus an additional variation selector. If you don't select the _VSS option, the variation selector isn't considered in the comparison.

VSS collations aren't currently supported by Babelfish.

• **BIN and BIN2 collations** – A BIN2 collation sorts characters according to code point order. The byte-by-byte binary order of UTF-8 preserves Unicode code point order, so this is also likely to be the best-performing collation. If Unicode code point order works for an application, consider using a BIN2 collation. However, using a BIN2 collation can result in data being displayed on the client in an order that is culturally unexpected. New mappings to lowercase characters are added to Unicode as time progresses, so the LOWER function might perform differently on different versions of ICU. This is a special case of the more general collation versioning problem rather than as something specific to the BIN2 collation.

Babelfish provides the BBF_Latin1_General_BIN2 collation with the Babelfish distribution to collate in Unicode code point order. In a BIN collation only the first character is sorted as a wchar. Remaining characters are sorted byte-by-byte, effectively in code point order according to its encoding. This approach doesn't follow Unicode collation rules and isn't supported by Babelfish.

• **Non-deterministic collations and CHARINDEX limitation** – For Babelfish releases older than version 2.1.0, you can't use CHARINDEX with non-deterministic collations. By default, Babelfish uses a case-insensitive (non-deterministic) collation. Using CHARINDEX for older versions of Babelfish raises the following runtime error:

  nondeterministic collations are not supported for substring searches
**Note**

This limitation and workaround apply to Babelfish version 1.x only (Aurora PostgreSQL 13.x versions). Babelfish 2.1.0 and higher releases don't have this issue.

You can work around this issue in one of the following ways:

- Explicitly convert the expression to a case-sensitive collation and case-fold both arguments by applying LOWER or UPPER. For example, SELECT charindex('x', a) FROM t1 would become the following:

  ```sql
  SELECT charindex(LOWER('x'), LOWER(a COLLATE sql_latin1_general_cp1_cs_as)) FROM t1
  ```

- Create a SQL function `f_charindex`, and replace CHARINDEX calls with calls to the following function:

  ```sql
  CREATE function f_charindex(@s1 varchar(max), @s2 varchar(max)) RETURNS int AS BEGIN declare @i int = 1 WHILE len(@s2) >= len(@s1) BEGIN if LOWER(@s1) = LOWER(substring(@s2,1,len(@s1))) return @i set @i += 1 set @s2 = substring(@s2,2,999999999) END return 0 END go
  ```
Managing Babelfish error handling with escape hatches

Babelfish mimics SQL behavior for control flow and transaction state whenever possible. When Babelfish encounters an error, it returns an error code similar to the SQL Server error code. If Babelfish can't map the error to a SQL Server code, it returns a fixed error code (33557097) and takes specific actions based on the type of error, as follows:

- For compile time errors, Babelfish rolls back the transaction.
- For runtime errors, Babelfish ends the batch and rolls back the transaction.
- For protocol error between client and server, the transaction isn't rolled back.

If an error code can't be mapped to an equivalent code and the code for a similar error is available, the error code is mapped to the alternative code. For example, the behaviors that cause SQL Server codes 8143 and 8144 are both mapped to 8143.

Errors that can't be mapped don't respect a TRY... CATCH construct.

You can use @@ERROR to return a SQL Server error code, or the @@PGERROR function to return a PostgreSQL error code. You can also use the fn_mapped_system_error_list function to return a list of mapped error codes. For information about PostgreSQL error codes, see the PostgreSQL website.

Modifying Babelfish escape hatch settings

To handle statements that might fail, Babelfish defines certain options called escape hatches. An escape hatch is an option that specifies Babelfish behavior when it encounters an unsupported feature or syntax.

You can use the sp_babelfish_configure stored procedure to control the settings of an escape hatch. Use the script to set the escape hatch to ignore or strict. If it's set to strict, Babelfish returns an error that you need to correct before continuing.

To apply changes to the current session and on the cluster level, include the server keyword.

The usage is as follows:

- To list all escape hatches and their status, plus usage information, run sp_babelfish_configure.
• To list the named escape hatches and their values, for the current session or cluster-wide, run the command `sp_babelfish_configure 'hatch_name'` where `hatch_name` is the identifier of one or more escape hatches. `hatch_name` can use SQL wildcards, such as '%'.

• To set one or more escape hatches to the value specified, run `sp_babelfish_configure ['hatch_name'] [, 'strict'|'ignore' [, 'server']]]. To make the settings permanent on a cluster-wide level, include the `server` keyword, such as shown in the following:

```
EXECUTE sp_babelfish_configure 'escape_hatch_unique_constraint', 'ignore', 'server'
```

To set them for the current session only, don't use `server`.

• To reset all escape hatches to their default values, run `sp_babelfish_configure 'default'` (Babelfish 1.2.0 and higher).

The string identifying the hatch (or hatches) can include SQL wildcards. For example, the following sets all syntax escape hatches to `ignore` for the Aurora PostgreSQL cluster.

```
EXECUTE sp_babelfish_configure '%', 'ignore', 'server'
```

In the following table you can find descriptions and default values for the Babelfish predefined escape hatches.

<table>
<thead>
<tr>
<th>Escape hatch</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>escape_hatch_checkpoint</code></td>
<td>Allows the use of CHECKPOINT statement in the procedural code, but the CHECKPOINT statement is currently not implemented.</td>
<td>ignore</td>
</tr>
<tr>
<td><code>escape_hatch_constraint_name_for_default</code></td>
<td>Controls Babelfish behavior related to default constraint names.</td>
<td>ignore</td>
</tr>
<tr>
<td><code>escape_hatch_database_misc_options</code></td>
<td>Controls Babelfish behavior related to the following options on CREATE or ALTER DATABASE:</td>
<td>ignore</td>
</tr>
<tr>
<td>Escape hatch</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>escape_hatch_for_replication</td>
<td>Controls Babelfish behavior related to the [NOT] FOR REPLICAATION clause when creating or altering a table.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_fulltext</td>
<td>Controls Babelfish behavior related to FULLTEXT features, such as DEFAULT_FULLTEXT_LANGUAGE in CREATE/ALTER DATABASE, CREATE FULLTEXT INDEX, or sp_fulltext_database.</td>
<td>ignore</td>
</tr>
<tr>
<td>escape_hatch_ignore_dup_key</td>
<td>Controls Babelfish behavior related to CREATE/ALTER TABLE and CREATE INDEX. When IGNORE_DUP_KEY=ON, raises an error when set to strict (the default) or ignores the error when set to ignore (Babelfish version 1.2.0 and higher).</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_index_clustering</td>
<td>Controls Babelfish behavior related to the CLUSTERED or NONCLUSTERED keywords for indexes and PRIMARY KEY or UNIQUE constraints. When CLUSTERED is ignored, the index or constraint is still created as if NONCLUSTERED was specified.</td>
<td>ignore</td>
</tr>
<tr>
<td>Escape hatch</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------</td>
</tr>
<tr>
<td>escape_hatch_index_columnstore</td>
<td>Controls Babelfish behavior related to the COLUMNSTORE clause. If you specify ignore, Babelfish creates a regular B-tree index.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_join_hints</td>
<td>Controls the behavior of keywords in a JOIN operator: LOOP, HASH, MERGE, REMOTE, REDUCE, REDISTRIBUTE, REPLICATE.</td>
<td>ignore</td>
</tr>
<tr>
<td>escape_hatch_language_non_english</td>
<td>Controls Babelfish behavior related to languages other than English for onscreen messages. Babelfish currently supports only us_english for onscreen messages. SET LANGUAGE might use a variable containing the language name, so the actual language being set can only be detected at run time.</td>
<td>strict</td>
</tr>
<tr>
<td>escape_hatch_login_hashed_password</td>
<td>When ignored, suppresses the error for the HASHED keyword for CREATE LOGIN and ALTER LOGIN.</td>
<td>strict</td>
</tr>
<tr>
<td>Escape hatch</td>
<td>Description</td>

</tbody>
</table>
Creating a Babelfish for Aurora PostgreSQL DB cluster

Babelfish for Aurora PostgreSQL is supported on Aurora PostgreSQL version 13.4 and higher.

You can use the AWS Management Console or the AWS CLI to create an Aurora PostgreSQL cluster with Babelfish.

**Note**

In an Aurora PostgreSQL cluster, the babelfish_db database name is reserved for Babelfish. Creating your own "babelfish_db" database on a Babelfish for Aurora PostgreSQL prevents Aurora from successfully provisioning Babelfish.

### Console

**To create a cluster with Babelfish running with the AWS Management Console**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/), and choose **Create database**.

2. For **Choose a database creation method**, do one of the following:
   - To specify detailed engine options, choose **Standard create**.
To use preconfigured options that support best practices for an Aurora cluster, choose **Easy create**.

3. For **Engine type**, choose **Aurora (PostgreSQL Compatible)**.

4. Choose **Show filters**, and then choose **Show versions that support the Babelfish for PostgreSQL feature** to list the engine types that support Babelfish. Babelfish is currently supported on Aurora PostgreSQL 13.4 and higher versions.

5. For **Available versions**, choose an Aurora PostgreSQL version. To get the latest Babelfish features, choose the highest Aurora PostgreSQL major version.

6. For **Templates**, choose the template that matches your use case.

7. For **DB cluster identifier**, enter a name that you can easily find later in the DB cluster list.

8. For **Master username**, enter an administrator user name. The default value for Aurora PostgreSQL is `postgres`. You can accept the default or choose a different name. For example, to follow the naming convention used on your SQL Server databases, you can enter `sa` (system administrator) for the Master username.

   If you don't create a user named `sa` at this time, you can create one later with your choice of client. After creating the user, use the `ALTER SERVER ROLE` command to add it to the `sysadmin` group (role) for the cluster.

   **Warning**

   Master username must always use lowercase characters failing which the DB cluster can't connect to Babelfish via the TDS port.
9. For **Master password**, create a strong password and confirm the password.

10. For the options that follow, until the **Babelfish settings** section, specify your DB cluster settings. For information about each setting, see [Settings for Aurora DB clusters](#).

11. To make Babelfish functionality available, select the **Turn on Babelfish** box.

   **Babelfish settings - new**
   
   - [ ] Turn on Babelfish
     
     Makes possible faster, cheaper, and lower-risk migrations from Microsoft SQL Server to Aurora PostgreSQL.

   **Babelfish default configurations**
   
   By default, RDS creates a DB cluster parameter group for you to store the Babelfish settings. Babelfish uses default values if you don't modify these settings in the "Additional configuration" section below.

12. For **DB cluster parameter group**, do one of the following:

   - Choose **Create new** to create a new parameter group with Babelfish turned on.
   
   - Choose **Choose existing** to use an existing parameter group. If you use an existing group, make sure to modify the group before creating the cluster and add values for Babelfish parameters. For information about Babelfish parameters, see [DB cluster parameter group settings for Babelfish](#).

   If you use an existing group, provide the group name in the box that follows.

13. For **Database migration mode**, choose one of the following:

   - **Single database** to migrate a single SQL Server database.

     In some cases, you might migrate multiple user databases together, with your end goal a complete migration to native Aurora PostgreSQL without Babelfish. If the final applications require consolidated schemas (a single dbo schema), make sure to first consolidate your SQL Server databases into a single SQL server database. Then migrate to Babelfish using **Single database** mode.

   - **Multiple databases** to migrate multiple SQL Server databases (originating from a single SQL Server installation). Multiple database mode doesn't consolidate multiple databases that don't originate from a single SQL Server installation. For information about migrating multiple databases, see [Using Babelfish with a single database or multiple databases](#).
Note

From Aurora PostgreSQL 16 version, Multiple databases is chosen by default as the Database migration mode.

Additional configuration

Database options

DB cluster parameter group

Choose a compatible DB Cluster parameter group to turn on Babelfish feature for your database.

- Create new
  
  Creates a custom DB cluster parameter group with Babelfish parameters turned on.

- Choose existing
  
  Choose an existing DB cluster parameter group with Babelfish parameters turned on.

New custom DB cluster parameter group name

custom-aurora-postgresql13-babelfish-compat-1

Babelfish configuration

Database migration mode

- Single database
  
  Use for migrating a single SQL Server database. Migrated schema names are identical between TDS connections and PostgreSQL connections.

- Multiple databases
  
  Use for migrating multiple SQL Server databases together. Migrated database and schema names are mapped to similar schema names in PostgreSQL.

14. For Default collation locale, enter your server locale. The default is en-US. For detailed information about collations, see Collations supported by Babelfish.

15. For Collation name field, enter your default collation. The default is sql_latin1_general_cp1_ci_as. For detailed information, see Collations supported by Babelfish.

16. For Babelfish TDS port, enter the default port 1433. Currently, Babelfish only supports port 1433 for your DB cluster.
17. For **DB parameter group**, choose a parameter group or have Aurora create a new group for you with default settings.

18. For **Failover priority**, choose a failover priority for the instance. If you don't choose a value, the default is `tier-1`. This priority determines the order in which replicas are promoted when recovering from a primary instance failure. For more information, see [Fault tolerance for an Aurora DB cluster](#).

19. For **Backup retention period**, choose the length of time (1–35 days) that Aurora retains backup copies of the database. You can use backup copies for point-in-time restores (PITR) of your database down to the second. The default retention period is seven days.

<table>
<thead>
<tr>
<th>Default collation locale</th>
<th>en-US</th>
</tr>
</thead>
<tbody>
<tr>
<td>Collation name</td>
<td>sql_latin1_general_cp1_ci_as</td>
</tr>
<tr>
<td>Babelfish TDS port</td>
<td>1433</td>
</tr>
<tr>
<td>DB parameter group</td>
<td>default.aurora-postgresql13</td>
</tr>
<tr>
<td>Option group</td>
<td>default:aurora-postgresql-13</td>
</tr>
<tr>
<td>Failover priority</td>
<td>No preference</td>
</tr>
</tbody>
</table>

**Backup**

| Backup retention period | 7 days |

Creating a Babelfish for Aurora PostgreSQL DB cluster
20. Choose **Copy tags to snapshots** to copy any DB instance tags to a DB snapshot when you create a snapshot.

21. Choose **Enable encryption** to turn on encryption at rest (Aurora storage encryption) for this DB cluster.

22. Choose **Enable Performance Insights** to turn on Amazon RDS Performance Insights.

23. Choose **Enable Enhanced monitoring** to start gathering metrics in real time for the operating system that your DB cluster runs on.

24. Choose **PostgreSQL log** to publish the log files to Amazon CloudWatch Logs.

25. Choose **Enable auto minor version upgrade** to automatically update your Aurora DB cluster when a minor version upgrade is available.

26. For **Maintenance window**, do the following:

   - To choose a time for Amazon RDS to make modifications or perform maintenance, choose **Select window**.
   - To perform Amazon RDS maintenance at an unscheduled time, choose **No preference**.

27. Select the **Enable deletion protection** box to protect your database from being deleted by accident.

   If you turn on this feature, you can't directly delete the database. Instead, you need to modify the database cluster and turn off this feature before deleting the database.
28. Choose **Create database**.

You can find your new database set up for Babelfish in the **Databases** listing. The **Status** column displays **Available** when the deployment is complete.

![](image.png)

**AWS CLI**

When you create an Babelfish for Aurora PostgreSQL; using the AWS CLI, you need to pass the command the name of the DB cluster parameter group to use for the cluster. For more information, see [DB cluster prerequisites](#).

Before you can use the AWS CLI to create an Aurora PostgreSQL cluster with Babelfish, do the following:

- Choose your endpoint URL from the list of services at [Amazon Aurora endpoints and quotas](#).
- Create a parameter group for the cluster. For more information about parameter groups, see [Working with parameter groups](#).
- Modify the parameter group, adding the parameter that turns on Babelfish.

**To create an Aurora PostgreSQL DB cluster with Babelfish using the AWS CLI**

The examples that follow use the default Master username, *postgres*. Replace as needed with the username that you created for your DB cluster, such as *sa* or whatever username you chose if you didn't accept the default.

1. Create a parameter group.

   For Linux, macOS, or Unix:

   ```bash
   aws rds create-db-cluster-parameter-group \
   ```
For Windows:

```bash
aws rds create-db-cluster-parameter-group ^
   --endpoint-url endpoint-url ^
   --db-cluster-parameter-group-name parameter-group ^
   --db-parameter-group-family aurora-postgresql14 ^
   --description "description"
```

2. Modify your parameter group to turn on Babelfish.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster-parameter-group \
   --endpoint-url endpoint-url \
   --db-cluster-parameter-group-name parameter-group \
   --parameters "ParameterName=rds.babelfish_status,ParameterValue=on,ApplyMethod=pending-reboot"
```

For Windows:

```bash
aws rds modify-db-cluster-parameter-group ^
   --endpoint-url endpoint-url ^
   --db-cluster-parameter-group-name parameter-group ^
   --parameters "ParameterName=rds.babelfish_status,ParameterValue=on,ApplyMethod=pending-reboot"
```

3. Identify your DB subnet group and the virtual private cloud (VPC) security group ID for your new DB cluster, and then call the `create-db-cluster` command.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster \
   --db-cluster-identifier cluster-name\n   --master-username postgres \n   --manage-master-user-password \n   --engine aurora-postgresql \n   --engine-version 14.3 \
```
--vpc-security-group-ids security-group \
--db-subnet-group-name subnet-group-name \
--db-cluster-parameter-group-name parameter-group

For Windows:

```bash
aws rds create-db-cluster ^
--db-cluster-identifier cluster-name ^
--master-username postgres ^
--manage-master-user-password ^
--engine aurora-postgresql ^
--engine-version 14.3 ^
--vpc-security-group-ids security-group ^
--db-subnet-group-name subnet-group ^
--db-cluster-parameter-group-name parameter-group
```

This example specifies the `--manage-master-user-password` option to generate the master user password and manage it in Secrets Manager. For more information, see Password management with Amazon Aurora and AWS Secrets Manager. Alternatively, you can use the `--master-password` option to specify and manage the password yourself.

4. **Explicitly create the primary instance for your DB cluster.** Use the name of the cluster that you created in step 3 for the `--db-cluster-identifier` argument when you call the `create-db-instance` command, as shown following.

For Linux, macOS, or Unix:

```bash
aws rds create-db-instance \
--db-instance-identifier instance-name \
--db-instance-class db.r6g \
--db-subnet-group-name subnet-group \
--db-cluster-identifier cluster-name \
--engine aurora-postgresql
```

For Windows:

```bash
aws rds create-db-instance ^
--db-instance-identifier instance-name ^
--db-instance-class db.r6g ^
--db-subnet-group-name subnet-group ^
--db-cluster-identifier cluster-name ^
```
--engine aurora-postgresql
Migrating a SQL Server database to Babelfish for Aurora PostgreSQL

You can use Babelfish for Aurora PostgreSQL to migrate an SQL Server database to an Amazon Aurora PostgreSQL DB cluster. Before migrating, review Using Babelfish with a single database or multiple databases.

**Topics**

- Overview of the migration process
- Evaluating and handling differences between SQL Server and Babelfish
- Import/export tools for migrating from SQL Server to Babelfish

**Overview of the migration process**

The following summary lists the steps required to successfully migrate your SQL Server application and make it work with Babelfish. For information about the tools you can use for the export and import processes and for more detail, see Import/export tools for migrating from SQL Server to Babelfish.

1. Create a new Aurora PostgreSQL DB cluster with Babelfish turned on. To learn how, see Creating a Babelfish for Aurora PostgreSQL DB cluster.

   To import the various SQL artifacts exported from your SQL Server database, connect to the Babelfish cluster using a SQL Server tool such as `sqlcmd`. For more information, see Using a SQL Server client to connect to your DB cluster.

2. On the SQL Server database that you want to migrate, export the data definition language (DDL). The DDL is SQL code that describes database objects that contain user data (such as tables, indexes, and views) and user-written database code (such as stored procedures, user-defined functions, and triggers).

   For more information, see Using SQL Server Management Studio (SSMS) to migrate to Babelfish.

3. Run an assessment tool to evaluate the scope of any changes that you might need to make so that Babelfish can effectively support the application running on SQL Server. For more information, see Evaluating and handling differences between SQL Server and Babelfish.

4. To load the data, we recommend using the AWS DMS with either Babelfish or Aurora PostgreSQL as a target endpoint based on your migration requirements. Make sure to modify the columns with the recommended Babelfish data types. To do so, see the Prerequisites to using Babelfish as a target for AWS DMS.
5. On your new Babelfish DB cluster, run the DDL within your specified T-SQL database to create only the schemas, user-defined data types, and tables with their primary key constraints.

6. Use AWS DMS to migrate your data from SQL Server to Babelfish tables. For continuous replication using SQL Server Change Data Capture or SQL Replication, use Aurora PostgreSQL instead of Babelfish as the endpoint. To do so, see the Using Babelfish for Aurora PostgreSQL as a target for AWS Database Migration Service.

7. When the data load completes, create all the remaining T-SQL objects that support the application on your Babelfish cluster.

8. Reconfigure your client application to connect to the Babelfish endpoint instead of your SQL Server database. For more information, see Connecting to a Babelfish DB cluster.

9. Modify your application as needed and retest. For more information, see Differences between Babelfish for Aurora PostgreSQL and SQL Server.

You still need to assess your client-side SQL queries. The schemas generated from your SQL Server instance convert only the server-side SQL code. We recommend that you take the following steps:

- Capture client-side queries by using the SQL Server Profiler with the TSQl_Replay predefined template. This template captures T-SQL statement information that you can then replay for iterative tuning and testing. You can start the profiler within SQL Server Management Studio from the Tools menu. Choose SQL Server Profiler to open the profiler and choose the TSQl_Replay template.

  To use for your Babelfish migration, start a trace and then run your application using your functional tests. The profiler captures the T-SQL statements. When you finish testing, stop the trace. Save the result to an XML file with your client-side queries (File > Save as > Trace XML File for Replay).

  For more information, see SQL Server Profiler in the Microsoft documentation. For more information about the TSQl_Replay template, see SQL Server Profiler Templates.

- For applications with complex client-side SQL queries, we recommend that you use Babelfish Compass to analyze these queries for Babelfish compatibility. If the analysis indicates that the client-side SQL statements contain unsupported SQL features, review the SQL aspects in the client application and modify as needed.

- You can also capture the SQL queries as extended events (.xel format). To do so, use the SSMS XEvent Profiler. After generating the .xel file, extract the SQL statements into .xml files that
Compass can then process. For more information, see Use the SSMS XEvent Profiler in the Microsoft documentation.

When you're satisfied with all testing, analysis, and any modifications needed for your migrated application, you can start using your Babelfish database for production. To do so, stop the original database and redirect live client applications to use the Babelfish TDS port.

Evaluating and handling differences between SQL Server and Babelfish

For best results, we recommend that you evaluate the generated DDL/DML and the client query code before actually migrating your SQL Server database application to Babelfish. Depending on the version of Babelfish and the specific features of SQL Server that your application implements, you might need to refactor your application or use alternatives for functionality that aren't fully supported yet in Babelfish.

• To assess your SQL Server application code, use Babelfish Compass on the generated DDL to determine how much T-SQL code is supported by Babelfish. Identify T-SQL code that might need modifications before running on Babelfish. For more information about this tool, see Babelfish Compass tool on GitHub.

Note

Babelfish Compass is an open-source tool. Report any issues with Babelfish Compass through GitHub instead of through AWS Support.

You can use Generate Script Wizard with SQL Server Management Studio (SSMS) to generate the SQL file that is assessed by Babelfish Compass or AWS Schema Conversion Tool CLI. We recommend the following steps to streamline the assessment.

1. On the Choose Objects page, choose Script entire database and all database objects.
2. For the **Set Scripting Options**, choose **Save as script file** as a **Single script file**.
3. Choose **Advanced** to change the default scripting options to identify features that normally are set to false for a full assessment:

- Script Change Tracking to True
- Script Full-Text Indexes to True
- Script Triggers to True
- Script Logins to True
- Script Owner to True
- Script Object-Level Permissions to True
- Script Collations to True
4. Perform the remaining steps in the wizard to generate the file.

**Import/export tools for migrating from SQL Server to Babelfish**

We recommend that you use AWS DMS as the primary tool for migrating from SQL Server to Babelfish. However, Babelfish supports several other ways to migrate data using SQL Server tools that includes the following.

- **SQL Server Integration Services (SSIS) for all versions of Babelfish.** For more information, see [Migrate from SQL Server to Aurora PostgreSQL using SSIS and Babelfish](#).
- **Use the SSMS Import/Export Wizard for Babelfish versions 2.1.0 and later.** This tool is available through the SSMS, but it's also available as a standalone tool. For more information, see [Welcome to SQL Server Import and Export Wizard](#) in the Microsoft documentation.
- **The Microsoft bulk data copy program (bcp) utility lets you copy data from a Microsoft SQL Server instance to a data file in the format you specify.** For more information, see [bcp Utility](#) in the Microsoft documentation. Babelfish now supports the data migration using the BCP client and the bcp utility now supports `-E` flag (for identity columns) and `-b` flag (for batching inserts). Certain bcp options aren't supported, including `-C`, `-T`, `-G`, `-K`, `-R`, `-V`, and `-h.
Using SQL Server Management Studio (SSMS) to migrate to Babelfish

We recommend generating separate files for each of the specific object types. You can use the Generate Scripts wizard in SSMS for each set of DDL statements first, and then modify the objects as a group to fix any issues found during the assessment.

Perform these steps to migrate the data using AWS DMS or other data migration methods. Run these create script types first for a better and faster approach to load the data on the Babelfish tables in Aurora PostgreSQL.

1. Run CREATE SCHEMA statements.
2. Run CREATE TYPE statements to create user-defined data types.
3. Run basic CREATE TABLE statements with the primary keys or unique constraints.

Perform the data load using the recommended import/export tool. Run the modified scripts for the following steps to add the remaining database objects. You need the create table statements to run these scripts for the constraints, triggers, and indexes. After the scripts generate, delete the create table statements.

1. Run ALTER TABLE statements for the check constraints, foreign key constraints, default constraints.
2. Run CREATE TRIGGER statements.
3. Run CREATE INDEX statements.
4. Run CREATE VIEW statements.
5. Run CREATE STORED PROCEDURE statements.

To generate scripts for each object type

Use the following steps to create the basic create table statements using the Generate Scripts wizard in SSMS. Follow the same steps to generate scripts for the different object types.

1. Connect to your existing SQL Server instance.
2. Open the context (right-click) menu for a database name.
3. Choose Tasks, and then choose Generate Scripts....
4. On the Choose Objects pane, choose Select specific database objects. Choose Tables, select all tables. Choose Next to continue.
5. On the **Set Scripting Options** page, choose **Advanced** to open the **Options** settings. To generate the basic create table statements, change the following default values:

- Script Defaults to False.
- Script Extended Properties to False. Babelfish does not support extended properties.
- Script Check Constraints to False. Script Foreign Keys to False.
6. Choose **OK**.

7. On the **Set Scripting Options** page, choose **Save as script file** and then choose the **Single script file** option. Enter your **File name**.
8. Choose **Next** to view the **Summary wizard** page.

9. Choose **Next** to start the script generation.

You can continue to generate scripts for the other object types in the wizard. Instead of choosing **Finish** after the file is saved, choose the **Previous** button three times to go back to the **Choose Objects** page. Then repeat the steps in the wizard to generate scripts for the other object types.
Database authentication with Babelfish for Aurora PostgreSQL

Babelfish for Aurora PostgreSQL supports two ways to authenticate database users. Password authentication is available by default for all Babelfish DB clusters. You can also add Kerberos authentication for the same DB cluster.

Topics

• Password authentication with Babelfish
• Kerberos authentication with Babelfish

Password authentication with Babelfish

Babelfish for Aurora PostgreSQL supports password authentication. Passwords are stored in encrypted form on disk. For more information about authentication on an Aurora PostgreSQL cluster, see Security with Amazon Aurora PostgreSQL.

You might be prompted for credentials each time you connect to Babelfish. Any user migrated to or created on Aurora PostgreSQL can use the same credentials on both the SQL Server port and the PostgreSQL port. Babelfish doesn't enforce password policies, but we recommend that you do the following:

• Require a complex password that's at least eight (8) characters long.
• Enforce a password expiration policy.

To review a complete list of database users, use the command SELECT * FROM pg_user;.
Kerberos authentication with Babelfish

Babelfish for Aurora PostgreSQL 15.2 version supports authentication to your DB cluster using Kerberos. This method allows you to use Microsoft Windows Authentication to authenticate users when they connect to your Babelfish database. To do so, you must first configure your DB cluster to use AWS Directory Service for Microsoft Active Directory for Kerberos authentication. For more information, see What is AWS Directory Service? in the AWS Directory Service Administration Guide.

Setting up Kerberos Authentication

Babelfish for Aurora PostgreSQL DB cluster can connect using two different ports, but Kerberos authentication setup is a one-time process. Therefore, you must first set up Kerberos authentication for your DB cluster. For more information, see Setting up Kerberos authentication. After completing the setup, ensure that you can connect with a PostgreSQL client using Kerberos. For more information, see Connecting with Kerberos Authentication.

Login and user provisioning in Babelfish

Windows logins created from the Tabular Data Stream (TDS) port can be used either with the TDS port or the PostgreSQL port. First, the login that can use Kerberos for authentication must be provisioned from the TDS port before it is used by the T-SQL users and applications to connect to a Babelfish database. When creating Windows logins, administrators can provide the login using either the DNS domain name or the NetBIOS domain name. Typically, NetBIOS domain is the subdomain of the DNS domain name. For example, if the DNS domain name is CORP.EXAMPLE.COM, then the NetBIOS domain can be CORP. If the NetBIOS domain name format is provided for a login, a mapping must exist to the DNS domain name.

Managing NetBIOS domain name to DNS domain name mapping

To manage mappings between the NetBIOS domain name and DNS domain name, Babelfish provides system stored procedures to add, remove, and truncate mappings. Only a user with a sysadmin role can run these procedures.

To create mapping between NetBIOS and DNS domain name, use the Babelfish provided system stored procedure babelfish_add_domain_mapping_entry. Both arguments must have a valid value and are not NULL.
Example

EXEC babelfish_add_domain_mapping_entry 'netbios_domain_name',
'fully_qualified_domain_name'

The following example shows how to create the mapping between the NetBIOS name CORP and DNS domain name CORP.EXAMPLE.COM.

Example

EXEC babelfish_add_domain_mapping_entry 'corp', 'corp.example.com'

To delete an existing mapping entry, use the system stored procedure babelfish_remove_domain_mapping_entry.

Example

EXEC babelfish_remove_domain_mapping_entry 'netbios_domain_name'

The following example shows how to remove the mapping for the NetBIOS name CORP.

Example

EXEC babelfish_remove_domain_mapping_entry 'corp'

To remove all existing mapping entries, use the system stored procedure babelfish_truncate_domain_mapping_table:

Example

EXEC babelfish_truncate_domain_mapping_table

To view all mappings between NetBIOS and DNS domain name, use the following query.

Example

SELECT netbios_domain_name, fq_domain_name FROM babelfish_domain_mapping;

Managing Logins

Create logins
Connect to the DB through the TDS endpoint using a login that has the correct permissions. If there is no database user created for the login, then the login is mapped to guest user. If the guest user is not enabled, then the login attempt fails.

Create a Windows login using the following query. The FROM WINDOWS option allows authentication using Active Directory.

CREATE LOGIN login_name FROM WINDOWS [WITH DEFAULT_DATABASE=database]

Example

The following example shows creating a login for the Active Directory user [corp\test1] with a default database of db1.

CREATE LOGIN [corp\test1] FROM WINDOWS WITH DEFAULT_DATABASE=db1

This example assumes that there is a mapping between the NetBIOS domain CORP and the DNS domain name CORP.EXAMPLE.COM. If there is no mapping, then you must provide the DNS domain name [CORP.EXAMPLE.COM\test1].

Note

Logins based on Active Directory users, are limited to names of fewer than 21 characters.

Drop login

To drop a login, use the same syntax as for any login, as shown in the following example:

DROP LOGIN [DNS domain name\login]

Alter login

To alter a login, use the same syntax as for any login, as in the following example:

ALTER LOGIN [DNS domain name\login] { ENABLE|DISABLE|WITH DEFAULT_DATABASE=[master] }

The ALTER LOGIN command supports limited options for Windows logins, including the following:

- DISABLE – To disable a login. You can't use a disabled login for authentication.
• **ENABLE** – To enable a disabled login.
• **DEFAULT_DATABASE** – To change the default database of a login.

---

**Note**

All password management is performed through AWS Directory Service, so the ALTER LOGIN command doesn't allow database administrators to change or set passwords for Windows logins.

---

**Connecting to Babelfish for Aurora PostgreSQL with Kerberos authentication**

Typically, the database users who authenticate using Kerberos are doing so from their client machines. These machines are members of the Active Directory domain. They use Windows Authentication from their client applications to access the Babelfish for Aurora PostgreSQL server on the TDS port.

**Connecting to Babelfish for Aurora PostgreSQL on the PostgreSQL port with Kerberos authentication**

You can use logins created from the TDS port with either the TDS port or the PostgreSQL port. However, PostgreSQL uses case-sensitive comparisons by default for usernames. For Aurora PostgreSQL to interpret Kerberos usernames as case-insensitive, you must set the `krb_caseins_users` parameter as `true` in the custom Babelfish cluster parameter group. This parameter is set to `false` by default. For more information, see [Configuring for case-insensitive user names](#). In addition, you must specify the login username in the format `<login@DNS domain name>` from the PostgreSQL client applications. You can't use `<DNS domain name\login>` format.

**Frequently occurring errors**

You can configure forest trust relationships between your on-premises Microsoft Active Directory and the AWS Managed Microsoft AD. For more information, see [Create a trust relationship](#). Then, you must connect using a specialized domain specific endpoint instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint. If you don't use the correct domain specific endpoint, you might encounter the following error:

```
Error: “Authentication method "NTLMSSP" not supported (Microsoft SQL Server, Error: 514)"
```
This error occurs when the TDS client can't cache the service ticket for the supplied endpoint URL. For more information, see Connecting with Kerberos.
Connecting to a Babelfish DB cluster

To connect to Babelfish, you connect to the endpoint of the Aurora PostgreSQL cluster running Babelfish. Your client can use one of the following client drivers compliant with TDS version 7.1 through 7.4:

- Open Database Connectivity (ODBC)
- OLE DB Driver/MSOLEDBSQL
- Java Database Connectivity (JDBC) version 8.2.2 (mssql-jdbc-8.2.2) and higher
- Microsoft SqlClient Data Provider for SQL Server
- .NET Data Provider for SQL Server
- SQL Server Native Client 11.0 (deprecated)
- OLE DB Provider/SQLOLEDB (deprecated)

With Babelfish, you run the following:

- SQL Server tools, applications, and syntax on the TDS port, by default port 1433.
- PostgreSQL tools, applications, and syntax on the PostgreSQL port, by default port 5432.

To learn more about connecting to Aurora PostgreSQL in general, see Connecting to an Amazon Aurora PostgreSQL DB cluster.

Note

Third-party developer tools using the SQL Server OLEDB provider to access metadata aren't supported. We recommend you to use SQL Server JDBC, ODBC, or SQL Native client connections for these tools.

Topics

- Finding the writer endpoint and port number
- Creating C# or JDBC client connections to Babelfish
- Using a SQL Server client to connect to your DB cluster
- Using a PostgreSQL client to connect to your DB cluster
Finding the writer endpoint and port number

To connect to your Babelfish DB cluster, you use the endpoint associated with the DB cluster's writer (primary) instance. The instance must have a status of Available. It can take up to 20 minutes for the instances to be available after creating the Babelfish for Aurora PostgreSQL DB cluster.

To find your database endpoint

1. Open the console for Babelfish.
2. Choose Databases from the navigation pane.
3. Choose your Babelfish for Aurora PostgreSQL DB cluster from those listed to see its details.
4. On the Connectivity & security tab, note the available cluster Endpoints values. Use the cluster endpoint for the writer instance in your connection strings for any applications that perform database write or read operations.

For more information about Aurora DB cluster details, see Creating an Amazon Aurora DB cluster.
Amazon Aurora

User Guide for Aurora

Creating C# or JDBC client connections to Babelﬁsh
In the following you can ﬁnd some examples of using C# and JDBC classes to connect to an
Babelﬁsh for Aurora PostgreSQL.
Example : Using C# code to connect to a DB cluster
string dataSource = 'babelfishServer_11_24';
//Create connection
connectionString = @"Data Source=" + dataSource
+";Initial Catalog=your-DB-name"
+";User ID=user-id;Password=password";
SqlConnection cnn = new SqlConnection(connectionString);
cnn.Open();

Example : Using generic JDBC API classes and interfaces to connect to a DB cluster
String dbServer =
"database-babelfish.cluster-123abc456def.us-east-1-rds.amazonaws.com";
String connectionUrl = "jdbc:sqlserver://" + dbServer + ":1433;" +
"databaseName=your-DB-name;user=user-id;password=password";
// Load the SQL Server JDBC driver and establish the connection.
System.out.print("Connecting Babelfish Server ... ");
Connection cnn = DriverManager.getConnection(connectionUrl);

Example : Using SQL Server-speciﬁc JDBC classes and interfaces to connect to a DB cluster
// Create datasource.
SQLServerDataSource ds = new SQLServerDataSource();
ds.setUser("user-id");
ds.setPassword("password");
String babelfishServer =
"database-babelfish.cluster-123abc456def.us-east-1-rds.amazonaws.com";
ds.setServerName(babelfishServer);
ds.setPortNumber(1433);
ds.setDatabaseName("your-DB-name");
Connection con = ds.getConnection();

Connecting to a Babelﬁsh DB cluster

2124


Using a SQL Server client to connect to your DB cluster

You can use a SQL Server client to connect with Babelfish on the TDS port. As of Babelfish 2.1.0 and higher releases, you can use the SSMS Object Explorer or the SSMS Query Editor to connect to your Babelfish cluster.

Limitations

- In Babelfish 2.1.0 and older versions, using PARSE to check SQL syntax doesn't work as it should. Rather than checking the syntax without running the query, the PARSE command runs the query but doesn't display any results. Using the SMSS <Ctrl><F5> key combination to check syntax has the same anomalous behavior, that is, Babelfish unexpectedly runs the query without providing any output.

- Babelfish doesn't support MARS (Multiple Active Result Sets). Be sure that any client applications that you use to connect to Babelfish aren't set to use MARS.

- For Babelfish 1.3.0 and older versions, only the Query Editor is supported for SSMS. To use SSMS with Babelfish, be sure to open the Query Editor connection dialog in SSMS, and not the Object Explorer. If the Object Explorer dialog does open, cancel the dialog and re-open the Query Editor. In the following image, you can find the menu options to choose when connecting to Babelfish 1.3.0 or older versions.

For more information about interoperability and behavioral differences between SQL Server and Babelfish, see Differences between Babelfish for Aurora PostgreSQL and SQL Server.

Using sqlcmd to connect to the DB cluster

You can connect to and interact with an Aurora PostgreSQL DB cluster that supports Babelfish by only using version 19.1 and earlier SQL Server sqlcmd command line client. SSMS version 19.2 isn't supported to connect to a Babelfish cluster. Use the following command to connect.

```
sqlcmd -S endpoint,port -U login-id -P password -d your-DB-name
```

The options are as follows:
- S is the endpoint and (optional) TDS port of the DB cluster.
- U is the login name of the user.
- P is the password associated with the user.
- d is the name of your Babelfish database.

After connecting, you can use many of the same commands that you use with SQL Server. For some examples, see Getting information from the Babelfish system catalog.

Using SSMS to connect to the DB cluster

You can connect to an Aurora PostgreSQL DB cluster running Babelfish by using Microsoft SQL Server Management Studio (SSMS). SSMS includes a variety of tools, including the SQL Server Import and Export Wizard discussed in Migrating a SQL Server database to Babelfish for Aurora PostgreSQL. For more information about SSMS, see Download SQL Server Management Studio (SSMS) in the Microsoft documentation.

To connect to your Babelfish database with SSMS

1. Start SSMS.
2. Open the Connect to Server dialog box. To continue with the connection, do one of the following:
   - Choose New Query.
   - If the Query Editor is open, choose Query, Connection, Connect.
3. Provide the following information for your database:
   a. For Server type, choose Database Engine.
   b. For Server name, enter the DNS name. For example, your server name should look similar to the following.

   cluster-name.cluster-555555555555.aws-region.rds.amazonaws.com,1433

   c. For Authentication, choose SQL Server Authentication.
   d. For Login, enter the user name that you chose when you created your database.
   e. For Password, enter the password that you chose when you created your database.
4. (Optional) Choose **Options**, and then choose the **Connection Properties** tab.
5. (Optional) For **Connect to database**, specify the name of the migrated SQL Server database to connect to, and choose **Connect**.

If a message appears indicating that SSMS can't apply connection strings, choose **OK**.

If you are having trouble connecting to Babelfish, see **Connection failure**.

For more information about SQL Server connection issues, see **Troubleshooting connections to your SQL Server DB instance** in the *Amazon RDS User Guide*. 
Using a PostgreSQL client to connect to your DB cluster

You can use a PostgreSQL client to connect to Babelfish on the PostgreSQL port.

Using psql to connect to the DB cluster

You can download the PostgreSQL client from the PostgreSQL website. Follow the instructions specific to your operating system version to install psql.

You can query an Aurora PostgreSQL DB cluster that supports Babelfish with the psql command line client. When connecting, use the PostgreSQL port (by default, port 5432). Typically, you don't need to specify the port number unless you changed it from the default. Use the following command to connect to Babelfish from the psql client:

```
psql -h bfish-db.cluster-123456789012.aws-region.rds.amazonaws.com
-p 5432 -U postgres -d babelfish_db
```

The parameters are as follows:

- `-h` – The host name of the DB cluster (cluster endpoint) that you want to access.
- `-p` – The PostgreSQL port number used to connect to your DB instance.
- `-d` – The database that you want to connect to. The default is babelfish_db.
- `-U` – The database user account that you want to access. (The example shows the default master username.)

When you run a SQL command on the psql client, you end the command with a semicolon. For example, the following SQL command queries the pg_tables system view to return information about each table in the database.

```
SELECT * FROM pg_tables;
```

The psql client also has a set of built-in metacommands. A metacommand is a shortcut that adjusts formatting or provides a shortcut that returns meta-data in an easy-to-use format. For example, the following metacommand returns similar information to the previous SQL command:

```
\d
```

Metacommands don't need to be terminated with a semicolon (;).
To exit the psql client, enter \q.

For more information about using the psql client to query an Aurora PostgreSQL cluster, see the PostgreSQL documentation.

Using pgAdmin to connect to the DB cluster

You can use the pgAdmin client to access your data in native PostgreSQL dialect.

To connect to the cluster with the pgAdmin client

1. Download and install the pgAdmin client from the pgAdmin website.
2. Open the client and authenticate with pgAdmin.
3. Open the context (right-click) menu for Servers, and then choose Create, Server.

   ![Create - Server dialog box](image)

4. Enter information in the Create - Server dialog box.

   On the Connection tab, add the Aurora PostgreSQL cluster address for Host and the PostgreSQL port number (by default, 5432) for Port. Provide authentication details, and choose Save.
After connecting, you can use pgAdmin functionality to monitor and manage your Aurora PostgreSQL cluster on the PostgreSQL port.
To learn more, see the pgAdmin web page.
Working with Babelfish

Following, you can find usage information for Babelfish, including some of the differences between working with Babelfish and SQL Server, and between Babelfish and PostgreSQL databases.

Topics

- Getting information from the Babelfish system catalog
- Differences between Babelfish for Aurora PostgreSQL and SQL Server
- Using Babelfish features with limited implementation
- Improving Babelfish query performance
- Using Aurora PostgreSQL extensions with Babelfish
- Babelfish supports linked servers
- Using Full Text Search in Babelfish
- Babelfish supports Geospatial data types

Getting information from the Babelfish system catalog

You can obtain information about the database objects that are stored in your Babelfish cluster by querying many of the same system views as used in SQL Server. Each new release of Babelfish adds support for more system views. For a list of available views currently available, see the SQL Server system catalog views table.

These system views provide information from the system catalog (sys.schemas). In the case of Babelfish, these views contain both SQL Server and PostgreSQL system schemas. To query Babelfish for system catalog information, you can use the TDS port or the PostgreSQL port, as shown in the following examples.

- Query the T-SQL port using sqlcmd or another SQL Server client.

```
1> SELECT * FROM sys.schemas
2> GO
```

This query returns SQL Server and Aurora PostgreSQL system schemas, as shown in the following.
Query the PostgreSQL port using psql or pgAdmin. This example uses the psql list schemas metacommand (\dn):

```
babelfish_db=> \dn
```

The query returns the same result set as that returned by sqlcmd on the T-SQL port.

SQL Server system catalogs available in Babelfish

In the following table you can find the SQL Server views currently implemented in Babelfish. For more information about the system catalogs in SQL Server, see System Catalog Views (Transact-SQL) in Microsoft documentation.

<table>
<thead>
<tr>
<th>View name</th>

</table>
**View name** | **Description or Babelfish limitation (if any)**
---|---
`sys.xml_schema_collections` | For information, see [sys.xml_schema_collections](#) in Microsoft Transact-SQL documentation.

PostgreSQL implements system catalogs that are similar to the SQL Server object catalog views. For a complete list of system catalogs, see [System Catalogs](#) in the PostgreSQL documentation.

**DDL exports supported by Babelfish**

From Babelfish 2.4.0 and 3.1.0 versions, Babelfish supports DDL exports using various tools. For example, you can use this functionality from SQL Server Management Studio (SSMS) to generate the data definition scripts for various objects in a Babelfish for Aurora PostgreSQL database. You can then use the generated DDL commands in this script to create the same objects in another Babelfish for Aurora PostgreSQL or SQL Server database.

Babelfish supports DDL exports for the following objects in the specified versions.

<table>
<thead>
<tr>
<th>List of objects</th>

<td>Yes</td>
</tr>
</tbody>
</table>
### Limitations with the exported DDLs

- **Use escape hatches before recreating the objects with the exported DDLs** – Babelfish doesn’t support all the commands in the exported DDL script. Use escape hatches to avoid errors caused when recreating the objects from the DDL commands in Babelfish. For more information on escape hatches, see [Managing Babelfish error handling with escape hatches](#).

- **Objects containing CHECK constraints with explicit COLLATE clauses** – The scripts with these objects generated from a SQL Server database have different but equivalent collations as in the Babelfish database. For example, a few collations, such as `sql_latin1_general_cp1_cs_as`, `sql_latin1_general_cp1251_cs_as`, and `latin1_general_cs_as` are generated as `latin1_general_cs_as`, which is the closest Windows collation.

### Differences between Babelfish for Aurora PostgreSQL and SQL Server

Babelfish is an evolving Aurora PostgreSQL feature, with new functionality added in each release since the initial offering in Aurora PostgreSQL 13.4. It’s designed to provide T-SQL semantics on top of PostgreSQL through the T-SQL dialect using the TDS port. Each new version of Babelfish adds features and functions that better align with T-SQL functionality and behavior, as shown in the [Supported functionality in Babelfish by version](#) table. For best results when working with Babelfish, we recommend that you understand the differences that currently exist between the T-SQL supported by SQL Server and Babelfish for the latest version. To learn more, see [T-SQL differences in Babelfish](#).
In addition to the differences between T-SQL supported by Babelfish and SQL Server, you might also need to consider interoperability issues between Babelfish and PostgreSQL in the context of the Aurora PostgreSQL DB cluster. As mentioned previously, Babelfish supports T-SQL semantics on top of PostgreSQL through the T-SQL dialect using the TDS port. At the same time, the Babelfish database can also be accessed through the standard PostgreSQL port with PostgreSQL SQL statements. If you're considering using both PostgreSQL and Babelfish functionality in a production deployment, you need to be aware of the potential interoperability issues between schema names, identifiers, permissions, transactional semantics, multiple result sets, default collations, and so on. In simple terms, when PostgreSQL statements or PostgreSQL access occur in the context of Babelfish, interference between PostgreSQL and Babelfish can occur and can potentially affecting syntax, semantics, and compatibility when new versions of Babelfish are released. For complete information and guidance about all the considerations, see the Guidance on Babelfish Interoperability in the Babelfish for PostgreSQL documentation.

**Note**

Before using both PostgreSQL native functionality and Babelfish functionality in the same application context, we strongly recommend that you consider the issues discussed in the Guidance on Babelfish Interoperability in the Babelfish for PostgreSQL documentation. These interoperability issues (Aurora PostgreSQL and Babelfish) are relevant only if you plan to use the PostgreSQL database instance in the same application context as Babelfish.

**Topics**

- Babelfish dump and restore
- T-SQL differences in Babelfish
- Transaction Isolation Levels in Babelfish

**Babelfish dump and restore**

Starting with version 4.0.0 and 3.4.0, Babelfish users can now utilize the dump and restore utilities to backup and restore their databases. For more information, see Babelfish dump and restore. This feature is built on top of PostgreSQL dump and restore utilities. For more information, see pg_dump and see pg_restore. In order to effectively use this feature in Babelfish, you need to use PostgreSQL-based tools that are specifically adapted for Babelfish. The backup and restore feature for Babelfish differs significantly from that of SQL Server. For more information on these
differences, see Dump and restore functionality differences : Babelfish and SQL Server. Babelfish for Aurora PostgreSQL provides additional capabilities for backing up and restoring Amazon Aurora PostgreSQL DB clusters. For more information, see Backing up and restoring an Amazon Aurora DB cluster.

T-SQL differences in Babelfish

Following, you can find a table of T-SQL functionality as supported in the current release of Babelfish with some notes about differences in the behavior from that of SQL Server.

For more information about support in various versions, see Supported functionality in Babelfish by version. For information about features that currently aren't supported, see Unsupported functionality in Babelfish.

Babelfish is available with Aurora PostgreSQL-Compatible Edition. For more information about Babelfish releases, see the Release Notes for Aurora PostgreSQL.

<table>
<thead>
<tr>
<th>Functionality or syntax</th>
<th>Description of behavior or difference</th>
</tr>
</thead>
<tbody>
<tr>
<td>\ (line continuation character)</td>
<td>The line continuation character (a backslash prior to a newline) for character and hexadecimal strings isn't currently supported. For character strings, the backslash-newline is interpreted as characters in the string. For hexadecimal strings, backslash-newline results in a syntax error.</td>
</tr>
<tr>
<td>@@version</td>
<td>The format of the value returned by @@version is slightly different from the value returned by SQL Server. Your code might not work correctly if it depends on the formatting of @@version.</td>
</tr>
<tr>
<td>Aggregate functions</td>
<td>Aggregate functions are partially supported (AVG, COUNT, COUNT_BIG, GROUPING, MAX, MIN, STRING_AGG, and SUM are supported). For a list of unsupported aggregate functions, see Functions that aren't supported.</td>

<tr>
<td>-------------------------</td>
<td>---------------------------------------</td>
</tr>
</tbody>
</table>
| CREATE, ALTER, DROP SERVER ROLE | ALTER SERVER ROLE is supported only for sysadmin. All other syntax is unsupported.  
The T-SQL user in Babelfish has an experience that is similar to SQL Server for the concepts of a login (server principal), a database, and a database user (database principal). |
| CREATE, ALTER LOGIN clauses are supported with limited syntax | The CREATE LOGIN... PASSWORD clause, ...DEFAULT_DATABASE clause, and ...DEFAULT_LANGUAGE clause are supported. The ALTER LOGIN... PASSWORD clause is supported, but ALTER LOGIN... OLD_PASSWORD clause isn't supported. Only a login that is a sysadmin member can modify a password. |
| CREATE DATABASE case-sensitive collation | Case-sensitive collations aren't supported with the CREATE DATABASE statement. |
| CREATE DATABASE keywords and clauses | Options except COLLATE and CONTAINMENT=NONE aren't supported. The COLLATE clause is accepted and is always set to the value of babelfishpg_tsql.server_collation_name. |
| CREATE SCHEMA... supporting clauses | You can use the CREATE SCHEMA command to create an empty schema. Use additional commands to create schema objects. |
| Database ID values are different on Babelfish | The master and tempdb databases won't be database IDs 1 and 2. |
| FORMAT date type function is supported with the following limitations | Single character meridian isn't supported.  
"yyy" format in SQL server returns 4 digits for year above 1000, but only 3 digits for others.  
"g" and "R" formats aren't supported  
"vi-VN" locale translation is slightly different. |
<table>
<thead>
<tr>
<th>Functionality or syntax</th>
<th>Description of behavior or difference</th>
</tr>
</thead>
</table>
| Identifiers exceeding 63 characters | PostgreSQL supports a maximum of 63 characters for identifiers. Babelfish converts identifiers longer than 63 characters to a name that includes a hash of the original name. For example, a table created as "AB(ABC12345678901234567890123456789012345678901234567890123456789012345678901234567890123456789012345678901234567890123456789012345678901234567890"
<p>| might be converted to &quot;ABC12345678901234567890123456789012345678901234567890123456789012345678901234567890123456789012345678901234567890123456789012345678901234567890&quot;. |
| IDENTITY columns support       | IDENTITY columns are supported for data types tinyint, smallint, int, bigint, numeric, and decimal.                                                                        |
|                                | SQL Server supports precision to 38 places for data types numeric and decimal in IDENTITY columns.                                                                        |
|                                | PostgreSQL supports precision to 19 places for data types numeric and decimal in IDENTITY columns.                                                                       |
| Indexes with IGNORE_DUP KEY    | Syntax that creates an index that includes IGNORE_DUP_KEY creates an index as if this property is omitted.                                                              |
| Indexes with more than 32 columns | An index can't include more than 32 columns. Included index columns count toward the maximum in PostgreSQL but not in SQL Server.                                      |
| Indexes (clustered)           | Clustered indexes are created as if NONCLUSTERED was specified.                                                                                                            |
| Index clauses                 | The following clauses are ignored: FILLFACTOR, ALLOW_PAGE_LOCKS, ALLOW_ROW_LOCKS, PAD_INDEX, STATISTICS_NORECOMPUTE, OPTIMIZE_FOR_SEQUENTIAL_KEY, SORT_IN_TEMPDB, DROP_EXISTING, ONLINE, COMPRESS_ON_DELAY, MAXDOP, and DATA_COMPRESSION |
| JSON support                  | Order of the name-value pairs isn't guaranteed. But the array type remains unaffected.                                                                               |</p>

Transaction Isolation Levels in Babelfish

Babelfish supports Transaction Isolation Levels READ UNCOMMITTED, READ COMMITTED and SNAPSHOT. Starting from Babelfish 3.4 version additional Isolation Levels REPEATABLE READ and SERIALIZABLE are supported. All the Isolation Levels in Babelfish are supported with the behavior of corresponding Isolation Levels in PostgreSQL. SQL Server and Babelfish use different underlying mechanisms for implementing Transaction Isolation Levels (blocking for concurrent access, locks held by transactions, error handling etc). And, there are some subtle differences in how concurrent access may work out for different workloads. For more information on this PostgreSQL behavior, see Transaction Isolation.

Topics

- Overview of the Transaction Isolation Levels
- Setting up the Transaction Isolation Levels
- Enabling or disabling Transaction Isolation Levels
- Differences between Babelfish and SQL Server Isolation Levels

Overview of the Transaction Isolation Levels

The original SQL Server Transaction Isolation Levels are based on pessimistic locking where only one copy of data exists and queries must lock resources such as rows before accessing them. Later, a variation of the Read Committed Isolation Level was introduced. This enables the use of row versions to provide better concurrency between readers and writers using non-blocking access. In addition, a new Isolation Level called Snapshot is available. It also uses row versions to provide better concurrency than REPEATABLE READ Isolation Level by avoiding shared locks on read data that are held till the end of the transaction.

Unlike SQL Server, all Transaction Isolation Levels in Babelfish are based on optimistic Locking (MVCC). Each transaction sees a snapshot of the data either at the beginning of the statement (READ COMMITTED) or at the beginning of the transaction (REPEATABLE READ, SERIALIZABLE), regardless of the current state of the underlying data. Therefore, the execution behavior of concurrent transactions in Babelfish might differ from SQL Server.

For example, consider a transaction with Isolation Level SERIALIZABLE that is initially blocked in SQL Server but succeeds later. It may end up failing in Babelfish due to a serialization conflict with a concurrent transaction that reads or updates the same rows. There could also be cases where executing multiple concurrent transactions yields a different final result in Babelfish as compared
to SQL Server. Applications that use Isolation Levels, should be thoroughly tested for concurrency scenarios.

</tbody>
</table>

⚠️ Note

The table hints are not currently supported and their behavior is controlled by using the Babelfish predefined escape hatch `escape_hatch_table_hints`.

### Setting up the Transaction Isolation Levels

Use the following command to set Transaction Isolation Level:

**Example**

```
SET TRANSACTION ISOLATION LEVEL { READ UNCOMMITTED | READ COMMITTED | REPEATABLE READ | SNAPSHOT | SERIALIZABLE }
```

### Enabling or disabling Transaction Isolation Levels

Transaction Isolation Levels REPEATABLE READ and SERIALIZABLE are disabled by default in Babelfish and you have to explicitly enable them by setting the `babelfishpg_tsql.isolation_level_serializable` or `babelfishpg_tsql.isolation_level_repeatable_read` escape hatch to `pg_isolation` using `sp_babelfish_configure`. For more information, see [Managing Babelfish error handling with escape hatches](#).

Below are examples for enabling or disabling the use of REPEATABLE READ and SERIALIZABLE in the current session by setting their respective escape hatches. Optionally include `server` parameter to set the escape hatch for the current session as well as for all subsequent new sessions.

To enable the use of SET TRANSACTION ISOLATION LEVEL REPEATABLE READ in current session only.
Example

```sql
EXECUTE sp_babelfish_configure 'isolation_level_repeatable_read', 'pg_isolation'
```

To enable the use of SET TRANSACTION ISOLATION LEVEL REPEATABLE READ in current session and all consequent new sessions.

Example

```sql
EXECUTE sp_babelfish_configure 'isolation_level_repeatable_read', 'pg_isolation', 'server'
```

To disable the use of SET TRANSACTION ISOLATION LEVEL REPEATABLE READ in current session and consequent new sessions.

Example

```sql
EXECUTE sp_babelfish_configure 'isolation_level_repeatable_read', 'off', 'server'
```

To enable the use of SET TRANSACTION ISOLATION LEVEL SERIALIZABLE in current session only.

Example

```sql
EXECUTE sp_babelfish_configure 'isolation_level_serializable', 'pg_isolation'
```

To enable the use of SET TRANSACTION ISOLATION LEVEL SERIALIZABLE in current session and all consequent new sessions.

Example

```sql
EXECUTE sp_babelfish_configure 'isolation_level_serializable', 'pg_isolation', 'server'
```

To disable the use of SET TRANSACTION ISOLATION LEVEL SERIALIZABLE in current session and consequent new sessions.
Example

EXECUTE sp_babelfish_configure 'isolation_level_serializable', 'off', 'server'

Differences between Babelfish and SQL Server Isolation Levels

Below are a few examples on the nuances in how SQL Server and Babelfish implement the ANSI Isolation Levels.

Note

- Isolation Level Repeatable Read and Snapshot are the same in Babelfish.
- Isolation Level Read Uncommitted and Read Committed are the same in Babelfish.

The following example shows how to create the base table for all the examples mentioned below:

CREATE TABLE employee (  
id sys.INT NOT NULL PRIMARY KEY,  
name sys.VARCHAR(255) NOT NULL,  
age sys.INT NOT NULL
);
INSERT INTO employee (id, name, age) VALUES (1, 'A', 10);
INSERT INTO employee (id, name, age) VALUES (2, 'B', 20);
INSERT INTO employee (id, name, age) VALUES (3, 'C', 30);

</table>
In Babelfish, concurrent transactions running with Isolation Level serializable will fail with serialization anomaly error if the execution of these transaction is inconsistent with all possible serial (one at a time) executions of those transactions.
## SERIALIZATION ANOMALY

<table>
<thead>
<tr>
<th>Transaction 1</th>
<th>Transaction 2</th>
<th>SQL Server Serializable</th>
<th>Babelfish Serializable</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEGIN TRANSACTION</td>
<td>BEGIN TRANSACTION</td>

<tr>
<td>COMMIT</td>
<td></td>
<td>Transaction 1 commits successfully.</td>
<td>Transaction 1 is committed first and is able to commit successfully.</td>
</tr>
<tr>
<td>COMMIT</td>
<td></td>
<td>Transaction 2 commits successfully.</td>
<td>Transaction 2 commit fails with serialization error, the whole transaction has been rolled back. Retry transaction 2.</td>
</tr>
</tbody>
</table>
### Working with Babelfish

In Babelfish, serialization anomaly is only possible if all the concurrent transactions are executing at Isolation Level SERIALIZABLE. For example, let's take the above example but set transaction 2 to Isolation Level REPEATABLE READ instead.

<table>
<thead>
<tr>
<th>Transaction 1</th>
<th>Transaction 2</th>
<th>SQL Server Isolation Levels</th>
<th>Babelfish Isolation Levels</th>

<td>Transaction 2 commits successfully.</td>
</tr>
</tbody>
</table>

Using Babelfish features with limited implementation

Each new version of Babelfish adds support for features that better align with T-SQL functionality and behavior. Still, there are some unsupported features and differences in the current implementation. In the following, you can find information about functional differences between Babelfish and T-SQL, with some workarounds or usage notes.

As of version 1.2.0 of Babelfish, the following features currently have limited implementations:

- **SQL Server catalogs (system views)** – The catalogs `sys.sysconfigures`, `sys.syscurconfigs`, and `sys.configurations` support a single read-only configuration only. The `sp_configure` isn’t currently supported. For more information about the other SQL Server views implemented by Babelfish, see Getting information from the Babelfish system catalog.

- **GRANT permissions** – GRANT...TO PUBLIC is supported, but GRANT..TO PUBLIC WITH GRANT OPTION is not currently supported.

- **SQL Server ownership chain and permission mechanism limitation** – In Babelfish, the SQL Server ownership chain works for views but not for stored procedures. This means that procedures must be granted explicit access to other objects owned by the same owner as the calling procedures. In SQL Server, granting the caller EXECUTE permissions on the procedure is sufficient to call other objects owned by same owner. In Babelfish, caller must also be granted permissions on the objects accessed by the procedure.

- **Resolution of unqualified (without schema name) object references** – When a SQL object (procedure, view, function or trigger) references an object without qualifying it with a schema
name, SQL Server resolves the object's schema name by using the schema name of the SQL object in which the reference occurs. Currently, Babelfish resolves this differently, by using the default schema of the database user executing the procedure.

- **Default schema changes, sessions, and connections** – If users change their default schema with ALTER USER...WITH DEFAULT SCHEMA, the change takes effect immediately in that session. However, for other currently connected sessions belonging to the same user, the timing differs, as follows:
  - For SQL Server: – The change takes effect across all other connections for this user immediately.
  - For Babelfish: – The change takes effect for this user for new connections only.

- **ROWVERSION and TIMESTAMP datatypes implementation and escape hatch setting**
  – The ROWVERSION and TIMESTAMP datatypes are now supported in Babelfish. To use ROWVERSION or TIMESTAMP in Babelfish, you must change the setting for the escape hatch babelfishpg_tsql.escape_hatch_rowversion from its default (strict) to ignore. The Babelfish implementation of the ROWVERSION and TIMESTAMP datatypes is mostly semantically identical to SQL Server, with the following exceptions:
    - The built-in @@DBTS function behaves similarly to SQL Server, but with small differences. Rather than returning the last-used value for SELECT @@DBTS, Babelfish generates a new timestamp, due to the underlying PostgreSQL database engine and its multi-version concurrency control (MVCC) implementation.
    - In SQL Server, every inserted or updated row gets a unique ROWVERSION/TIMESTAMP value. In Babelfish, every inserted row updated by the same statement is assigned the same ROWVERSION/TIMESTAMP value.

For example, when an UPDATE statement or INSERT-SELECT statement affects multiple rows, in SQL Server, the affected rows all have different values in their ROWVERSION/TIMESTAMP column. In Babelfish (PostgreSQL), the rows have the same value.

- In SQL Server, when you create a new table with SELECT-INTO, you can cast an explicit value (such as NULL) to a to-be-created ROWVERSION/TIMESTAMP column. When you do the same thing in Babelfish, an actual ROWVERSION/TIMESTAMP value is assigned to each row in the new table for you, by Babelfish.

These minor differences in ROWVERSION/TIMESTAMP datatypes shouldn't have an adverse impact on applications running on Babelfish.
Schema creation, ownership, and permissions – Permissions to create and access objects in a schema owned by a non-DBO user (using `CREATE SCHEMA schema name AUTHORIZATION user name`) differ for SQL Server and Babelfish non-DBO users, as shown in the following table:

<table>
<thead>
<tr>
<th>Database user (non-DBO) who owns the schema can do the following:</th>
<th>SQL Server</th>
<th>Babelfish</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create objects in the schema without additional grants by the DBO?</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Access objects created by DBO in the schema without additional grants?</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

Improving Babelfish query performance

You can achieve faster query processing in Babelfish using query hints and the PostgreSQL optimizer.

Topics

- Using `explain plan` to improve Babelfish query performance
- Using T-SQL query hints to improve Babelfish query performance

You can also improve the query performance using `sp_babelfish_volatility` procedure. For more information, see `sp_babelfish_volatility`.

Using `explain plan` to improve Babelfish query performance

Starting with version 2.1.0, Babelfish includes two functions that transparently use the PostgreSQL optimizer to generate estimated and actual query plans for T-SQL queries on the TDS port. These functions are similar to using `SET STATISTICS PROFILE` or `SET SHOWPLAN_ALL` with SQL Server databases to identify and improve slow running queries.

Note

Getting query plans from functions, control flows, and cursors isn’t currently supported.
In the table you can find a comparison of query plan explain functions across SQL Server, Babelfish, and PostgreSQL.

Use the Babelfish functions as follows:
• SET BABELFISH_SHOWPLAN_ALL [ON|OFF] – Set to ON to generate an estimated query execution plan. This function implements the behavior of the PostgreSQL EXPLAIN command. Use this command to obtain the explain plan for given query.

• SET BABELFISH_STATISTICS PROFILE [ON|OFF] – Set to ON for actual query execution plans. This function implements the behavior of PostgreSQL's EXPLAIN ANALYZE command.

For more information about PostgreSQL EXPLAIN and EXPLAIN ANALYZE see EXPLAIN in the PostgreSQL documentation.

⚠️ Note
Starting with version 2.2.0, you can set the escape_hatch_showplan_all parameter to ignore in order to avoid the use of BABELFISH_ prefix in the SQL Server syntax for SHOWPLAN_ALL and STATISTICS PROFILE SET commands.

For example, the following command sequence turns on query planning and then returns an estimated query execution plan for the SELECT statement without running the query. This example uses the SQL Server sample northwind database using the sqlcmd command-line tool to query the TDS port:

```
1> SET BABELFISH_SHOWPLAN_ALL ON
2> GO
1> SELECT t.territoryid, e.employeeid FROM
dbo.employeeterritories e, dbo.territories t
3> WHERE e.territoryid=e.territoryid ORDER BY t.territoryid;
4> GO

QUERY PLAN
```

Query Text: SELECT t.territoryid, e.employeeid FROM
dbo.employeeterritories e, dbo.territories t
WHERE e.territoryid=e.territoryid ORDER BY t.territoryid
Sort (cost=6231.74..6399.22 rows=66992 width=10)
  Sort Key: t.territoryid NULLS FIRST
  -> Nested Loop (cost=0.00..861.76 rows=66992 width=10)
When you finish reviewing and adjusting your query, you turn off the function as shown following:

```sql
1> SET BABELFISH_SHOWPLAN_ALL OFF
```

With BABELFISH_STATISTICS PROFILE set to ON, each executed query returns its regular result set followed by an additional result set that shows actual query execution plans. Babelfish generates the query plan that provides the fastest result set when it invokes the SELECT statement.

```sql
1> SET BABELFISH_STATISTICS PROFILE ON
1>
2> GO
1> SELECT e.employeeid, t.territoryid FROM
dbo.employeeterritories e, dbo.territories t
2> WHERE t.territoryid=e.territoryid ORDER BY t.territoryid;
4> GO
```

The result set and the query plan are returned (this example shows only the query plan).
To learn more about how to analyze your queries and the results returned by the PostgreSQL optimizer, see [explain.depesz.com](http://explain.depesz.com). For more information about PostgreSQL EXPLAIN and EXPLAIN ANALYZE, see [EXPLAIN](http://explain.depesz.com) in the PostgreSQL documentation.

**Parameters that control Babelfish explain options**

You can use the parameters shown in the following table to control the type of information that's displayed by your query plan.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>babelfishpg_tsql.explain_buffers</td>
<td>A boolean that turns on (and off) buffer usage information for the optimizer. (Default: off) (Allowable: off, on)</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_costs</td>
<td>A boolean that turns on (and off) estimated startup and total cost information for the optimizer. (Default: on) (Allowable: off, on)</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_format</td>
<td>Specifies the output format for the EXPLAIN plan. (Default: text) (Allowable: text, xml, json, yaml)</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_settings</td>
<td>A boolean that turns on (or off) the inclusion of information about configuration parameters in the EXPLAIN plan output. (Default: off) (Allowable: off, on)</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_summary</td>
<td>A boolean that turns on (or off) summary information such as total time after the query plan. (Default: on) (Allowable: off, on)</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_timing</td>
<td>A boolean that turns on (or off) actual startup time and time spent in each node in the output. (Default: on) (Allowable: off, on)</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_verbose</td>
<td>A boolean that turns on (or off) the most detailed version of an explain plan. (Default: off) (Allowable: off, on)</td>
</tr>
</tbody>
</table>
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>babelfishpg_tsql.explain_wal</td>
<td>A boolean that turns on (or off) generation of WAL record information as part of an explain plan. (Default: off) (Allowable: off, on)</td>
</tr>
</tbody>
</table>

You can check the values of any Babelfish-related parameters on your system by using either PostgreSQL client or SQL Server client. Run the following command to get your current parameter values:

```sql
1> execute sp_babelfish_configure '%explain%';
2> GO
```

In the following output, you can see that all settings on this particular Babelfish DB cluster are at their default values. Not all output is shown in this example.

<table>
<thead>
<tr>
<th>name</th>
<th>setting</th>
<th>short_desc</th>
</tr>
</thead>
<tbody>
<tr>
<td>babelfishpg_tsql.explain_buffers</td>
<td>off</td>
<td>Include information on buffer usage</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_costs</td>
<td>on</td>
<td>Include information on estimated startup and total cost</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_format</td>
<td>text</td>
<td>Specify the output format, which can be TEXT, XML, JSON, or YAML</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_settings</td>
<td>off</td>
<td>Include information on configuration parameters</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_summary</td>
<td>on</td>
<td>Include summary information (e.g., totaled timing information) after the query plan</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_timing</td>
<td>on</td>
<td>Include actual startup time and time spent in each node in the output</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_verbose</td>
<td>off</td>
<td>Display additional information regarding the plan</td>
</tr>
<tr>
<td>babelfishpg_tsql.explain_wal</td>
<td>off</td>
<td>Include information on WAL record</td>
</tr>
</tbody>
</table>

(8 rows affected)

You can change the setting for these parameters using `sp_babelfish_configure`, as shown in the following example.
If you want to make the setting permanent on a cluster-wide level, include the keyword `server`, as shown in the following example.

```
1> execute sp_babelfish_configure 'explain_verbose', 'on', 'server';
2> GO
```

### Using T-SQL query hints to improve Babelfish query performance

Starting with version 2.3.0, Babelfish supports the use of query hints using `pg_hint_plan`. In Aurora PostgreSQL, `pg_hint_plan` is installed by default. For more information about the PostgreSQL extension `pg_hint_plan`, see [https://github.com/ossc-db/pg_hint_plan](https://github.com/ossc-db/pg_hint_plan). For details about the version of this extension supported by Aurora PostgreSQL, see [Extension versions for Amazon Aurora PostgreSQL](https://aws.amazon.com/about-aws/leaders/iaas/postgresql/) in [Release Notes for Aurora PostgreSQL](https://aws.amazon.com/about-aws/leaders/iaas/postgresql/).

The query optimizer is well-designed to find the optimal execution plan for a SQL statement. When selecting a plan, the query optimizer considers both the engine's cost model, and column and table statistics. However, the suggested plan might not meet the needs of your datasets. Thus, query hints address the performance issues to improve execution plans. A query hint is syntax added to the SQL standard that instructs the database engine about how to execute the query. For example, a hint may instruct the engine to follow a sequential scan and override any plan that the query optimizer had selected.

### Turning on T-SQL query hints in Babelfish

Currently, Babelfish ignores all T-SQL hints by default. To apply T-SQL hints, run the command `sp_babelfish_configure` with the `enable_pg_hint` value as ON.

```
EXECUTE sp_babelfish_configure 'enable_pg_hint', 'on' [, 'server']
```

You can make the settings permanent on a cluster-wide level by including the `server` keyword. To configure the setting for the current session only, don't use `server`.

After `enable_pg_hint` is ON, Babelfish applies the following T-SQL hints.

- INDEX hints
- JOIN hints
• FORCE ORDER hint

• MAXDOP hint

For example, the following command sequence turns on pg_hint_plan.

1> CREATE TABLE t1 (a1 INT PRIMARY KEY, b1 INT);
2> CREATE TABLE t2 (a2 INT PRIMARY KEY, b2 INT);
3> GO
1> EXECUTE sp_babelfish_configure 'enable_pg_hint', 'on';
2> GO
1> SET BABELFISH_SHOWPLAN_ALL ON;
2> GO
1> SELECT * FROM t1 JOIN t2 ON t1.a1 = t2.a2; --NO HINTS (HASH JOIN)
2> GO

No hint is applied to the SELECT statement. The query plan with no hint is returned.

QUERY PLAN

----------------------------------------------------------
Query Text: SELECT * FROM t1 JOIN t2 ON t1.a1 = t2.a2
Hash Join (cost=60.85..99.39 rows=2260 width=16)
 Hash Cond: (t1.a1 = t2.a2)
  => Seq Scan on t1 (cost=0.00..32.60 rows=2260 width=8)
  => Hash (cost=32.60..32.60 rows=2260 width=8)
  => Seq Scan on t2 (cost=0.00..32.60 rows=2260 width=8)

1> SELECT * FROM t1 INNER MERGE JOIN t2 ON t1.a1 = t2.a2;
2> GO

The query hint is applied to the SELECT statement. The following output shows that the query plan with merge join is returned.

QUERY PLAN
Query Text: SELECT/*+ MergeJoin(t1 t2) Leading(t1 t2)*/ * FROM t1 INNER JOIN t2 ON t1.a1 = t2.a2
Merge Join (cost=0.31..190.01 rows=2260 width=16)
  Merge Cond: (t1.a1 = t2.a2)
  -> Index Scan using t1_pkey on t1 (cost=0.15..78.06 rows=2260 width=8)
  -> Index Scan using t2_pkey on t2 (cost=0.15..78.06 rows=2260 width=8)

1> SET BABELFISH_SHOWPLAN_ALL OFF;
2> GO

Limitations

While using the query hints, consider the following limitations:

- If a query plan is cached before enable_pg_hint is turned on, hints won't be applied in the same session. It will be applied in the new session.
- If schema names are explicitly given, then hints can't be applied. You can use table aliases as a workaround.
- A query hint can't be applied to views and sub-queries.
- Hints don't work for UPDATE/DELETE statements with JOINs.
- An index hint for a non-existing index or table is ignored.
- The FORCE ORDER hint doesn't work for HASH JOINs and non-ANSI JOINs.

Using Aurora PostgreSQL extensions with Babelfish

Aurora PostgreSQL provides extensions for working with other AWS services. These are optional extensions that support various use cases, such as using Amazon S3 with your DB cluster for importing or exporting data.

- To import data from an Amazon S3 bucket to your Babelfish DB cluster, you set up the aws_s3 Aurora PostgreSQL extension. This extension also lets you export data from your Aurora PostgreSQL DB cluster to an Amazon S3 bucket.
- AWS Lambda is a compute service that lets you run code without provisioning or managing servers. You can use Lambda functions to do things like process event notifications from your DB instance. To learn more about Lambda, see What is AWS Lambda? in the AWS Lambda Developer
To invoke Lambda functions from your Babelfish DB cluster, you set up the `aws__lambda` Aurora PostgreSQL extension.

To set up these extensions for your Babelfish cluster, you first need to grant permission to the internal Babelfish user to load the extensions. After granting permission, you can then load Aurora PostgreSQL extensions.

**Enabling Aurora PostgreSQL extensions in your Babelfish DB cluster**

Before you can load the `aws_s3` or the `aws__lambda` extensions, you grant the needed privileges to your Babelfish DB cluster.

The procedure following uses the `psql` PostgreSQL command line tool to connect to the DB cluster. For more information, see Using `psql` to connect to the DB cluster. You can also use pgAdmin. For details, see Using pgAdmin to connect to the DB cluster.

This procedure loads both `aws_s3` and `aws__lambda`, one after the other. You don't need to load both if you want to use only one of these extensions. The `aws__commons` extension is required by each, and it's loaded by default as shown in the output.

**To set up your Babelfish DB cluster with privileges for the Aurora PostgreSQL extensions**

1. Connect to your Babelfish DB cluster. Use the name for the "master" user (-U) that you specified when you created the Babelfish DB cluster. The default (`postgres`) is shown in the examples.

For Linux, macOS, or Unix:

```
psql -h your-Babelfish.cluster.44455556666-us-east-1.rds.amazonaws.com \
-U postgres \
-d babelfish_db \
-p 5432
```

For Windows:

```
psql -h your-Babelfish.cluster.44455556666-us-east-1.rds.amazonaws.com ^
-U postgres ^
-d babelfish_db ^
-p 5432
```
The command responds with a prompt to enter the password for the user name (-U).

Password:

Enter the password for the user name (-U) for the DB cluster. When you successfully connect, you see output similar to the following.

```
psql (13.4)
Type "help" for help.
postgres=>
```

2. Grant privileges to the internal Babelfish user to create and load extensions.

```
babelfish_db=> GRANT rds_superuser TO master_dbo;
GRANT ROLE
```

3. Create and load the `aws_s3` extension. The `aws_commons` extension is required, and it's installed automatically when the `aws_s3` is installed.

```
babelfish_db=> create extension aws_s3 cascade;
NOTICE: installing required extension "aws_commons"
CREATE EXTENSION
```

4. Create and load the `aws_lambda` extension.

```
babelfish_db=> create extension aws_lambda cascade;
CREATE EXTENSION
```

Using Babelfish with Amazon S3

If you don't already have an Amazon S3 bucket to use with your Babelfish DB cluster, you can create one. For any Amazon S3 bucket that you want to use, you provide access.

Before trying to import or export data using an Amazon S3 bucket, complete the following one-time steps.
To set up access for your Babelfish DB instance to your Amazon S3 bucket

1. Create an Amazon S3 bucket for your Babelfish instance, if needed. To do so, follow the instructions in Create a bucket in the Amazon Simple Storage Service User Guide.

2. Upload files to your Amazon S3 bucket. To do so, follow the steps in Add an object to a bucket in the Amazon Simple Storage Service User Guide.

3. Set up permissions as needed:
   - To import data from Amazon S3, the Babelfish DB cluster needs permission to access the bucket. We recommend using an AWS Identity and Access Management (IAM) role and attaching an IAM policy to that role for your cluster. To do so, follow the steps in Using an IAM role to access an Amazon S3 bucket.
   - To export data from your Babelfish DB cluster, your cluster must be granted access to the Amazon S3 bucket. As with importing, we recommend using an IAM role and policy. To do so, follow the steps in Setting up access to an Amazon S3 bucket.

You can now use Amazon S3 with the aws_s3 extension with your Babelfish DB cluster.

To import data from Amazon S3 to Babelfish and to export Babelfish data to Amazon S3

1. Use the aws_s3 extension with your Babelfish DB cluster.

   When you do, make sure to reference the tables as they exist in the context of PostgreSQL. That is, if you want to import into a Babelfish table named `[database].[schema].[tableA]`, refer to that table as `database_schema_tableA` in the aws_s3 function:

   - For an example of using an aws_s3 function to import data, see Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster.
   - For examples of using aws_s3 functions to export data, see Exporting query data using the aws_s3.query_export_to_s3 function.

2. Make sure to reference Babelfish tables using PostgreSQL naming when using the aws_s3 extension and Amazon S3, as shown in the following table.

<table>
<thead>
<tr>
<th>Babelfish table</th>
<th>Aurora PostgreSQL table</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>database.schema.table</code></td>
<td><code>database_schema_table</code></td>
</tr>
</tbody>
</table>
To learn more about using Amazon S3 with Aurora PostgreSQL, see Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster and Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3.

Using Babelfish with AWS Lambda

After the aws_lambda extension is loaded in your Babelfish DB cluster but before you can invoke Lambda functions, you give Lambda access to your DB cluster by following this procedure.

To set up access for your Babelfish DB cluster to work with Lambda

This procedure uses the AWS CLI to create the IAM policy and role, and associate these with the Babelfish DB cluster.

1. Create an IAM policy that allows access to Lambda from your Babelfish DB cluster.

   ```bash
   aws iam create-policy  --policy-name rds-lambda-policy --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   {
   "Sid": "AllowAccessToExampleFunction",
   "Effect": "Allow",
   "Action": "lambda:InvokeFunction",
   }
   ]
   }'
   ```

2. Create an IAM role that the policy can assume at runtime.

   ```bash
   aws iam create-role  --role-name rds-lambda-role --assume-role-policy-document '{
   "Version": "2012-10-17",
   "Statement": [
   {
   "Effect": "Allow",
   "Principal": {
   "Service": "rds.amazonaws.com"
   },
   "Action": "sts:AssumeRole"
   }
   ]
   }'
   ```
3. Attach the policy to the role.

```shell
aws iam attach-role-policy 
   --policy-arn arn:aws:iam::4444555666:policy/rds-lambda-policy 
   --role-name rds-lambda-role --region aws-region
```

4. Attach the role to your Babelfish DB cluster

```shell
aws rds add-role-to-db-cluster 
   --db-cluster-identifier my-cluster-name 
   --feature-name Lambda 
   --role-arn arn:aws:iam::4444555666:role/rds-lambda-role 
   --region aws-region
```

After you complete these tasks, you can invoke your Lambda functions. For more information and examples of setting up AWS Lambda for Aurora PostgreSQL DB cluster with AWS Lambda, see Step 2: Configure IAM for your Aurora PostgreSQL DB cluster and AWS Lambda.

To invoke a Lambda function from your Babelfish DB cluster

AWS Lambda supports functions written in Java, Node.js, Python, Ruby, and other languages. If the function returns text when invoked, you can invoke it from your Babelfish DB cluster. The following example is a placeholder python function that returns a greeting.

```python
lambda_function.py
import json
def lambda_handler(event, context):
    #TODO implement
    return {
        'statusCode': 200,
        'body': json.dumps('Hello from Lambda!')
    }
```

Currently, Babelfish doesn't support JSON. If your function returns JSON, you use a wrapper to handle the JSON. For example, say that the `lambda_function.py` shown preceding is stored in Lambda as `my-function`.

1. Connect to your Babelfish DB cluster using the `psql` client (or the pgAdmin client). For more information, see Using psql to connect to the DB cluster.
2. Create the wrapper. This example uses PostgreSQL's procedural language for SQL, PL/pgSQL. To learn more, see [PL/pgSQL–SQL Procedural Language](#).

```sql
create or replace function master_dbo.lambda_wrapper()
returns text
language plpgsql
as
$$
declare
  r_status_code integer;
  r_payload text;
begin
  SELECT payload INTO r_payload
  FROM aws_lambda.invoke( aws_commons.create_lambda_function_arn('my-function', 'us-east-1'),
                         '{"body": "Hello from Postgres!"'}::json);
  return r_payload ;
end;
$$;
```

The function can now be run from the Babelfish TDS port (1433) or from the PostgreSQL port (5433).

a. To invoke (call) this function from your PostgreSQL port:

```sql
SELECT * from aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-
function', 'us-east-1'), '{"body": "Hello from Postgres!"'}::json );
```

The output is similar to the following:

```
status_code | payload | executed_version | log_result
------------|---------|-----------------|-------------
200 | {"statusCode": 200, "body": "Hello from Lambda!"} | $LATEST
```
(1 row)
b. To invoke (call) this function from the TDS port, connect to the port using the SQL Server sqlcmd command line client. For details, see Using a SQL Server client to connect to your DB cluster. When connected, run the following:

```sql
1> select lambda_wrapper();
2> go
```

The command returns output similar to the following:

```json
{"statusCode": 200, "body": "Hello from Lambda!"}
```

To learn more about using Lambda with Aurora PostgreSQL, see Invoking an AWS Lambda function from an Aurora PostgreSQL DB cluster. For more information about working with Lambda functions, see Getting started with Lambda in the AWS Lambda Developer Guide.

**Using pg_stat_statements in Babelfish**

Babelfish for Aurora PostgreSQL supports pg_stat_statements extension from 3.3.0. To learn more, see pg_stat_statements.

For details about the version of this extension supported by Aurora PostgreSQL, see Extension versions.

**Creating pg_stat_statements extension**

To turn on pg_stat_statements, you must turn on the Query identifier calculation. This is done automatically if compute_query_id is set to on or auto in the parameter group. The default value of compute_query_id parameter is auto. You also need to create this extension to turn on this feature. Use the following command to install the extension from T-SQL endpoint:

```sql
1> EXEC sp_execute_postgresql 'CREATE EXTENSION pg_stat_statements WITH SCHEMA sys';
```

You can access the query statistics using the following query:

```sql
postgres=>select * from pg_stat_statements;
```
Note

During installation, if you don't provide the schema name for the extension then by default it will create it in public schema. To access it, you must use square brackets with schema qualifier as shown below:

```
postgres=> select * from [public].pg_stat_statements;
```

You can also create the extension from PSQL endpoint.

Authorizing the extension

By default, you can see the statistics for queries performed within your T-SQL database without the need of any authorization.

To access query statistics created by others, you need to have `pg_read_all_stats` PostgreSQL role. Follow the steps mentioned below to construct GRANT `pg_read_all_stats` command.

1. In T-SQL, use the following query that returns the internal PG role name.

   ```
   SELECT rolname FROM pg_roles WHERE oid = USER_ID();
   ```

2. Connect to Babelfish for Aurora PostgreSQL database with rds_superuser privilege and use the following command:

   ```
   GRANT pg_read_all_stats TO <rolname_from_above_query>
   ```

Example

From T-SQL endpoint:

```
1>SELECT rolname FROM pg_roles WHERE oid = USER_ID();
2>go

rolname
-------
```
From PSQL endpoint:

```
babelfish_db=# grant pg_read_all_stats to master_dbo;

GRANT ROLE
```

You can access the query statistics using the `pg_stat_statements` view:

```
1>create table t1(cola int);
2>go
1>insert into t1 values (1),(2),(3);
2>go

(3 rows affected)
```

```
1>select userid, dbid, queryid, query from pg_stat_statements;
2>go
```

```
<table>
<thead>
<tr>
<th>userid</th>
<th>dbid</th>
<th>queryid</th>
<th>query</th>
</tr>
</thead>
<tbody>
<tr>
<td>37503</td>
<td>34582</td>
<td>6487973085327558478</td>
<td>select * from t1</td>
</tr>
<tr>
<td>37503</td>
<td>34582</td>
<td>6284378402749466286</td>
<td>SET QUOTED_IDENTIFIER OFF</td>
</tr>
<tr>
<td>37503</td>
<td>34582</td>
<td>2864302298511657420</td>
<td>insert into t1 values ($1),($2),($3)</td>
</tr>
<tr>
<td>10</td>
<td>34582</td>
<td>NULL</td>
<td>&lt;insufficient privilege&gt;</td>
</tr>
<tr>
<td>37503</td>
<td>34582</td>
<td>5615368793313871642</td>
<td>SET TEXTSIZE 4096</td>
</tr>
<tr>
<td>37503</td>
<td>34582</td>
<td>639400815330803392</td>
<td>create table t1(cola int)</td>
</tr>
</tbody>
</table>

(6 rows affected)
```

Resetting query statistics

You can use `pg_stat_statements_reset()` to reset the statistics gathered so far by `pg_stat_statements`. To learn more, see [pg_stat_statements](#). It is currently supported through
PSQL endpoint only. Connect to Babelfish for Aurora PostgreSQL with rds_superuser privilege, use the following command:

```
SELECT pg_stat_statements_reset();
```

**Limitations**

- Currently, `pg_stat_statements()` is not supported through T-SQL endpoint. `pg_stat_statements` view is the recommended way to gather the statistics.

- Some of the queries might be re-written by the T-SQL parser implemented by Aurora PostgreSQL engine, `pg_stat_statements` view will show the re-written query and not the original query.

**Example**

```
select next value for [dbo].[newCounter];
```

The above query is re-written as the following in the `pg_stat_statements` view.

```
select nextval($1);
```

- Based on the execution flow of the statements, some of the queries might not be tracked by `pg_stat_statements` and will not be visible in the view. This includes the following statements: `use dbname`, `goto`, `print`, `raise error`, `set`, `throw`, `declare cursor`.

- For CREATE LOGIN and ALTER LOGIN statements, query and queryid will not be shown. It will show insufficient privileges.

- `pg_stat_statements` view always contains the below two entries, as these are executed internally by sqlcmd client.
  - SET QUOTED_IDENTIFIER OFF
  - SET TEXTSIZE 4096

**Using pgvector in Babelfish**

pgvector, an open-source extension, lets you search for similar data directly within your Postgres database. Babelfish now supports this extension starting with versions 15.6 and 16.2. For more information, [pgvector Open source Documentation](#).
Prerequisites

To enable pgvector functionality, install the extension in sys schema using one of the following methods:

- Run the following command in sqlcmd client:

  ```sql
  exec sys.sp_execute_postgresql 'CREATE EXTENSION vector WITH SCHEMA sys';
  ```

- Connect to babelfish_db and run the following command in psql client:

  ```sql
  CREATE EXTENSION vector WITH SCHEMA sys;
  ```

Note

After installing the pgvector extension, the vector data type will only be available in new database connections you establish. Existing connections won't recognize the new data type.

Supported Functionality

Babelfish extends the T-SQL functionality to support the following:

- **Storing**

  Babelfish now supports vector datatype compatible syntax, enhancing its T-SQL compatibility. To learn more about storing data with pgvector, see Storing.

- **Querying**

  Babelfish expands T-SQL expression support to include vector similarity operators. However, for all other queries, standard T-SQL syntax is still required.

Note

T-SQL doesn't support Array type, and the database drivers do not have any interface to handle them. As a workaround, Babelfish uses text strings (varchar/nvarchar) to store vector data. For example, when you request a vector value [1,2,3], Babelfish will return a
string '1,2,3' as the response. You can parse and split this string at application level as per your needs.

To learn more about querying data with pgvector, see Querying.

- **Indexing**

  T-SQL Create Index now supports USING INDEX_METHOD syntax. You can now define similarity search operator to be used on a specific column when creating an index.

  The grammar is also extended to support Vector similarity operations on the required column (Check column_name_list_with_order_for_vector grammar).

  ```
  CREATE [UNIQUE] [clustered] [COLUMNSTORE] INDEX <index_name> ON <table_name> [USING vector_index_method] (<column_name_list_with_order_for_vector>)
  Where column_name_list_with_order_for_vector is:
  <column_name> [ASC | DESC] [VECTOR_COSINE_OPS | VECTOR_IP_OPS | VECTOR_L2_OPS]
  (COMMA simple_column_name [ASC | DESC] [VECTOR_COSINE_OPS | VECTOR_IP_OPS | VECTOR_L2_OPS])
  ```

  To learn more about indexing data with pgvector, see Indexing.

- **Performance**

  - Use SET BABELFISH_STATISTICS PROFILE ON to debug Query Plans from T-SQL endpoint.
  - Increase max_parallel_workers_get_gather using the set_config function supported in T-SQL.
  - Use IVFFlat for approximate searches. For more information, see IVFFlat.

  To improve performance with pgvector, see Performance.

- **Limitations**

  - Babelfish doesn't support Full Text Search for Hybrid Search. For more information, see Hybrid Search.
  - Babelfish doesn't currently support re-indexing functionality. However, you can still use PostgreSQL endpoint to re-index. For more information, see Vacuuming.
Using Amazon Aurora machine learning with Babelfish

You can extend the capabilities of your Babelfish for Aurora PostgreSQL DB cluster by integrating it with Amazon Aurora machine learning. This seamless integration grants you access to a range of powerful services like Amazon Comprehend or Amazon SageMaker or Amazon Bedrock, each tailored to address distinct machine learning needs.

As a Babelfish user, you can use existing knowledge of T-SQL syntax and semantics when working with Aurora machine learning. Follow the instructions provided in the AWS documentation for Aurora PostgreSQL. For more information, see Using Amazon Aurora machine learning with Aurora PostgreSQL.

Prerequisites

- Before trying to set up your Babelfish for Aurora PostgreSQL DB cluster to use Aurora machine learning, you must understand the related requirements and prerequisites. For more information, see Requirements for using Aurora machine learning with Aurora PostgreSQL.
- Make sure you install the aws_ml extension either using Postgres endpoint or the sp_execute_postgresql store procedure.

exec sys.sp_execute_postgresql 'Create Extension aws_ml'

**Note**

Currently Babelfish doesn't support cascade operations with sp_execute_postgresql in Babelfish. Since aws_ml relies on aws_commons, you'll need to install it separately using Postgres endpoint.

create extension aws_common;

Handling T-SQL syntax and semantics with aws_ml functions

The following examples explains how T-SQL syntax and semantics are applied to the Amazon ML services:
Example: `aws_bedrock.invoke_model` – A simple query using Amazon Bedrock functions

```python
aws_bedrock.invoke_model(
    model_id varchar,
    content_type text,
    accept_type text,
    model_input text)
Returns VARCHAR(MAX)
```

The following example shows how to invoke a Anthropic Claude 2 model for Bedrock using `invoke_model`.

```sql
SELECT aws_bedrock.invoke_model ('anthropic.claude-v2', 'application/json', 'application/json', '{"prompt": "\n\nHuman:
You are a helpful assistant that answers questions directly
and only using the information provided in the context below.
\nDescribe the answer in detail.\n\nContext: %s \n\nQuestion: %s \n\nAssistant:","max_tokens_to_sample":4096,"temperature":0.5,"top_k":250,"top_p":0.5,"stop_sequences":[]}')
```

Example: `aws_comprehend.detect_sentiment` – A simple query using Amazon Comprehend functions

```python
aws_comprehend.detect_sentiment(
    input_text varchar,
    language_code varchar,
    max_rows_per_batch int)
Returns table (sentiment varchar, confidence real)
```

The following example shows how to invoke the Amazon Comprehend service.

```sql
select sentiment from aws_comprehend.detect_sentiment('This is great', 'en');
```
Example: `aws_sagemaker.invoke_endpoint` – A simple query using Amazon SageMaker functions

```sql
aws_sagemaker.invoke_endpoint(
    endpoint_name varchar,
    max_rows_per_batch int,
    VARIADIC model_input "any") -- Babelfish inherits PG's variadic parameter type
Returns Varchar(MAX)
```

Since model_input is marked as VARIADIC and of type “any”, users can pass a list of any length and any datatype to the function which will act as the input to the model. The following example shows how to invoke the Amazon SageMaker service.

```sql
SELECT CAST (aws_sagemaker.invoke_endpoint(
    'sagemaker_model_endpoint_name',
    NULL,
    arg1, arg2 -- model inputs are separate arguments )
AS INT) -- cast the output to INT
```

For more detailed information on using Aurora machine learning with Aurora PostgreSQL, see [Using Amazon Aurora machine learning with Aurora PostgreSQL](#).

**Limitations**

- While Babelfish doesn't allow creating arrays, it can still handle data that represents arrays. When you use functions like `aws_bedrock.invoke_model_get_embeddings` that return arrays, the results is delivered as a string containing the array elements.

**Babelfish supports linked servers**

Babelfish for Aurora PostgreSQL supports linked servers by using the PostgreSQL `tds_fdw` extension in version 3.1.0. To work with linked servers, you must install the `tds_fdw` extension. For more information about the `tds_fdw` extension, see [Working with the supported foreign data wrappers for Amazon Aurora PostgreSQL](#).
Installing the tds_fdw extension

You can install tds_fdw extension using the following methods.

Using CREATE EXTENSION from PostgreSQL endpoint

1. Connect to your PostgreSQL DB instance on the Babelfish database in the PostgreSQL port. Use an account that has the rds_superuser role.

   ```
   psql --host=your-DB-instance.aws-region.rds.amazonaws.com --port=5432 --username=test --dbname=babelfish_db --password
   ```

2. Install the tds_fdw extension. This is a one-time installation process. You don't need to reinstall when the DB cluster restarts.

   ```
   babelfish_db=> CREATE EXTENSION tds_fdw;
   CREATE EXTENSION
   ```

Calling sp_execute_postgresql stored procedure from TDS endpoint

Babelfish supports installing tds_fdw extension by calling sp_execute_postgresql procedure from version 3.3.0. You can execute PostgreSQL statements from T-SQL endpoint without exiting the T-SQL port. For more information, see Babelfish for Aurora PostgreSQL procedure reference

1. Connect to your PostgreSQL DB instance on the Babelfish database in the T-SQL port.

   ```
   sqlcmd -S your-DB-instance.aws-region.rds.amazonaws.com -U test -P password
   ```

2. Install the tds_fdw extension.

   ```
   1>EXEC sp_execute_postgresql N'CREATE EXTENSION tds_fdw';
   2>go
   ```

Supported functionality

Babelfish supports adding remote RDS for SQL Server or Babelfish for Aurora PostgreSQL endpoints as the linked server. You can also add other remote SQL Server instances as linked
servers. Then, use OPENQUERY( ) to retrieve data from these linked servers. Starting from Babelfish version 3.2.0, four-part names are also supported.

The following stored procedures and catalog views are supported in order to use the linked servers.

**Stored procedures**

- **sp_addlinkedserver** – Babelfish doesn't support the @provstr parameter.
- **sp_addlinkedsrvlogin**
  - You must provide an explicit remote username and password to connect to the remote data source. You can't connect with the user's self credentials. Babelfish supports only @useself = false.
  - Babelfish doesn't support the @locallogin parameter since configuring remote server access specific to local login isn't supported.
- **sp_linkedservers**
- **sp_helplinkedsrvlogin**
- **sp_dropserver**
- **sp_droplinkedsrvlogin** – Babelfish doesn't support the @locallogin parameter since configuring remote server access specific to local login isn't supported.
- **sp_serveroption** – Babelfish supports the following server options:
  - query timeout (from Babelfish version 3.2.0)
  - connect timeout (from Babelfish version 3.3.0)
- **sp_testlinkedserver** (from Babelfish version 3.3.0)
- **sp_enum_oledb_providers** (from Babelfish version 3.3.0)

**Catalog views**

- **sys.servers**
- **sys.linked_logins**

**Using encryption in transit for the connection**

The connection from the source Babelfish for Aurora PostgreSQL server to the target remote server uses encryption in transit (TLS/SSL), depending on the remote server database configuration. If
the remote server isn't configured for encryption, the Babelfish server making the request to the remote database falls back to unencrypted.

To enforce connection encryption

- If the target linked server is an RDS for SQL Server instance, set `rds.force_ssl = on` for the target SQL Server instance. For more information about SSL/TLS configuration for RDS for SQL Server, see Using SSL with a Microsoft SQL Server DB instance.
- If the target linked server is a Babelfish for Aurora PostgreSQL cluster, set `babelfishpg_tsql.tds_ssl_encrypt = on` and `ssl = on` for the target server. For more information about SSL/TLS, see Babelfish SSL settings and client connections.

Adding Babelfish as a linked server from SQL Server

Babelfish for Aurora PostgreSQL can be added as a linked server from a SQL Server. On a SQL Server database, you can add Babelfish as a linked server using Microsoft OLE DB provider for ODBC : MSDASQL.

There are two ways to configure Babelfish as a linked server from SQL Server using MSDASQL provider:

- Providing ODBC connection string as the provider string.
- Provide the System DSN of ODBC data source while adding the linked server.

Limitations

- OPENQUERY() works only for SELECT and doesn't work for DML.
- Four-part object names work only for reading and doesn't work for modifying the remote table. An UPDATE can reference a remote table in the FROM clause without modifying it.
- Executing stored procedures against Babelfish linked servers isn't supported.
- Babelfish major version upgrade might not work if there are objects dependent on OPENQUERY() or objects referenced through four-part names. You must ensure that any objects referencing OPENQUERY() or four-part names are dropped before a major version upgrade.
- The following datatypes don't work as expected against remote Babelfish server: `nvarchar(max), varchar(max), varbinary(max), binary(max)` and `time`. We recommend using the CAST function to convert these to the supported datatypes.
Example

In the following example, a Babelfish for Aurora PostgreSQL instance is connecting to an instance of RDS for SQL Server in the cloud.

```sql
EXEC master.dbo.sp_addlinkedserver @server=N'rds_sqlserver', @srvproduct=N'',
    @provider=N'SQLNCLI', @datasrc=N'myserver.CB2XFSSFFMY7.US-WEST-2.RDS.AMAZONAWS.COM';
EXEC master.dbo.sp_addlinkedsrvlogin
    @rmtsrvname=N'rds_sqlserver',@useself=N'False',@locallogin=NULL,@rmtuser=N'username',@rmtpassword='password';
```

When the linked server is in place, you can then use T-SQL OPENQUERY() or standard four-part naming to reference a table, view, or other supported objects, on the remote server:

```sql
SELECT * FROM OPENQUERY(rds_sqlserver, 'SELECT * FROM TestDB.dbo.t1');
SELECT * FROM rds_sqlserver.TestDB.dbo.t1;
```

To drop the linked server and all associated logins:

```sql
EXEC master.dbo.sp_dropserver @server=N'rds_sqlserver', @droplogins=N'droplogins';
```

Troubleshooting

You can use the same security group for both source and remote servers to allow them to communicate with each other. Security group should allow only inbound traffic on TDS port (1433 by default) and source IP in security group can be set as the security group ID itself. For more information on how to set the rules for connecting to an instance from another instance with the same security group, see [Rules to connect to instances from an instance with the same security group](#). If access isn't configured correctly, an error message similar to the following example appears when you try to query the remote server.
Using Full Text Search in Babelfish

Starting with version 4.0.0, Babelfish provides limited support for Full Text Search (FTS). FTS is a powerful feature in relational databases that enables efficient searching and indexing of text-heavy data. It allows you to perform complex text searches and retrieve relevant results quickly. FTS is particularly valuable for applications that deal with large volumes of textual data, such as content management systems, e-commerce platforms, and document archives.

Understanding Babelfish Full Text Search supported features

Babelfish supports the following Full Text Search features:

- CONTAINS Clause:
  - Basic support for the CONTAINS clause.

```sql
CONTAINS (  
  {   
    column_name  
  }  
  , '<contains_search_condition>'  
)
```

- **Note**
  - Currently, only English language is supported.

- Comprehensive handling and translation of simple_term search strings.

- FULLTEXT INDEX Clause:
  - Supports only `CREATE FULLTEXT INDEX ON table_name(column_name [ ...n]) KEY INDEX index_name` statement.
  - Supports full `DROP FULLTEXT INDEX` statement.
**Note**

In order to re-index the Full Text Index, you need to drop the Full Text Index and create a new one on the same column.

- Special characters in search condition:
  - Babelfish ensures that single occurrences of special characters in search strings are handled effectively.

**Note**

While Babelfish now identifies special characters in search string, it's essential to recognize that the results obtained may vary compared to those obtained with T-SQL.

- Table alias in column_name:
  - With table alias support, users can create more concise and readable SQL queries for Full-Text Search.

**Limitations in Babelfish Full Text Search**

- Currently, the following options aren't supported in Babelfish for CONTAINS Clause.
  - Special characters and Languages other than English aren't supported. You will receive the generic error message for unsupported characters and language

```
Full-text search conditions with special characters or languages other than English are not currently supported in Babelfish
```

- Multiple columns like column_list
- PROPERTY attribute
- prefix_term, generation_term, generic_proximity_term, custom_proximity_term, and weighted_term
- Boolean operators aren't supported and you will receive the following error message when used:
**boolean operators not supported**

- Identifier names with dots aren't supported.
- Currently, the following options aren't supported in Babelfish for `CREATE FULLTEXT INDEX` Clause.
  - `[ TYPE COLUMN type_column_name ]`
  - `[ LANGUAGE language_term ]`
  - `[ STATISTICAL_SEMANTICS ]`
  - catalog filegroup options
  - with options
- Creating a full text catalog isn't supported. Creating a full text index doesn't require a full text catalog.
- `CREATE FULLTEXT INDEX` doesn't support identifier names with dots.
- Babelfish doesn't currently support consecutive special characters in search strings. You will receive the following error message when used:

Consecutive special characters in the full-text search condition are not currently supported in Babelfish

**Babelfish supports Geospatial data types**

Starting with versions 3.5.0 and 4.1.0, Babelfish includes support for the following two spatial data types:

- **Geometry data type** – This data type is intended for storing planar or Euclidean (flat-earth) data.
- **Geography data type** – This data type is intended for storing ellipsoidal or round-earth data, such as GPS latitude and longitude coordinates.

These data types allow for the storage and manipulation of spatial data, but with limitations.

**Understanding the Geospatial data types in Babelfish**

- Geospatial data types are supported in various database objects such as views, procedures, and tables.
• Supports 2-D point data type to store location data as points defined by latitude, longitude, and a valid Spatial Reference System Identifier (SRID).

• Applications connecting to Babelfish through drivers like JDBC, ODBC, DOTNET, and PYTHON can utilize this Geospatial feature.

Geometry data type functions supported in Babelfish

• STGeomFromText (geometry_tagged_text, SRID) – Creates a geometry instance using Well-Known Text (WKT) representation.

• STPointFromText (point_tagged_text, SRID) – Creates a point instance using WKT representation.

• Point (X, Y, SRID) – Creates a point instance using float values of x and y coordinates.

• <geometry_instance>.STAsText () – Extracts WKT representation from geometry instance.

• <geometry_instance>.STDistance (other_geometry) – Calculates the distance between two geometry instances.

• <geometry_instance>.STX – Extracts the X coordinate (longitude) for geometry instance.

• <geometry_instance>.STY – Extracts the Y coordinate (latitude) for geometry instance.

Geography data type functions supported in Babelfish

• STGeomFromText (geography_tagged_text, SRID) – Creates a geography instance using WKT representation.

• STPointFromText (point_tagged_text, SRID) – Creates a point instance using WKT representation.

• Point (Lat, Long, SRID) – Creates a point instance using float values of Latitude and Longitude.

• <geography_instance>.STAsText () – Extracts WKT representation from geography instance.

• <geography_instance>.STDistance (other_geography) – Calculates the distance between two geography instances.

• <geography_instance>.Lat – Extracts the Latitude value for geography instance.

• <geography_instance>.Long – Extracts the Longitude value for geography instance.
Limitations in Babelfish for Geospatial data types

- Currently, Babelfish doesn't support more advanced features like Z-M flags for point instances of Geospatial data types.

- Geometry types other than point instance aren't currently supported:
  - LineString
  - CircularString
  - CompoundCurve
  - Polygon
  - CurvePolygon
  - MultiPoint
  - MultiLineString
  - MultiPolygon
  - GeometryCollection

- Currently, spatial indexing isn't supported for Geospatial data types.

- Only the listed functions are currently supported for these data types. For more information, see Geometry data type functions supported in Babelfish and Geography data type functions supported in Babelfish.

- STDistance function output for Geography data might have minor precision variations compared to T-SQL. This is due to the underlying PostGIS implementation. For more information, see ST_Distance

- For optimal performance, use built-in Geospatial data types, without creating additional layers of abstraction in Babelfish.

Tip

While you can create custom data types, it's not recommended to create it on top of Geospatial data. This could introduce complexities, potentially leading to unexpected behavior due to the limited support.

- In Babelfish, Geospatial function names are used as keywords and will perform spatial operations only if used in the intended way.
Tip

When creating user-defined functions and procedures in Babelfish, avoid using the same names as built-in Geospatial functions. If you have any existing database objects with the same names, use `sp_rename` to rename them.
Troubleshooting Babelfish

Following, you can find troubleshooting ideas and workarounds for some Babelfish DB cluster issues.

Topics

• **Connection failure**

Connection failure

Common causes of connection failures to a new Aurora DB cluster with Babelfish include the following:

• **Security group doesn't allow access** – If you're having trouble connecting to a Babelfish, make sure that you added your IP address to the default Amazon EC2 security group. You can use https://checkip.amazonaws.com/ to determine your IP address and then add it to your in-bound rule for the TDS port and the PostgreSQL port. For more information, see Add rules to a security group in the Amazon EC2 User Guide.

• **Mismatching SSL configurations** – If the `rds.force_ssl` parameter is turned on (set to 1) on Aurora PostgreSQL, then clients must connect to Babelfish over SSL. If your client isn't set up correctly, you see an error message such as the following:

    Cannot connect to your-Babelfish-DB-cluster, 1433
    ---------------------
    ADDITIONAL INFORMATION:
    no pg_hba_conf entry for host "256.256.256.256", user "your-user-name",
    "database babelfish_db", SSL off (Microsoft SQL Server, Error: 33557097)
    ...

This error indicates a possible SSL configuration issue between your local client and the Babelfish DB cluster, and that the cluster requires clients to use SSL (its `rds.force_ssl` parameter is set to 1). For more information about configuring SSL, see Using SSL with a PostgreSQL DB instance in the Amazon RDS User Guide.

If you are using SQL Server Management Studio (SSMS) to connect to Babelfish and you see this error, you can choose Encrypt connection and Trust server certificate connection options on the Connection Properties pane and try again. These settings handle the SSL connection requirement for SSMS.
For more information about troubleshooting Aurora connection issues, see Can't connect to Amazon RDS DB instance.
**Turning off Babelfish**

When you no longer need Babelfish, you can turn off Babelfish functionality.

Be aware of some considerations:

- In some cases, you might turn off Babelfish before completing a migration to Aurora PostgreSQL. If you do and your DDL depends on SQL Server data types or you use any T-SQL functionality in your code, your code fails.
- If after provisioning a Babelfish instance you turn off the Babelfish extension, you can't provision that same database again on the same cluster.

To turn off Babelfish, modify your parameter group, setting `rds.babelfish_status` to OFF. You can continue to use your SQL Server data types with Babelfish off, by setting `rds.babelfish_status` to `datatypeonly`.

If you turn off Babelfish in parameter group, all clusters that use that parameter group lose Babelfish functionality.

For more information about modifying parameter groups, see [Working with parameter groups](#). For information about Babelfish–specific parameters, see [DB cluster parameter group settings for Babelfish](#).
Babelfish version updates

Babelfish is an option available with Aurora PostgreSQL version 13.4 and higher releases. Updates to Babelfish become available with certain new releases of the Aurora PostgreSQL database engine. For more information, see the Release Notes for Aurora PostgreSQL.

Note

Babelfish DB clusters running on any version of Aurora PostgreSQL 13 can’t be upgraded to Aurora PostgreSQL 14.3, 14.4, and 14.5. Also, Babelfish doesn’t support a direct upgrade from 13.x to 15.x. You must first upgrade your 13.x DB cluster to 14.6 and higher version and then upgrade to 15.x version.

For a list of supported functionality across different Babelfish releases, see Supported functionality in Babelfish by version.

For a list of currently unsupported functionality, see Unsupported functionality in Babelfish.

You can use the describe-db-engine-versions AWS CLI command to get a list of Aurora PostgreSQL versions in your AWS Region that support Babelfish, as shown in the following example.

For Linux, macOS, or Unix:

```
$ aws rds describe-db-engine-versions --region us-east-1 \
  --engine aurora-postgresql \
  --query '*[]|[?SupportsBabelfish==`true`].[EngineVersion]' \
  --output text
13.4
13.5
13.6
13.7
13.8
14.3
14.4
14.5
14.6
14.7
14.8
14.9
14.10
15.2
```
Identifying your version of Babelfish

You can query Babelfish to find details about the Babelfish version, the Aurora PostgreSQL version, and the compatible Microsoft SQL Server version. You can use the TDS port or the PostgreSQL port.

To use the TDS port to query for version information

To use the PostgreSQL port to query for version information

1. Use sqlcmd or ssms to connect to the endpoint for your Babelfish DB cluster.
2. To identify the Babelfish version, run the following query:

```
1> SELECT CAST(serverproperty('babelfishversion') AS VARCHAR)
2> GO
```

The query returns results similar to the following:

```
serverproperty
-------------------
3.4.0
```

(1 rows affected)

3. To identify the version of the Aurora PostgreSQL DB cluster, run the following query:

```
1> SELECT aurora_version() AS aurora_version
2> GO
```

The query returns results similar to the following:

```
aurora_version
-------------------
15.5.0
```

(1 rows affected)

4. To identify the compatible Microsoft SQL Server version, run the following query:

```
1> SELECT @@VERSION AS version
2> GO
```

The query returns results similar to the following:

```
Babelfish for Aurora PostgreSQL with SQL Server Compatibility - 12.0.2000.8
Dec 7 2023 09:43:06
```
As an example that shows one minor difference between Babelfish and Microsoft SQL Server, you can run the following query. On Babelfish, the query returns 1, while on Microsoft SQL Server, the query returns NULL.

```
SELECT CAST(serverproperty('babelfish') AS VARCHAR) AS runs_on_babelfish
```

You can also use the PostgreSQL port to obtain version information, as shown in the following procedure.

**To use the PostgreSQL port to query for version information**

1. Use `psql` or pgAdmin to connect to the endpoint for your Babelfish DB cluster.

   ```
   psql host=bfish_db.cluster-123456789012.aws-region.rds.amazonaws.com
   port=5432 dbname=babelfish_db user=sa
   ```

2. Turn on the extended feature (\x) of psql for more readable output.

   ```
babelfish_db=> \x
babelfish_db=> SELECT
babelfish_db=>   aurora_version() AS aurora_version,
babelfish_db=>   version() AS postgresql_version,
babelfish_db=>   sys.version() AS Babelfish_compatibility,
babelfish_db=>   sys.SERVERPROPERTY('BabelfishVersion') AS Babelfish_Version;
```

The query returns output similar to the following:

```
| RECORD 1 |
+----------
| aurora_version | 15.5.0 |
| postgresql_version | PostgreSQL 15.5 on x86_64-pc-linux-gnu, compiled by x86_64-pc-linux-gnu-gcc (GCC) 9.5.0, 64-bit |
| babelfish_compatibility | Babelfish for Aurora Postgres with SQL Server Compatibility - 12.0.2000.8 |
```
Upgrading your Babelfish cluster to a new version

New versions of Babelfish become available with some new releases of the Aurora PostgreSQL database engine after version 13.4. Each new release of Babelfish has its own version number. As with Aurora PostgreSQL, Babelfish uses the major.minor.patch naming scheme for versions. For example, the first Babelfish release, Babelfish version 1.0.0, became available as part of Aurora PostgreSQL 13.4.0.

Babelfish doesn't require a separate installation process. As discussed in Creating a Babelfish for Aurora PostgreSQL DB cluster, Turn on Babelfish is an option that you choose when you create an Aurora PostgreSQL DB cluster.

Likewise, you can't upgrade Babelfish independently from the supporting Aurora DB cluster. To upgrade an existing Babelfish for Aurora PostgreSQL DB cluster to a new version of Babelfish, you upgrade the Aurora PostgreSQL DB cluster to a new version that supports the version of Babelfish that you want to use. The procedure that you follow for the upgrade depends on the version of Aurora PostgreSQL that's supporting your Babelfish deployment, as follows.

**Major version upgrades**

You must upgrade the following Aurora PostgreSQL versions to Aurora PostgreSQL 14.6 and higher version before upgrading to Aurora PostgreSQL 15.2 version.

- Aurora PostgreSQL 13.8 and all higher versions
- Aurora PostgreSQL 13.7.1 and all higher minor versions
- Aurora PostgreSQL 13.6.4 and all higher minor versions

You can upgrade Aurora PostgreSQL 14.6 and higher versions to Aurora PostgreSQL 15.2 and higher versions.

Upgrading an Aurora PostgreSQL DB cluster to a new major version involves several preliminary tasks. For more information, see [How to perform a major version upgrade](#). To successfully
upgrade your Babelfish for Aurora PostgreSQL DB cluster, you need to create a custom DB cluster parameter group for the new Aurora PostgreSQL version. This new parameter group must contain the same Babelfish parameter settings as that of the cluster that you're upgrading. For more information and for a table of major version upgrade sources and targets, see Upgrading Babelfish to a new major version.

**Minor version upgrades and patches**

Minor versions and patches don't require the creation of a new DB cluster parameter group for the upgrade. Minor versions and patches can use the minor version upgrade process, whether that's applied automatically or manually. For more information and a table of version sources and targets, see Upgrading Babelfish to a new minor version.

**Note**

Before performing a major or a minor upgrade, apply all pending maintenance tasks to your Babelfish for Aurora PostgreSQL cluster.

**Topics**

- Upgrading Babelfish to a new minor version
- Upgrading Babelfish to a new major version

**Upgrading Babelfish to a new minor version**

A new minor version includes only changes that are backward compatible. A patch version includes important fixes for a minor version after its release. For example, the version label for the first release of Aurora PostgreSQL 13.4 was Aurora PostgreSQL 13.4.0. Several patches for that minor version have been released to date, including Aurora PostgreSQL 13.4.1, 13.4.2, and 13.4.4. You can find the patches available for each Aurora PostgreSQL version in the Patch releases list at the top of the Aurora PostgreSQL release notes for that version. For an example, see PostgreSQL 14.3 in the Release Notes for Aurora PostgreSQL.

If your Aurora PostgreSQL DB cluster is configured with the **Auto minor version upgrade** option, your Babelfish for Aurora PostgreSQL DB cluster is upgraded automatically during the cluster's maintenance window. To learn more about auto minor version upgrade (AmVU) and how to use it, see Automatic minor version upgrades for Aurora DB clusters. If your cluster isn't using AmVU,
you can manually upgrade your Babelfish for Aurora PostgreSQL DB cluster to new minor versions either by responding to maintenance tasks, or by modifying the cluster to use the new version.

When you choose an Aurora PostgreSQL version to install and when you view an existing Aurora PostgreSQL DB cluster in the AWS Management Console, the version displays the major.minor digits only. For example, the following image from the Console for an existing Babelfish for Aurora PostgreSQL DB cluster with Aurora PostgreSQL 13.4 recommends upgrading the cluster to version 13.7, a new minor release of Aurora PostgreSQL.

To get complete version details, including the patch level, you can query the Aurora PostgreSQL DB cluster using the aurora_version Aurora PostgreSQL function. For more information, see aurora_version in the Aurora PostgreSQL functions reference. You can find an example of using the function in the To use the PostgreSQL port to query for version information procedure in Identifying your version of Babelfish.

The following table shows Aurora PostgreSQL and Babelfish version and the available target versions that can support the minor version upgrade process.
<table>
<thead>
<tr>
<th>Current source versions</th>
<th>Newest upgrade targets</th>
<th>Other available upgrade versions</th>

Upgrading Babelfish to a new major version

For a major version upgrade, you need to first upgrade your Babelfish for Aurora PostgreSQL DB cluster to a version that supports the major version upgrade. To achieve this, apply patch updates or minor version upgrades to your DB cluster. For more information, see Upgrading Babelfish to a new minor version.

The following table shows Aurora PostgreSQL version and Babelfish version that can support a major version upgrade.

<table>
<thead>
<tr>
<th>Current source versions</th>
<th>Newest available upgrade target</th>
<th>Other available versions (minor version upgrades)</th>
</tr>
</thead>
<tbody>

</table>

### Before upgrading Babelfish to a new major version

An upgrade might involve brief outages. For that reason, we recommend that you perform or schedule upgrades during your maintenance window or during other periods of low usage.

### Before you perform a major version upgrade

1. Identify the Babelfish version of your existing Aurora PostgreSQL DB cluster by using the commands outlined in [Identifying your version of Babelfish](#). The Aurora PostgreSQL version and Babelfish version information is handled by PostgreSQL, so follow the steps detailed in the [To use the PostgreSQL port to query for version information](#) procedure to get the details.

2. Verify if your version supports the major version upgrade. For the list of versions that support the major version upgrade feature, see [Upgrading Babelfish to a new minor version](#) and perform the necessary pre-upgrade tasks.

   For example, if your Babelfish version is running on an Aurora PostgreSQL 13.5 DB cluster and you want to upgrade to Aurora PostgreSQL 15.2, then first apply all the minor releases and patches to upgrade your cluster to Aurora PostgreSQL 14.6 or higher version. When your cluster is at version 14.6 or higher, continue with the major version upgrade process.

3. Create a manual snapshot of your current Babelfish DB cluster as a backup. The backup lets you restore the cluster to its Aurora PostgreSQL version, Babelfish version, and restore all data to the state before the upgrade. For more information, see [Creating a DB cluster snapshot](#). Be sure to keep your existing custom DB cluster parameter group to use again if you decide to
restore this cluster to its pre-upgraded state. For more information, see `Restoring from a DB cluster snapshot` and `Parameter group considerations`.

4. Prepare a custom DB cluster parameter group for the target Aurora PostgreSQL DB version. Duplicate the settings for the Babelfish parameters from your current Babelfish for Aurora PostgreSQL DB cluster. To find a list of all Babelfish parameters, see `DB cluster parameter group settings for Babelfish`. For a major version upgrade, the following parameters require the same settings as the source DB cluster. For the upgrade to succeed, all the settings must be the same.

- `rds.babelfish_status`
- `babelfishpg_tds.tds_default_numeric_precision`
- `babelfishpg_tds.tds_default_numeric_scale`
- `babelfishpg_tsql.database_name`
- `babelfishpg_tsql.default_locale`
- `babelfishpg_tsql.migration_mode`
- `babelfishpg_tsql.server_collation_name`

**Warning**

If the settings for the Babelfish parameters in the custom DB cluster parameter group for the new Aurora PostgreSQL version don't match the parameter values of the cluster that you're upgrading, the `ModifyDBCluster` operation fails. An `InvalidParameterCombination` error message appears in the AWS Management Console or in the output from the `modify-db-cluster` AWS CLI command.

5. Use the AWS Management Console or the AWS CLI to create the custom DB cluster parameter group. Choose the applicable Aurora PostgreSQL family for the version of Aurora PostgreSQL that you want for the upgrade.

**Tip**

Parameter groups are managed at the AWS Region level. When you work with AWS CLI, you can configure with a default Region instead of specifying the `--region` in the command. To learn more about using the AWS CLI, see `Quick setup` in the `AWS Command Line Interface User Guide`. 

Babelfish versions
Performing major version upgrade

1. Upgrade Aurora PostgreSQL DB cluster to a new major version. For more information, see Upgrading the Aurora PostgreSQL engine to a new major version.

2. Reboot the writer instance of the cluster, so that the parameter settings can take effect.

After upgrading to a new major version

After a major version upgrade to a new Aurora PostgreSQL version, the IDENTITY value in tables with an IDENTITY column might be larger (+32) than the value was before the upgrade. The result is that when the next row is inserted into such tables, the generated identity column value jumps to the +32 number and starts the sequence from there. This condition won't negatively affect the functions of your Babelfish DB cluster. However, if you want, you can reset the sequence object based on the maximum value of the column. To do so, connect to the T-SQL port on your Babelfish writer instance using sqlcmd or another SQL Server client. For more information, see Using a SQL Server client to connect to your DB cluster.

```sql
DECLARE @schema_prefix NVARCHAR(200) = ''
IF current_setting('babelfishpg_tsql.migration_mode') = 'multi-db'
    SET @schema_prefix = db_name() + '_'
SELECT 'SELECT setval(pg_get_serial_sequence(''' + @schema_prefix +
    schema_name(tables.schema_id) + '.' + tables.name + ''', ''' + columns.name + '''),(select max(' + columns.name + ')
    FROM ' + schema_name(tables.schema_id) + '.' + tables.name + '));
FROM sys.tables tables JOIN sys.columns
    ON tables.object_id = columns.object_id
WHERE columns.is_identity = 1
GO
```

When connected, use the following SQL command to generate statements that you can use to seed the associated sequence object. This SQL command works for both single database and multiple database Babelfish configurations. For more information about these two deployment models, see Using Babelfish with a single database or multiple databases.

```sql
sqlcmd -S bfish-db.cluster-123456789012.aws-region.rds.amazonaws.com,1433 -U sa -P ******** -d dbname
```
The query generates a series of SELECT statements that you can then run to reset the maximum IDENTITY value and close any gap. The following shows the output when using the sample SQL Server database, Northwind, running on a Babelfish cluster.

```
--------------------------------------------------------
SELECT setval(pg_get_serial_sequence('northwind_dbo.categories', 'categoryid'),(select max(categoryid)
                                    FROM dbo.categories));

SELECT setval(pg_get_serial_sequence('northwind_dbo.orders', 'orderid'),(select max(orderid)
                                    FROM dbo.orders));

SELECT setval(pg_get_serial_sequence('northwind_dbo.products', 'productid'),(select max(productid)
                                    FROM dbo.products));

SELECT setval(pg_get_serial_sequence('northwind_dbo.shippers', 'shipperid'),(select max(shipperid)
                                    FROM dbo.shippers));

SELECT setval(pg_get_serial_sequence('northwind_dbo.suppliers', 'supplierid'),(select max(supplierid)
                                    FROM dbo.suppliers));

(5 rows affected)
```

Run the statements one by one to reset the sequence values.

**Example: Upgrading the Babelfish DB cluster to a major release**

In this example, you can find the series of AWS CLI commands that explains how to upgrade an Aurora PostgreSQL 13.6.4 DB cluster running Babelfish version 1.2.2 to Aurora PostgreSQL 14.6. First, you create a custom DB cluster parameter group for Aurora PostgreSQL 14. Next, you modify the parameter values to match those of your Aurora PostgreSQL version 13 source. Finally, you perform the upgrade by modifying the source cluster. For more information, see [DB cluster parameter group settings for Babelfish](https://docs.aws.amazon.com/ramen-auctions/latest/userguide/db-cluster-parameter-group-settings-for-babelfish.html). In that topic, you can also find information about using the AWS Management Console to perform the upgrade.
Use the `create-db-cluster-parameter-group` CLI command to create the DB cluster parameter group for the new version.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster-parameter-group \
  --db-cluster-parameter-group-name docs-lab-babelfish-apg-14 \
  --db-parameter-group-family aurora-postgresql14 \
  --description 'New custom parameter group for upgrade to new major version' \
  --region us-west-1
```

When you issue this command, the custom DB cluster parameter group is created in the AWS Region. You see output similar to the following.

```
{
  "DBClusterParameterGroup": {
    "DBClusterParameterGroupName": "docs-lab-babelfish-apg-14",
    "DBParameterGroupFamily": "aurora-postgresql14",
    "Description": "New custom parameter group for upgrade to new major version",
  }
}
```

For more information, see [Creating a DB cluster parameter group](#).

Use the `modify-db-cluster-parameter-group` CLI command to modify the settings so that they match the source cluster.

For Windows:

```bash
aws rds modify-db-cluster-parameter-group --db-cluster-parameter-group-name docs-lab-babelfish-apg-14 \
  --parameters
  "ParameterName=rds.babelfish_status,ParameterValue=on,ApplyMethod=pending-reboot" \
  "ParameterName=babelfishpg_tds.tds_default_numeric_precision,ParameterValue=38,ApplyMethod=pending-reboot" \
  "ParameterName=babelfishpg_tds.tds_default_numeric_scale,ParameterValue=8,ApplyMethod=pending-reboot" \
  "ParameterName=babelfishpg_tsql.database_name,ParameterValue=babelfish_db,ApplyMethod=pending-reboot"
```

Babelfish versions

2216
"ParameterName=babelfishpg_tsql.default_locale,ParameterValue=\texttt{en-US},ApplyMethod=pending-reboot" ^
"ParameterName=babelfishpg_tsql.migration_mode,ParameterValue=\texttt{single-db},ApplyMethod=pending-reboot" ^
"ParameterName=babelfishpg_tsql.server_collation_name,ParameterValue=\texttt{sql_latin1_general_cp1_ci_as},ApplyMethod=pending-reboot"

The response looks similar to the following.

```json
{
   "DBClusterParameterGroupName": "docs-lab-babelfish-apg-14"
}
```

Use the  \texttt{modify-db-cluster} CLI command to modify the cluster to use the new version and the new custom DB cluster parameter group. You also specify the  \texttt{--allow-major-version-upgrade} argument, as shown in the following sample.

```
aws rds modify-db-cluster \
--db-cluster-identifier docs-lab-bfish-apg-14 \ 
--engine-version 14.6 \ 
--db-cluster-parameter-group-name docs-lab-babelfish-apg-14 \ 
--allow-major-version-upgrade \ 
--region us-west-1 \ 
--apply-immediately
```

Use the  \texttt{reboot-db-instance} CLI command to reboot the writer instance of the cluster, so that the parameter settings can take effect.

```
aws rds reboot-db-instance \ 
--db-instance-identifier docs-lab-bfish-apg-14-instance-1\ 
--region us-west-1
```

**Using Babelfish product version parameter**

A new Grand Unified Configuration (GUC) parameter called \texttt{babelfishpg_tds.product_version} is introduced from Babelfish 2.4.0 and 3.1.0 versions. This parameter allows you to set the SQL Server product version number as the output of Babelfish.

The parameter is a 4-part version ID string, and each part should be separated by ".".
Syntax

Major.Minor.Build.Revision

- Major Version: A number between 11 and 16.
- Minor Version: A number between 0 and 255.
- Build Version: A number between 0 and 65535.
- Revision: 0 and any positive number.

Configuring Babelfish product version parameter

You must use the cluster parameter group to set the babelfishpg_tds.product_version parameter in the console. For more information on how to modify the DB cluster parameter, see Modifying parameters in a DB cluster parameter group.

When you set the product version parameter to an invalid value, the change will not take effect. Although the console might show you the new value, the parameter retains the previous value. Check the engine log file for details about the error messages.

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
    --db-cluster-parameter-group-name mydbparametergroup \
    --parameters
    "ParameterName=babelfishpg_tds.product_version,ParameterValue=15.2.4000.1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^
    --db-cluster-parameter-group-name mydbparametergroup ^
    --parameters
    "ParameterName=babelfishpg_tds.product_version,ParameterValue=15.2.4000.1,ApplyMethod=immediate"
```
### Affected queries and parameter

<table>
<thead>
<tr>
<th>Query/Parameter</th>
<th>Result</th>
<th>Effective time</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT @@VERSION</td>
<td>Returns user defined SQL Server version (babelfishpg_tsql.version value = Default)</td>
<td>Immediately</td>
</tr>
<tr>
<td>SELECT SERVERPROPERTY('ProductVersion')</td>
<td>Returns user defined SQL Server version</td>
<td>Immediately</td>
</tr>
<tr>
<td>SELECT SERVERPROPERTY('ProductMajorVersion')</td>
<td>Returns Major Version of the user defined SQL Server version</td>
<td>Immediately</td>
</tr>
<tr>
<td>VERSION tokens in PRELOGIN Response Message</td>
<td>Server returns PRELOGIN messages with user defined SQL Server version</td>
<td>Takes effect when a user creates a new session</td>
</tr>
<tr>
<td>SQLServerVersion in LoginAck when using JDBC</td>
<td>DatabaseMetaData.getDatabaseProductVersion() returns user defined SQL Server version</td>
<td>Takes effect when a user creates a new session</td>
</tr>
</tbody>
</table>

### Interface with babelfishpg_tsql.version parameter

You can set the output of the @@VERSION using the parameters babelfishpg_tsql.version and babelfishpg_tds.product_version. The following examples show how these two parameters interface.

- When babelfishpg_tsql.version parameter is "default" and babelfishpg_tds.product_version is 15.0.2000.8.
- When babelfishpg_tsql.version parameter is set to 13.0.2000.8 and babelfishpg_tds.product_version parameter is 15.0.2000.8.

<td>Without SCHEMABINDING clause</td>
<td>Creating a view without SCHEMABINDING isn't supported, but the view is created as if WITH SCHEMABINDING was specified. Using SCHEMABINDING when creating functions, procedures, triggers is silently ignored.</td>
</tr>
</tbody>
</table>

**Settings that aren't supported**

The following settings aren't supported:

- SET ANSI_NULL_DFLT_OFF ON
- SET ANSI_NULL_DFLT_ON OFF
- SET ANSI_PADDING OFF
- SET ANSI_WARNINGS OFF
- SET ARITHABORT OFF
- SET ARITHIGNORE ON
- SET CURSOR_CLOSE_ON_COMMIT ON
- SET NUMERIC_ROUNDABORT ON
- SET PARSEONLY ON (command doesn't work as expected)
- SET FMTONLY ON (command doesn't work as expected. It suppresses only the execution of SELECT statements but not others.)
Commands that aren't supported

Certain functionality for the following commands isn't supported:

- ADD SIGNATURE
- ALTER DATABASE, ALTER DATABASE SET
- BACKUP/RESTORE DATABASE/LOG
- BACPAC and DACPAC FILES RESTORE
- CREATE, ALTER, DROP AUTHORIZATION. ALTER AUTHORIZATION is supported for database objects.
- CREATE, ALTER, DROP AVAILABILITY GROUP
- CREATE, ALTER, DROP BROKER PRIORITY
- CREATE, ALTER, DROP COLUMN ENCRYPTION KEY
- CREATE, ALTER, DROP DATABASE ENCRYPTION KEY
- CREATE, ALTER, DROP, BACKUP CERTIFICATE
- CREATE AGGREGATE
- CREATE CONTRACT
- CHECKPOINT

Column names or attributes that aren't supported

The following column names aren't supported:

- $IDENTITY
- $ROWGUID
- IDENTITYCOL

Data types that aren't supported

The following data types aren't supported:

- Geospatial (GEOGRAPHY and GEOMETRY)
- HIERARCHYID
Object types that aren't supported

The following object types aren't supported:

- COLUMN MASTER KEY
- CREATE, ALTER EXTERNAL DATA SOURCE
- CREATE, ALTER, DROP DATABASE AUDIT SPECIFICATION
- CREATE, ALTER, DROP EXTERNAL LIBRARY
- CREATE, ALTER, DROP SERVER AUDIT
- CREATE, ALTER, DROP SERVER AUDIT SPECIFICATION
- CREATE, ALTER, DROP, OPEN/CLOSE SYMMETRIC KEY
- CREATE, DROP DEFAULT
- CREDENTIAL
- CRYPTOGRAPHIC PROVIDER
- DIAGNOSTIC SESSION
- Indexed views
- SERVICE MASTER KEY
- SYNONYM

Functions that aren't supported

The following built-in functions aren't supported:

Aggregate functions

- APPROX_COUNT_DISTINCT
- CHECKSUM_AGG
- GROUPING_ID
- STRING_AGG using the WITHIN GROUP clause

Cryptographic functions

- CERTENCODED function
• CERTID function
• CERTPROPERTY function

**Metadata functions**

• COLUMNPROPERTY
• TYPEPROPERTY

• SERVERPROPERTY function – The following properties aren't supported:
  • BuildClrVersion
  • ComparisonStyle
  • ComputerNamePhysicalNetBIOS
  • HadrManagerStatus
  • InstanceDefaultDataPath
  • InstanceDefaultLogPath
  • IsClustered
  • IsHadrEnabled
  • LCID
  • NumLicenses
  • ProcessID
  • ProductBuild
  • ProductBuildType
  • ProductUpdateReference
  • ResourceLastUpdateDateTime
  • ResourceVersion
  • ServerName
  • SqlCharSet
  • SqlCharSetName
  • SqlSortOrder
  • SqlSortOrderName
  • FilestreamShareName
  • FilestreamConfiguredLevel
• FilestreamEffectiveLevel

Security functions

• CERTPRIVATEKEY
• LOGINPROPERTY

Statements, operators, other functions

• EVENTDATA function
• GET_TRANSMISSION_STATUS
• OPENXML

Syntax that isn't supported

The following syntax isn't supported:

• ALTER DATABASE
• ALTER DATABASE SCOPED CONFIGURATION
• ALTER DATABASE SCOPED CREDENTIAL
• ALTER DATABASE SET HADR
• ALTER FUNCTION
• ALTER INDEX
• ALTER PROCEDURE statement
• ALTER SCHEMA
• ALTER SERVER CONFIGURATION
• ALTER SERVICE, BACKUP/RESTORE SERVICE MASTER KEY clause
• ALTER VIEW
• BEGIN CONVERSATION TIMER
• BEGIN DISTRIBUTED TRANSACTION
• BEGIN DIALOG CONVERSATION
• BULK INSERT
• CREATE COLUMNSTORE INDEX
• CREATE EXTERNAL FILE FORMAT
• CREATE EXTERNAL TABLE
• CREATE, ALTER, DROP APPLICATION ROLE
• CREATE, ALTER, DROP ASSEMBLY
• CREATE, ALTER, DROP ASYMMETRIC KEY
• CREATE, ALTER, DROP CREDENTIAL
• CREATE, ALTER, DROP CRYPTOGRAPHIC PROVIDER
• CREATE, ALTER, DROP ENDPOINT
• CREATE, ALTER, DROP EVENT SESSION
• CREATE, ALTER, DROP EXTERNAL LANGUAGE
• CREATE, ALTER, DROP EXTERNAL RESOURCE POOL
• CREATE, ALTER, DROP FULLTEXT CATALOG
• CREATE, ALTER, DROP FULLTEXT INDEX
• CREATE, ALTER, DROP FULLTEXT STOPLIST
• CREATE, ALTER, DROP MESSAGE TYPE
• CREATE, ALTER, DROP, OPEN/CLOSE, BACKUP/RESTORE MASTER KEY
• CREATE, ALTER, DROP PARTITION FUNCTION
• CREATE, ALTER, DROP PARTITION SCHEME
• CREATE, ALTER, DROP QUEUE
• CREATE, ALTER, DROP RESOURCE GOVERNOR
• CREATE, ALTER, DROP RESOURCE POOL
• CREATE, ALTER, DROP ROUTE
• CREATE, ALTER, DROP SEARCH PROPERTY LIST
• CREATE, ALTER, DROP SECURITY POLICY
• CREATE, ALTER, DROP SELECTIVE XML INDEX clause
• CREATE, ALTER, DROP SERVICE
• CREATE, ALTER, DROP SPATIAL INDEX
• CREATE, ALTER, DROP TYPE
• CREATE, ALTER, DROP XML INDEX
• CREATE, ALTER, DROP XML SCHEMA COLLECTION
• CREATE/DROP RULE
• CREATE, DROP WORKLOAD CLASSIFIER
• CREATE, ALTER, DROP WORKLOAD GROUP
• ALTER TRIGGER
• CREATE TABLE... GRANT clause
• CREATE TABLE... IDENTITY clause
• CREATE USER – This syntax isn't supported. The PostgreSQL statement CREATE USER doesn't create a user that is equivalent to the SQL Server CREATE USER syntax. For more information, see T-SQL differences in Babelfish.
• DENY
• END, MOVE CONVERSATION
• EXECUTE with AS LOGIN or AT option
• GET CONVERSATION GROUP
• GROUP BY ALL clause
• GROUP BY CUBE clause
• GROUP BY ROLLUP clause
• INSERT... DEFAULT VALUES
• MERGE
• READTEXT
• REVERT
• SELECT PIVOT(supported from 3.4.0 and higher releases except when used in a view definition, a common table expression, or a join)/UNPIVOT
• SELECT TOP x PERCENT WHERE x <> 100
• SELECT TOP... WITH TIES
• SELECT... FOR BROWSE
• SELECT... FOR XML AUTO
• SELECT... FOR XML EXPLICIT
• SEND
• SET DATEFORMAT
• SET DEADLOCK_PRIORITY
• SET FMTONLY
• SET FORCEPLAN
• SET NUMERIC_ROUNDABORT ON
• SET OFFSETS
• SET REMOTE_PROC_TRANSACTIONS
• SET SHOWPLAN_TEXT
• SET SHOWPLAN_XML
• SET STATISTICS
• SET STATISTICS PROFILE
• SET STATISTICS TIME
• SET STATISTICS XML
• SHUTDOWN statement
• UPDATE STATISTICS
• UPDATETEXT
• Using EXECUTE to call a SQL function
• VIEW... CHECK OPTION clause
• VIEW... VIEW_METADATA clause
• WAITFOR DELAY
• WAITFOR TIME
• WAITFOR, RECEIVE
• WITH XMLNAMESPACES construct
• WRITETEXT
• XPATH expressions
Supported functionality in Babelfish by version

In the following table you can find T-SQL functionality supported by different Babelfish versions. For lists of unsupported functionality, see Unsupported functionality in Babelfish. For information about various Babelfish releases, see the Release Notes for Aurora PostgreSQL.

T-SQL Functionality or syntax

Cross-database references:
- SELECT, SELECT INTO, INSERT, UPDATE, DELETE

Cursor-ped parameters for input parameters only (not output)
T-SQL Functionality

Data migration using the bcp client utility

Datatypes TIMESTAMP, ROWVERSION (for usage information, see Features with limited implementation)

Babelfish for Aurora PostgreSQL procedure reference

Overview

You can use the following procedure for Amazon RDS DB instances running Babelfish for Aurora PostgreSQL for a better query performance:

- `sp_babelfish_volatility`
- `sp_execute_postgresql`

**sp_babelfish_volatility**

PostgreSQL function volatility helps the optimizer for a better query execution which when used in parts of certain clauses has a significant impact on query performance.

**Syntax**

```
sp_babelfish_volatility 'function_name', 'volatility'
```

**Arguments**

*function_name (optional)*

You can either specify the value of this argument with a two-part name as `schema_name.function_name` or only the `function_name`. If you specify only the `function_name`, the schema name is the default schema for the current user.

*volatility (optional)*

The valid PostgreSQL values of volatility are stable, volatile, or immutable. For more information, see [https://www.postgresql.org/docs/current/xfunc-volatility.html](https://www.postgresql.org/docs/current/xfunc-volatility.html)

**Note**

When `sp_babelfish_volatility` is called with `function_name` which has multiple definitions, it will throw an error.
Result set

If the parameters are not mentioned then the result set is displayed under the following columns: schemaname, functionname, volatility.

Usage notes

PostgreSQL function volatility helps the optimizer for a better query execution which when used in parts of certain clauses has a significant impact on query performance.

Examples

The following examples shows how to create simple functions and later explains how to use sp_babelfish_volatility on these functions using different methods.

```
1> create function f1() returns int as begin return 0 end
2> go

1> create schema test_schema
2> go

1> create function test_schema.f1() returns int as begin return 0 end
2> go
```

The following example displays volatility of the functions:

```
1> exec sp_babelfish_volatility
2> go

schemaname functionname volatility
----------------- -----------
dbo  f1           volatile
test_schema f1   volatile
```

The following example shows how to change the volatility of the functions:

```
1> exec sp_babelfish_volatility 'f1','stable'
2> go
1> exec sp_babelfish_volatility 'test_schema.f1','immutable'
2> go
```
When you specify only the function_name, it displays the schema name, function name and volatility of that function. The following example displays volatility of functions after changing the values:

```
1> exec sp_babelfish_volatility 'test_schema.f1'
2> go

schemaname functionname volatility
----------------- ---------------
test_schema f1 immutable
```

```
1> exec sp_babelfish_volatility 'f1'
2> go

schemaname functionname volatility
----------------- ---------------
dbo f1 stable
```

When you don't specify any argument, it displays a list of functions (schema name, function name, volatility of the functions) present in the current database:

```
1> exec sp_babelfish_volatility
2> go

schemaname functionname volatility
----------------- ---------------
dbo f1 stable
	test_schema f1 immutable
```

**sp_execute_postgresql**

You can execute PostgreSQL statements from T-SQL endpoint. This simplifies your applications as you don’t need to exit T-SQL port to execute these statements.

**Syntax**
sp_execute_postgresql [ @stmt = ] statement

Arguments

[ @stmt ] statement

The argument is of datatype varchar. This argument accept PG dialect statements.

⚠️ Note

You can only pass one PG dialect statement as an argument otherwise it will raise the following error.

```
1>exec sp_execute_postgresql 'create extension pg_stat_statements; drop extension pg_stat_statements'
2>go
```

Msg 33557097, Level 16, State 1, Server BABELFISH, Line 1
expected 1 statement but got 2 statements after parsing

Usage notes

**CREATE EXTENSION**

Creates and loads a new extension into the current database.

```
1>EXEC sp_execute_postgresql 'create extension [ IF NOT EXISTS ] <extension name>
[ WITH ] [SCHEMA schema_name] [VERSION version]';
2>go
```

The following example shows how to create an extension:

```
1>EXEC sp_execute_postgresql 'create extension pg_stat_statements with schema sys
version "1.10"';
2>go
```
Use the following command to access extension objects:

```
1> select * from pg_stat_statements;
2> go
```

**Note**
If schema name is not provided explicitly during extension creation, by default the extensions are installed in the public schema. You must provide the schema qualifier to access the extension objects as mentioned below:

```
1> select * from [public].pg_stat_statements;
2> go
```

**Supported extensions**

The following extensions available with Aurora PostgreSQL works with Babelfish.

- `pg_stat_statements`
- `tds_fdw`
- `fuzzystrmatch`

**Limitations**

- Users need to have sysadmin role on T-SQL and rds_superuser on postgres to install the extensions.
- Extensions cannot be installed in user created schemas and also in dbo and guest schemas for master, tempdb and msdb database.
- CASCADE option is not supported.

**ALTER EXTENSION**

You can upgrade to a new extension version using ALTER extension.
 LIMITATIONS

- You can upgrade the version of your extension only using the ALTER Extension statement. Other operations aren't supported.

DROP EXTENSION

Drops the specified extension. You can also use `if exists` or `restrict` options to drop the extension.

LIMITATIONS

- CASCADE option is not supported.

Managing Amazon Aurora PostgreSQL

The following section discusses managing performance and scaling for an Amazon Aurora PostgreSQL DB cluster. It also includes information about other maintenance tasks.

Topics

- Scaling Aurora PostgreSQL DB instances
- Maximum connections to an Aurora PostgreSQL DB instance
- Temporary storage limits for Aurora PostgreSQL
- Huge pages for Aurora PostgreSQL
- Testing Amazon Aurora PostgreSQL by using fault injection queries
- Displaying volume status for an Aurora PostgreSQL DB cluster
- Specifying the RAM disk for the stats_temp_directory
- Managing temporary files with PostgreSQL
Scaling Aurora PostgreSQL DB instances

You can scale Aurora PostgreSQL DB instances in two ways, instance scaling and read scaling. For more information about read scaling, see Read scaling.

You can scale your Aurora PostgreSQL DB cluster by modifying the DB instance class for each DB instance in the DB cluster. Aurora PostgreSQL supports several DB instance classes optimized for Aurora. Don't use db.t2 or db.t3 instance classes for larger Aurora clusters of size greater than 40 terabytes (TB).

Note

We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more details on the T instance classes, see DB instance class types.

Scaling isn't instantaneous. It can take 15 minutes or more to complete the change to a different DB instance class. If you use this approach to modify the DB instance class, you apply the change during the next scheduled maintenance window (rather than immediately) to avoid affecting users.

As an alternative to modifying the DB instance class directly, you can minimize downtime by using the high availability features of Amazon Aurora. First, add an Aurora Replica to your cluster. When creating the replica, choose the DB instance class size that you want to use for your cluster. When the Aurora Replica is synchronized with the cluster, you then failover to the newly added Replica. To learn more, see Aurora Replicas and Fast failover with Amazon Aurora PostgreSQL.

For detailed specifications of the DB instance classes supported by Aurora PostgreSQL, see Supported DB engines for DB instance classes.

Maximum connections to an Aurora PostgreSQL DB instance

An Aurora PostgreSQL DB cluster allocates resources based on the DB instance class and its available memory. Each connection to the DB cluster consumes incremental amounts of these resources, such as memory and CPU. Memory consumed per connection varies based on query type, count, and whether temporary tables are used. Even an idle connection consumes memory and CPU. That's because when queries run on a connection, more memory is allocated for each query and it's not released completely, even when processing stops. Thus, we recommend that you make sure your applications aren't holding on to idle connections: each one of these wastes
resources and affects performance negatively. For more information, see Resources consumed by idle PostgreSQL connections.

The maximum number of connections allowed by an Aurora PostgreSQL DB instance is determined by the max_connections parameter value specified in the parameter group for that DB instance. The ideal setting for the max_connections parameter is one that supports all the client connections your application needs, without an excess of unused connections, plus at least 3 more connections to support AWS automation. Before modifying the max_connections parameter setting, we recommend that you consider the following:

- If the max_connections value is too low, the Aurora PostgreSQL DB instance might not have sufficient connections available when clients attempt to connect. If this happens, attempts to connect using psql raise error messages such as the following:

```
psql: FATAL: remaining connection slots are reserved for non-replication superuser connections
```

- If the max_connections value exceeds the number of connections that are actually needed, the unused connections can cause performance to degrade.

The default value of max_connections is derived from the following Aurora PostgreSQL LEAST function:

```
LEAST([{DBInstanceClassMemory/9531392},5000]).
```

If you want to change the value for max_connections, you need to create a custom DB cluster parameter group and change its value there. After applying your custom DB parameter group to your cluster, be sure to reboot the primary instance so the new value takes effect. For more information, see Amazon Aurora PostgreSQL parameters and Creating a DB cluster parameter group.

Tip

If your applications frequently open and close connections, or keep a large number of long-lived connections open, we recommend that you use Amazon RDS Proxy. RDS Proxy is a fully managed, highly available database proxy that uses connection pooling to share database connections securely and efficiently. To learn more about RDS Proxy, see Using Amazon RDS Proxy for Aurora.
For details about how Aurora Serverless v2 instances handle this parameter, see Maximum connections for Aurora Serverless v2.

**Temporary storage limits for Aurora PostgreSQL**

Aurora PostgreSQL stores tables and indexes in the Aurora storage subsystem. Aurora PostgreSQL uses separate temporary storage for non-persistent temporary files. This includes files that are used for such purposes as sorting large data sets during query processing or for index build operations. For more information, see the article How can I troubleshoot local storage issues in Aurora PostgreSQL-Compatible instances?

These local storage volumes are backed by Amazon Elastic Block Store and can be extended by using a larger DB instance class. For more information about storage, see Amazon Aurora storage and reliability. You can also increase your local storage for temporary objects by using an NVMe enabled instance type and Aurora Optimized Reads-enabled temporary objects. For more information, see Improving query performance for Aurora PostgreSQL with Aurora Optimized Reads.

**Note**

You might see storage-optimization events when scaling DB instances, for example, from db.r5.2xlarge to db.r5.4xlarge.

The following table shows the maximum amount of temporary storage available for each Aurora PostgreSQL DB instance class. For more information on DB instance class support for Aurora, see Aurora DB instance classes.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Note**

NVMe enabled instance types can increase the temporary space available by up to the total NVMe size. For more information, see [Improving query performance for Aurora PostgreSQL with Aurora Optimized Reads](#).

You can monitor the temporary storage available for a DB instance with the `FreeLocalStorage` CloudWatch metric, as described in [Amazon CloudWatch metrics for Amazon Aurora](#). (This doesn't apply to Aurora Serverless v2.)

For some workloads, you can reduce the amount of temporary storage by allocating more memory to the processes that are performing the operation. To increase the memory available to an operation, increasing the values of the `work_mem` or `maintenance_work_mem` PostgreSQL parameters.

### Huge pages for Aurora PostgreSQL

**Huge pages** are a memory management feature that reduces overhead when a DB instance is working with large contiguous chunks of memory, such as that used by shared buffers. This PostgreSQL feature is supported by all currently available Aurora PostgreSQL versions.

The `huge_pages` parameter is turned on by default for all DB instance classes other than `t3.medium`, `db.t3.large`, `db.t4g.medium`, `db.t4g.large` instance classes. You can't change the `huge_pages` parameter value or turn off this feature in the supported instance classes of Aurora PostgreSQL.

### Testing Amazon Aurora PostgreSQL by using fault injection queries

You can test the fault tolerance of your Aurora PostgreSQL DB cluster by using fault injection queries. Fault injection queries are issued as SQL commands to an Amazon Aurora instance. Fault
injection queries let you crash the instance so that you can test failover and recovery. You can also simulate Aurora Replica failure, disk failure, and disk congestion. Fault injection queries are supported by all available Aurora PostgreSQL versions, as follows.

- Aurora PostgreSQL versions 12, 13, 14, and higher
- Aurora PostgreSQL version 11.7 and higher
- Aurora PostgreSQL version 10.11 and higher

**Topics**

- Testing an instance crash
- Testing an Aurora Replica failure
- Testing a disk failure
- Testing disk congestion

When a fault injection query specifies a crash, it forces a crash of the Aurora PostgreSQL DB instance. The other fault injection queries result in simulations of failure events, but don't cause the event to occur. When you submit a fault injection query, you also specify an amount of time for the failure event simulation to occur.

You can submit a fault injection query to one of your Aurora Replica instances by connecting to the endpoint for the Aurora Replica. For more information, see Amazon Aurora connection management.

**Testing an instance crash**

You can force a crash of an Aurora PostgreSQL instance by using the fault injection query function aurora_inject_crash().

For this fault injection query, a failover does not occur. If you want to test a failover, then you can choose the Failover instance action for your DB cluster in the RDS console, or use the failover-db-cluster AWS CLI command or the FailoverDBCluster RDS API operation.

**Syntax**

```sql
SELECT aurora_inject_crash ('instance' | 'dispatcher' | 'node');
```
Options

This fault injection query takes one of the following crash types. The crash type is not case sensitive:

'instance'

A crash of the PostgreSQL-compatible database for the Amazon Aurora instance is simulated.

'dispatcher'

A crash of the dispatcher on the primary instance for the Aurora DB cluster is simulated. The dispatcher writes updates to the cluster volume for an Amazon Aurora DB cluster.

'node'

A crash of both the PostgreSQL-compatible database and the dispatcher for the Amazon Aurora instance is simulated.

Testing an Aurora Replica failure

You can simulate the failure of an Aurora Replica by using the fault injection query function `aurora_inject_replica_failure()`.

An Aurora Replica failure blocks replication to the Aurora Replica or all Aurora Replicas in the DB cluster by the specified percentage for the specified time interval. When the time interval completes, the affected Aurora Replicas are automatically synchronized with the primary instance.

Syntax

```
SELECT aurora_inject_replica_failure(
   percentage_of_failure,
   time_interval,
   'replica_name'
);
```

Options

This fault injection query takes the following parameters:
**percentage_of_failure**

The percentage of replication to block during the failure event. This value can be a double between 0 and 100. If you specify 0, then no replication is blocked. If you specify 100, then all replication is blocked.

**time_interval**

The amount of time to simulate the Aurora Replica failure. The interval is in seconds. For example, if the value is 20, the simulation runs for 20 seconds.

**Note**

Take care when specifying the time interval for your Aurora Replica failure event. If you specify too long an interval, and your writer instance writes a large amount of data during the failure event, then your Aurora DB cluster might assume that your Aurora Replica has crashed and replace it.

**replica_name**

The Aurora Replica in which to inject the failure simulation. Specify the name of an Aurora Replica to simulate a failure of the single Aurora Replica. Specify an empty string to simulate failures for all Aurora Replicas in the DB cluster.

To identify replica names, see the `server_id` column from the `aurora_replica_status()` function. For example:

```sql
postgres=> SELECT server_id FROM aurora_replica_status();
```

**Testing a disk failure**

You can simulate a disk failure for an Aurora PostgreSQL DB cluster by using the fault injection query function `aurora_inject_disk_failure()`.

During a disk failure simulation, the Aurora PostgreSQL DB cluster randomly marks disk segments as faulting. Requests to those segments are blocked for the duration of the simulation.

**Syntax**

```sql
SELECT aurora_inject_disk_failure()
```
Options

This fault injection query takes the following parameters:

**percentage_of_failure**

The percentage of the disk to mark as faulting during the failure event. This value can be a double between 0 and 100. If you specify 0, then none of the disk is marked as faulting. If you specify 100, then the entire disk is marked as faulting.

**index**

A specific logical block of data in which to simulate the failure event. If you exceed the range of available logical blocks or storage nodes data, you receive an error that tells you the maximum index value that you can specify. To avoid this error, see [Displaying volume status for an Aurora PostgreSQL DB cluster](#).

**is_disk**

Indicates whether the injection failure is to a logical block or a storage node. Specifying true means injection failures are to a logical block. Specifying false means injection failures are to a storage node.

**time_interval**

The amount of time to simulate the disk failure. The interval is in seconds. For example, if the value is 20, the simulation runs for 20 seconds.

Testing disk congestion

You can simulate a disk congestion for an Aurora PostgreSQL DB cluster by using the fault injection query function `aurora_inject_disk_congestion()`.

During a disk congestion simulation, the Aurora PostgreSQL DB cluster randomly marks disk segments as congested. Requests to those segments are delayed between the specified minimum and maximum delay time for the duration of the simulation.
Syntax

```sql
SELECT aurora_inject_disk_congestion(
    percentage_of_failure,
    index,
    is_disk,
    time_interval,
    minimum,
    maximum
);
```

Options

This fault injection query takes the following parameters:

**percentage_of_failure**

The percentage of the disk to mark as congested during the failure event. This is a double value between 0 and 100. If you specify 0, then none of the disk is marked as congested. If you specify 100, then the entire disk is marked as congested.

**index**

A specific logical block of data or storage node to use to simulate the failure event.

If you exceed the range of available logical blocks or storage nodes of data, you receive an error that tells you the maximum index value that you can specify. To avoid this error, see [Displaying volume status for an Aurora PostgreSQL DB cluster](#).

**is_disk**

Indicates whether the injection failure is to a logical block or a storage node. Specifying true means injection failures are to a logical block. Specifying false means injection failures are to a storage node.

**time_interval**

The amount of time to simulate the disk congestion. The interval is in seconds. For example, if the value is 20, the simulation runs for 20 seconds.

**minimum, maximum**

The minimum and maximum amount of congestion delay, in milliseconds. Valid values range from 0.0 to 100.0 milliseconds. Disk segments marked as congested are delayed for a random
amount of time within the minimum and maximum range for the duration of the simulation.
The maximum value must be greater than the minimum value.

Displaying volume status for an Aurora PostgreSQL DB cluster

In Amazon Aurora, a DB cluster volume consists of a collection of logical blocks. Each of these represents 10 gigabytes of allocated storage. These blocks are called protection groups.

The data in each protection group is replicated across six physical storage devices, called storage nodes. These storage nodes are allocated across three Availability Zones (AZs) in the region where the DB cluster resides. In turn, each storage node contains one or more logical blocks of data for the DB cluster volume. For more information about protection groups and storage nodes, see Introducing the Aurora storage engine on the AWS Database Blog. To learn more about Aurora cluster volumes in general, see Amazon Aurora storage and reliability.

Use the aurora_show_volume_status() function to return the following server status variables:

- Disks — The total number of logical blocks of data for the DB cluster volume.
- Nodes — The total number of storage nodes for the DB cluster volume.

You can use the aurora_show_volume_status() function to help avoid an error when using the aurora_inject_disk_failure() fault injection function. The aurora_inject_disk_failure() fault injection function simulates the failure of an entire storage node, or a single logical block of data within a storage node. In the function, you specify the index value of a specific logical block of data or storage node. However, the statement returns an error if you specify an index value greater than the number of logical blocks of data or storage nodes used by the DB cluster volume. For more information about fault injection queries, see Testing Amazon Aurora PostgreSQL by using fault injection queries.

Note

The aurora_show_volume_status() function is available for Aurora PostgreSQL version 10.11. For more information about Aurora PostgreSQL versions, see Amazon Aurora PostgreSQL releases and engine versions.
Specifying the RAM disk for the stats_temp_directory

You can use the Aurora PostgreSQL parameter, \texttt{rds.pg_stat_ramdisk_size}, to specify the system memory allocated to a RAM disk for storing the PostgreSQL \texttt{stats_temp_directory}. The RAM disk parameter is only available in Aurora PostgreSQL 14 and lower versions.

Under certain workloads, setting this parameter can improve performance and decrease IO requirements. For more information about the \texttt{stats_temp_directory}, see \texttt{Run-time Statistics} in the PostgreSQL documentation. From PostgreSQL version 15, the PostgreSQL community switched to use dynamic shared memory. So, there is no need to set \texttt{stats_temp_directory}.

To enable a RAM disk for your \texttt{stats_temp_directory}, set the \texttt{rds.pg_stat_ramdisk_size} parameter to a non-zero value in the DB cluster parameter group used by your DB cluster. This parameter denotes MB, so you must use an integer value. Expressions, formulas, and functions aren't valid for the \texttt{rds.pg_stat_ramdisk_size} parameter. Be sure to restart the DB cluster so that the change takes effect. For information about setting parameters, see \texttt{Working with parameter groups}. For more information about restarting the DB cluster, see \texttt{Rebooting an Amazon Aurora DB cluster or Amazon Aurora DB instance}.

As an example, the following AWS CLI command sets the RAM disk parameter to 256 MB.

```bash
aws rds modify-db-cluster-parameter-group \
   --db-cluster-parameter-group-name db-cl-pg-ramdisk-testing \
   --parameters "ParameterName=rds.pg_stat_ramdisk_size, ParameterValue=256, ApplyMethod=pending-reboot"
```

After you restart the DB cluster, run the following command to see the status of the \texttt{stats_temp_directory}:

```bash
postgres=> \texttt{SHOW stats_temp_directory};
```
Managing temporary files with PostgreSQL

In PostgreSQL, a query performing sort and hash operations uses the instance memory to store results up to the value specified in the `work_mem` parameter. When the instance memory is not sufficient, temporary files are created to store the results. These are written to disk to complete the query execution. Later, these files are automatically removed after the query completes. In Aurora PostgreSQL, these files share local storage with other log files. You can monitor your Aurora PostgreSQL DB cluster's local storage space by watching the Amazon CloudWatch metric for `FreeLocalStorage`. For more information, see [Troubleshoot local storage issues](#).

You can use the following parameters and functions to manage the temporary files in your instance.

- **temp_file_limit** – This parameter cancels any query exceeding the size of `temp_files` in KB. This limit prevents any query from running endlessly and consuming disk space with temporary files. You can estimate the value using the results from the `log_temp_files` parameter. As a best practice, examine the workload behavior and set the limit according to the estimation. The following example shows how a query is canceled when it exceeds the limit.

```sql
postgres=> select * from pgbench_accounts, pg_class, big_table;
ERROR: temporary file size exceeds temp_file_limit (64kB)
```

- **log_temp_files** – This parameter sends messages to the `postgresql.log` when the temporary files of a session are removed. This parameter produces logs after a query successfully completes. Therefore, it might not help in troubleshooting active, long-running queries.

The following example shows that when the query successfully completes, the entries are logged in the `postgresql.log` file while the temporary files are cleaned up.
Managing temporary files with PostgreSQL

pg_ls_tmpdir – This function that is available from RDS for PostgreSQL 13 and above provides visibility into the current temporary file usage. The completed query doesn't appear in the results of the function. In the following example, you can view the results of this function.

postgres=> select * from pg_ls_tmpdir();

<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
<th>modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>psql_tmp8355.1</td>
<td>1072250880</td>
<td>2023-02-06 22:54:56+00</td>
</tr>
<tr>

<td>2</td>
<td>2144501760</td>
</tr>
</tbody>
</table>

(4 rows)

- `pg_stat_statements` – If you activate the `pg_stat_statements` parameter, then you can view the average temporary file usage per call. You can identify the query_id of the query and use it to examine the temporary file usage as shown in the following example.

```sql
postgres=> select queryid from pg_stat_statements where query like 'select a.aid from pgbench%';
```

<table>
<thead>
<tr>
<th>queryid</th>
</tr>
</thead>
<tbody>
<tr>
<td>-7170349228837045701</td>
</tr>
</tbody>
</table>

(1 row)

```sql
postgres=> select queryid, substr(query,1,25), calls, temp_blks_read/calls temp_blks_read_per_call, temp_blks_written/calls temp_blks_written_per_call from pg_stat_statements where queryid = -7170349228837045701;
```

<table>
<thead>
<tr>
<th>queryid</th>
<th>substr</th>
<th>calls</th>
<th>temp_blks_read_per_call</th>
<th>temp_blks_written_per_call</th>
</tr>
</thead>
<tbody>
<tr>
<td>-7170349228837045701</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**Performance Insights** – In the Performance Insights dashboard, you can view temporary file usage by turning on the metrics `temp_bytes` and `temp_files`. Then, you can see the average of both of these metrics and see how they correspond to the query workload. The view within Performance Insights doesn't show specifically the queries that are generating the temporary files. However, when you combine Performance Insights with the query shown for `pg_ls_tmpdir`, you can troubleshoot, analyze, and determine the changes in your query workload.

For more information about how to analyze metrics and queries with Performance Insights, see [Analyzing metrics with the Performance Insights dashboard](#).

To view the temporary file usage with Performance Insights

1. In the Performance Insights dashboard, choose **Manage Metrics**.
2. Choose **Database metrics**, and select the `temp_bytes` and `temp_files` metrics as shown in the following image.
3. In the **Top SQL** tab, choose the **Preferences** icon.

4. In the **Preferences** window, turn on the following statistics to appear in the **Top SQL** tab and choose **Continue**.
   - Temp writes/sec
   - Temp reads/sec
   - Tmp blk write/call
   - Tmp blk read/call

5. The temporary file is broken out when combined with the query shown for `pg_ls_tmpdir`, as shown in the following example.
The IO:BufFileRead and IO:BufFileWrite events occur when the top queries in your workload often create temporary files. You can use Performance Insights to identify top queries waiting on IO:BufFileRead and IO:BufFileWrite by reviewing Average Active Session (AAS) in Database Load and Top SQL sections.

For more information on how to analyze top queries and load by wait event with Performance Insights, see [Overview of the Top SQL tab](#). You should identify and tune the queries that cause increase in temporary file usage and related wait events. For more information on these wait events and remediation, see [IO:BufFileRead and IO:BufFileWrite](#).

**Note**

The `work_mem` parameter controls when the sort operation runs out of memory and results are written into temporary files. We recommend that you don't change the setting of this parameter higher than the default value because it would permit every database session to consume more memory. Also, a single session that performs complex joins and sorts can perform parallel operations in which each operation consumes memory.

As a best practice, when you have a large report with multiple joins and sorts, set this parameter at the session level by using the `SET work_mem` command. Then the change is only applied to the current session and doesn't change the value globally.
Tuning with wait events for Aurora PostgreSQL

Wait events are an important tuning tool for Aurora PostgreSQL. When you can find out why sessions are waiting for resources and what they are doing, you're better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions. Before delving into this section, we strongly recommend that you understand basic Aurora concepts, especially the following topics:

- Amazon Aurora storage and reliability
- Managing performance and scaling for Aurora DB clusters

⚠️ Important

The wait events in this section are specific to Aurora PostgreSQL. Use the information in this section to tune Amazon Aurora only, not RDS for PostgreSQL. Some wait events in this section have no analogs in the open source versions of these database engines. Other wait events have the same names as events in open source engines, but behave differently. For example, Amazon Aurora storage works differently from open source storage, so storage-related wait events indicate different resource conditions.

- Lock:extend
Essential concepts for Aurora PostgreSQL tuning

Before you tune your Aurora PostgreSQL database, make sure to learn what wait events are and why they occur. Also review the basic memory and disk architecture of Aurora PostgreSQL. For a helpful architecture diagram, see the PostgreSQL wikibook.

Topics

- Aurora PostgreSQL wait events
- Aurora PostgreSQL memory
- Aurora PostgreSQL processes

Aurora PostgreSQL wait events

A *wait event* indicates a resource for which a session is waiting. For example, the wait event `Client:ClientRead` occurs when Aurora PostgreSQL is waiting to receive data from the client. Typical resources that a session waits for include the following:

- Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
- A row that is currently locked by another session
- A data file read
- A log file write

For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into
memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.

A wait event doesn't by itself show a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

Large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now runs for hours, you can identify the wait events that contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.

**Aurora PostgreSQL memory**

Aurora PostgreSQL memory is divided into shared and local.

**Topics**

- [Shared memory in Aurora PostgreSQL](#)
- [Local memory in Aurora PostgreSQL](#)

**Shared memory in Aurora PostgreSQL**

Aurora PostgreSQL allocates shared memory when the instance starts. Shared memory is divided into multiple subareas. Following, you can find a description of the most important ones.

**Topics**

- [Shared buffers](#)
- [Write ahead log (WAL) buffers](#)

**Shared buffers**

The *shared buffer pool* is an Aurora PostgreSQL memory area that holds all pages that are or were being used by application connections. A *page* is the memory version of a disk block. The shared
buffer pool caches the data blocks read from disk. The pool reduces the need to reread data from disk, making the database operate more efficiently.

Every table and index is stored as an array of pages of a fixed size. Each block contains multiple tuples, which correspond to rows. A tuple can be stored in any page.

The shared buffer pool has finite memory. If a new request requires a page that isn't in memory, and no more memory exists, Aurora PostgreSQL evicts a less frequently used page to accommodate the request. The eviction policy is implemented by a clock sweep algorithm.

The `shared_buffers` parameter determines how much memory the server dedicates to caching data.

**Write ahead log (WAL) buffers**

A write-ahead log (WAL) buffer holds transaction data that Aurora PostgreSQL later writes to persistent storage. Using the WAL mechanism, Aurora PostgreSQL can do the following:

- Recover data after a failure
- Reduce disk I/O by avoiding frequent writes to disk

When a client changes data, Aurora PostgreSQL writes the changes to the WAL buffer. When the client issues a `COMMIT`, the WAL writer process writes transaction data to the WAL file.

The `wal_level` parameter determines how much information is written to the WAL.

**Local memory in Aurora PostgreSQL**

Every backend process allocates local memory for query processing.

**Topics**

- Work memory area
- Maintenance work memory area
- Temporary buffer area

**Work memory area**

The work memory area holds temporary data for queries that performs sorts and hashes. For example, a query with an ORDER BY clause performs a sort. Queries use hash tables in hash joins and aggregations.
The `work_mem` parameter is the amount of memory to be used by internal sort operations and hash tables before writing to temporary disk files. The default value is 4 MB. Multiple sessions can run simultaneously, and each session can run maintenance operations in parallel. For this reason, the total work memory used can be multiples of the `work_mem` setting.

**Maintenance work memory area**

The *maintenance work memory area* caches data for maintenance operations. These operations include vacuuming, creating an index, and adding foreign keys.

The `maintenance_work_mem` parameter specifies the maximum amount of memory to be used by maintenance operations. The default value is 64 MB. A database session can only run one maintenance operation at a time.

**Temporary buffer area**

The *temporary buffer area* caches temporary tables for each database session.

Each session allocates temporary buffers as needed up to the limit you specify. When the session ends, the server clears the buffers.

The `temp_buffers` parameter sets the maximum number of temporary buffers used by each session. Before the first use of temporary tables within a session, you can change the `temp_buffers` value.

**Aurora PostgreSQL processes**

Aurora PostgreSQL uses multiple processes.

**Topics**

- [Postmaster process](#)
- [Backend processes](#)
- [Background processes](#)

**Postmaster process**

The *postmaster process* is the first process started when you start Aurora PostgreSQL. The postmaster process has the following primary responsibilities:
• Fork and monitor background processes
• Receive authentication requests from client processes, and authenticate them before allowing the database to service requests

**Backend processes**

If the postmaster authenticates a client request, the postmaster forks a new backend process, also called a postgres process. One client process connects to exactly one backend process. The client process and the backend process communicate directly without intervention by the postmaster process.

**Background processes**

The postmaster process forks several processes that perform different backend tasks. Some of the more important include the following:

• WAL writer

  Aurora PostgreSQL writes data in the WAL (write ahead logging) buffer to the log files. The principle of write ahead logging is that the database can't write changes to the data files until after the database writes log records describing those changes to disk. The WAL mechanism reduces disk I/O, and allows Aurora PostgreSQL to use the logs to recover the database after a failure.

• Background writer

  This process periodically write dirty (modified) pages from the memory buffers to the data files. A page becomes dirty when a backend process modifies it in memory.

• Autovacuum daemon

  The daemon consists of the following:
  • The autovacuum launcher
  • The autovacuum worker processes

  When autovacuum is turned on, it checks for tables that have had a large number of inserted, updated, or deleted tuples. The daemon has the following responsibilities:
  • Recover or reuse disk space occupied by updated or deleted rows
  • Update statistics used by the planner
  • Protect against loss of old data because of transaction ID wraparound
The autovacuum feature automates the execution of VACUUM and ANALYZE commands. VACUUM has the following variants: standard and full. Standard vacuum runs in parallel with other database operations. VACUUM FULL requires an exclusive lock on the table it is working on. Thus, it can't run in parallel with operations that access the same table. VACUUM creates a substantial amount of I/O traffic, which can cause poor performance for other active sessions.

**Aurora PostgreSQL wait events**

The following table lists the wait events for Aurora PostgreSQL that most commonly indicate performance problems, and summarizes the most common causes and corrective actions. The following wait events are a subset of the list in Amazon Aurora PostgreSQL wait events.

<table>
<thead>
<tr>
<th>Wait event</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client:ClientRead</td>
<td>This event occurs when Aurora PostgreSQL is waiting to receive data from the client.</td>
</tr>
<tr>
<td>Client:ClientWrite</td>
<td>This event occurs when Aurora PostgreSQL is waiting to write data to the client.</td>
</tr>
<tr>
<td>CPU</td>
<td>This event occurs when a thread is active in CPU or is waiting for CPU.</td>
</tr>
<tr>
<td>IO:BufFileRead and IO:BufFileWrite</td>
<td>These events occur when Aurora PostgreSQL creates temporary files.</td>
</tr>
<tr>
<td>IO:DataFileRead</td>
<td>This event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.</td>
</tr>
<tr>
<td>IO:XactSync</td>
<td>This event occurs when the database is waiting for the Aurora storage subsystem to acknowledge the commit of a regular transaction, or the commit or rollback of a prepared transaction.</td>
</tr>
<tr>
<td>IPC:DamRecordTxAck</td>
<td>This event occurs when Aurora PostgreSQL in a session using database activity streams generates</td>
</tr>
<tr>
<td>Wait event</td>
<td>Definition</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Lock:advisory</strong></td>
<td>This event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.</td>
</tr>
<tr>
<td><strong>Lock:extend</strong></td>
<td>This event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.</td>
</tr>
<tr>
<td><strong>Lock:Relation</strong></td>
<td>This event occurs when a query is waiting to acquire a lock on a table or view that's currently locked by another transaction.</td>
</tr>
<tr>
<td><strong>Lock:transactionid</strong></td>
<td>This event occurs when a transaction is waiting for a row-level lock.</td>
</tr>
<tr>
<td><strong>Lock:tuple</strong></td>
<td>This event occurs when a backend process is waiting to acquire a lock on a tuple.</td>
</tr>
<tr>
<td><strong>LWLock:buffer_content (BufferContent)</strong></td>
<td>This event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing.</td>
</tr>
<tr>
<td><strong>LWLock:buffer_mapping</strong></td>
<td>This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.</td>
</tr>
<tr>
<td><strong>LWLock:BufferIO (IPC:BufferIO)</strong></td>
<td>This event occurs when Aurora PostgreSQL or RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page.</td>
</tr>
<tr>
<td>Wait event</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>LWLock:lock_manager</strong></td>
<td>This event occurs when the Aurora PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.</td>
</tr>
<tr>
<td><strong>LWLock:MultiXact</strong></td>
<td>This type of event occurs when Aurora PostgreSQL is keeping a session open to complete multiple transactions that involve the same row in a table. The wait event denotes which aspect of multiple transaction processing is generating the wait event, that is, LWLock:MultiXactOffsetSLRU, LWLock:MultiXactOffsetBuffer, LWLock:MultiXactMemberSLRU, or LWLock:MultiXactMemberBuffer.</td>
</tr>
<tr>
<td><strong>Timeout:PgSleep</strong></td>
<td>This event occurs when a server process has called the <code>pg_sleep</code> function and is waiting for the sleep timeout to expire.</td>
</tr>
</tbody>
</table>

**Client:ClientRead**

The **Client:ClientRead** event occurs when Aurora PostgreSQL is waiting to receive data from the client.

**Topics**

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

**Supported engine versions**

This wait event information is supported for Aurora PostgreSQL version 10 and higher.
Context

An Aurora PostgreSQL DB cluster is waiting to receive data from the client. The Aurora PostgreSQL DB cluster must receive the data from the client before it can send more data to the client. The time that the cluster waits before receiving data from the client is a Client:ClientRead event.

Likely causes of increased waits

Common causes for the Client:ClientRead event to appear in top waits include the following:

Increased network latency

There might be increased network latency between the Aurora PostgreSQL DB cluster and client. Higher network latency increases the time required for DB cluster to receive data from the client.

Increased load on the client

There might be CPU pressure or network saturation on the client. An increase in load on the client can delay transmission of data from the client to the Aurora PostgreSQL DB cluster.

Excessive network round trips

A large number of network round trips between the Aurora PostgreSQL DB cluster and the client can delay transmission of data from the client to the Aurora PostgreSQL DB cluster.

Large copy operation

During a copy operation, the data is transferred from the client's file system to the Aurora PostgreSQL DB cluster. Sending a large amount of data to the DB cluster can delay transmission of data from the client to the DB cluster.

Idle client connection

A connection to an Aurora PostgreSQL DB instance is in idle in transaction state and is waiting for a client to send more data or issue a command. This state can lead to an increase in Client:ClientRead events.

PgBouncer used for connection pooling

PgBouncer has a low-level network configuration setting called pkt_buf, which is set to 4,096 by default. If the workload is sending query packets larger than 4,096 bytes through PgBouncer, we recommend increasing the pkt_buf setting to 8,192. If the new setting doesn't decrease the number of Client:ClientRead events, we recommend increasing the pkt_buf setting
to larger values, such as 16,384 or 32,768. If the query text is large, the larger setting can be particularly helpful.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- [Place the clients in the same Availability Zone and VPC subnet as the cluster](#)
- [Scale your client](#)
- [Use current generation instances](#)
- [Increase network bandwidth](#)
- [Monitor maximums for network performance](#)
- [Monitor for transactions in the "idle in transaction" state](#)

**Place the clients in the same Availability Zone and VPC subnet as the cluster**

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the Aurora PostgreSQL DB cluster. Make sure that the clients are as geographically close to the DB cluster as possible.

**Scale your client**

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

**Use current generation instances**

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see [Jumbo frames (9001 MTU)](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/aurora-configuring-network.html) in the [Amazon EC2 User Guide](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/). For information about DB instance classes, see [Aurora DB instance classes](https://docs.aws.amazon.com/Aurora/latest/êu/aurora-user-guide/aurora-creating-clusters.html). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place `db.` before the Amazon EC2 instance type name. For example, the `r5.8xlarge` Amazon EC2 instance is equivalent to the `db.r5.8xlarge` DB instance class.
**Increase network bandwidth**

Use `NetworkReceiveThroughput` and `NetworkTransmitThroughput` Amazon CloudWatch metrics to monitor incoming and outgoing network traffic on the DB cluster. These metrics can help you to determine if network bandwidth is sufficient for your workload.

If your network bandwidth isn't enough, increase it. If the AWS client or your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see [Amazon CloudWatch metrics for Amazon Aurora](#).

**Monitor maximums for network performance**

If you are using Amazon EC2 clients, Amazon EC2 provides maximums for network performance metrics, including aggregate inbound and outbound network bandwidth. It also provides connection tracking to ensure that packets are returned as expected and link-local services access for services such as the Domain Name System (DNS). To monitor these maximums, use a current enhanced networking driver and monitor network performance for your client.

For more information, see [Monitor network performance for your Amazon EC2 instance](#) in the Amazon EC2 User Guide and [Monitor network performance for your Amazon EC2 instance](#) in the Amazon EC2 User Guide.

**Monitor for transactions in the "idle in transaction" state**

Check whether you have an increasing number of `idle in transaction` connections. To do this, monitor the `state` column in the `pg_stat_activity` table. You might be able to identify the connection source by running a query similar to the following.

```sql
select client_addr, state, count(1) from pg_stat_activity
where state like 'idle in transaction%'
group by 1,2
order by 3 desc
```

**Client:ClientWrite**

The **Client:ClientWrite** event occurs when Aurora PostgreSQL is waiting to write data to the client.
Supported engine versions

This wait event information is supported for Aurora PostgreSQL version 10 and higher.

Context

A client process must read all of the data received from an Aurora PostgreSQL DB cluster before the cluster can send more data. The time that the cluster waits before sending more data to the client is a Client:ClientWrite event.

Reduced network throughput between the Aurora PostgreSQL DB cluster and the client can cause this event. CPU pressure and network saturation on the client can also cause this event. CPU pressure is when the CPU is fully utilized and there are tasks waiting for CPU time. Network saturation is when the network between the database and client is carrying more data than it can handle.

Likely causes of increased waits

Common causes for the Client:ClientWrite event to appear in top waits include the following:

Increased network latency

There might be increased network latency between the Aurora PostgreSQL DB cluster and client. Higher network latency increases the time required for the client to receive the data.

Increased load on the client

There might be CPU pressure or network saturation on the client. An increase in load on the client delays the reception of data from the Aurora PostgreSQL DB cluster.

Large volume of data sent to the client

The Aurora PostgreSQL DB cluster might be sending a large amount of data to the client. A client might not be able to receive the data as fast as the cluster is sending it. Activities such as a copy of a large table can result in an increase in Client:ClientWrite events.
**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- **Place the clients in the same Availability Zone and VPC subnet as the cluster**
- **Use current generation instances**
- **Reduce the amount of data sent to the client**
- **Scale your client**

**Place the clients in the same Availability Zone and VPC subnet as the cluster**

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the Aurora PostgreSQL DB cluster.

**Use current generation instances**

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see [Jumbo frames (9001 MTU)] in the Amazon EC2 User Guide.

For information about DB instance classes, see [Aurora DB instance classes](#). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place `db.` before the Amazon EC2 instance type name. For example, the `r5.8xlarge` Amazon EC2 instance is equivalent to the `db.r5.8xlarge` DB instance class.

**Reduce the amount of data sent to the client**

When possible, adjust your application to reduce the amount of data that the Aurora PostgreSQL DB cluster sends to the client. Making such adjustments relieves CPU and network contention on the client.

**Scale your client**

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.
CPU

This event occurs when a thread is active in CPU or is waiting for CPU.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is relevant for Aurora PostgreSQL version 9.6 and higher.

Context

The central processing unit (CPU) is the component of a computer that runs instructions. For example, CPU instructions perform arithmetic operations and exchange data in memory. If a query increases the number of instructions that it performs through the database engine, the time spent running the query increases. CPU scheduling is giving CPU time to a process. Scheduling is orchestrated by the kernel of the operating system.

Topics

- How to tell when this wait occurs
- DBLoadCPU metric
- os.cpuUtilization metrics
- Likely cause of CPU scheduling

How to tell when this wait occurs

This CPU wait event indicates that a backend process is active in CPU or is waiting for CPU. You know that it's occurring when a query shows the following information:

- The pg_stat_activity.state column has the value active.
- The wait_event_type and wait_event columns in pg_stat_activity are both null.
To see the backend processes that are using or waiting on CPU, run the following query.

```sql
SELECT *
FROM   pg_stat_activity
WHERE  state = 'active'
AND    wait_event_type IS NULL
AND    wait_event IS NULL;
```

**DBLoadCPU metric**

The Performance Insights metric for CPU is DBLoadCPU. The value for DBLoadCPU can differ from the value for the Amazon CloudWatch metric CPUUtilization. The latter metric is collected from the HyperVisor for a database instance.

**os.cpuUtilization metrics**

Performance Insights operating-system metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

- `os.cpuUtilization.nice.avg`
- `os.cpuUtilization.total.avg`
- `os.cpuUtilization.wait.avg`
- `os.cpuUtilization.idle.avg`

Performance Insights reports the CPU usage by the database engine as `os.cpuUtilization.nice.avg`.

**Likely cause of CPU scheduling**

From an operating system perspective, the CPU is active when it isn't running the idle thread. The CPU is active while it performs a computation, but it's also active when it waits on memory I/O. This type of I/O dominates a typical database workload.

Processes are likely to wait to get scheduled on a CPU when the following conditions are met:

- The CloudWatch CPUUtilization metric is near 100 percent.
- The average load is greater than the number of vCPUs, indicating a heavy load. You can find the `loadAverageMinute` metric in the OS metrics section in Performance Insights.
Likely causes of increased waits

When the CPU wait event occurs more than normal, possibly indicating a performance problem, typical causes include the following.

Topics

- Likely causes of sudden spikes
- Likely causes of long-term high frequency
- Corner cases

Likely causes of sudden spikes

The most likely causes of sudden spikes are as follows:

- Your application has opened too many simultaneous connections to the database. This scenario is known as a "connection storm."
- Your application workload changed in any of the following ways:
  - New queries
  - An increase in the size of your dataset
  - Index maintenance or creation
  - New functions
  - New operators
  - An increase in parallel query execution
- Your query execution plans have changed. In some cases, a change can cause an increase in buffers. For example, the query is now using a sequential scan when it previously used an index. In this case, the queries need more CPU to accomplish the same goal.

Likely causes of long-term high frequency

The most likely causes of events that recur over a long period:

- Too many backend processes are running concurrently on CPU. These processes can be parallel workers.
- Queries are performing suboptimally because they need a large number of buffers.
Corner cases

If none of the likely causes turn out to be actual causes, the following situations might be occurring:

- The CPU is swapping processes in and out.
- CPU context switching has increased.
- Aurora PostgreSQL code is missing wait events.

Actions

If the CPU wait event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

Topics

- Investigate whether the database is causing the CPU increase
- Determine whether the number of connections increased
- Respond to workload changes

Investigate whether the database is causing the CPU increase

Examine the os.cpuUtilization.nice.avg metric in Performance Insights. If this value is far less than the CPU usage, nondatabase processes are the main contributor to CPU.

Determine whether the number of connections increased

Examine the DatabaseConnections metric in Amazon CloudWatch. Your action depends on whether the number increased or decreased during the period of increased CPU wait events.

The connections increased

If the number of connections went up, compare the number of backend processes consuming CPU to the number of vCPUs. The following scenarios are possible:

- The number of backend processes consuming CPU is less than the number of vCPUs.

  In this case, the number of connections isn't an issue. However, you might still try to reduce CPU utilization.
• The number of backend processes consuming CPU is greater than the number of vCPUs.

   In this case, consider the following options:
   • Decrease the number of backend processes connected to your database. For example, implement a connection pooling solution such as RDS Proxy. To learn more, see Using Amazon RDS Proxy for Aurora.
   • Upgrade your instance size to get a higher number of vCPUs.
   • Redirect some read-only workloads to reader nodes, if applicable.

The connections didn't increase

Examine the blks_hit metrics in Performance Insights. Look for a correlation between an increase in blks_hit and CPU usage. The following scenarios are possible:

• CPU usage and blks_hit are correlated.

   In this case, find the top SQL statements that are linked to the CPU usage, and look for plan changes. You can use either of the following techniques:
   • Explain the plans manually and compare them to the expected execution plan.
   • Look for an increase in block hits per second and local block hits per second. In the Top SQL section of Performance Insights dashboard, choose Preferences.

• CPU usage and blks_hit aren't correlated.

   In this case, determine whether any of the following occurs:
   • The application is rapidly connecting to and disconnecting from the database.

      Diagnose this behavior by turning on log_connections and log_disconnections, then analyzing the PostgreSQL logs. Consider using the pgbadger log analyzer. For more information, see https://github.com/darold/pgbadger.

   • The OS is overloaded.

      In this case, Performance Insights shows that backend processes are consuming CPU for a longer time than usual. Look for evidence in the Performance Insights os.cpuUtilization metrics or the CloudWatch CPUUtilization metric. If the operating system is overloaded, look at Enhanced Monitoring metrics to diagnose further. Specifically, look at the process list and the percentage of CPU consumed by each process.

• Top SQL statements are consuming too much CPU.
Examine statements that are linked to the CPU usage to see whether they can use less CPU. Run an EXPLAIN command, and focus on the plan nodes that have the most impact. Consider using a PostgreSQL execution plan visualizer. To try out this tool, see http://explain.dalibo.com/.

**Respond to workload changes**

If your workload has changed, look for the following types of changes:

**New queries**

Check whether the new queries are expected. If so, ensure that their execution plans and the number of executions per second are expected.

**An increase in the size of the data set**

Determine whether partitioning, if it's not already implemented, might help. This strategy might reduce the number of pages that a query needs to retrieve.

**Index maintenance or creation**

Check whether the schedule for the maintenance is expected. A best practice is to schedule maintenance activities outside of peak activities.

**New functions**

Check whether these functions perform as expected during testing. Specifically, check whether the number of executions per second is expected.

**New operators**

Check whether they perform as expected during the testing.

**An increase in running parallel queries**

Determine whether any of the following situations has occurred:

- The relations or indexes involved have suddenly grown in size so that they differ significantly from `min_parallel_table_scan_size` or `min_parallel_index_scan_size`.
- Recent changes have been made to `parallel_setup_cost` or `parallel_tuple_cost`.
- Recent changes have been made to `max_parallel_workers` or `max_parallel_workers_per_gather`. 
IO:BufFileRead and IO:BufFileWrite

The IO:BufFileRead and IO:BufFileWrite events occur when Aurora PostgreSQL creates temporary files. When operations require more memory than the working memory parameters currently define, they write temporary data to persistent storage. This operation is sometimes called "spilling to disk."

Topics
- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

IO:BufFileRead and IO:BufFileWrite relate to the work memory area and maintenance work memory area. For more information about these local memory areas, see Work memory area and Maintenance work memory area.

The default value for work_mem is 4 MB. If one session performs operations in parallel, each worker handling the parallelism uses 4 MB of memory. For this reason, set work_mem carefully. If you increase the value too much, a database running many sessions might consume too much memory. If you set the value too low, Aurora PostgreSQL creates temporary files in local storage. The disk I/O for these temporary files can reduce performance.

If you observe the following sequence of events, your database might be generating temporary files:

1. Sudden and sharp decreases in availability
2. Fast recovery for the free space

You might also see a "chainsaw" pattern. This pattern can indicate that your database is creating small files constantly.
Likely causes of increased waits

In general, these wait events are caused by operations that consume more memory than the `work_mem` or `maintenance_work_mem` parameters allocate. To compensate, the operations write to temporary files. Common causes for the `IO:BufFileRead` and `IO:BufFileWrite` events include the following:

Queries that need more memory than exists in the work memory area

Queries with the following characteristics use the work memory area:

- Hash joins
- `ORDER BY` clause
- `GROUP BY` clause
- `DISTINCT`
- Window functions
- `CREATE TABLE AS SELECT`
- Materialized view refresh

Statements that need more memory than exists in the maintenance work memory area

The following statements use the maintenance work memory area:

- `CREATE INDEX`
- `CLUSTER`

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- [Identify the problem](#)
- [Examine your join queries](#)
- [Examine your ORDER BY and GROUP BY queries](#)
- [Avoid using the DISTINCT operation](#)
- [Consider using window functions instead of GROUP BY functions](#)
Investigate materialized views and CTAS statements
• Use pg_repack when you create indexes
• Increase maintenance_work_mem when you cluster tables
• Tune memory to prevent IO:BufFileRead and IO:BufFileWrite

Identify the problem

Assume a situation in which Performance Insights isn’t turned on and you suspect that IO:BufFileRead and IO:BufFileWrite are occurring more frequently than is normal. Do the following:

1. Examine the FreeLocalStorage metric in Amazon CloudWatch.
2. Look for a chainsaw pattern, which is a series of jagged spikes.

A chainsaw pattern indicates a quick consumption and release of storage, often associated with temporary files. If you notice this pattern, turn on Performance Insights. When using Performance Insights, you can identify when the wait events occur and which queries are associated with them. Your solution depends on the specific query causing the events.

Or set the parameter log_temp_files. This parameter logs all queries generating more than threshold KB of temporary files. If the value is 0, Aurora PostgreSQL logs all temporary files. If the value is 1024, Aurora PostgreSQL logs all queries that produces temporary files larger than 1 MB. For more information about log_temp_files, see Error Reporting and Logging in the PostgreSQL documentation.

Examine your join queries

Your application probably use joins. For example, the following query joins four tables.

```sql
SELECT *
  FROM order
INNER JOIN order_item
    ON (order.id = order_item.order_id)
INNER JOIN customer
    ON (customer.id = order.customer_id)
INNER JOIN customer_address
    ON (customer_address.customer_id = customer.id AND order.customer_address_id = customer_address.id)
```
WHERE customer.id = 1234567890;

A possible cause of spikes in temporary file usage is a problem in the query itself. For example, a broken clause might not filter the joins properly. Consider the second inner join in the following example.

```sql
SELECT *
FROM order
INNER JOIN order_item
    ON (order.id = order_item.order_id)
INNER JOIN customer
    ON (customer.id = customer.id)
INNER JOIN customer_address
    ON (customer_address.customer_id = customer.id AND order.customer_address_id = customer_address.id)
WHERE customer.id = 1234567890;
```

The preceding query mistakenly joins `customer.id` to `customer.id`, generating a Cartesian product between every customer and every order. This type of accidental join generates large temporary files. Depending on the size of the tables, a Cartesian query can even fill up storage.

Your application might have Cartesian joins when the following conditions are met:

- You see large, sharp decreases in storage availability, followed by fast recovery.
- No indexes are being created.
- No `CREATE TABLE FROM SELECT` statements are being issued.
- No materialized views are being refreshed.

To see whether the tables are being joined using the proper keys, inspect your query and object-relational mapping directives. Bear in mind that certain queries of your application are not called all the time, and some queries are dynamically generated.

**Examine your ORDER BY and GROUP BY queries**

In some cases, an ORDER BY clause can result in excessive temporary files. Consider the following guidelines:

- Only include columns in an ORDER BY clause when they need to be ordered. This guideline is especially important for queries that return thousands of rows and specify many columns in the ORDER BY clause.
• Considering creating indexes to accelerate ORDER BY clauses when they match columns that have the same ascending or descending order. Partial indexes are preferable because they are smaller. Smaller indexes are read and traversed more quickly.

• If you create indexes for columns that can accept null values, consider whether you want the null values stored at the end or at the beginning of the indexes.

If possible, reduce the number of rows that need to be ordered by filtering the result set. If you use WITH clause statements or subqueries, remember that an inner query generates a result set and passes it to the outside query. The more rows that a query can filter out, the less ordering the query needs to do.

• If you don't need to obtain the full result set, use the LIMIT clause. For example, if you only want the top five rows, a query using the LIMIT clause doesn't keep generating results. In this way, the query requires less memory and temporary files.

A query that uses a GROUP BY clause can also require temporary files. GROUP BY queries summarize values by using functions such as the following:

• COUNT
• AVG
• MIN
• MAX
• SUM
• STDDEV

To tune GROUP BY queries, follow the recommendations for ORDER BY queries.

**Avoid using the DISTINCT operation**

If possible, avoid using the DISTINCT operation to remove duplicated rows. The more unnecessary and duplicated rows that your query returns, the more expensive the DISTINCT operation becomes. If possible, add filters in the WHERE clause even if you use the same filters for different tables. Filtering the query and joining correctly improves your performance and reduces resource use. It also prevents incorrect reports and results.

If you need to use DISTINCT for multiple rows of a same table, consider creating a composite index. Grouping multiple columns in an index can improve the time to evaluate distinct rows. Also,
if you use Amazon Aurora PostgreSQL version 10 or higher, you can correlate statistics among multiple columns by using the `CREATE STATISTICS` command.

**Consider using window functions instead of GROUP BY functions**

Using `GROUP BY`, you change the result set, and then retrieve the aggregated result. Using window functions, you aggregate data without changing the result set. A window function uses the `OVER` clause to perform calculations across the sets defined by the query, correlating one row with another. You can use all the `GROUP BY` functions in window functions, but also use functions such as the following:

- RANK
- ARRAY_AGG
- ROW_NUMBER
- LAG
- LEAD

To minimize the number of temporary files generated by a window function, remove duplications for the same result set when you need two distinct aggregations. Consider the following query.

```sql
SELECT sum(salary) OVER (PARTITION BY dept ORDER BY salary DESC) as sum_salary,
       avg(salary) OVER (PARTITION BY dept ORDER BY salary ASC) as avg_salary
FROM empsalary;
```

You can rewrite the query with the `WINDOW` clause as follows.

```sql
SELECT sum(salary) OVER w as sum_salary,
       avg(salary) OVER w as_avg_salary
FROM empsalary
WINDOW w AS (PARTITION BY dept ORDER BY salary DESC);
```

By default, the Aurora PostgreSQL execution planner consolidates similar nodes so that it doesn’t duplicate operations. However, by using an explicit declaration for the window block, you can maintain the query more easily. You might also improve performance by preventing duplication.

**Investigate materialized views and CTAS statements**

When a materialized view refreshes, it runs a query. This query can contain an operation such as `GROUP BY`, `ORDER BY`, or `DISTINCT`. During a refresh, you might observe large numbers of...
temporary files and the wait events \texttt{IO:BufFileWrite} and \texttt{IO:BufFileRead}. Similarly, when you create a table based on a \texttt{SELECT} statement, the \texttt{CREATE TABLE} statement runs a query. To reduce the temporary files needed, optimize the query.

**Use \texttt{pg_repack} when you create indexes**

When you create an index, the engine orders the result set. As tables grow in size, and as values in the indexed column become more diverse, the temporary files require more space. In most cases, you can't prevent the creation of temporary files for large tables without modifying the maintenance work memory area. For more information, see \texttt{Maintenance work memory area}.

A possible workaround when recreating a large index is to use the \texttt{pg_repack} tool. For more information, see \texttt{Reorganize tables in PostgreSQL databases with minimal locks} in the \texttt{pg_repack} documentation.

**Increase maintenance\_work\_mem when you cluster tables**

The \texttt{CLUSTER} command clusters the table specified by \texttt{table\_name} based on an existing index specified by \texttt{index\_name}. Aurora PostgreSQL physically recreates the table to match the order of a given index.

When magnetic storage was prevalent, clustering was common because storage throughput was limited. Now that SSD-based storage is common, clustering is less popular. However, if you cluster tables, you can still increase performance slightly depending on the table size, index, query, and so on.

If you run the \texttt{CLUSTER} command and observe the wait events \texttt{IO:BufFileWrite} and \texttt{IO:BufFileRead}, tune \texttt{maintenance\_work\_mem}. Increase the memory size to a fairly large amount. A high value means that the engine can use more memory for the clustering operation.

**Tune memory to prevent \texttt{IO:BufFileRead} and \texttt{IO:BufFileWrite}**

In some situation, you need to tune memory. Your goal is to balance the following requirements:

- The \texttt{work\_mem} value (see \texttt{Work memory area})
- The memory remaining after discounting the \texttt{shared\_buffers} value (see \texttt{Buffer pool})
- The maximum connections opened and in use, which is limited by \texttt{max\_connections}
Increase the size of the work memory area

In some situations, your only option is to increase the memory used by your session. If your queries are correctly written and are using the correct keys for joins, consider increasing the `work_mem` value. For more information, see **Work memory area**.

To find out how many temporary files a query generates, set `log_temp_files` to 0. If you increase the `work_mem` value to the maximum value identified in the logs, you prevent the query from generating temporary files. However, `work_mem` sets the maximum per plan node for each connection or parallel worker. If the database has 5,000 connections, and if each one uses 256 MiB memory, the engine needs 1.2 TiB of RAM. Thus, your instance might run out of memory.

Reserve sufficient memory for the shared buffer pool

Your database uses memory areas such as the shared buffer pool, not just the work memory area. Consider the requirements of these additional memory areas before you increase `work_mem`. For more information about the buffer pool, see **Buffer pool**.

For example, assume that your Aurora PostgreSQL instance class is `db.r5.2xlarge`. This class has 64 GiB of memory. By default, 75 percent of the memory is reserved for the shared buffer pool. After you subtract the amount allocated to the shared memory area, 16,384 MB remains. Don't allocate the remaining memory exclusively to the work memory area because the operating system and the engine also require memory.

The memory that you can allocate to `work_mem` depends on the instance class. If you use a larger instance class, more memory is available. However, in the preceding example, you can't use more than 16 GiB. Otherwise, your instance becomes unavailable when it runs out of memory. To recover the instance from the unavailable state, the Aurora PostgreSQL automation services automatically restart.

Manage the number of connections

Suppose that your database instance has 5,000 simultaneous connections. Each connection uses at least 4 MiB of `work_mem`. The high memory consumption of the connections is likely to degrade performance. In response, you have the following options:

- Upgrade to a larger instance class.
- Decrease the number of simultaneous database connections by using a connection proxy or pooler.
For proxies, consider Amazon RDS Proxy, pgBouncer, or a connection pooler based on your application. This solution alleviates the CPU load. It also reduces the risk when all connections require the work memory area. When fewer database connections exist, you can increase the value of `work_mem`. In this way, you reduce the occurrence of the `IO:BufFileRead` and `IO:BufFileWrite` wait events. Also, the queries waiting for the work memory area speed up significantly.

**IO:DataFileRead**

The `IO:DataFileRead` event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.

**Topics**

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

**Supported engine versions**

This wait event information is supported for all versions of Aurora PostgreSQL.

**Context**

All queries and data manipulation (DML) operations access pages in the buffer pool. Statements that can induce reads include `SELECT`, `UPDATE`, and `DELETE`. For example, an `UPDATE` can read pages from tables or indexes. If the page being requested or updated isn't in the shared buffer pool, this read can lead to the `IO:DataFileRead` event.

Because the shared buffer pool is finite, it can fill up. In this case, requests for pages that aren't in memory force the database to read blocks from disk. If the `IO:DataFileRead` event occurs frequently, your shared buffer pool might be too small to accommodate your workload. This problem is acute for `SELECT` queries that read a large number of rows that don't fit in the buffer pool. For more information about the buffer pool, see [Buffer pool](#).

** Likely causes of increased waits**

Common causes for the `IO:DataFileRead` event include the following:
Connection spikes

You might find multiple connections generating the same number of IO:DataFileRead wait events. In this case, a spike (sudden and large increase) in IO:DataFileRead events can occur.

**SELECT and DML statements performing sequential scans**

Your application might be performing a new operation. Or an existing operation might change because of a new execution plan. In such cases, look for tables (particularly large tables) that have a greater seq_scan value. Find them by querying pg_stat_user_tables. To track queries that are generating more read operations, use the extension pg_stat_statements.

**CTAS and CREATE INDEX for large data sets**

A CTAS is a CREATE TABLE AS SELECT statement. If you run a CTAS using a large data set as a source, or create an index on a large table, the IO:DataFileRead event can occur. When you create an index, the database might need to read the entire object using a sequential scan. A CTAS generates IO:DataFile reads when pages aren't in memory.

**Multiple vacuum workers running at the same time**

Vacuum workers can be triggered manually or automatically. We recommend adopting an aggressive vacuum strategy. However, when a table has many updated or deleted rows, the IO:DataFileRead waits increase. After space is reclaimed, the vacuum time spent on IO:DataFileRead decreases.

**Ingesting large amounts of data**

When your application ingests large amounts of data, ANALYZE operations might occur more often. The ANALYZE process can be triggered by an autovacuum launcher or invoked manually.

The ANALYZE operation reads a subset of the table. The number of pages that must be scanned is calculated by multiplying 30 by the default_statistics_target value. For more information, see the PostgreSQL documentation. The default_statistics_target parameter accepts values between 1 and 10,000, where the default is 100.

**Resource starvation**

If instance network bandwidth or CPU are consumed, the IO:DataFileRead event might occur more frequently.

**Actions**

We recommend different actions depending on the causes of your wait event.
Check predicate filters for queries that generate waits

Assume that you identify specific queries that are generating IO:DataFileRead wait events. You might identify them using the following techniques:

- Performance Insights
- Catalog views such as the one provided by the extension pg_stat_statements
- The catalog view pg_stat_all_tables, if it periodically shows an increased number of physical reads
- The pg_statio_all_tables view, if it shows that _read counters are increasing

We recommend that you determine which filters are used in the predicate (WHERE clause) of these queries. Follow these guidelines:

- Run the EXPLAIN command. In the output, identify which types of scans are used. A sequential scan doesn’t necessarily indicate a problem. Queries that use sequential scans naturally produce more IO:DataFileRead events when compared to queries that use filters.

Find out whether the column listed in the WHERE clause is indexed. If not, consider creating an index for this column. This approach avoids the sequential scans and reduces the IO:DataFileRead events. If a query has restrictive filters and still produces sequential scans, evaluate whether the proper indexes are being used.

- Find out whether the query is accessing a very large table. In some cases, partitioning a table can improve performance, allowing the query to only read necessary partitions.

- Examine the cardinality (total number of rows) from your join operations. Note how restrictive the values are that you’re passing in the filters for your WHERE clause. If possible, tune your query to reduce the number of rows that are passed in each step of the plan.
Minimize the effect of maintenance operations

Maintenance operations such as VACUUM and ANALYZE are important. We recommend that you don't turn them off because you find IO:DataFileRead wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours. This technique prevents the database from reaching the threshold for automatic operations.
- For very large tables, consider partitioning the table. This technique reduces the overhead of maintenance operations. The database only accesses the partitions that require maintenance.
- When you ingest large amounts of data, consider disabling the autoanalyze feature.

The autovacuum feature is automatically triggered for a table when the following formula is true.

\[
\text{pg\_stat\_user\_tables.n\_dead\_tup} > (\text{pg\_class.reltuples} \times \text{autovacuum\_vacuum\_scale\_factor}) + \text{autovacuum\_vacuum\_threshold}
\]

The view pg_stat_user_tables and catalog pg_class have multiple rows. One row can correspond to one row in your table. This formula assumes that the reltuples are for a specific table. The parameters autovacuum_vacuum_scale_factor (0.20 by default) and autovacuum_vacuum_threshold (50 tuples by default) are usually set globally for the whole instance. However, you can set different values for a specific table.

Topics

- Find tables consuming space unnecessarily
- Find indexes consuming unnecessary space
- Find tables that are eligible to be autovacuumed

Find tables consuming space unnecessarily

To find tables consuming more space than necessary, run the following query. When this query is run by a database user role that doesn't have the rds_superuser role, it returns information about only those tables that the user role has permissions to read. This query is supported by PostgreSQL version 12 and later versions.

```sql
WITH report AS (
    SELECT  schemaname
    FROM    pg_stat_user_tables
    WHERE   n_dead_tup > (reltuples * autovacuum_vacuum_scale_factor) + autovacuum_vacuum_threshold
)
```

\[
\begin{align*}
&\text{FROM (} \\
&\quad \text{SELECT ceil( reltuples / ( (block_size-page_hdr)/tpl_size ) ) +} \\
&\quad \text{ceil( toasttuples / 4 ) AS est_tblpages} \\
&\quad ,ceil( reltuples / ( (block_size-page_hdr)*fillfactor/} \\
&\quad \text{(tpl_size*100) ) ) + ceil( toasttuples / 4 ) AS est_tblpages_ff} \\
&\quad ,tblpages \\
&\quad ,fillfactor \\
&\quad ,block_size \\
&\quad ,tblid \\
&\quad ,schemaname \\
&\quad ,tblname \\
&\quad ,n_dead_tup \\
&\quad ,n_live_tup \\
&\quad ,heappages \\
&\quad ,toastpages \\
&\quad ,is_na \\
&\quad \text{FROM (} \\
&\quad \quad \text{SELECT ( 4 + tpl_hdr_size + tpl_data_size + (2*ma)} \\
&\quad \quad - \text{CASE WHEN tpl_hdr_size%ma = 0 THEN ma ELSE} \\
&\quad \quad \text{tpl_hdr_size%ma END)} \\
&\quad \quad - \text{CASE WHEN ceil(tpl_data_size)::int%ma = 0 THEN ma ELSE} \\
&\quad \quad \text{ceil(tpl_data_size)::int%ma END)} \\
&\quad \quad \text{AS tpl_size} \\
&\quad \quad ,block_size - page_hdr AS size_per_block \\
&\quad \quad ,(heappages + toastpages) AS tblpages \\
&\quad \quad ,heappages \\
&\quad \quad ,toastpages \\
&\quad \quad ,reltuples \\
&\quad \quad ,toasttuples \\
\end{align*}
\]
```sql
SELECT  tbl.oid                       AS tblid
,ns.nspname                    AS schemaname
,tbl.relname                   AS tblname

,current_setting('block_size')::numeric AS block_size

,coalesce(substring( array_to_string(tbl.reloptions, ' ') FROM
'fillfactor=([0-9]+)')::smallint, 100) AS fillfactor
,CASE WHEN version()~'mingw32' OR version()~'64-bit|x86_64|ia64|amd64' THEN 8 ELSE 4 END        AS ma
,23 + CASE WHEN MAX(coalesce(null_frac,0)) > 0
THEN ( 7 + count(*)) / 8 ELSE 0::int END              AS tpl_hdr_size
,coalesce(s.avg_width, 1024) )                                    AS tpl_data_size
,bool_or(att.atttypid =
'pg_catalog.name '::regtype) OR count(att.attname) <> count(s.attname)         AS is_na
FROM  pg_attribute       AS att
JOIN  pg_class           AS tbl    ON (att.attrelid =
tbl.oid)
JOIN pg_stat_all_tables AS psat   ON (tbl.oid =
psat.relid)
JOIN pg_namespace       AS ns     ON (ns.oid =
tbl.relnamespace)
LEFT JOIN pg_stats           AS s      ON
(s.schemaname=ns.nspname AND s.tablename = tbl.relname AND s.inherited=false AND
s.attname=att.attname)
```

You can check for table and index bloat in your application. For more information, see

You can use PostgreSQL Multiversion Concurrency Control (MVCC) to help preserve data integrity. PostgreSQL MVCC works by saving an internal copy of updated or deleted rows (also called tuples) until a transaction is either committed or rolled back. This saved internal copy is invisible to users. However, table bloat can occur when those invisible copies aren't cleaned up regularly by the VACUUM or AUTOVACUUM utilities. Unchecked, table bloat can incur increased storage costs and slow your processing speed.

In many cases, the default settings for VACUUM or AUTOVACUUM on Aurora are sufficient for handling unwanted table bloat. However, you may want to check for bloat if your application is experiencing the following conditions:

- Processes a large number of transactions in a relatively short time between VACUUM processes.
- Performs poorly and runs out of storage.
To get started, gather the most accurate information about how much space is used by dead tuples and how much you can recover by cleaning up the table and index bloat. To do so, use the pgstattuple extension to gather statistics on your Aurora cluster. For more information, see pgstattuple. Privileges to use the pgstattuple extension are limited to the pg_stat_scan_tables role and database superusers.

To create the pgstattuple extension on Aurora, connect a client session to the cluster, for example, psql or pgAdmin, and use the following command:

```
CREATE EXTENSION pgstattuple;
```

Create the extension in each database that you want to profile. After creating the extension, use the command line interface (CLI) to measure how much unusable space you can reclaim. Before gathering statistics, modify the cluster parameter group by setting AUTOVACUUM to 0. A setting of 0 prevents Aurora from automatically cleaning up any dead tuples left behind by your application, which can impact the accuracy of the results. Enter the following command to create a simple table:

```
postgres=> CREATE TABLE lab AS SELECT generate_series (0,100000);
```

```
SELECT 100001
```

In the following example, we run the query with AUTOVACUUM turned on for the DB cluster. The dead_tuple_count is 0, which indicates that the AUTOVACUUM has deleted the obsolete data or tuples from the PostgreSQL database.

To use pgstattuple to gather information about the table, specify the name of a table or an object identifier (OID) in the query:

```
postgres=> SELECT * FROM pgstattuple('lab');
```

```
<table>
<thead>
<tr>
<th>table_len</th>
<th>tuple_count</th>
<th>tuple_len</th>
<th>tuple_percent</th>
<th>dead_tuple_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>3629056</td>
<td>100001</td>
<td>2800028</td>
<td>77.16</td>
<td>0</td>
</tr>
</tbody>
</table>
```

To use pgstattuple to gather information about the table, specify the name of a table or an object identifier (OID) in the query:
In the following query, we turn off AUTOVACUUM and enter a command that deletes 25,000 rows from the table. As a result, the `dead_tuple_count` increases to 25000.

```sql
postgres=> DELETE FROM lab WHERE generate_series < 25000;
```

```
DELETE 25000
```

```sql
SELECT * FROM pgstattuple('lab');
```

<table>
<thead>
<tr>
<th>table_len</th>
<th>tuple_count</th>
<th>tuple_len</th>
<th>tuple_percent</th>
<th>dead_tuple_count</th>
<th>dead_tuple_len</th>
<th>dead_tuple_percent</th>
<th>free_space</th>
<th>free_percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>3629056</td>
<td>75001</td>
<td>2100028</td>
<td>57.87</td>
<td>25000</td>
<td>700000</td>
<td>19.29</td>
<td>16616</td>
<td>0.46</td>
</tr>
</tbody>
</table>

To reclaim those dead tuples, start a VACUUM process.

**Observing bloat without interrupting your application**
After running your applications and viewing the result, use `pg_repack` or `VACUUM FULL` on the restored copy and compare the differences. If you see a significant drop in the `dead_tuple_count`, `dead_tuple_len`, or `dead_tuple_percent`, then adjust the vacuum schedule on your production cluster to minimize the bloat.

**Avoiding bloat in temporary tables**

If your application creates temporary tables, make sure that your application removes those temporary tables when they're no longer needed. Autovacuum processes don't locate temporary tables. Left unchecked, temporary tables can quickly create database bloat. Moreover, the bloat can extend into the system tables, which are the internal tables that track PostgreSQL objects and attributes, like `pg_attribute` and `pg_depend`.

When a temporary table is no longer needed, you can use a `TRUNCATE` statement to empty the table and free up the space. Then, manually vacuum the `pg_attribute` and `pg_depend` tables. Vacuuming these tables ensures that creating and truncating/deleting temporary tables continually isn't adding tuples and contributing to system bloat.

You can avoid this problem while creating a temporary table by including the following syntax that deletes the new rows when content is committed:

```sql
CREATE TEMP TABLE IF NOT EXISTS table_name(table_description) ON COMMIT DELETE ROWS;
```

The `ON COMMIT DELETE ROWS` clause truncates the temporary table when the transaction is committed.

**Avoiding bloat in indexes**

When you change an indexed field in a table, the index update results in one or more dead tuples in that index. By default, the autovacuum process cleans up bloat in indexes, but that cleanup uses a significant amount of time and resources. To specify index cleanup preferences when you create a table, include the `vacuum_index_cleanup` clause. By default, at table creation time, the clause is set to `AUTO`, which means that the server decides if your index requires cleanup when it vacuums the table. You can set the clause to `ON` to turn on index cleanup for a specific table, or `OFF` to turn off index cleanup for that table. Remember, turning off index cleanup might save time, but can potentially lead to a bloated index.

You can manually control index cleanup when you `VACUUM` a table at the command line. To vacuum a table and remove dead tuples from the indexes, include the `INDEX_CLEANUP` clause with a value of `ON` and the table name:
account=> VACUM (INDEX_CLEANUP ON) receivables;

INFO: aggressively vacuuming "public.receivables"

VACuum

To vacuum a table without cleaning the indexes, specify a value of OFF:

account=> VACUM (INDEX_CLEANUP OFF) receivables;

INFO: aggressively vacuuming "public.receivables"

VACuum

Find indexes consuming unnecessary space

To find indexes consuming unnecessary space, run the following query.

```
-- WARNING: run with a nonsuperuser role, the query inspects
-- only indexes on tables you have permissions to read.
-- WARNING: rows with is_na = 't' are known to have bad statistics ("name" type is not
-- supported).
-- This query is compatible with PostgreSQL 8.2 and later.

Respond to high numbers of connections

When you monitor Amazon CloudWatch, you might find that the DatabaseConnections metric spikes. This increase indicates an increased number of connections to your database. We recommend the following approach:

- Limit the number of connections that the application can open with each instance. If your application has an embedded connection pool feature, set a reasonable number of connections. Base the number on what the vCPUs in your instance can parallelize effectively.

If your application doesn't use a connection pool feature, considering using Amazon RDS Proxy or an alternative. This approach lets your application open multiple connections with the load balancer. The balancer can then open a restricted number of connections with the database. As fewer connections are running in parallel, your DB instance performs less context switching in the kernel. Queries should progress faster, leading to fewer wait events. For more information, see Using Amazon RDS Proxy for Aurora.

- Whenever possible, take advantage of reader nodes for Aurora PostgreSQL and read replicas for RDS for PostgreSQL. When your application runs a read-only operation, send these requests to the reader-only endpoint. This technique spreads application requests across all reader nodes, reducing the I/O pressure on the writer node.

- Consider scaling up your DB instance. A higher-capacity instance class gives more memory, which gives Aurora PostgreSQL a larger shared buffer pool to hold pages. The larger size also gives the DB instance more vCPUs to handle connections. More vCPUs are particularly helpful when the operations that are generating IO:DataFileRead wait events are writes.

**IO:XactSync**

The IO:XactSync event occurs when the database is waiting for the Aurora storage subsystem to acknowledge the commit of a regular transaction, or the commit or rollback of a prepared transaction. A prepared transaction is part of PostgreSQL's support for a two-phase commit.

**Topics**

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions
Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

The event IO:XactSync indicates that the instance is spending time waiting for the Aurora storage subsystem to confirm that transaction data was processed.

Likely causes of increased waits

When the IO:XactSync event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Network saturation

Traffic between clients and the DB instance or traffic to the storage subsystem might be too heavy for the network bandwidth.

CPU pressure

A heavy workload might be preventing the Aurora storage daemon from getting sufficient CPU time.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Monitor your resources
- Scale up the CPU
- Increase network bandwidth
- Reduce the number of commits

Monitor your resources

To determine the cause of the increased IO:XactSync events, check the following metrics:

- WriteThroughput and CommitThroughput – Changes in write throughput or commit throughput can show an increase in workload.
• **WriteLatency** and **CommitLatency** – Changes in write latency or commit latency can show that the storage subsystem is being asked to do more work.

• **CPUUtilization** – If the instance's CPU utilization is above 90 percent, the Aurora storage daemon might not be getting sufficient time on the CPU. In this case, I/O performance degrades.

For information about these metrics, see [Instance-level metrics for Amazon Aurora](#).

**Scale up the CPU**

To address CPU starvation issues, consider changing to an instance type with more CPU capacity. For information about CPU capacity for a DB instance class, see [Hardware specifications for DB instance classes for Aurora](#).

**Increase network bandwidth**

To determine whether the instance is reaching its network bandwidth limits, check for the following other wait events:

• **IO:DataFileRead**, **IO:BufferRead**, **IO:BufferWrite**, and **IO:XactWrite** – Queries using large amounts of I/O can generate more of these wait events.

• **Client:ClientRead** and **Client:ClientWrite** – Queries with large amounts of client communication can generate more of these wait events.

If network bandwidth is an issue, consider changing to an instance type with more network bandwidth. For information about network performance for a DB instance class, see [Hardware specifications for DB instance classes for Aurora](#).

**Reduce the number of commits**

To reduce the number of commits, combine statements into transaction blocks.

**IPC:DamRecordTxAck**

The **IPC:DamRecordTxAck** event occurs when Aurora PostgreSQL in a session using database activity streams generates an activity stream event, then waits for that event to become durable.

**Topics**

• [Relevant engine versions](#)

• [Context](#)
Relevant engine versions

This wait event information is relevant for all Aurora PostgreSQL 10.7 and higher 10 versions, 11.4 and higher 11 versions, and all 12 and 13 versions.

Context

In synchronous mode, durability of activity stream events is favored over database performance. While waiting for a durable write of the event, the session blocks other database activity, causing the IPC:DamRecordTxAck wait event.

Causes

The most common cause for the IPC:DamRecordTxAck event to appear in top waits is that the Database Activity Streams (DAS) feature is a holistic audit. Higher SQL activity generates activity stream events that need to be recorded.

Actions

We recommend different actions depending on the causes of your wait event:

- Reduce the number of SQL statements or turn off database activity streams. Doing this reduces the number of events that require durable writes.
- Change to asynchronous mode. Doing this helps to reduce contention on the IPC:DamRecordTxAck wait event.
  However, the DAS feature can't guarantee the durability of every event in asynchronous mode.

Lock:advisory

The Lock:advisory event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.

Topics

- Relevant engine versions
- Context
Relevant engine versions

This wait event information is relevant for Aurora PostgreSQL versions 9.6 and higher.

Context

PostgreSQL advisory locks are application-level, cooperative locks explicitly locked and unlocked by the user's application code. An application can use PostgreSQL advisory locks to coordinate activity across multiple sessions. Unlike regular, object- or row-level locks, the application has full control over the lifetime of the lock. For more information, see Advisory Locks in the PostgreSQL documentation.

Advisory locks can be released before a transaction ends or be held by a session across transactions. This isn't true for implicit, system-enforced locks, such as an access-exclusive lock on a table acquired by a CREATE INDEX statement.

For a description of the functions used to acquire (lock) and release (unlock) advisory locks, see Advisory Lock Functions in the PostgreSQL documentation.

Advisory locks are implemented on top of the regular PostgreSQL locking system and are visible in the pg_locks system view.

Causes

This lock type is exclusively controlled by an application explicitly using it. Advisory locks that are acquired for each row as part of a query can cause a spike in locks or a long-term buildup.

These effects happen when the query is run in a way that acquires locks on more rows than are returned by the query. The application must eventually release every lock, but if locks are acquired on rows that aren't returned, the application can't find all of the locks.

The following example is from Advisory Locks in the PostgreSQL documentation.

```sql
SELECT pg_advisory_lock(id) FROM foo WHERE id > 12345 LIMIT 100;
```

In this example, the LIMIT clause can only stop the query's output after the rows have already been internally selected and their ID values locked. This can happen suddenly when a growing
data volume causes the planner to choose a different execution plan that wasn't tested during development. The buildup in this case happens because the application explicitly calls pg_advisory_unlock for every ID value that was locked. However, in this case it can't find the set of locks acquired on rows that weren't returned. Because the locks are acquired on the session level, they aren't released automatically at the end of the transaction.

Another possible cause for spikes in blocked lock attempts is unintended conflicts. In these conflicts, unrelated parts of the application share the same lock ID space by mistake.

**Actions**

Review application usage of advisory locks and detail where and when in the application flow each type of advisory lock is acquired and released.

Determine whether a session is acquiring too many locks or a long-running session isn't releasing locks early enough, leading to a slow buildup of locks. You can correct a slow buildup of session-level locks by ending the session using `pg_terminate_backend(pid)`.

A client waiting for an advisory lock appears in `pg_stat_activity` with `wait_event_type=Lock` and `wait_event=advisory`. You can obtain specific lock values by querying the `pg_locks` system view for the same `pid`, looking for `locktype=advisory` and `granted=f`.

You can then identify the blocking session by querying `pg_locks` for the same advisory lock having `granted=t`, as shown in the following example.

```sql
SELECT blocked_locks.pid AS blocked_pid,
       blocking_locks.pid AS blocking_pid,
       blocked_activity.usename AS blocked_user,
       blocking_activity.usename AS blocking_user,
       now() - blocked_activity.xact_start AS blocked_transaction_duration,
       now() - blocking_activity.xact_start AS blocking_transaction_duration,
       concat(blocked_activity.wait_event_type,':',blocked_activity.wait_event) AS blocked_wait_event,
       concat(blocking_activity.wait_event_type,':',blocking_activity.wait_event) AS blocking_wait_event,
       blocked_activity.state AS blocked_state,
       blocking_activity.state AS blocking_state,
       blocked_locks.locktype AS blocked_locktype,
       blocking_locks.locktype AS blocking_locktype,
       blocked_activity.query AS blocked_statement,
```
blocking_activity.query AS blocking_statement
FROM pg_catalog.pg_locks blocked_locks
JOIN pg_catalog.pg_stat_activity blocked_activity ON blocked_activity.pid = blocked_locks.pid
JOIN pg_catalog.pg_locks blocking_locks
  ON blocking_locks.locktype = blocked_locks.locktype
  AND blocking_locks.DATABASE IS NOT DISTINCT FROM blocked_locks.DATABASE
  AND blocking_locks.relation IS NOT DISTINCT FROM blocked_locks.relation
  AND blocking_locks.page IS NOT DISTINCT FROM blocked_locks.page
  AND blocking_locks.tuple IS NOT DISTINCT FROM blocked_locks.tuple
  AND blocking_locks.virtualxid IS NOT DISTINCT FROM blocked_locks.virtualxid
  AND blocking_locks.transactionid IS NOT DISTINCT FROM
      blocked_locks.transactionid
JOIN pg_catalog.pg_stat_activity blocking_activity ON blocking_activity.pid =
  blocking_locks.pid
WHERE NOT blocked_locks.GRANTED;

All of the advisory lock API functions have two sets of arguments, either one bigint argument or two integer arguments:

- For the API functions with one bigint argument, the upper 32 bits are in `pg_locks.classid` and the lower 32 bits are in `pg_locks.objid`.
- For the API functions with two integer arguments, the first argument is `pg_locks.classid` and the second argument is `pg_locks.objid`.

The `pg_locks.objsubid` value indicates which API form was used: 1 means one bigint argument; 2 means two integer arguments.

**Lock:extend**

The Lock:extend event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.

**Topics**

- [Supported engine versions](#)
- [Context](#)
• **Likely causes of increased waits**

• **Actions**

**Supported engine versions**

This wait event information is supported for all versions of Aurora PostgreSQL.

**Context**

The event `Lock:extend` indicates that a backend process is waiting to extend a relation that another backend process holds a lock on while it's extending that relation. Because only one process at a time can extend a relation, the system generates a `Lock:extend` wait event. INSERT, COPY, and UPDATE operations can generate this event.

**Likely causes of increased waits**

When the `Lock:extend` event appears more than normal, possibly indicating a performance problem, typical causes include the following:

**Surge in concurrent inserts or updates to the same table**

There might be an increase in the number of concurrent sessions with queries that insert into or update the same table.

**Insufficient network bandwidth**

The network bandwidth on the DB instance might be insufficient for the storage communication needs of the current workload. This can contribute to storage latency that causes an increase in `Lock:extend` events.

**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

• **Reduce concurrent inserts and updates to the same relation**

• **Increase network bandwidth**
Reduce concurrent inserts and updates to the same relation

First, determine whether there's an increase in `tup_inserted` and `tup_updated` metrics and an accompanying increase in this wait event. If so, check which relations are in high contention for insert and update operations. To determine this, query the `pg_stat_all_tables` view for the values in `n_tup_ins` and `n_tup_upd` fields. For information about the `pg_stat_all_tables` view, see `pg_stat_all_tables` in the PostgreSQL documentation.

To get more information about blocking and blocked queries, query `pg_stat_activity` as in the following example:

```sql
SELECT
    blocked.pid,
    blocked.usename,
    blocked.query,
    blocking.pid AS blocking_id,
    blocking.query AS blocking_query,
    blocking.wait_event AS blocking_wait_event,
    blocking.wait_event_type AS blocking_wait_event_type
FROM pg_stat_activity AS blocked
JOIN pg_stat_activity AS blocking ON blocking.pid = ANY(pg_blocking_pids(blocked.pid))
where
    blocked.wait_event = 'extend'
and blocked.wait_event_type = 'Lock';
```

<table>
<thead>
<tr>
<th>pid</th>
<th>usename</th>
<th>query</th>
<th>blocking_id</th>
<th>blocking_wait_event</th>
<th>blocking_wait_event_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>7143</td>
<td>myuser</td>
<td>insert into tab1 values (1);</td>
<td>4600</td>
<td>INSERT INTO tab1 (a)</td>
<td>DataFileExtend</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SELECT s FROM generate_series(1,1000000) s;</td>
<td></td>
<td></td>
<td>IO</td>
</tr>
</tbody>
</table>

After you identify relations that contribute to increase `Lock:extend` events, use the following techniques to reduce the contention:

- Find out whether you can use partitioning to reduce contention for the same table. Separating inserted or updated tuples into different partitions can reduce contention. For information about partitioning, see [Managing PostgreSQL partitions with the `pg_partman` extension](https://docs.aws.amazon.com/AmazonAurora/latest/UserGuide/USER_Partitions.html).
If the wait event is mainly due to update activity, consider reducing the relation's fillfactor value. This can reduce requests for new blocks during the update. The fillfactor is a storage parameter for a table that determines the maximum amount of space for packing a table page. It's expressed as a percentage of the total space for a page. For more information about the fillfactor parameter, see CREATE TABLE in the PostgreSQL documentation.

⚠️ Important

We highly recommend that you test your system if you change the fillfactor because changing this value can negatively impact performance, depending on your workload.

Increase network bandwidth

To see whether there's an increase in write latency, check the WriteLatency metric in CloudWatch. If there is, use the WriteThroughput and ReadThroughput Amazon CloudWatch metrics to monitor the storage related traffic on the DB cluster. These metrics can help you to determine if network bandwidth is sufficient for the storage activity of your workload.

If your network bandwidth isn't enough, increase it. If your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size.

For more information about CloudWatch metrics, see Amazon CloudWatch metrics for Amazon Aurora. For information about network performance for each DB instance class, see Hardware specifications for DB instance classes for Aurora.

Lock:Relation

The Lock:Relation event occurs when a query is waiting to acquire a lock on a table or view (relation) that's currently locked by another transaction.

Topics

- Supported engine versions
- Context
- Likely causes of increased waits
- Actions
Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

Most PostgreSQL commands implicitly use locks to control concurrent access to data in tables. You can also use these locks explicitly in your application code with the LOCK command. Many lock modes aren't compatible with each other, and they can block transactions when they're trying to access the same object. When this happens, Aurora PostgreSQL generates a Lock:Relation event. Some common examples are the following:

- Exclusive locks such as ACCESS EXCLUSIVE can block all concurrent access. Data definition language (DDL) operations such as DROP TABLE, TRUNCATE, VACUUM FULL, and CLUSTER acquire ACCESS EXCLUSIVE locks implicitly. ACCESS EXCLUSIVE is also the default lock mode for LOCK TABLE statements that don't specify a mode explicitly.
- Using CREATE INDEX (without CONCURRENT) on a table conflicts with data manipulation language (DML) statements UPDATE, DELETE, and INSERT, which acquire ROW EXCLUSIVE locks.

For more information about table-level locks and conflicting lock modes, see Explicit Locking in the PostgreSQL documentation.

Blocking queries and transactions typically unblock in one of the following ways:

- Blocking query – The application can cancel the query or the user can end the process. The engine can also force the query to end because of a session's statement-timeout or a deadlock detection mechanism.
- Blocking transaction – A transaction stops blocking when it runs a ROLLBACK or COMMIT statement. Rollbacks also happen automatically when sessions are disconnected by a client or by network issues, or are ended. Sessions can be ended when the database engine is shut down, when the system is out of memory, and so forth.

Likely causes of increased waits

When the Lock:Relation event occurs more frequently than normal, it can indicate a performance issue. Typical causes include the following:
Increased concurrent sessions with conflicting table locks

There might be an increase in the number of concurrent sessions with queries that lock the same table with conflicting locking modes.

Maintenance operations

Health maintenance operations such as VACUUM and ANALYZE can significantly increase the number of conflicting locks. VACUUM FULL acquires an ACCESS EXCLUSIVE lock, and ANALYZE acquires a SHARE UPDATE EXCLUSIVE lock. Both types of locks can cause a Lock:Relation wait event. Application data maintenance operations such as refreshing a materialized view can also increase blocked queries and transactions.

Locks on reader instances

There might be a conflict between the relation locks held by the writer and readers. Currently, only ACCESS EXCLUSIVE relation locks are replicated to reader instances. However, the ACCESS EXCLUSIVE relation lock will conflict with any ACCESS SHARE relation locks held by the reader. This can cause an increase in lock relation wait events on the reader.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- Reduce the impact of blocking SQL statements
- Minimize the effect of maintenance operations
- Check for reader locks

Reduce the impact of blocking SQL statements

To reduce the impact of blocking SQL statements, modify your application code where possible. Following are two common techniques for reducing blocks:

- Use the NOWAIT option – Some SQL commands, such as SELECT and LOCK statements, support this option. The NOWAIT directive cancels the lock-requesting query if the lock can't be acquired immediately. This technique can help prevent a blocking session from causing a pile-up of blocked sessions behind it.
For example: Assume that transaction A is waiting on a lock held by transaction B. Now, if B requests a lock on a table that’s locked by transaction C, transaction A might be blocked until transaction C completes. But if transaction B uses a NOWAIT when it requests the lock on C, it can fail fast and ensure that transaction A doesn't have to wait indefinitely.

- Use SET `lock_timeout` – Set a `lock_timeout` value to limit the time a SQL statement waits to acquire a lock on a relation. If the lock isn't acquired within the timeout specified, the transaction requesting the lock is cancelled. Set this value at the session level.

**Minimize the effect of maintenance operations**

Maintenance operations such as VACUUM and ANALYZE are important. We recommend that you don't turn them off because you find Lock:Relation wait events related to these maintenance operations. The following approaches can minimize the effect of these operations:

- Run maintenance operations manually during off-peak hours.
- To reduce Lock:Relation waits caused by autovacuum tasks, perform any needed autovacuum tuning. For information about tuning autovacuum, see [Working with PostgreSQL autovacuum on Amazon RDS](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_AutoVacuum.html) in the *Amazon RDS User Guide*.

**Check for reader locks**

You can see how concurrent sessions on a writer and readers might be holding locks that block each other. One way to do this is by running queries that return the lock type and relation. In the table you can find a sequence of queries to two such concurrent sessions, a writer session (left-hand column) and a reader session (right-hand column).

The replay process waits for the duration of `max_standby_streaming_delay` before cancelling the reader query. As shown in the example, the lock timeout of 100ms is well below the default `max_standby_streaming_delay` of 30 seconds. The lock times out before it's an issue.

<table>
<thead>
<tr>
<th><strong>Writer session</strong></th>
<th><strong>Reader session</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>export WRITER=aurorapg1.12345678910.us-west-1.rds.amazonaws.com</td>
<td>export READER=aurorapg2.12345678910.us-west-1.rds.amazonaws.com</td>
</tr>
<tr>
<td>psql -h $WRITER</td>
<td>psql -h $READER</td>
</tr>
<tr>
<td>psql (15devel, server 10.14)</td>
<td>psql (15devel, server 10.14)</td>
</tr>
</tbody>
</table>
The writer session creates table `t1` on the writer instance. The ACCESS EXCLUSIVE lock is acquired on the writer immediately, assuming that there are no conflicting queries on the writer.

```
postgres=> CREATE TABLE t1(b integer);
CREATE TABLE
```

The reader session sets a lock timeout interval of 100 milliseconds.

```
postgres=> SET lock_timeout=100;
SET
```

The reader session tries to read data from table `t1` on the reader instance.

```
postgres=> SELECT * FROM t1;
b
---
(0 rows)
```

The writer session drops `t1`.

```
postgres=> BEGIN;
BEGIN
postgres=> DROP TABLE t1;
DROP TABLE
postgres=>
```

The query times out and is canceled on the reader.

```
postgres=> SELECT * FROM t1;
ERROR: canceling statement due to lock timeout
LINE 1: SELECT * FROM t1;
   ^
```

---

Lock:Relation 2354
Writer session

The reader session queries `pg_locks` and `pg_stat_activity` to determine the cause of the error. The result indicates that the `aurora wal replay` process is holding an `ACCESS EXCLUSIVE` lock on table `t1`.

```
postgres=> SELECT locktype, relation, mode, backend_type
        FROM pg_locks l, pg_stat_activity t1
        WHERE l.pid=t1.pid AND
              relation = 't1'::regclass::oid;
```

```
locktype | relation |        mode | backend_type
----------+----------+----------+-------------------
AccessExc | 68628525 | AccessExc | aurora wal replay

(1 row)
```

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

**Supported engine versions**

This wait event information is supported for all versions of Aurora PostgreSQL.

**Context**

The event `Lock:transactionid` occurs when a transaction is trying to acquire a row-level lock that has already been granted to a transaction that is running at the same time. The session that...
shows the Lock:transactionid wait event is blocked because of this lock. After the blocking transaction ends in either a COMMIT or ROLLBACK statement, the blocked transaction can proceed.

The multiversion concurrency control semantics of Aurora PostgreSQL guarantee that readers don’t block writers and writers don’t block readers. For row-level conflicts to occur, blocking and blocked transactions must issue conflicting statements of the following types:

- UPDATE
- SELECT ... FOR UPDATE
- SELECT ... FOR KEY SHARE

The statement SELECT ... FOR KEY SHARE is a special case. The database uses the clause FOR KEY SHARE to optimize the performance of referential integrity. A row-level lock on a row can block INSERT, UPDATE, and DELETE commands on other tables that reference the row.

**Likely causes of increased waits**

When this event appears more than normal, the cause is typically UPDATE, SELECT ... FOR UPDATE, or SELECT ... FOR KEY SHARE statements combined with the following conditions.

**Topics**

- **High concurrency**
- **Idle in transaction**
- **Long-running transactions**

**High concurrency**

Aurora PostgreSQL can use granular row-level locking semantics. The probability of row-level conflicts increases when the following conditions are met:

- A highly concurrent workload contends for the same rows.
- Concurrency increases.

**Idle in transaction**

Sometimes the pg_stat_activity.state column shows the value idle in transaction. This value appears for sessions that have started a transaction, but haven’t yet issued a COMMIT.
or ROLLBACK. If the pg_stat_activity.state value isn't active, the query shown in pg_stat_activity is the most recent one to finish running. The blocking session isn't actively processing a query because an open transaction is holding a lock.

If an idle transaction acquired a row-level lock, it might be preventing other sessions from acquiring it. This condition leads to frequent occurrence of the wait event Lock:transactionid. To diagnose the issue, examine the output from pg_stat_activity and pg_locks.

Long-running transactions

Transactions that run for a long time get locks for a long time. These long-held locks can block other transactions from running.

Actions

Row-locking is a conflict among UPDATE, SELECT … FOR UPDATE, or SELECT … FOR KEY SHARE statements. Before attempting a solution, find out when these statements are running on the same row. Use this information to choose a strategy described in the following sections.

Topics

• Respond to high concurrency
• Respond to idle transactions
• Respond to long-running transactions

Respond to high concurrency

If concurrency is the issue, try one of the following techniques:

• Lower the concurrency in the application. For example, decrease the number of active sessions.
• Implement a connection pool. To learn how to pool connections with RDS Proxy, see Using Amazon RDS Proxy for Aurora.
• Design the application or data model to avoid contending UPDATE and SELECT … FOR UPDATE statements. You can also decrease the number of foreign keys accessed by SELECT … FOR KEY SHARE statements.

Respond to idle transactions

If pg_stat_activity.state shows idle in transaction, use the following strategies:
• Turn on autocommit wherever possible. This approach prevents transactions from blocking other transactions while waiting for a COMMIT or ROLLBACK.

• Search for code paths that are missing COMMIT, ROLLBACK, or END.

• Make sure that the exception handling logic in your application always has a path to a valid end of transaction.

• Make sure that your application processes query results after ending the transaction with COMMIT or ROLLBACK.

Respond to long-running transactions

If long-running transactions are causing the frequent occurrence of Lock:transactionid, try the following strategies:

• Keep row locks out of long-running transactions.

• Limit the length of queries by implementing autocommit whenever possible.

Lock:tuple

The Lock:tuple event occurs when a backend process is waiting to acquire a lock on a tuple.

Topics

• Supported engine versions

• Context

• Likely causes of increased waits

• Actions

Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

The event Lock:tuple indicates that a backend is waiting to acquire a lock on a tuple while another backend holds a conflicting lock on the same tuple. The following table illustrates a scenario in which sessions generate the Lock:tuple event.
Or you can simulate this wait event by using the benchmarking tool pgbench. Configure a high number of concurrent sessions to update the same row in a table with a custom SQL file.

To learn more about conflicting lock modes, see [Explicit Locking](https://www.postgresql.org/docs/current/lock-implication.html) in the PostgreSQL documentation. To learn more about pgbench, see [pgbench](https://www.postgresql.org/docs/current/pgbench.html) in the PostgreSQL documentation.

**Likely causes of increased waits**

When this event appears more than normal, possibly indicating a performance problem, typical causes include the following:

- A high number of concurrent sessions are trying to acquire a conflicting lock for the same tuple by running UPDATE or DELETE statements.
- Highly concurrent sessions are running a SELECT statement using the FOR UPDATE or FOR NO KEY UPDATE lock modes.
- Various factors drive application or connection pools to open more sessions to execute the same operations. As new sessions are trying to modify the same rows, DB load can spike, and Lock:tuple can appear.

For more information, see [Row-Level Locks](https://www.postgresql.org/docs/current/lock-implication.html) in the PostgreSQL documentation.
**Actions**

We recommend different actions depending on the causes of your wait event.

**Topics**

- **Investigate your application logic**
- **Find the blocker session**
- **Reduce concurrency when it is high**
- **Troubleshoot bottlenecks**

**Investigate your application logic**

Find out whether a blocker session has been in the `idle in transaction` state for long time. If so, consider ending the blocker session as a short-term solution. You can use the `pg_terminate_backend` function. For more information about this function, see [Server Signaling Functions](https://www.postgresql.org/docs/current/server-signaling-functions.html) in the PostgreSQL documentation.

For a long-term solution, do the following:

- Adjust the application logic.
- Use the `idle_in_transaction_session_timeout` parameter. This parameter ends any session with an open transaction that has been idle for longer than the specified amount of time. For more information, see [Client Connection Defaults](https://www.postgresql.org/docs/current/conninfo.html#CONNECT-CONNECTION-TIMEOUT) in the PostgreSQL documentation.
- Use autocommit as much as possible. For more information, see [SET AUTOCOMMIT](https://www.postgresql.org/docs/current/sql-setautocommit.html) in the PostgreSQL documentation.

**Find the blocker session**

While the `Lock:tuple` wait event is occurring, identify the blocker and blocked session by finding out which locks depend on one another. For more information, see [Lock dependency information](https://www.postgresql.org/docs/current/lockinfo.html) in the PostgreSQL wiki. To analyze past `Lock:tuple` events, use the Aurora function `aurora_stat_backend_waits`.

The following example queries all sessions, filtering on `tuple` and ordering by `wait_time`.

```sql
--AURORA_STAT_BACKEND_WAITS
SELECT a.pid,
       a.usename,
       a.wait_time
FROM...
```

---

Lock:tuple
a.app_name,
a.current_query,
a.current_wait_type,
a.current_wait_event,
a.current_state,
w.t.type_name AS wait_type,
we.event_name AS wait_event,
a.waits,
a.wait_time
FROM (SELECT pid,
        usename,
        left(application_name,16) AS app_name,
        coalesce(wait_event_type,'CPU') AS current_wait_type,
        coalesce(wait_event,'CPU') AS current_wait_event,
        state AS current_state,
        left(query,80) as current_query,
        (aurora_stat_backend_waits(pid)).*
    FROM pg_stat_activity
    WHERE pid <> pg_backend_pid()
    AND usename<>'rdsadmin') a
NATURAL JOIN aurora_stat_wait_type() wt
NATURAL JOIN aurora_stat_wait_event() we
WHERE we.event_name = 'tuple'
ORDER BY a.wait_time;

<table>
<thead>
<tr>
<th>pid</th>
<th>usename</th>
<th>app_name</th>
<th>current_query</th>
<th>current_wait_type</th>
<th>current_wait_event</th>
<th>current_state</th>
<th>wait_type</th>
<th>wait_event</th>
<th>waits</th>
<th>wait_time</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

Reduce concurrency when it is high

The Lock:tuple event might occur constantly, especially in a busy workload time. In this situation, consider reducing the high concurrency for very busy rows. Often, just a few rows control a queue or the Boolean logic, which makes these rows very busy.
You can reduce concurrency by using different approaches based in the business requirement, application logic, and workload type. For example, you can do the following:

- Redesign your table and data logic to reduce high concurrency.
- Change the application logic to reduce high concurrency at the row level.
- Leverage and redesign queries with row-level locks.
- Use the NOWAIT clause with retry operations.
- Consider using optimistic and hybrid-locking logic concurrency control.
- Consider changing the database isolation level.

Troubleshoot bottlenecks

The Lock: snapshot can occur with bottlenecks such as CPU starvation or maximum usage of Amazon EBS bandwidth. To reduce bottlenecks, consider the following approaches:

- Scale up your instance class type.
- Optimize resource-intensive queries.
- Change the application logic.
- Archive data that is rarely accessed.

LWLock:buffer_content (BufferContent)

The LWLock:buffer_content event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing. In Aurora PostgreSQL 13 and higher, this wait event is called BufferContent.

Topics
- Supported engine versions
- Context
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.
Context

To read or manipulate data, PostgreSQL accesses it through shared memory buffers. To read from the buffer, a process gets a lightweight lock (LWLock) on the buffer content in shared mode. To write to the buffer, it gets that lock in exclusive mode. Shared locks allow other processes to concurrently acquire shared locks on that content. Exclusive locks prevent other processes from getting any type of lock on it.

The LWLock:buffer_content (BufferContent) event indicates that multiple processes are attempting to get a lock on contents of a specific buffer.

Likely causes of increased waits

When the LWLock:buffer_content (BufferContent) event appears more than normal, possibly indicating a performance problem, typical causes include the following:

Increased concurrent updates to the same data

There might be an increase in the number of concurrent sessions with queries that update the same buffer content. This contention can be more pronounced on tables with a lot of indexes.

Workload data is not in memory

When data that the active workload is processing is not in memory, these wait events can increase. This effect is because processes holding locks can keep them longer while they perform disk I/O operations.

Excessive use of foreign key constraints

Foreign key constraints can increase the amount of time a process holds onto a buffer content lock. This effect is because read operations require a shared buffer content lock on the referenced key while that key is being updated.

Actions

We recommend different actions depending on the causes of your wait event. You might identify LWLock:buffer_content (BufferContent) events by using Amazon RDS Performance Insights or by querying the view pg_stat_activity.

Topics
• **Improve in-memory efficiency**

• **Reduce usage of foreign key constraints**

• **Remove unused indexes**

**Improve in-memory efficiency**

To increase the chance that active workload data is in memory, partition tables or scale up your instance class. For information about DB instance classes, see [Aurora DB instance classes](#).

**Reduce usage of foreign key constraints**

Investigate workloads experiencing high numbers of `LWLock:buffer_content` (BufferContent) wait events for usage of foreign key constraints. Remove unnecessary foreign key constraints.

**Remove unused indexes**

For workloads experiencing high numbers of `LWLock:buffer_content` (BufferContent) wait events, identify unused indexes and remove them.

**LWLock:buffer_mapping**

This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.

---

**Note**

This event appears as `LWLock:buffer_mapping` in Aurora PostgreSQL version 12 and lower, and `LWLock:BufferMapping` in version 13 and higher.

---

**Topics**

• [Supported engine versions](#)

• [Context](#)

• [Causes](#)

• [Actions](#)
Supported engine versions

This wait event information is relevant for Aurora PostgreSQL version 9.6 and higher.

Context

The *shared buffer pool* is an Aurora PostgreSQL memory area that holds all pages that are or were being used by processes. When a process needs a page, it reads the page into the shared buffer pool. The `shared_buffers` parameter sets the shared buffer size and reserves a memory area to store the table and index pages. If you change this parameter, make sure to restart the database. For more information, see [Shared buffers](#).

The `LWLock:buffer_mapping` wait event occurs in the following scenarios:

- A process searches the buffer table for a page and acquires a shared buffer mapping lock.
- A process loads a page into the buffer pool and acquires an exclusive buffer mapping lock.
- A process removes a page from the pool and acquires an exclusive buffer mapping lock.

Causes

When this event appears more than normal, possibly indicating a performance problem, the database is paging in and out of the shared buffer pool. Typical causes include the following:

- Large queries
- Bloated indexes and tables
- Full table scans
- A shared pool size that is smaller than the working set

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- [Monitor buffer-related metrics](#)
- [Assess your indexing strategy](#)
- [Reduce the number of buffers that must be allocated quickly](#)
Monitor buffer-related metrics

When `LWLock:buffer_mapping` waits spike, investigate the buffer hit ratio. You can use these metrics to get a better understanding of what is happening in the buffer cache. Examine the following metrics:

BufferCacheHitRatio

This Amazon CloudWatch metric measures the percentage of requests that are served by the buffer cache of a DB instance in your DB cluster. You might see this metric decrease in the lead-up to the `LWLock:buffer_mapping` wait event.

blks_hit

This Performance Insights counter metric indicates the number of blocks that were retrieved from the shared buffer pool. After the `LWLock:buffer_mapping` wait event appears, you might observe a spike in `blks_hit`.

blks_read

This Performance Insights counter metric indicates the number of blocks that required I/O to be read into the shared buffer pool. You might observe a spike in `blks_read` in the lead-up to the `LWLock:buffer_mapping` wait event.

Assess your indexing strategy

To confirm that your indexing strategy is not degrading performance, check the following:

Index bloat

Ensure that index and table bloat aren't leading to unnecessary pages being read into the shared buffer. If your tables contain unused rows, consider archiving the data and removing the rows from the tables. You can then rebuild the indexes for the resized tables.

Indexes for frequently used queries

To determine whether you have the optimal indexes, monitor DB engine metrics in Performance Insights. The `tup_returned` metric shows the number of rows read. The `tup_fetched` metric shows the number of rows returned to the client. If `tup_returned` is significantly larger than `tup_fetched`, the data might not be properly indexed. Also, your table statistics might not be current.
Reduce the number of buffers that must be allocated quickly

To reduce the LWLock:buffer_mapping wait events, try to reduce the number of buffers that must be allocated quickly. One strategy is to perform smaller batch operations. You might be able to achieve smaller batches by partitioning your tables.

**LWLock:BufferIO (IPC:BufferIO)**

The LWLock:BufferIO event occurs when Aurora PostgreSQL or RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page. Its purpose is for the same page to be read into the shared buffer.

**Topics**

- Relevant engine versions
- Context
- Causes
- Actions

**Relevant engine versions**

This wait event information is relevant for all Aurora PostgreSQL versions. For Aurora PostgreSQL 12 and earlier versions this wait event is named as lwlock:buffer_io whereas in Aurora PostgreSQL 13 version it is named as lwlock:bufferio. From Aurora PostgreSQL 14 version BufferIO wait event moved from LWLock to IPC wait event type (IPC:BufferIO).

**Context**

Each shared buffer has an I/O lock that is associated with the LWLock:BufferIO wait event, each time a block (or a page) has to be retrieved outside the shared buffer pool.

This lock is used to handle multiple sessions that all require access to the same block. This block has to be read from outside the shared buffer pool, defined by the shared_buffers parameter.

As soon as the page is read inside the shared buffer pool, the LWLock:BufferIO lock is released.
Note

The LWLock:BufferIO wait event precedes the IO:DataFileRead wait event. The IO:DataFileRead wait event occurs while data is being read from storage.

For more information on lightweight locks, see Locking Overview.

Causes

Common causes for the LWLock:BufferIO event to appear in top waits include the following:

- Multiple backends or connections trying to access the same page that's also pending an I/O operation
- The ratio between the size of the shared buffer pool (defined by the shared_buffers parameter) and the number of buffers needed by the current workload
- The size of the shared buffer pool not being well balanced with the number of pages being evicted by other operations
- Large or bloated indexes that require the engine to read more pages than necessary into the shared buffer pool
- Lack of indexes that forces the DB engine to read more pages from the tables than necessary
- Sudden spikes for database connections trying to perform operations on the same page

Actions

We recommend different actions depending on the causes of your wait event:

- Observe Amazon CloudWatch metrics for correlation between sharp decreases in the BufferCacheHitRatio and LWLock:BufferIO wait events. This effect can mean that you have a small shared buffers setting. You might need to increase it or scale up your DB instance class. You can split your workload into more reader nodes.
- Tune max_wal_size and checkpoint_timeout based on your workload peak time if you see LWLock:BufferIO coinciding with BufferCacheHitRatio metric dips. Then identify which query might be causing it.
- Verify whether you have unused indexes, then remove them.
• Use partitioned tables (which also have partitioned indexes). Doing this helps to keep index reordering low and reduces its impact.

• Avoid indexing columns unnecessarily.

• Prevent sudden database connection spikes by using a connection pool.

• Restrict the maximum number of connections to the database as a best practice.

**LWLock:lock_manager**

This event occurs when the Aurora PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.

**Topics**

• [Supported engine versions](#)

• [Context](#)

• [Likely causes of increased waits](#)

• [Actions](#)

**Supported engine versions**

This wait event information is relevant for Aurora PostgreSQL version 9.6 and higher.

**Context**

When you issue a SQL statement, Aurora PostgreSQL records locks to protect the structure, data, and integrity of your database during concurrent operations. The engine can achieve this goal using a fast path lock or a path lock that isn't fast. A path lock that isn't fast is more expensive and creates more overhead than a fast path lock.

**Fast path locking**

To reduce the overhead of locks that are taken and released frequently, but that rarely conflict, backend processes can use fast path locking. The database uses this mechanism for locks that meet the following criteria:

• They use the DEFAULT lock method.

• They represent a lock on a database relation rather than a shared relation.
They are weak locks that are unlikely to conflict.

The engine can quickly verify that no conflicting locks can possibly exist.

The engine can't use fast path locking when either of the following conditions is true:

- The lock doesn't meet the preceding criteria.
- No more slots are available for the backend process.

For more information about fast path locking, see fast path in the PostgreSQL lock manager README and pg-locks in the PostgreSQL documentation.

**Example of a scaling problem for the lock manager**

In this example, a table named purchases stores five years of data, partitioned by day. Each partition has two indexes. The following sequence of events occurs:

1. You query many days worth of data, which requires the database to read many partitions.
2. The database creates a lock entry for each partition. If partition indexes are part of the optimizer access path, the database creates a lock entry for them, too.
3. When the number of requested locks entries for the same backend process is higher than 16, which is the value of FP_LOCK_SLOTS_PER_BACKEND, the lock manager uses the non–fast path lock method.

Modern applications might have hundreds of sessions. If concurrent sessions are querying the parent without proper partition pruning, the database might create hundreds or even thousands of non–fast path locks. Typically, when this concurrency is higher than the number of vCPUs, the LWLock:lock_manager wait event appears.

**Note**

The LWLock:lock_manager wait event isn't related to the number of partitions or indexes in a database schema. Instead, it's related to the number of non–fast path locks that the database must control.
Likely causes of increased waits

When the LWLock:lock_manager wait event occurs more than normal, possibly indicating a performance problem, the most likely causes of sudden spikes are as follows:

- Concurrent active sessions are running queries that don't use fast path locks. These sessions also exceed the maximum vCPU.
- A large number of concurrent active sessions are accessing a heavily partitioned table. Each partition has multiple indexes.
- The database is experiencing a connection storm. By default, some applications and connection pool software create more connections when the database is slow. This practice makes the problem worse. Tune your connection pool software so that connection storms don't occur.
- A large number of sessions query a parent table without pruning partitions.
- A data definition language (DDL), data manipulation language (DML), or a maintenance command exclusively locks either a busy relation or tuples that are frequently accessed or modified.

Actions

We recommend different actions depending on the causes of your wait event.

Topics

- **Use partition pruning**
- **Remove unnecessary indexes**
- **Tune your queries for fast path locking**
- **Tune for other wait events**
- **Reduce hardware bottlenecks**
- **Use a connection pooler**
- **Upgrade your Aurora PostgreSQL version**

Use partition pruning

*Partition pruning* is a query optimization strategy that excludes unneeded partitions from table scans, thereby improving performance. Partition pruning is turned on by default. If it is turned off, turn it on as follows.
SET enable_partition_pruning = on;

Queries can take advantage of partition pruning when their WHERE clause contains the column used for the partitioning. For more information, see Partition Pruning in the PostgreSQL documentation.

**Remove unnecessary indexes**

Your database might contain unused or rarely used indexes. If so, consider deleting them. Do either of the following:

- Learn how to find unnecessary indexes by reading Unused Indexes in the PostgreSQL wiki.
- Run PG Collector. This SQL script gathers database information and presents it in a consolidated HTML report. Check the "Unused indexes" section. For more information, see pg-collector in the AWS Labs GitHub repository.

**Tune your queries for fast path locking**

To find out whether your queries use fast path locking, query the fastpath column in the pg_locks table. If your queries aren't using fast path locking, try to reduce number of relations per query to fewer than 16.

**Tune for other wait events**

If LWLock:lock_manager is first or second in the list of top waits, check whether the following wait events also appear in the list:

- Lock:Relation
- Lock:transactionid
- Lock:tuple

If the preceding events appear high in the list, consider tuning these wait events first. These events can be a driver for LWLock:lock_manager.

**Reduce hardware bottlenecks**

You might have a hardware bottleneck, such as CPU starvation or maximum usage of your Amazon EBS bandwidth. In these cases, consider reducing the hardware bottlenecks. Consider the following actions:
• Scale up your instance class.
• Optimize queries that consume large amounts of CPU and memory.
• Change your application logic.
• Archive your data.

For more information about CPU, memory, and EBS network bandwidth, see Amazon RDS Instance Types.

Use a connection pooler

If your total number of active connections exceeds the maximum vCPU, more OS processes require CPU than your instance type can support. In this case, consider using or tuning a connection pool. For more information about the vCPUs for your instance type, see Amazon RDS Instance Types.

For more information about connection pooling, see the following resources:

• Using Amazon RDS Proxy for Aurora
• pgbouncer
• Connection Pools and Data Sources in the PostgreSQL Documentation

Upgrade your Aurora PostgreSQL version

If your current version of Aurora PostgreSQL is lower than 12, upgrade to version 12 or higher. PostgreSQL versions 12 and 13 have an improved partition mechanism. For more information about version 12, see PostgreSQL 12.0 Release Notes. For more information about upgrading Aurora PostgreSQL, see Amazon Aurora PostgreSQL updates.

**LWLock:MultiXact**

The LWLock:MultiXactMemberBuffer, LWLock:MultiXactOffsetBuffer, LWLock:MultiXactMemberSLRU, and LWLock:MultiXactOffsetSLRU wait events indicate that a session is waiting to retrieve a list of transactions that modifies the same row in a given table.

• LWLock:MultiXactMemberBuffer – A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a multixact member.
• LWLock:MultiXactMemberSLRU – A process is waiting to access the simple least-recently used (SLRU) cache for a multixact member.
• LWLock:MultiXactOffsetBuffer – A process is waiting for I/O on a simple least-recently used (SLRU) buffer for a multixact offset.

• LWLock:MultiXactOffsetSLRU – A process is waiting to access the simple least-recently used (SLRU) cache for a multixact offset.

Topics

• Supported engine versions
• Context
• Likely causes of increased waits
• Actions

Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Context

A multixact is a data structure that stores a list of transaction IDs (XIDs) that modify the same table row. When a single transaction references a row in a table, the transaction ID is stored in the table header row. When multiple transactions reference the same row in a table, the list of transaction IDs is stored in the multixact data structure. The multixact wait events indicate that a session is retrieving from the data structure the list of transactions that refer to a given row in a table.

Likely causes of increased waits

Three common causes of multixact use are as follows:

• Sub-transactions from explicit savepoints – Explicitly creating a savepoint in your transactions spawns new transactions for the same row. For example, using SELECT FOR UPDATE, then SAVEPOINT, and then UPDATE.

Some drivers, object-relational mappers (ORMs), and abstraction layers have configuration options for automatically wrapping all operations with savepoints. This can generate many multixact wait events in some workloads. The PostgreSQL JDBC Driver's autosave option is an example of this. For more information, see pgJDBC in the PostgreSQL JDBC documentation. Another example is the PostgreSQL ODBC driver and its protocol option. For more information, see psqlODBC Configuration Options in the PostgreSQL ODBC driver documentation.
• **Sub-transactions from PL/pgSQL EXCEPTION clauses** – Each EXCEPTION clause that you write in your PL/pgSQL functions or procedures creates a SAVEPOINT internally.

• **Foreign keys** – Multiple transactions acquire a shared lock on the parent record.

When a given row is included in a multiple transaction operation, processing the row requires retrieving transaction IDs from the multixact listings. If lookups can’t get the multixact from the memory cache, the data structure must be read from the Aurora storage layer. This I/O from storage means that SQL queries can take longer. Memory cache misses can start occurring with heavy usage due to a large number of multiple transactions. All these factors contribute to an increase in this wait event.

**Actions**

We recommend different actions depending on the causes of your wait event. Some of these actions can help in immediate reduction of the wait events. But, others might require investigation and correction to scale your workload.

**Topics**

• [Perform vacuum freeze on tables with this wait event](#)

• [Increase autovacuum frequency on tables with this wait event](#)

• [Increase memory parameters](#)

• [Reduce long-running transactions](#)

• [Long term actions](#)

**Perform vacuum freeze on tables with this wait event**

If this wait event spikes suddenly and affects your production environment, you can use any of the following temporary methods to reduce its count.

• Use `VACUUM FREEZE` on the affected table or table partition to resolve the issue immediately. For more information, see [VACUUM](#).

• Use the VACUUM (FREEZE, INDEX_CLEANUP FALSE) clause to perform a quick vacuum by skipping the indexes. For more information, see [Vacuuming a table as quickly as possible](#).
Increase autovacuum frequency on tables with this wait event

After scanning all tables in all databases, VACUUM will eventually remove multixacts, and their oldest multixact values are advanced. For more information, see Multixacts and Wraparound. To keep the LWLock:MultiXact wait events to its minimum, you must run the VACUUM as often as necessary. To do so, ensure that the VACUUM in your Aurora PostgreSQL DB cluster is configured optimally.

If using VACUUM FREEZE on the affected table or table partition resolves the wait event issue, we recommend using a scheduler, such as pg_cron, to perform the VACUUM instead of adjusting autovacuum at the instance level.

For the autovacuum to happen more frequently, you can reduce the value of the storage parameter autovacuum_multixact_freeze_max_age in the affected table. For more information, see autovacuum_multixact_freeze_max_age.

Increase memory parameters

You can set the following parameters at the cluster level so that all instances in your cluster remain consistent. This helps in reducing the wait events in your workload. We recommend you to not set these values so high that you run out of memory.

- multixact_offsets_cache_size to 128
- multixact_members_cache_size to 256

You must reboot the instance for the parameter change to take affect. With these parameters, you can use more of the instance RAM to store the multixact structure in memory before spilling to disk.

Reduce long-running transactions

Long-running transaction causes the vacuum to retain its information until the transaction is committed or until the read-only transaction is closed. We recommend that you proactively monitor and manage long-running transactions. For more information, see Database has long running idle in transaction connection. Try to modify your application to avoid or minimize your use of long-running transactions.
Long term actions

Examine your workload to discover the cause for the multixact spillover. You must fix the issue in order to scale your workload and reduce the wait event.

- You must analyze the DDL (data definition language) used to create your tables. Make sure that the table structures and indexes are well designed.
- When the affected tables have foreign keys, determine whether they are needed or if there is another way to enforce referential integrity.
- When a table has large unused indexes, it can cause autovacuum to not fit your workload and might block it from running. To avoid this, check for unused indexes and remove them completely. For more information, see Managing autovacuum with large indexes.
- Reduce the use of savepoints in your transactions.

Timeout: PgSleep

The Timeout: PgSleep event occurs when a server process has called the pg_sleep function and is waiting for the sleep timeout to expire.

Topics

- Supported engine versions
- Likely causes of increased waits
- Actions

Supported engine versions

This wait event information is supported for all versions of Aurora PostgreSQL.

Likely causes of increased waits

This wait event occurs when an application, stored function, or user issues a SQL statement that calls one of the following functions:

- pg_sleep
- pg_sleep_for
- pg_sleep_until
The preceding functions delay execution until the specified number of seconds have elapsed. For example, `SELECT pg_sleep(1)` pauses for 1 second. For more information, see Delaying Execution in the PostgreSQL documentation.

**Actions**

Identify the statement that was running the `pg_sleep` function. Determine if the use of the function is appropriate.

**Tuning Aurora PostgreSQL with Amazon DevOps Guru proactive insights**

DevOps Guru proactive insights detects conditions on your Aurora PostgreSQL DB clusters that can cause problems, and lets you know about them before they occur. DevOps Guru can do the following:

- Prevent many common database issues by cross-checking your database configuration against common recommended settings.
- Alert you to critical issues in your fleet that, if left unchecked, can lead to larger problems later.
- Alert you to newly discovered problems.

Every proactive insight contains an analysis of the cause of the problem and recommendations for corrective actions.

**Topics**

- [Database has long running idle in transaction connection](#)

**Database has long running idle in transaction connection**

A connection to the database has been in the `idle in transaction` state for more than 1800 seconds.

**Topics**

- [Supported engine versions](#)
- [Context](#)
• **Likely causes for this issue**

• **Actions**

• **Relevant metrics**

### Supported engine versions

This insight information is supported for all versions of Aurora PostgreSQL.

### Context

A transaction in the *idle in transaction* state can hold locks that block other queries. It can also prevent VACUUM (including autovacuum) from cleaning up dead rows, leading to index or table bloat or transaction ID wraparound.

### Likely causes for this issue

A transaction initiated in an interactive session with BEGIN or START TRANSACTION hasn't ended by using a COMMIT, ROLLBACK, or END command. This causes the transaction to move to *idle in transaction* state.

### Actions

You can find idle transactions by querying `pg_stat_activity`.

In your SQL client, run the following query to list all connections in *idle in transaction* state and to order them by duration:

```sql
SELECT now() - state_change as idle_in_transaction_duration, now() - xact_start as xact_duration,*
FROM pg_stat_activity
WHERE state = 'idle in transaction'
AND xact_start is not null
ORDER BY 1 DESC;
```

We recommend different actions depending on the causes of your insight.

### Topics

• **End transaction**
- Terminate the connection
- Configure the `idle_in_transaction_session_timeout` parameter
- Check the AUTOCOMMIT status
- Check the transaction logic in your application code

**End transaction**

When you initiate a transaction in an interactive session with `BEGIN` or `START TRANSACTION`, it moves to `idle in transaction` state. It remains in this state until you end the transaction by issuing a `COMMIT`, `ROLLBACK`, `END` command or disconnect the connection completely to roll back the transaction.

**Terminate the connection**

Terminate the connection with an idle transaction using the following query:

```sql
SELECT pg_terminate_backend(pid);
```

pid is the process ID of the connection.

**Configure the `idle_in_transaction_session_timeout` parameter**

Configure the `idle_in_transaction_session_timeout` parameter in the parameter group. The advantage of configuring this parameter is that it does not require a manual intervention to terminate the long idle in transaction. For more information on this parameter, see [the PostgreSQL documentation](https://www.postgresql.org/docs/current/static/runtime-parameters.html).

The following message will be reported in the PostgreSQL log file after the connection is terminated, when a transaction is in the `idle_in_transaction` state for longer than the specified time.

```
FATAL: terminating connection due to idle in transaction timeout
```

**Check the AUTOCOMMIT status**

AUTOCOMMIT is turned on by default. But if it is accidentally turned off in the client ensure that you turn it back on.
• In your psql client, run the following command:

```
postgres=> \set AUTOCOMMIT on
```

• In pgadmin, turn it on by choosing the AUTOCOMMIT option from the down arrow.

---

**Check the transaction logic in your application code**

Investigate your application logic for possible problems. Consider the following actions:

• Check if the JDBC auto commit is set true in your application. Also, consider using explicit `COMMIT` commands in your code.

• Check your error handling logic to see whether it closes a transaction after errors.

• Check whether your application is taking long to process the rows returned by a query while the transaction is open. If so, consider coding the application to close the transaction before processing the rows.

• Check whether a transaction contains many long-running operations. If so, divide a single transaction into multiple transactions.

**Relevant metrics**

The following PI metrics are related to this insight:

• `idle_in_transaction_count` - Number of sessions in `idle in transaction` state.

• `idle_in_transaction_max_time` - The duration of the longest running transaction in the `idle in transaction` state.
Best practices with Amazon Aurora PostgreSQL

Following, you can find several best practices for managing your Amazon Aurora PostgreSQL DB cluster. Be sure to also review basic maintenance tasks. For more information, see Managing Amazon Aurora PostgreSQL.

Topics

- Avoiding slow performance, automatic restart, and failover for Aurora PostgreSQL DB instances
- Diagnosing table and index bloat
- Improved memory management in Aurora PostgreSQL
- Fast failover with Amazon Aurora PostgreSQL
- Fast recovery after failover with cluster cache management for Aurora PostgreSQL
- Managing Aurora PostgreSQL connection churn with pooling
- Tuning memory parameters for Aurora PostgreSQL
- Using Amazon CloudWatch metrics to analyze resource usage for Aurora PostgreSQL
- Using logical replication to perform a major version upgrade for Aurora PostgreSQL
- Troubleshooting storage issues

Avoiding slow performance, automatic restart, and failover for Aurora PostgreSQL DB instances

If you're running a heavy workload or workloads that spike beyond the allocated resources of your DB instance, you can exhaust the resources on which you're running your application and Aurora database. To get metrics on your database instance such as CPU utilization, memory usage, and number of database connections used, you can refer to the metrics provided by Amazon CloudWatch, Performance Insights, and Enhanced Monitoring. For more information on monitoring your DB instance, see Monitoring metrics in an Amazon Aurora cluster.

If your workload exhausts the resources you're using, your DB instance might slow down, restart, or even fail over to another DB instance. To avoid this, monitor your resource utilization, examine the workload running on your DB instance, and make optimizations where necessary. If optimizations don't improve the instance metrics and mitigate the resource exhaustion, consider scaling up your DB instance before you reach its limits. For more information on available DB instance classes and their specifications, see Aurora DB instance classes.
Diagnosing table and index bloat

You can use PostgreSQL Multiversion Concurrency Control (MVCC) to help preserve data integrity. PostgreSQL MVCC works by saving an internal copy of updated or deleted rows (also called tuples) until a transaction is either committed or rolled back. This saved internal copy is invisible to users. However, table bloat can occur when those invisible copies aren't cleaned up regularly by the VACUUM or AUTOVACUUM utilities. Unchecked, table bloat can incur increased storage costs and slow your processing speed.

In many cases, the default settings for VACUUM or AUTOVACUUM on Aurora are sufficient for handling unwanted table bloat. However, you may want to check for bloat if your application is experiencing the following conditions:

- Processes a large number of transactions in a relatively short time between VACUUM processes.
- Performs poorly and runs out of storage.

To get started, gather the most accurate information about how much space is used by dead tuples and how much you can recover by cleaning up the table and index bloat. To do so, use the pgstattuple extension to gather statistics on your Aurora cluster. For more information, see pgstattuple. Privileges to use the pgstattuple extension are limited to the pg_stat_scan_tables role and database superusers.

To create the pgstattuple extension on Aurora, connect a client session to the cluster, for example, psql or pgAdmin, and use the following command:

```
CREATE EXTENSION pgstattuple;
```

Create the extension in each database that you want to profile. After creating the extension, use the command line interface (CLI) to measure how much unusable space you can reclaim. Before gathering statistics, modify the cluster parameter group by setting AUTOVACUUM to 0. A setting of 0 prevents Aurora from automatically cleaning up any dead tuples left behind by your application, which can impact the accuracy of the results. Enter the following command to create a simple table:

```
postgres=> CREATE TABLE lab AS SELECT generate_series (0,100000);
SELECT 100001
```
In the following example, we run the query with AUTOVACUUM turned on for the DB cluster. The dead_tuple_count is 0, which indicates that the AUTOVACUUM has deleted the obsolete data or tuples from the PostgreSQL database.

To use pgstattuple to gather information about the table, specify the name of a table or an object identifier (OID) in the query:

```sql
postgres=> SELECT * FROM pgstattuple('lab');
```

```
<table>
<thead>
<tr>
<th>table_len</th>
<th>tuple_count</th>
<th>tuple_len</th>
<th>tuple_percent</th>
<th>dead_tuple_count</th>
<th>dead_tuple_len</th>
<th>dead_tuple_percent</th>
<th>free_space</th>
<th>free_percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>3629056</td>
<td>100001</td>
<td>2800028</td>
<td>77.16</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>16616</td>
<td>0.46</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
(1 row)
```

In the following query, we turn off AUTOVACUUM and enter a command that deletes 25,000 rows from the table. As a result, the dead_tuple_count increases to 25000.

```sql
postgres=> DELETE FROM lab WHERE generate_series < 25000;
```

```
DELETE 25000
```

```sql
SELECT * FROM pgstattuple('lab');
```

```
<table>
<thead>
<tr>
<th>table_len</th>
<th>tuple_count</th>
<th>tuple_len</th>
<th>tuple_percent</th>
<th>dead_tuple_count</th>
<th>dead_tuple_len</th>
<th>dead_tuple_percent</th>
<th>free_space</th>
<th>free_percent</th>
</tr>
</thead>
<tbody>
<tr>
<td>3629056</td>
<td>75001</td>
<td>2100028</td>
<td>57.87</td>
<td>25000</td>
<td>700000</td>
<td>19.29</td>
<td>16616</td>
<td>0.46</td>
</tr>
</tbody>
</table>
```

Diagnosing table and index bloat
To reclaim those dead tuples, start a VACUUM process.

**Observing bloat without interrupting your application**

Settings on an Aurora cluster are optimized to provide the best practices for most workloads. However, you might want to optimize a cluster to better suit your applications and use patterns. In this case, you can use the `pgstatstuple` extension without disrupting a busy application. To do so, perform the following steps:

1. Clone your Aurora instance.
2. Modify the parameter file to turn off AUTOVACUUM in the clone.
3. Perform a `pgstatstuple` query while testing the clone with a sample workload or with `pgbench`, which is a program for running benchmark tests on PostgreSQL. For more information, see [pgbench](https://www.postgresql.org/docs/current/pgbench.html).

After running your applications and viewing the result, use `pg_repack` or VACUUM FULL on the restored copy and compare the differences. If you see a significant drop in the `dead_tuple_count`, `dead_tuple_len`, or `dead_tuple_percent`, then adjust the vacuum schedule on your production cluster to minimize the bloat.

**Avoiding bloat in temporary tables**

If your application creates temporary tables, make sure that your application removes those temporary tables when they’re no longer needed. Autovacuum processes don’t locate temporary tables. Left unchecked, temporary tables can quickly create database bloat. Moreover, the bloat can extend into the system tables, which are the internal tables that track PostgreSQL objects and attributes, like `pg_attribute` and `pg_depend`.

When a temporary table is no longer needed, you can use a TRUNCATE statement to empty the table and free up the space. Then, manually vacuum the `pg_attribute` and `pg_depend` tables. Vacuuming these tables ensures that creating and truncating/deleting temporary tables continually isn’t adding tuples and contributing to system bloat.

You can avoid this problem while creating a temporary table by including the following syntax that deletes the new rows when content is committed:
CREATE TEMP TABLE IF NOT EXISTS table_name(table_description) ON COMMIT DELETE ROWS;

The ON COMMIT DELETE ROWS clause truncates the temporary table when the transaction is committed.

**Avoiding bloat in indexes**

When you change an indexed field in a table, the index update results in one or more dead tuples in that index. By default, the autovacuum process cleans up bloat in indexes, but that cleanup uses a significant amount of time and resources. To specify index cleanup preferences when you create a table, include the vacuum_index_cleanup clause. By default, at table creation time, the clause is set to AUTO, which means that the server decides if your index requires cleanup when it vacuums the table. You can set the clause to ON to turn on index cleanup for a specific table, or OFF to turn off index cleanup for that table. Remember, turning off index cleanup might save time, but can potentially lead to a bloated index.

You can manually control index cleanup when you VACUUM a table at the command line. To vacuum a table and remove dead tuples from the indexes, include the INDEX_CLEANUP clause with a value of ON and the table name:

```
acctg=> VACUUM (INDEX_CLEANUP ON) receivables;
INFO: aggressively vacuuming "public.receivables"
VACUUM
```

To vacuum a table without cleaning the indexes, specify a value of OFF:

```
acctg=> VACUUM (INDEX_CLEANUP OFF) receivables;
INFO: aggressively vacuuming "public.receivables"
VACUUM
```

**Improved memory management in Aurora PostgreSQL**

Customer workloads exhausting the free memory available in the DB instance leads to database restart by the operating system causing database unavailability. Aurora PostgreSQL has introduced improved memory management capabilities that proactively prevents stability issues and database restarts caused by insufficient free memory. This improvement is available by default in the following versions:
• 15.3 and higher 15 versions
• 14.8 and higher 14 versions
• 13.11 and higher 13 versions
• 12.15 and higher 12 versions
• 11.20 and higher 11 versions

To improve the memory management, it does the following:

• Cancelling database transactions that request more memory when the system is approaching critical memory pressure.
• The system is said to be under critical memory pressure, when it exhausts all the physical memory and is about to exhaust the swap. In these circumstances, any transaction that requests memory will be cancelled in an effort to immediately reduce memory pressure in the DB instance.
• Essential PostgreSQL launchers and background workers such as autovacuum workers are always protected.

Configuring memory management parameters

To turn on memory management

This feature is turned on by default. An error message is displayed when a transaction is cancelled due to insufficient memory as shown in the following example:

```
ERROR: out of memory  Detail: Failed on request of size 16777216.
```

To turn off memory management

To turn off this feature, connect to the Aurora PostgreSQL DB cluster with psql and use the SET statement for the parameter values as mentioned below.

For Aurora PostgreSQL versions 11.21, 12.16, 13.12, 14.9, 15.4, and older versions:

```
postgres=>SET rds.memory_allocation_guard = true;
```

The default value of rds.memory_allocation_guard parameter is set to false in the Parameter group.
For Aurora PostgreSQL 12.17, 13.13, 14.10, 15.5, and higher versions:

```
postgres=>rds.enable_memory_management = false;
```

The default value of `rds.enable_memory_management` parameter is set to `true` in the Parameter group.

Setting the values of these parameters in the DB cluster parameter group prevents the queries from being canceled. For more information about DB cluster parameter group, see [Working with parameter groups](#).

The value of these dynamic parameters can also be set at a session level to include or exclude a session in improved memory management.

---

**Note**

We don't recommend turning off this feature as it might lead to out-of-memory error that can cause workload induced database restart due to the memory exhaustion in the system.

---

**Fast failover with Amazon Aurora PostgreSQL**

Following, you can learn how to make sure that failover occurs as fast as possible. To recover quickly after failover, you can use cluster cache management for your Aurora PostgreSQL DB cluster. For more information, see [Fast recovery after failover with cluster cache management for Aurora PostgreSQL](#).

Some of the steps that you can take to make failover perform fast include the following:

- Set Transmission Control Protocol (TCP) keepalives with short time frames, to stop longer running queries before the read timeout expires if there's a failure.
- Set timeouts for Java Domain Name System (DNS) caching aggressively. Doing this helps ensure the Aurora read-only endpoint can properly cycle through read-only nodes on later connection attempts.
- Set the timeout variables used in the JDBC connection string as low as possible. Use separate connection objects for short- and long-running queries.
- Use the read and write Aurora endpoints that are provided to connect to the cluster.
• Use RDS API operations to test application response on server-side failures. Also, use a packet dropping tool to test application response for client-side failures.

• Use the AWS JDBC Driver to take full advantage of the failover capabilities of Aurora PostgreSQL. For more information about the AWS JDBC Driver and complete instructions for using it, see the Amazon Web Services (AWS) JDBC Driver GitHub repository.

These are covered in more detail following.

Topics

• Setting TCP keepalives parameters
• Configuring your application for fast failover
• Testing failover
• Fast failover example in Java

Setting TCP keepalives parameters

When you set up a TCP connection, a set of timers is associated with the connection. When the keepalive timer reaches zero, a keepalive probe packet is sent to the connection endpoint. If the probe receives a reply, you can assume that the connection is still up and running.

Turning on TCP keepalive parameters and setting them aggressively ensures that if your client can't connect to the database, any active connections are quickly closed. The application can then connect to a new endpoint.

Make sure to set the following TCP keepalive parameters:

• `tcp_keepalive_time` controls the time, in seconds, after which a keepalive packet is sent when no data has been sent by the socket. ACKs aren't considered data. We recommend the following setting:

  `tcp_keepalive_time = 1`

• `tcp_keepalive_intvl` controls the time, in seconds, between sending subsequent keepalive packets after the initial packet is sent. Set this time by using the `tcp_keepalive_time` parameter. We recommend the following setting:

  `tcp_keepalive_intvl = 1`
• `tcp_keepalive_probes` is the number of unacknowledged keepalive probes that occur before the application is notified. We recommend the following setting:

```
tcp_keepalive_probes = 5
```

These settings should notify the application within five seconds when the database stops responding. If keepalive packets are often dropped within the application's network, you can set a higher `tcp_keepalive_probes` value. Doing this allows for more buffer in less reliable networks, although it increases the time that it takes to detect an actual failure.

To set TCP keepalive parameters on Linux

1. Test how to configure your TCP keepalive parameters.

   We recommend doing so by using the command line with the following commands. This suggested configuration is system-wide. In other words, it also affects all other applications that create sockets with the `SO_KEEPALIVE` option on.

   ```
   sudo sysctl net.ipv4.tcp_keepalive_time=1
   sudo sysctl net.ipv4.tcp_keepalive_intvl=1
   sudo sysctl net.ipv4.tcp_keepalive_probes=5
   ```

2. After you've found a configuration that works for your application, persist these settings by adding the following lines to `/etc/sysctl.conf`, including any changes you made:

   ```
   tcp_keepalive_time = 1
   tcp_keepalive_intvl = 1
   tcp_keepalive_probes = 5
   ```

Configuring your application for fast failover

Following, you can find a discussion of several configuration changes for Aurora PostgreSQL that you can make for fast failover. To learn more about PostgreSQL JDBC driver setup and configuration, see the [PostgreSQL JDBC Driver](#) documentation.

Topics

- [Reducing DNS cache timeouts](#)
- [Setting an Aurora PostgreSQL connection string for fast failover](#)
Other options for obtaining the host string

Reducing DNS cache timeouts

When your application tries to establish a connection after a failover, the new Aurora PostgreSQL writer will be a previous reader. You can find it by using the Aurora read-only endpoint before DNS updates have fully propagated. Setting the java DNS time to live (TTL) to a low value, such as under 30 seconds, helps cycle between reader nodes on later connection attempts.

```java
// Sets internal TTL to match the Aurora RO Endpoint TTL
java.security.Security.setProperty("networkaddress.cache.ttl", "1");
// If the lookup fails, default to something like small to retry
java.security.Security.setProperty("networkaddress.cache.negative.ttl", "3");
```

Setting an Aurora PostgreSQL connection string for fast failover

To use Aurora PostgreSQL fast failover, make sure that your application's connection string has a list of hosts instead of just a single host. Following is an example connection string that you can use to connect to an Aurora PostgreSQL cluster. In this example, the hosts are in bold.

```java
jdbc:postgresql://
myauroracluster.cluster-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432,
myauroracluster.cluster-ro-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432
/postgres?user=<primaryuser>&password=<primarypw>&loginTimeout=2
&connectTimeout=2&cancelSignalTimeout=2&socketTimeout=60
&tcpKeepAlive=true&targetServerType=primary
```

For best availability and to avoid a dependency on the RDS API, we recommend that you maintain a file to connect with. This file contains a host string that your application reads from when you establish a connection to the database. This host string has all the Aurora endpoints available for the cluster. For more information about Aurora endpoints, see Amazon Aurora connection management.

For example, you might store your endpoints in a local file as shown following.

```java
myauroracluster.cluster-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432,
myauroracluster.cluster-ro-c9bfei4hjlrd.us-east-1-beta.rds.amazonaws.com:5432
```
Your application reads from this file to populate the host section of the JDBC connection string. Renaming the DB cluster causes these endpoints to change. Make sure that your application handles this event if it occurs.

Another option is to use a list of DB instance nodes, as follows.

```
my-node1.cksc6x1mwcwyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node2.cksc6x1mwcwyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node3.cksc6x1mwcwyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node4.cksc6x1mwcwyw.us-east-1-beta.rds.amazonaws.com:5432
```

The benefit of this approach is that the PostgreSQL JDBC connection driver loops through all nodes on this list to find a valid connection. In contrast, when you use the Aurora endpoints only two nodes are tried in each connection attempt. However, there's a downside to using DB instance nodes. If you add or remove nodes from your cluster and the list of instance endpoints becomes stale, the connection driver might never find the correct host to connect to.

To help ensure that your application doesn't wait too long to connect to any one host, set the following parameters aggressively:

- **targetServerType** – Controls whether the driver connects to a write or read node. To ensure that your applications reconnect only to a write node, set the `targetServerType` value to `primary`.

  Values for the `targetServerType` parameter include `primary`, `secondary`, `any`, and `preferSecondary`. The `preferSecondary` value attempts to establish a connection to a reader first. It connects to the writer if no reader connection can be established.

- **loginTimeout** – Controls how long your application waits to log in to the database after a socket connection has been established.

- **connectTimeout** – Controls how long the socket waits to establish a connection to the database.

You can modify other application parameters to speed up the connection process, depending on how aggressive you want your application to be:

- **cancelSignalTimeout** – In some applications, you might want to send a "best effort" cancel signal on a query that has timed out. If this cancel signal is in your failover path, consider setting it aggressively to avoid sending this signal to a dead host.
• **socketTimeout** – This parameter controls how long the socket waits for read operations. This parameter can be used as a global "query timeout" to ensure no query waits longer than this value. A good practice is to have two connection handlers. One connection handler runs short-lived queries and sets this value lower. Another connection handler, for long-running queries, has this value set much higher. With this approach, you can rely on TCP keepalive parameters to stop long-running queries if the server goes down.

• **tcpKeepAlive** – Turn on this parameter to ensure the TCP keepalive parameters that you set are respected.

• **loadBalanceHosts** – When set to true, this parameter has the application connect to a random host chosen from a list of candidate hosts.

**Other options for obtaining the host string**

You can get the host string from several sources, including the `aurora_replica_status` function and by using the Amazon RDS API.

In many cases, you need to determine who the writer of the cluster is or to find other reader nodes in the cluster. To do this, your application can connect to any DB instance in the DB cluster and query the `aurora_replica_status` function. You can use this function to reduce the amount of time it takes to find a host to connect to. However, in certain network failure scenarios the `aurora_replica_status` function might show out-of-date or incomplete information.

A good way to ensure that your application can find a node to connect to is to try to connect to the cluster writer endpoint and then the cluster reader endpoint. You do this until you can establish a readable connection. These endpoints don't change unless you rename your DB cluster. Thus, you can generally leave them as static members of your application or store them in a resource file that your application reads from.

After you establish a connection using one of these endpoints, you can get information about the rest of the cluster. To do this, call the `aurora_replica_status` function. For example, the following command retrieves information with `aurora_replica_status`.

```sql
postgres=> SELECT server_id, session_id, highest_lsn_rcvd, cur_replay_latency_in_usec, now(), last_update_timestamp
FROM aurora_replica_status();
```

<table>
<thead>
<tr>
<th>server_id</th>
<th>session_id</th>
<th>highest_lsn_rcvd</th>
<th>cur_replay_latency_in_usec</th>
<th>now</th>
<th>last_update_timestamp</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
For example, the hosts section of your connection string might start with both the writer and reader cluster endpoints, as shown following.

```
myaurorACLuster.cluster-c9be14hj1rd.us-east-1-beta.rds.amazonaws.com:5432,
myaurorACLuster.cluster-ro-c9be14hj1rd.us-east-1-beta.rds.amazonaws.com:5432
```

In this scenario, your application attempts to establish a connection to any node type, primary or secondary. When your application is connected, a good practice is to first examine the read/write status of the node. To do this, query for the result of the command `SHOW transaction_read_only`.

If the return value of the query is `OFF`, then you successfully connected to the primary node. However, suppose that the return value is `ON` and your application requires a read/write connection. In this case, you can call the `aurora_replica_status` function to determine the `server_id` that has `session_id='MASTER_SESSION_ID'`. This function gives you the name of the primary node. You can use this with the `endpointPostfix` described following.

Make sure that you're aware when you connect to a replica that has stale data. When this happens, the `aurora_replica_status` function might show out-of-date information. You can set a threshold for staleness at the application level. To check this, you can look at the difference between the server time and the `last_update_timestamp` value. In general, your application should avoid flipping between two hosts due to conflicting information returned by the `aurora_replica_status` function. Your application should try all known hosts first instead of following the data returned by `aurora_replica_status`.

### Listing instances using the DescribeDBClusters API operation, example in Java

You can programmatically find the list of instances by using the [AWS SDK for Java](https://aws.amazon.com/sdk-for-java), specifically the [DescribeDBClusters](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/USER_Aurora-Clusters.html#USER_Aurora-Clusters-DescribeDBClusters) API operation.
Following is a small example of how you might do this in Java 8.

```java
AmazonRDSClient client = AmazonRDSClientBuilder.defaultClient();
DescribeDBClustersRequest request = new DescribeDBClustersRequest()
    .withDBClusterIdentifier(clusterName);
DescribeDBClustersResult result = rdsClient.describeDBClusters(request);

DBCluster singleClusterResult = result.getDBClusters().get(0);

String pgJDBCEndpointStr =
    singleClusterResult.getDBClusterMembers().stream()
    .sorted(Comparator.comparing(DBClusterMember::getIsClusterWriter)
      .reversed()) // This puts the writer at the front of the list
    .map(m -> m.getDBInstanceIdentifier() + endpointPostfix + ":" +
        singleClusterResult.getPort())
    .collect(Collectors.joining("", ");
```

Here, `pgJDBCEndpointStr` contains a formatted list of endpoints, as shown following.

```
my-node1.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432,
my-node2.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com:5432
```

The variable `endpointPostfix` can be a constant that your application sets. Or your application can get it by querying the `DescribeDBInstances` API operation for a single instance in your cluster. This value remains constant within an AWS Region and for an individual customer. So it saves an API call to simply keep this constant in a resource file that your application reads from. In the example preceding, it's set to the following.

```
.cksc6xlmwcyw.us-east-1-beta.rds.amazonaws.com
```

For availability purposes, a good practice is to default to using the Aurora endpoints of your DB cluster if the API isn't responding or takes too long to respond. The endpoints are guaranteed to be up to date within the time it takes to update the DNS record. Updating the DNS record with an endpoint typically takes less than 30 seconds. You can store the endpoint in a resource file that your application consumes.

**Testing failover**

In all cases you must have a DB cluster with two or more DB instances in it.
From the server side, certain API operations can cause an outage that can be used to test how your applications responds:

- **FailoverDBCluster** – This operation attempts to promote a new DB instance in your DB cluster to writer.

  The following code example shows how you can use `failoverDBCluster` to cause an outage. For more details about setting up an Amazon RDS client, see Using the AWS SDK for Java.

  ```java
  public void causeFailover() {
      final AmazonRDS rdsClient = AmazonRDSClientBuilder.defaultClient();
      FailoverDBClusterRequest request = new FailoverDBClusterRequest();
      request.setDBClusterIdentifier("cluster-identifier");
      rdsClient.failoverDBCluster(request);
  }
  ```

- **RebootDBInstance** – Failover isn't guaranteed with this API operation. It shuts down the database on the writer, however. You can use it to test how your application responds to connections dropping. The `ForceFailover` parameter doesn't apply for Aurora engines. Instead, use the `FailoverDBCluster` API operation.

- **ModifyDBCluster** – Modifying the `Port` parameter causes an outage when the nodes in the cluster begin listening on a new port. In general, your application can respond to this failure first by ensuring that only your application controls port changes. Also, ensure that it can appropriately update the endpoints it depends on. You can do this by having someone manually update the port when they make modifications at the API level. Or you can do this by using the RDS API in your application to determine if the port has changed.

- **ModifyDBInstance** – Modifying the `DBInstanceClass` parameter causes an outage.

- **DeleteDBInstance** – Deleting the primary (writer) causes a new DB instance to be promoted to writer in your DB cluster.

From the application or client side, if you use Linux, you can test how the application responds to sudden packet drops. You can do this based on whether port, host, or if TCP keepalive packets are sent or received by using the `iptables` command.
Fast failover example in Java

The following code example shows how an application might set up an Aurora PostgreSQL driver manager.

The application calls the getConnection function when it needs a connection. A call to getConnection can fail to find a valid host. An example is when no writer is found but the targetServerType parameter is set to primary. In this case, the calling application should simply retry calling the function.

To avoid pushing the retry behavior onto the application, you can wrap this retry call into a connection pooler. With most connection poolers, you can specify a JDBC connection string. So your application can call into getJdbcConnectionString and pass that to the connection pooler. Doing this means you can use faster failover with Aurora PostgreSQL.

```java
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.sql.Statement;
import java.util.ArrayList;
import java.util.List;
import java.util.stream.Collectors;
import java.util.stream.IntStream;
import org.joda.time.Duration;

public class FastFailoverDriverManager {
    private static Duration LOGIN_TIMEOUT = Duration.standardSeconds(2);
    private static Duration CONNECT_TIMEOUT = Duration.standardSeconds(2);
    private static Duration CANCEL_SIGNAL_TIMEOUT = Duration.standardSeconds(1);
    private static Duration DEFAULT_SOCKET_TIMEOUT = Duration.standardSeconds(5);

    public FastFailoverDriverManager() {
        try {
            Class.forName("org.postgresql.Driver");
        } catch (ClassNotFoundException e) {
            e.printStackTrace();
        }

        /*
         * RO endpoint has a TTL of 1s, we should honor that here. Setting this aggressively makes sure that when
         */
    }
}
```
* the PG JDBC driver creates a new connection, it will resolve a new different
  RO endpoint on subsequent attempts
  * (assuming there is > 1 read node in your cluster)
  */
  java.security.Security.setProperty("networkaddress.cache.ttl", "1");
  // If the lookup fails, default to something like small to retry
  java.security.Security.setProperty("networkaddress.cache.negative.ttl", "3");
}

public Connection getConnection(String targetServerType) throws SQLException {
  return getConnection(targetServerType, DEFAULT_SOCKET_TIMEOUT);
}

public Connection getConnection(String targetServerType, Duration queryTimeout)
  throws SQLException {
  Connection conn =
  DriverManager.getConnection(getJdbcConnectionString(targetServerType, queryTimeout));

  /*
   * A good practice is to set socket and statement timeout to be the same thing
   * since both
   * the client AND server will stop the query at the same time, leaving no
   * running queries
   * on the backend
   */
  Statement st = conn.createStatement();
  st.execute("set statement_timeout to " + queryTimeout.getMillis());
  st.close();

  return conn;
}

        .collect(Collectors.joining(","));
}

Fast recovery after failover with cluster cache management for Aurora PostgreSQL

For fast recovery of the writer DB instance in your Aurora PostgreSQL clusters if there's a failover, use cluster cache management for Amazon Aurora PostgreSQL. Cluster cache management ensures that application performance is maintained if there's a failover.
In a typical failover situation, you might see a temporary but large performance degradation after failover. This degradation occurs because when the failover DB instance starts, the buffer cache is empty. An empty cache is also known as a *cold cache*. A cold cache degrades performance because the DB instance has to read from the slower disk, instead of taking advantage of values stored in the buffer cache.

With cluster cache management, you set a specific reader DB instance as the failover target. Cluster cache management ensures that the data in the designated reader's cache is kept synchronized with the data in the writer DB instance's cache. The designated reader's cache with prefilled values is known as a *warm cache*. If a failover occurs, the designated reader uses values in its warm cache immediately when it's promoted to the new writer DB instance. This approach provides your application much better recovery performance.

Cluster cache management requires that the designated reader instance have the same instance class type and size (db.r5.2xlarge or db.r5.xlarge, for example) as the writer. Keep this in mind when you create your Aurora PostgreSQL DB clusters so that your cluster can recover during a failover. For a listing of instance class types and sizes, see [Hardware specifications for DB instance classes for Aurora](#).

**Note**

Cluster cache management is not supported for Aurora PostgreSQL DB clusters that are part of Aurora global databases. It is recommended that no workload should run on the designated tier-0 reader.

**Contents**

- Configuring cluster cache management
  - Enabling cluster cache management
  - Setting the promotion tier priority for the writer DB instance
  - Setting the promotion tier priority for a reader DB instance
- Monitoring the buffer cache
- Troubleshooting CCM configuration

**Configuring cluster cache management**

To configure cluster cache management, do the following processes in order.
Enabling cluster cache management

To enable cluster cache management, take the steps described following.

**Console**

**To enable cluster cache management**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose Parameter groups.
3. In the list, choose the parameter group for your Aurora PostgreSQL DB cluster.
   
   The DB cluster must use a parameter group other than the default, because you can't change values in a default parameter group.
4. For Parameter group actions, choose Edit.
5. Set the value of the apg_ccm_enabled cluster parameter to 1.
6. Choose Save changes.

**AWS CLI**

To enable cluster cache management for an Aurora PostgreSQL DB cluster, use the AWS CLI `modify-db-cluster-parameter-group` command with the following required parameters:

- `--db-cluster-parameter-group-name`
• --parameters

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-cluster-parameter-group \
  --db-cluster-parameter-group-name my-db-cluster-parameter-group \
  --parameters "ParameterName=apg_ccm_enabled,ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-cluster-parameter-group ^
  --db-cluster-parameter-group-name my-db-cluster-parameter-group ^
  --parameters "ParameterName=apg_ccm_enabled,ParameterValue=1,ApplyMethod=immediate"
```

Setting the promotion tier priority for the writer DB instance

For cluster cache management, make sure that the promotion priority is **tier-0** for the writer DB instance of the Aurora PostgreSQL DB cluster. The *promotion tier priority* is a value that specifies the order in which an Aurora reader is promoted to the writer DB instance after a failure. Valid values are 0–15, where 0 is the first priority and 15 is the last priority. For more information about the promotion tier, see [Fault tolerance for an Aurora DB cluster](#).

Console

To set the promotion priority for the writer DB instance to tier-0

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the **Writer** DB instance of the Aurora PostgreSQL DB cluster.
4. Choose **Modify**. The **Modify DB Instance** page appears.
5. On the **Additional configuration** panel, choose **tier-0** for the **Failover priority**.
6. Choose **Continue** and check the summary of modifications.
7. To apply the changes immediately after you save them, choose **Apply immediately**.
8. Choose **Modify DB Instance** to save your changes.
AWS CLI

To set the promotion tier priority to 0 for the writer DB instance using the AWS CLI, call the `modify-db-instance` command with the following required parameters:

- `--db-instance-identifier`
- `--promotion-tier`
- `--apply-immediately`

Example

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
   --db-instance-identifier writer-db-instance \
   --promotion-tier 0 \
   --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
   --db-instance-identifier writer-db-instance ^
   ---promotion-tier 0 ^
   --apply-immediately
```

Setting the promotion tier priority for a reader DB instance

You must set only one reader DB instance for cluster cache management. To do so, choose a reader from the Aurora PostgreSQL cluster that is the same instance class and size as the writer DB instance. For example, if the writer uses `db.r5.xlarge`, choose a reader that uses this same instance class type and size. Then set its promotion tier priority to 0.

The *promotion tier priority* is a value that specifies the order in which an Aurora reader is promoted to the writer DB instance after a failure. Valid values are 0–15, where 0 is the first priority and 15 is the last priority.
**Console**

**To set the promotion priority of the reader DB instance to tier-0**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose a **Reader DB instance** of the Aurora PostgreSQL DB cluster that is the same instance class as the writer DB instance.
4. Choose **Modify**. The **Modify DB Instance** page appears.
5. On the **Additional configuration** panel, choose **tier-0** for the **Failover priority**.
6. Choose **Continue** and check the summary of modifications.
7. To apply the changes immediately after you save them, choose **Apply immediately**.
8. Choose **Modify DB Instance** to save your changes.

**AWS CLI**

To set the promotion tier priority to 0 for the reader DB instance using the AWS CLI, call the `modify-db-instance` command with the following required parameters:

- `--db-instance-identifier`
- `--promotion-tier`
- `--apply-immediately`

**Example**

For Linux, macOS, or Unix:

```bash
aws rds modify-db-instance \
    --db-instance-identifier reader-db-instance \
    --promotion-tier 0 \
    --apply-immediately
```

For Windows:

```bash
aws rds modify-db-instance ^
```
Monitoring the buffer cache

After setting up cluster cache management, you can monitor the state of synchronization between the writer DB instance's buffer cache and the designated reader's warm buffer cache. To examine the buffer cache contents on both the writer DB instance and the designated reader DB instance, use the PostgreSQL pg_buffercache module. For more information, see the PostgreSQL pg_buffercache documentation.

Using the aurora_ccm_status Function

Cluster cache management also provides the aurora_ccm_status function. Use the aurora_ccm_status function on the writer DB instance to get the following information about the progress of cache warming on the designated reader:

- **buffers_sent_last_minute** – How many buffers have been sent to the designated reader in the last minute.
- **buffers_found_last_minute** – The number of frequently accessed buffers identified during the past minute.
- **buffers_sent_last_scan** – How many buffers have been sent to the designated reader during the last complete scan of the buffer cache.
- **buffers_found_last_scan** – How many buffers have been identified as frequently accessed and needed to be sent during the last complete scan of the buffer cache. Buffers already cached on the designated reader aren't sent.
- **buffers_sent_current_scan** – How many buffers have been sent so far during the current scan.
- **buffers_found_current_scan** – How many buffers have been identified as frequently accessed in the current scan.
- **current_scan_progress** – How many buffers have been visited so far during the current scan.

The following example shows how to use the aurora_ccm_status function to convert some of its output into a warm rate and warm percentage.

```
SELECT buffers_sent_last_minute*8/60 AS warm_rate_kbps,
```
Troubleshooting CCM configuration

When you enable `apg_ccm_enabled` cluster parameter, cluster cache management is automatically turned on at the instance level on the writer DB instance and one reader DB instance on the Aurora PostgreSQL DB cluster. The writer and reader instance should use the same instance class type and size. Their promotion tier priority is set to 0. Other reader instances in the DB cluster should have a non-zero promotion tier and cluster cache management is disabled for those instances.

The following reasons may lead to issues in the configuration and disable cluster cache management:

- When there is no single reader DB instance set to promotion tier 0.
- When the writer DB instance is not set to promotion tier 0.
- When more than one reader DB instances are set to promotion tier 0.
- When the writer and one reader DB instances with promotion tier 0 doesn't have the same instance size.

Managing Aurora PostgreSQL connection churn with pooling

When client applications connect and disconnect so often that Aurora PostgreSQL DB cluster response time slows, the cluster is said to be experiencing connection churn. Each new connection to the Aurora PostgreSQL DB cluster endpoint consumes resources, thus reducing the resources that can be used to process the actual workload. Connection churn is an issue that we recommend that you manage by following some of the best practices discussed following.

For starters, you can improve response times on Aurora PostgreSQL DB clusters that have high rates of connection churn. To do this, you can use a connection pooler, such as RDS Proxy. A connection pooler provides a cache of ready to use connections for clients. Almost all versions of Aurora PostgreSQL support RDS Proxy. For more information, see Amazon RDS Proxy with Aurora PostgreSQL.

If your specific version of Aurora PostgreSQL doesn't support RDS Proxy, you can use another PostgreSQL-compatible connection pooler, such as PgBouncer. To learn more, see the PgBouncer website.
To see if your Aurora PostgreSQL DB cluster can benefit from connection pooling, you can check the `postgresql.log` file for connections and disconnections. You can also use Performance Insights to find out how much connection churn your Aurora PostgreSQL DB cluster is experiencing. Following, you can find information about both topics.

**Logging connections and disconnections**

The PostgreSQL `log_connections` and `log_disconnections` parameters can capture connections and disconnections to the writer instance of the Aurora PostgreSQL DB cluster. By default, these parameters are turned off. To turn these parameters on, use a custom parameter group and turn on by changing the value to 1. For more information about custom parameter groups, see [Working with DB cluster parameter groups](#). To check the settings, connect to your DB cluster endpoint for Aurora PostgreSQL by using psql and query as follows.

```sql
labdb=> SELECT setting FROM pg_settings
     WHERE name = 'log_connections';
   setting
----------
on
(1 row)
labdb=> SELECT setting FROM pg_settings
     WHERE name = 'log_disconnections';
   setting
----------
on
(1 row)
```

With both of these parameters turned on, the log captures all new connections and disconnections. You see the user and database for each new authorized connection. At disconnection time, the session duration is also logged, as shown in the following example.

```
database=labdb application_name=psql
2022-03-07 21:44:55.718 UTC [16641] LOG: disconnection: session time: 0:00:01.740
   user=labtek database=labdb host=[local]
```

To check your application for connection churn, turn on these parameters if they're not on already. Then gather data in the PostgreSQL log for analysis by running your application with a realistic workload and time period. You can view the log file in the RDS console. Choose the writer
instance of your Aurora PostgreSQL DB cluster, and then choose the **Logs & events** tab. For more information, see [Viewing and listing database log files](https://aws.amazon.com). Or you can download the log file from the console and use the following command sequence. This sequence finds the total number of connections authorized and dropped per minute.

```bash
grep "connection authorized\|disconnection: session time:"
  postgresql.log.2022-03-21-16\|
awk {'print $1,$2'} |
sort |
uniq -c |
sort -n -k1
```

In the example output, you can see a spike in authorized connections followed by disconnections starting at 16:12:10.

```
.....
,....... 
...........
5 2022-03-21 16:11:55 connection authorized:
9 2022-03-21 16:11:55 disconnection: session
5 2022-03-21 16:11:56 connection authorized:
5 2022-03-21 16:11:57 connection authorized:
5 2022-03-21 16:11:57 disconnection: session
32 2022-03-21 16:12:10 connection authorized:
30 2022-03-21 16:12:10 disconnection: session
31 2022-03-21 16:12:11 connection authorized:
27 2022-03-21 16:12:11 disconnection: session
27 2022-03-21 16:12:12 connection authorized:
27 2022-03-21 16:12:12 disconnection: session
41 2022-03-21 16:12:13 connection authorized:
46 2022-03-21 16:12:13 disconnection: session
41 2022-03-21 16:12:14 connection authorized:
41 2022-03-21 16:12:14 disconnection: session
24 2022-03-21 16:12:15 connection authorized:
29 2022-03-21 16:12:15 disconnection: session
28 2022-03-21 16:12:16 connection authorized:
24 2022-03-21 16:12:16 disconnection: session
40 2022-03-21 16:12:17 connection authorized:
42 2022-03-21 16:12:17 disconnection: session
40 2022-03-21 16:12:18 connection authorized:
40 2022-03-21 16:12:18 disconnection: session
```
With this information, you can decide if your workload can benefit from a connection pooler. For more detailed analysis, you can use Performance Insights.

**Detecting connection churn with Performance Insights**

You can use Performance Insights to assess the amount of connection churn on your Aurora PostgreSQL-Compatible Edition DB cluster. When you create an Aurora PostgreSQL DB cluster, the setting for Performance Insights is turned on by default. If you cleared this choice when you created your DB cluster, modify your cluster to turn on the feature. For more information, see [Modifying an Amazon Aurora DB cluster](##).

With Performance Insights running on your Aurora PostgreSQL DB cluster, you can choose the metrics that you want to monitor. You can access Performance Insights from the navigation pane in the console. You can also access Performance Insights from the **Monitoring** tab of the writer instance for your Aurora PostgreSQL DB cluster, as shown in the following image.

![Performance Insights in Aurora console](image-url)
From the Performance Insights console, choose **Manage metrics**. To analyze your Aurora PostgreSQL DB cluster's connection and disconnection activity, choose the following metrics. These are all metrics from PostgreSQL.

- **xact_commit** – The number of committed transactions.
- **total_auth_attempts** – The number of attempted authenticated user connections per minute.
- **numbackends** – The number of backends currently connected to the database.

To save the settings and display connection activity, choose **Update graph**.
In the following image, you can see the impact of running pgbench with 100 users. The line showing connections is on a consistent upward slope. To learn more about pgbench and how to use it, see [pgbench](https://www.postgresql.org/docs/current/pgbench.html) in PostgreSQL documentation.

![Counter metrics](image)

The image shows that running a workload with as few as 100 users without a connection pooler can cause a significant increase in the number of `total_auth_attempts` throughout the duration of workload processing.

With RDS Proxy connection pooling, the connection attempts increase at the start of the workload. After setting up the connection pool, the average declines. The resources used by transactions and backend use stays consistent throughout workload processing.

![Counter metrics](image)

For more information about using Performance Insights with your Aurora PostgreSQL DB cluster, see [Monitoring DB load with Performance Insights on Amazon Aurora](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraPostgreSQLUserGuide/monitoring-performance-insights.html). To analyze the metrics, see [Analyzing metrics with the Performance Insights dashboard](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraPostgreSQLUserGuide/monitoring-performance-insights.html).

**Demonstrating the benefits of connection pooling**

As mentioned previously, if you determine that your Aurora PostgreSQL DB cluster has a connection churn problem, you can use RDS Proxy for improved performance. Following, you can find an example that shows the differences in processing a workload when connections are pooled and when they're not. The example uses pgbench to model a transaction workload.
As is psql, pgbench is a PostgreSQL client application that you can install and run from your local client machine. You can also install and run it from the Amazon EC2 instance that you use for managing your Aurora PostgreSQL DB cluster. For more information, see pgbench in the PostgreSQL documentation.

To step through this example, you first create the pgbench environment in your database. The following command is the basic template for initializing the pgbench tables in the specified database. This example uses the default main user account, postgres, for the login. Change it as needed for your Aurora PostgreSQL DB cluster. You create the pgbench environment in a database on the writer instance of your cluster.

```
pgbench -U postgres -h db-cluster-instance-1.111122223333.aws-region.rds.amazonaws.com -p 5432 -d -i -s 50 dbname
```

For pgbench, specify the following parameters.

- **-d**
  
  Outputs a debugging report as pgbench runs.

- **-h**
  
  Specifies the endpoint of the Aurora PostgreSQL DB cluster's writer instance.

- **-i**
  
  Initializes the pgbench environment in the database for the benchmark tests.

- **-p**
  
  Identifies the port used for database connections. The default for Aurora PostgreSQL is typically 5432 or 5433.
-S

Specifies the scaling factor to use for populating the tables with rows. The default scaling factor is 1, which generates 1 row in the `pgbench_branches` table, 10 rows in the `pgbench_tellers` table, and 100000 rows in the `pgbench_accounts` table.

-U

Specifies the user account for the Aurora PostgreSQL DB cluster's writer instance.

After the `pgbench` environment is set up, you can then run benchmarking tests with and without connection pooling. The default test consists of a series of five SELECT, UPDATE, and INSERT commands per transaction that run repeatedly for the time specified. You can specify scaling factor, number of clients, and other details to model your own use cases.

As an example, the command that follows runs the benchmark for 60 seconds (-T option, for time) with 20 concurrent connections (the -c option). The -C option makes the test run using a new connection each time, rather than once per client session. This setting gives you an indication of the connection overhead.

```
pgbench -h docs-lab-apg-133-test-instance-1.c3zr2auzukpa.us-west-1.rds.amazonaws.com -U postgres -p 5432 -T 60 -c 20 -C labdb
Password:**********
gbench (14.3, server 13.3)
  starting vacuum...end.
  transaction type: <builtin: TPC-B (sort of)>
   scaling factor: 50
   query mode: simple
   number of clients: 20
   number of threads: 1
   duration: 60 s
   number of transactions actually processed: 495
   latency average = 2430.798 ms
   average connection time = 120.330 ms
   tps = 8.227750 (including reconnection times)
```

Running `pgbench` on the writer instance of an Aurora PostgreSQL DB cluster without reusing connections shows that only about 8 transactions are processed each second. This gives a total of 495 transactions during the 1-minute test.
If you reuse connections, the response from Aurora PostgreSQL DB cluster for the number of users is almost 20 times faster. With reuse, a total of 9,042 transactions is processed compared to 495 in the same amount of time and for the same number of user connections. The difference is that in the following, each connection is being reused.

```
pgbench -h docs-lab-apg-133-test-instance-1.c3zr2auzukpa.us-west-1.rds.amazonaws.com -U postgres -p 5432 -T 60 -c 20 labdb
Password:**********
pbench (14.3, server 13.3)
  starting vacuum...end.
  transaction type: <builtin: TPC-B (sort of)>
  scaling factor: 50
  query mode: simple
  number of clients: 20
  number of threads: 1
  duration: 60 s
  number of transactions actually processed: 9042
  latency average = 127.880 ms
  initial connection time = 2311.188 ms
  tps = 156.396765 (without initial connection time)
```

This example shows you that pooling connections can significantly improve response times. For information about setting up RDS Proxy for your Aurora PostgreSQL DB cluster, see Using Amazon RDS Proxy for Aurora.

### Tuning memory parameters for Aurora PostgreSQL

In Amazon Aurora PostgreSQL, you can use several parameters that control the amount of memory used for various processing tasks. If a task takes more memory than the amount set for a given parameter, Aurora PostgreSQL uses other resources for processing, such as by writing to disk. This can cause your Aurora PostgreSQL DB cluster to slow or potentially halt, with an out-of-memory error.

The default setting for each memory parameter can usually handle its intended processing tasks. However, you can also tune your Aurora PostgreSQL DB cluster's memory-related parameters. You do this tuning to ensure that enough memory is allocated for processing your specific workload.

Following, you can find information about parameters that control memory management. You can also learn how to assess memory utilization.
Checking and setting parameter values

The parameters that you can set to manage memory and assess your Aurora PostgreSQL DB cluster's memory usage include the following:

- **work_mem** – Specifies the amount of memory that the Aurora PostgreSQL DB cluster uses for internal sort operations and hash tables before it writes to temporary disk files.

- **log_temp_files** – Logs temporary file creation, file names, and sizes. When this parameter is turned on, a log entry is stored for each temporary file that gets created. Turn this on to see how frequently your Aurora PostgreSQL DB cluster needs to write to disk. Turn it off again after you’ve gathered information about your Aurora PostgreSQL DB cluster's temporary file generation, to avoid excessive logging.

- **logical_decoding_work_mem** – Specifies the amount of memory (in megabytes) to use for logical decoding. *Logical decoding* is the process used to create a replica. This process is done by converting data from the write-ahead log (WAL) file to the logical streaming output needed by the target.

  The value of this parameter creates a single buffer of the size specified for each replication connection. By default, it's 65536 KB. After this buffer is filled, the excess is written to disk as a file. To minimize disk activity, you can set the value of this parameter to a much higher value than that of work_mem.

These are all dynamic parameters, so you can change them for the current session. To do this, connect to the Aurora PostgreSQL DB cluster with psql and using the SET statement, as shown following.

```
SET parameter_name TO parameter_value;
```

Session settings last for the duration of the session only. When the session ends, the parameter reverts to its setting in the DB cluster parameter group. Before changing any parameters, first check the current values by querying the pg_settings table, as follows.

```
SELECT unit, setting, max_val
FROM pg_settings WHERE name='parameter_name';
```

For example, to find the value of the work_mem parameter, connect to the Aurora PostgreSQL DB cluster's writer instance and run the following query.
Changing parameter settings so that they persist requires using a custom DB cluster parameter group. After exercising your Aurora PostgreSQL DB cluster with different values for these parameters using the SET statement, you can create a custom parameter group and apply to your Aurora PostgreSQL DB cluster. For more information, see Working with parameter groups.

Understanding the working memory parameter

The working memory parameter (`work_mem`) specifies the maximum amount of memory that Aurora PostgreSQL can use to process complex queries. Complex queries include those that involve sorting or grouping operations—in other words, queries that use the following clauses:

- ORDER BY
- DISTINCT
- GROUP BY
- JOIN (MERGE and HASH)

The query planner indirectly affects how your Aurora PostgreSQL DB cluster uses working memory. The query planner generates execution plans for processing SQL statements. A given plan might break up a complex query into multiple units of work that can be run in parallel. When possible, Aurora PostgreSQL uses the amount of memory specified in the `work_mem` parameter for each session before writing to disk for each parallel process.

Multiple database users running multiple operations concurrently and generating multiple units of work in parallel can exhaust your Aurora PostgreSQL DB cluster's allocated working memory. This can lead to excessive temporary file creation and disk I/O, or worse, it can lead to an out-of-memory error.

Identifying temporary file use

Whenever the memory required to process queries exceeds the value specified in the `work_mem` parameter, the working data is offloaded to disk in a temporary file. You can see how often this
occurs by turning on the log_temp_files parameter. By default, this parameter is off (it’s set to -1). To capture all temporary file information, set this parameter to 0. Set log_temp_files to any other positive integer to capture temporary file information for files equal to or greater than that amount of data (in kilobytes). In the following image, you can see an example from AWS Management Console.

After configuring temporary file logging, you can test with your own workload to see if your working memory setting is sufficient. You can also simulate a workload by using pgbench, a simple benchmarking application from the PostgreSQL community.

The following example initializes (-i) pgbench by creating the necessary tables and rows for running the tests. In this example, the scaling factor (-s 50) creates 50 rows in the pgbench_branches table, 500 rows in pgbench_tellers, and 5,000,000 rows in the pgbench_accounts table in the labdb database.

```
pgbench -U postgres -h your-cluster-instance-1.111122223333.aws-region.rds.amazonaws.com -p 5432 -i -s 50 labdb
Password: dropping old tables...
NOTICE: table "pgbench_accounts" does not exist, skipping
NOTICE: table "pgbench_branches" does not exist, skipping
NOTICE: table "pgbench_history" does not exist, skipping
NOTICE: table "pgbench_tellers" does not exist, skipping
creating tables...
generating data (client-side)...
5000000 of 5000000 tuples (100%) done (elapsed 15.46 s, remaining 0.00 s)
vacuuming...
creating primary keys...
done in 61.13 s (drop tables 0.08 s, create tables 0.39 s, client-side generate 54.85 s, vacuum 2.30 s, primary keys 3.51 s)
```
After initializing the environment, you can run the benchmark for a specific time (-T) and the number of clients (-c). This example also uses the -d option to output debugging information as the transactions are processed by the Aurora PostgreSQL DB cluster.

```
pgbench -h -U postgres your-cluster-instance-1.111122223333.aws-region rds.amazonaws.com -p 5432 -d -T 60 -c 10 labdb
Password:*******
pbench (14.3)
starting vacuum...end.
transaction type: <builtin: TPC-B (sort of)>
scaling factor: 50
query mode: simple
number of clients: 10
number of threads: 1
duration: 60 s
number of transactions actually processed: 1408
latency average = 398.467 ms
initial connection time = 4280.846 ms
tps = 25.096201 (without initial connection time)
```

For more information about pgbench, see [pgbench](https://www.postgresql.org/docs/14/pgbench.html) in the PostgreSQL documentation.

You can use the psql metacommand command (\d) to list the relations such as tables, views, and indexes created by pgbench.

```
labdb=> \d pgbench_accounts
    Table "public.pgbench_accounts"
       Column |     Type      | Collation | Nullable | Default
-----------------+---------------+-----------+----------+---------
         aid | integer       |           | not null |         
         bid | integer       |           |          |         
    abalance | integer       |           |          |         
           filler | character(84) |           |          |         
    Indexes:
            "pgbench_accounts_pkey" PRIMARY KEY, btree (aid)
```

As shown in the output, the pgbench_accounts table is indexed on the aid column. To ensure that this next query uses working memory, query any nonindexed column, such as that shown in the following example.

```
postgres=> SELECT * FROM pgbench_accounts ORDER BY bid;
```
Check the log for the temporary files. To do so, open the AWS Management Console, choose the Aurora PostgreSQL DB cluster instance, and then choose the **Logs & Events** tab. View the logs in the console or download for further analysis. As shown in the following image, the size of the temporary files needed to process the query indicates that you should consider increasing the amount specified for the `work_mem` parameter.

![Log view of temporary files](image)

You can configure this parameter differently for individuals and groups, based on your operational needs. For example, you can set the `work_mem` parameter to 8 GB for the role named `dev_team`.

```
postgres=> ALTER ROLE dev_team SET work_mem='8GB';
```

With this setting for `work_mem`, any role that's a member of the `dev_team` role is allotted up to 8 GB of working memory.

### Using indexes for faster response time

If your queries are taking too long to return results, you can verify that your indexes are being used as expected. First, turn on `\timing`, the psql metacommand, as follows.

```
postgres=> \timing on
```

After turning on timing, use a simple SELECT statement.

```
postgres=> SELECT COUNT(*) FROM
  (SELECT * FROM pgbench_accounts ORDER BY bid)
  AS accounts;
```
As shown in the output, this query took just over 3 seconds to complete. To improve the response time, create an index on `pgbench_accounts`, as follows.

```sql
postgres=> CREATE INDEX ON pgbench_accounts(bid);
CREATE INDEX
```

Rerun the query, and notice the faster response time. In this example, the query completed about 5 times faster, in about half a second.

```sql
postgres=> SELECT COUNT(*) FROM (SELECT * FROM pgbench_accounts ORDER BY bid) AS accounts;
  count
  -------
   5000000
(1 row)
Time: 567.095 ms
```

### Adjusting working memory for logical decoding

Logical replication has been available in all versions of Aurora PostgreSQL since its introduction in PostgreSQL version 10. When you configure logical replication, you can also set the `logical_decoding_work_mem` parameter to specify the amount of memory that the logical decoding process can use for the decoding and streaming process.

During logical decoding, write-ahead log (WAL) records are converted to SQL statements that are then sent to another target for logical replication or another task. When a transaction is written to the WAL and then converted, the entire transaction must fit into the value specified for `logical_decoding_work_mem`. By default, this parameter is set to 65536 KB. Any overflow is written to disk. This means that it must be reread from the disk before it can be sent to its destination, thus slowing the overall process.

You can assess the amount of transaction overflow in your current workload at a specific point in time by using the `aurora_stat_file` function as shown in the following example.

```sql
SELECT split_part (filename, '/', 2)
```

Tuning memory parameters for Aurora PostgreSQL
This query returns the count and size of spill files on your Aurora PostgreSQL DB cluster when the query is invoked. Longer running workloads might not have any spill files on disk yet. To profile long-running workloads, we recommend that you create a table to capture the spill file information as the workload runs. You can create the table as follows.

```sql
CREATE TABLE spill_file_tracking AS
    SELECT now() AS spill_time, *
    FROM aurora_stat_file()
    WHERE filename LIKE '%spill%';
```

To see how spill files are used during logical replication, set up a publisher and subscriber and then start a simple replication. For more information, see Setting up logical replication for your Aurora PostgreSQL DB cluster. With replication under way, you can create a job that captures the result set from the `aurora_stat_file()` spill file function, as follows.

```sql
INSERT INTO spill_file_tracking
    SELECT now(), *
    FROM aurora_stat_file()
    WHERE filename LIKE '%spill%';
```

Use the following psql command to run the job once per second.

```sql
\watch 0.5
```

As the job is running, connect to the writer instance from another psql session. Use the following series of statements to run a workload that exceeds the memory configuration and causes Aurora PostgreSQL to create a spill file.

```sql
labdb=> CREATE TABLE my_table (a int PRIMARY KEY, b int);
```
CREATE TABLE
labdb=> INSERT INTO my_table SELECT x,x FROM generate_series(0,10000000) x;
INSERT 0 10000001
labdb=> UPDATE my_table SET b=b+1;
UPDATE 10000001

These statements take several minutes to complete. When finished, press the Ctrl key and the C key together to stop the monitoring function. Then use the following command to create a table to hold the information about the Aurora PostgreSQL DB cluster's spill file usage.

```
SELECT spill_time, split_part (filename, '/', 2)
  AS slot_name, count(1)
  AS spills, sum(used_bytes)
  AS slot_total_bytes, pg_size_pretty(sum(used_bytes))
  AS slot_total_size FROM spill_file_tracking
GROUP BY 1,2 ORDER BY 1;
```

<table>
<thead>
<tr>
<th>spill_time</th>
<th>slot_name</th>
<th>spills</th>
<th>slot_total_bytes</th>
<th>slot_total_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>2022-04-15 13:42:52.528272+00</td>
<td>replication_slot_name</td>
<td>1</td>
<td>142352280</td>
<td>136 MB</td>
</tr>
<tr>
<td>2022-04-15 14:11:33.962216+00</td>
<td>replication_slot_name</td>
<td>4</td>
<td>467637996</td>
<td>446 MB</td>
</tr>
<tr>
<td>2022-04-15 14:12:00.997636+00</td>
<td>replication_slot_name</td>
<td>4</td>
<td>569409176</td>
<td>543 MB</td>
</tr>
<tr>
<td>2022-04-15 14:12:03.030245+00</td>
<td>replication_slot_name</td>
<td>4</td>
<td>569409176</td>
<td>543 MB</td>
</tr>
<tr>
<td>2022-04-15 14:12:05.059761+00</td>
<td>replication_slot_name</td>
<td>5</td>
<td>618410996</td>
<td>590 MB</td>
</tr>
<tr>
<td>2022-04-15 14:12:07.22905+00</td>
<td>replication_slot_name</td>
<td>5</td>
<td>640585316</td>
<td>611 MB</td>
</tr>
</tbody>
</table>

(6 rows)

The output shows that running the example created five spill files that used 611 MB of memory. To avoid writing to disk, we recommend setting the `logical_decoding_work_mem` parameter to the next highest memory size, 1024.
Using Amazon CloudWatch metrics to analyze resource usage for Aurora PostgreSQL

Aurora automatically sends metric data to CloudWatch in 1-minute periods. You can analyze resource usage for Aurora PostgreSQL using CloudWatch metrics. You can evaluate the network throughput and the network usage with the metrics.

Evaluating network throughput with CloudWatch

When your system usage approaches the resource limits for your instance type, the processing can slow down. You can use CloudWatch Logs Insights to monitor your storage resource usage and ensure that sufficient resources are available. When needed, you can modify the DB instance to a larger instance class.

Aurora storage processing may be slow because of:

- Insufficient network bandwidth between the client and DB instance.
- Insufficient network bandwidth to the storage subsystem.
- A workload that is large for your instance type.

You can query CloudWatch Logs Insights to generate a graph of Aurora storage resource usage to monitor the resources. The graph shows the CPU utilization and metrics to help you decide whether to scale up to a larger instance size. For information about the query syntax for CloudWatch Logs Insights, see CloudWatch Logs Insights query syntax

To use CloudWatch, you need to export your Aurora PostgreSQL log files to CloudWatch. You can also modify your existing cluster to export logs to CloudWatch. For information about exporting logs to CloudWatch, see Turning on the option to publish logs to Amazon CloudWatch.

You need the Resource ID of your DB instance to query the CloudWatch Logs Insights. The Resource ID is available in the Configuration tab in your console:
To query your log files for resource storage metrics:

   The CloudWatch overview home page appears.

2. If necessary, change the AWS Region. In the navigation bar, choose the AWS Region where your AWS resources are located. For more information, see [Regions and endpoints](https://aws.amazon.com/about-aws/global-infrastructure/region-and-endpoint-table/).

3. In the navigation pane, choose **Logs** and then **Logs Insights**.

   The **Logs Insights** page appears.

4. Select the log files from the drop-down list to analyze.

5. Enter the following query in the field, replacing `<resource ID>` with the resource ID of your DB cluster:

   ```
   filter @logStream = <resource ID> | parse @message "\"Aurora Storage Daemon\"*memoryUsedPc\":*," as a,memoryUsedPc,cpuUsedPc | display memoryUsedPc,cpuUsedPc #| stats avg(xcpu) as avgCpu by bin(5m) | limit 10000
   ```

6. Click **Run query**.

   The storage utilization graph is displayed.

   The following image provides the **Logs Insights** page and the graph display.
Evaluating DB instance usage with CloudWatch metrics

You can use CloudWatch metrics to watch your instance throughput and discover if your instance class provides sufficient resources for your applications. For information about your DB instance class limits, go to [Hardware specifications for DB instance classes for Aurora](#) and locate the specifications for your DB instance class to find your network performance.

If your DB instance usage is near the instance class limit, then performance may begin to slow. The CloudWatch metrics can confirm this situation so you can plan to manually scale-up to a larger instance class.

Combine the following CloudWatch metrics values to find out if you are nearing the instance class limit:
• **NetworkThroughput** – The amount of network throughput received and transmitted by the clients for each instance in the Aurora DB cluster. This throughput value doesn't include network traffic between instances in the DB cluster and the cluster volume.

• **StorageNetworkThroughput** – The amount of network throughput received and sent to the Aurora storage subsystem by each instance in the Aurora DB cluster.

Add the **NetworkThroughput** to the **StorageNetworkThroughput** to find the network throughput received from and sent to the Aurora storage subsystem by each instance in your Aurora DB cluster. The instance class limit for your instance should be greater than the sum of these two combined metrics.

You can use the following metrics to review additional details of the network traffic from your client applications when sending and receiving:

• **NetworkReceiveThroughput** – The amount of network throughput received from clients by each instance in the Aurora PostgreSQL DB cluster. This throughput doesn't include network traffic between instances in the DB cluster and the cluster volume.

• **NetworkTransmitThroughput** – The amount of network throughput sent to clients by each instance in the Aurora DB cluster. This throughput doesn't include network traffic between instances in the DB cluster and the cluster volume.

• **StorageNetworkReceiveThroughput** – The amount of network throughput received from the Aurora storage subsystem by each instance in the DB cluster.

• **StorageNetworkTransmitThroughput** – The amount of network throughput sent to the Aurora storage subsystem by each instance in the DB cluster.

Add all of these metrics together to evaluate how your network usage compares to the instance class limit. The instance class limit should be greater than the sum of these combined metrics.

The network limits and CPU utilization for storage are mutual. When the network throughput increases, then the CPU utilization also increases. Monitoring the CPU and network usage provides information about how and why the resources are being exhausted.

To help minimize network usage, you can consider:

• Using a larger instance class.

• Using `pg_partman` partitioning strategies.

• Dividing the write requests in batches to reduce overall transactions.
• Directing the read-only workload to a read-only instance.
• Deleting any unused indexes.
• Checking for bloated objects and VACUUM. In the case of severe bloat, use the PostgreSQL extension pg_repack. For more information about pg_repack, see Reorganize tables in PostgreSQL databases with minimal locks.

Using logical replication to perform a major version upgrade for Aurora PostgreSQL

Using logical replication and Aurora fast cloning, you can perform a major version upgrade that uses the current version of Aurora PostgreSQL database while gradually migrating the changing data to the new major version database. This low downtime upgrade process is referred to as a blue/green upgrade. The current version of the database is referred as the "blue" environment and the new database version is referred as the "green" environment.

Aurora fast cloning fully loads the existing data by taking a snapshot of the source database. Fast cloning uses a copy-on-write protocol built on top of the Aurora storage layer, which allows you to create a clone of database in a short time. This method is very effective when upgrading to a large database.

Logical replication in PostgreSQL tracks and transfers your data changes from initial instance to a new instance running in parallel until you move to the newer version of PostgreSQL. Logical replication uses a publish and subscribe model. For more information about Aurora PostgreSQL logical replication, see Replication with Amazon Aurora PostgreSQL.

Tip

You can minimize the downtime required for a major version upgrade by using the managed Amazon RDS Blue/Green Deployment feature. For more information, see Using Amazon RDS Blue/Green Deployments for database updates.

Topics
• Requirements
• Limitations
• Setting and checking parameter values
• **Upgrading Aurora PostgreSQL to a new major version**

• **Performing post-upgrade tasks**

## Requirements

You must meet the following requirements to perform this low downtime upgrade process:

• You must have rds_superuser permissions.

• The Aurora PostgreSQL DB cluster you intend to upgrade must be running a supported version that can perform major version upgrades using logical replication. Make sure to apply any minor version updates and patches to your DB cluster. The `aurora_volume_logical_start_lsn` function that is used in this technique is supported in the following versions of Aurora PostgreSQL:
  
  • 15.2 and higher 15 versions
  • 14.3 and higher 14 versions
  • 13.6 and higher 13 versions
  • 12.10 and higher 12 versions
  • 11.15 and higher 11 versions
  • 10.20 and higher 10 versions

For more information on `aurora_volume_logical_start_lsn` function, see [aurora_volume_logical_start_lsn](aurora_volume_logical_start_lsn).

• All of your tables must have a primary key or include a [PostgreSQL identity column](postgresql_identity_column).

• Configure the security group for your VPC to allow inbound and outbound access between the two Aurora PostgreSQL DB clusters, both old and new. You can grant access to a specific classless inter-domain routing (CIDR) range or to another security group in your VPC or in a peer VPC. (Peer VPC requires a VPC peering connection.)

### Note

For detailed information about the permissions required to configure and manage a running logical replication scenario, see the [PostgreSQL core documentation](postgresql_core_documentation).
Limitations

When you are performing low downtime upgrade on your Aurora PostgreSQL DB cluster to upgrade it to a new major version, you are using the native PostgreSQL logical replication feature. It has the same capabilities and limitations as the PostgreSQL logical replication. For more information, see [PostgreSQL logical replication](https://www.postgresql.org/docs/current/replication.html).

- Data definition language (DDL) commands are not replicated.
- Replication doesn't support schema changes in a live database. The schema is recreated in its original form during the cloning process. If you change the schema after cloning, but before completing the upgrade, it isn't reflected in the upgraded instance.
- Large objects are not replicated, but you can store data in normal tables.
- Replication is only supported by tables, including partitioned tables. Replication to other types of relations, such as views, materialized views, or foreign tables, is not supported.
- Sequence data is not replicated and requires a manual update post-failover.

**Note**

This upgrade doesn't support auto-scripting. You should perform all the steps manually.

Setting and checking parameter values

Before upgrading, configure the writer instance of your Aurora PostgreSQL DB cluster to act as a publication server. The instance should use a custom DB cluster parameter group with the following settings:

- `rds.logical_replication` – Set this parameter to 1. The `rds.logical_replication` parameter serves the same purpose as a standalone PostgreSQL server's `wal_level` parameter and other parameters that control the write-ahead log file management.
- `max_replication_slots` – Set this parameter to the total number of subscriptions that you plan to create. If you are using AWS DMS, set this parameter to the number of AWS DMS tasks that you plan to use for changed data capture from this DB cluster.
- `max_wal_senders` – Set to the number of concurrent connections, plus a few extra, to make available for management tasks and new sessions. If you are using AWS DMS, the number of
max_wal_senders should be equal to the number of concurrent sessions plus the number of AWS DMS tasks that may be working at any given time.

• max_logical_replication_workers – Set to the number of logical replication workers and table synchronization workers that you expect. It's generally safe to set the number of replication workers to the same value used for max_wal_senders. The workers are taken from the pool of background processes (max_worker_processes) allocated for the server.

• max_worker_processes – Set to the number of background processes for the server. This number should be large enough to allocate workers for replication, auto-vacuum processes, and other maintenance processes that may take place concurrently.

When you upgrade to a newer version of Aurora PostgreSQL, you need to duplicate any parameters that you modified in the earlier version of the parameter group. These parameters are applied to the upgraded version. You can query the pg_settings table to get a list of parameter settings so that you can re-create them on your new Aurora PostgreSQL DB cluster.

For example, to get the settings for replication parameters, run the following query:

```sql
SELECT name, setting FROM pg_settings WHERE name in
('rds.logical_replication', 'max_replication_slots',
'max_wal_senders', 'max_logical_replication_workers',
'max_worker_processes');
```

### Upgrading Aurora PostgreSQL to a new major version

#### To prepare the publisher (blue)

1. In the example that follows, the source writer instance (blue) is an Aurora PostgreSQL DB cluster running PostgreSQL version 11.15. This is the publication node in our replication scenario. For this demonstration, our source writer instance hosts a sample table that holds a series of values:

   ```sql
   CREATE TABLE my_table (a int PRIMARY KEY);
   INSERT INTO my_table VALUES (generate_series(1,100));
   ```

2. To create a publication on the source instance, connect to the writer node of the instance with psql (the CLI for PostgreSQL) or with the client of your choice). Enter the following command in each database:
CREATE PUBLICATION publication_name FOR ALL TABLES;

The publication_name specifies the name of the publication.

3. You also need to create a replication slot on the instance. The following command creates a replication slot and loads the pgoutput **logical decoding plug-in**. The plug-in changes content read from write-ahead logging (WAL) to the logical replication protocol, and filters the data according to the publication specification.

```
SELECT pg_create_logical_replication_slot('replication_slot_name', 'pgoutput');
```

To clone the publisher

1. Use the Amazon RDS Console to create a clone of the source instance. Highlight the instance name in the Amazon RDS Console, and then choose **Create clone** in the Actions menu.

2. Provide a unique name for the instance. Most of the settings are defaults from the source instance. When you've made changes required for the new instance, choose **Create clone**.

3. While the target instance is initiating, the **Status** column of the writer node displays Creating in the **Status** column. When the instance is ready, the status changes to Available.
To prepare the clone for an upgrade

1. The clone is the ‘green’ instance in the deployment model. It is the host of the replication subscription node. When the node becomes available, connect with psql and query the new writer node to obtain the log sequence number (LSN). The LSN identifies the beginning of a record in the WAL stream.

   ```sql
   SELECT aurora_volume_logical_start_lsn();
   ```

2. In the response from the query, you find the LSN number. You need this number later in the process, so make a note of it.

   ```sql
   postgres=> SELECT aurora_volume_logical_start_lsn();
   aurora_volume_logical_start_lsn
   --------------
   0/402E2F0
   (1 row)
   ```

3. Before upgrading the clone, drop the clone’s replication slot.

   ```sql
   SELECT pg_drop_replication_slot('replication_slot_name');
   ```

To upgrade the cluster to a new major version

- After cloning the provider node, use the Amazon RDS Console to initiate a major version upgrade on the subscription node. Highlight the instance name in the RDS console, and select the Modify button. Select the updated version and your updated parameter groups, and apply the settings immediately to upgrade the target instance.
• You can also use the CLI to perform an upgrade:

```bash
aws rds modify-db-cluster --db-cluster-identifier $TARGET_Aurora_ID --engine-version 13.6 --allow-major-version-upgrade --apply-immediately
```

**To prepare the subscriber (green)**

1. When the clone becomes available after the upgrade, connect with psql and define the subscription. To do so, you need to specify the following options in the `CREATE SUBSCRIPTION` command:

   - `subscription_name` – The name of the subscription.
   - `admin_user_name` – The name of an administrative user with `rds_superuser` permissions.
   - `admin_user_password` – The password associated with the administrative user.
   - `source_instance_URL` – The URL of the publication server instance.
   - `database` – The database that the subscription server will connect with.
   - `publication_name` – The name of the publication server.
   - `replication_slot_name` – The name of the replication slot.

```
CREATE SUBSCRIPTION subscription_name
```
2. After creating the subscription, query the `pg_replication_origin` view to retrieve the `roname` value, which is the identifier of the replication origin. Each instance has one `roname`:

   ```
   SELECT * FROM pg_replication_origin;
   
   For example:
   
   postgres=>
   SELECT * FROM pg_replication_origin;
   
   roident | roname
   --------+----------
   1       | pg_24586
   ```

3. Provide the LSN that you saved from the earlier query of the publication node and the `roname` returned from the subscription node [INSTANCE] in the command. This command uses the `pg_replication_origin_advance` function to specify the starting point in the log sequence for replication.

   ```
   SELECT pg_replication_origin_advance(’roname’, ’log_sequence_number’);
   
   `roname` is the identifier returned by the `pg_replication_origin` view.

   `log_sequence_number` is the value returned by the earlier query of the `aurora_volume_logical_start_lsn` function.

4. Then, use the ALTER SUBSCRIPTION... ENABLE clause to turn on logical replication.

   ```
   ALTER SUBSCRIPTION `subscription_name` ENABLE;
   ```

5. At this point, you can confirm that replication is working. Add a value to the publication instance, then confirm that the value is replicated to the subscription node.

   Then, use the following command to monitor replication lag on the publication node:
You can monitor the replication lag using `diff_size` and `diff_bytes` values. When these values reach 0, the replica has caught up to the source DB instance.

### Performing post-upgrade tasks

When the upgrade is complete, the instance status displays as **Available** in the **Status** column of the console dashboard. On the new instance, we recommend you do the following:

- Redirect your applications to point to the writer node.
- Add reader nodes to manage the caseload and provide high-availability in the event of an issue with the writer node.
- Aurora PostgreSQL DB clusters occasionally require operating system updates. These updates might include a newer version of glibc library. During such updates, we recommend you to follow the guidelines as described in [Collations supported in Aurora PostgreSQL](https://aws.amazon.com/documentation/aurora/collations-support/).
- Update user permissions on the new instance to ensure access.
After testing your application and data on the new instance, we recommend that you make a final backup of your initial instance before removing it. For more information about using logical replication on an Aurora host, see Setting up logical replication for your Aurora PostgreSQL DB cluster.

Troubleshooting storage issues

If the amount of working memory needed for sort or index-creation operations exceeds the amount allocated by the work_mem parameter, Aurora PostgreSQL writes the excess data to temporary disk files. When it writes the data, Aurora PostgreSQL uses the same storage space that it uses for storing error and message logs, that is, local storage. Each instance in your Aurora PostgreSQL DB cluster has an amount of local storage available. The amount of storage is based on its DB instance class. To increase the amount of local storage, you need to modify the instance to use a larger DB instance class. For DB instance class specifications, see Hardware specifications for DB instance classes for Aurora.

You can monitor your Aurora PostgreSQL DB cluster’s local storage space by watching the Amazon CloudWatch metric for FreeLocalStorage. This metric reports the amount of storage available to each DB instance in the Aurora DB cluster for temporary tables and logs. For more information, see Monitoring Amazon Aurora metrics with Amazon CloudWatch.

Sorting, indexing, and grouping operations start in working memory but often must be offloaded to local storage. If your Aurora PostgreSQL DB cluster runs out of local storage because of these types of operations, you can resolve the issue by taking one of the following actions.

- Increase the amount of working memory. This reduces the need to use local storage. By default, PostgreSQL allocates 4 MB for each sort, group, and index operation. To check the current working memory value for your Aurora PostgreSQL DB cluster’s writer instance, connect to the instance using psql and run the following command.

```
postgres=> SHOW work_mem;
work_mem
----------
 4MB
(1 row)
```

You can increase the working memory at the session level before sort, group, and other operations, as follows.
SET work_mem TO '1 GB';

For more information about working memory, see Resource Consumption in the PostgreSQL documentation.

- Change the log retention period so that logs are stored for shorter timeframes. To learn how, see Aurora PostgreSQL database log files.

For Aurora PostgreSQL DB clusters larger than 40 TB, don't use db.t2, db.t3, or db.t4g instance classes. We recommend using the T DB instance classes only for development and test servers, or other non-production servers. For more information, see DB instance class types.

**Replication with Amazon Aurora PostgreSQL**

Following, you can find information about replication with Amazon Aurora PostgreSQL, including how to monitor replication.

**Topics**

- Using Aurora Replicas
- Improving the read availability of Aurora Replicas
- Monitoring Aurora PostgreSQL replication
- Using PostgreSQL logical replication with Aurora

**Using Aurora Replicas**

An *Aurora Replica* is an independent endpoint in an Aurora DB cluster, best used for scaling read operations and increasing availability. An Aurora DB cluster can include up to 15 Aurora Replicas located throughout the Availability Zones of the Aurora DB cluster's AWS Region.

The DB cluster volume is made up of multiple copies of the data for the DB cluster. However, the data in the cluster volume is represented as a single, logical volume to the primary writer DB instance and to Aurora Replicas in the DB cluster. For more information about Aurora Replicas, see Aurora Replicas.

Aurora Replicas work well for read scaling because they're fully dedicated to read operations on your cluster volume. The writer DB instance manages write operations. The cluster volume is
shared among all instances in your Aurora PostgreSQL DB cluster. Thus, no extra work is needed to replicate a copy of the data for each Aurora Replica.

With Aurora PostgreSQL, when an Aurora Replica is deleted, its instance endpoint is removed immediately, and the Aurora Replica is removed from the reader endpoint. If there are statements running on the Aurora Replica that is being deleted, there is a three minute grace period. Existing statements can finish gracefully during the grace period. When the grace period ends, the Aurora Replica is shut down and deleted.

Aurora PostgreSQL DB clusters support Aurora Replicas in different AWS Regions, using Aurora global database. For more information, see Using Amazon Aurora global databases.

**Note**

With the improved read availability feature, if you want to reboot the Aurora Replicas in the DB cluster, you have to perform it manually. For the DB clusters created prior to this feature rebooting the writer DB instance automatically reboots the Aurora Replicas. The automatic reboot re-establishes an entry point that guarantees read/write consistency across the DB cluster.

### Improving the read availability of Aurora Replicas

Aurora PostgreSQL improves the read availability in the DB cluster by continuously serving the read requests when the writer DB instance restarts or when the Aurora Replica is unable to keep up with the write traffic.

The read availability feature is available by default on the following versions of Aurora PostgreSQL:

- 15.2 and higher 15 versions
- 14.7 and higher 14 versions
- 13.10 and higher 13 versions
- 12.14 and higher 12 versions

The read availability feature is supported by Aurora global database in the following versions:

- 15.4 and higher 15 versions
- 14.9 and higher 14 versions
• 13.12 and higher 13 versions
• 12.16 and higher 12 versions

To use the read availability feature for a DB cluster created on one of these versions prior to this launch, restart the writer instance of the DB cluster.

When you modify static parameters of your Aurora PostgreSQL DB cluster, you must restart the writer instance so that the parameter changes take effect. For example, you must restart the writer instance when you set the value of `shared_buffers`. With the improved availability of Aurora Replicas, the DB cluster maintains read availability during these restarts, which reduces the impact of changes to the writer instance. The reader instances don't restart and continue to respond to the read requests. To apply static parameter changes, reboot each individual reader instance.

An Aurora PostgreSQL DB cluster's Aurora Replica can recover from replication errors such as writer restarts, failover, slow replication, and network issues by quickly recovering to in-memory database state after it reconnects with the writer. This approach allows Aurora Replica instances to reach consistency with the latest storage updates while the client database is still available.

The in-progress transactions that conflict with replication recovery might receive an error but the client can retry these transactions, after the readers catch up with the writer.

**Monitoring Aurora Replicas**

You can monitor the Aurora Replicas when recovering from a writer disconnect. Use the metrics below to check for the latest information about the reader instance and to track in-process read-only transactions.

- The `aurora_replica_status` function is updated to return the most up-to-date information for the reader instance when it is still connected. The last update time stamp in `aurora_replica_status` is always empty for the row corresponding to the DB instance that the query is executed on. This indicates that the reader instance has the latest data.
- When the Aurora replica disconnects from the writer instance and reconnects back, the following database event is emitted:

  Read replica has been disconnected from the writer instance and reconnected.
- When a read-only query is canceled due to a recovery conflict, you might see one or more of the following error messages in the database error log:
Canceling statement due to conflict with recovery.

User query may not have access to page data to replica disconnect.

User query might have tried to access a file that no longer exists.

When the replica reconnects, you will be able to repeat your command.

Limitations

The following limitations apply to Aurora Replicas with improved availability:

• Aurora Replicas of secondary DB cluster can restart if the data can't be streamed from the writer instance during replication recovery.

• Aurora Replicas don't support online replication recovery if one is already in progress and will restart.

• Aurora Replicas will restart when your DB instance is nearing the transaction ID wraparound. For more information on transaction ID wraparound, see Preventing Transaction ID Wraparound Failures.

• Aurora Replicas can restart when the replication process is blocked under certain circumstances.

Monitoring Aurora PostgreSQL replication

Read scaling and high availability depend on minimal lag time. You can monitor how far an Aurora Replica is lagging behind the writer DB instance of your Aurora PostgreSQL DB cluster by monitoring the Amazon CloudWatch ReplicaLag metric. Because Aurora Replicas read from the same cluster volume as the writer DB instance, the ReplicaLag metric has a different meaning for an Aurora PostgreSQL DB cluster. The ReplicaLag metric for an Aurora Replica indicates the lag for the page cache of the Aurora Replica compared to that of the writer DB instance.

For more information on monitoring RDS instances and CloudWatch metrics, see Monitoring metrics in an Amazon Aurora cluster.

Using PostgreSQL logical replication with Aurora

By using PostgreSQL's logical replication feature with your Aurora PostgreSQL DB cluster, you can replicate and synchronize individual tables rather than the entire database instance. Logical
replication uses a publish and subscribe model to replicate changes from a source to one or more recipients. It works by using change records from the PostgreSQL write-ahead log (WAL). The source, or publisher, sends WAL data for the specified tables to one or more recipients (subscriber), thus replicating the changes and keeping a subscriber's table synchronized with the publisher's table. The set of changes from the publisher are identified using a publication. Subscribers get the changes by creating a subscription that defines the connection to the publisher's database and its publications. A replication slot is the mechanism used in this scheme to track progress of a subscription.

For Aurora PostgreSQL DB clusters, the WAL records are saved on Aurora storage. The Aurora PostgreSQL DB cluster that’s acting as the publisher in a logical replication scenario reads the WAL data from Aurora storage, decodes it, and sends it to the subscriber so that the changes can be applied to the table on that instance. The publisher uses a logical decoder to decode the data for use by subscribers. By default, Aurora PostgreSQL DB clusters use the native PostgreSQL pgoutput plugin when sending data. Other logical decoders are available. For example, Aurora PostgreSQL also supports the wal2json plugin that converts WAL data to JSON.

As of Aurora PostgreSQL version 14.5, 13.8, 12.12, and 11.17, Aurora PostgreSQL augments the PostgreSQL logical replication process with a write-through cache to improve performance. The WAL transaction logs are cached locally, in a buffer, to reduce the amount of disk I/O, that is, reading from Aurora storage during logical decoding. The write-through cache is used by default whenever you use logical replication for your Aurora PostgreSQL DB cluster. Aurora provides several functions that you can use to manage the cache. For more information, see Managing the Aurora PostgreSQL logical replication write-through cache.

Logical replication is supported by all currently available Aurora PostgreSQL versions. For more information, Amazon Aurora PostgreSQL updates in the Release Notes for Aurora PostgreSQL.

Note

In addition to the native PostgreSQL logical replication feature introduced in PostgreSQL 10, Aurora PostgreSQL also supports the pglogical extension. For more information, see Using pglogical to synchronize data across instances.

For more information about PostgreSQL logical replication, see Logical replication and Logical decoding concepts in the PostgreSQL documentation.
In the following topics, you can find information about how to set up logical replication between your Aurora PostgreSQL DB clusters.

**Topics**

- Setting up logical replication for your Aurora PostgreSQL DB cluster
- Turning off logical replication
- Managing the Aurora PostgreSQL logical replication write-through cache
- Managing logical slots for Aurora PostgreSQL
- Example: Using logical replication with Aurora PostgreSQL DB clusters
- Example: Logical replication using Aurora PostgreSQL and AWS Database Migration Service

**Setting up logical replication for your Aurora PostgreSQL DB cluster**

Setting up logical replication requires `rds_superuser` privileges. Your Aurora PostgreSQL DB cluster must be configured to use a custom DB cluster parameter group so that you can set the necessary parameters as detailed in the procedure following. For more information, see [Working with DB cluster parameter groups](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/DBEngine-Setup.html#DBEngine-Setup.WorkingWithDBClusterParameterGroups).

**To set up PostgreSQL logical replication for an Aurora PostgreSQL DB cluster**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your Aurora PostgreSQL DB cluster.
3. Open the **Configuration** tab. Among the Instance details, find the **Parameter group** link with **DB cluster parameter group** for **Type**.
4. Choose the link to open the custom parameters associated with your Aurora PostgreSQL DB cluster.
5. In the **Parameters** search field, type `rds` to find the `rds.logical_replication` parameter. The default value for this parameter is 0, meaning that it's turned off by default.
6. Choose **Edit parameters** to access the property values, and then choose 1 from the selector to turn on the feature. Depending on your expected usage, you might also need to change the settings for the following parameters. However, in many cases, the default values are sufficient.
   - `max_replication_slots` – Set this parameter to a value that's at least equal to your planned total number of logical replication publications and subscriptions. If you are using
AWS DMS, this parameter should equal at least your planned change data capture tasks from the cluster, plus logical replication publications and subscriptions.

- **max_wal_senders** and **max_logical_replication_workers** – Set these parameters to a value that's at least equal to the number of logical replication slots that you intend to be active, or the number of active AWS DMS tasks for change data capture. Leaving a logical replication slot inactive prevents the vacuum from removing obsolete tuples from tables, so we recommend that you monitor replication slots and remove inactive slots as needed.

- **max_worker_processes** – Set this parameter to a value that's at least equal to the total of the **max_logical_replication_workers**, **autovacuum_max_workers**, and **max_parallel_workers** values. On small DB instance classes, background worker processes can affect application workloads, so monitor the performance of your database if you set **max_worker_processes** higher than the default value. (The default value is the result of $\text{GREATEST}($\{DBInstanceVCPU*2\}, 8), which means that, by default, this is either 8 or twice the CPU equivalent of the DB instance class, whichever is greater).

### Note
You can modify parameter values in a customer-created DB parameter group. You can’t change the parameter values in a default DB parameter group.

7. Choose **Save changes**.

8. Reboot the writer instance of your Aurora PostgreSQL DB cluster so that your changes take effect. In the Amazon RDS console, choose the primary DB instance of the cluster and choose **Reboot** from the **Actions** menu.

9. When the instance is available, you can verify that logical replication is turned on, as follows.

   a. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster.

```
psql --host=your-db-cluster-instance-1.aws-region.rds.amazonaws.com --port=5432  
--username=postgres --password --dbname=labdb
```

   b. Verify that logical replication has been enabled by using the following command.

```
labdb=> SHOW rds.logical_replication;  
rds.logical_replication  
-------------------------  
on
```
c. Verify that the `wal_level` is set to `logical`.

```sql
labdb=> SHOW wal_level;
  wal_level
--------
    logical
(1 row)
```

For an example of using logical replication to keep a database table synchronized with changes from a source Aurora PostgreSQL DB cluster, see [Example: Using logical replication with Aurora PostgreSQL DB clusters](#).

### Turning off logical replication

After completing your replication tasks, you should stop the replication process, drop replication slots, and turn off logical replication. Before dropping slots, make sure that they're no longer needed. Active replication slots can't be dropped.

**To turn off logical replication**

1. **Drop all replication slots.**

   To drop all of the replication slots, connect to the publisher and run the following SQL command.

   ```sql
   SELECT pg_drop_replication_slot(slot_name)
   FROM pg_replication_slots
   WHERE slot_name IN (SELECT slot_name FROM pg_replication_slots);
   ```

   The replication slots can't be active when you run this command.

2. **Modify the custom DB cluster parameter group associated with the publisher as detailed in [Setting up logical replication for your Aurora PostgreSQL DB cluster](#), but set the `rds.logical_replication` parameter to 0.**

   For more information about custom parameter groups, see [Modifying parameters in a DB cluster parameter group](#).
3. Restart the publisher Aurora PostgreSQL DB cluster for the change to the `rds.logical_replication` parameter to take effect.

Managing the Aurora PostgreSQL logical replication write-through cache

By default, Aurora PostgreSQL versions 14.5, 13.8, 12.12, and 11.17 and higher use a write-through cache to improve the performance for logical replication. Without the write-through cache, Aurora PostgreSQL uses the Aurora storage layer in its implementation of the native PostgreSQL logical replication process. It does so by writing WAL data to storage and then reading the data back from storage to decode it and send (replicate) to its targets (subscribers). This can result in bottlenecks during logical replication for Aurora PostgreSQL DB clusters.

The write-through cache reduces the need to use the Aurora storage layer. Instead of always writing and reading from the Aurora storage layer, Aurora PostgreSQL uses a buffer to cache the logical WAL stream so that it can be used during the replication process, rather than always pulling from disk. This buffer is the PostgreSQL native cache used by logical replication, identified in Aurora PostgreSQL DB cluster parameters as `rds.logical_wal_cache`. By default, this cache uses 1/32 of the Aurora PostgreSQL DB cluster's buffer cache setting (`shared_buffers`) but not less than 64kB nor more than the size of one WAL segment, typically 16MB.

When you use logical replication with your Aurora PostgreSQL DB cluster (for the versions that support the write-through cache), you can monitor the cache hit ratio to see how well it's working for your use case. To do so, connect to your Aurora PostgreSQL DB cluster's write instance using `psql` and then use the Aurora function, `aurora_stat_logical_wal_cache`, as shown in the following example.

```
SELECT * FROM aurora_stat_logical_wal_cache();
```

The function returns output such as the following.

```
name       | active_pid | cache_hit | cache_miss | blks_read | hit_rate |
-----------+------------+-----------+------------+-----------+----------+--------------
| test_slot1 | 79183      | 24        | 0          | 24        | 100.00%  | 2022-08-05 17:39... |
| test_slot2 |            | 1         | 0          | 1         | 100.00%  | 2022-08-05 17:34... |
(2 rows)
```
The last_reset_timestamp values have been shortened for readability. For more information about this function, see `aurora_stat_logical_wal_cache`.

Aurora PostgreSQL provides the following two functions for monitoring the write-through cache.

- The `aurora_stat_logical_wal_cache` function – For reference documentation, see `aurora_stat_logical_wal_cache`.
- The `aurora_stat_reset_wal_cache` function – For reference documentation, see `aurora_stat_reset_wal_cache`.

If you find that the automatically adjusted WAL cache size isn't sufficient for your workloads, you can change the value of the `rds.logical_wal_cache` manually, by modifying the parameter in your custom DB cluster parameter group. Note that any positive value less than 32kB is treated as 32kB. For more information about the `wal_buffers`, see `Write Ahead Log` in the PostgreSQL documentation.

**Managing logical slots for Aurora PostgreSQL**

Streaming activity is captured in the `pg_replication_origin_status` view. To see the contents of this view, you can use the `pg_show_replication_origin_status()` function, as shown following:

```
SELECT * FROM pg_show_replication_origin_status();
```

You can get a list of your logical slots by using the following SQL query.

```
SELECT * FROM pg_replication_slots;
```

To drop a logical slot, use the `pg_drop_replication_slot` with the name of the slot, as shown in the following command.

```
SELECT pg_drop_replication_slot('test_slot');
```

**Example: Using logical replication with Aurora PostgreSQL DB clusters**

The following procedure shows you how to start logical replication between two Aurora PostgreSQL DB clusters. Both the publisher and the subscriber must be configured for logical replication as detailed in [Setting up logical replication for your Aurora PostgreSQL DB cluster](#).
The Aurora PostgreSQL DB cluster that's the designated publisher must also allow access to the replication slot. To do so, modify the security group associated with the Aurora PostgreSQL DB cluster's virtual public cloud (VPC) based on the Amazon VPC service. Allow inbound access by adding the security group associated with the subscriber's VPC to the publisher's security group. For more information, see Control traffic to resources using security groups in the Amazon VPC User Guide.

With these preliminary steps complete, you can use PostgreSQL commands CREATE PUBLICATION on the publisher and the CREATE SUBSCRIPTION on the subscriber, as detailed in the following procedure.

To start the logical replication process between two Aurora PostgreSQL DB clusters

These steps assume that your Aurora PostgreSQL DB clusters have a writer instance with a database in which to create the example tables.

1. **On the publisher Aurora PostgreSQL DB cluster**

   a. Create a table using the following SQL statement.

   ```sql
   CREATE TABLE LogicalReplicationTest (a int PRIMARY KEY);
   ```

   b. Insert data into the publisher database by using the following SQL statement.

   ```sql
   INSERT INTO LogicalReplicationTest VALUES (generate_series(1,10000));
   ```

   c. Verify that data exists in the table by using the following SQL statement.

   ```sql
   SELECT count(*) FROM LogicalReplicationTest;
   ```

   d. Create a publication for this table by using the CREATE PUBLICATION statement, as follows.

   ```sql
   CREATE PUBLICATION testpub FOR TABLE LogicalReplicationTest;
   ```

2. **On the subscriber Aurora PostgreSQL DB cluster**

   a. Create the same LogicalReplicationTest table on the subscriber that you created on the publisher, as follows.
CREATE TABLE LogicalReplicationTest (a int PRIMARY KEY);

b. Verify that this table is empty.

SELECT count(*) FROM LogicalReplicationTest;

c. Create a subscription to get the changes from the publisher. You need to use the following details about the publisher Aurora PostgreSQL DB cluster.

- **host** – The publisher Aurora PostgreSQL DB cluster's writer DB instance.
- **port** – The port on which the writer DB instance is listening. The default for PostgreSQL is 5432.
- **dbname** – The name of the database.

CREATE SUBSCRIPTION testsub CONNECTION 'host=publisher-cluster-writer-endpoint port=5432 dbname=db-name user=user password=password' PUBLICATION testpub;

**Note**

Specify a password other than the prompt shown here as a security best practice.

After the subscription is created, a logical replication slot is created at the publisher.

d. To verify for this example that the initial data is replicated on the subscriber, use the following SQL statement on the subscriber database.

SELECT count(*) FROM LogicalReplicationTest;

Any further changes on the publisher are replicated to the subscriber.

Logical replication affects performance. We recommend that you turn off logical replication after your replication tasks are complete.
Example: Logical replication using Aurora PostgreSQL and AWS Database Migration Service

You can use the AWS Database Migration Service (AWS DMS) to replicate a database or a portion of a database. Use AWS DMS to migrate your data from an Aurora PostgreSQL database to another open source or commercial database. For more information about AWS DMS, see the AWS Database Migration Service User Guide.

The following example shows how to set up logical replication from an Aurora PostgreSQL database as the publisher and then use AWS DMS for migration. This example uses the same publisher and subscriber that were created in Example: Using logical replication with Aurora PostgreSQL DB clusters.

To set up logical replication with AWS DMS, you need details about your publisher and subscriber from Amazon RDS. In particular, you need details about the publisher's writer DB instance and the subscriber's DB instance.

Get the following information for the publisher's writer DB instance:

- The virtual private cloud (VPC) identifier
- The subnet group
- The Availability Zone (AZ)
- The VPC security group
- The DB instance ID

Get the following information for the subscriber's DB instance:

- The DB instance ID
- The source engine

To use AWS DMS for logical replication with Aurora PostgreSQL

1. Prepare the publisher database to work with AWS DMS.

   To do this, PostgreSQL 10.x and later databases require that you apply AWS DMS wrapper functions to the publisher database. For details on this and later steps, see the instructions in Using PostgreSQL version 10.x and later as a source for AWS DMS in the AWS Database Migration Service User Guide.
2. Sign in to the AWS Management Console and open the AWS DMS console at https://console.aws.amazon.com/dms/v2. At top right, choose the same AWS Region in which the publisher and subscriber are located.

3. Create an AWS DMS replication instance.

Choose values that are the same as for your publisher's writer DB instance. These include the following settings:

- For **VPC**, choose the same VPC as for the writer DB instance.
- For **Replication Subnet Group**, choose a subnet group with the same values as the writer DB instance. Create a new one if necessary.
- For **Availability zone**, choose the same zone as for the writer DB instance.
- For **VPC Security Group**, choose the same group as for the writer DB instance.

4. Create an AWS DMS endpoint for the source.

Specify the publisher as the source endpoint by using the following settings:

- For **Endpoint type**, choose **Source endpoint**.
- Choose **Select RDS DB Instance**.
- For **RDS Instance**, choose the DB identifier of the publisher's writer DB instance.
- For **Source engine**, choose **postgres**.

5. Create an AWS DMS endpoint for the target.

Specify the subscriber as the target endpoint by using the following settings:

- For **Endpoint type**, choose **Target endpoint**.
- Choose **Select RDS DB Instance**.
- For **RDS Instance**, choose the DB identifier of the subscriber DB instance.
- Choose a value for **Source engine**. For example, if the subscriber is an RDS PostgreSQL database, choose **postgres**. If the subscriber is an Aurora PostgreSQL database, choose **aurora-postgresql**.

6. Create an AWS DMS database migration task.

You use a database migration task to specify what database tables to migrate, to map data using the target schema, and to create new tables on the target database. At a minimum, use the following settings for **Task configuration**:
• For **Replication instance**, choose the replication instance that you created in an earlier step.

• For **Source database endpoint**, choose the publisher source that you created in an earlier step.

• For **Target database endpoint**, choose the subscriber target that you created in an earlier step.

The rest of the task details depend on your migration project. For more information about specifying all the details for DMS tasks, see [Working with AWS DMS tasks](#) in the *AWS Database Migration Service User Guide*.

After AWS DMS creates the task, it begins migrating data from the publisher to the subscriber.

### Using Aurora PostgreSQL as a Knowledge Base for Amazon Bedrock

From Aurora PostgreSQL 15.4, 14.9, 13.12, 12.16 versions, you can use the Aurora PostgreSQL DB cluster as a Knowledge Base for Amazon Bedrock. For more information, see [Create a vector store in Amazon Aurora](#). A Knowledge Base automatically takes unstructured text data stored in a Amazon S3 bucket, converts it to text chunks and vectors, and stores it in a PostgreSQL database. With the generative AI applications, you can use Agents for Amazon Bedrock to query the data stored in the Knowledge Base and use the results of those queries to augment answers provided by foundational models. This workflow is called Retrieval Augmented Generation (RAG). For more information on RAG, see [Retrieval Augmented Generation (RAG)](#).

**Topics**

• [Prerequisites](#)

• [Preparing Aurora PostgreSQL to be used as a Knowledge Base for Amazon Bedrock](#)

• [Creating a knowledge base in the Bedrock console](#)

**Prerequisites**

Familiarize yourself with the following prerequisites to use Aurora PostgreSQL cluster as a Knowledge Base for Amazon Bedrock. At a high-level, you need to configure the following services for use with Bedrock:
Amazon Aurora PostgreSQL DB cluster created in the following versions:

- 15.4 and higher versions
- 14.9 and higher versions
- 13.12 and higher versions
- 12.16 and higher versions

**Note**
You must enable the `pgvector` extension in your target database and use version 0.5.0 or higher. For more information, see *pgvector v0.5.0 with HNSW indexing*.

Data API

A user managed in Secrets Manager. For more information, see *Password management with Amazon Aurora and AWS Secrets Manager*.

Preparing Aurora PostgreSQL to be used as a Knowledge Base for Amazon Bedrock

You need to follow the steps below to create and configure an Aurora PostgreSQL DB cluster to use it as a Knowledge Base for Amazon Bedrock.

1. Create an Aurora PostgreSQL DB cluster. For more information, see *Creating and connecting to an Aurora PostgreSQL DB cluster*.
2. Enable Data API while creating Aurora PostgreSQL DB cluster. For more information on the versions supported, see *Using RDS Data API*.
3. Note the Aurora PostgreSQL DB cluster Amazon Resource Names (ARN) to use it in the Amazon Bedrock. For more information, see *Amazon Resource Names (ARNs)*.
4. Log in to the database with your master user and setup `pgvector`. Use the following command if the extension is not installed:

```
CREATE EXTENSION IF NOT EXISTS vector;
```

Use `pgvector` 0.5.0 and higher version that supports HNSW indexing. For more information, see *pgvector v0.5.0 with HNSW indexing*.
Use the following command to check the version of the pg_vector installed:

```
postgres=>SELECT extversion FROM pg_extension WHERE extname='vector';
```

5. Create a specific schema that Bedrock can use to query the data. Use the following command to create a schema:

```
CREATE SCHEMA bedrock_integration;
```

6. Create a new role that Bedrock can use to query the database. Use the following command to create a new role:

```
CREATE ROLE bedrock_user WITH PASSWORD password LOGIN;
```

**Note**

Make a note of this password as you would be using the same to create a Secrets Manager password.

7. To grant the bedrock_user permission to manage the bedrock_integration schema, so they can create tables or indexes in it.

```
GRANT ALL ON SCHEMA bedrock_integration to bedrock_user;
```

8. Login as the bedrock_user and create a table in the bedrock_integration schema.

```
CREATE TABLE bedrock_integration.bedrock_kb (id uuid PRIMARY KEY, embedding vector(1536), chunks text, metadata json);
```

9. We recommend you to create an index with the cosine operator which the bedrock can use to query the data.

```
CREATE INDEX on bedrock_integration.bedrock_kb USING hnsw (embedding vector_cosine_ops);
```

10. Create an AWS Secrets Manager database secret. For more information, see AWS Secrets Manager database secret.
Creating a knowledge base in the Bedrock console

While preparing Aurora PostgreSQL to be used as the vector store for a Knowledge Base, gather the following details that you need to supply to Amazon Bedrock console.

- Amazon Aurora DB cluster ARN
- Secret ARN
- Database name (e.g. postgres)
- Table name - Advise to provide a schema qualified name, ie. CREATE TABLE bedrock_integration.bedrock_kb; which will create the bedrock_kb table in the bedrock_integration schema
- Table fields:
  - ID: (id)
  - Text chunks (chunks)
  - Vector embedding (embedding)
  - Metadata (metadata)

With these details you can create a knowledge base in the Bedrock console. For more information, see Create a vector store in Amazon Aurora.

Once Aurora is added as a knowledge base, you ingest the data sources into it. For more information, see Ingest your data sources into the knowledge base.

Integrating Amazon Aurora PostgreSQL with other AWS services

Amazon Aurora integrates with other AWS services so that you can extend your Aurora PostgreSQL DB cluster to use additional capabilities in the AWS Cloud. Your Aurora PostgreSQL DB cluster can use AWS services to do the following:

- Quickly collect, view, and assess performance for your Aurora PostgreSQL DB instances with Amazon RDS Performance Insights. Performance Insights expands on existing Amazon RDS monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load...
and filter the load by waits, SQL statements, hosts, or users. For more information about Performance Insights, see Monitoring DB load with Performance Insights on Amazon Aurora.

• Configure your Aurora PostgreSQL DB cluster to publish log data to Amazon CloudWatch Logs. CloudWatch Logs provide highly durable storage for your log records. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. For more information, see Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs.

• Import data from an Amazon S3 bucket to an Aurora PostgreSQL DB cluster, or export data from an Aurora PostgreSQL DB cluster to an Amazon S3 bucket. For more information, see Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster and Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3.

• Add machine learning-based predictions to database applications using the SQL language. Aurora machine learning uses a highly optimized integration between the Aurora database and the AWS machine learning (ML) services SageMaker and Amazon Comprehend. For more information, see Using Amazon Aurora machine learning with Aurora PostgreSQL.

• Invoke AWS Lambda functions from an Aurora PostgreSQL DB cluster. To do this, use the aws_1ambda PostgreSQL extension provided with Aurora PostgreSQL. For more information, see Invoking an AWS Lambda function from an Aurora PostgreSQL DB cluster.

• Integrate queries from Amazon Redshift and Aurora PostgreSQL. For more information, see Getting started with using federated queries to PostgreSQL in the Amazon Redshift Database Developer Guide.

Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster

You can import data that's been stored using Amazon Simple Storage Service into a table on an Aurora PostgreSQL DB cluster instance. To do this, you first install the Aurora PostgreSQL aw_s3 extension. This extension provides the functions that you use to import data from an Amazon S3 bucket. A bucket is an Amazon S3 container for objects and files. The data can be in a comma-separated value (CSV) file, a text file, or a compressed (gzip) file. Following, you can learn how to install the extension and how to import data from Amazon S3 into a table.

Your database must be running PostgreSQL version 10.7 or higher to import from Amazon S3 into Aurora PostgreSQL.

If you don't have data stored on Amazon S3, you need to first create a bucket and store the data. For more information, see the following topics in the Amazon Simple Storage Service User Guide.
• **Create a bucket**

• **Add an object to a bucket**

Cross-account import from Amazon S3 is supported. For more information, see **Granting cross-account permissions** in the *Amazon Simple Storage Service User Guide*.

You can use the customer managed key for encryption while importing data from S3. For more information, see **KMS keys stored in AWS KMS** in the *Amazon Simple Storage Service User Guide*.

**Note**

Importing data from Amazon S3 isn't supported for Aurora Serverless v1. It is supported for Aurora Serverless v2.

**Topics**

• **Installing the aws_s3 extension**

• **Overview of importing data from Amazon S3 data**

• **Setting up access to an Amazon S3 bucket**

• **Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster**

• **Function reference**

**Installing the aws_s3 extension**

Before you can use Amazon S3 with your Aurora PostgreSQL DB cluster, you need to install the aws_s3 extension. This extension provides functions for importing data from an Amazon S3. It also provides functions for exporting data from an instance of an Aurora PostgreSQL DB cluster to an Amazon S3 bucket. For more information, see **Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3**. The aws_s3 extension depends on some of the helper functions in the aws_commons extension, which is installed automatically when needed.

**To install the aws_s3 extension**

1. Use psql (or pgAdmin) to connect to the writer instance of your Aurora PostgreSQL DB cluster as a user that has rds_superuser privileges. If you kept the default name during the setup process, you connect as postgres.
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password

2. To install the extension, run the following command.

postgres=> CREATE EXTENSION aws_s3 CASCADE;
NOTICE: installing required extension "aws_commons"
CREATE EXTENSION

3. To verify that the extension is installed, you can use the psql \dx metacommand.

postgres=> \dx
List of installed extensions
<table>
<thead>
<tr>
<th>Name</th>
<th>Version</th>
<th>Schema</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws_commons</td>
<td>1.2</td>

</tr>
</tbody>
</table>
(3 rows)

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

**Overview of importing data from Amazon S3 data**

**To import S3 data into Aurora PostgreSQL**

First, gather the details that you need to supply to the function. These include the name of the table on your Aurora PostgreSQL DB cluster's instance, and the bucket name, file path, file type, and AWS Region where the Amazon S3 data is stored. For more information, see View an object in the Amazon Simple Storage Service User Guide.

**Note**

Multi part data import from Amazon S3 isn't currently supported.
1. Get the name of the table into which the `aws_s3.table_import_from_s3` function is to import the data. As an example, the following command creates a table `t1` that can be used in later steps.

   ```
   postgres=> CREATE TABLE t1
   (col1 varchar(80),
    col2 varchar(80),
    col3 varchar(80));
   ```

2. Get the details about the Amazon S3 bucket and the data to import. To do this, open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/), and choose **Buckets**. Find the bucket containing your data in the list. Choose the bucket, open its Object overview page, and then choose Properties.

   Make a note of the bucket name, path, the AWS Region, and file type. You need the Amazon Resource Name (ARN) later, to set up access to Amazon S3 through an IAM role. For more information, see [Setting up access to an Amazon S3 bucket](#). The image following shows an example.

3. You can verify the path to the data on the Amazon S3 bucket by using the AWS CLI command `aws s3 cp`. If the information is correct, this command downloads a copy of the Amazon S3 file.
aws s3 cp s3://DOC-EXAMPLE-BUCKET/sample_file_path ./

4. Set up permissions on your Aurora PostgreSQL DB cluster to allow access to the file on the Amazon S3 bucket. To do so, you use either an AWS Identity and Access Management (IAM) role or security credentials. For more information, see Setting up access to an Amazon S3 bucket.

5. Supply the path and other Amazon S3 object details gathered (see step 2) to the create_s3_uri function to construct an Amazon S3 URI object. To learn more about this function, see aws_commons.create_s3_uri. The following is an example of constructing this object during a psql session.

```sql
postgres=> SELECT aws_commons.create_s3_uri(
              'docs-lab-store-for-rpg',
              'versions_and_jdks_listing.csv',
              'us-west-1'
          ) AS s3_uri \gset
```

In the next step, you pass this object (aws_commons._s3_uri_1) to the aws_s3.table_import_from_s3 function to import the data to the table.

6. Invoke the aws_s3.table_import_from_s3 function to import the data from Amazon S3 into your table. For reference information, see aws_s3.table_import_from_s3. For examples, see Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster.

### Setting up access to an Amazon S3 bucket

To import data from an Amazon S3 file, give the Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket containing the file. You provide access to an Amazon S3 bucket in one of two ways, as described in the following topics.

**Topics**

- [Using an IAM role to access an Amazon S3 bucket](#)
- [Using security credentials to access an Amazon S3 bucket](#)
- [Troubleshooting access to Amazon S3](#)
Using an IAM role to access an Amazon S3 bucket

Before you load data from an Amazon S3 file, give your Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket the file is in. This way, you don't have to manage additional credential information or provide it in the `aws_s3.table_import_from_s3` function call.

To do this, create an IAM policy that provides access to the Amazon S3 bucket. Create an IAM role and attach the policy to the role. Then assign the IAM role to your DB cluster.

Note
You can't associate an IAM role with an Aurora Serverless v1 DB cluster, so the following steps don't apply.

To give an Aurora PostgreSQL DB cluster access to Amazon S3 through an IAM role

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your Aurora PostgreSQL DB cluster to access Amazon S3.

   Include in the policy the following required actions to allow the transfer of files from an Amazon S3 bucket to Aurora PostgreSQL:

   - `s3:GetObject`
   - `s3:ListBucket`

   Include in the policy the following resources to identify the Amazon S3 bucket and objects in the bucket. This shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

   - `arn:aws:s3:::DOC-EXAMPLE-BUCKET`
   - `arn:aws:s3:::DOC-EXAMPLE-BUCKET/*`

   For more information on creating an IAM policy for Aurora PostgreSQL, see Creating and using an IAM policy for IAM database access. See also Tutorial: Create and attach your first customer managed policy in the IAM User Guide.
The following AWS CLI command creates an IAM policy named `rds-s3-import-policy` with these options. It grants access to a bucket named `DOC-EXAMPLE-BUCKET`.

**Note**
Make a note of the Amazon Resource Name (ARN) of the policy returned by this command. You need the ARN in a subsequent step when you attach the policy to an IAM role.

**Example**

For Linux, macOS, or Unix:

```bash
aws iam create-policy \
--policy-name rds-s3-import-policy \
--policy-document '{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "s3import",
         "Action": [
            "s3:GetObject",
            "s3:ListBucket"
         ],
         "Effect": "Allow",
         "Resource": [
            "arn:aws:s3:::DOC-EXAMPLE-BUCKET",
            "arn:aws:s3:::DOC-EXAMPLE-BUCKET/*"
         ]
      }
   ]
}
```

For Windows:

```bash
aws iam create-policy ^
--policy-name rds-s3-import-policy ^
--policy-document '{
   "Version": "2012-10-17",
```
2. Create an IAM role.

You do this so Aurora PostgreSQL can assume this IAM role to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-import-role`.

**Example**

For Linux, macOS, or Unix:
Importing data from Amazon S3 into Aurora PostgreSQL

```
aws iam create-role \
  --role-name rds-s3-import-role \
  --assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "111122223333",
          "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:cluster:clustern"name"
        }"n
      }
    ]
  }''

For Windows:

```
aws iam create-role ^
  --role-name rds-s3-import-role ^
  --assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "111122223333",
          "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:cluster:clustern"name"
        }"n
      }
    ]
  }''
```

```
3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created in the previous step to the role named rds-s3-import-role Replace \textit{your-policy-arn} with the policy ARN that you noted in an earlier step.

\textbf{Example}

For Linux, macOS, or Unix:

\begin{verbatim}
aws iam attach-role-policy \\
  --policy-arn \textit{your-policy-arn} \\
  --role-name rds-s3-import-role
\end{verbatim}

For Windows:

\begin{verbatim}
aws iam attach-role-policy ^
  --policy-arn \textit{your-policy-arn} ^
  --role-name rds-s3-import-role
\end{verbatim}

4. Add the IAM role to the DB cluster.

You do so by using the AWS Management Console or AWS CLI, as described following.

\textbf{Console}

\textbf{To add an IAM role for a PostgreSQL DB cluster using the console}

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.

2. Choose the PostgreSQL DB cluster name to display its details.

3. On the \textbf{Connectivity \& security} tab, in the \textbf{Manage IAM roles} section, choose the role to add under \textbf{Add IAM roles to this cluster}.

4. Under \textbf{Feature}, choose \textbf{s3Import}.

5. Choose \textbf{Add role}.
AWS CLI

To add an IAM role for a PostgreSQL DB cluster using the CLI

- Use the following command to add the role to the PostgreSQL DB cluster named my-db-cluster. Replace `your-role-arn` with the role ARN that you noted in a previous step. Use `s3Import` for the value of the `--feature-name` option.

  **Example**

  For Linux, macOS, or Unix:

  ```
  aws rds add-role-to-db-cluster \\
  --db-cluster-identifier my-db-cluster \\
  --feature-name s3Import \\
  --role-arn your-role-arn \\
  --region your-region
  ```

  For Windows:

  ```
  aws rds add-role-to-db-cluster ^
  --db-cluster-identifier my-db-cluster ^
  --feature-name s3Import ^
  --role-arn your-role-arn ^
  --region your-region
  ```

RDS API

To add an IAM role for a PostgreSQL DB cluster using the Amazon RDS API, call the `AddRoleToDBCluster` operation.

Using security credentials to access an Amazon S3 bucket

If you prefer, you can use security credentials to provide access to an Amazon S3 bucket instead of providing access with an IAM role. You do so by specifying the `credentials` parameter in the `aws_s3.table_import_from_s3` function call.

The `credentials` parameter is a structure of type `aws_commons._aws_credentials_1`, which contains AWS credentials. Use the `aws_commons.create_aws_credentials` function to set the access key and secret key in an `aws_commons._aws_credentials_1` structure, as shown following.
postgres=> SELECT aws_commons.create_aws_credentials('sample_access_key', 'sample_secret_key', '')
AS creds \gset

After creating the aws_commons._aws_credentials_1 structure, use the aws_s3.table_import_from_s3 function with the credentials parameter to import the data, as shown following.

postgres=> SELECT aws_s3.table_import_from_s3('t', '', '(format csv)', 's3_uri', 'creds');

Or you can include the aws_commons.create_aws_credentials function call inline within the aws_s3.table_import_from_s3 function call.

postgres=> SELECT aws_s3.table_import_from_s3('t', '', '(format csv)', 's3_uri', aws_commons.create_aws_credentials('sample_access_key', 'sample_secret_key', ''));

Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to import data from Amazon S3, see the following for recommendations:

- Troubleshooting Amazon Aurora identity and access
- Troubleshooting Amazon S3 in the Amazon Simple Storage Service User Guide
- Troubleshooting Amazon S3 and IAM in the IAM User Guide

Importing data from Amazon S3 to your Aurora PostgreSQL DB cluster

You import data from your Amazon S3 bucket by using the table_import_from_s3 function of the aws_s3 extension. For reference information, see aws_s3.table_import_from_s3.
Note

The following examples use the IAM role method to allow access to the Amazon S3 bucket. Thus, the `aws_s3.table_import_from_s3` function calls don't include credential parameters.

The following shows a typical example.

```sql
postgres=> SELECT aws_s3.table_import_from_s3(
    't1',
    '',
    '(format csv)',
    '"s3_uri"
);
```

The parameters are the following:

- **t1** – The name for the table in the PostgreSQL DB cluster to copy the data into.
- **''** – An optional list of columns in the database table. You can use this parameter to indicate which columns of the S3 data go in which table columns. If no columns are specified, all the columns are copied to the table. For an example of using a column list, see [Importing an Amazon S3 file that uses a custom delimiter](#).
- **(format csv)** – PostgreSQL COPY arguments. The copy process uses the arguments and format of the `PostgreSQL COPY` command to import the data. Choices for format include comma-separated value (CSV) as shown in this example, text, and binary. The default is text.
- **"s3_uri"** – A structure that contains the information identifying the Amazon S3 file. For an example of using the `aws_commons.create_s3_uri` function to create an `s3_uri` structure, see [Overview of importing data from Amazon S3 data](#).

For more information about this function, see [aws_s3.table_import_from_s3](#).

The `aws_s3.table_import_from_s3` function returns text. To specify other kinds of files for import from an Amazon S3 bucket, see one of the following examples.
**Note**
Importing 0 bytes file will cause an error.

**Topics**

- Importing an Amazon S3 file that uses a custom delimiter
- Importing an Amazon S3 compressed (gzip) file
- Importing an encoded Amazon S3 file

**Importing an Amazon S3 file that uses a custom delimiter**

The following example shows how to import a file that uses a custom delimiter. It also shows how to control where to put the data in the database table using the `column_list` parameter of the `aws_s3.table_import_from_s3` function.

For this example, assume that the following information is organized into pipe-delimited columns in the Amazon S3 file.

```
1|foo1|bar1|elephant1
2|foo2|bar2|elephant2
3|foo3|bar3|elephant3
4|foo4|bar4|elephant4
...```

**To import a file that uses a custom delimiter**

1. Create a table in the database for the imported data.

   ```
   postgres=> CREATE TABLE test (a text, b text, c text, d text, e text);
   ```

2. Use the following form of the `aws_s3.table_import_from_s3` function to import data from the Amazon S3 file.

   You can include the `aws_commons.create_s3_uri` function call inline within the `aws_s3.table_import_from_s3` function call to specify the file.

   ```
   postgres=> SELECT aws_s3.table_import_from_s3(
   ```
The data is now in the table in the following columns.

```
postgres=> SELECT * FROM test;
 a  | b   | c  | d   | e
-----+-----+----+-----+-----
 1   | foo1 |   | bar1 | elephant1
 2   | foo2 |   | bar2 | elephant2
 3   | foo3 |   | bar3 | elephant3
 4   | foo4 |   | bar4 | elephant4
```

**Importing an Amazon S3 compressed (gzip) file**

The following example shows how to import a file from Amazon S3 that is compressed with gzip. The file that you import needs to have the following Amazon S3 metadata:

- **Key:** Content-Encoding
- **Value:** gzip

If you upload the file using the AWS Management Console, the metadata is typically applied by the system. For information about uploading files to Amazon S3 using the AWS Management Console, the AWS CLI, or the API, see [Uploading objects](https://docs.aws.amazon.com/AmazonS3/latest/userguide/uploading-objects.html) in the Amazon Simple Storage Service User Guide.

For more information about Amazon S3 metadata and details about system-provided metadata, see [Editing object metadata in the Amazon S3 console](https://docs.aws.amazon.com/AmazonS3/latest/userguide/object-metadata.html) in the Amazon Simple Storage Service User Guide.

Import the gzip file into your Aurora PostgreSQL DB cluster as shown following.

```
postgres=> CREATE TABLE test_gzip(id int, a text, b text, c text, d text);
postgres=> SELECT aws_s3.table_import_from_s3('test_gzip', '', 'format csv',
' 'DOC-EXAMPLE-BUCKET', 'test-data.gz', 'us-east-2')
```
Importing an encoded Amazon S3 file

The following example shows how to import a file from Amazon S3 that has Windows-1252 encoding.

```
postgres=> SELECT aws_s3.table_import_from_s3('test_table', '', 'encoding 'WIN1252''

aws_commons.create_s3_uri('DOC-EXAMPLE-BUCKET', 'SampleFile', 'us-east-2')
);
```

Function reference

Functions

- `aws_s3.table_import_from_s3`
- `aws_commons.create_s3_uri`
- `aws_commons.create_aws_credentials`

**aws_s3.table_import_from_s3**

Imports Amazon S3 data into an Aurora PostgreSQL table. The `aws_s3` extension provides the `aws_s3.table_import_from_s3` function. The return value is text.

**Syntax**

The required parameters are `table_name`, `column_list` and `options`. These identify the database table and specify how the data is copied into the table.

You can also use the following parameters:

- The `s3_info` parameter specifies the Amazon S3 file to import. When you use this parameter, access to Amazon S3 is provided by an IAM role for the PostgreSQL DB cluster.
The credentials parameter specifies the credentials to access Amazon S3. When you use this parameter, you don't use an IAM role.

```python
aws_s3.table_import_from_s3 (
    table_name text,
    column_list text,
    options text,
    s3_info aws_commons._s3_uri_1,
    credentials aws_commons._aws_credentials_1
)
```

### Parameters

**table_name**

A required text string containing the name of the PostgreSQL database table to import the data into.

**column_list**

A required text string containing an optional list of the PostgreSQL database table columns in which to copy the data. If the string is empty, all columns of the table are used. For an example, see [Importing an Amazon S3 file that uses a custom delimiter](#).

**options**

A required text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied into the PostgreSQL table. For more details, see the [PostgreSQL COPY documentation](#).

**s3_info**

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

- **bucket** – The name of the Amazon S3 bucket containing the file.
- **file_path** – The Amazon S3 file name including the path of the file.
- **region** – The AWS Region that the file is in. For a listing of AWS Region names and associated values, see [Regions and Availability Zones](#).
credentials

An `aws_commons._aws_credentials_1` composite type containing the following credentials to use for the import operation:

- Access key
- Secret key
- Session token

For information about creating an `aws_commons._aws_credentials_1` composite structure, see `aws_commons.create_aws_credentials`.

Alternate syntax

To help with testing, you can use an expanded set of parameters instead of the `s3_info` and `credentials` parameters. Following are additional syntax variations for the `aws_s3.table_import_from_s3` function:

- Instead of using the `s3_info` parameter to identify an Amazon S3 file, use the combination of the `bucket`, `file_path`, and `region` parameters. With this form of the function, access to Amazon S3 is provided by an IAM role on the PostgreSQL DB instance.

```sql
aws_s3.table_import_from_s3 (    table_name text,    column_list text,    options text,    bucket text,    file_path text,    region text)
```

- Instead of using the `credentials` parameter to specify Amazon S3 access, use the combination of the `access_key`, `session_key`, and `session_token` parameters.

```sql
aws_s3.table_import_from_s3 (    table_name text,    column_list text,    options text,    bucket text,    file_path text,    region text,    access_key text,    session_key text,    session_token text)
```
access_key text,
secret_key text,
session_token text
)

Alternate parameters

bucket

A text string containing the name of the Amazon S3 bucket that contains the file.

file_path

A text string containing the Amazon S3 file name including the path of the file.

region

A text string identifying the AWS Region location of the file. For a listing of AWS Region names and associated values, see [Regions and Availability Zones](#).

access_key

A text string containing the access key to use for the import operation. The default is NULL.

secret_key

A text string containing the secret key to use for the import operation. The default is NULL.

session_token

(Optional) A text string containing the session key to use for the import operation. The default is NULL.

aws_commons.create_s3_uri

Creates an aws_commons._s3_uri_1 structure to hold Amazon S3 file information. Use the results of the aws_commons.create_s3_uri function in the s3_info parameter of the aws_s3.table_import_from_s3 function.

Syntax

```python
aws_commons.create_s3_uri(
    bucket text,
    file_path text,
```
Parameters

bucket

A required text string containing the Amazon S3 bucket name for the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.

region

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions and Availability Zones.

aws_commons.create_aws_credentials

Sets an access key and secret key in an aws_commons._aws_credentials_1 structure. Use the results of the aws_commons.create_aws_credentials function in the credentials parameter of the aws_s3.table_import_from_s3 function.

Syntax

```python
aws_commons.create_aws_credentials(
    access_key text,
    secret_key text,
    session_token text
)
```

Parameters

access_key

A required text string containing the access key to use for importing an Amazon S3 file. The default is NULL.

secret_key

A required text string containing the secret key to use for importing an Amazon S3 file. The default is NULL.
An optional text string containing the session token to use for importing an Amazon S3 file. The default is NULL. If you provide an optional `session_token`, you can use temporary credentials.

**Exporting data from an Aurora PostgreSQL DB cluster to Amazon S3**

You can query data from an Aurora PostgreSQL DB cluster and export it directly into files stored in an Amazon S3 bucket. To do this, you first install the Aurora PostgreSQL `aws_s3` extension. This extension provides you with the functions that you use to export the results of queries to Amazon S3. Following, you can find out how to install the extension and how to export data to Amazon S3.

You can export from a provisioned or an Aurora Serverless v2 DB instance. These steps aren't supported for Aurora Serverless v1.

**Note**

Cross-account export to Amazon S3 isn't supported.

All currently available versions of Aurora PostgreSQL support exporting data to Amazon Simple Storage Service. For detailed version information, see [Amazon Aurora PostgreSQL updates](#) in the *Release Notes for Aurora PostgreSQL*.

If you don't have a bucket set up for your export, see the following topics the *Amazon Simple Storage Service User Guide*.

- [Setting up Amazon S3](#)
- [Create a bucket](#)

By default, the data exported from Aurora PostgreSQL to Amazon S3 uses server-side encryption with AWS managed key. You can alternatively use customer managed key that you have already created. If you are using bucket encryption, the Amazon S3 bucket must be encrypted with AWS Key Management Service (AWS KMS) key (SSE-KMS). Currently, buckets encrypted with Amazon S3 managed keys (SSE-S3) are not supported.
Note
You can save DB and DB cluster snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see Exporting DB cluster snapshot data to Amazon S3.

Topics
• Installing the aws_s3 extension
• Overview of exporting data to Amazon S3
• Specifying the Amazon S3 file path to export to
• Setting up access to an Amazon S3 bucket
• Exporting query data using the aws_s3.query_export_to_s3 function
• Troubleshooting access to Amazon S3
• Function reference

Installing the aws_s3 extension
Before you can use Amazon Simple Storage Service with your Aurora PostgreSQL DB cluster, you need to install the aw_s3 extension. This extension provides functions for exporting data from the writer instance of an Aurora PostgreSQL DB cluster to an Amazon S3 bucket. It also provides functions for importing data from an Amazon S3. For more information, see Importing data from Amazon S3 into an Aurora PostgreSQL DB cluster. The aws_s3 extension depends on some of the helper functions in the aws_commons extension, which is installed automatically when needed.

To install the aws_s3 extension
1. Use psql (or pgAdmin) to connect to the writer instance of your Aurora PostgreSQL DB cluster as a user that has rds_superuser privileges. If you kept the default name during the setup process, you connect as postgres.

   ```bash
   psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. To install the extension, run the following command.

   ```bash
   postgres=> CREATE EXTENSION aws_s3 CASCADE;
   ```
3. To verify that the extension is installed, you can use the psql `\dx` metacommand.

```
postgres=> \dx
               List of installed extensions
          Name     | Version |   Schema   |                 Description
---------------------+----------+------------+-------------------------------------------------------------
         aws_commons | 1.2      | public     | Common data types across AWS services
            aws_s3   | 1.1      | public     | AWS S3 extension for importing data from S3
           plpgsql   | 1.0      | pg_catalog | PL/pgSQL procedural language
(3 rows)
```

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

**Verify that your Aurora PostgreSQL version supports exports to Amazon S3**

You can verify that your Aurora PostgreSQL version supports export to Amazon S3 by using the `describe-db-engine-versions` command. The following example checks to see if version 10.14 can export to Amazon S3.

```
aws rds describe-db-engine-versions --region us-east-1 \
   --engine aurora-postgresql --engine-version 10.14 | grep s3Export
```

If the output includes the string "s3Export", then the engine supports Amazon S3 exports. Otherwise, the engine doesn't support them.

**Overview of exporting data to Amazon S3**

To export data stored in an Aurora PostgreSQL database to an Amazon S3 bucket, use the following procedure.

**To export Aurora PostgreSQL data to S3**

1. Identify an Amazon S3 file path to use for exporting data. For details about this process, see [Specifying the Amazon S3 file path to export to](#).
2. Provide permission to access the Amazon S3 bucket.
To export data to an Amazon S3 file, give the Aurora PostgreSQL DB cluster permission to access the Amazon S3 bucket that the export will use for storage. Doing this includes the following steps:

1. Create an IAM policy that provides access to an Amazon S3 bucket that you want to export to.
2. Create an IAM role.
3. Attach the policy you created to the role you created.
4. Add this IAM role to your DB cluster.

For details about this process, see Setting up access to an Amazon S3 bucket.

3. Identify a database query to get the data. Export the query data by calling the `aws_s3.query_export_to_s3` function.

After you complete the preceding preparation tasks, use the `aws_s3.query_export_to_s3` function to export query results to Amazon S3. For details about this process, see Exporting query data using the `aws_s3.query_export_to_s3` function.

**Specifying the Amazon S3 file path to export to**

Specify the following information to identify the location in Amazon S3 where you want to export data to:

- **Bucket name** – A *bucket* is a container for Amazon S3 objects or files.

  For more information on storing data with Amazon S3, see Create a bucket and View an object in the Amazon Simple Storage Service User Guide.

- **File path** – The file path identifies where the export is stored in the Amazon S3 bucket. The file path consists of the following:
  - An optional path prefix that identifies a virtual folder path.
  - A file prefix that identifies one or more files to be stored. Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_partXX` appended. The `XX` represents 2, then 3, and so on.

  For example, a file path with an `exports` folder and a `query-1-export` file prefix is `/exports/query-1-export`. 

Exporting PostgreSQL data to Amazon S3
• AWS Region (optional) – The AWS Region where the Amazon S3 bucket is located. If you don't specify an AWS Region value, then Aurora saves your files into Amazon S3 in the same AWS Region as the exporting DB cluster.

<i>Note</i>
Currently, the AWS Region must be the same as the region of the exporting DB cluster.

For a listing of AWS Region names and associated values, see <a>Regions and Availability Zones</a>.

To hold the Amazon S3 file information about where the export is to be stored, you can use the <code>aws_commons.create_s3_uri</code> function to create an <code>aws_commons._s3_uri_1</code> composite structure as follows.

```sql
psql=> SELECT aws_commons.create_s3_uri(
    'DOC-EXAMPLE-BUCKET',
    'sample-filepath',
    'us-west-2'
) AS s3_uri_1 \gset
```

You later provide this <code>s3_uri_1</code> value as a parameter in the call to the <code>aws_s3.query_export_to_s3</code> function. For examples, see <a>Exporting query data using the aws_s3.query_export_to_s3 function</a>.

**Setting up access to an Amazon S3 bucket**

To export data to Amazon S3, give your PostgreSQL DB cluster permission to access the Amazon S3 bucket that the files are to go in.

To do this, use the following procedure.

**To give a PostgreSQL DB cluster access to Amazon S3 through an IAM role**

1. Create an IAM policy.

   This policy provides the bucket and object permissions that allow your PostgreSQL DB cluster to access Amazon S3.

   As part of creating this policy, take the following steps:
a. Include in the policy the following required actions to allow the transfer of files from your PostgreSQL DB cluster to an Amazon S3 bucket:

- `s3:PutObject`
- `s3:AbortMultipartUpload`

b. Include the Amazon Resource Name (ARN) that identifies the Amazon S3 bucket and objects in the bucket. The ARN format for accessing Amazon S3 is: `arn:aws:s3:::DOC-EXAMPLE-BUCKET/*`

For more information on creating an IAM policy for Aurora PostgreSQL, see [Creating and using an IAM policy for IAM database access](#). See also [Tutorial: Create and attach your first customer managed policy](#) in the [IAM User Guide](#).

The following AWS CLI command creates an IAM policy named `rds-s3-export-policy` with these options. It grants access to a bucket named `DOC-EXAMPLE-BUCKET`.

```bash
aws iam create-policy --policy-name rds-s3-export-policy --policy-document '{
  "Version": "2012-10-17",
  "Statement": [
  {
    "Sid": "s3export",
    "Action": [
"Exporting PostgreSQL data to Amazon S3"
```
2. Create an IAM role.

You do this so Aurora PostgreSQL can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see Creating a role to delegate permissions to an IAM user in the IAM User Guide.

We recommend using the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the confused deputy problem.

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-export-role`.

**Example**

For Linux, macOS, or Unix:
For Windows:

```bash
aws iam create-role \\n--role-name rds-s3-export-role \\n--assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": "111122223333",
        }
      }
    }
  ]
}'
```
3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named rds-s3-export-role. Replace your-policy-arn with the policy ARN that you noted in an earlier step.

```
aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-export-role
```

4. Add the IAM role to the DB cluster. You do so by using the AWS Management Console or AWS CLI, as described following.

**Console**

**To add an IAM role for a PostgreSQL DB cluster using the console**

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Choose the PostgreSQL DB cluster name to display its details.
3. On the Connectivity & security tab, in the Manage IAM roles section, choose the role to add under Add IAM roles to this instance.
4. Under Feature, choose s3Export.
5. Choose Add role.

**AWS CLI**

**To add an IAM role for a PostgreSQL DB cluster using the CLI**

- Use the following command to add the role to the PostgreSQL DB cluster named my-db-cluster. Replace your-role-arn with the role ARN that you noted in a previous step. Use s3Export for the value of the --feature-name option.

**Example**

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-cluster \
```
Exporting query data using the aws_s3.query_export_to_s3 function

Export your PostgreSQL data to Amazon S3 by calling the `aws_s3.query_export_to_s3` function.

Topics

- **Prerequisites**
- **Calling aws_s3.query_export_to_s3**
- **Exporting to a CSV file that uses a custom delimiter**
- **Exporting to a binary file with encoding**

Prerequisites

Before you use the `aws_s3.query_export_to_s3` function, be sure to complete the following prerequisites:

- Install the required PostgreSQL extensions as described in [Overview of exporting data to Amazon S3](#).
- Determine where to export your data to Amazon S3 as described in [Specifying the Amazon S3 file path to export to](#).
- Make sure that the DB cluster has export access to Amazon S3 as described in [Setting up access to an Amazon S3 bucket](#).
The examples following use a database table called sample_table. These examples export the data into a bucket called **DOC-EXAMPLE-BUCKET**. The example table and data are created with the following SQL statements in psql.

```sql
psql=> CREATE TABLE sample_table (bid bigint PRIMARY KEY, name varchar(80));
psql=> INSERT INTO sample_table (bid,name) VALUES (1, 'Monday'), (2,'Tuesday'), (3, 'Wednesday');
```

### Calling `aws_s3.query_export_to_s3`

The following shows the basic ways of calling the `aws_s3.query_export_to_s3` function.

These examples use the variable `s3_uri_1` to identify a structure that contains the information identifying the Amazon S3 file. Use the `aws_commons.create_s3_uri` function to create the structure.

```sql
psql=> SELECT aws_commons.create_s3_uri('DOC-EXAMPLE-BUCKET', 'sample-filepath', 'us-west-2') AS s3_uri_1 \gset
```

Although the parameters vary for the following two `aws_s3.query_export_to_s3` function calls, the results are the same for these examples. All rows of the sample_table table are exported into a bucket called **DOC-EXAMPLE-BUCKET**.

```sql
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', :'s3_uri_1');
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM sample_table', :'s3_uri_1', options :='format text');
```

The parameters are described as follows:

- `'SELECT * FROM sample_table'` – The first parameter is a required text string containing an SQL query. The PostgreSQL engine runs this query. The results of the query are copied to the S3 bucket identified in other parameters.
- `:'s3_uri_1'` – This parameter is a structure that identifies the Amazon S3 file. This example uses a variable to identify the previously created structure. You can instead create the
structure by including the `aws_commons.create_s3_uri` function call inline within the `aws_s3.query_export_to_s3` function call as follows.

```sql
SELECT * from aws_s3.query_export_to_s3('select * from sample_table',
    aws_commons.create_s3_uri('DOC-EXAMPLE-BUCKET', 'sample-filepath', 'us-west-2'))
```

- `options := 'format text'` – The `options` parameter is an optional text string containing PostgreSQL COPY arguments. The copy process uses the arguments and format of the PostgreSQL COPY command.

If the file specified doesn't exist in the Amazon S3 bucket, it's created. If the file already exists, it's overwritten. The syntax for accessing the exported data in Amazon S3 is the following.

```
s3-region://bucket-name[/path-prefix]/file-prefix
```

Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_partXX` appended. The `XX` represents 2, then 3, and so on. For example, suppose that you specify the path where you store data files as the following.

```
s3-us-west-2://DOC-EXAMPLE-BUCKET/my-prefix
```

If the export has to create three data files, the Amazon S3 bucket contains the following data files.

```
s3-us-west-2://DOC-EXAMPLE-BUCKET/my-prefix
s3-us-west-2://DOC-EXAMPLE-BUCKET/my-prefix_part2
s3-us-west-2://DOC-EXAMPLE-BUCKET/my-prefix_part3
```

For the full reference for this function and additional ways to call it, see `aws_s3.query_export_to_s3`. For more about accessing files in Amazon S3, see View an object in the Amazon Simple Storage Service User Guide.

**Exporting to a CSV file that uses a custom delimiter**

The following example shows how to call the `aws_s3.query_export_to_s3` function to export data to a file that uses a custom delimiter. The example uses arguments of the PostgreSQL COPY command to specify the comma-separated value (CSV) format and a colon (:) delimiter.
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :s3_uri_1',
options :='format csv, delimiter $:$');

Exporting to a binary file with encoding

The following example shows how to call the aws_s3.query_export_to_s3 function to export data to a binary file that has Windows-1253 encoding.

SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :s3_uri_1',
options :='format binary, encoding WIN1253');

Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to export data to Amazon S3, first confirm that the outbound access rules for the VPC security group associated with your DB instance permit network connectivity. Specifically, the security group must have a rule that allows the DB instance to send TCP traffic to port 443 and to any IPv4 addresses (0.0.0.0/0). For more information, see Provide access to the DB cluster in the VPC by creating a security group.

- Troubleshooting Amazon S3 and IAM in the IAM User Guide

Function reference

Functions

- aws_s3.query_export_to_s3
- aws_commons.create_s3_uri

aws_s3.query_export_to_s3

Exports a PostgreSQL query result to an Amazon S3 bucket. The aws_s3 extension provides the aws_s3.query_export_to_s3 function.

The two required parameters are query and s3_info. These define the query to be exported and identify the Amazon S3 bucket to export to. An optional parameter called options provides for
defining various export parameters. For examples of using the `aws_s3.query_export_to_s3` function, see [Exporting query data using the `aws_s3.query_export_to_s3` function](#).

**Syntax**

```python
aws_s3.query_export_to_s3(
    query text,
    s3_info aws_commons._s3_uri_1,
    options text,
    kms_key text
)
```

**Input parameters**

**query**

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the `s3_info` parameter.

**s3_info**

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

- **bucket** – The name of the Amazon S3 bucket to contain the file.
- **file_path** – The Amazon S3 file name and path.
- **region** – The AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see [Regions and Availability Zones](#).

Currently, this value must be the same AWS Region as that of the exporting DB cluster. The default is the AWS Region of the exporting DB cluster.

To create an `aws_commons._s3_uri_1` composite structure, see the `aws_commons.create_s3_uri` function.

**options**

An optional text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied when exported. For more details, see the [PostgreSQL COPY documentation](#).
An optional text string containing the customer managed KMS key of the S3 bucket to export the data to.

Alternate input parameters

To help with testing, you can use an expanded set of parameters instead of the s3_info parameter. Following are additional syntax variations for the aws_s3.query_export_to_s3 function.

Instead of using the s3_info parameter to identify an Amazon S3 file, use the combination of the bucket, file_path, and region parameters.

```
aws_s3.query_export_to_s3(
    query text,
    bucket text,
    file_path text,
    region text,
    options text,
    kms_key text
)
```

query

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the s3_info parameter.

bucket

A required text string containing the name of the Amazon S3 bucket that contains the file.

file_path

A required text string containing the Amazon S3 file name including the path of the file.

region

An optional text string containing the AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see Regions and Availability Zones.

Currently, this value must be the same AWS Region as that of the exporting DB cluster. The default is the AWS Region of the exporting DB cluster.
options

An optional text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied when exported. For more details, see the PostgreSQL COPY documentation.

kms_key text

An optional text string containing the customer managed KMS key of the S3 bucket to export the data to.

Output parameters

```sql
aws_s3.query_export_to_s3(
    OUT rows_uploaded bigint,
    OUT files_uploaded bigint,
    OUT bytes_uploaded bigint
)
```

rows_uploaded

The number of table rows that were successfully uploaded to Amazon S3 for the given query.

files_uploaded

The number of files uploaded to Amazon S3. Files are created in sizes of approximately 6 GB. Each additional file created has `_partXX` appended to the name. The `XX` represents 2, then 3, and so on as needed.

bytes_uploaded

The total number of bytes uploaded to Amazon S3.

Examples

```sql
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'DOC-EXAMPLE-BUCKET', 'sample-filepath');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'DOC-EXAMPLE-BUCKET', 'sample-filepath','us-west-2');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'DOC-EXAMPLE-BUCKET', 'sample-filepath','us-west-2','format text');
```
aws_commons.create_s3_uri

Creates an aws_commons._s3_uri_1 structure to hold Amazon S3 file information. You use the results of the aws_commons.create_s3_uri function in the s3_info parameter of the aws_s3.query_export_to_s3 function. For an example of using the aws_commons.create_s3_uri function, see Specifying the Amazon S3 file path to export to.

Syntax

```python
aws_commons.create_s3_uri(
    bucket text,
    file_path text,
    region text
)
```

Input parameters

**bucket**

A required text string containing the Amazon S3 bucket name for the file.

**file_path**

A required text string containing the Amazon S3 file name including the path of the file.

**region**

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see Regions and Availability Zones.

Invoking an AWS Lambda function from an Aurora PostgreSQL DB cluster

AWS Lambda is an event-driven compute service that lets you run code without provisioning or managing servers. It's available for use with many AWS services, including Aurora PostgreSQL. For example, you can use Lambda functions to process event notifications from a database, or to load data from files whenever a new file is uploaded to Amazon S3. To learn more about Lambda, see What is AWS Lambda? in the AWS Lambda Developer Guide.
Setting up Aurora PostgreSQL to work with Lambda functions is a multi-step process involving AWS Lambda, IAM, your VPC, and your Aurora PostgreSQL DB cluster. Following, you can find summaries of the necessary steps.

For more information about Lambda functions, see Getting started with Lambda and AWS Lambda foundations in the AWS Lambda Developer Guide.

Topics
- Step 1: Configure your Aurora PostgreSQL DB cluster for outbound connections to AWS Lambda
- Step 2: Configure IAM for your Aurora PostgreSQL DB cluster and AWS Lambda
- Step 3: Install the aws_lambda extension for an Aurora PostgreSQL DB cluster
- Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster (Optional)
- Step 5: Invoke a Lambda function from your Aurora PostgreSQL DB cluster
- Step 6: Grant other users permission to invoke Lambda functions
- Examples: Invoking Lambda functions from your Aurora PostgreSQL DB cluster
- Lambda function error messages
- AWS Lambda function and parameter reference

Step 1: Configure your Aurora PostgreSQL DB cluster for outbound connections to AWS Lambda

Lambda functions always run inside an Amazon VPC that's owned by the AWS Lambda service. Lambda applies network access and security rules to this VPC and it maintains and monitors the VPC automatically. Your Aurora PostgreSQL DB cluster sends network traffic to the Lambda service's VPC. How you configure this depends on whether your Aurora DB cluster's primary DB instance is public or private.

- Public Aurora PostgreSQL DB cluster – A DB cluster's primary DB instance is public if it's located in a public subnet on your VPC, and if the instance's "PubliclyAccessible" property is true. To
find the value of this property, you can use the `describe-db-instances` AWS CLI command. Or, you can use the AWS Management Console to open the Connectivity & security tab and check that Publicly accessible is Yes. To verify that the instance is in the public subnet of your VPC, you can use the AWS Management Console or the AWS CLI.

To set up access to Lambda, you use the AWS Management Console or the AWS CLI to create an outbound rule on your VPC’s security group. The outbound rule specifies that TCP can use port 443 to send packets to any IPv4 addresses (0.0.0.0/0).

- **Private Aurora PostgreSQL DB cluster** – In this case, the instance's "PubliclyAccessible" property is false or it's in a private subnet. To allow the instance to work with Lambda, you can use a Network Address Translation) NAT gateway. For more information, see NAT gateways. Or, you can configure your VPC with a VPC endpoint for Lambda. For more information, see VPC endpoints in the Amazon VPC User Guide. The endpoint responds to calls made by your Aurora PostgreSQL DB cluster to your Lambda functions.

Your VPC can now interact with the AWS Lambda VPC at the network level. Next, you configure the permissions using IAM.

**Step 2: Configure IAM for your Aurora PostgreSQL DB cluster and AWS Lambda**

Invoking Lambda functions from your Aurora PostgreSQL DB cluster requires certain privileges. To configure the necessary privileges, we recommend that you create an IAM policy that allows invoking Lambda functions, assign that policy to a role, and then apply the role to your DB cluster. This approach gives the DB cluster privileges to invoke the specified Lambda function on your behalf. The following steps show you how to do this using the AWS CLI.

**To configure IAM permissions for using your cluster with Lambda**

1. Use the `create-policy` AWS CLI command to create an IAM policy that allows your Aurora PostgreSQL DB cluster to invoke the specified Lambda function. (The statement ID (Sid) is an optional description for your policy statement and has no effect on usage.) This policy gives your Aurora DB cluster the minimum permissions needed to invoke the specified Lambda function.

   ```bash
   aws iam create-policy --policy-name rds-lambda-policy --policy-document '{
   "Version": "2012-10-17",
   "Statement": [
     {
       "Sid": "AllowAccessToExampleFunction",
       "Effect": "Allow",
       "Action": "lambda:InvokeFunction",
       "Resource": "arn:aws:lambda:*:*:function:ExampleFunction"
     }
   ]
   }
   '}
   ```
Alternatively, you can use the predefined AWSLambdaRole policy that allows you to invoke any of your Lambda functions. For more information, see Identity-based IAM policies for Lambda.

2. Use the `create-role` AWS CLI command to create an IAM role that the policy can assume at runtime.

```bash
aws iam create-role --role-name rds-lambda-role --assume-role-policy-document '{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "Service": "rds.amazonaws.com"
         },
         "Action": "sts:AssumeRole"
      }
   ]
}
```

3. Apply the policy to the role by using the `attach-role-policy` AWS CLI command.

```bash
aws iam attach-role-policy \
   --policy-arn arn:aws:iam::444455556666:policy/rds-lambda-policy \
   --role-name rds-lambda-role --region aws-region
```

4. Apply the role to your Aurora PostgreSQL DB cluster by using the `add-role-to-db-cluster` AWS CLI command. This last step allows your DB cluster's database users to invoke Lambda functions.

```bash
aws rds add-role-to-db-cluster \
   --db-cluster-identifier my-cluster-name \
   --feature-name Lambda \
   --role-arn arn:aws:iam::444455556666:role/rds-lambda-role \
   --region aws-region
```
With the VPC and the IAM configurations complete, you can now install the `aws_lambdata` extension. (Note that you can install the extension at any time, but until you set up the correct VPC support and IAM privileges, the `aws_lambdata` extension adds nothing to your Aurora PostgreSQL DB cluster's capabilities.)

**Step 3: Install the `aws_lambdata` extension for an Aurora PostgreSQL DB cluster**

To use AWS Lambda with your Aurora PostgreSQL DB cluster, add the `aws_lambdata` PostgreSQL extension to your Aurora PostgreSQL DB cluster. This extension provides your Aurora PostgreSQL DB cluster with the ability to call Lambda functions from PostgreSQL.

**To install the `aws_lambdata` extension in your Aurora PostgreSQL DB cluster**

Use the PostgreSQL `psql` command-line or the pgAdmin tool to connect to your Aurora PostgreSQL DB cluster.

1. Connect to your Aurora PostgreSQL DB cluster instance as a user with `rds_superuser` privileges. The default `postgres` user is shown in the example.

   ```
   psql -h cluster-instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
   ```

2. Install the `aws_lambdata` extension. The `aws_commons` extension is also required. It provides helper functions to `aws_lambdata` and many other Aurora extensions for PostgreSQL. If it's not already on your Aurora PostgreSQL DB cluster, it's installed with `aws_lambdata` as shown following.

   ```
   CREATE EXTENSION IF NOT EXISTS aws_lambdata CASCADE;
   NOTICE:  installing required extension "aws_commons"
   CREATE EXTENSION
   ```

The `aws_lambdata` extension is installed in your Aurora PostgreSQL DB cluster's primary DB instance. You can now create convenience structures for invoking your Lambda functions.
Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster (Optional)

You can use the helper functions in the aws_commons extension to prepare entities that you can more easily invoke from PostgreSQL. To do this, you need to have the following information about your Lambda functions:

- **Function name** – The name, Amazon Resource Name (ARN), version, or alias of the Lambda function. The IAM policy created in Step 2: Configure IAM for your cluster and Lambda requires the ARN, so we recommend that you use your function's ARN.

- **AWS Region** – (Optional) The AWS Region where the Lambda function is located if it's not in the same Region as your Aurora PostgreSQL DB cluster.

To hold the Lambda function name information, you use the `aws_commons.create_lambda_function_arn` function. This helper function creates an `aws_commons._lambda_function_arn_1` composite structure with the details needed by the `invoke` function. Following, you can find three alternative approaches to setting up this composite structure.

```sql
SELECT aws_commons.create_lambda_function_arn(    
    'my-function', 
    'aws-region'
) AS aws_lambda_arn_1 \gset
```

```sql
SELECT aws_commons.create_lambda_function_arn(    
    '111122223333:function:my-function', 
    'aws-region'
) AS lambda_partial_arn_1 \gset
```

```sql
SELECT aws_commons.create_lambda_function_arn(    
) AS lambda_arn_1 \gset
```

Any of these values can be used in calls to the `aws_lambda.invoke` function. For examples, see Step 5: Invoke a Lambda function from your Aurora PostgreSQL DB cluster.
Step 5: Invoke a Lambda function from your Aurora PostgreSQL DB cluster

The `aws_lambda.invoke` function behaves synchronously or asynchronously, depending on the `invocation_type`. The two alternatives for this parameter are `RequestResponse` (the default) and `Event`, as follows.

- **RequestResponse** – This invocation type is *synchronous*. It's the default behavior when the call is made without specifying an invocation type. The response payload includes the results of the `aws_lambda.invoke` function. Use this invocation type when your workflow requires receiving results from the Lambda function before proceeding.

- **Event** – This invocation type is *asynchronous*. The response doesn't include a payload containing results. Use this invocation type when your workflow doesn't need a result from the Lambda function to continue processing.

As a simple test of your setup, you can connect to your DB instance using `psql` and invoke an example function from the command line. Suppose that you have one of the basic functions set up on your Lambda service, such as the simple Python function shown in the following screenshot.

![Lambda function code](image)

To invoke an example function

1. Connect to your primary DB instance using `psql` or `pgAdmin`.

   ```
   psql -h cluster.4444555666.aws-region.rds.amazonaws.com -U postgres -p 5432
   ```

2.Invoke the function using its ARN.

   ```
   SELECT * from aws_lambda.invoke(aws_commons.create_lambda_function_arn('arn:aws:lambda:aws-...)
   ```
The response looks as follows.

<table>
<thead>
<tr>
<th>status_code</th>
<th>payload</th>
<th>executed_version</th>
<th>log_result</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>&quot;{&quot;statusCode&quot;: 200, &quot;body&quot;: &quot;Hello from Lambda!&quot;}&quot;</td>
<td>$LATEST</td>
<td></td>
</tr>
</tbody>
</table>

If your invocation attempt doesn't succeed, see Lambda function error messages.

Step 6: Grant other users permission to invoke Lambda functions

At this point in the procedures, only you as rds_superuser can invoke your Lambda functions. To allow other users to invoke any functions that you create, you need to grant them permission.

To grant others permission to invoke Lambda functions

1. Connect to your primary DB instance using psql or pgAdmin.

   ```
   psql -h cluster.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
   ```

2. Run the following SQL commands:

   ```
   postgres=> GRANT USAGE ON SCHEMA aws_lambda TO db_username;
   GRANT EXECUTE ON ALL FUNCTIONS IN SCHEMA aws_lambda TO db_username;
   ```

Examples: Invoking Lambda functions from your Aurora PostgreSQL DB cluster

Following, you can find several examples of calling the aws_lambda.invoke function. Most all the examples use the composite structure aws_lambda_arn_1 that you create in Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster (Optional) to simplify passing the function details. For an example of asynchronous invocation, see Example: Asynchronous (Event) invocation of Lambda functions. All the other examples listed use synchronous invocation.
To learn more about Lambda invocation types, see Invoking Lambda functions in the AWS Lambda Developer Guide. For more information about aws_lambda_arn_1, see aws_commons.create_lambda_function_arn.

**Examples list**

- **Example: Synchronous (RequestResponse) invocation of Lambda functions**
- **Example: Asynchronous (Event) invocation of Lambda functions**
- **Example: Capturing the Lambda execution log in a function response**
- **Example: Including client context in a Lambda function**
- **Example: Invoking a specific version of a Lambda function**

**Example: Synchronous (RequestResponse) invocation of Lambda functions**

Following are two examples of a synchronous Lambda function invocation. The results of these aws_lambda.invoke function calls are the same.

```sql
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':json);
```

```sql
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':json, 'RequestResponse');
```

The parameters are described as follows:

- `:aws_lambda_arn_1:` – This parameter identifies the composite structure created in Step 4: Use Lambda helper functions with your Aurora PostgreSQL DB cluster (Optional), with the aws_commons.create_lambda_function_arn helper function. You can also create this structure inline within your aws_lambda.invoke call as follows.

```sql
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function', 'aws-region'),
{"body": "Hello from Postgres!"}:json);
```

- `{"body": "Hello from PostgreSQL!"}:json` – The JSON payload to pass to the Lambda function.
- `'RequestResponse'` – The Lambda invocation type.
Example: Asynchronous (Event) invocation of Lambda functions

Following is an example of an asynchronous Lambda function invocation. The Event invocation type schedules the Lambda function invocation with the specified input payload and returns immediately. Use the Event invocation type in certain workflows that don't depend on the results of the Lambda function.

```sql
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!”}'::json, 'Event');
```

Example: Capturing the Lambda execution log in a function response

You can include the last 4 KB of the execution log in the function response by using the log_type parameter in your `aws_lambda.invoke` function call. By default, this parameter is set to None, but you can specify Tail to capture the results of the Lambda execution log in the response, as shown following.

```sql
SELECT *, select convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!”}'::json, 'RequestResponse', 'Tail');
```

Set the `aws_lambda.invoke` function's log_type parameter to Tail to include the execution log in the response. The default value for the log_type parameter is None.

The log_result that's returned is a base64 encoded string. You can decode the contents using a combination of the `decode` and `convert_from` PostgreSQL functions.

For more information about log_type, see `aws_lambda.invoke`.

Example: Including client context in a Lambda function

The `aws_lambda.invoke` function has a context parameter that you can use to pass information separate from the payload, as shown following.

```sql
SELECT *, convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!”}'::json, 'RequestResponse', 'Tail');
```

To include client context, use a JSON object for the `aws_lambda.invoke` function's context parameter.
For more information about the context parameter, see the `aws_lambda.invoke` reference.

**Example: Invoking a specific version of a Lambda function**

You can specify a particular version of a Lambda function by including the `qualifier` parameter with the `aws_lambda.invoke` call. Following, you can find an example that does this using `'custom_version'` as an alias for the version.

```sql
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json, 'RequestResponse', 'None', NULL, 'custom_version');
```

You can also supply a Lambda function qualifier with the function name details instead, as follows.

```sql
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function:custom_version', 'us-west-2'), '{"body": "Hello from Postgres!"}'::json);
```

For more information about `qualifier` and other parameters, see the `aws_lambda.invoke` reference.

**Lambda function error messages**

In the following list you can find information about error messages, with possible causes and solutions.

- **VPC configuration issues**

  VPC configuration issues can raise the following error messages when trying to connect:

  ```sql
  ERROR:  invoke API failed
  DETAIL: AWS Lambda client returned 'Unable to connect to endpoint'.
  CONTEXT:  SQL function "invoke" statement 1
  ```

  A common cause for this error is improperly configured VPC security group. Make sure you have an outbound rule for TCP open on port 443 of your VPC security group so that your VPC can connect to the Lambda VPC.

- **Lack of permissions needed to invoke Lambda functions**

  If you see either of the following error messages, the user (role) invoking the function doesn't have proper permissions.
A user (role) must be given specific grants to invoke Lambda functions. For more information, see Step 6: Grant other users permission to invoke Lambda functions.

- Improper handling of errors in your Lambda functions

If a Lambda function throws an exception during request processing, `aws_lambda.invoke` fails with a PostgreSQL error such as the following.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"} '::json);
ERROR:  lambda invocation failed
```

Be sure to handle errors in your Lambda functions or in your PostgreSQL application.

AWS Lambda function and parameter reference

Following is the reference for the functions and parameters to use for invoking Lambda with Aurora PostgreSQL.

Functions and parameters

- `aws_lambda.invoke`
- `aws_commons.create_lambda_function_arn`
- `aws_lambda.parameters`

**aws_lambda.invoke**

Runs a Lambda function for an Aurora PostgreSQL DB cluster.

For more details about invoking Lambda functions, see also Invoke in the AWS Lambda Developer Guide.

**Syntax**
**JSON**

```sql
aws_lambda.invoke(
    IN function_name TEXT,
    IN payload JSON,
    IN region TEXT DEFAULT NULL,
    IN invocation_type TEXT DEFAULT 'RequestResponse',
    IN log_type TEXT DEFAULT 'None',
    IN context JSON DEFAULT NULL,
    IN qualifier VARCHAR(128) DEFAULT NULL,
    OUT status_code INT,
    OUT payload JSON,
    OUT executed_version TEXT,
    OUT log_result TEXT)
```

```sql
aws_lambda.invoke(
    IN function_name aws_commons._lambda_function_arn_1,
    IN payload JSON,
    IN invocation_type TEXT DEFAULT 'RequestResponse',
    IN log_type TEXT DEFAULT 'None',
    IN context JSON DEFAULT NULL,
    IN qualifier VARCHAR(128) DEFAULT NULL,
    OUT status_code INT,
    OUT payload JSON,
    OUT executed_version TEXT,
    OUT log_result TEXT)
```

**JSONB**

```sql
aws_lambda.invoke(
    IN function_name TEXT,
    IN payload JSONB,
    IN region TEXT DEFAULT NULL,
    IN invocation_type TEXT DEFAULT 'RequestResponse',
    IN log_type TEXT DEFAULT 'None',
    IN context JSONB DEFAULT NULL,
    IN qualifier VARCHAR(128) DEFAULT NULL,
    OUT status_code INT,
    OUT payload JSONB,
    OUT executed_version TEXT,
    OUT log_result TEXT)
```
aws_lambda.invoke(
    IN function_name aws_commons._lambda_function_arn_1,
    IN payload JSONB,
    IN invocation_type TEXT DEFAULT 'RequestResponse',
    IN log_type TEXT DEFAULT 'None',
    IN context JSONB DEFAULT NULL,
    IN qualifier VARCHAR(128) DEFAULT NULL,
    OUT status_code INT,
    OUT payload JSONB,
    OUT executed_version TEXT,
    OUT log_result TEXT )

Input parameters

function_name

The identifying name of the Lambda function. The value can be the function name, an ARN, or a partial ARN. For a listing of possible formats, see Lambda function name formats in the AWS Lambda Developer Guide.

payload

The input for the Lambda function. The format can be JSON or JSONB. For more information, see JSON Types in the PostgreSQL documentation.

region

(Optional) The Lambda Region for the function. By default, Aurora resolves the AWS Region from the full ARN in the function_name or it uses the Aurora PostgreSQL DB instance Region. If this Region value conflicts with the one provided in the function_name ARN, an error is raised.

invocation_type

The invocation type of the Lambda function. The value is case-sensitive. Possible values include the following:

- RequestResponse – The default. This type of invocation for a Lambda function is synchronous and returns a response payload in the result. Use the RequestResponse invocation type when your workflow depends on receiving the Lambda function result immediately.
- **Event** – This type of invocation for a Lambda function is asynchronous and returns immediately without a returned payload. Use the Event invocation type when you don't need results of the Lambda function before your workflow moves on.

- **DryRun** – This type of invocation tests access without running the Lambda function.

$log_type$

The type of Lambda log to return in the log_result output parameter. The value is case-sensitive. Possible values include the following:

- **Tail** – The returned log_result output parameter will include the last 4 KB of the execution log.
- **None** – No Lambda log information is returned.

$context$

Client context in JSON or JSONB format. Fields to use include than custom and env.

$qualifier$

A qualifier that identifies a Lambda function's version to be invoked. If this value conflicts with one provided in the function_name ARN, an error is raised.

**Output parameters**

$status_code$

An HTTP status response code. For more information, see Lambda Invoke response elements in the AWS Lambda Developer Guide.

$payload$

The information returned from the Lambda function that ran. The format is in JSON or JSONB.

$executed_version$

The version of the Lambda function that ran.

$log_result$

The execution log information returned if the log_type value is Tail when the Lambda function was invoked. The result contains the last 4 KB of the execution log encoded in Base64.
**aws_commons.create_lambda_function_arn**

Creates an aws_commons._lambda_function_arn_1 structure to hold Lambda function name information. You can use the results of the aws_commons.create_lambda_function_arn function in the `function_name` parameter of the `aws_lambda.invoke` function.

**Syntax**

```python
aws_commons.create_lambda_function_arn(
    function_name TEXT,
    region TEXT DEFAULT NULL
) RETURNS aws_commons._lambda_function_arn_1
```

**Input parameters**

- **function_name**
  
  A required text string containing the Lambda function name. The value can be a function name, a partial ARN, or a full ARN.

- **region**
  
  An optional text string containing the AWS Region that the Lambda function is in. For a listing of Region names and associated values, see [Regions and Availability Zones](#).

**aws_lambda parameters**

In this table, you can find parameters associated with the `aws_lambda` function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>aws_lambda.connect_timeout_ms</code></td>
<td>This is a dynamic parameter and it sets the maximum wait time while connecting to AWS Lambda. The default values is 1000. Allowed values for this parameter are 1 - 900000.</td>
</tr>
<tr>
<td><code>aws_lambda.request_timeout_ms</code></td>
<td>This is a dynamic parameter and it sets the maximum wait time while waiting for response from AWS Lambda. The default values is 3000. Allowed values for this parameter are 1 - 900000.</td>
</tr>
</tbody>
</table>
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>aws_lambda.endpoint_override</code></td>
<td>Specifies the endpoint that can be used to connect to AWS Lambda. An empty string selects the default AWS Lambda endpoint for the region. You must restart the database for this static parameter change to take effect.</td>
</tr>
</tbody>
</table>

### Publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs

You can configure your Aurora PostgreSQL DB cluster to export log data to Amazon CloudWatch Logs on a regular basis. When you do so, events from your Aurora PostgreSQL DB cluster's PostgreSQL log are automatically *published* to Amazon CloudWatch, as Amazon CloudWatch Logs. In CloudWatch, you can find the exported log data in a *log group* for your Aurora PostgreSQL DB cluster. The log group contains one or more *log streams* that contain the events from the PostgreSQL log from each instance in the cluster.

Publishing the logs to CloudWatch Logs allows you to keep your cluster's PostgreSQL log records in highly durable storage. With the log data available in CloudWatch Logs, you can evaluate and improve your cluster's operations. You can also use CloudWatch to create alarms and view metrics. To learn more, see [Monitoring log events in Amazon CloudWatch](#).

**Note**

Publishing your PostgreSQL logs to CloudWatch Logs consumes storage, and you incur charges for that storage. Be sure to delete any CloudWatch Logs that you no longer need.

Turning the export log option off for an existing Aurora PostgreSQL DB cluster doesn't affect any data that's already held in CloudWatch Logs. Existing logs remain available in CloudWatch Logs based on your log retention settings. To learn more about CloudWatch Logs, see [What is Amazon CloudWatch Logs?](#)

Aurora PostgreSQL supports publishing logs to CloudWatch Logs for the following versions.

- 14.3 and higher 14 versions
- 13.3 and higher 13 versions
- 12.8 and higher 12 versions
• 11.12 and higher 11 versions

Turning on the option to publish logs to Amazon CloudWatch

To publish your Aurora PostgreSQL DB cluster's PostgreSQL log to CloudWatch Logs, choose the **Log export** option for the cluster. You can choose the Log export setting when you create your Aurora PostgreSQL DB cluster. Or, you can modify the cluster later on. When you modify an existing cluster, its PostgreSQL logs from each instance are published to CloudWatch cluster from that point on. For Aurora PostgreSQL, the PostgreSQL log (*postgresql.log*) is the only log that gets published to Amazon CloudWatch.

You can use the AWS Management Console, the AWS CLI, or the RDS API to turn on the Log export feature for your Aurora PostgreSQL DB cluster.

**Console**

You choose the Log exports option to start publishing the PostgreSQL logs from your Aurora PostgreSQL DB cluster to CloudWatch Logs.

**To turn on the Log export feature from the console**

1. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose **Databases**.
3. Choose the Aurora PostgreSQL DB cluster whose log data you want to publish to CloudWatch Logs.
4. Choose **Modify**.
5. In the **Log exports** section, choose **PostgreSQL log**.
6. Choose **Continue**, and then choose **Modify cluster** on the summary page.

**AWS CLI**

You can turn on the log export option to start publishing Aurora PostgreSQL logs to Amazon CloudWatch Logs with the AWS CLI. To do so, run the `modify-db-cluster` AWS CLI command with the following options:

- `--db-cluster-identifier`—The DB cluster identifier.
- `--cloudwatch-logs-export-configuration`—The configuration setting for the log types to be set for export to CloudWatch Logs for the DB cluster.
You can also publish Aurora PostgreSQL logs by running one of the following AWS CLI commands:

- `create-db-cluster`
- `restore-db-cluster-from-s3`
- `restore-db-cluster-from-snapshot`
- `restore-db-cluster-to-point-in-time`

Run one of these AWS CLI commands with the following options:

- `--db-cluster-identifier`—The DB cluster identifier.
- `--engine`—The database engine.
- `--enable-cloudwatch-logs-exports`—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other options might be required depending on the AWS CLI command that you run.

**Example**

The following command creates an Aurora PostgreSQL DB cluster to publish log files to CloudWatch Logs.

For Linux, macOS, or Unix:

```bash
aws rds create-db-cluster \\
    --db-cluster-identifier my-db-cluster \\
    --engine aurora-postgresql \\
    --enable-cloudwatch-logs-exports postgresql
```

For Windows:

```bash
aws rds create-db-cluster ^
    --db-cluster-identifier my-db-cluster ^
    --engine aurora-postgresql ^
    --enable-cloudwatch-logs-exports postgresql
```
Example

The following command modifies an existing Aurora PostgreSQL DB cluster to publish log files to CloudWatch Logs. The \(--\text{cloudwatch-logs-export-configuration}\) value is a JSON object. The key for this object is \(\text{EnableLogTypes}\), and its value is postgresql.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier my-db-cluster \
  --cloudwatch-logs-export-configuration '{"EnableLogTypes":["postgresql"]}'
```

For Windows:

```bash
aws rds modify-db-cluster ^
  --db-cluster-identifier my-db-cluster ^
  --cloudwatch-logs-export-configuration '{"EnableLogTypes":["postgresql"]}'
```

**Note**

When using the Windows command prompt, make sure to escape double quotation marks (") in JSON code by prefixing them with a backslash (\).

Example

The following example modifies an existing Aurora PostgreSQL DB cluster to disable publishing log files to CloudWatch Logs. The \(--\text{cloudwatch-logs-export-configuration}\) value is a JSON object. The key for this object is \(\text{DisableLogTypes}\), and its value is postgresql.

For Linux, macOS, or Unix:

```bash
aws rds modify-db-cluster \
  --db-cluster-identifier mydbinstance \
  --cloudwatch-logs-export-configuration '{"DisableLogTypes":["postgresql"]}'
```

For Windows:

```bash
aws rds modify-db-cluster ^
```

--db-cluster-identifier **mydbinstance** ^
--cloudwatch-logs-export-configuration "{"DisableLogTypes":["postgresql"]}"

⚠ **Note**

When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

---

**RDS API**

You can turn on the log export option to start publishing Aurora PostgreSQL logs with the RDS API. To do so, run the **ModifyDBCluster** operation with the following options:

- **DBClusterIdentifier** – The DB cluster identifier.
- **CloudwatchLogsExportConfiguration** – The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

You can also publish Aurora PostgreSQL logs with the RDS API by running one of the following RDS API operations:

- **CreateDBCluster**
- **RestoreDBClusterFromS3**
- **RestoreDBClusterFromSnapshot**
- **RestoreDBClusterToPointInTime**

Run the RDS API action with the following parameters:

- **DBClusterIdentifier**—The DB cluster identifier.
- **Engine**—The database engine.
- **EnableCloudwatchLogsExports**—The configuration setting for the log types to be enabled for export to CloudWatch Logs for the DB cluster.

Other parameters might be required depending on the AWS CLI command that you run.
Monitoring log events in Amazon CloudWatch

With Aurora PostgreSQL log events published and available as Amazon CloudWatch Logs, you can view and monitor events using Amazon CloudWatch. For more information about monitoring, see View log data sent to CloudWatch Logs.

When you turn on Log exports, a new log group is automatically created using the prefix `/aws/rds/cluster/` with the name of your Aurora PostgreSQL and the log type, as in the following pattern.

```
/aws/rds/cluster/your-cluster-name/postgresql
```

As an example, suppose that an Aurora PostgreSQL DB cluster named `docs-lab-apg-small` exports its log to Amazon CloudWatch Logs. Its log group name in Amazon CloudWatch is shown following.

```
/aws/rds/cluster/docs-lab-apg-small/postgresql
```

If a log group with the specified name exists, Aurora uses that log group to export log data for the Aurora DB cluster. Each DB instance in the Aurora PostgreSQL DB cluster uploads its PostgreSQL log to the log group as a distinct log stream. You can examine the log group and its log streams using the various graphical and analytical tools available in Amazon CloudWatch.

For example, you can search for information within the log events from your Aurora PostgreSQL DB cluster, and filter events by using the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API. For more information, Searching and filtering log data in the Amazon CloudWatch Logs User Guide.

By default, new log groups are created using Never expire for their retention period. You can use the CloudWatch Logs console, the AWS CLI, or the CloudWatch Logs API to change the log retention period. To learn more, see Change log data retention in CloudWatch Logs in the Amazon CloudWatch Logs User Guide.

Tip

You can use automated configuration, such as AWS CloudFormation, to create log groups with predefined log retention periods, metric filters, and access permissions.
Analyzing PostgreSQL logs using CloudWatch Logs Insights

With the PostgreSQL logs from your Aurora PostgreSQL DB cluster published as CloudWatch Logs, you can use CloudWatch Logs Insights to interactively search and analyze your log data in Amazon CloudWatch Logs. CloudWatch Logs Insights includes a query language, sample queries, and other tools for analyzing your log data so that you can identify potential issues and verify fixes. To learn more, see Analyzing log data with CloudWatch Logs Insights in the Amazon CloudWatch Logs User Guide. Amazon CloudWatch Logs

To analyze PostgreSQL logs with CloudWatch Logs Insights

2. In the navigation pane, open Logs and choose Log insights.
3. In Select log group(s), select the log group for your Aurora PostgreSQL DB cluster.
4. In the query editor, delete the query that is currently shown, enter the following, and then choose Run query.

```sql
# Autovacuum execution time in seconds per 5 minute fields @message
| parse @message "elapsed: * s" as @duration_sec
| filter @message like / automatic vacuum /
| display @duration_sec
```
5. Choose the **Visualization** tab.
6. Choose **Add to dashboard**.

7. In **Select a dashboard**, either select a dashboard or enter a name to create a new dashboard.

8. In **Widget type**, choose a widget type for your visualization.

9. **(Optional)** Add more widgets based on your log query results.
   
   a. Choose **Add widget**.
   
   b. Choose a widget type, such as **Line**.
c. In the **Add to this dashboard** window, choose **Logs**.

d. In **Select log group(s)**, select the log group for your DB cluster.

e. In the query editor, delete the query that is currently shown, enter the following, and then choose **Run query**.

```
#Autovacuum tuples statistics per 5 min
fields @timestamp, @message
| parse @message "tuples: " as @tuples_temp
```
| parse @tuples_temp "* removed," as @tuples_removed  
| parse @tuples_temp "remain, * are dead but not yet removable," as @tuples_not_removable  
| filter @message like / automatic vacuum /  
| sort @timestamp  
| stats  avg(@tuples_removed) as avg_tuples_removed,  
avg(@tuples_not_removable) as avg_tuples_not_removable  
by bin(5 min)

f. Choose **Create widget**.

Your dashboard should look similar to the following image.
Monitoring query execution plans for Aurora PostgreSQL

You can monitor query execution plans in your Aurora PostgreSQL DB instance to detect the execution plans contributing to current database load and to track performance statistics of execution plans over time using `aurora_compute_plan_id` parameter. Whenever a query executes, the execution plan used by the query is assigned an identifier and the same identifier is used by subsequent executions of the same plan.

The `aurora_compute_plan_id` is turned on by default in DB parameter group from Aurora PostgreSQL versions 14.10, 15.5, and higher versions. Assignment of a plan identifier is default behavior and can be turned off by setting `aurora_compute_plan_id` to OFF in the parameter group.

This plan identifier is used in several utilities that serve a different purpose.

Topics
• Accessing query execution plans using Aurora functions
• Parameter reference for Aurora PostgreSQL query execution plans

Accessing query execution plans using Aurora functions

With `aurora_compute_plan_id`, you can access the execution plans using the following functions:

• `aurora_stat_activity`
• `aurora_stat_plans`

For more information on these functions, see Aurora PostgreSQL functions reference.

Parameter reference for Aurora PostgreSQL query execution plans

You can monitor the query execution plans using the below parameters in a DB parameter group.

Parameters
• `aurora_compute_plan_id`
• `aurora_stat_plans.minutes_until_recapture`
- `aurora_stat_plans.calls_until_recapture`
- `aurora_stat_plans.with_costs`
- `aurora_stat_plans.with_analyze`
- `aurora_stat_plans.with_timing`
- `aurora_stat_plans.with_buffers`
- `aurora_stat_plans.with_wal`
- `aurora_stat_plans.with_triggers`

**Note**

The configuration for `aurora_stat_plans.with_*` parameters takes effect only for newly captured plans.

### `aurora_compute_plan_id`

Set to off to prevent a plan identifier from being assigned.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>on</td>
<td>0(off)</td>
<td>Set to off to prevent a plan identifier from being assigned.</td>
</tr>
<tr>
<td></td>
<td>1(on)</td>
<td>Set to on to assign a plan identifier.</td>
</tr>
</tbody>
</table>

### `aurora_stat_plans.minutes_until_recapture`

The number of minutes to pass before a plan is recaptured. Default is 0 which will disable recapturing a plan. When the `aurora_stat_plans.calls_until_recapture` threshold is passed, the plan will be recaptured.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0-1073741823</td>
<td>Set the number of minutes to pass before a plan is recaptured.</td>
</tr>
</tbody>
</table>
**aurora_stat_plans.calls_until_recapture**

The number of calls to a plan before it is recaptured. Default is 0 which will disable recapturing a plan after a number of calls. When the `aurora_stat_plans.minutes_until_recapture` threshold is passed, the plan will be recaptured.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0-1073741823</td>
<td>Set the number of calls before a plan is recaptured.</td>
</tr>
</tbody>
</table>

**aurora_stat_plans.with_costs**

Captures an EXPLAIN plan with estimated costs. The allowed values are on and off. The default is on.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>on</td>
<td>0(off)</td>
<td>Doesn't show estimated cost and rows for each plan node.</td>
</tr>
<tr>
<td></td>
<td>1(on)</td>
<td>Shows estimated cost and rows for each plan node.</td>
</tr>
</tbody>
</table>

**aurora_stat_plans.with_analyze**

Controls the EXPLAIN plan with ANALYZE. This mode is only used the first time a plan is captured. The allowed values are on and off. The default is off.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>0(off)</td>
<td>Doesn't include actual run time statistics for the plan.</td>
</tr>
<tr>
<td></td>
<td>1(on)</td>
<td>Includes actual run time statistics for the plan.</td>
</tr>
</tbody>
</table>

**aurora_stat_plans.with_timing**

Plan timing will be captured in the explain when ANALYZE is used. The default is on.
aurora_stat_plans.with_buffers

Plan buffer usage statistics will be captured in the explain when ANALYZE is used. The default is off.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>0(off)</td>
<td>Doesn't include information on buffer usage.</td>
</tr>
<tr>
<td></td>
<td>1(on)</td>
<td>Includes information on buffer usage.</td>
</tr>
</tbody>
</table>

aurora_stat_plans.with_wal

Plan wal usage statistics will be captured in the explain when ANALYZE is used. The default is off.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>0(off)</td>
<td>Doesn't include information on WAL record generation.</td>
</tr>
<tr>
<td></td>
<td>1(on)</td>
<td>Includes information on WAL record generation.</td>
</tr>
</tbody>
</table>

aurora_stat_plans.with_triggers

Plan trigger execution statistics will be captured in the explain when ANALYZE is used. The default is off.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>0(off)</td>
<td>Doesn't include triggers execution statistics.</td>
</tr>
<tr>
<td>Default</td>
<td>Allowed values</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>---------------</td>
<td>---------------------------</td>
</tr>
<tr>
<td>1(on)</td>
<td></td>
<td>Includes triggers execution statistics.</td>
</tr>
</tbody>
</table>
Managing query execution plans for Aurora PostgreSQL

Aurora PostgreSQL query plan management is an optional feature that you can use with your Amazon Aurora PostgreSQL-Compatible Edition DB cluster. This feature is packaged as the apg_plan_mgmt extension that you can install in your Aurora PostgreSQL DB cluster. Query plan management allows you to manage the query execution plans generated by the optimizer for your SQL applications. The apg_plan_mgmt AWS extension builds on the native query processing functionality of the PostgreSQL database engine.

Following, you can find information about Aurora PostgreSQL query plan management features, how to set it up, and how to use it with your Aurora PostgreSQL DB cluster. Before you get started, we recommend that you review any release notes for the specific version of the apg_plan_mgmt extension available for your Aurora PostgreSQL version. For more information, see Aurora PostgreSQL apg_plan_mgmt extension versions in the Release Notes for Aurora PostgreSQL.

Overview of Aurora PostgreSQL query plan management

Aurora PostgreSQL query plan management is designed to ensure plan stability regardless of changes to the database that might cause query plan regression. Query plan regression occurs when the optimizer chooses a sub-optimal plan for a given SQL statement after system or database changes. Changes to statistics, constraints, environment settings, query parameter bindings, and upgrades to the PostgreSQL database engine can all cause plan regression.

With Aurora PostgreSQL query plan management, you can control how and when query execution plans change. The benefits of Aurora PostgreSQL query plan management include the following.
• Improve plan stability by forcing the optimizer to choose from a small number of known, good plans.

• Optimize plans centrally and then distribute the best plans globally.

• Identify indexes that aren't used and assess the impact of creating or dropping an index.

• Automatically detect a new minimum-cost plan discovered by the optimizer.

• Try new optimizer features with less risk, because you can choose to approve only the plan changes that improve performance.

You can use the tools provided by query plan management proactively, to specify the best plan for certain queries. Or you can use query plan management to react to changing circumstances and avoid plan regressions. For more information, see Best practices for Aurora PostgreSQL query plan management.

Topics

• Supported SQL statements

• Query plan management limitations

• Query plan management terminology

• Aurora PostgreSQL query plan management versions

• Turning on Aurora PostgreSQL query plan management

• Upgrading Aurora PostgreSQL query plan management

• Turning off Aurora PostgreSQL query plan management

Supported SQL statements

Query plan management supports the following types of SQL statements.

• Any SELECT, INSERT, UPDATE, or DELETE statement, regardless of complexity.

• Prepared statements. For more information, see PREPARE in the PostgreSQL documentation.

• Dynamic statements, including those run in immediate-mode. For more information, see Dynamic SQL and EXECUTE IMMEDIATE in PostgreSQL documentation.

• Embedded SQL commands and statements. For more information, see Embedded SQL Commands in the PostgreSQL documentation.

• Statements inside named functions. For more information, see CREATE FUNCTION in the PostgreSQL documentation.
• Statements containing temp tables.
• Statements inside procedures and DO-blocks.

You can use query plan management with EXPLAIN in manual mode to capture a plan without actually running it. For more information, see Analyzing the optimizer's chosen plan. To learn more about query plan management's modes (manual, automatic), see Capturing Aurora PostgreSQL execution plans.

Aurora PostgreSQL query plan management supports all PostgreSQL language features, including partitioned tables, inheritance, row-level security, and recursive common table expressions (CTEs). To learn more about these PostgreSQL language features, see Table Partitioning, Row Security Policies, and WITH Queries (Common Table Expressions) and other topics in the PostgreSQL documentation.

For information about different versions of the Aurora PostgreSQL query plan management feature, see Aurora PostgreSQL apg_plan_mgmt extension versions in the Release Notes for Aurora PostgreSQL.

Query plan management limitations

The current release of Aurora PostgreSQL query plan management has the following limitations.

• Plans aren't captured for statements that reference system relations – Statements that reference system relations, such as pg_class, aren't captured. This is by design, to prevent a large number of system-generated plans that are used internally from being captured. This also applies to system tables inside views.

• Larger DB instance class might be needed for your Aurora PostgreSQL DB cluster – Depending on the workload, query plan management might need a DB instance class that has more than 2 vCPUs. The number of max_worker_processes is limited by the DB instance class size. The number of max_worker_processes provided by a 2-vCPU DB instance class (db.t3.medium, for example) might not be sufficient for a given workload. We recommend that you choose a DB instance class with more than 2 vCPUs for your Aurora PostgreSQL DB cluster if you use query plan managment.

When the DB instance class can't support the workload, query plan management raises an error message such as the following.

WARNING: could not register plan insert background process
HINT: You may need to increase max_worker_processes.

In this case, you should scale up your Aurora PostgreSQL DB cluster to a DB instance class size with more memory. For more information, see [Supported DB engines for DB instance classes](https://docs.aws.amazon.com/AmazonAurora/latest/UserGuide/Concepts.Aurora.DBClusterFeatures.html).

- **Plans already stored in sessions aren't affected** – Query plan management provides a way to influence query plans without changing the application code. However, when a generic plan is already stored in an existing session and if you want to change its query plan, then you must first set `plan_cache_mode` to `force_custom_plan` in the DB cluster parameter group.

- `queryid` in `apg_plan_mgmt.dba_plans` and `pg_stat_statements` can diverge when:
  - Objects are dropped and recreated after storing in `apg_plan_mgmt.dba_plans`.
  - `apg_plan_mgmt.plans` table is imported from another cluster.

For information about different versions of the Aurora PostgreSQL query plan management feature, see [Aurora PostgreSQL apg_plan_mgmt extension versions](https://docs.aws.amazon.com/AmazonAurora/latest/UserGuide/Concepts.Aurora.APGPlanMgmt.html) in the *Release Notes for Aurora PostgreSQL*.

**Query plan management terminology**

The following terms are used throughout this topic.

**managed statement**

A SQL statement captured by the optimizer under query plan management. A managed statement has one or more query execution plans stored in the `apg_plan_mgmt.dba_plans` view.

**plan baseline**

The set of approved plans for a given managed statement. That is, all the plans for the managed statement that have "Approved" for their status column in the `dba_plan` view.

**plan history**

The set of all captured plans for a given managed statement. The plan history contains all plans captured for the statement, regardless of status.

**query plan regression**

The case when the optimizer chooses a less optimal plan than it did before a given change to the database environment, such as a new PostgreSQL version or changes to statistics.
Aurora PostgreSQL query plan management versions

Query plan management is supported by all currently available Aurora PostgreSQL releases. For more information, see the list of Amazon Aurora PostgreSQL updates in the Release Notes for Aurora PostgreSQL.

Query plan management functionality is added to your Aurora PostgreSQL DB cluster when you install the `apg_plan_mgmt` extension. Different versions of Aurora PostgreSQL support different versions of the `apg_plan_mgmt` extension. We recommend that you upgrade the query plan management extension to the latest release for your version of Aurora PostgreSQL.

Note

For release notes for each `apg_plan_mgmt` extension versions, see Aurora PostgreSQL apg_plan_mgmt extension versions in the Release Notes for Aurora PostgreSQL.

You can identify the version running on your cluster by connecting to an instance using `psql` and using the metacommand `\dx` to list extensions as shown following.

```
labdb=> \dx
List of installed extensions
<table>
<thead>
<tr>
<th>Name</th>
<th>Version</th>
<th>Schema</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+----------+---------+------------+-----------------------------------------------------------------------------</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>apg_plan_mgmt</td>
<td>1.0</td>
<td>apg_plan_mgmt</td>
<td>Amazon Aurora with PostgreSQL compatibility Query Plan Management</td>
</tr>
<tr>
<td>plpgsql</td>
<td>1.0</td>
<td>pg_catalog</td>
<td>PL/pgSQL procedural language</td>
</tr>
</tbody>
</table>
(2 rows)
```

The output shows that this cluster is using 1.0 version of the extension. Only certain `apg_plan_mgmt` versions are available for a given Aurora PostgreSQL version. In some cases, you might need to upgrade the Aurora PostgreSQL DB cluster to a new minor release or apply a patch so that you can upgrade to the most recent version of query plan management. The `apg_plan_mgmt` version 1.0 shown in the output is from an Aurora PostgreSQL version 10.17 DB cluster, which doesn't have a newer version of `apg_plan_mgmt` available. In this case, the Aurora PostgreSQL DB cluster should be upgraded to a more recent version of PostgreSQL.

For more information about upgrading your Aurora PostgreSQL DB cluster to a new version of PostgreSQL, see Amazon Aurora PostgreSQL updates.
To learn how to upgrade the apg_plan_mgmt extension, see Upgrading Aurora PostgreSQL query plan management.

Turning on Aurora PostgreSQL query plan management

Setting up query plan management for your Aurora PostgreSQL DB cluster involves installing an extension and changing several DB cluster parameter settings. You need rds_superuser permissions to install the apg_plan_mgmt extension and to turn on the feature for the Aurora PostgreSQL DB cluster.

Installing the extension creates a new role, apg_plan_mgmt. This role allows database users to view, manage, and maintain query plans. As an administrator with rds_superuser privileges, be sure to grant the apg_plan_mgmt role to database users as needed.

Only users with the rds_superuser role can complete the following procedure. The rds_superuser is required for creating the apg_plan_mgmt extension and its apg_plan_mgmt role. Users must be granted the apg_plan_mgmt role to administer the apg_plan_mgmt extension.

To turn on query plan management for your Aurora PostgreSQL DB cluster

The following steps turn on query plan management for all SQL statements that get submitted to the Aurora PostgreSQL DB cluster. This is known as automatic mode. To learn more about the difference between modes, see Capturing Aurora PostgreSQL execution plans.

1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. Create a custom DB cluster parameter group for your Aurora PostgreSQL DB cluster. You need to change certain parameters to activate query plan management and to set its behavior. For more information, see Creating a DB parameter group.
3. Open the custom DB cluster parameter group and set the rds.enable_plan_management parameter to 1, as shown in the following image.
For more information, see Modifying parameters in a DB cluster parameter group.

4. Create a custom DB parameter group that you can use to set query plan parameters at the instance level. For more information, see Creating a DB cluster parameter group.

5. Modify the writer instance of the Aurora PostgreSQL DB cluster to use the custom DB parameter group. For more information, see Modifying a DB instance in a DB cluster.

6. Modify the Aurora PostgreSQL DB cluster to use the custom DB cluster parameter group. For more information, see Modifying the DB cluster by using the console, CLI, and API.

7. Reboot your DB instance to enable the custom parameter group settings.

8. Connect to your Aurora PostgreSQL DB cluster's DB instance endpoint using `psql` or `pgAdmin`. The following example uses the default `postgres` account for the `rds_superuser` role.

```bash
curl http://127.0.0.1:5432/postgresql
```

9. Create the `apg_plan_mgmt` extension for your DB instance, as shown following.

```sql
labdb=> CREATE EXTENSION apg_plan_mgmt;
CREATE EXTENSION
```

**Tip**

Install the `apg_plan_mgmt` extension in the template database for your application. The default template database is named `template1`. To learn more, see Template Databases in the PostgreSQL documentation.

10. Change the `apg_plan_mgmt.capture_plan_baselines` parameter to `automatic`. This setting causes the optimizer to generate plans for every SQL statement that is either planned or executed two or more times.

**Note**

Query plan management also has a `manual` mode that you can use for specific SQL statements. To learn more, see Capturing Aurora PostgreSQL execution plans.
11. Change the value of `apg_plan_mgmt.use_plan_baselines` parameter to "on." This parameter causes the optimizer to choose a plan for the statement from its plan baseline. To learn more, see Using Aurora PostgreSQL managed plans.

### Note
You can modify the value of either of these dynamic parameters for the session without needing to reboot the instance.

When your query plan management set up is complete, be sure to grant the `apg_plan_mgmt` role to any database users that need to view, manage, or maintain query plans.

**Upgrading Aurora PostgreSQL query plan management**

We recommend that you upgrade the query plan management extension to the latest release for your version of Aurora PostgreSQL.

1. Connect to the writer instance of your Aurora PostgreSQL DB cluster as a user that has `rds_superuser` privileges. If you kept the default name when you set up your instance, you connect as `postgres`. This example shows how to use `psql`, but you can also use pgAdmin if you prefer.

   ```bash
   psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

2. Run the following query to upgrade the extension.

   ```sql
   ALTER EXTENSION apg_plan_mgmt UPDATE TO '2.1';
   ```

3. Use the `apg_plan_mgmt.validate_plans` function to update the hashes of all plans. The optimizer validates all Approved, Unapproved, and Rejected plans to ensure that they're still viable plans for new version of the extension.

   ```sql
   SELECT apg_plan_mgmt.validate_plans('update_plan_hash');
   ```

To learn more about using this function, see Validating plans.

4. Use the `apg_plan_mgmt.reload` function to refresh any plans in the shared memory with the validated plans from the `dba_plans` view.
To learn more about all functions available for query plan management, see [Function reference for Aurora PostgreSQL query plan management](#).

### Turning off Aurora PostgreSQL query plan management

You can disable query plan management at any time by turning off the `apg_plan_mgmt.use_plan_baselines` and `apg_plan_mgmt.capture_plan_baselines`.

```
labdb=> SET apg_plan_mgmt.use_plan_baselines = off;
labdb=> SET apg_plan_mgmt.capture_plan_baselines = off;
```

### Best practices for Aurora PostgreSQL query plan management

Query plan management lets you control how and when query execution plans change. As a DBA, your main goals when using QPM include preventing regressions when there are changes to your database, and controlling whether to allow the optimizer to use a new plan. In the following, you can find some recommended best practices for using query plan management. Proactive and reactive plan management approaches differ in how and when new plans get approved for use.

**Contents**

- [Proactive plan management to help prevent performance regression](#)
  - [Ensuring plan stability after a major version upgrade](#)
- [Reactive plan management to detect and repair performance regressions](#)

**Proactive plan management to help prevent performance regression**

To prevent plan performance regressions from occurring, you *evolve* plan baselines by running a procedure that compares the performance of newly discovered plans to the performance of the existing baseline of Approved plans, and then automatically approves the fastest set of plans as the new baseline. In this way, the baseline of plans improves over time as faster plans are discovered.
1. In a development environment, identify the SQL statements that have the greatest impact on performance or system throughput. Then capture the plans for these statements as described in Manually capturing plans for specific SQL statements and Automatically capturing plans.

2. Export the captured plans from the development environment and import them into the production environment. For more information, see Exporting and importing plans.

3. In production, run your application and enforce the use of approved managed plans. For more information, see Using Aurora PostgreSQL managed plans. While the application runs, also add new plans as the optimizer discovers them. For more information, see Automatically capturing plans.

4. Analyze the unapproved plans and approve those that perform well. For more information, see Evaluating plan performance.

5. While your application continues to run, the optimizer begins to use the new plans as appropriate.

Ensuring plan stability after a major version upgrade

Each major version of PostgreSQL includes enhancements and changes to the query optimizer that are designed to improve performance. However, query execution plans generated by the optimizer in earlier versions might cause performance regressions in newer upgraded versions. You can use query plan management to resolve these performance issues and to ensure plan stability after a major version upgrade.

The optimizer always uses a minimum-cost Approved plan, even if more than one Approved plan for the same statement exists. After an upgrade the optimizer might discover new plans but they will be saved as Unapproved plans. These plans are performed only if approved using the reactive style of plan management with the unapproved_plan_execution_threshold parameter. You can maximize plan stability using the proactive style of plan management with the evolve_plan_baselines parameter. This compares the performance of the new plans to the old plans and approves or rejects plans that are at least 10% faster than the next best plan.

After upgrading, you can use the evolve_plan_baselines function to compare plan performance before and after the upgrade using your query parameter bindings. The following steps assume that you have been using approved managed plans in your production environment, as detailed in Using Aurora PostgreSQL managed plans.
1. Before upgrading, run your application with the query plan manager running. While the application runs, add new plans as the optimizer discovers them. For more information, see \textit{Automatically capturing plans}.

2. Evaluate each plan's performance. For more information, see \textit{Evaluating plan performance}.

3. After upgrading, analyze your approved plans again using the \texttt{evolve_plan_baselines} function. Compare performance before and after using your query parameter bindings. If the new plan is faster, you can add it to your approved plans. If it's faster than another plan for the same parameter bindings, then you can mark the slower plan as Rejected.

   For more information, see \textit{Approving better plans}. For reference information about this function, see \texttt{apg_plan_mgmt.evolve_plan_baselines}.

For more information, see \textit{Ensuring consistent performance after major version upgrades with Amazon Aurora PostgreSQL-Compatible Edition Query Plan Management}.

\textbf{Note}

When you perform a major version upgrade using logical replication or AWS DMS, make sure that you replicate the \texttt{apg_plan_mgmt} schema to ensure existing plans are copied to the upgraded instance. For more information on logical replication, see \textit{Using logical replication to perform a major version upgrade for Aurora PostgreSQL}.

\textbf{Reactive plan management to detect and repair performance regressions}

By monitoring your application as it runs, you can detect plans that cause performance regressions. When you detect regressions, you manually reject or fix the bad plans by following these steps:

1. While your application runs, enforce the use of managed plans and automatically add newly discovered plans as unapproved. For more information, see \textit{Using Aurora PostgreSQL managed plans} and \textit{Automatically capturing plans}.

3. When you discover a plan regression, set the plan's status to \texttt{rejected}. The next time the optimizer runs the SQL statement, it automatically ignores the rejected plan and uses a different approved plan instead. For more information, see \textit{Rejecting or disabling slower plans}.
In some cases, you might prefer to fix a bad plan rather than reject, disable, or delete it. Use the pg_hint_plan extension to experiment with improving a plan. With pg_hint_plan, you use special comments to tell the optimizer to override how it normally creates a plan. For more information, see Fixing plans using pg_hint_plan.

**Understanding Aurora PostgreSQL query plan management**

With query plan management turned on for your Aurora PostgreSQL DB cluster, the optimizer generates and stores query execution plans for any SQL statement that it processes more than once. The optimizer always sets the status of a managed statement's first generated plan to Approved, and stores it in the dba_plans view.

The set of approved plans saved for a managed statement is known as its *plan baseline*. As your application runs, the optimizer might generate additional plans for managed statements. The optimizer sets additional captured plans to a status of Unapproved.

Later, you can decide if the Unapproved plans perform well and change them to Approved, Rejected, or Preferred. To do so, you use the apg_plan_mgmnt.evolve_plan_baselines function or the apg_plan_mgmnt.set_plan_status function.

When the optimizer generates a plan for a SQL statement, query plan management saves the plan in the apg_plan_mgmnt.plans table. Database users that have been granted the apg_plan_mgmnt role can see the plan details by querying the apg_plan_mgmnt.dba_plans view. For example, the following query lists details for plans currently in the view for a non-production Aurora PostgreSQL DB cluster.

- **sql_hash** – An identifier for the SQL statement that's the hash value for the normalized text of the SQL statement.
- **plan_hash** – A unique identifier for the plan that's a combination of the sql_hash and a hash of the plan.
- **status** – The status of the plan. The optimizer can run an approved plan.
- **enabled** – Indicates whether the plan is ready to use (true) or not (false).
- **plan_outline** – A representation of the plan that's used to recreate the actual execution plan. Operators in the tree structure map to operators in EXPLAIN output.
The `apg_plan_mgmt.dba_plans` view has many more columns that contain all details of the plan, such as when the plan was last used. For complete details, see [Reference for the `apg_plan_mgmt.dba_plans` view](#).

### Normalization and the SQL hash

In the `apg_plan_mgmt.dba_plans` view, you can identify a managed statement by its SQL hash value. The SQL hash is calculated on a normalized representation of the SQL statement that removes some differences, such as literal values.

The *normalization* process for each SQL statement preserves space and case, so that you can still read and understand the gist of the SQL statement. Normalization removes or replaces the following items.

- Leading block comments
- The EXPLAIN keyword and EXPLAIN options, and EXPLAIN ANALYZE
- Trailing spaces
- All literals

As an example, take the following statement.

```sql
/*Leading comment*/ EXPLAIN SELECT /* Query 1 */ * FROM t WHERE x > 7 AND y = 1;
```

The optimizer normalizes this statement as shown following.

```sql
SELECT /* Query 1 */ * FROM t WHERE x > CONST AND y = CONST;
```

Normalization allows the same SQL hash to be used for similar SQL statements that might differ only in their literal or parameter values. In other words, multiple plans for the same SQL hash can exist, with a different plan that's optimal under different conditions.

**Note**

A single SQL statement that's used with different schemas has different plans because it's bound to the specific schema at runtime. The planner uses the statistics for schema binding to choose the optimal plan.
To learn more about how the optimizer chooses a plan, see Using Aurora PostgreSQL managed plans. In that section, you can learn how to use EXPLAIN and EXPLAIN ANALYZE to preview a plan before it's actually used. For details, see Analyzing the optimizer's chosen plan. For an image that outlines the process for choosing a plan, see How the optimizer chooses which plan to run.

Capturing Aurora PostgreSQL execution plans

Aurora PostgreSQL query plan management offers two different modes for capturing query execution plans, automatic or manual. You choose the mode by setting the value of the apg_plan_mgmt.capture_plans_baselines to automatic or to manual. You can capture execution plans for specific SQL statements by using manual plan capture. Alternatively, you can capture all (or the slowest) plans that are executed two or more times as your application runs by using automatic plan capture.

When capturing plans, the optimizer sets the status of a managed statement's first captured plan to approved. The optimizer sets the status of any additional plans captured for a managed statement to unapproved. However, more than one plan might occasionally be saved with the approved status. This can happen when multiple plans are created for a statement in parallel and before the first plan for the statement is committed.

To control the maximum number of plans that can be captured and stored in the dba_plans view, set the apg_plan_mgmt.max_plans parameter in your DB instance-level parameter group. A change to the apg_plan_mgmt.max_plans parameter requires a DB instance reboot for a new value to take effect. For more information, see the apg_plan_mgmt.max_plans parameter.

Manually capturing plans for specific SQL statements

If you have a known set of SQL statements to manage, put the statements into a SQL script file and then manually capture plans. The following shows a psql example of how to capture query plans manually for a set of SQL statements.

```
psql> SET apg_plan_mgmt.capture_plan_baselines = manual;
psql> \i my-statements.sql
psql> SET apg_plan_mgmt.capture_plan_baselines = off;
```

After capturing a plan for each SQL statement, the optimizer adds a new row to the apg_plan_mgmt.db_plans view.
We recommend that you use either EXPLAIN or EXPLAIN EXECUTE statements in the SQL script file. Make sure that you include enough variations in parameter values to capture all the plans of interest.

If you know of a better plan than the optimizer's minimum cost plan, you might be able to force the optimizer to use the better plan. To do so, specify one or more optimizer hints. For more information, see Fixing plans using pg_hint_plan. To compare the performance of the unapproved and approved plans and approve, reject, or delete them, see Evaluating plan performance.

Automatically capturing plans

Use automatic plan capture for situations such as the following:

- You don't know the specific SQL statements that you want to manage.
- You have hundreds or thousands of SQL statements to manage.
- Your application uses a client API. For example, JDBC uses unnamed prepared statements or bulk-mode statements that can't be expressed in psql.

To capture plans automatically

1. Turn on automatic plan capture by setting apg_plan_mgmt.capture_plan_baselines to automatic in the DB instance-level parameter group. For more information, see Modifying parameters in a DB parameter group.
2. Reboot your DB instance.
3. As the application runs, the optimizer captures plans for each SQL statement that runs at least twice.

As the application runs with default query plan management parameter settings, the optimizer captures plans for each SQL statement that runs at least twice. Capturing all plans while using the defaults has very little run-time overhead and can be enabled in production.

To turn off automatic plan capture

- Set the apg_plan_mgmt.capture_plan_baselines parameter to off from the DB instance-level parameter group.
To measure the performance of the unapproved plans and approve, reject, or delete them, see [Evaluating plan performance](#).
Using Aurora PostgreSQL managed plans

To get the optimizer to use captured plans for your managed statements, set the parameter `apg_plan_mgmt.use_plan_baselines` to `true`. The following is a local instance example.

```
SET apg_plan_mgmt.use_plan_baselines = true;
```

While the application runs, this setting causes the optimizer to use the minimum-cost, preferred, or approved plan that is valid and enabled for each managed statement.

Analyzing the optimizer's chosen plan

When the `apg_plan_mgmt.use_plan_baselines` parameter is set to `true`, you can use EXPLAIN ANALYZE SQL statements to cause the optimizer to show the plan it would use if it were to run the statement. The following is an example.

```
EXPLAIN ANALYZE EXECUTE rangeQuery (1,10000);
```

```
QUERY PLAN
--------------------------------------------------------------------------
Aggregate  (cost=393.29..393.30 rows=1 width=8) (actual time=7.251..7.251 rows=1 loops=1)
  ->  Index Only Scan using t1_pkey on t1 t  (cost=0.29..368.29 rows=10000 width=0)
      (actual time=0.061..4.859 rows=10000 loops=1)
Index Cond: ((id >= 1) AND (id <= 10000))
Heap Fetches: 10000
Planning time: 1.408 ms
Execution time: 7.291 ms
Note: An Approved plan was used instead of the minimum cost plan.
SQL Hash: 1984047223, Plan Hash: 512153379
```

The output shows the Approved plan from the baseline that would run. However, the output also shows that it found a lower-cost plan. In this case, you capture this new minimum cost plan by turning on automatic plan capture as described in Automatically capturing plans.

New plans are always captured by the optimizer as Unapproved. Use the `apg_plan_mgmt.evolve_plan_baselines` function to compare plans and change them to approved, rejected, or disabled. For more information, see Evaluating plan performance.
How the optimizer chooses which plan to run

The cost of an execution plan is an estimate that the optimizer makes to compare different plans. When calculating a plan's cost, the optimizer includes factors such as CPU and I/O operations required by that plan. To learn more about PostgreSQL query planner cost estimates, see Query Planning in the PostgreSQL documentation.

The following image shows how a plan is chosen for a given SQL statement when query plan management is active, and when it's not.
The flow is as follows:

1. The optimizer generates a minimum-cost plan for the SQL statement.

2. If query plan management isn't active, the optimizer's plan is run immediately (A. Run Optimizer's plan). Query plan management is inactive when the `apg_plan_mgmt.capture_plan_baselines` and the `apg_plan_mgmt.use_plan_baselines` parameters are both at their default settings ("off" and "false," respectively).

   Otherwise, query plan management is active. In this case, the SQL statement and the optimizer's plan for it are further assessed before a plan is chosen.

   **Tip**
   Database users with the `apg_plan_mgmt` role can pro-actively compare plans, change status of plans, and force the use of specific plans as needed. For more information, see [Maintaining Aurora PostgreSQL execution plans](#).

3. The SQL statement might already have plans that were stored by query plan management in the past. Plans are stored in the `apg_plan_mgmt.dba_plans`, along with information about the SQL statements that were used to create them. Information about a plan includes its status. A plan's status can determine whether it's used or not, as follows.

   a. If the plan isn't among the stored plans for the SQL statement, it means that it's the first time this particular plan was generated by the optimizer for the given SQL statement. The plan is sent to Capture Plan Processing (4).

   b. If the plan is among the stored plans and its status is Approved or Preferred, the plan is run (A. Run Optimizer's plan).

      If the plan is among the stored plans but it's neither Approved nor Preferred, the plan is sent to Capture Plan Processing (4).

4. When a plan is captured for the first time for a given SQL statement, the plan's status is always set to Approved (P1). If the optimizer subsequently generates the same plan for the same SQL statement, the status of that plan is changed to Unapproved (P1+n).

   With the plan captured and its status updated, the evaluation continues at the next step (5).
5. A plan's baseline consists of the history of the SQL statement and its plans at various states. Query plan management can take the baseline into account when choosing a plan, depending on whether the use plan baselines option is turned on or not, as follows.

- Use plan baselines is "off" when the `apg_plan_mgmt.use_plan_baselines` parameter is set to its default value (`false`). The plan isn't compared to the baseline before it's run (A. Run Optimizer's plan).

- Use plan baselines is "on" when the `apg_plan_mgmt.use_plan_baselines` parameter is set to `true`. The plan is further assessed using the baseline (6).

6. The plan is compared to other plans for the statement in the baseline.

   a. If the optimizer's plan is among the plans in the baseline, its status is checked (7a).

   b. If the optimizer's plan isn't among plans in the baseline, the plan is added to the plans for the statement as a new Unapproved plan.

7. The plan's status is checked to determine only if it's Unapproved.

   a. If the plan's status is Unapproved, the plan's estimated cost is compared to the cost estimate specified for the unapproved execution plan threshold.

      - If the plan's estimated cost is below the threshold, the optimizer uses it even though it's an Unapproved plan (A. Run Optimizer's plan). Generally, the optimizer won't run an Unapproved plan. However, when the `apg_plan_mgmt.unapproved_plan_execution_threshold` parameter specifies a cost threshold value, the optimizer compares the Unapproved plan's cost to the threshold. If the estimated cost is less than the threshold, the optimizer runs the plan. For more information, see `apg_plan_mgmt.unapproved_plan_execution_threshold`.

      - If the plan's estimated cost isn't below the threshold, the plan's other attributes are checked (8a).

   b. If the plan's status is anything other than Unapproved, its other attributes are checked (8a).

8. The optimizer won't use a plan that's disabled. That is, the plan that has its `enable` attribute set to 'f' (false). The optimizer also won't use a plan that has a status of Rejected.

   The optimizer can't use any plans that aren't valid. Plans can become invalid over time when the objects that they depend on, such as indexes and table partitions, are removed or deleted.

   a. If the statement has any enabled and valid Preferred plans, the optimizer chooses the minimum-cost plan from among the Preferred plans stored for this SQL statement. The optimizer then runs the minimum-cost Preferred plan.
b. If the statement doesn't have any enabled and valid Preferred plans, it's assessed in the next step (9).

9. If the statement has any enabled and valid Approved plans, the optimizer chooses the minimum-cost plan from among the Approved plans stored for this SQL statement. The optimizer then runs the minimum-cost Approved plan.

If the statement doesn't have any valid and enabled Approved plans, the optimizer uses the minimum cost plan (A. Run Optimizer's plan).

**Examining Aurora PostgreSQL query plans in the dba_plans view**

Database users and administrators that have been granted the `apg_plan_mgmt` role can view and manage the plans stored in the `apg_plan_mgmt.dba_plans`. An Aurora PostgreSQL DB cluster's administrator (someone with `rds_superuser` permissions) must explicitly grant this role to the database users who need to work with query plan management.

The `apg_plan_mgmt` view contains the plan history for all managed SQL statements for every database on the writer instance of the Aurora PostgreSQL DB cluster. This view lets you examine plans, their state, when last used, and all other relevant details.

As discussed in [Normalization and the SQL hash](#), each managed plan is identified by the combined SQL hash value and a plan hash value. With these identifiers, you can use tools such as Amazon RDS Performance Insights to track individual plan performance. For more information about Performance Insights, see [Using Amazon RDS performance insights](#).

**Listing managed plans**

To list the managed plans, use a SELECT statement on the `apg_plan_mgmt.dba_plans` view. The following example displays some columns in the `dba_plans` view such as the status, which identifies the approved and unapproved plans.

```sql
SELECT sql_hash, plan_hash, status, enabled, stmt_name
FROM apg_plan_mgmt.dba_plans;
```

```
sql_hash       plan_hash       status      enabled | stmt_name
----------------+-----------------+-------------+---------+------------
1984047223      512153379     Approved    t         | rangequery
1984047223      512284451     Unapproved  t         | rangequery
```
Maintaining Aurora PostgreSQL execution plans

Query plan management provides techniques and functions to add, maintain, and improve execution plans.

Evaluating plan performance

After the optimizer captures plans as unapproved, use the `apg_plan_mgmt.evolve_plan_baselines` function to compare plans based on their actual performance. Depending on the outcome of your performance experiments, you can change a plan's status from unapproved to either approved or rejected. You can instead decide to use the `apg_plan_mgmt.evolve_plan_baselines` function to temporarily disable a plan if it does not meet your requirements.

Approving better plans

The following example demonstrates how to change the status of managed plans to approved using the `apg_plan_mgmt.evolve_plan_baselines` function.

```sql
SELECT apg_plan_mgmt.evolve_plan_baselines ( sql_hash, plan_hash, min_speedup_factor := 1.0, action := 'approve' )
FROM apg_plan_mgmt.dba_plans WHERE status = 'Unapproved';
```

```
NOTICE: rangequery (1,10000)
NOTICE: Baseline [ Planning time 0.761 ms, Execution time 13.261 ms]
NOTICE: Baseline+1 [ Planning time 0.204 ms, Execution time 8.956 ms]
NOTICE: Total time benefit: 4.862 ms, Execution time benefit: 4.305 ms
NOTICE: Unapproved -> Approved
---------
0
(1 row)
```
The output shows a performance report for the rangequery statement with parameter bindings of 1 and 10,000. The new unapproved plan (Baseline+1) is better than the best previously approved plan (Baseline). To confirm that the new plan is now Approved, check the apg_plan_mgmt.dba_plans view.

```
SELECT sql_hash, plan_hash, status, enabled, stmt_name
FROM apg_plan_mgmt.dba_plans;
```

<table>
<thead>
<tr>
<th>sql_hash</th>
<th>plan_hash</th>
<th>status</th>
<th>enabled</th>
<th>stmt_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1984047223</td>
<td>512153379</td>
<td>Approved</td>
<td>t</td>
<td>rangequery</td>
</tr>
<tr>
<td>1984047223</td>
<td>512284451</td>
<td>Approved</td>
<td>t</td>
<td>rangequery</td>
</tr>
</tbody>
</table>

(2 rows)

The managed plan now includes two approved plans that are the statement's plan baseline. You can also call the apg_plan_mgmt.set_plan_status function to directly set a plan's status field to 'Approved', 'Rejected', 'Unapproved', or 'Preferred'.

**Rejecting or disabling slower plans**

To reject or disable plans, pass 'reject' or 'disable' as the action parameter to the apg_plan_mgmt.evolve_plan_baselines function. This example disables any captured Unapproved plan that is slower by at least 10 percent than the best Approved plan for the statement.

```
SELECT apg_plan_mgmt.evolve_plan_baselines(
    sql_hash,  -- The managed statement ID
    plan_hash,  -- The plan ID
    1.1,  -- number of times faster the plan must be
    'disable'  -- The action to take. This sets the enabled field to false.
)
FROM apg_plan_mgmt.dba_plans
WHERE status = 'Unapproved' AND  -- plan is Unapproved
    origin = 'Automatic';  -- plan was auto-captured
```

You can also directly set a plan to rejected or disabled. To directly set a plan's enabled field to true or false, call the apg_plan_mgmt.set_plan_enabled function. To directly set a plan's status field to 'Approved', 'Rejected', 'Unapproved', or 'Preferred', call the apg_plan_mgmt.set_plan_status function.
Validating plans

Use the `apg_plan_mgmt.validate_plans` function to delete or disable plans that are invalid.

Plans can become invalid or stale when objects that they depend on are removed, such as an index or a table. However, a plan might be invalid only temporarily if the removed object gets recreated. If an invalid plan can become valid later, you might prefer to disable an invalid plan or do nothing rather than delete it.

To find and delete all plans that are invalid and haven't been used in the past week, use the `apg_plan_mgmt.validate_plans` function as follows.

```sql
SELECT apg_plan_mgmt.validate_plans(sql_hash, plan_hash, 'delete')
FROM apg_plan_mgmt.dba_plans
WHERE last_used < (current_date - interval '7 days');
```

To enable or disabled a plan directly, use the `apg_plan_mgmt.set_plan_enabled` function.

Fixing plans using `pg_hint_plan`

The query optimizer is well-designed to find an optimal plan for all statements, and in most cases the optimizer finds a good plan. However, occasionally you might know that a much better plan exists than that generated by the optimizer. Two recommended ways to get the optimizer to generate a desired plan include using the `pg_hint_plan` extension or setting Grand Unified Configuration (GUC) variables in PostgreSQL:

- **pg_hint_plan extension** – Specify a "hint" to modify how the planner works by using PostgreSQL's `pg_hint_plan` extension. To install and learn more about how to use the `pg_hint_plan` extension, see the [pg_hint_plan documentation](https).
- **GUC variables** – Override one or more cost model parameters or other optimizer parameters, such as the `fromCollapseLimit` or `GEOThreshold`.

When you use one of these techniques to force the query optimizer to use a plan, you can also use query plan management to capture and enforce use of the new plan.

You can use the `pg_hint_plan` extension to change the join order, the join methods, or the access paths for a SQL statement. You use a SQL comment with special `pg_hint_plan` syntax to modify how the optimizer creates a plan. For example, assume the problem SQL statement has a two-way join.
```sql
SELECT *
FROM t1, t2
WHERE t1.id = t2.id;
```

Then suppose that the optimizer chooses the join order (t1, t2), but you know that the join order (t2, t1) is faster. The following hint forces the optimizer to use the faster join order, (t2, t1). Include EXPLAIN so that the optimizer generates a plan for the SQL statement but without running the statement. (Output not shown.)

```sql
/*+ Leading ((t2 t1)) */ EXPLAIN SELECT *
FROM t1, t2
WHERE t1.id = t2.id;
```

The following steps show how to use `pg_hint_plan`.

**To modify the optimizer's generated plan and capture the plan using pg_hint_plan**

1. Turn on the manual capture mode.

   ```sql
   SET apg_plan_mgmt.capture_plan_baselines = manual;
   ```

2. Specify a hint for the SQL statement of interest.

   ```sql
   /*+ Leading ((t2 t1)) */ EXPLAIN SELECT *
   FROM t1, t2
   WHERE t1.id = t2.id;
   ```

   After this runs, the optimizer captures the plan in the `apg_plan_mgmt.dba_plans` view. The captured plan doesn't include the special `pg_hint_plan` comment syntax because query plan management normalizes the statement by removing leading comments.

3. View the managed plans by using the `apg_plan_mgmt.dba_plans` view.

   ```sql
   SELECT sql_hash, plan_hash, status, sql_text, planoutline
   FROM apg_plan_mgmt.dba_plans;
   ```

4. Set the status of the plan to Preferred. Doing so makes sure that the optimizer chooses to run it, instead of selecting from the set of approved plans, when the minimum-cost plan isn't already Approved or Preferred.
5. Turn off manual plan capture and enforce the use of managed plans.

   ```sql
   SET apg_plan_mgmt.capture_plan_baselines = false;
   SET apg_plan_mgmt.use_plan_baselines = true;
   
   Now, when the original SQL statement runs, the optimizer chooses either an Approved or Preferred plan. If the minimum-cost plan isn't Approved or Preferred, then the optimizer chooses the Preferred plan.
   
   **Deleting plans**
   
   Plans are automatically deleted if they haven't been used in over a month, specifically, 32 days. That's the default setting for the `apg_plan_mgmt.plan_retention_period` parameter. You can change the plan retention period to a longer period of time, or to a shorter period of time starting from the value of 1. Determining the number of days since a plan was last used is calculated by subtracting the `last_used` date from the current date. The `last_used` date is the most recent date that the optimizer chose the plan as the minimum cost plan or that the plan was run. The date is stored for the plan in the `apg_plan_mgmt.dba_plans` view.

   We recommend that you delete plans that haven't been used for a long time or that aren't useful. Every plan has a `last_used` date that the optimizer updates each time it executes a plan or chooses the plan as the minimum-cost plan for a statement. Check the last `last_used` dates to identify the plans that you can safely delete.

   The following query returns a three column table with the count on the total number of plans, plans failed to delete, and the plans successfully deleted. It has a nested query that is an example of how to use the `apg_plan_mgmt.delete_plan` function to delete all plans that haven't been chosen as the minimum-cost plan in the last 31 days and its status is not Rejected.

   ```sql
   SELECT (SELECT COUNT(*) from apg_plan_mgmt.dba_plans) total_plans,
           COUNT(*) FILTER (WHERE result = -1) failed_to_delete,
           COUNT(*) FILTER (WHERE result = 0) successfully_deleted
      FROM (SELECT apg_plan_mgmt.delete_plan(sql_hash, plan_hash) as result
               FROM apg_plan_mgmt.dba_plans
               WHERE last_used < (current_date - interval '31 days')
         )
   ```
AND status <> 'Rejected'
) as dba_plans;

<table>
<thead>
<tr>
<th>total_plans</th>
<th>failed_to_delete</th>
<th>successfully_deleted</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>0</td>
<td>2</td>
</tr>
</tbody>
</table>

For more information, see `apg_plan_mgmt.delete_plan`.

To delete plans that aren't valid and that you expect to remain invalid, use the `apg_plan_mgmt.validate_plans` function. This function lets you delete or disable invalid plans. For more information, see `Validating plans`.

⚠️ **Important**

If you don't delete extraneous plans, you might eventually run out of shared memory that's set aside for query plan management. To control how much memory is available for managed plans, use the `apg_plan_mgmt.max_plans` parameter. Set this parameter in your custom DB parameter group and reboot your DB instance for changes to take effect. For more information, see the `apg_plan_mgmt.max_plans` parameter.

### Exporting and importing plans

You can export your managed plans and import them into another DB instance.

**To export managed plans**

An authorized user can copy any subset of the `apg_plan_mgmt.plans` table to another table, and then save it using the `pg_dump` command. The following is an example.

```sql
CREATE TABLE plans_copy AS SELECT * FROM apg_plan_mgmt.plans [ WHERE predicates ] ;

% pg_dump --table apg_plan_mgmt.plans_copy -Ft mysourcedatabase > plans_copy.tar

DROP TABLE apg_plan_mgmt.plans_copy;
```

Maintaining Aurora PostgreSQL execution plans
To import managed plans

1. Copy the .tar file of the exported managed plans to the system where the plans are to be restored.

2. Use the `pg_restore` command to copy the tar file into a new table.

   ```
   % pg_restore --dbname mytargetdatabase -Ft plans_copy.tar
   ```

3. Merge the `plans_copy` table with the `apg_plan_mgmt.plans` table, as shown in the following example.

   ```
   INSERT INTO apg_plan_mgmt.plans
   SELECT * FROM plans_copy
   ON CONFLICT ON CONSTRAINT plans_pkey
   DO UPDATE SET
   status = EXCLUDED.status,
   enabled = EXCLUDED.enabled,
   -- Save the most recent last_used date
   --
   last_used = CASE WHEN EXCLUDED.last_used > plans.last_used
   THEN EXCLUDED.last_used ELSE plans.last_used END,
   -- Save statistics gathered by evolve_plan_baselines, if it ran:
   --
   estimated_startup_cost = EXCLUDED.estimated_startup_cost,
   estimated_total_cost = EXCLUDED.estimated_total_cost,
   planning_time_ms = EXCLUDED.planning_time_ms,
   execution_time_ms = EXCLUDED.execution_time_ms,
   total_time_benefit_ms = EXCLUDED.total_time_benefit_ms,
   execution_time_benefit_ms = EXCLUDED.execution_time_benefit_ms;
   ```

4. Reload the managed plans into shared memory and remove the temporary plans table.

   ```
   SELECT apg_plan_mgmt.reload(); -- refresh shared memory
   DROP TABLE plans_copy;
   ```
Reference for Aurora PostgreSQL query plan management

Following, you can find reference information for several Aurora PostgreSQL query plan management features and functionality.

Topics

- Parameter reference for Aurora PostgreSQL query plan management
- Function reference for Aurora PostgreSQL query plan management
- Reference for the `apg_plan_mgmt.dba_plans` view

Parameter reference for Aurora PostgreSQL query plan management

You can set your preferences for the `apg_plan_mgmt` extension by using the parameters listed in this section. These are available in the custom DB cluster parameter and the DB parameter group associated with your Aurora PostgreSQL DB cluster. These parameters control the behavior of the query plan management feature and how it affects the optimizer. For information about setting up query plan management, see Turning on Aurora PostgreSQL query plan management. Changing the parameters following has no effect if the `apg_plan_mgmt` extension isn't set up as detailed in that section. For information about modifying parameters, see Modifying parameters in a DB cluster parameter group and Working with DB parameter groups in a DB instance.

Parameters

- `apg_plan_mgmt.capture_plan_baselines`
- `apg_plan_mgmt.plan_capture_threshold`
- `apg_plan_mgmt.explain_hashes`
- `apg_plan_mgmt.log_plan_enforcement_result`
- `apg_plan_mgmt.max_databases`
- `apg_plan_mgmt.max_plans`
- `apg_plan_mgmt.plan_hash_version`
- `apg_plan_mgmt.plan_retention_period`
- `apg_plan_mgmt.unapproved_plan_execution_threshold`
- `apg_plan_mgmt.use_plan_baselines`
- `auto_explain.hashes`
**apg_plan_mgmt.capture_plan_baselines**

Captures query execution plans generated by the optimizer for each SQL statement and stores them in the `dba_plans` view. By default, the maximum number of plans that can be stored is 10,000 as specified by the `apg_plan_mgmt.max_plans` parameter. For reference information, see `apg_plan_mgmt.max_plans`.

You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group. Changing the value of this parameter doesn't require a reboot.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>off</td>
<td>automatic</td>
<td>Turns on plan capture for all databases on the DB instance. Collects a plan for each SQL statement that runs two or more times. Use this setting for large or evolving workloads to provide plan stability.</td>
</tr>
<tr>
<td>manual</td>
<td></td>
<td>Turns on plan capture for subsequent statements only, until you turn it off again. Using this setting lets you capture query execution plans for specific critical SQL statements only or for known problematic queries.</td>
</tr>
<tr>
<td>off</td>
<td></td>
<td>Turns off plan capture.</td>
</tr>
</tbody>
</table>

For more information, see [Capturing Aurora PostgreSQL execution plans](#).

**apg_plan_mgmt.plan_capture_threshold**

Specifies a threshold so that if the total cost of the query execution plan is below the threshold, the plan won't be captured in the `apg_plan_mgmt.dba_plans` view.

Changing the value of this parameter doesn't require a reboot.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0 - 1.79769e+308</td>
<td>Sets the threshold of the <code>apg_plan_mgmt</code> query plan total execution cost for capturing plans.</td>
</tr>
</tbody>
</table>
For more information, see [Examining Aurora PostgreSQL query plans in the dba_plans view](#).

**apg_plan_mgmt.explain_hashes**

Specifies if the EXPLAIN [ANALYZE] shows sql_hash and plan_hash at the end of its output. Changing the value of this parameter doesn't require a reboot.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0 (off)</td>
<td>EXPLAIN does not show sql_hash and plan_hash without hashes true option.</td>
</tr>
<tr>
<td></td>
<td>1 (on)</td>
<td>EXPLAIN shows sql_hash and plan_hash without hashes true option.</td>
</tr>
</tbody>
</table>

**apg_plan_mgmt.log_plan_enforcement_result**

Specifies if the results has to be recorded to see if the QPM managed plans are used properly. When a stored generic plan is used, there will be no records written in the log files. Changing the value of this parameter doesn't require a reboot.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>none</td>
<td>Does not show any plan enforcement result in log files.</td>
</tr>
<tr>
<td></td>
<td>on_error</td>
<td>Only shows plan enforcement result in log files when QPM fails to use managed plans.</td>
</tr>
<tr>
<td></td>
<td>all</td>
<td>Shows all plan enforcement results in log files including both successes and failures.</td>
</tr>
</tbody>
</table>

**apg_plan_mgmt.max_databases**

Specifies the maximum number of databases on your Aurora PostgreSQL DB cluster's Writer instance that can use query plan management. By default, up to 10 databases can use query plan management. If you have more than 10 databases on the instance, you can change the value of this setting. To find out how many databases are on a given instance, connect to the instance using `psql`. Then, use the `psql` metacommand, `\l`, to list the databases.
Changing the value of this parameter requires that you reboot the instance for the setting to take effect.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>10-2147483647</td>
<td>Maximum number of databases that can use query plan management on the instance.</td>
</tr>
</tbody>
</table>

You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group.

**apg_plan_mgmt.max_plans**

Sets the maximum number of SQL statements that the query plan manager can maintain in the `apg_plan_mgmt.dba_plans` view. We recommend setting this parameter to 10000 or higher for all Aurora PostgreSQL versions.

You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group. Changing the value of this parameter requires that you reboot the instance for the setting to take effect.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>10000</td>
<td>10-2147483647</td>
<td>Maximum number of plans that can be stored in the <code>apg_plan_mgmt.dba_plans</code> view. Default for Aurora PostgreSQL version 10 and older versions is 1000.</td>
</tr>
</tbody>
</table>

For more information, see [Examining Aurora PostgreSQL query plans in the dba_plans view](#).

**apg_plan_mgmt.plan_hash_version**

Specifies the use cases that the plan_hash calculation is designed to cover. A higher version of `apg_plan_mgmt.plan_hash_version` covers all the functionality of the lower version. For example, version 3 covers the use cases supported by version 2.

Changing the value of this parameter must be followed by a call to `apg_plan_mgmt.validate_plans('update_plan_hash')`. It updates the plan_hash values in
each database with apg_plan_mgmt installed and entries in the plans table. For more information, see [Validating plans](#).

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>Default plan_hash calculation.</td>
</tr>
<tr>
<td>2</td>
<td></td>
<td>plan_hash calculation modified for multi-schema support.</td>
</tr>
<tr>
<td>3</td>
<td></td>
<td>plan_hash calculation modified for multi-schema support and partitioned table support.</td>
</tr>
<tr>
<td>4</td>
<td></td>
<td>plan_hash calculation modified for parallel operators and to support materialize nodes.</td>
</tr>
</tbody>
</table>

**apg_plan_mgmt.plan_retention_period**

Specifies the number of days to keep plans in the apg_plan_mgmt.dba_plans view, after which they're automatically deleted. By default, a plan is deleted when 32 days have elapsed since the plan was last used (the last_used column in the apg_plan_mgmt.dba_plans view). You can change this setting to any number, 1 and over.

Changing the value of this parameter requires that you reboot the instance for the setting to take effect.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>32</td>
<td>1-2147483647</td>
<td>Maximum number of days since a plan was last used before it's deleted.</td>
</tr>
</tbody>
</table>

For more information, see [Examining Aurora PostgreSQL query plans in the dba_plans view](#).

**apg_plan_mgmt.unapproved_plan_execution_threshold**

Specifies a cost threshold below which an Unapproved plan can be used by the optimizer. By default the threshold is 0, so the optimizer doesn't run Unapproved plans. Setting this parameter to a trivially low cost threshold such as 100 avoids plan enforcement overhead on trivial plans.
You can also set this parameter to an extremely large value like 10000000 using the reactive style of plan management. This allows the optimizer to use all chosen plans with no plan enforcement overhead. But, when a bad plan is found, you can manually mark it as "rejected" so that it is not used next time.

The value of this parameter represents a cost estimate for running a given plan. If an Unapproved plan is below that estimated cost, the optimizer uses it for the SQL statement. You can see captured plans and their status (Approved, Unapproved) in the dba_plans view. To learn more, see Examining Aurora PostgreSQL query plans in the dba_plans view.

Changing the value of this parameter doesn't require a reboot.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0-2147483647</td>
<td>Estimated plan cost below which an Unapproved plan is used.</td>
</tr>
</tbody>
</table>

For more information, see Using Aurora PostgreSQL managed plans.

apyg_plan_mgmt.use_plan_baselines

Specifies that the optimizer should use one of the Approved plans captured and stored in the apg_plan_mgmt.dba_plans view. By default, this parameter is off (false), causing the optimizer to use the minimum-cost plan that it generates without any further assessment. Turning this parameter on (setting it to true) forces the optimizer to choose a query execution plan for the statement from its plan baseline. For more information, see Using Aurora PostgreSQL managed plans. To find an image detailing this process, see How the optimizer chooses which plan to run.

You can set this parameter in the custom DB cluster parameter group or in the custom DB parameter group. Changing the value of this parameter doesn't require a reboot.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>false</td>
<td>true</td>
<td>Use an Approved, Preferred, or Unapproved plan from the apg_plan_mgmt.dba_plans. If none of those meet all evaluation criterion for the optimizer, it can then use its own generated minimum-cost plan. For more information, see How the optimizer chooses which plan to run.</td>
</tr>
<tr>
<td>Default</td>
<td>Allowed values</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>false</td>
<td></td>
<td>Use the minimum cost plan generated by the optimizer.</td>
</tr>
</tbody>
</table>

You can evaluate response times of different captured plans and change plan status, as needed. For more information, see [Maintaining Aurora PostgreSQL execution plans](#).

**auto_explain.hashes**

Specifies if the auto_explain output shows sql_hash and plan_hash. Changing the value of this parameter doesn't require a reboot.

<table>
<thead>
<tr>
<th>Default</th>
<th>Allowed values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0(off)</td>
<td>0(off)</td>
<td>auto_explain result does not show sql_hash and plan_hash.</td>
</tr>
<tr>
<td>1(on)</td>
<td></td>
<td>auto_explain result shows sql_hash and plan_hash.</td>
</tr>
</tbody>
</table>

**Function reference for Aurora PostgreSQL query plan management**

The `apg_plan_mgmt` extension provides the following functions.

**Functions**

- `apg_plan_mgmt.copy_outline`
- `apg_plan_mgmt.delete_plan`
- `apg_plan_mgmt.evolve_plan_baselines`
- `apg_plan_mgmt.get_explain_plan`
- `apg_plan_mgmt.plan_last_used`
- `apg_plan_mgmt.reload`
- `apg_plan_mgmt.set_plan_enabled`
- `apg_plan_mgmt.set_plan_status`
- `apg_plan_mgmt.update_plans_last_used`
- `apg_plan_mgmt.validate_plans`
**apg_plan_mgmt.copy_outline**

Copy a given SQL plan hash and plan outline to a target SQL plan hash and outline, thereby overwriting the target's plan hash and outline. This function is available in apg_plan_mgmt 2.3 and higher releases.

**Syntax**

```python
apg_plan_mgmt.copy_outline(
    source_sql_hash,
    source_plan_hash,
    target_sql_hash,
    target_plan_hash,
    force_update_target_plan_hash
)
```

**Return value**

Returns 0 when the copy is successful. Raises exceptions for invalid inputs.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_sql_hash</td>
<td>The sql_hash ID associated with the plan_hash to copy to the target query.</td>
</tr>
<tr>
<td>source_plan_hash</td>
<td>The plan_hash ID to copy to the target query.</td>
</tr>
<tr>
<td>target_sql_hash</td>
<td>The sql_hash ID of the query to update with the source plan hash and outline.</td>
</tr>
<tr>
<td>target_plan_hash</td>
<td>The plan_hash ID of the query to update with the source plan hash and outline.</td>
</tr>
<tr>
<td>force_update_target_plan_hash</td>
<td>(Optional) The target_plan_hash ID of the query is updated even if the source plan isn't reproducible for the target_sql_hash. When set to true, the function can</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>be used to copy plans across schemas where relation names and columns are consistent.</td>
<td></td>
</tr>
</tbody>
</table>

Usage notes

This function allows you to copy a plan hash and plan outline that uses hints to other, similar statements, and thus saves you from needing to use in-line hint statements at every occurrence in the target statements. If the updated target query results in an invalid plan, this function raises an error and rolls back the attempted update.

**apg_plan_mgmt.delete_plan**

Delete a managed plan.

**Syntax**

```python
apg_plan_mgmt.delete_plan(
    sql_hash,
    plan_hash
)
```

**Return value**

Returns 0 if the delete was successful or -1 if the delete failed.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The sql_hash ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's plan_hash ID.</td>
</tr>
</tbody>
</table>
**apg_plan_mgmt.evolve_plan_baselines**

Verifies whether an already approved plan is faster or whether a plan identified by the query optimizer as a minimum cost plan is faster.

**Syntax**

```
apg_plan_mgmt.evolve_plan_baselines(
    sql_hash,
    plan_hash,
    min_speedup_factor,
    action
)
```

**Return value**

The number of plans that were not faster than the best approved plan.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The sql_hash ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's plan_hash ID. Use NULL to mean all plans that have the same sql_hash ID value.</td>
</tr>
<tr>
<td>min_speedup_factor</td>
<td>The <em>minimum speedup factor</em> can be the number of times faster that a plan must be than the best of the already approved plans to approve it. Alternatively, this factor can be the number of times slower that a plan must be to reject or disable it. This is a positive float value.</td>
</tr>
<tr>
<td>action</td>
<td>The action the function is to perform. Valid values include the following. Case does not matter.</td>
</tr>
<tr>
<td></td>
<td>• 'disable' – Disable each matching plan that does not meet the minimum speedup factor.</td>
</tr>
<tr>
<td></td>
<td>• 'approve' – Enable each matching plan that meets the minimum speedup factor and set its status to approved.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>'reject'</td>
<td>For each matching plan that does not meet the minimum speedup factor, set its status to rejected.</td>
</tr>
<tr>
<td>NULL</td>
<td>The function simply returns the number of plans that have no performance benefit because they do not meet the minimum speedup factor.</td>
</tr>
</tbody>
</table>

**Usage notes**

Set specified plans to approved, rejected, or disabled based on whether the planning plus execution time is faster than the best approved plan by a factor that you can set. The action parameter might be set to 'approve' or 'reject' to automatically approve or reject a plan that meets the performance criteria. Alternatively, it might be set to " (empty string) to do the performance experiment and produce a report, but take no action.

You can avoid pointlessly rerunning of the `apg_plan_mgmt.evolve_plan_baselines` function for a plan on which it was recently run. To do so, restrict the plans to just the recently created unapproved plans. Alternatively, you can avoid running the `apg_plan_mgmt.evolve_plan_baselines` function on any approved plan that has a recent `last_verified` timestamp.

Conduct a performance experiment to compare the planning plus execution time of each plan relative to the other plans in the baseline. In some cases, there is only one plan for a statement and the plan is approved. In such a case, compare the planning plus execution time of the plan to the planning plus execution time of using no plan.

The incremental benefit (or disadvantage) of each plan is recorded in the `apg_plan_mgmt.dba_plans` view in the `total_time_benefit_ms` column. When this value is positive, there is a measurable performance advantage to including this plan in the baseline.

In addition to collecting the planning and execution time of each candidate plan, the `last_verified` column of the `apg_plan_mgmt.dba_plans` view is updated with the `current_timestamp`. The `last_verified` timestamp might be used to avoid running this function again on a plan that recently had its performance verified.

**`apg_plan_mgmt.get_explain_plan`**

Generates the text of an EXPLAIN statement for the specified SQL statement.
Syntax

```python
apg_plan_mgmt.get_explain_plan(
    sql_hash,
    plan_hash,
    [explainOptionList]
)
```

**Return value**

Returns runtime statistics for the specified SQL statements. Use without `explainOptionList` to return a simple `EXPLAIN` plan.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sql_hash</code></td>
<td>The <code>sql_hash</code> ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td><code>plan_hash</code></td>
<td>The managed plan's <code>plan_hash</code> ID.</td>
</tr>
<tr>
<td><code>explainOptionList</code></td>
<td>A comma-separated list of explain options. Valid values include 'analyze', 'verbose', 'buffers', 'hashes', and 'format json'. If the <code>explainOptionList</code> is NULL or an empty string (''), this function generates an <code>EXPLAIN</code> statement, without any statistics.</td>
</tr>
</tbody>
</table>

**Usage notes**

For the `explainOptionList`, you can use any of the same options that you would use with an `EXPLAIN` statement. The Aurora PostgreSQL optimizer concatenates the list of options that you provide to the `EXPLAIN` statement.

**apg_plan_mgmt.plan_last_used**

Returns the `last_used` date of the specified plan from shared memory.
Note

The value in shared memory is always current on the primary DB instance in the DB cluster. The value is only periodically flushed to the last_used column of the apg_plan_mgmt.dba_plans view.

Syntax

```plaintext
apg_plan_mgmt.plan_last_used(
    sql_hash,
    plan_hash
)
```

Return value

Returns the last_used date.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The sql_hash ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's plan_hash ID.</td>
</tr>
</tbody>
</table>

`apg_plan_mgmt.reload`

Reload plans into shared memory from the apg_plan_mgmt.dba_plans view.

Syntax

```plaintext
apg_plan_mgmt.reload()
```

Return value

None.
Parameters

None.

Usage notes

Call `reload` for the following situations:

- Use it to refresh the shared memory of a read-only replica immediately, rather than wait for new plans to propagate to the replica.
- Use it after importing managed plans.

`apg_plan_mgmt.set_plan_enabled`

Enable or disable a managed plan.

Syntax

```python
apg_plan_mgmt.set_plan_enabled(
    sql_hash,
    plan_hash,
    [true | false]
)
```

Return value

Returns 0 if the setting was successful or -1 if the setting failed.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The <code>sql_hash</code> ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's <code>plan_hash</code> ID.</td>
</tr>
<tr>
<td>enabled</td>
<td>Boolean value of true or false:</td>
</tr>
<tr>
<td></td>
<td>• A value of true enables the plan.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sql_hash</td>
<td>The sql_hash ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's plan_hash ID.</td>
</tr>
<tr>
<td>status</td>
<td>A string with one of the following values:</td>
</tr>
<tr>
<td></td>
<td>• 'Approved'</td>
</tr>
<tr>
<td></td>
<td>• 'Unapproved'</td>
</tr>
<tr>
<td></td>
<td>• 'Rejected'</td>
</tr>
<tr>
<td></td>
<td>• 'Preferred'</td>
</tr>
</tbody>
</table>

The case you use does not matter, however the status value is set to initial uppercase in the apg_plan_mgmt.dba_plans view. For more information.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>apg_plan_mgmt.update_plans_last_used</td>
<td>Immediately updates the plans table with the <code>last_used</code> date stored in shared memory.</td>
</tr>
</tbody>
</table>

**Syntax**

```python
apg_plan_mgmt.update_plans_last_used()
```

**Return value**

None.

**Parameters**

None.

**Usage notes**

Call `update_plans_last_used` to make sure queries against the `dba_plans.last_used` column use the most current information. If the `last_used` date isn't updated immediately, a background process updates the plans table with the `last_used` date once every hour (by default).

For example, if a statement with a certain `sql_hash` begins to run slowly, you can determine which plans for that statement were executed since the performance regression began. To do that, first flush the data in shared memory to disk so that the `last_used` dates are current, and then query for all plans of the `sql_hash` of the statement with the performance regression. In the query, make sure the `last_used` date is greater than or equal to the date on which the performance regression began. The query identifies the plan or set of plans that might be responsible for the performance regression. You can use `apg_plan_mgmt.get_explain_plan` with `explainOptionList` set to `verbose, hashes`. You can also use `apg_plan_mgmt.evolve_plan_baselines` to analyze the plan and any alternative plans that might perform better.
The update_plans_last_used function has an effect only on the primary DB instance of the DB cluster.

**apg_plan_mgmt.validate_plans**

Validate that the optimizer can still recreate plans. The optimizer validates Approved, Unapproved, and Preferred plans, whether the plan is enabled or disabled. Rejected plans are not validated. Optionally, you can use the `apg_plan_mgmt.validate_plans` function to delete or disable invalid plans.

**Syntax**

```python
apg_plan_mgmt.validate_plans(
    sql_hash,
    plan_hash,
    action)

apg_plan_mgmt.validate_plans(
    action)
```

**Return value**

The number of invalid plans.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_hash</td>
<td>The <code>sql_hash</code> ID of the plan's managed SQL statement.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The managed plan's <code>plan_hash</code> ID. Use <code>NULL</code> to mean all plans for the same <code>sql_hash</code> ID value.</td>
</tr>
<tr>
<td>action</td>
<td>The action the function is to perform for invalid plans. Valid string values include the following. Case does not matter.</td>
</tr>
<tr>
<td></td>
<td>'disable' – Each invalid plan is disabled.</td>
</tr>
<tr>
<td></td>
<td>'delete' – Each invalid plan is deleted.</td>
</tr>
<tr>
<td></td>
<td>'update_plan_hash' – Updates the <code>plan_hash</code> ID for plans that can't be reproduced exactly. It also allows you to fix a plan by rewriting the SQL. You can then register the good plan as an Approved plan for the original SQL.</td>
</tr>
</tbody>
</table>

Reference

2568
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• NULL –</td>
<td>The function simply returns the number of invalid plans. No other action is performed.</td>
</tr>
<tr>
<td>• &quot; –</td>
<td>An empty string produces a message indicating the number of both valid and invalid plans.</td>
</tr>
</tbody>
</table>

Any other value is treated like the empty string.

**Usage notes**

Use the form `validate_plans(action)` to validate all the managed plans for all the managed statements in the entire `apg_plan_mgmt.dba_plans` view.

Use the form `validate_plans(sql_hash, plan_hash, action)` to validate a managed plan specified with `plan_hash`, for a managed statement specified with `sql_hash`.

Use the form `validate_plans(sql_hash, NULL, action)` to validate all the managed plans for the managed statement specified with `sql_hash`.

**Reference for the `apg_plan_mgmt.dba_plans` view**

The columns of plan information in the `apg_plan_mgmt.dba_plans` view include the following.

<table>
<thead>
<tr>
<th>dba_plans column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cardinality_error</td>
<td>A measure of the error between the estimated cardinality versus the actual cardinality. <em>Cardinality</em> is the number of table rows that the plan is to process. If the cardinality error is large, then it increases the likelihood that the plan isn't optimal. This column is populated by the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
<tr>
<td>compatibility_level</td>
<td>The feature level of the Aurora PostgreSQL optimizer.</td>
</tr>
<tr>
<td>created_by</td>
<td>The authenticated user (session_user) who created the plan.</td>
</tr>
<tr>
<td><strong>dba_plans column</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>enabled</td>
<td>An indicator of whether the plan is enabled or disabled. All plans are enabled by default. You can disable plans to prevent them from being used by the optimizer. To modify this value, use the \texttt{apg_plan_mgmt.set_plan_enabled} function.</td>
</tr>
<tr>
<td>environment_variables</td>
<td>The PostgreSQL Grand Unified Configuration (GUC) parameters and values that the optimizer has overridden at the time the plan was captured.</td>
</tr>
<tr>
<td>estimated_startup_cost</td>
<td>The estimated optimizer setup cost before the optimizer delivers rows of a table.</td>
</tr>
<tr>
<td>estimated_total_cost</td>
<td>The estimated optimizer cost to deliver the final table row.</td>
</tr>
<tr>
<td>execution_time_benefit_ms</td>
<td>The execution time benefit in milliseconds of enabling the plan. This column is populated by the \texttt{apg_plan_mgmt.evolve_plan_baselines} function.</td>
</tr>
<tr>
<td>execution_time_ms</td>
<td>The estimated time in milliseconds that the plan would run. This column is populated by the \texttt{apg_plan_mgmt.evolve_plan_baselines} function.</td>
</tr>
<tr>
<td>has_side_effects</td>
<td>A value that indicates that the SQL statement is a data manipulation language (DML) statement or a SELECT statement that contains a VOLATILE function.</td>
</tr>
<tr>
<td>last_used</td>
<td>This value is updated to the current date whenever the plan is either executed or when the plan is the query optimizer's minimum-cost plan. This value is stored in shared memory and periodically flushed to disk. To get the most up-to-date value, read the date from shared memory by calling the function \texttt{apg_plan_mgmt.plan_last_used(sql_hash, plan_hash)} instead of reading the \texttt{last_used} value. For additional information, see the \texttt{apg_plan_mgmt.plan_retention_period} parameter.</td>
</tr>
</tbody>
</table>
### dba_plans column

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>last_validated</td>
<td>The most recent date and time when it was verified that the plan could be recreated by either the <code>apg_plan_mgmt.validate_plans</code> function or the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
<tr>
<td>last_verified</td>
<td>The most recent date and time when a plan was verified to be the best-performing plan for the specified parameters by the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
<tr>
<td>origin</td>
<td>How the plan was captured with the <code>apg_plan_mgmt.capture_plan_baselines</code> parameter. Valid values include the following:</td>
</tr>
<tr>
<td></td>
<td>M – The plan was captured with manual plan capture.</td>
</tr>
<tr>
<td></td>
<td>A – The plan was captured with automatic plan capture.</td>
</tr>
<tr>
<td>param_list</td>
<td>The parameter values that were passed to the statement if this is a prepared statement.</td>
</tr>
<tr>
<td>plan_created</td>
<td>The date and time the plan that was created.</td>
</tr>
<tr>
<td>plan_hash</td>
<td>The plan identifier. The combination of <code>plan_hash</code> and <code>sql_hash</code> uniquely identifies a specific plan.</td>
</tr>
<tr>
<td>plan_outline</td>
<td>A representation of the plan that is used to recreate the actual execution plan, and that is database-independent. Operators in the tree correspond to operators that appear in the EXPLAIN output.</td>
</tr>
<tr>
<td>planning_time_ms</td>
<td>The actual time to run the planner, in milliseconds. This column is populated by the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
<tr>
<td><strong>dba_plans column</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>----------------------</td>
<td>----------------</td>
</tr>
<tr>
<td><code>queryId</code></td>
<td>A statement hash, as calculated by the pg_stat_statements extension. This isn't a stable or database-independent identifier because it depends on object identifiers (OIDs). The value will be 0 if <code>compute_query_id</code> is off when capturing the query plan.</td>
</tr>
<tr>
<td><code>sql_hash</code></td>
<td>A hash value of the SQL statement text, normalized with literals removed.</td>
</tr>
<tr>
<td><code>sql_text</code></td>
<td>The full text of the SQL statement.</td>
</tr>
<tr>
<td><code>status</code></td>
<td>A plan's status, which determines how the optimizer uses a plan. Valid values include the following.</td>
</tr>
<tr>
<td></td>
<td>• Approved – A usable plan that the optimizer can choose to run. The optimizer runs the least-cost plan from a managed statement's set of approved plans (baseline). To reset a plan to approved, use the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
<tr>
<td></td>
<td>• Unapproved – A captured plan that you have not verified for use. For more information, see Evaluating plan performance.</td>
</tr>
<tr>
<td></td>
<td>• Rejected – A plan that the optimizer won't use. For more information, see Rejecting or disabling slower plans.</td>
</tr>
<tr>
<td></td>
<td>• Preferred – A plan that you have determined is a preferred plan to use for a managed statement.</td>
</tr>
</tbody>
</table>

If the optimizer's minimum-cost plan isn't an approved or preferred plan, you can reduce plan enforcement overhead. To do so, make a subset of the approved plans Preferred. When the optimizer's minimum cost isn't an Approved plan, a Preferred plan is chosen before an Approved plan.

To reset a plan to Preferred, use the `apg_plan_mgmt.set_plan_status` function.
<table>
<thead>
<tr>
<th><strong>dba_plans column</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>stmt_name</td>
<td>The name of the SQL statement within a PREPARE statement. This value is an empty string for an unnamed prepared statement. This value is NULL for a nonprepared statement.</td>
</tr>
<tr>
<td>total_time_benefit_ms</td>
<td>The total time benefit in milliseconds of enabling this plan. This value considers both planning time and execution time.</td>
</tr>
<tr>
<td></td>
<td>If this value is negative, there is a disadvantage to enabling this plan. This column is populated by the <code>apg_plan_mgmt.evolve_plan_baselines</code> function.</td>
</tr>
</tbody>
</table>

**Advanced features in Query Plan Management**

Following you can find information about the advanced Aurora PostgreSQL Query Plan Management (QPM) features:

**Topics**

- Capturing Aurora PostgreSQL execution plans in Replicas
- Supporting table partition

**Capturing Aurora PostgreSQL execution plans in Replicas**

QPM (Query Plan Management) allows you to capture the query plans generated by Aurora Replicas and stores them on the primary DB instance of the Aurora DB cluster. You can collect the query plans from all the Aurora Replicas, and maintain a set of optimal plans in a central persistent table on the primary instance. You can then apply these plans on other Replicas when needed. This helps you to maintain the stability of execution plans and improve performance of the queries across the DB clusters and engine versions.

**Topics**

- Prerequisites
- Managing plan capture for Aurora Replicas
- Troubleshooting
Prerequisites

**Turn on capture_plan_baselines parameter in Aurora Replica** - Set capture_plan_baselines parameter to automatic or manual to capture plans in Aurora Replicas. For more information, see `apg_plan_mgmt.capture_plan_baselines`.

**Install postgres_fdw extension** - You must install `postgres_fdw` foreign data wrapper extension to capture plans in Aurora Replicas. Run the following command in each database, to install the extension.

```
postgres=> CREATE EXTENSION IF NOT EXISTS postgres_fdw;
```

Managing plan capture for Aurora Replicas

**Turn on plan capture for Aurora Replicas**

You must have `rds_superuser` privileges to create or remove Plan Capture in Aurora Replicas. For more information on user roles and permissions, see [Understanding PostgreSQL roles and permissions](#).

To capture plans, call the function `apg_plan_mgmt.create_replica_plan_capture` in the writer DB instance, as shown in the following:

```
postgres=> CALL apg_plan_mgmt.create_replica_plan_capture('cluster_endpoint', 'password');
```

- **cluster_endpoint** - `cluster_endpoint` (writer endpoint) provides failover support for Plan Capture in Aurora Replicas.
- **password** - We recommend you to follow the below guidelines while creating the password to enhance the security:
  - It must contain at least 8 characters.
  - It must contain at least one uppercase, one lowercase letter, and one number.
  - It must have at least one special character (`?`, `!`, `#`, `<`, `>`, `*`, and so on).

ℹ️ **Note**

If you change the `cluster endpoint`, `password`, or port number, you must run `apg_plan_mgmt.create_replica_plan_capture()` again with the cluster endpoint.
and password to re-initialize the plan capture. If not, capturing plans from Aurora Replicas will fail.

**Turn off plan capture for Aurora Replicas**

You can turn off `capture_plan_baselines` parameter in Aurora Replica by setting its value to `off` in the Parameter group.

**Remove plan capture for Aurora Replicas**

You can completely remove Plan Capture in Aurora Replicas but make sure before you do. To remove plan capture, call `apg_plan_mgmt.remove_replica_plan_capture` as shown:

```
postgres=> CALL apg_plan_mgmt.remove_replica_plan_capture();
```

You must call `apg_plan_mgmt.create_replica_plan_capture()` again to turn on plan capture in Aurora Replicas with the cluster endpoint and password.

**Troubleshooting**

Following, you can find troubleshooting ideas and workarounds if the plan is not captured in Aurora Replicas as expected.

- **Parameter settings** - Check if the `capture_plan_baselines` parameter is set to proper value to turn on plan capture.

- **`postgres_fdw` extension is installed** - Use the following query to check if `postgres_fdw` is installed.

  ```
  postgres=> SELECT * FROM pg_extension WHERE extname = 'postgres_fdw'
  ```

- **`create_replica_plan_capture()` is called** - Use the following command to check if the user mapping exits. Otherwise, call `create_replica_plan_capture()` to initialize the feature.

  ```
  postgres=> SELECT * FROM pg_foreign_server WHERE srvname = 'apg_plan_mgmt_writer_foreign_server';
  ```

- **Cluster endpoint and port number** - Check if the cluster endpoint and port number if appropriate. There won't be any error message displayed if these values are incorrect.
Use the following command to verify if the endpoint used in the create() and to check which database it resides in:

```
postgres=> SELECT srvoptions FROM pg_foreign_server WHERE srvname = 'apg_plan_mgmt_writer_foreign_server';
```

- **reload()** - You must call `apg_plan_mgmt.reload()` after calling `apg_plan_mgmt.delete_plan()` in Aurora Replicas to make the delete function effective. This ensures that the change has been successfully implemented.

- **Password** - You must enter password in `create_replica_plan_capture()` as per the guidelines mentioned. Otherwise, you will receive an error message. For more information, see [Managing plan capture for Aurora Replicas](#). Use another password that aligns with the requirements.

- **Cross-Region connection** - Plan capture in Aurora Replicas is also supported in Aurora global database, where writer instance and Aurora Replicas can be in different regions. The writer instance and cross-Region Replica must be able to communicate, using VPC Peering. For more information, see [VPC peering](#). If a cross-Region failover happens, you must reconfigure the endpoint to new primary DB cluster endpoint.

**Supporting table partition**

Aurora PostgreSQL Query Plan Management (QPM) supports declarative table partitioning in the following versions:

- 15.3 and higher 15 versions
- 14.8 and higher 14 versions
- 13.11 and higher 13 versions

For more information, see [Table Partitioning](#).

**Topics**

- Setting up table partition
- Capturing plans for table partition
- Enforcing a table partition plan
- Naming Convention
### Setting up table partition

To set up table partition in Aurora PostgreSQL QPM, do as follows:

1. Set `apg_plan_mgmt.plan_hash_version` to 3 or more in the DB cluster parameter group.
2. Navigate to a database that uses Query Plan Management and has entries in `apg_plan_mgmt.dba_plans` view.
3. Call `apg_plan_mgmt.validate_plans('update_plan_hash')` to update the `plan_hash` value in the plans table.
4. Repeat steps 2-3 for all databases with Query Plan Management enabled that have entries in `apg_plan_mgmt.dba_plans` view.

For more information on these parameters, see [Parameter reference for Aurora PostgreSQL query plan management](#).

### Capturing plans for table partition

In QPM, different plans are distinguished by their `plan_hash` value. To understand how the `plan_hash` changes, you must first understand similar kind of plans.

The combination of access methods, digit-stripped index names and digit-stripped partition names, accumulated at the Append node level must be constant for plans to be considered the same. The specific partitions accessed in the plans are not significant. In the following example, a table `tbl_a` is created with 4 partitions.

```sql
postgres=>create table tbl_a(i int, j int, k int, l int, m int) partition by range(i);
CREATE TABLE
postgres=>create table tbl_a1 partition of tbl_a for values from (0) to (1000);
CREATE TABLE
postgres=>create table tbl_a2 partition of tbl_a for values from (1001) to (2000);
CREATE TABLE
postgres=>create table tbl_a3 partition of tbl_a for values from (2001) to (3000);
CREATE TABLE
postgres=>create table tbl_a4 partition of tbl_a for values from (3001) to (4000);
CREATE TABLE
postgres=>create index t_i on tbl_a using btree (i);
CREATE INDEX
postgres=>create index t_j on tbl_a using btree (j);
CREATE INDEX
```
postges=>create index t_k on tbl_a using btree (k);
CREATE INDEX

The following plans are considered the same because a single scan method is being used to scan tbl_a irrespective of the number of partitions that the query looks up.

postges=>explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 999 and j < 9910 and k > 50;

QUERY PLAN

-------------------------------------------------------------------
Seq Scan on tbl_a1 tbl_a
  Filter: ((i >= 990) AND (i <= 999) AND (j < 9910) AND (k > 50))
SQL Hash: 1553185667, Plan Hash: -694232056
(3 rows)

postges=>explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 1100 and j < 9910 and k > 50;

QUERY PLAN

-------------------------------------------------------------------
Append
  -> Seq Scan on tbl_a1 tbl_a_1
     Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
  -> Seq Scan on tbl_a2 tbl_a_2
     Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
SQL Hash: 1553185667, Plan Hash: -694232056
(6 rows)

postges=>explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 2100 and j < 9910 and k > 50;

QUERY PLAN

-------------------------------------------------------------------
Append
  -> Seq Scan on tbl_a1 tbl_a_1
     Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
  -> Seq Scan on tbl_a2 tbl_a_2
     Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
  -> Seq Scan on tbl_a3 tbl_a_3
     Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
SQL Hash: 1553185667, Plan Hash: -694232056
The following 3 plans are also considered the same because at the parent level, the access methods, digit-stripped index names and digit-stripped partition names are `SeqScan tbl_a`, `IndexScan (i_idx) tbl_a`.

```
postgres=> explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 1100 and j < 9910 and k > 50;

QUERY PLAN

Append
  ->  Seq Scan on tbl_a1 tbl_a_1
    Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
  ->  Index Scan using tbl_a2_i_idx on tbl_a2 tbl_a_2
    Index Cond: ((i >= 990) AND (i <= 1100))
    Filter: ((j < 9910) AND (k > 50))

SQL Hash: 1553185667, Plan Hash: -993736942
(7 rows)
```

```
postgres=> explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 2100 and j < 9910 and k > 50;

QUERY PLAN

Append
  ->  Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
    Index Cond: ((i >= 990) AND (i <= 2100))
    Filter: ((j < 9910) AND (k > 50))
  ->  Seq Scan on tbl_a2 tbl_a_2
    Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
  ->  Index Scan using tbl_a3_i_idx on tbl_a3 tbl_a_3
    Index Cond: ((i >= 990) AND (i <= 2100))
    Filter: ((j < 9910) AND (k > 50))

SQL Hash: 1553185667, Plan Hash: -993736942
(10 rows)
```

```
postgres=> explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 3100 and j < 9910 and k > 50;

QUERY PLAN

```

Advanced features in Query Plan Management
Irrespective of different order and number of occurrences in child partitions, the access methods, digit-stripped index names and digit-stripped partition names are constant at the parent level for each of the above plans.

However, the plans would be considered different if any of the following conditions are met:

- Any additional access methods are used in the plan.

- Any of the access methods in the plan are not used anymore.

```
postgres=> explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 2100 and j < 9910 and k > 50;
```

```
Append
  -> Seq Scan on tbl_a1 tbl_a_1
     Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
  -> Seq Scan on tbl_a2 tbl_a_2
     Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
  -> Bitmap Heap Scan on tbl_a3 tbl_a_3
     Recheck Cond: ((i >= 990) AND (i <= 2100))
     Filter: ((j < 9910) AND (k > 50))
     -> Bitmap Index Scan on tbl_a3_i_idx
      Index Cond: ((i >= 990) AND (i <= 2100))
      SQL Hash: 1553185667, Plan Hash: 1134525070
(11 rows)
```
The index associated with an index method is changed.

```
postgres=> explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 1100 and j < 9910 and k > 50;
```

```
<table>
<thead>
<tr>
<th>QUERY PLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Append</td>
</tr>
<tr>
<td>-&gt; Seq Scan on tbl_a1 tbl_a_1</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>-&gt; Seq Scan on tbl_a2 tbl_a_2</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>SQL Hash: 1553185667, Plan Hash: -694232056</td>
</tr>
<tr>
<td>(7 rows)</td>
</tr>
</tbody>
</table>
```

**Enforcing a table partition plan**

Approved plans for partitioned tables are enforced with positional correspondence. The plans are not specific to the partitions, and can be enforced on partitions other than the plans referenced in the original query. Plans also have the capability of being enforced for queries accessing a different number of partitions than the original approved outline.

For example, if the approved outline is for the following plan:

```
postgres=> explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 2100 and j < 9910 and k > 50;
```

```
<table>
<thead>
<tr>
<th>QUERY PLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Append</td>
</tr>
<tr>
<td>-&gt; Seq Scan on tbl_a1 tbl_a_1</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>-&gt; Index Scan using tbl_a2_j_idx on tbl_a2 tbl_a_2</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>SQL Hash: 1553185667, Plan Hash: -993343726</td>
</tr>
<tr>
<td>(7 rows)</td>
</tr>
</tbody>
</table>
```
Then, this plan can be enforced on SQL queries referencing 2, 4, or more partitions as well. The possible plans that could arise from these scenarios for 2 and 4 partition access are:

```
postgres=>
explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 1100 and j < 9910 and k > 50;

QUERY PLAN

--------------------------------------------------------------------------------------------------
Append
  ->  Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
      Index Cond: ((i >= 990) AND (i <= 1100))
      Filter: ((j < 9910) AND (k > 50))
  ->  Seq Scan on tbl_a2 tbl_a_2
      Filter: ((i >= 990) AND (i <= 1100) AND (j < 9910) AND (k > 50))
Note: An Approved plan was used instead of the minimum cost plan.
SQL Hash: 1553185667, Plan Hash: -993736942, Minimum Cost Plan Hash: -1873216041
(8 rows)
```

```
postgres=>
explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 3100 and j < 9910 and k > 50;

QUERY PLAN

--------------------------------------------------------------------------
Append
  ->  Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
      Index Cond: ((i >= 990) AND (i <= 3100))
      Filter: ((j < 9910) AND (k > 50))
  ->  Seq Scan on tbl_a2 tbl_a_2
      Filter: ((i >= 990) AND (i <= 3100) AND (j < 9910) AND (k > 50))
  ->  Index Scan using tbl_a3_i_idx on tbl_a3 tbl_a_3
      Index Cond: ((i >= 990) AND (i <= 3100))
      Filter: ((j < 9910) AND (k > 50))
```

Advanced features in Query Plan Management
Consider another approved plan with different access methods for each partition:

postgres=>explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 2100 and j < 9910 and k > 50;

QUERY PLAN

--------------------------------------------------------------------------
Append
  ->  Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
      Index Cond: ((i >= 990) AND (i <= 2100))
      Filter: ((j < 9910) AND (k > 50))
  ->  Seq Scan on tbl_a2 tbl_a_2
      Filter: ((i >= 990) AND (i <= 2100) AND (j < 9910) AND (k > 50))
  ->  Bitmap Heap Scan on tbl_a3 tbl_a_3
      Recheck Cond: ((i >= 990) AND (i <= 2100))
      Filter: ((j < 9910) AND (k > 50))

Note: An Approved plan was used instead of the minimum cost plan.
SQL Hash: 1553185667, Plan Hash: -993736942, Minimum Cost Plan Hash: -1873216041
(14 rows)
In this case, any plan that reads from two partitions would fail to be enforced. Unless all of the (access method, index name) combinations from the approved plan are usable, the plan cannot be enforced. For example, the following plans have different plan hashes and the approved plan can't be enforced in these cases:

```
postgres=> explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 1900 and j < 9910 and k > 50;
```

**QUERY PLAN**

```
Append
  -> Bitmap Heap Scan on tbl_a1 tbl_a_1
      Recheck Cond: ((i >= 990) AND (i <= 1900))
      Filter: ((j < 9910) AND (k > 50))
  -> Bitmap Index Scan on tbl_a1_i_idx
      Index Cond: ((i >= 990) AND (i <= 1900))
-> Bitmap Heap Scan on tbl_a2 tbl_a_2
     Recheck Cond: ((i >= 990) AND (i <= 1900))
     Filter: ((j < 9910) AND (k > 50))
  -> Bitmap Index Scan on tbl_a2_i_idx
     Index Cond: ((i >= 990) AND (i <= 1900))
Note: This is not an Approved plan. No usable Approved plan was found.
SQL Hash: 1553185667, Plan Hash: -568647260
(13 rows)
```

```
postgres=> explain (hashes true, costs false) select j, k from tbl_a where i between 990 and 1900 and j < 9910 and k > 50;
```

**QUERY PLAN**

```
Append
  -> Index Scan using tbl_a1_i_idx on tbl_a1 tbl_a_1
      Index Cond: ((i >= 990) AND (i <= 1900))
      Filter: ((j < 9910) AND (k > 50))
  -> Seq Scan on tbl_a2 tbl_a_2
      Filter: ((i >= 990) AND (i <= 1900) AND (j < 9910) AND (k > 50))
Note: This is not an Approved plan. No usable Approved plan was found.
```
Naming Convention

For QPM to enforce a plan with declarative partitioned tables, you must follow specific naming rules for parent tables, table partitions, and indexes:

- **Parent table names** – These names must differ by alphabets or special characters, and not by just digits. For example, tA, tB, and tC are acceptable names for separate parent tables while t1, t2, and t3 are not.

- **Individual partition table names** – Partitions of the same parent should differ from one another by digits only. For example, acceptable partition names of tA could be tA1, tA2 or t1A, t2A or even multiple digits.

  Any other differences (letters, special characters) will not guarantee plan enforcement.

- **Index names** – In partition table hierarchy, make sure that all indexes have unique names. This means that the non-numeric parts of the names must be different. For example, if you have a partitioned table named tA with an index named tA_col1_idx1, you can't have another index named tA_col1_idx2. However, you can have an index called tA_a_col1_idx2 because the non-numeric part of the name is unique. This rule applies to indexes created on both the parent table and individual partition tables.

Failure to adhere to the above naming conventions may result in failure of approved plans enforcement. The following example illustrates such a failed enforcement:

```
postgres=>create table t1(i int, j int, k int, l int, m int) partition by range(i);
CREATE TABLE
postgres=>create table t1a partition of t1 for values from (0) to (1000);
CREATE TABLE
postgres=>create table t1b partition of t1 for values from (1001) to (2000);
CREATE TABLE
postgres=>SET apg_plan_mgmt.capture_plan_baselines TO 'manual';
SET
postgres=>explain (hashes true, costs false) select count(*) from t1 where i > 0;
QUERY PLAN

Aggregate
- >  Append
```

Advanced features in Query Plan Management
Even though the two plans might appear identical, their Plan Hash values are different due to the names of the child tables. The table names vary by alpha characters instead of just digits leading to an enforcement failure.
To extend the functionality to your Aurora PostgreSQL-Compatible Edition DB cluster, you can install and use various PostgreSQL extensions. For example, if your use case calls for intensive data entry across very large tables, you can install the `pg_partman` extension to partition your data and thus spread the workload.

### Note
As of Aurora PostgreSQL 14.5, Aurora PostgreSQL supports Trusted Language Extensions for PostgreSQL. This feature is implemented as the extension `pg_tle`, which you can add to your Aurora PostgreSQL. By using this extension, developers can create their own PostgreSQL extensions in a safe environment that simplifies the setup and configuration requirements, as well as much of the preliminary testing for new extensions. For more information, see [Working with Trusted Language Extensions for PostgreSQL](#).

In some cases, rather than installing an extension, you might add a specific module to the list of `shared_preload_libraries` in your Aurora PostgreSQL DB cluster's custom DB cluster parameter group. Typically, the default DB cluster parameter group loads only the `pg_stat_statements`, but several other modules are available to add to the list. For example, you can add scheduling capability by adding the `pg_cron` module, as detailed in [Scheduling maintenance with the PostgreSQL pg_cron extension](#). As another example, you can log query execution plans by loading the `auto_explain` module. To learn more, see [Logging execution plans of queries](#) in the AWS knowledge center.

An extension that provides access to external data is more specifically known as a foreign data wrapper (FDW). As one example, the `oracle_fdw` extension allows your Aurora PostgreSQL DB cluster to work with Oracle databases.

You can also specify precisely which extensions can be installed on your Aurora PostgreSQL DB instance, by listing them in the `rds.allowed_extensions` parameter. For more information, see [Restricting installation of PostgreSQL extensions](#).

Following, you can find information about setting up and using some of the extensions, modules, and FDWs available for Aurora PostgreSQL. For simplicity's sake, these are all referred to as "extensions." You can find listings of extensions that you can use with the currently available
Aurora PostgreSQL versions, see Extension versions for Amazon Aurora PostgreSQL in the Release Notes for Aurora PostgreSQL.

- Managing large objects with the lo module
- Managing spatial data with the PostGIS extension
- Managing PostgreSQL partitions with the pg_partman extension
- Scheduling maintenance with the PostgreSQL pg_cron extension
- Using pgAudit to log database activity
- Using pglogical to synchronize data across instances
- Working with Oracle databases by using the oracle_fdw extension
- Working with SQL Server databases by using the tds_fdw extension

**Using Amazon Aurora delegated extension support for PostgreSQL**

Using Amazon Aurora delegated extension support for PostgreSQL, you can delegate the extension management to a user who need not be an rds_superuser. With this delegated extension support, a new role called rds_extension is created and you must assign this to a user to manage other extensions. This role can create, update, and drop extensions.

You can specify the extensions that can be installed on your Aurora PostgreSQL DB instance, by listing them in the rds.allowed_extensions parameter. For more information, see Using PostgreSQL extensions with Amazon RDS for PostgreSQL.

You can restrict the list of extensions available that can be managed by the user with the rds_extension role using rds.allowed_delegated_extensions parameter.

The delegated extension support is available in the following versions:

- All higher versions
- 15.5 and higher 15 versions
- 14.10 and higher 14 versions
- 13.13 and higher 13 versions
- 12.17 and higher 12 versions

**Topics**
Turning on delegate extension support to a user

You must perform the following to enable delegate extension support to a user:

1. **Grant rds_extension role to a user** – Connect to the database as rds_superuser and execute the following command:

   ```
   Postgres => grant rds_extension to user_name;
   ```

2. **Set the list of extensions available for delegated users to manage** – The rds.allowed_delegated_extensions allows you to specify a subset of the available extensions using rds.allowed_extensions in the DB cluster parameter. You can perform this at one of the following levels:

   - In the cluster or the instance parameter group, through the AWS Management Console or API. For more information, see Working with parameter groups.
   - Use the following command at the database level:

     ```
     alter database database_name set rds.allowed_delegated_extensions = 'extension_name_1,
     extension_name_2,...extension_name_n';
     ```

   - Use the following command at the user level:

     ```
     alter user user_name set rds.allowed_delegated_extensions = 'extension_name_1,
     extension_name_2,...extension_name_n';
     ```
### Note

You need not restart the database after changing the `rds.allowed_delegated_extensions` dynamic parameter.

3. **Allow access to the delegated user to objects created during the extension creation process**

   Certain extensions create objects that require additional permissions to be granted before the user with `rds_extension` role can access them. The `rds_superuser` must grant the delegated user access to those objects. One of the options is to use an event trigger to automatically grant permission to the delegated user. For more information, refer to the event trigger example in [Turning off the support for the delegated extension](#).

### Configuration used in Aurora delegated extension support for PostgreSQL

<table>
<thead>
<tr>
<th>Configuration Name</th>
<th>Description</th>
<th>Default Value</th>

</thead>
<tbody>
<tr>
<td>rds-delegated_extension_allow_drop_cascade</td>
<td>This parameter controls the ability for users with rds_extension to drop the extension using a cascade option.</td>
<td>off</td>
<td>By default, rds-delegated_extension_allow_drop_cascade is set to off. This means that users with rds_extension are not allowed to drop an extension using the cascade option.</td>
<td>rds_superuser</td>
</tr>
</tbody>
</table>

**Turning off the support for the delegated extension**

**Turning off partially**

The delegated users can’t create new extensions but can still update existing extensions.

- Reset rds.allowed_delegated_extensions to the default value in the DB cluster parameter group.
- Use the following command at the database level:
alter database database_name reset rds.allowed_delegated_extensions;

- Use the following command at the user level:

    alter user user_name reset rds.allowed_delegated_extensions;

**Turning off fully**

Revoking rds_extension role from a user will revert the user to standard permissions. The user can no longer create, update, or drop extensions.

    postgres => revoke rds_extension from user_name;

**Example of event trigger**

If you want to allow a delegated user with rds_extension to use extensions that require setting permissions on their objects created by the extension creation, you can customize the below example of an event trigger and add only the extensions for which you want the delegated users to have access to the full functionality. This event trigger can be created on template1 (the default template), therefore all database created from template1 will have that event trigger. When a delegated user installs the extension, this trigger will automatically grant ownership on the objects created by the extension.

    CREATE OR REPLACE FUNCTION create_ext()

          RETURNS event_trigger AS $$

CREATE EVENT TRIGGER log_create_ext ON ddl_command_end EXECUTE PROCEDURE create_ext();

Benefits of using Amazon Aurora delegated extension support

By using Amazon Aurora delegated extension support for PostgreSQL, you securely delegate the extension management to users who do not have the rds_superuser role. This feature provides the following benefits:

- You can easily delegate extension management to users of your choice.
- This doesn’t require rds_superuser role.
- Provides ability to support different set of extensions for different databases in the same DB cluster.

Limitation of Aurora delegated extension support for PostgreSQL

- Objects created during the extension creation process may require additional privileges for the extension to function properly.

Permissions required for certain extensions

In order to create, use, or update the following extensions, the delegated user should have the necessary privileges on the following functions, tables, and schema.
<table>

**Security Considerations**

Keep in mind that a user with rds_extension role will be able to manage extensions on all databases they have the connect privilege on. If the intention is to have a delegated user manage extension on a single database, a good practice is to revoke all privileges from public on each database, then explicitly grant the connect privilege for that specific database to the delegate user.
There are several extensions that can allow a user to access information from multiple database. Ensure the users you grant rds_extension has cross database capabilities before adding these extensions to rds.allowed_delegated_extensions. For example, postgres_fdw and dblink provide functionality to query across databases on the same instance or remote instances. log_fdw reads the postgres engine log files, which are for all databases in the instance, potentially containing slow queries or error messages from multiple databases. pg_cron enables running scheduled background jobs on the DB instance and can configure jobs to run in a different database.

**Drop extension cascade disabled**

The ability to drop the extension with cascade option by a user with the rds_extension role is controlled by rds.delegated_extension_allow_drop_cascade parameter. By default, rds-delegated_extension_allow_drop_cascade is set to off. This means that users with the rds_extension role are not allowed to drop an extension using the cascade option as shown in the below query.

```
DROP EXTENSION CASCADE;
```

As this will automatically drop objects that depend on the extension, and in turn all objects that depend on those objects. Attempting to use the cascade option will result in an error.

To grant that ability, the rds.delegated_extension_allow_drop_cascade parameter should be set to on.

Changing the rds.delegated_extension_allow_drop_cascade dynamic parameter doesn't require a database restart. You can do this at one of the following levels:

- In the cluster or the instance parameter group, through the AWS Management Console or API.
- Using the following command at the database level:

```
alter database database_name set rds.delegated_extension_allow_drop_cascade = 'on';
```

- Using the following command at the user level:

```
alter role tenant_user set rds.delegated_extension_allow_drop_cascade = 'on';
```
Example extensions that can be added using delegated extension support

- rds_tools

```sql
extension_test_db=> create extension rds_tools;
CREATE EXTENSION
extension_test_db=> SELECT * from rds_tools.role_password_encryption_type() where rolname = 'pg_read_server_files';
ERROR: permission denied for function role_password_encryption_type
```

- amcheck

```sql
extension_test_db=> CREATE TABLE amcheck_test (id int);
CREATE TABLE
extension_test_db=> INSERT INTO amcheck_test VALUES (generate_series(1,100000));
INSERT 0 100000
extension_test_db=> CREATE INDEX amcheck_test_btree_idx ON amcheck_test USING btree (id);
CREATE INDEX
extension_test_db=> create extension amcheck;
CREATE EXTENSION
extension_test_db=> SELECT bt_index_check('amcheck_test_btree_idx'::regclass);
ERROR: permission denied for function bt_index_check
extension_test_db=> SELECT bt_index_parent_check('amcheck_test_btree_idx'::regclass);
ERROR: permission denied for function bt_index_parent_check
```

- pg_freespacemap

```sql
extension_test_db=> create extension pg_freespacemap;
CREATE EXTENSION
extension_test_db=> SELECT * FROM pg_freespace('pg_authid');
ERROR: permission denied for function pg_freespace
extension_test_db=> SELECT * FROM pg_freespace('pg_authid',0);
ERROR: permission denied for function pg_freespace
```

- pg_visibility

```sql
extension_test_db=> create extension pg_visibility;
CREATE EXTENSION
extension_test_db=> select * from pg_visibility('pg_database'::regclass);
ERROR: permission denied for function pg_visibility
```

- postgres_fdw

```sql
extension_test_db=> create extension postgres_fdw;
CREATE EXTENSION
```
Managing large objects with the lo module

The lo module (extension) is for database users and developers working with PostgreSQL databases through JDBC or ODBC drivers. Both JDBC and ODBC expect the database to handle deletion of large objects when references to them change. However, PostgreSQL doesn't work that way. PostgreSQL doesn't assume that an object should be deleted when its reference changes. The result is that objects remain on disk, unreferenced. The lo extension includes a function that you use to trigger on reference changes to delete objects if needed.

Tip

To determine if your database can benefit from the lo extension, use the vacuumlo utility to check for orphaned large objects. To get counts of orphaned large objects without taking any action, run the utility with the -n option (no-op). To learn how, see vacuumlo utility following.

The lo module is available for Aurora PostgreSQL 13.7, 12.11, 11.16, 10.21 and higher minor versions.

To install the module (extension), you need rds_superuser privileges. Installing the lo extension adds the following to your database:

- lo – This is a large object (lo) data type that you can use for binary large objects (BLOBs) and other large objects. The lo data type is a domain of the oid data type. In other words, it's an object identifier with optional constraints. For more information, see Object identifiers in the PostgreSQL documentation. In simple terms, you can use the lo data type to distinguish your database columns that hold large object references from other object identifiers (OIDs).

- lo_manage – This is a function that you can use in triggers on table columns that contain large object references. Whenever you delete or modify a value that references a large object, the...
trigger unlinks the object (lo_unlink) from its reference. Use the trigger on a column only if the column is the sole database reference to the large object.

For more information about the large objects module, see lo in the PostgreSQL documentation.

**Installing the lo extension**

Before installing the lo extension, make sure that you have rds_superuser privileges.

**To install the lo extension**

1. Use psql to connect to the primary DB instance of your Aurora PostgreSQL DB cluster.

   ```bash
   psql --host=your-cluster-instance-1.666666666666.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
   ```

   When prompted, enter your password. The psql client connects and displays the default administrative connection database, postgres=>, as the prompt.

2. Install the extension as follows.

   ```sql
   postgres=> CREATE EXTENSION lo;
   ```

   You can now use the lo data type to define columns in your tables. For example, you can create a table (images) that contains raster image data. You can use the lo data type for a column raster, as shown in the following example, which creates a table.

   ```sql
   postgres=> CREATE TABLE images (image_name text, raster lo);
   ```

**Using the lo_manage trigger function to delete objects**

You can use the lo_manage function in a trigger on a lo or other large object columns to clean up (and prevent orphaned objects) when the lo is updated or deleted.

**To set up triggers on columns that reference large objects**

- Do one of the following:
• Create a BEFORE UPDATE OR DELETE trigger on each column to contain unique references to large objects, using the column name for the argument.

```sql
postgres=> CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON images
          FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

• Apply a trigger only when the column is being updated.

```sql
postgres=> CREATE TRIGGER t_raster BEFORE UPDATE OF images
          FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

The `lo_manage` trigger function works only in the context of inserting or deleting column data, depending on how you define the trigger. It has no effect when you perform a DROP or TRUNCATE operation on a database. That means that you should delete object columns from any tables before dropping, to prevent creating orphaned objects.

For example, suppose that you want to drop the database containing the `images` table. You delete the column as follows.

```sql
postgres=> DELETE FROM images COLUMN raster
```

Assuming that the `lo_manage` function is defined on that column to handle deletes, you can now safely drop the table.

### Using the vacuumlo utility

The `vacuumlo` utility identifies and can remove orphaned large objects from databases. This utility has been available since PostgreSQL 9.1.24. If your database users routinely work with large objects, we recommend that you run `vacuumlo` occasionally to clean up orphaned large objects.

Before installing the lo extension, you can use `vacuumlo` to assess whether your Aurora PostgreSQL DB cluster can benefit. To do so, run `vacuumlo` with the `-n` option (no-op) to show what would be removed, as shown in the following:

```bash
$ vacuumlo -v -n -h your-cluster-instance-1.6666666666666666.aws-region.rds.amazonaws.com -p 5433 -U postgres docs-lab-spatial-db
Password:*****
Connected to database "docs-lab-spatial-db"
Test run: no large objects will be removed!
```
Would remove 0 large objects from database "docs-lab-spatial-db".

As the output shows, orphaned large objects aren't a problem for this particular database.

For more information about this utility, see `vacuumlo` in the PostgreSQL documentation.

**Managing spatial data with the PostGIS extension**

PostGIS is an extension to PostgreSQL for storing and managing spatial information. To learn more about PostGIS, see [PostGIS.net](http://PostGIS.net).

Starting with version 10.5, PostgreSQL supports the libprotobuf 1.3.0 library used by PostGIS for working with map box vector tile data.

Setting up the PostGIS extension requires `rds_superuser` privileges. We recommend that you create a user (role) to manage the PostGIS extension and your spatial data. The PostGIS extension and its related components add thousands of functions to PostgreSQL. Consider creating the PostGIS extension in its own schema if that makes sense for your use case. The following example shows how to install the extension in its own database, but this isn't required.

**Topics**

- Step 1: Create a user (role) to manage the PostGIS extension
- Step 2: Load the PostGIS extensions
- Step 3: Transfer ownership of the extensions
- Step 4: Transfer ownership of the PostGIS objects
- Step 5: Test the extensions
- Step 6: Upgrade the PostGIS extension
- PostGIS extension versions
- Upgrading PostGIS 2 to PostGIS 3

**Step 1: Create a user (role) to manage the PostGIS extension**

First, connect to your RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges. If you kept the default name when you set up your instance, you connect as `postgres`.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password
```
Create a separate role (user) to administer the PostGIS extension.

```
postgres-> CREATE ROLE gis_admin LOGIN PASSWORD 'change_me';
```

Grant this role rds_superuser privileges, to allow the role to install the extension.

```
postgres-> GRANT rds_superuser TO gis_admin;
```

Create a database to use for your PostGIS artifacts. This step is optional. Or you can create a schema in your user database for the PostGIS extensions, but this also isn't required.

```
postgres-> CREATE DATABASE lab_gis;
```

Give the gis_admin all privileges on the lab_gis database.

```
postgres-> GRANT ALL PRIVILEGES ON DATABASE lab_gis TO gis_admin;
```

Exit the session and reconnect to your RDS for PostgreSQL DB instance as gis_admin.

```
postgres> psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=gis_admin --password --dbname=lab_gis
Password for user gis_admin:...
lab_gis=>
```

Continue setting up the extension as detailed in the next steps.

**Step 2: Load the PostGIS extensions**

The PostGIS extension includes several related extensions that work together to provide geospatial functionality. Depending on your use case, you might not need all the extensions created in this step.

Use CREATE EXTENSION statements to load the PostGIS extensions.

```
CREATE EXTENSION postgis;
```
CREATE EXTENSION postgis_raster;
 CREATE EXTENSION fuzzystrmatch;
 CREATE EXTENSION postgis_tiger_geocoder;
 CREATE EXTENSION postgis_topology;
 CREATE EXTENSION address_standardizer_data_us;

You can verify the results by running the SQL query shown in the following example, which lists the extensions and their owners.

```
SELECT n.nspname AS "Name",
    pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
FROM pg_catalog.pg_namespace n
WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
ORDER BY 1;
```

List of schemas

<table>
<thead>
<tr>
<th>Name</th>
<th>Owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>postgres</td>
</tr>
<tr>
<td>tiger</td>
<td>rdsadmin</td>
</tr>
<tr>
<td>tiger_data</td>
<td>rdsadmin</td>
</tr>
<tr>
<td>topology</td>
<td>rdsadmin</td>
</tr>
</tbody>
</table>

(4 rows)

### Step 3: Transfer ownership of the extensions

Use the ALTER SCHEMA statements to transfer ownership of the schemas to the gis_admin role.

```
ALTER SCHEMA tiger OWNER TO gis_admin;
ALTER SCHEMA tiger_data OWNER TO gis_admin;
ALTER SCHEMA topology OWNER TO gis_admin;
```

You can confirm the ownership change by running the following SQL query. Or you can use the \dn metacommand from the psql command line.
```sql
SELECT n.nspname AS "Name",
    pg_catalog.pg_get_userbyid(n.nspowner) AS "Owner"
FROM pg_catalog.pg_namespace n
WHERE n.nspname !~ '^pg_' AND n.nspname <> 'information_schema'
ORDER BY 1;
```

List of schemas

<table>
<thead>
<tr>
<th>Name</th>
<th>Owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>postgres</td>
</tr>
<tr>
<td>tiger</td>
<td>gis_admin</td>
</tr>
<tr>
<td>tiger_data</td>
<td>gis_admin</td>
</tr>
<tr>
<td>topology</td>
<td>gis_admin</td>
</tr>
</tbody>
</table>

(4 rows)

**Step 4: Transfer ownership of the PostGIS objects**

Use the following function to transfer ownership of the PostGIS objects to the gis_admin role. Run the following statement from the psql prompt to create the function.

```sql
CREATE FUNCTION exec(text) returns text language plpgsql volatile AS $f$
BEGIN EXECUTE $1; RETURN $1; END; $f$;
CREATE FUNCTION
```

Next, run the following query to run the exec function that in turn runs the statements and alters the permissions.

```sql
SELECT exec('ALTER TABLE ' || quote_ident(s.nspname) || '.' || quote_ident(s.relname) || ' OWNER TO gis_admin;')
FROM (SELECT nspname, relname
      FROM pg_class c JOIN pg_namespace n ON (c.relnamespace = n.oid)
      WHERE nspname in ('tiger','topology') AND relkind IN ('r','S','v') ORDER BY relkind = 'S') s;
```

**Step 5: Test the extensions**

To avoid needing to specify the schema name, add the tiger schema to your search path using the following command.
SET search_path=public,tiger;

Test the tiger schema by using the following SELECT statement.

```
SELECT address, streetname, streettypeabbrev, zip  
FROM normalize_address('1 Devonshire Place, Boston, MA 02109') AS na;
```

<table>
<thead>
<tr>
<th>address</th>
<th>streetname</th>
<th>streettypeabbrev</th>
<th>zip</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Devonshire</td>
<td>Pl</td>
<td>02109</td>
</tr>
</tbody>
</table>

(1 row)

To learn more about this extension, see Tiger Geocoder in the PostGIS documentation.

Test access to the topology schema by using the following SELECT statement. This calls the createtopology function to register a new topology object (my_new_topo) with the specified spatial reference identifier (26986) and default tolerance (0.5). To learn more, see CreateTopology in the PostGIS documentation.

```
SELECT topology.createtopology('my_new_topo',26986,0.5);
```

<table>
<thead>
<tr>
<th>createtopology</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

(1 row)

**Step 6: Upgrade the PostGIS extension**

Each new release of PostgreSQL supports one or more versions of the PostGIS extension compatible with that release. Upgrading the PostgreSQL engine to a new version doesn't automatically upgrade the PostGIS extension. Before upgrading the PostgreSQL engine, you typically upgrade PostGIS to the newest available version for the current PostgreSQL version. For details, see PostGIS extension versions.

After the PostgreSQL engine upgrade, you then upgrade the PostGIS extension again, to the version supported for the newly upgraded PostgreSQL engine version. For more information about upgrading the PostgreSQL engine, see Testing an upgrade of your production DB cluster to a new major version.
You can check for available PostGIS extension version updates on your Aurora PostgreSQL DB cluster at any time. To do so, run the following command. This function is available with PostGIS 2.5.0 and higher versions.

```sql
SELECT postGIS_extensions_upgrade();
```

If your application doesn't support the latest PostGIS version, you can install an older version of PostGIS that's available in your major version as follows.

```sql
CREATE EXTENSION postgis VERSION "2.5.5";
```

If you want to upgrade to a specific PostGIS version from an older version, you can also use the following command.

```sql
ALTER EXTENSION postgis UPDATE TO "2.5.5";
```

Depending on the version that you're upgrading from, you might need to use this function again. The result of the first run of the function determines if an additional upgrade function is needed. For example, this is the case for upgrading from PostGIS 2 to PostGIS 3. For more information, see [Upgrading PostGIS 2 to PostGIS 3](#).

If you upgraded this extension to prepare for a major version upgrade of the PostgreSQL engine, you can continue with other preliminary tasks. For more information, see [Testing an upgrade of your production DB cluster to a new major version](#).

### PostGIS extension versions

We recommend that you install the versions of all extensions such as PostGIS as listed in [Extension versions for Aurora PostgreSQL-Compatible Edition](#) in the [Release Notes for Aurora PostgreSQL](#). To get a list of versions that are available in your release, use the following command.

```sql
SELECT * FROM pg_available_extension_versions WHERE name='postgis';
```

You can find version information in the following sections in the [Release Notes for Aurora PostgreSQL](#):

- [Extension versions for Aurora PostgreSQL 14](#)
- [Extension versions for Aurora PostgreSQL-Compatible Edition 13](#)
- [Extension versions for Aurora PostgreSQL-Compatible Edition 12](#)
Upgrading PostGIS 2 to PostGIS 3

Starting with version 3.0, the PostGIS raster functionality is now a separate extension, *postgis_raster*. This extension has its own installation and upgrade path. This removes dozens of functions, data types, and other artifacts required for raster image processing from the core *postgis* extension. That means that if your use case doesn't require raster processing, you don't need to install the *postgis_raster* extension.

In the following upgrade example, the first upgrade command extracts raster functionality into the *postgis_raster* extension. A second upgrade command is then required to upgrade *postgres_raster* to the new version.

**To upgrade from PostGIS 2 to PostGIS 3**

1. Identify the default version of PostGIS that's available to the PostgreSQL version on your Aurora PostgreSQL DB cluster. To do so, run the following query.

```sql
SELECT * FROM pg_available_extensions
WHERE default_version > installed_version;
```

<table>
<thead>
<tr>
<th>name</th>
<th>default_version</th>
<th>installed_version</th>
<th>comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgis</td>
<td>3.1.4</td>
<td>2.3.7</td>
<td>PostGIS geometry and geography spatial types and functions</td>
</tr>
</tbody>
</table>

2. Identify the versions of PostGIS installed in each database on the writer instance of your Aurora PostgreSQL DB cluster. In other words, query each user database as follows.

```sql
SELECT e.extname AS "Name",
       e.extversion AS "Version",
       n.nspname AS "Schema",
       c.description AS "Description"
FROM pg_catalog.pg_extension e
```
This mismatch between the default version (PostGIS 3.1.4) and the installed version (PostGIS 2.3.7) means that you need to upgrade the PostGIS extension.

ALTER EXTENSION postgis UPDATE;
ALTER EXTENSION
WARNING: unpackaging raster
WARNING: PostGIS Raster functionality has been unpackaged

3. Run the following query to verify that the raster functionality is now in its own package.

The output shows that there's still a difference between versions. The PostGIS functions are version 3 (postgis-3), while the raster functions (rtpostgis) are version 2 (rtpostgis-2.3). To complete the upgrade, you run the upgrade command again, as follows.
You can safely ignore the warning messages. Run the following query again to verify that the upgrade is complete. The upgrade is complete when PostGIS and all related extensions aren't marked as needing upgrade.

```
SELECT postgis_full_version();
```

4. Use the following query to see the completed upgrade process and the separately packaged extensions, and verify that their versions match.

```
SELECT 
    e.extname AS "Name",
    e.extversion AS "Version",
    n.nspname AS "Schema",
    c.description AS "Description"
FROM
    pg_catalog.pg_extension e
LEFT JOIN pg_catalog.pg_namespace n ON n.oid = e.extnamespace
LEFT JOIN pg_catalog.pg_description c ON c.objoid = e.oid
    AND c.classoid = 'pg_catalog.pg_extension'::pg_catalog.regclass
WHERE
    e.extname LIKE '%postgis%'
ORDER BY
    1;
```

```
<table>
<thead>
<tr>
<th>Name</th>
<th>Version</th>
<th>Schema</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgis</td>
<td>3.1.5</td>
<td>public</td>
<td>PostGIS geometry, geography, and raster spatial types and functions</td>
</tr>
<tr>
<td>postgis_raster</td>
<td>3.1.5</td>
<td>public</td>
<td>PostGIS raster types and functions</td>
</tr>
</tbody>
</table>
```

The output shows that the PostGIS 2 extension was upgraded to PostGIS 3, and both `postgis` and the now separate `postgis_raster` extension are version 3.1.5.

After this upgrade completes, if you don't plan to use the raster functionality, you can drop the extension as follows.
Managing PostgreSQL partitions with the pg_partman extension

PostgreSQL table partitioning provides a framework for high-performance handling of data input and reporting. Use partitioning for databases that require very fast input of large amounts of data. Partitioning also provides for faster queries of large tables. Partitioning helps maintain data without impacting the database instance because it requires less I/O resources.

By using partitioning, you can split data into custom-sized chunks for processing. For example, you can partition time-series data for ranges such as hourly, daily, weekly, monthly, quarterly, yearly, custom, or any combination of these. For a time-series data example, if you partition the table by hour, each partition contains one hour of data. If you partition the time-series table by day, the partitions holds one day's worth of data, and so on. The partition key controls the size of a partition.

When you use an INSERT or UPDATE SQL command on a partitioned table, the database engine routes the data to the appropriate partition. PostgreSQL table partitions that store the data are child tables of the main table.

During database query reads, the PostgreSQL optimizer examines the WHERE clause of the query and, if possible, directs the database scan to only the relevant partitions.

Starting with version 10, PostgreSQL uses declarative partitioning to implement table partitioning. This is also known as native PostgreSQL partitioning. Before PostgreSQL version 10, you used triggers to implement partitions.

PostgreSQL table partitioning provides the following features:

- Creation of new partitions at any time.
- Variable partition ranges.
- Detachable and reattachable partitions using data definition language (DDL) statements.

  For example, detachable partitions are useful for removing historical data from the main partition but keeping historical data for analysis.

- New partitions inherit the parent database table properties, including the following:
  - Indexes
- Primary keys, which must include the partition key column
- Foreign keys
- Check constraints
- References
- Creating indexes for the full table or each specific partition.

You can't alter the schema for an individual partition. However, you can alter the parent table (such as adding a new column), which propagates to partitions.

**Topics**

- [Overview of the PostgreSQL `pg_partman` extension](#)
- [Enabling the `pg_partman` extension](#)
- [Configuring partitions using the `create_parent` function](#)
- [Configuring partition maintenance using the `run_maintenance_proc` function](#)

**Overview of the PostgreSQL `pg_partman` extension**

You can use the PostgreSQL `pg_partman` extension to automate the creation and maintenance of table partitions. For more general information, see [PG Partition Manager](#) in the `pg_partman` documentation.

⚠️ **Note**

The `pg_partman` extension is supported on Aurora PostgreSQL versions 12.6 and higher.

Instead of having to manually create each partition, you configure `pg_partman` with the following settings:

- Table to be partitioned
- Partition type
- Partition key
- Partition granularity
- Partition precreation and management options
After you create a PostgreSQL partitioned table, you register it with `pg_partman` by calling the `create_parent` function. Doing this creates the necessary partitions based on the parameters you pass to the function.

The `pg_partman` extension also provides the `run_maintenance_proc` function, which you can call on a scheduled basis to automatically manage partitions. To ensure that the proper partitions are created as needed, schedule this function to run periodically (such as hourly). You can also ensure that partitions are automatically dropped.

## Enabling the `pg_partman` extension

If you have multiple databases inside the same PostgreSQL DB instance for which you want to manage partitions, enable the `pg_partman` extension separately for each database. To enable the `pg_partman` extension for a specific database, create the partition maintenance schema and then create the `pg_partman` extension as follows.

```sql
CREATE SCHEMA partman;
CREATE EXTENSION pg_partman WITH SCHEMA partman;
```

### Note

To create the `pg_partman` extension, make sure that you have `rds_superuser` privileges.

If you receive an error such as the following, grant the `rds_superuser` privileges to the account or use your superuser account.

```
ERROR: permission denied to create extension "pg_partman"
HINT: Must be superuser to create this extension.
```

To grant `rds_superuser` privileges, connect with your superuser account and run the following command.

```
GRANT rds_superuser TO user-or-role;
```

For the examples that show using the `pg_partman` extension, we use the following sample database table and partition. This database uses a partitioned table based on a timestamp.
schema data_mart contains a table named events with a column named created_at. The following settings are included in the events table:

- Primary keys event_id and created_at, which must have the column used to guide the partition.
- A check constraint ck_valid_operation to enforce values for an operation table column.
- Two foreign keys, where one (fk_orga_membership) points to the external table organization and the other (fk_parent_event_id) is a self-referenced foreign key.
- Two indexes, where one (idx_org_id) is for the foreign key and the other (idx_event_type) is for the event type.

The following DDL statements create these objects, which are automatically included on each partition.

```sql
CREATE SCHEMA data_mart;
CREATE TABLE data_mart.organization ( org_id BIGSERIAL,
   org_name TEXT,
   CONSTRAINT pk_organization PRIMARY KEY (org_id)
);

CREATE TABLE data_mart.events(
   event_id        BIGSERIAL,
   operation       CHAR(1),
   value           FLOAT(24),
   parent_event_id BIGINT,
   event_type      VARCHAR(25),
   org_id          BIGSERIAL,
   created_at      timestamp,
   CONSTRAINT pk_data_mart_event PRIMARY KEY (event_id, created_at),
   CONSTRAINT ck_valid_operation CHECK (operation = 'C' OR operation = 'D'),
   CONSTRAINT fk_orga_membership
      FOREIGN KEY(org_id)
      REFERENCES data_mart.organization (org_id),
   CONSTRAINT fk_parent_event_id
      FOREIGN KEY(parent_event_id, created_at)
      REFERENCES data_mart.events (event_id,created_at)
 ) PARTITION BY RANGE (created_at);

CREATE INDEX idx_org_id     ON  data_mart.events(org_id);
CREATE INDEX idx_event_type ON  data_mart.events(event_type);
```
Configuring partitions using the create_parent function

After you enable the pg_partman extension, use the create_parent function to configure partitions inside the partition maintenance schema. The following example uses the events table example created in Enabling the pg_partman extension. Call the create_parent function as follows.

```sql
SELECT partman.create_parent( p_parent_table => 'data_mart.events',
                             p_control => 'created_at',
                             p_type => 'native',
                             p_interval=> 'daily',
                             p_premake => 30);
```

The parameters are as follows:

- **p_parent_table** – The parent partitioned table. This table must already exist and be fully qualified, including the schema.
- **p_control** – The column on which the partitioning is to be based. The data type must be an integer or time-based.
- **p_type** – The type is either 'native' or 'partman'. You typically use the native type for its performance improvements and flexibility. The partman type relies on inheritance.
- **p_interval** – The time interval or integer range for each partition. Example values include daily, hourly, and so on.
- **p_premake** – The number of partitions to create in advance to support new inserts.

For a complete description of the create_parent function, see Creation Functions in the pg_partman documentation.

Configuring partition maintenance using the run_maintenance_proc function

You can run partition maintenance operations to automatically create new partitions, detach partitions, or remove old partitions. Partition maintenance relies on the run_maintenance_proc function of the pg_partman extension and the pg_cron extension, which initiates an internal scheduler. The pg_cron scheduler automatically executes SQL statements, functions, and procedures defined in your databases.
The following example uses the events table example created in [Enabling the pg_partman extension](#) to set partition maintenance operations to run automatically. As a prerequisite, add pg_cron to the shared_preload_libraries parameter in the DB instance's parameter group.

```
CREATE EXTENSION pg_cron;

UPDATE partman.part_config
SET infinite_time_partitions = true,
   retention = '3 months',
   retention_keep_table=true
WHERE parent_table = 'data_mart.events';
SELECT cron.schedule('@hourly', $$CALL partman.run_maintenance_proc()$$);
```

Following, you can find a step-by-step explanation of the preceding example:

1. Modify the parameter group associated with your DB instance and add pg_cron to the shared_preload_libraries parameter value. This change requires a DB instance restart for it to take effect. For more information, see [Modifying parameters in a DB parameter group](#).

2. Run the command `CREATE EXTENSION pg_cron;` using an account that has the rds_superuser permissions. Doing this enables the pg_cron extension. For more information, see [Scheduling maintenance with the PostgreSQL pg_cron extension](#).

3. Run the command `UPDATE partman.part_config` to adjust the pg_partman settings for the data_mart.events table.

4. Run the command `SET ...` to configure the data_mart.events table, with these clauses:
   
   a. `infinite_time_partitions = true`, – Configures the table to be able to automatically create new partitions without any limit.
   
   b. `retention = '3 months'`, – Configures the table to have a maximum retention of three months.
   
   c. `retention_keep_table=true` – Configures the table so that when the retention period is due, the table isn’t deleted automatically. Instead, partitions that are older than the retention period are only detached from the parent table.

5. Run the command `SELECT cron.schedule ...` to make a pg_cron function call. This call defines how often the scheduler runs the pg_partman maintenance procedure, `partman.run_maintenance_proc`. For this example, the procedure runs every hour.
For a complete description of the run_maintenance_proc function, see Maintenance Functions in the pg_partman documentation.

**Scheduling maintenance with the PostgreSQL pg_cron extension**

You can use the PostgreSQL pg_cron extension to schedule maintenance commands within a PostgreSQL database. For more information about the extension, see What is pg_cron? in the pg_cron documentation.

The pg_cron extension is supported on Aurora PostgreSQL engine versions 12.6 and higher.

To learn more about using pg_cron, see Schedule jobs with pg_cron on your RDS for PostgreSQL or your Aurora PostgreSQL-Compatible Edition databases.

**Topics**

- Setting up the pg_cron extension
- Granting database users permissions to use pg_cron
- Scheduling pg_cron jobs
- Reference for the pg_cron extension

**Setting up the pg_cron extension**

Set up the pg_cron extension as follows:

1. Modify the custom parameter group associated with your PostgreSQL DB instance by adding pg_cron to the shared_preload_libraries parameter value.

   Restart the PostgreSQL DB instance to have changes to the parameter group take effect. To learn more about working with parameter groups, see Amazon Aurora PostgreSQL parameters.

2. After the PostgreSQL DB instance has restarted, run the following command using an account that has rds_superuser permissions. For example, if you used the default settings when you created your Aurora PostgreSQL DB cluster, connect as user postgres and create the extension.

   ```sql
   CREATE EXTENSION pg_cron;
   ```
The pg_cron scheduler is set in the default PostgreSQL database named postgres. The pg_cron objects are created in this postgres database and all scheduling actions run in this database.

3. You can use the default settings, or you can schedule jobs to run in other databases within your PostgreSQL DB instance. To schedule jobs for other databases within your PostgreSQL DB instance, see the example in Scheduling a cron job for a database other than the default database.

Granting database users permissions to use pg_cron

Installing the pg_cron extension requires the rds_superuser privileges. However, permissions to use the pg_cron can be granted (by a member of the rds_superuser group/role) to other database users, so that they can schedule their own jobs. We recommend that you grant permissions to the cron schema only as needed if it improves operations in your production environment.

To grant a database user permission in the cron schema, run the following command:

```sql
postgres=> GRANT USAGE ON SCHEMA cron TO db-user;
```

This gives db-user permission to access the cron schema to schedule cron jobs for the objects that they have permissions to access. If the database user doesn't have permissions, the job fails after posting the error message to the postgresql.log file, as shown in the following:

```
2020-12-08 16:41:00 UTC::@:[30647]:ERROR: permission denied for table table-name
2020-12-08 16:41:00 UTC::@:[27071]:LOG: background worker "pg_cron" (PID 30647) exited with exit code 1
```

In other words, make sure that database users that are granted permissions on the cron schema also have permissions on the objects (tables, schemas, and so on) that they plan to schedule.

The details of the cron job and its success or failure are also captured in the cron.job_run_details table. For more information, see Tables for scheduling jobs and capturing status.

Scheduling pg_cron jobs

The following sections show how you can schedule various management tasks using pg_cron jobs.
Note

When you create pg_cron jobs, check that the max_worker_processes setting is larger than the number of cron.max_running_jobs. A pg_cron job fails if it runs out of background worker processes. The default number of pg_cron jobs is 5. For more information, see [Parameters for managing the pg_cron extension](#).

Topics

- **Vacuuming a table**
- **Purging the pg_cron history table**
- **Logging errors to the postgresql.log file only**
- **Scheduling a cron job for a database other than the default database**

Vacuuming a table

Autovacuum handles vacuum maintenance for most cases. However, you might want to schedule a vacuum of a specific table at a time of your choosing.

Following is an example of using the cron.schedule function to set up a job to use VACUUM FREEZE on a specific table every day at 22:00 (GMT).

```sql
SELECT cron.schedule('manual vacuum', '0 22 * * *', 'VACUUM FREEZE pgbench_accounts');
```

After the preceding example runs, you can check the history in the cron.job_run_details table as follows.

```sql
postgres=> SELECT * FROM cron.job_run_details;
```

Scheduling maintenance with the pg_cron extension
Following is a query of the `cron.job_run_details` table to see the failed jobs.

```
postgres=> SELECT * FROM cron.job_run_details WHERE status = 'failed';
jobid | runid | job_pid | database | username | command                       | status          | start_time | end_time
------+-------+---------+----------+----------+-------------------------------+-----------------+------------+------------
      |       |         |          |          | vacuum freeze pgbench_account | failed          |           |            
5    | 4     | 30339   | postgres | adminuser| vacuum freeze pgbench_account | failed          | 2020-12-04 21:48:00.015145+00 | 2020-12-04 21:48:00.029567+00
(1 row)
```

For more information, see [Tables for scheduling jobs and capturing status](#).

**Purging the pg_cron history table**

The `cron.job_run_details` table contains a history of cron jobs that can become very large over time. We recommend that you schedule a job that purges this table. For example, keeping a week's worth of entries might be sufficient for troubleshooting purposes.

The following example uses the `cron.schedule` function to schedule a job that runs every day at midnight to purge the `cron.job_run_details` table. The job keeps only the last seven days. Use your `rds_superuser` account to schedule the job such as the following.

```
SELECT cron.schedule('0 0 * * *', $$DELETE FROM cron.job_run_details
WHERE end_time < now() - interval '7 days'$$);
```

For more information, see [Tables for scheduling jobs and capturing status](#).

**Logging errors to the postgresql.log file only**

To prevent writing to the `cron.job_run_details` table, modify the parameter group associated with the PostgreSQL DB instance and set the `cron.log_run` parameter to off. The `pg_cron`
extension no longer writes to the table and captures errors to the postgresql.log file only. For more information, see [Modifying parameters in a DB parameter group](#).

Use the following command to check the value of the `cron.log_run` parameter.

```bash
postgres=> SHOW cron.log_run;
```

For more information, see [Parameters for managing the pg_cron extension](#).

### Scheduling a cron job for a database other than the default database

The metadata for `pg_cron` is all held in the PostgreSQL default database named `postgres`. Because background workers are used for running the maintenance cron jobs, you can schedule a job in any of your databases within the PostgreSQL DB instance:

1. In the cron database, schedule the job as you normally do using the `cron.schedule`.

```bash
postgres=> SELECT cron.schedule('database1 manual vacuum', '29 03 * * *', 'vacuum freeze test_table');
```

2. As a user with the `rds_superuser` role, update the database column for the job that you just created so that it runs in another database within your PostgreSQL DB instance.

```bash
postgres=> UPDATE cron.job SET database = 'database1' WHERE jobid = 106;
```

3. Verify by querying the `cron.job` table.

```bash
postgres=> SELECT * FROM cron.job;
jobid | schedule    | command                        | nodename  | nodeport | database | username  | active | jobname
-------+-------------+--------------------------------+-----------+----------+----------+-----------+--------+-------------------------
      | 29 03 * * * | vacuum freeze test_table       | localhost | 8192     | database1| adminuser | t      | database1 manual vacuum
      | 59 23 * * * | vacuum freeze pgbench_accounts | localhost | 8192     | postgres | adminuser | t      | manual vacuum
(2 rows)
```
Note

In some situations, you might add a cron job that you intend to run on a different database. In such cases, the job might try to run in the default database (postgres) before you update the correct database column. If the user name has permissions, the job successfully runs in the default database.

Reference for the pg_cron extension

You can use the following parameters, functions, and tables with the pg_cron extension. For more information, see What is pg_cron? in the pg_cron documentation.

Topics

- Parameters for managing the pg_cron extension
- Function reference: cron.schedule
- Function reference: cron.unschedule
- Tables for scheduling jobs and capturing status

Parameters for managing the pg_cron extension

Following is a list of parameters that control the pg_cron extension behavior.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cron.database_name</td>
<td>The database in which pg_cron metadata is kept.</td>
</tr>
<tr>
<td>cron.host</td>
<td>The hostname to connect to PostgreSQL. You can't modify this value.</td>
</tr>
<tr>
<td>cron.log_run</td>
<td>Log every job that runs in the job_run_details table. Values are on or off. For more information, see Tables for scheduling jobs and capturing status.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>cron.log_statement</code></td>
<td>Log all cron statements before running them. Values are on or off.</td>
</tr>
<tr>
<td><code>cron.max_running_jobs</code></td>
<td>The maximum number of jobs that can run concurrently.</td>
</tr>
<tr>
<td><code>cron.use_background_workers</code></td>
<td>Use background workers instead of client sessions. You can't modify this value.</td>
</tr>
</tbody>
</table>

Use the following SQL command to display these parameters and their values.

```sql
postgres=> SELECT name, setting, short_desc FROM pg_settings WHERE name LIKE 'cron.%' ORDER BY name;
```

**Function reference: `cron.schedule`**

This function schedules a cron job. The job is initially scheduled in the default `postgres` database. The function returns a `bigint` value representing the job identifier. To schedule jobs to run in other databases within your PostgreSQL DB instance, see the example in [Scheduling a cron job for a database other than the default database](#).

The function has two syntax formats.

**Syntax**

```sql
cron.schedule (job_name,
  schedule,
  command
);

cron.schedule (schedule,
  command
);
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>The name of the cron job.</td>
</tr>
<tr>
<td>schedule</td>
<td>Text indicating the schedule for the cron job.</td>
</tr>
<tr>
<td></td>
<td>The format is the standard cron format.</td>
</tr>
<tr>
<td>command</td>
<td>Text of the command to run.</td>
</tr>
</tbody>
</table>

Examples

```sql
postgres=> SELECT cron.schedule ('test','0 10 * * *', 'VACUUM pgbench_history');
schedule
----------
145
(1 row)
```

```sql
postgres=> SELECT cron.schedule ('0 15 * * *', 'VACUUM pgbench_accounts');
schedule
----------
146
(1 row)
```

Function reference: cron.unschedule

This function deletes a cron job. You can specify either the job_name or the job_id. A policy makes sure that you are the owner to remove the schedule for the job. The function returns a Boolean indicating success or failure.

The function has the following syntax formats.

Syntax

```sql
cron.unschedule (job_id);
cron.unschedule (job_name);
```
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_id</td>
<td>A job identifier that was returned from the \texttt{cron.schedule} function when the cron job was scheduled.</td>
</tr>
<tr>
<td>job_name</td>
<td>The name of a cron job that was scheduled with the \texttt{cron.schedule} function.</td>
</tr>
</tbody>
</table>

### Examples

```
postgres=> SELECT cron.unschedule(108);
 unschedule
    ---------
     t        
(1 row)

postgres=> SELECT cron.unschedule('test');
 unschedule
    ---------
     t        
(1 row)
```

### Tables for scheduling jobs and capturing status

The following tables are used to schedule the cron jobs and record how the jobs completed.

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{cron.job}</td>
<td>Contains the metadata about each scheduled job. Most interactions with this table should be done by using the \texttt{cron.schedule} and \texttt{cron.unschedule} functions.</td>
</tr>
<tr>
<td>Table</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Important</strong></td>
<td>We recommend that you don’t give update or insert privileges directly to this table. Doing so would allow the user to update the <code>username</code> column to run as <code>rds-superuser</code>.</td>
</tr>
<tr>
<td><code>cron.job_run_details</code></td>
<td>Contains historic information about past scheduled jobs that ran. This is useful to investigate the status, return messages, and start and end time from the job that ran.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>To prevent this table from growing indefinitely, purge it on a regular basis. For an example, see Purging the <code>pg_cron history table</code>.</td>
</tr>
</tbody>
</table>

**Using pgAudit to log database activity**

Financial institutions, government agencies, and many industries need to keep audit logs to meet regulatory requirements. By using the PostgreSQL Audit extension (pgAudit) with your Aurora PostgreSQL DB cluster, you can capture the detailed records that are typically needed by auditors or to meet regulatory requirements. For example, you can set up the pgAudit extension to track changes made to specific databases and tables, to record the user who made the change, and many other details.

The pgAudit extension builds on the functionality of the native PostgreSQL logging infrastructure by extending the log messages with more detail. In other words, you use the same approach to view your audit log as you do to view any log messages. For more information about PostgreSQL logging, see [Aurora PostgreSQL database log files](#).

The pgAudit extension redacts sensitive data such as cleartext passwords from the logs. If your Aurora PostgreSQL DB cluster is configured to log data manipulation language (DML) statements
as detailed in Turning on query logging for your Aurora PostgreSQL DB cluster, you can avoid the cleartext password issue by using the PostgreSQL Audit extension.

You can configure auditing on your database instances with a great degree of specificity. You can audit all databases and all users. Or, you can choose to audit only certain databases, users, and other objects. You can also explicitly exclude certain users and databases from being audited. For more information, see Excluding users or databases from audit logging.

Given the amount of detail that can be captured, we recommend that if you do use pgAudit, you monitor your storage consumption.

The pgAudit extension is supported on all available Aurora PostgreSQL versions. For a list of pgAudit versions supported by Aurora PostgreSQL version, see Extension versions for Amazon Aurora PostgreSQL in the Release Notes for Aurora PostgreSQL.

**Topics**

- Setting up the pgAudit extension
- Auditing database objects
- Excluding users or databases from audit logging
- Reference for the pgAudit extension

**Setting up the pgAudit extension**

To set up the pgAudit extension on your Aurora PostgreSQL DB cluster, you first add pgAudit to the shared libraries on the custom DB cluster parameter group for your Aurora PostgreSQL DB cluster. For information about creating a custom DB cluster parameter group, see [Working with parameter groups](#). Next, you install the pgAudit extension. Finally, you specify the databases and objects that you want to audit. The procedures in this section show you how. You can use the AWS Management Console or the AWS CLI.

You must have permissions as the `rds_superuser` role to perform all these tasks.

The steps following assume that your Aurora PostgreSQL DB cluster is associated with a custom DB cluster parameter group.
Console

To set up the pgAudit extension

1. Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/.
2. In the navigation pane, choose your Aurora PostgreSQL DB cluster's Writer instance.
3. Open the Configuration tab for your Aurora PostgreSQL DB cluster writer instance. Among the Instance details, find the Parameter group link.
4. Choose the link to open the custom parameters associated with your Aurora PostgreSQL DB cluster.
5. In the Parameters search field, type shared_pre to find the shared_preload_libraries parameter.
6. Choose Edit parameters to access the property values.
7. Add pgaudit to the list in the Values field. Use a comma to separate items in the list of values.

8. Reboot the writer instance of your Aurora PostgreSQL DB cluster so that your change to the shared_preload_libraries parameter takes effect.
9. When the instance is available, verify that pgAudit has been initialized. Use psql to connect to the writer instance of your Aurora PostgreSQL DB cluster, and then run the following command.

SHOW shared_preload_libraries;
10. With pgAudit initialized, you can now create the extension. You need to create the extension after initializing the library because the `pgaudit` extension installs event triggers for auditing data definition language (DDL) statements.

```
CREATE EXTENSION pgaudit;
```

11. Close the `psql` session.

```
labdb=> \q
```

12. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

13. Find the `pgaudit.log` parameter in the list and set to the appropriate value for your use case. For example, setting the `pgaudit.log` parameter to `write` as shown in the following image captures inserts, updates, deletes, and some other types of changes to the log.

![Parameter Group](image-url)

You can also choose one of the following values for the `pgaudit.log` parameter:

- none – This is the default. No database changes are logged.
- all – Logs everything (read, write, function, role, ddl, misc).
• **ddl** – Logs all data definition language (DDL) statements that aren't included in the ROLE class.
• **function** – Logs function calls and DO blocks.
• **misc** – Logs miscellaneous commands, such as DISCARD, FETCH, CHECKPOINT, VACUUM, and SET.
• **read** – Logs SELECT and COPY when the source is a relation (such as a table) or a query.
• **role** – Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.
• **write** – Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation (table).

14. Choose **Save changes**.

15. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

16. Choose your Aurora PostgreSQL DB cluster's writer instance from the Databases list to select it, and then choose **Reboot** from the Actions menu.

### AWS CLI

**To setup pgAudit**

To setup pgAudit using the AWS CLI, you call the `modify-db-parameter-group` operation to modify the audit log parameters in your custom parameter group, as shown in the following procedure.

1. Use the following AWS CLI command to add `pgaudit` to the `shared_preload_libraries` parameter.

   ```bash
   aws rds modify-db-parameter-group \\
   --db-parameter-group-name *custom-param-group-name* \\
   --parameters \\
   "ParameterName=shared_preload_libraries,ParameterValue=pgaudit,ApplyMethod=pending-reboot" \\
   --region *aws-region*
   ```

2. Use the following AWS CLI command to reboot the writer instance of your Aurora PostgreSQL DB cluster so that the `pgaudit` library is initialized.

   ```bash
   aws rds reboot-db-instance \\
   --db-instance-identifier *writer-instance*
   ```

---

Using pgAudit to log database activity
3. When the instance is available, you can verify that `pgaudit` has been initialized. Use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster, and then run the following command.

```
SHOW shared_preload_libraries;
shared_preload_libraries
--------------------------
rdsutils,pgaudit
(1 row)
```

With `pgAudit` initialized, you can now create the extension.

```
CREATE EXTENSION pgaudit;
```

4. Close the `psql` session so that you can use the AWS CLI.

```
labdb=> \q
```

5. Use the following AWS CLI command to specify the classes of statement that want logged by session audit logging. The example sets the `pgaudit.log` parameter to `write`, which captures inserts, updates, and deletes to the log.

```
aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters \
   "ParameterName=pgaudit.log,ParameterValue=write,ApplyMethod=pending-reboot" \
   --region aws-region
```

You can also choose one of the following values for the `pgaudit.log` parameter.

- **none** – This is the default. No database changes are logged.
- **all** – Logs everything (read, write, function, role, ddl, misc).
- **ddl** – Logs all data definition language (DDL) statements that aren't included in the ROLE class.
- **function** – Logs function calls and `DO` blocks.
- **misc** – Logs miscellaneous commands, such as `DISCARD`, `FETCH`, `CHECKPOINT`, `VACUUM`, and `SET`. 
- **read** – Logs SELECT and COPY when the source is a relation (such as a table) or a query.
- **role** – Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.
- **write** – Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation (table).

Reboot the writer instance of your Aurora PostgreSQL DB cluster using the following AWS CLI command.

```bash
aws rds reboot-db-instance \
  --db-instance-identifier writer-instance \
  --region aws-region
```

**Auditing database objects**

With pgAudit set up on your Aurora PostgreSQL DB cluster and configured for your requirements, more detailed information is captured in the PostgreSQL log. For example, while the default PostgreSQL logging configuration identifies the date and time that a change was made in a database table, with the pgAudit extension the log entry can include the schema, user who made the change, and other details depending on how the extension parameters are configured. You can set up auditing to track changes in the following ways.

- For each session, by user. For the session level, you can capture the fully qualified command text.
- For each object, by user and by database.

The object auditing capability is activated when you create the `rds_pgaudit` role on your system and then add this role to the `pgaudit.role` parameter in your custom parameter parameter group. By default, the `pgaudit.role` parameter is unset and the only allowable value is `rds_pgaudit`. The following steps assume that pgaudit has been initialized and that you have created the pgaudit extension by following the procedure in Setting up the pgAudit extension.
As shown in this example, the "LOG: AUDIT: SESSION" line provides information about the table and its schema, among other details.

To set up object auditing

1. Use psql to connect to the writer instance of your Aurora PostgreSQL DB cluster.

   ```bash
   psql --host=your-instance-name.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

2. Create a database role named `rds_pgaudit` using the following command.

   ```bash
   labdb=> CREATE ROLE rds_pgaudit;
   CREATE ROLE
   labdb=>
   ```

3. Close the psql session.

   ```bash
   labdb=> \q
   ```

   In the next few steps, use the AWS CLI to modify the audit log parameters in your custom parameter group.

4. Use the following AWS CLI command to set the `pgaudit.role` parameter to `rds_pgaudit`. By default, this parameter is empty, and `rds_pgaudit` is the only allowable value.

   ```bash
   aws rds modify-db-parameter-group \
   --db-parameter-group-name custom-param-group-name \
   --parameters \
   "ParameterName=pgaudit.role,ParameterValue=rds_pgaudit,ApplyMethod=pending-reboot" \
   --region aws-region
   ```
5. Use the following AWS CLI command to reboot the writer instance of your Aurora PostgreSQL DB cluster so that your changes to the parameters take effect.

```bash
aws rds reboot-db-instance \
   --db-instance-identifier writer-instance \
   --region aws-region
```

6. Run the following command to confirm that the `pgaudit.role` is set to `rds_pgaudit`.

```
SHOW pgaudit.role;
pgaudit.role
------------------
rds_pgaudit
```

To test pgAudit logging, you can run several example commands that you want to audit. For example, you might run the following commands.

```
CREATE TABLE t1 (id int);
GRANT SELECT ON t1 TO rds_pgaudit;
SELECT * FROM t1;
id
----
(0 rows)
```

The database logs should contain an entry similar to the following.

```
... 2017-06-12 19:09:49 UTC:...:rds_test@postgres:[11701]:LOG: AUDIT: OBJECT,1,1,READ,SELECT,TABLE,public.t1,select * from t1;
...```

For information on viewing the logs, see [Monitoring Amazon Aurora log files](#).

To learn more about the pgAudit extension, see [pgAudit](#) on GitHub.

**Excluding users or databases from audit logging**

As discussed in [Aurora PostgreSQL database log files](#), PostgreSQL logs consume storage space. Using the pgAudit extension adds to the volume of data gathered in your logs to varying degrees,
depending on the changes that you track. You might not need to audit every user or database in your Aurora PostgreSQL DB cluster.

To minimize impacts to your storage and to avoid needlessly capturing audit records, you can exclude users and databases from being audited. You can also change logging within a given session. The following examples show you how.

**Note**

Parameter settings at the session level take precedence over the settings in the custom DB cluster parameter group for the Aurora PostgreSQL DB cluster's writer instance. If you don't want database users to bypass your audit logging configuration settings, be sure to change their permissions.

Suppose that your Aurora PostgreSQL DB cluster is configured to audit the same level of activity for all users and databases. You then decide that you don't want to audit the user `myuser`. You can turn off auditing for `myuser` with the following SQL command.

```
ALTER USER myuser SET pgaudit.log TO 'NONE';
```

Then, you can use the following query to check the `user_specific_settings` column for `pgaudit.log` to confirm that the parameter is set to `NONE`.

```
SELECT
    usename AS user_name,
    useconfig AS user_specific_settings
FROM
    pg_user
WHERE
    usename = 'myuser';
```

You see output such as the following.

```
user_name | user_specific_settings
----------+------------------------
myuser    | {pgaudit.log=NONE}
(1 row)
```
You can turn off logging for a given user in the midst of their session with the database with the following command.

```
ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'none';
```

Use the following query to check the settings column for pgaudit.log for a specific user and database combination.

```
SELECT
    usename AS "user_name",
    datname AS "database_name",
    pg_catalog.array_to_string(setconfig, E'\n') AS "settings"
FROM
    pg_catalog.pg_db_role_setting s
    LEFT JOIN pg_catalog.pg_database d ON d.oid = setdatabase
    LEFT JOIN pg_catalog.pg_user r ON r.usesysid = setrole
WHERE
    usename = 'myuser'
    AND datname = 'mydatabase'
ORDER BY
    1,
    2;
```

You see output similar to the following.

```
user_name | database_name |     settings
-----------+---------------+------------------
myuser    | mydatabase    | pgaudit.log=none
(1 row)
```

After turning off auditing for myuser, you decide that you don't want to track changes to mydatabase. You turn off auditing for that specific database by using the following command.

```
ALTER DATABASE mydatabase SET pgaudit.log to 'NONE';
```

Then, use the following query to check the database_specific_settings column to confirm that pgaudit.log is set to NONE.

```
SELECT
    a.datname AS database_name,
```
You see output such as the following.

```
<table>
<thead>
<tr>
<th>database_name</th>
<th>database_specific_settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>mydatabase</td>
<td>{pgaudit.log=NONE}</td>
</tr>
</tbody>
</table>
```

(1 row)

To return settings to the default setting for myuser, use the following command:

```
ALTER USER myuser RESET pgaudit.log;
```

To return settings to their default setting for a database, use the following command.

```
ALTER DATABASE mydatabase RESET pgaudit.log;
```

To reset user and database to the default setting, use the following command.

```
ALTER USER myuser IN DATABASE mydatabase RESET pgaudit.log;
```

You can also capture specific events to the log by setting the `pgaudit.log` to one of the other allowed values for the `pgaudit.log` parameter. For more information, see [List of allowable settings for the `pgaudit.log` parameter](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/USER-pgaudit.html).

```
ALTER USER myuser SET pgaudit.log TO 'read';
ALTER DATABASE mydatabase SET pgaudit.log TO 'function';
ALTER USER myuser IN DATABASE mydatabase SET pgaudit.log TO 'read,function'
```

**Reference for the pgAudit extension**

You can specify the level of detail that you want for your audit log by changing one or more of the parameters listed in this section.
Controlling pgAudit behavior

You can control the audit logging by changing one or more of the parameters listed in the following table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgaudit.log</td>
<td>Specifies the statement classes that will be logged by session audit logging. Allowable values include ddl, function, misc, read, role, write, none, all. For more information, see List of allowable settings for the pgaudit.log parameter.</td>
</tr>
<tr>
<td>pgaudit.log_catalog</td>
<td>When turned on (set to 1), adds statements to audit trail if all relations in a statement are in pg_catalog.</td>
</tr>
<tr>
<td>pgaudit.log_level</td>
<td>Specifies the log level to use for log entries. Allowed values: debug5, debug4, debug3, debug2, debug1, info, notice, warning, log</td>
</tr>
<tr>
<td>pgaudit.log_parameter</td>
<td>When turned on (set to 1), parameters passed with the statement are captured in the audit log.</td>
</tr>
<tr>
<td>pgaudit.log_relation</td>
<td>When turned on (set to 1), the audit log for the session creates a separate log entry for each relation (TABLE, VIEW, and so on) referenced in a SELECT or DML statement.</td>
</tr>
<tr>
<td>pgaudit.log_statement_once</td>
<td>Specifies whether logging will include the statement text and parameters with the first log entry for a statement/substatement combination or with every entry.</td>
</tr>
<tr>
<td>pgaudit.role</td>
<td>Specifies the master role to use for object audit logging. The only allowable entry is rds_pgaudit.</td>
</tr>
</tbody>
</table>

List of allowable settings for the pgaudit.log parameter
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>This is the default. No database changes are logged.</td>
</tr>
<tr>
<td>all</td>
<td>Logs everything (read, write, function, role, ddl, misc).</td>
</tr>
<tr>
<td>ddl</td>
<td>Logs all data definition language (DDL) statements that aren't included in the ROLE class.</td>
</tr>
<tr>
<td>function</td>
<td>Logs function calls and DO blocks.</td>
</tr>
<tr>
<td>misc</td>
<td>Logs miscellaneous commands, such as DISCARD, FETCH, CHECKPOINT, VACUUM, and SET.</td>
</tr>
<tr>
<td>read</td>
<td>Logs SELECT and COPY when the source is a relation (such as a table) or a query.</td>
</tr>
<tr>
<td>role</td>
<td>Logs statements related to roles and privileges, such as GRANT, REVOKE, CREATE ROLE, ALTER ROLE, and DROP ROLE.</td>
</tr>
<tr>
<td>write</td>
<td>Logs INSERT, UPDATE, DELETE, TRUNCATE, and COPY when the destination is a relation (table).</td>
</tr>
</tbody>
</table>

To log multiple event types with session auditing, use a comma-separated list. To log all event types, set `pgaudit.log` to `ALL`. Reboot your DB instance to apply the changes.

With object auditing, you can refine audit logging to work with specific relations. For example, you can specify that you want audit logging for READ operations on one or more tables.

**Using pglogical to synchronize data across instances**

All currently available Aurora PostgreSQL versions support the `pglogical` extension. The `pglogical` extension predates the functionally similar logical replication feature that was introduced by PostgreSQL in version 10. For more information, see [Using PostgreSQL logical replication with Aurora](#).

The `pglogical` extension supports logical replication between two or more Aurora PostgreSQL DB clusters. It also supports replication between different PostgreSQL versions, and between databases running on RDS for PostgreSQL DB instances and Aurora PostgreSQL DB clusters. The
pglogical extension uses a publish-subscribe model to replicate changes to tables and other objects, such as sequences, from a publisher to a subscriber. It relies on a replication slot to ensure that changes are synchronized from a publisher node to a subscriber node, defined as follows.

- **The publisher node** is the Aurora PostgreSQL DB cluster that's the source of data to be replicated to other nodes. The publisher node defines the tables to be replicated in a publication set.
- **The subscriber node** is the Aurora PostgreSQL DB cluster that receives WAL updates from the publisher. The subscriber creates a subscription to connect to the publisher and get the decoded WAL data. When the subscriber creates the subscription, the replication slot is created on the publisher node.

Following, you can find information about setting up the pglogical extension.

**Topics**

- Requirements and limitations for the pglogical extension
- Setting up the pglogical extension
- Setting up logical replication for Aurora PostgreSQL DB cluster
- Reestablishing logical replication after a major upgrade
- Managing logical replication slots for Aurora PostgreSQL
- Parameter reference for the pglogical extension

**Requirements and limitations for the pglogical extension**

All currently available releases of Aurora PostgreSQL support the pglogical extension.

Both the publisher node and the subscriber node must be set up for logical replication.

The tables that you want to replicate from subscriber to publisher must have the same names and the same schema. These tables must also contain the same columns, and the columns must use the same data types. Both publisher and subscriber tables must have the same primary keys. We recommend that you use only the PRIMARY KEY as the unique constraint.

The tables on the subscriber node can have more permissive constraints than those on the publisher node for CHECK constraints and NOT NULL constraints.
The `pglogical` extension provides features such as two-way replication that aren't supported by the logical replication feature built into PostgreSQL (version 10 and higher). For more information, see [PostgreSQL bi-directional replication using pglogical](https://github.com/pglogical/pglogical).

### Setting up the pglogical extension

To set up the `pglogical` extension on your Aurora PostgreSQL DB cluster, you add `pglogical` to the shared libraries on the custom DB cluster parameter group for your Aurora PostgreSQL DB cluster. You also need to set the value of the `rds.logical_replication` parameter to 1, to turn on logical decoding. Finally, you create the extension in the database. You can use the AWS Management Console or the AWS CLI for these tasks.

You must have permissions as the `rds_superuser` role to perform these tasks.

The steps following assume that your Aurora PostgreSQL DB cluster is associated with a custom DB cluster parameter group. For information about creating a custom DB cluster parameter group, see [Working with parameter groups](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/CHVZZEY4C.html).

#### Console

**To set up the pglogical extension**

1. Sign in to the AWS Management Console and open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).
2. In the navigation pane, choose your Aurora PostgreSQL DB cluster's Writer instance.
3. Open the **Configuration** tab for your Aurora PostgreSQL DB cluster writer instance. Among the Instance details, find the **Parameter group** link.
4. Choose the link to open the custom parameters associated with your Aurora PostgreSQL DB cluster.
5. In the **Parameters** search field, type `shared_pre` to find the `shared_preload_libraries` parameter.
6. Choose **Edit parameters** to access the property values.
7. Add `pglogical` to the list in the **Values** field. Use a comma to separate items in the list of values.
8. Find the `rds.logical_replication` parameter and set it to 1, to turn on logical replication.

9. Reboot the writer instance of your Aurora PostgreSQL DB cluster so that your changes take effect.

10. When the instance is available, you can use `psql` (or pgAdmin) to connect to the writer instance of your Aurora PostgreSQL DB cluster.

    ```
    psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
    ```

11. To verify that `pglogical` is initialized, run the following command.

    ```
    SHOW shared_preload_libraries;
    shared_preload_libraries
    --------------------------
    rdsutils,pglogical
    (1 row)
    ```

12. Verify the setting that enables logical decoding, as follows.

    ```
    SHOW wal_level;
    wal_level
    -----------
    logical
    (1 row)
    ```
13. Create the extension, as follows.

```
CREATE EXTENSION pglogical;
EXTENSION CREATED
```

14. Choose **Save changes**.

15. Open the Amazon RDS console at [https://console.aws.amazon.com/rds/](https://console.aws.amazon.com/rds/).

16. Choose your Aurora PostgreSQL DB cluster's writer instance from the Databases list to select it, and then choose **Reboot** from the Actions menu.

**AWS CLI**

**To setup the pglogical extension**

To setup pglogical using the AWS CLI, you call the [modify-db-parameter-group](https://docs.aws.amazon.com/cli/latest/reference/rds/modify-db-parameter-group.html) operation to modify certain parameters in your custom parameter group as shown in the following procedure.

1. Use the following AWS CLI command to add `pglogical` to the `shared_preload_libraries` parameter.

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name custom-param-group-name \
    --parameters \
    "ParameterName=shared_preload_libraries,ParameterValue=pglogical,ApplyMethod=pending-reboot" \
    --region aws-region
```

2. Use the following AWS CLI command to set `rds.logical_replication` to 1 to turn on the logical decoding capability for the writer instance of the Aurora PostgreSQL DB cluster.

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name custom-param-group-name \
    --parameters \
    "ParameterName=rds.logical_replication,ParameterValue=1,ApplyMethod=pending-reboot" \
    --region aws-region
```

3. Use the following AWS CLI command to reboot the writer instance of your Aurora PostgreSQL DB cluster so that the pglogical library is initialized.
4. When the instance is available, use `psql` to connect to the writer instance of your Aurora PostgreSQL DB cluster.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
```

5. Create the extension, as follows.

```
CREATE EXTENSION pglogical;
EXTENSION CREATED
```

6. Reboot the writer instance of your Aurora PostgreSQL DB cluster using the following AWS CLI command.

```
aws rds reboot-db-instance \
--db-instance-identifier writer-instance \
--region aws-region
```

### Setting up logical replication for Aurora PostgreSQL DB cluster

The following procedure shows you how to start logical replication between two Aurora PostgreSQL DB clusters. The steps assume that both the source (publisher) and the target (subscriber) have the `pglogical` extension set up as detailed in [Setting up the pglogical extension](#).

**To create the publisher node and define the tables to replicate**

These steps assume that your Aurora PostgreSQL DB cluster has a writer instance with a database that has one or more tables that you want to replicate to another node. You need to recreate the table structure from the publisher on the subscriber, so first, get the table structure if necessary. You can do that by using the `psql` metacommand `\d tablename` and then creating the same table on the subscriber instance. The following procedure creates an example table on the publisher (source) for demonstration purposes.
1. Use `psql` to connect to the instance that has the table you want to use as a source for subscribers.

   ```sql
   psql --host=source-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

   If you don’t have an existing table that you want to replicate, you can create a sample table as follows.

   a. Create an example table using the following SQL statement.

   ```sql
   CREATE TABLE docs_lab_table (a int PRIMARY KEY);
   ```

   b. Populate the table with generated data by using the following SQL statement.

   ```sql
   INSERT INTO docs_lab_table VALUES (generate_series(1,5000));
   ```

   c. Verify that data exists in the table by using the following SQL statement.

   ```sql
   SELECT count(*) FROM docs_lab_table;
   ```

2. Identify this Aurora PostgreSQL DB cluster as the publisher node, as follows.

   ```sql
   SELECT pglogical.create_node(
       node_name := 'docs_lab_provider',
       dsn := 'host=source-instance.aws-region.rds.amazonaws.com port=5432 dbname=labdb');
   ```

   ```
   create_node
   ------------
   3410995529
   (1 row)
   ```

3. Add the table that you want to replicate to the default replication set. For more information about replication sets, see Replication sets in the pglogical documentation.

   ```sql
   SELECT pglogical.replication_set_add_table('default', 'docs_lab_table', 'true', NULL, NULL);
   ```

   ```
   replication_set_add_table
   --------------------------
   t
The publisher node setup is complete. You can now set up the subscriber node to receive the updates from the publisher.

**To set up the subscriber node and create a subscription to receive updates**

These steps assume that the Aurora PostgreSQL DB cluster has been set up with the pglogical extension. For more information, see Setting up the pglogical extension.

1. Use `psql` to connect to the instance that you want to receive updates from the publisher.

   ```bash
   psql --host=target-instance.aws-region.rds.amazonaws.com --port=5432 --username=postgres --password --dbname=labdb
   ```

2. On the subscriber Aurora PostgreSQL DB cluster, create the same table that exists on the publisher. For this example, the table is `docs_lab_table`. You can create the table as follows.

   ```sql
   CREATE TABLE docs_lab_table (a int PRIMARY KEY);
   ```

3. Verify that this table is empty.

   ```sql
   SELECT count(*) FROM docs_lab_table;
   count
   -------
   0
   (1 row)
   ```

4. Identify this Aurora PostgreSQL DB cluster as the subscriber node, as follows.

   ```sql
   SELECT pglogical.create_node(
       node_name := 'docs_lab_target',
       dsn := 'host=target-instance.aws-region.rds.amazonaws.com port=5432
       sslmode=require dbname=labdb user=postgres password=*********
   );
   create_node
   ------------
   2182738256
   (1 row)
   ```

5. Create the subscription.
When you complete this step, the data from the table on the publisher is created in the table on the subscriber. You can verify that this has occurred by using the following SQL query.

```
SELECT count(*) FROM docs_lab_table;
```

```
<table>
<thead>
<tr>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>5000</td>
</tr>
</tbody>
</table>
```

From this point forward, changes made to the table on the publisher are replicated to the table on the subscriber.

**Reestablishing logical replication after a major upgrade**

Before you can perform a major version upgrade of an Aurora PostgreSQL DB cluster that's set up as a publisher node for logical replication, you must drop all replication slots, even those that aren't active. We recommend that you temporarily divert database transactions from the publisher node, drop the replication slots, upgrade the Aurora PostgreSQL DB cluster, and then re-establish and restart replication.

The replication slots are hosted on the publisher node only. The Aurora PostgreSQL subscriber node in a logical replication scenario has no slots to drop. The Aurora PostgreSQL major version upgrade process supports upgrading the subscriber to a new major version of PostgreSQL independent of the publisher node. However, the upgrade process does disrupt the replication process and interferes with the synchronization of WAL data between publisher node and subscriber node. You need to re-establish logical replication between publisher and subscriber.
after upgrading the publisher, the subscriber, or both. The following procedure shows you how to determine that replication has been disrupted and how to resolve the issue.

**Determining that logical replication has been disrupted**

You can determine that the replication process has been disrupted by querying either the publisher node or the subscriber node, as follows.

**To check the publisher node**

- Use `psql` to connect to the publisher node, and then query the `pg_replication_slots` function. Note the value in the active column. Normally, this will return t (true), showing that replication is active. If the query returns f (false), it's an indication that replication to the subscriber has stopped.

```
SELECT slot_name, plugin, slot_type, active FROM pg_replication_slots;
```

```
slot_name              |      plugin      | slot_type | active
-------------------------------------------+------------------+-----------+--------
pgl_labdb_docs_labcb4fa94_docs_lab3de412c | pglogical_output | logical   | f
(1 row)
```

**To check the subscriber node**

On the subscriber node, you can check the status of replication in three different ways.

- Look through the PostgreSQL logs on the subscriber node to find failure messages. The log identifies failure with messages that include exit code 1, as shown following.

```
2022-07-06 16:17:03 UTC::@:[7361]:LOG: background worker "pglogical apply 16404:2880255011" (PID 14610) exited with exit code 1
2022-07-06 16:19:44 UTC::@:[7361]:LOG: background worker "pglogical apply 16404:2880255011" (PID 21783) exited with exit code 1
```

- Query the `pg_replication_origin` function. Connect to the database on the subscriber node using `psql` and query the `pg_replication_origin` function, as follows.

```
SELECT * FROM pg_replication_origin;
```

```
roident | roname
---------+--------
(0 rows)
```
The empty result set means that replication has been disrupted. Normally, you see output such as the following.

```
roident | roname
---------+----------------------------------------------------
   1 | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

• Query the `pglogical.show_subscription_status` function as shown in the following example.

```
SELECT subscription_name, status, slot_name FROM pglogical.show_subscription_status();
```

```
subscription_name | status | slot_name
---====----------------+--------+-------------------------------------
docs_lab_subscription | down   | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

This output shows that replication has been disrupted. Its status is down. Normally, the output shows the status as `replicating`.

If your logical replication process has been disrupted, you can re-establish replication by following these steps.

**To reestablish logical replication between publisher and subscriber nodes**

To re-establish replication, you first disconnect the subscriber from the publisher node and then re-establish the subscription, as outlined in these steps.

1. Connect to the subscriber node using `psql` as follows.

   ```bash
   psql --host=2222222222.aws-region.rds.amazonaws.com --port=5432 --
   username=postgres --password --dbname=labdb
   ```

2. Deactivate the subscription by using the `pglogical.alter_subscription_disable` function.

   ```sql
   SELECT pglogical.alter_subscription_disable('docs_lab_subscription',true);
   ```
3. Get the publisher node's identifier by querying the `pg_replication_origin`, as follows.

```sql
SELECT * FROM pg_replication_origin;
roident |               roname
---------+-------------------------------------
  1 | pgl_labdb_docs_labcb4fa94_docs_lab3de412c
(1 row)
```

4. Use the response from the previous step with the `pg_replication_origin_create` command to assign the identifier that can be used by the subscription when re-established.

```sql
SELECT pg_replication_origin_create('pgl_labdb_docs_labcb4fa94_docs_lab3de412c');
pagreplication_origin_create
---------------------------
  1
(1 row)
```

5. Turn on the subscription by passing its name with a status of `true`, as shown in the following example.

```sql
SELECT pglogical.alter_subscription_enable('docs_lab_subscription',true);
alter_subscription_enable
---------------------------
  t
(1 row)
```

Check the status of the node. Its status should be `replicating` as shown in this example.

```sql
SELECT subscription_name,status,slot_name
FROM pglogical.show_subscription_status();
subscription_name | status | slot_name
-------------------------------+-------------+-------------------------------------
docs_lab_subscription         | replicating | pgl_labdb_docs_lab98f517b_docs_lab3de412c
(1 row)
```

Check the status of the subscriber's replication slot on the publisher node. The slot's active column should return `t` (true), indicating that replication has been re-established.
Managing logical replication slots for Aurora PostgreSQL

Before you can perform a major version upgrade on an Aurora PostgreSQL DB cluster's writer instance that's serving as a publisher node in a logical replication scenario, you must drop the replication slots on the instance. The major version upgrade pre-check process notifies you that the upgrade can't proceed until the slots are dropped.

To identify replication slots that were created using the pglogical extension, log in to each database and get the name of the nodes. When you query the subscriber node, you get both the publisher and the subscriber nodes in the output, as shown in this example.

```
SELECT * FROM pglogical.node;
node_id   |     node_name
------------+-------------------
2182738256 | docs_lab_target
3410995529 | docs_lab_provider
(2 rows)
```

You can get the details about the subscription with the following query.

```
SELECT sub_name,sub_slot_name,sub_target
FROM pglogical.subscription;
sub_name   | sub_slot_name               | sub_target
------------+-----------------------------+------------
docs_lab_subscription | pgl_labdb_docs_labcb4fa94_docs_lab3de412c | 2182738256
(1 row)
```

You can now drop the subscription, as follows.

```
SELECT pglogical.drop_subscription(subscription_name := 'docs_lab_subscription');
drop_subscription
-------------------
1
```
After dropping the subscription, you can delete the node.

```sql
SELECT pglogical.drop_node(node_name := 'docs-lab-subscriber');
  drop_node
 -----------
    t
(1 row)
```

You can verify that the node no longer exists, as follows.

```sql
SELECT * FROM pglogical.node;
 node_id | node_name
---------+-----------
(0 rows)
```

**Parameter reference for the pglogical extension**

In the table you can find parameters associated with the pglogical extension. Parameters such as `pglogical.conflict_log_level` and `pglogical.conflict_resolution` are used to handle update conflicts. Conflicts can emerge when changes are made locally to the same tables that are subscribed to changes from the publisher. Conflicts can also occur during various scenarios, such as two-way replication or when multiple subscribers are replicating from the same publisher. For more information, see [PostgreSQL bi-directional replication using pglogical](https://www.postgresql.org/docs/current/static/pglogical.html).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pglogical.batch_inserts</td>
<td>Batch inserts if possible. Not set by default. Change to '1' to turn on, '0' to turn off.</td>
</tr>
<tr>
<td>pglogical.conflict_log_level</td>
<td>Sets the log level to use for logging resolved conflicts. Supported string values are debug5, debug4, debug3, debug2, debug1, info, notice, warning, error, log, fatal, panic.</td>
</tr>
<tr>
<td>pglogical.conflict_resolution</td>
<td>Sets method to use to resolve conflicts when conflicts are resolvable. Supported string values are error, apply_remote, keep_local, last_update_wins, first_update_wins.</td>
</tr>

<td>Use SPI (server programming interface) instead of low-level API to apply changes. Set to '1' to turn on, '0' to turn off. For more information about SPI, see <a href="index.html">Server Programming Interface</a> in the PostgreSQL documentation.</td>
</tr>
</tbody>
</table>

**Working with the supported foreign data wrappers for Amazon Aurora PostgreSQL**

A foreign data wrapper (FDW) is a specific type of extension that provides access to external data. For example, the `oracle_fdw` extension allows your Aurora PostgreSQL DB instance to work with Oracle databases.

Following, you can find information about several supported PostgreSQL foreign data wrappers.

**Topics**

- [Using the log_fdw extension to access the DB log using SQL](index.html)
- [Using the postgres_fdw extension to access external data](index.html)
- [Working with MySQL databases by using the mysql_fdw extension](index.html)
- [Working with Oracle databases by using the oracle_fdw extension](index.html)
- [Working with SQL Server databases by using the tds_fdw extension](index.html)

**Using the log_fdw extension to access the DB log using SQL**

Aurora PostgreSQL DB cluster supports the `log_fdw` extension, which you can use to access your database engine log using a SQL interface. The `log_fdw` extension provides two functions that make it easy to create foreign tables for database logs:
- **list_postgres_log_files** – Lists the files in the database log directory and the file size in bytes.
- **create_foreign_table_for_log_file**
  - **table_name** text, **server_name** text, **log_file_name** text – Builds a foreign table for the specified file in the current database.

All functions created by `log_fdw` are owned by `rds_superuser`. Members of the `rds_superuser` role can grant access to these functions to other database users.

By default, the log files are generated by Amazon Aurora in `stderr` (standard error) format, as specified in `log_destination` parameter. There are only two options for this parameter, `stderr` and `csvlog` (comma-separated values, CSV). If you add the `csvlog` option to the parameter, Amazon Aurora generates both `stderr` and `csvlog` logs. This can affect the storage capacity on your DB cluster, so you need to be aware of the other parameters that affect log handling. For more information, see [Setting the log destination](#) (`stderr`, `csvlog`).

One benefit of generating `csvlog` logs is that the `log_fdw` extension lets you build foreign tables with the data neatly split into several columns. To do this, your instance needs to be associated with a custom DB parameter group so that you can change the setting for `log_destination`. For more information about how to do so, see [Working with parameter groups](#).

The following example assumes that the `log_destination` parameter includes `csvlog`.

**To use the log_fdw extension**

1. Install the `log_fdw` extension.

   ```sql
   postgres=> CREATE EXTENSION log_fdw;
   CREATE EXTENSION
   ```

2. Create the log server as a foreign data wrapper.

   ```sql
   postgres=> CREATE SERVER log_server FOREIGN DATA WRAPPER log_fdw;
   CREATE SERVER
   ```

3. Select all from a list of log files.

   ```sql
   postgres=> SELECT * FROM list_postgres_log_files() ORDER BY 1;
   ```

   A sample response is as follows.
<table>
<thead>
<tr>
<th>file_name</th>
<th>file_size_bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgresql.log.2023-08-09-22.csv</td>
<td>1111</td>
</tr>
<tr>
<td>postgresql.log.2023-08-09-23.csv</td>
<td>1172</td>
</tr>
<tr>
<td>postgresql.log.2023-08-10-00.csv</td>
<td>1744</td>
</tr>
<tr>
<td>postgresql.log.2023-08-10-01.csv</td>
<td>1102</td>
</tr>
</tbody>
</table>

(4 rows)

4. Create a table with a single 'log_entry' column for the selected file.

```sql
postgres=> SELECT create_foreign_table_for_log_file('my_postgres_error_log',
            'log_server', 'postgresql.log.2023-08-09-22.csv');

The response provides no detail other than that the table now exists.

(1 row)
```

5. Select a sample of the log file. The following code retrieves the log time and error message description.

```sql
postgres=> SELECT log_time, message FROM my_postgres_error_log ORDER BY 1;

A sample response is as follows.

<table>
<thead>
<tr>
<th>log_time</th>
<th>message</th>
</tr>
</thead>
<tbody>
<tr>
<td>+--------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.172 2023 PDT</td>
<td>ending log output to stderr</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.175 2023 PDT</td>
<td>database system was interrupted; last known up at 2023-08-09 22:43:34 UTC</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2023 PDT</td>
<td>checkpoint record is at 0/90002E0</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2023 PDT</td>
<td>redo record is at 0/90002A8; shutdown FALSE</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2023 PDT</td>
<td>next transaction ID: 0/1879; next OID: 24578</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2023 PDT</td>
<td>next MultiXactId: 1; next MultiXactOffset: 0</td>
</tr>
<tr>
<td>Tue Aug 09 15:45:18.223 2023 PDT</td>
<td>oldest unfrozen transaction ID: 1822, in database 1</td>
</tr>
</tbody>
</table>

(7 rows)
Using the postgres_fdw extension to access external data

You can access data in a table on a remote database server with the `postgres_fdw` extension. If you set up a remote connection from your PostgreSQL DB instance, access is also available to your read replica.

**To use postgres_fdw to access a remote database server**

1. Install the postgres_fdw extension.

   ```sql
   CREATE EXTENSION postgres_fdw;
   ```

2. Create a foreign data server using `CREATE SERVER`.

   ```sql
   CREATE SERVER foreign_server
   FOREIGN DATA WRAPPER postgres_fdw
   OPTIONS (host 'xxx.xx.xxx.xx', port '5432', dbname 'foreign_db');
   ```

3. Create a user mapping to identify the role to be used on the remote server.

   ```sql
   CREATE USER MAPPING FOR local_user
   SERVER foreign_server
   OPTIONS (user 'foreign_user', password 'password');
   ```

4. Create a table that maps to the table on the remote server.

   ```sql
   CREATE FOREIGN TABLE foreign_table (
       id integer NOT NULL,
       data text
   )
   SERVER foreign_server
   OPTIONS (schema_name 'some_schema', table_name 'some_table');
   ```

**Working with MySQL databases by using the mysql_fdw extension**

To access a MySQL-compatible database from your Aurora PostgreSQL DB cluster, you can install and use the `mysql_fdw` extension. This foreign data wrapper lets you work with RDS for MySQL, Aurora MySQL, MariaDB, and other MySQL-compatible databases. The connection from Aurora PostgreSQL DB cluster to the MySQL database is encrypted on a best-effort basis, depending on the client and server configurations. However, you can enforce encryption if you like. For more information, see [Using encryption in transit with the extension](#).
The mysql_fdw extension is supported on Amazon Aurora PostgreSQL version 15.4, 14.9, 13.12, 12.16, and higher releases. It supports selects, inserts, updates, and deletes from an RDS for PostgreSQL DB to tables on a MySQL-compatible database instance.

- Example: Working with an Aurora MySQL database from Aurora PostgreSQL
- Using encryption in transit with the extension

Setting up your Aurora PostgreSQL DB to use the mysql_fdw extension

Setting up the mysql_fdw extension on your Aurora PostgreSQL DB cluster involves loading the extension in your DB cluster and then creating the connection point to the MySQL DB instance. For that task, you need to have the following details about the MySQL DB instance:

- Hostname or endpoint. For an Aurora MySQL DB cluster, you can find the endpoint by using the Console. Choose the Connectivity & security tab and look in the "Endpoint and port" section.
- Port number. The default port number for MySQL is 3306.
- Name of the database. The DB identifier.

You also need to provide access on the security group or the access control list (ACL) for the MySQL port, 3306. Both the Aurora PostgreSQL DB cluster and the Aurora MySQL DB cluster need access to port 3306. If access isn't configured correctly, when you try to connect to MySQL-compatible table you see an error message similar to the following:

```
ERROR: failed to connect to MySQL: Can't connect to MySQL server on 'hostname.aws-region.rds.amazonaws.com:3306' (110)
```

In the following procedure, you (as the rds_superuser account) create the foreign server. You then grant access to the foreign server to specific users. These users then create their own mappings to the appropriate MySQL user accounts to work with the MySQL DB instance.

To use mysql_fdw to access a MySQL database server

1. Connect to your PostgreSQL DB instance using an account that has the rds_superuser role. If you accepted the defaults when you created your Aurora PostgreSQL DB cluster, the user name is postgres, and you can connect using the psql command line tool as follows:
Install the mysql_fdw extension as follows:

```
postgres=> CREATE EXTENSION mysql_fdw;
CREATE EXTENSION
```

After the extension is installed on your Aurora PostgreSQL DB cluster, you set up the foreign server that provides the connection to a MySQL database.

**To create the foreign server**

Perform these tasks on the Aurora PostgreSQL DB cluster. The steps assume that you're connected as a user with `rds_superuser` privileges, such as `postgres`.

1. Create a foreign server in the Aurora PostgreSQL DB cluster:

```
postgres=> CREATE SERVER mysql-db FOREIGN DATA WRAPPER mysql_fdw OPTIONS (host 'db-name.111122223333.aws-region.rds.amazonaws.com', port '3306');
CREATE SERVER
```

2. Grant the appropriate users access to the foreign server. These should be non-administrator users, that is, users without the `rds_superuser` role.
